DNR-Based Professional Development: Factors that Afford or Constrain Implementation

Guershon Harel
University of California, San Diego

Osvaldo D. Soto
Patrick Henry High School
University of California, San Diego

Brandon Olszewski
International Society for Technology in Education

DNR-based professional development (DBPD) is a long-running program spanning seven years with multiple cohorts of in-service secondary mathematics teacher participants. This report investigates teacher change among five key variables: facilitating public debate, using holistic problems, attending to students' intellectual need, attending to meaning of quantities and use of students' contributions. Is there evidence that DBPD contributed to higher implementation among participants over time? What factors afford/constrain DNR implementation over time? Classroom observation data indicate the largest impact was found in teachers' attention to meaning of quantities and students' intellectual necessity while interview data provide insights to what affords and constrains DNR implementation.

Key words: Teacher change, DNR-based instruction, Intellectual Need, Professional Development, In-service

In their review of 106 articles reporting findings on mathematics professional development programs between 1985 and 2008, Goldsmith, Doerr and Lewis (2013, p. 21) point out that "existing research tends to focus on program effectiveness rather than on teachers' learning," while much less has been said about "*how* teachers develop knowledge, beliefs, or instructional practices". Indeed, DNR researchers have conducted, and continue to conduct, studies exploring the processes by which teachers develop knowledge of mathematics, pedagogy and student thinking while also describing the contexts in which this learning occurs. For example, Harel, Fuller and Soto (2014) described characteristics of the teaching practice of a DNR expert aimed at helping a group of teachers transition from result pattern generalizing (RPG), a form of the empirical proof scheme, to process pattern generalizing (PPG), a form of deductive proof scheme (RPG and PPG are described in Harel, 2001). Harel (2013b, 2014) describe two of the content areas covered by DBPD in summer institutes and follow-up sessions.

An extension of these studies – our current study – examines the extent to which the evidence that DNR-based professional development (DBPD) has contributed to the implementation of DNR principles by participating teachers and, in keeping with the recommendation of Goldsmith et al, seeks information about the factors that help or hinder implementation. This study reports such findings and contributes in areas by specifying a set of teaching practices we take as indicators of DNR implementation and combining direct classroom observation with participant interviews to yield both information about program effectiveness and provide insight into learning processes.

Theoretical Framework

DNR-based instruction in mathematics (Harel, 2008a; Harel, 2008b), is a theoretical framework that stipulates conditions for achieving critical goals such as provoking students' intellectual need to learn mathematics, helping them acquire mathematical ways of understanding and ways of thinking, and assuring that they internalize and retain the mathematics they learn. Though DNR is a system of premises, constructs and instructional principles, here we attend to only the necessity principle and the construct of teaching practices.

In DNR, the necessity principle stipulates that in order for students to learn what teachers intend they must have an *intellectual need* for that targeted piece of knowledge and the construction of this knowledge is brought about through a series of equilibrium and disequilibrium phases as learners engage in problematic situations (Harel, 2013a).

Harel (2008b) defines, "a *teaching action* is a curricular or instructional measure or decision a teacher carries out for the purpose of achieving a cognitive objective, establishing a new didactical contract (Brousseau, 1997), or implementing an existing one." Characteristics of teaching actions are called *teaching behaviors*. Teaching actions and teaching behaviors taken together are called teaching practices. The necessity principle, described above, is a foundational claim about the importance of teacher awareness of students' thinking and difficulties, the need to plan for and handle students' problem-solving approaches, as well as the importance of availing oneself of the opportunities that could arise if the right problems are posed and students are given the chance to make and express their own meaning for problems that are not broken down for them in advance.

Methods

DBPD consisted of two related support structures: (1) summer institutes and mid-year follow-up and sessions similar to what was described in Harel, Fuller and Soto (2014) and (2) on-site professional development. Both efforts targeted the teachers' knowledge of mathematics (in terms of ways of understanding and ways of thinking), knowledge of student learning, and knowledge of pedagogy. This report examined DNR implementation for 34 teachers, focusing on the following five teaching practices: *public debate, holistic problems, intellectual need, attention to meaning,* and *taking contributions seriously* as defined below.

- *Assigning Holistic Problems:* A holistic problem is one where a person must figure out, from the problem statement, the elements needed for its solution (Harel and Stevens, 2011). It does not contain hints or cues as to what is needed to solve it. In contrast, a non-holistic problem is broken down into small parts, each of which attends to one or two isolated elements. Often each of such parts is a one-step problem. (No/Yes)
- *Intellectual need:* Do students have a need for understanding the mathematics the teacher intends to teach? Does the teacher appeal to a problematic situation that puzzles students when introducing new mathematics? (No/Yes)
- *Attention to meaning*: When a problem has a context, unknown quantities have meaning with respect to that context (e.g. units related to quantities). Does the teacher attempt to attend to the meaning of quantities within the context of the problem? (No/Yes)
- *Public debate*: Is there evidence to believe that the whole class is following the discussion? Is the teacher making a successful effort to engage the whole class in debate through questioning and solicitation of contributions? Public debate also includes the need to evaluate mental images and their validity and efficiency. (No/Yes)
- *Taking student contributions seriously*: A student's contribution is considered to be taken seriously when it is allowed to live in the public space for discussion without immediate teacher evaluation. When taking contributions seriously, teachers solicit ideas and mental images from students, and facilitate public debate about these ideas to highlight and critique both underlying mathematics. (No/Yes)

Repeated classroom observations of teacher participants were conducted and used to evaluate participants' implementation of DNR and to chart changes in participants' teaching over time. Two forms of data were generated using these observations. First, researchers examined whether or not a particular teaching practice was demonstrated in each participant's classroom during an entire classroom observation across two later years of the program's existence. Second, researchers looked at interview data with participants conducted after classroom observations that could be used to give insight into factors that afford or constrain implementation. A summary of findings follows.

Findings

Three forms of findings constitute results of investigation into the program's impact on DNR implementation.

Classroom Observation Data (All classes)

The following tables show percentages of classrooms in which a particular teaching practice was present during year 3 and 4 of the program.

Attention to Meaning		
	Year 3	Year 4
Present	25.9 %	61.5 %

Intellectual Need		
	Year 3	Year 4
Present	63 %	80.8 %

Public Debate		
	Year 3	Year 4
Present	70.4 %	76.9 %

Taking student contributions seriously		
	Year 3	Year 4
Present	81.5%	84.6 %

Holistic Problems		
	Year 3	Year 4
Present	81.5%	80.8 %

The most dramatic results can be seen in the change of the percentage of classrooms in which teachers attended to meaning and to the intellectual need of students and raise questions about aspects of DBPD that may have contributed to these shifts. Similarly, one might ask what may have constrained increased implementation of holding public debate, taking student contributions seriously and using holistic problems. There are many possibilities, including the difficulties inherent in the teaching practices themselves, the students' comfort levels sharing ideas in class or even a potential ceiling effect. Note that each of these three teaching practices began with a relatively high rate of classrooms demonstrating them, 70%, 81.5% and 81.5% respectively. For this reason, we decided to investigate individual data.

Interview Data. During interviews with project staff, the following factors were reported as reasons participants felt they were able to implement DNR in their own classrooms.

- Resonance of the major principles of the DNR framework with their own values, including a strong dedication to problem-solving, belief in student-centered instruction, and a belief that current curriculum needs modifications to accomplish meaningful instruction.
- Community-driven programmatic elements such as a time, place, and leadership for sharing ideas and peer support building, one-on-one mentoring from more experienced teachers and regular contact with community members

- Academic freedom/autonomy to implement DNR-compatible teaching practices by administrators
- The program's on-site support
- Adoption of the Common Core State Standards in Mathematics and compatibility with DNR
- A strong sense of dedication to students

Factors reported to constrain DNR implementation included:
- Dissonance with the major principles of DNR, either throughout or growing with time
- Difficulty of Didactical Engineering/adapting DNR's instructional principles to curriculum
- Lack of academic freedom with respect to content and/or teaching practices (either perceived or embodied in administrators and/or parents including pressure to teach algorithmic proficiency at sites/desire to maintain consistent testing results with high SES from parents, students and administrators and large class sizes generating extraneous work)
- Self-efficacy and retention issues

Discussion

We began the report with insights from Goldsmith, Doerr and Lewis (2013) describing some of what has been done and what still needs attention in mathematics professional development over nearly three decades. On the surface, this report seems to do the opposite of what Goldsmith et al recommend, appearing, at least initially, to focus on "program effectiveness" rather than teacher learning. However, we argue that DNR researchers have been carrying out the work of investigating how teachers develop the forms of knowledge, beliefs and instructional practices needed in the common core era for quite some time. Evaluation of a PD program attempting to implement DNR is a necessary part of theory building. Indeed, knowledge about the kinds of hurdles teachers face when attempting to turn theory into practice can inform the theory itself as researchers attempt to make adjustments to their theoretical perspectives moving forward, starting a new cycle of theory building, implementation and evaluation.

Intended Questions for the Audience

1. We are aware that there lurking methodological questions we have yet to ask about classroom observation protocols with respect to each of the five teaching practices. What are some of them? Would duration help on some of these variables?
2. How can these findings inform future DBPD? DNR as a theoretical framework?
3. We have data, by individual participant, with respect to each of the five teaching practices discussed. I have bar graphs readily available with mean and standard deviations. How might this data be used to address our questions?

An exploration of students' discourse using Sim2Bil within group work: A commognitive perspective

Ninni Marie Hogstad, Olov Viirman
University of Agder, Norway

This paper reports on critical aspects of three engineering students' discourse in group work using a digital tool called Sim2Bil while solving mathematical tasks. Applying a commognitive perspective, where mathematical discourse is characterized by words used, visual mediators applied, narratives developed and routines established, we investigate how these characteristics are influenced by the technological environment. It is found that all of the aspects of the students' discourse are influenced by Sim2Bil. For instance, a "trial and error" routine directly connected to the use of the tool is present in the students' discourse.

Key words: Commognition, Discourse, Engineering, Group work, Technological environment

Introduction

Working with mathematics involves using different resources. For instance, students use computers, calculators, and textbooks. These artifacts have been developed through history, and technological tools in particular have undergone major changes in the last decades. Nowadays, software for simulations, animations, graph plotting, dynamic geometry, CAS, and so forth, have emerged in mathematics education. These cultural tools change practices and give possibilities to work with mathematics in new ways.

Much research has been conducted on students' interaction with technological tools (Beatty & Geiger, 2010; Wijers, Jonker, & Drijvers, 2010), and an important aspect of future education may lay in expanding technology-supported collaborative work between students (Lowyck, 2014). The technological tools considered are, for instance, computer algebra systems (CAS) (e.g. Artigue, 2002) and tools for graph plotting (e.g. Swidan & Yerushalmy, 2014). Some studies have applied the commognitive framework to study how students are communicating using a digital tool (e.g. Ng, 2016) and the impact technological environments have on pupils' mathematical thinking (e.g. Sinclair & Yurita, 2008).

Previous studies conclude that technology can support students in their graphical approach to integrals (Berry & Nyman, 2003; Swidan & Yerushalmy, 2014). To supplement this research, in the study reported in the present paper we set up a kinematical context for integrals, and the students use integrals for a simulation of movement within a technological environment where students work with a digital tool called Sim2Bil. The students' interaction with words and visualizations and how they were used in their communication has been analyzed in a previous paper by Hogstad, Isabwe, and Vos (2016). In the present paper, we will view the data from a discursive perspective, analyzing the characteristics of the students' discourse with the aim of investigating how the digital tool influences the discourse.

Theoretical Framework

The commognitive theory (Sfard, 2008) takes a participationist perspective (Sfard, 1998) – learning is seen as the process of changing and individualizing discourse to become increasingly able to participate in a certain discourse community. The theory provides analytical tools for analyzing discourses, and especially mathematical discourse. From a commognitive perspective, discourses are different types of communication "set apart by their objects, the kinds of mediators used, and the rules followed by participants and thus defining different communities of communicating actors" (Sfard, 2008, p. 93). Thus, doing mathematics is engaging in mathematical discourse, and this mathematical discourse – indeed any discourse – can be distinguished by four characteristics: word use, visual mediators, narratives and routines (ibid, p. 133-134). *Word use* refers to words specific to the discourse or common words used in discourse-specific ways. *Visual mediators* are "the visible objects that are operated upon as a part of the process of communication" (Sfard, 2008, p.133). Every image of concretes, symbols and icons operated on in communication are visual mediators. *Narratives* are "any sequence of utterances framed as a description of objects, of relations between objects, or of processes with or by objects, that is subject to endorsement or rejection" within the discourse (ibid, p.134). Sfard includes mathematical definitions, theorems, axioms and proofs, as well as formulas and equations, under the term narrative. Other examples could be statements students make during a problem solving process, such as the statement they consider to be a solution to a given problem. Finally, *routines* are "repetitive patterns characteristic of the given discourse" (ibid, p. 135). Such repetitive patterns can be seen in almost any aspect of mathematical discourse: in forms of categorizing, modes of attending to the environment, in ways of viewing situations as "the same" or different and so on (ibid, p.135).

Routines are divided into three types: explorations, deeds and rituals. *Explorations* are routines where the goal is to produce endorsed narratives (ibid, p. 223). *Deeds* involve actions performed with the goal of achieving change in objects. A routine may either be an exploration or a deed, depending on what the performers (in our case the students) are trying to achieve. In particular, the difference can become unclear in those cases when "the objects on which the deed is performed are, in themselves, discursive rather than primary" (p.239). *Rituals* are those actions whose goal is neither to produce an endorsed narrative nor a change in objects but rather to gain the attention and approval of others and to become a part of a social group.

Methods

The overall aim of the study is to investigate how students' mathematical practice is influenced by working in a specially designed small-scale digital learning environment outside of regular lectures. The participants in the activity reported on in this paper were three engineering students. They were in the second semester of their first year at university. Their first year included courses in calculus, linear algebra and physics (including kinematics). Sim2Bil was not familiar to them.

Sim2Bil is an interactive digital tool, the interface of which is shown in Figure 1. At the top left there are two cars – one red, one green – which can drive from a starting line to a finish line. This is called the simulation window. Below, there are visualized two graphs, one for the velocity-time function of each car. This is called the graph window. At the bottom right, there are velocity functions for each of the cars. A user can insert parameters here to make 3rd degree polynomials. This is called the formula window. At the top right is a menu window, which is not used in the study and will not be further explained. As a default setting, there are two functions given in the formula window: v1 = 100 (for the green car); and v2 = 50t (for the red car). With these functions, the students can engage in the environment by pressing the start-button to see the cars run differently and finish together. The distance between the starting line and the finish line is 400 meters. The preset functions make the cars reach the finish line simultaneously (thus framing the forthcoming requirements), and they also make the graphical representations appear, thus showing how a user can operate with the tool. The shading of the areas under the graphs will appear gradually through an animation, increasing with time. These areas represent the distance travelled for the cars.

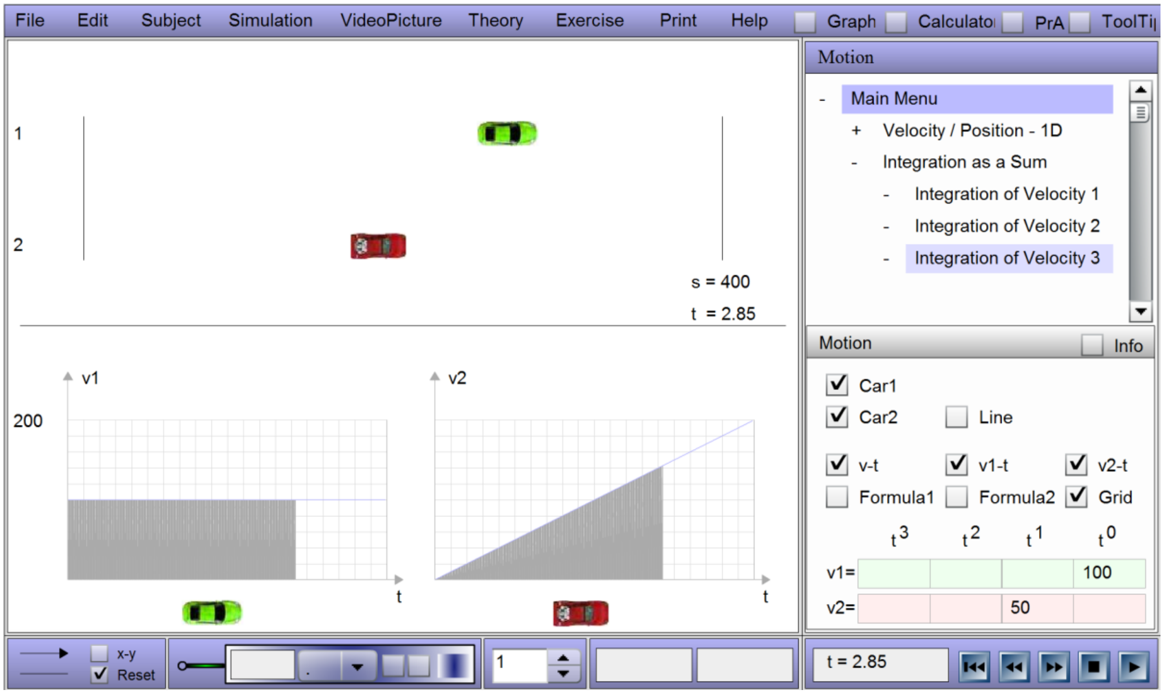

Figure 1. Interface of Sim2Bil.

The students received the following problem consisting of four tasks:

> Look around the screen. Find the start button (down at the right corner). The simulation runs for maximum 4 seconds.
>
> a) Press "Start" in the program, and explain to each other what happens. What do the shaded areas represent?
> b) Determine other numbers in the table, so that the cars run with different velocities, and arrive at the finish line at the same time.
> c) What can you do to make the green car be only half way when the red car reaches the finish line?
> d) Find the velocities of the green and the red car (v1 and v2), so that v2 is half of v1 when they reach the finish line simultaneously at 4 sec. Can you prove that your answer is correct?

The problem is designed for collaboration between the students since the tasks can be solved using different approaches. The formulation of the problem was presented on paper and Sim2Bil was set up on a laptop in front of the students. Other available resources were a calculator, book of formulae, and pen and paper for writing. It was anticipated that the students would see relations between distances travelled, shaded areas under the graphs, and the integral of the velocity functions. The formula window constrains possible solutions by allowing the students to set in parameters only up to 3rd degree functions.

The activity was video recorded using two cameras: one moving, directed at the students and their writing; and one fixed, directed at the computer screen to capture mouse movement, students' inputs within the interface and gestures like pointing towards the computer screen. One researcher was present during the activity and introduced the interface and tasks to the students. No specific time frame was given for the group work, and it turned out that the students spent in total of 45 minutes on the tasks. The video recordings were then transcribed and coded in terms of the different characteristics of discourse. In what follows, for reasons of space, attention is restricted to the first two subtasks.

Analysis

Briefly describing the students' work on the subtasks, they begun by reading the tasks aloud. They then pressed the start-button and watched the cars run before discussing what the shaded areas represent. Thereafter they discussed the degree of velocity functions in order to find new parameters which they in turn set in the formula window to see if the cars arrive together.

Looking at the discursive practice of the students, a number of characteristic features can be found. Starting with discourse-specific words, there are several words used to describe mathematical objects, such as: function, graph, area, integral, unknown, rectangle and triangle to mention a few. Still, although the students are mainly engaging in mathematical discourse, they also use terminology that might be considered to belong mainly to discourses of other disciplines. For instance, there are words used which belong to a discourse of physics, such as: position, distance, velocity and acceleration. Actually, one of the students recognized the discourse as being within physics by stating at the end of the session: "that is enough physics for today". There are also a number of words directly connected to the interface, for instance start (-button), start line and finish line.

Different visual mediators are present in the discourse of the students. Some are of types traditionally connected to mathematical discourse, for instance mathematical symbols and graphs. These are in some cases written on paper, and in some cases are aspects of the digital tool. There are also visual mediators directly connected to the tool, such as the moving cars and the representation of the two velocity functions by a number of boxes (see the bottom right corner of the interface depicted in Figure 1). In addition, gestures such as pointing or tracing the shape of a parabola with your hand are also used. Such gestural actions seem to be used partly for making sure that the students are talking about the same objects.

Concerning narratives, these are also of different types – those connected to the tool and those connected to the underlying mathematical content. Mathematical narratives include, for instance, formulas for the velocity functions as general third-degree polynomials, as well as expressions for distances in terms of integrals of velocity functions. Narratives more specifically connected to the digital tool include interpretations of the various features of the interface in terms of a discourse of mathematics or physics:

Student E: What do the shaded areas represent? It's the area under the graph.
Student S: Yes. The area, which then is the distance. It is a function.

Another example concerns formulating connections between different features of the interface: "It [pointing at the graph] changes when we push here [by inserting parameters].

The influence of the Sim2Bil tool can also be seen in the types of routines present in the students' discourse. Some routines are directly connected to the use of the tool. One of the most common is “running the simulation”, that is, inserting values for the parameters, pressing start, watching the cars run and then pressing reset. On some occasions, this routine had the characteristics of a deed, concentrating on the running of the cars, with the students’ attention focused on whether they arrived simultaneously at the finish line. On other occasions, the routine was more exploratory, with the focus on the graphs describing the velocity functions, and how these influence the movement of the cars. This routine is closely connected to a routine which we might call “trial and error”. Here, values for the parameters are for the most part picked seemingly at random or at least without any explicit reasoning on the students’ part. Then the resulting effect on the graphs and the running of the cars is noted, new values are picked, the effects are noted, and so on. This process is denoted by the students as “playing around”, and particularly one of the students repeatedly invokes this when the other students shift their attention to symbolic and numerical calculations away from the screen: “Can’t we just play around a little? Isn’t that good?”

On the other hand, there are also examples of routines that are more conventionally mathematical, such as “calculating values of expressions”. The calculations consist of writing algebraic expressions (mostly integrals of polynomial velocity functions) on paper and then using a calculator to calculate numerical values. These routines were mostly of an exploratory character. You might argue that there is an element of the deed about them, since the focus is on the numerical results, but these numbers are in turn going to be used to formulate narratives about the comparative movement of the cars in the digital environment.

Discussion

What we have presented above is a mostly descriptive account of the characteristics of the students’ discourse when working on the tasks. Still, looking at these characteristics it is clear that the Sim2Bil tool influences all aspects of the discourse. In particular, there is evidence of routines directly connected to the tool. This corresponds to the findings of Sinclair and Yurita (2008), where the introduction of a digital tool (Geometer’s Sketchpad) changes the routines engaged in the classroom.

The study is also in tune with other studies reporting on new forms of communication mobilized in dynamic environments. For example, Ng (2016) shows how students utilized a variety of resources in their communication, and developed routines for conjecturing and verifying calculus relationships. Such routines can also be found in the discourse of the students in the present study.

The environment described in this study enabled the students to connect algebraic expressions, graphical representations and movements of objects. As the students in the present paper see the growth of the shaded areas as an animation in the graphical window, the idea of area as a function is visually mediated. Although the distinction between dynamic and static visual mediators has so far not been explicitly addressed in the commognitive framework, the distinction is important because of the potential for dynamic visual mediators to evoke mathematical relations, as also stated by Ng (2016).

However, the findings presented in the present paper are only a first step, and in future publications we intend to deepen this analysis, looking at what opportunities for learning are offered by the tool, and how the tool (and the tasks) influences the mathematical thinking and reasoning of the students, as manifested in their discursive practice.

Question for discussions: How to interpret the complex interplay between technological aspects and mathematical aspects?

The role of undergraduate mathematics faculty in the development of African American male mathematics majors

Christopher C. Jett, Ph.D.
University of West Georgia

Historically Black Colleges and Universities (HBCUs) have a longstanding legacy of supporting African American students in mathematics. The undergraduate mathematics faculty members play a unique role in supporting and developing astute mathematics students, especially African American male students. This preliminary research report highlights the experiences of a cohort of 16 African American male mathematics majors at an all-male, private HBCU by investigating the role of the mathematics faculty members. Using qualitative research methods grounded in critical race theory, preliminary data show these African American male mathematics majors benefited (mathematically and racially) by their supportive mathematics faculty members.

Keywords: Undergraduate mathematics education, HBCUs, African American men, Supportive faculty

Introduction

This preliminary research report analyzes the mathematics experiences of a cohort of 16 African American male mathematics majors at an all-male, private Historically Black College/University (HBCU) in the southeastern region in the United States. HBCUs have a historical legacy of developing mathematics majors/mathematicians, and this institution was recently recognized by the American Mathematical Society (AMS) as the Programs that Make a Difference Award for their commitment to producing African American male mathematics majors to increase diversity in the mathematical sciences (Borum, Hilton, & Walker, 2016; Jett, 2013). This research report hones in on the role of undergraduate mathematics faculty members in the development of these 16 African American male mathematics majors. The overarching research aim was to ascertain intrinsic and extrinsic factors that led to the undergraduate mathematical persistence for this cohort of students.

As it stands, this research study adds to the body of scholarship investigating the schooling experiences of African American male students (see, e.g., Duncan, 2002; Harper, 2013; Noguera, 2008; Strayhorn, 2015). In addition, this study adds to the thread of research highlighting the mathematical strengths of African American male mathematics students (Berry, 2008; Stinson, 2013). Given that a large number of these studies have been conducted at the K–12 level, it is important to gain insights from studying African American male students who are persisting in college mathematics. African American male students' stories of mathematical undergraduate persistence are largely absent in the research literature. Thus, this research project is designed to fill this void in the research literature and shift the discourse concerning the mathematics experiences of African American male mathematics collegians with respect to their mathematics faculty members.

Review of the Literature

There have been fruitful efforts designed to improve the mathematics achievement outcomes of African American students. One effort that has been successful in promoting high levels of undergraduate mathematics performance among African American students is the

Mathematics Workshop Program (MWP) at the University of California, Berkeley (Fullilove & Treisman, 1990). The MWP is cited as being successful for the following reasons: the workshops create environments that promote mathematics academic excellence among peers; the students spend more time on learning activities and learning tasks as opposed to just solving mathematics problems; and the students who participate in MWP are believed to continue in college longer than those students who do not participate in the workshop because they obtain social and study skills that can be used throughout their college matriculation.

A research team at the University of Maryland Baltimore County studied high-achieving African American men (Hrabowski, Maton, & Greif, 1998). At this institution, researchers became concerned about the status of African American male students in college science, mathematics, and engineering (SME; SME is synonymous with STEM) majors and decided to learn more about this group by studying the habits of the highest-achieving students who were enrolled in the Meyerhoff Program. Although the program now serves students from all racial and ethnic backgrounds who desire to pursue a doctorate in the sciences or engineering, the first year consisted of African American male students only. Hrabowski et al. (1998) hoped to identify attitudes, behaviors, habits, perspectives, and strategies of the highest-achieving African American male students in the program. According to Hrabowski et al. (1998), the following factors are critical for success in college among African Americans in mathematics and science: an adequate high school academic preparation, analytical skills, strong study skills, time management skills, advising, academic as well as social integration, and motivation and support.

Ellington and Frederick (2010) examined the experiences of eight high-achieving junior and senior mathematics majors to ascertain the factors that shaped their mathematical success and persistence. Their findings revealed the majors' success was informed by participation in academic programs at the K–12 level and college scholarship programs, access to advanced mathematics courses, and support from family, classmates, and teachers. In another study, McGee (2015) investigated the factors undergirding academic resilience among 23 high-achieving African American mathematics and engineering majors at the junior, senior, and graduate levels. Using the life-story interview process, she reported on a subset of two participants (one Black female and one Black male) from her larger study. McGee introduced the Fragile and Robust Mathematical Identity Framework to understand the interplay between mathematics and racial identity. Using this framework, she found that her two participants were able to thrive in these majors while grappling with various forms of racialization.

While the previously mentioned studies have moved the field forward concerning the experiences of African American students, we know comparatively little about the role of undergraduate mathematics faculty in the development of African American (male) students. This study, therefore, complements and expands existing research efforts in the field by examining the role of mathematics faculty in the development of mathematics majors for this population of students. All in all, this research report builds on scholarship from scholars who honor the mathematical talents and gifts in African American students (see, e.g. Berry, 2008; Cooper, 2004; Delpit, 2012; Ellington & Frederick, 2010; Jett, Stinson, & Williams, 2015; Leonard & Martin, 2013; McGee & Martin, 2011; Stinson, 2006; Thompson & Lewis, 2005; Walker, 2006, 2014). Moreover, this study also reveals how complexities about the constructs of race and/or gender may influence the mathematical development of African American male students given the theoretical frame.

Theoretical Framework

The experiences of African American students have been documented in the mathematics education research literature, and scholars in the field have paid attention to how their raciliazed experiences influence their mathematics learning (Larnell, 2016; McGee, 2015). As such, Critical Race Theory (CRT) was employed as the theoretical framework for this research project (see Bell, 1992; DuBois, 1903/2003 for comprehensive discussions concerning the country's racial history). Racism is an institutionalized force that has been used both historically and currently to dismiss and oppress people of African descent and other people of color. Solórzano and Yosso (2002) argue that "substantive discussions of racism are missing from critical discourse in education" (p. 37). As it stands, issues of race and racism have been underexplored in mathematics education research (Martin, 2009). There are, however, a contemporary group of mathematics education researchers foregrounding issues of race and racism in their analyses (see, Jett, 2016; Larnell, 2016; McGee, 2015; Stinson, 2013; Terry, 2011). In an attempt to extend analogous mathematics education research drawing from race-based frameworks, CRT was used to examine the role of undergraduate mathematics faculty members in the development of a cohort of 16 African American male mathematics majors.

With CRT, there are five foundational tenets, and these tenets are the hallmarks driving this theoretical perspective. These philosophical underpinnings include the following:

1) CRT asserts that "racism is normal, not aberrant, in American society" (Delgado & Stefancic, 2000, p. xvi).
2) CRT adheres to interest convergence, which advances that the dominant culture advances racial justice and other race based initiatives when it serves their interest (Delgado & Stefancic, 2001).
3) CRT asserts that race is orchestrated as a social construction (Ladson-Billings, 2013).
4) CRT explores the intersectionality of various constructs such as race, sex, class, gender, and sexual orientation to explore how these intersections make for broader understandings of these constructs (Delgado & Stefancic, 2001).
5) CRT utilizes voice to serve as a counter-narrative to the dominant discourse surrounding racial groups (Dixson & Rousseau, 2005).

These tenets of CRT were be used to frame the interview questions and to analyze the data.

Research Question

The overarching research questions (RQ) for this portion of study were as follows:

RQ1: How do undergraduate mathematics faculty members (at this particular HBCU) either help or hinder the mathematical development of African American male mathematics majors?

RQ2: What are the (student) identified strengths and weaknesses of the undergraduate mathematics faculty members as it pertains to the development of African American male mathematics majors?

Methodology

This research study employed qualitative research methods. More specifically, the qualitative research data collection methods included the following: 1) a pre-survey, 2) a semi-structured interview, and 3) a member checking prompt (Bogdan & Biklen, 2007; Patton, 2015).

1) The pre-survey was given to the participants prior to the first interview. This pre-survey solicited information from the participants pertaining to their demographics, family dynamics, and education. The information obtained from the pre-survey was used to inform the

first interview as well as to substantiate the data for coding and analysis. 2) Next, the participants completed a semi-structured interview (ranging from one to two hours in length). The interview amplified the participants' voices by honoring and using their own words to share their mathematics experiences. The utilization of "voice" as well as narratives aligns with qualitative research methods and CRT's fifth tenet. 3) The final method included allowing the participants to member check my findings. In other words, the member checking aspect allowed the participants to verify whether I reported their words, findings, and interpretations accurately.

With regard to data analysis, I employed coding to analyze the data. After analyzing the individual interviews, I searched for similar and dissimilar patterns in the data and articulated explanations for different phenomena (Glesne, 2006). In addition, I wrote reflective notes in my researcher's notebook, which aided during both the data collection and coding processes (Bogdan & Biklen, 2007). Tenets of CRT were used to code and assist with analyzing their experiences as racialized beings. All in all, this qualitative data analysis process offered me an opportunity to verify my findings with the participants and to address questions pertinent to the analysis of data on the role of undergraduate mathematics faculty members in the development of African American male mathematics majors.

Preliminary Findings

Qualitative data have been collected for this research project, but the data are in the early stages of data analysis. However, preliminary data indicate that these 16 African American male mathematics majors were affirmed at their HBCU by their supportive mathematics faculty members. More specifically, the mathematics faculty members were dedicated to providing the mathematics majors with a challenging undergraduate curriculum. The faculty members were supporting and caring, and the majors spoke deliberately about the effective guidance and mentorship offered by these departmental members, especially the department chair (an African American male alumnus of the department). Conclusively, these faculty members had social constructions about who could be mathematically astute, and these ideological orientations informed their mathematical and racial empowerment of these African American male mathematics majors (Ladson-Billings, 2013).

A more thorough discussion of the preliminary finding concerning the role of the undergraduate mathematics faculty members will be shared during this presentation. In doing so, I will also share some ways to improve the undergraduate mathematics space as articulated by the majors. The data will be shared in light of the research questions, with connections to the previously cited literature, and with theoretical linkage to CRT.

Discussion Questions

The following discussion questions and prompts will allow participants in this session to engage in dialogue, offer feedback for strengthening the work, reflect on their own undergraduate mathematics practices, and recommend suggestions for future areas of scholarly exploration for this line of research:

• Please share any suggestions or insights from your experiences working with African American male mathematics majors that have yielded successful mathematics outcomes.
• Please share any suggestions or insights from your experiences working with mathematics majors from other marginalized groups that have yielded successful mathematics outcomes for that particular population of students.
• What are some implications of this work for undergraduate mathematics instructors?

• What are some implications of this work for undergraduate mathematics education researchers?
• What are your thoughts and recommendations concerning extending and furthering this work?

<u>Goals</u>

One goal of this session is to highlight the critical role of the mathematics faculty in the development of African American male mathematics majors at an all-male, private HBCU. This particular institution has a legacy of producing many African American male mathematics majors as espoused by national data and reports. Another goal is to disseminate more stories of mathematical persistence to influence and develop more African American male students into the mathematics pipeline who have a desire to explore various mathematical and mathematics-related pursuits. Finally, a goal is to generate more conversations concerning the participation and underrepresentation of African American male students in undergraduate mathematics degree programs.

Abstraction and Quantitative Reasoning in Construction of Fractions as Operators

Eun Jung
University of Georgia

Drawing from task-based interviews, classroom observation, and participants' homework, the present study examines ten middle grades preservice teachers' understanding of the role of fractions as operators, with an eye toward exploring how fractional reasoning is constructed. The results point to the construction of the reversible distributive partitioning scheme as a requisite for understanding fractions as operators. Further discussion will suggest that school curricula and teacher education programs may need to be adjusted to reflect more current understanding of both early childhood cognitive development and future teachers' fractional knowledge.

Key words: Cognition, Teacher Education-Preservice, Teacher Knowledge

Writing about four decades ago, Kieran (1976) remarked that "most school curriculum materials simply treat rational numbers as objects of computation. Hence, child and adolescents miss many of the important interpretations of rational numbers" (p. 102). Since then, substantial research has further emphasized that there are multiple interpretations—or "subconstructs"—of fractions (e.g., Behr, Khoury, Harel, Post, & Lesh, 1997), and numerous books have been written reflecting this point of review in teaching rational numbers (e.g., Clarke, Fisher, Marks, Ross, 2010). The current study concerns itself primarily with the role of fractions as "operators," referring to fractions that link two quantities of the same kind or of different kinds (see Vergnaud, 1988).

Students are normally taught fractions from third to fifth grade, before reaching the expected age range identified by Lovell (1972) for developing the proportionality schema (i.e., ages 12-14). Two subsequent studies on adolescents' comprehension of fractions as operators (Kieren, 1976) add some empirical weight to Lovell's (1972) earlier findings, showing a strong relationship between age level and scores that is consistent with this suggested age range. In that regard, Kieren (1976) suggest an important relationship between students' development of the proportionality schema and their comprehension of fractions as operators.

Post, Behr, and Lesh (1982) noted that understanding proportional reasoning is only possible once students have reached Piaget's "formal operational state," which generally happens in the fifth grade. In that case, many students – perhaps a majority – are not ready to learn the operator role of fractions at the time when fractional foundations are being laid in school curricula. However, in the middle grades, if students cannot understand fractions both as quantities and operators, this can be a barrier to their comprehension of later topics in mathematics.

In light of these considerations, this study investigates preservice teachers' understanding of fractions as operators through task–based clinical interviews designed to reveal any areas of struggle, in order to further analyze the nature of these issues—particularly in regard to what they can reveal about how fractional reasoning is constructed—and to discuss possible solutions.

Theoretical Framework

Steffe (2003) conducted a study that can serve as an exemplar of the radical constructivist approach that forms an essential basis of my epistemological and analytical framework. Steffe

(2003) adopted as part of his analytical framework the notion that both social interaction and an individual's action are crucial in learning. He regarded social interaction as a means of " generating situation" for the construction of students' cognitive schemes, and learning as a product of the "auto-regulation" of constructs within the individual's understanding. The emphasis on the individual's self-regulation and auto-regulation is in line with von Glasersfeld basic principles of radical constructivism (1990, p.22). What we perceive as reality is thus regarded as a construct within the mind of each individual.

Hackenberg and Lee (2015) showed that only MC3 (able to coordinate three levels of units) students could use fractions as multipliers in the context of writing equations. Unit coordination is related to the ability to construct certain schemes, such as distributive sharing and reversible distributive partitioning (Steffe & Olive, 2010). To illustrate, students who can share two identical bars among three people have constructed the "distributive sharing" scheme. To carry out this operation, they would partition each of the two bars into three parts and pull out one part from each bar, understanding that those two parts make up 2/6 of the original two bars. However, unless they had also constructed the "reversible distributive partitioning scheme," they would not understand that 1/3 of two bars is identical to the two individual thirds of each bar. Thus, students who have constructed the reversible distributive partitioning scheme understand that taking one-third of each of two objects (not necessarily identical) is equivalent to taking one-third of both objects together.

While I make use of a constructivist theoretical framework, my conceptual framework includes both the constructivist notions of fractional schemes and operations and Vergnaud's (1988) explanation of fractions as quantities and operators. For the purposes of the current study, it seems appropriate to make use of a qualitative case study design that will allow for a context-rich and focused investigation using task-based clinical interviews and participant observation.

Research Design

The present research is designed to address the following questions: How do middle grades preservice teachers' reason with fractions as operators?

1. What can their reasoning with fractions as operators reveal about their construction of fractional knowledge?
2. What is the nature of their struggles in constructing fractions as operators, and what are some possible solutions to these issues in their understanding?

Building on the concept of the clinical interview developed by Piaget (1951), the "constructivist teaching experiment" (see Steffe & Thompson, 2000, p. 285; Steffe, 2003) is a method by which the researcher's ongoing analysis can interact with data in a fluid way. According to a description by Steffe & Ulrich (2014), "[a] teacher/researcher, through reviewing the records of one or more earlier teaching episodes, may formulate hypotheses to be tested in the next episode…" (p.104). While this research tracks students' learning trajectories across successive teaching episodes, the pedagogical interventions themselves are supplied by the participants' course instructor, rather than directly by the interviewer. The method employed in the current research, therefore, may be regarded as a modified teaching experiment method; rather than one person acting as the "teacher-researcher" in "teaching episodes" (Steffe & Thompson, 2000). I conduct interviews as the "researcher," while the course instructor acts as the "teacher." The interviews themselves—without the expressly pedagogical element characteristic of the teaching episodes of a teaching experiment—closely resemble "task-based clinical interviews" (Goldin, 2000).

This study makes use of a multiple case study design, examining the fractional knowledge of preservice middle grades math teachers in a Math Education department at a major public university located in the Southeastern United States. The primary data source is a series of clinical interviews conducted over the course of two semesters using ten volunteer participants from a math content course. More specifically, I make use of data from task-based clinical interviews, as well as from classroom observation notes and homework submissions.

From among the initial volunteers in the math content course, I divide the participants into groups according to whether or not they have constructed the distributive sharing scheme. These selections are based on analysis of an initial round of interviews, classroom observation notes and homework submissions.

Result and Significance

All clinical interviews were recorded on video, transcribed verbatim, coded and annotated for emerging themes, and analyzed. At the beginning of the interview all of participants were unable to make composite units for fractions acting as operators, which means that they had not constructed the reversible distributive partitioning scheme. In fraction multiplication and fraction equation problems, two of the participants either could not produce the drawn model of certain problems, or they could not provide a coherent interpretation of their own drawings. All participants showed signs of confusion as a result of incorrectly applying procedural knowledge. Moreover, the current progress of my data analysis indicates that the construction of the distributive sharing scheme is necessary but not sufficient to ensure a students' conceptual understanding of fractions as operators.

During each interview, variations of fraction multiplication problems were given, and students were asked to design word problems and represent the problem situation visually. For one of the problems, 4/5 times 1/3, several students drew a rectangle and partitioning it into 3 rows and 4 columns (or vice versa). They shaded 1 row and 4 columns and identified the 4 parts in the overlapping region as their answer. One of the word problems a student designed for this problem was: "You have a recipe that calls for one-third cups of flour, and you want to make four fifths of the recipe, so how much flower do you need to use?" When I asked her to show one cup and one recipe, she identified the largest box as both one cup and one recipe. This indicates that she used both fractions as extensive quantities (instead of 4/5 as the operator to show the relationship between the quantity 1/3 and the product 4/15). This shows her limitations in representing two different units in one drawing and in using one fraction as on operator.

Another identifiable limitation was in making composite units. Before classroom instruction, when asked to show 7/3 of two unit bars, two students responded that they must find one-third of one bar and then repeat it 7 times. Thus, by partitioning both unit bars into three parts and repeating one of these parts seven times, in fact they showed 7/3 of just one bar. Their difficulty was in understanding the two bars together as one composite unit (treating it as the "whole" for 7/3).

After the completion of the unit on fractions in the participants' math course, students already knew that the correct answer to the problem (finding 7/3 of two unit bars) could be given as 14 parts, each being 1/3 the size of one unit bar. However, in explaining the anser with a drawing, three out of ten students showed limitations in partitioning and iterating with composite units. All students gave the answer as 14/3 of one bar, but three students still answered that they needed to understand 7/3 as equivalent to 14/6 to determine the result relative to two bars. If they could form one composite unit out of the two bars, they were able to find 1/3 of the two bars by partitioning each bars into thirds and taking 1/3 from each bar, after which they could also make a composite unit of these two parts and iterate it seven times to make 7/3 of the two unit bars. In that case, the students do not need to consider 1/3 of one bar as 1/6 of two bars. This shows the limitation of these three students' reasoning with iterable composite units, corresponding to limitations in using fractions as operators.

Conclusion

In fraction multiplication contexts, the multiplicand represents an extensive or intensive quantity with one unit as a whole. However, the multiplier shows the relationship between the multiplicand and the product of multiplication. Thus the whole of the multiplier becomes the multiplicand, and students have to be able to use the multiplicand as one composite unit to perform the operation. This requires students' construction of the distributive sharing scheme.

These preliminary findings, although limited in scope, may direct further research that can case additional light on the construction of fractional reasoning, both in preservice teachers and in primary school students. Considering the foundational importance of being able to understand fractions as operators, in the very least we need to ensure that preservice teachers have a strong grasp of this fundamental fractional concept in order to teach middle grades students effectively. Moreover, if further research lends additional support to the notion that primary school is generally too early for students to understand the operator role of fractions, school curricula may need to be adjusted to reflect this.

Students' Social Adaptation to Mathematical Tasks

Jeffrey J. King
University of Northern Colorado

In this study, an advanced undergraduate geometry class taught in an inquiry-based learning setting was observed for social and socio-mathematical norms. Three pairs of students engaged in three task-based, semi-structured interviews: paired, individually, then paired again, solving the Seven Bridges of Königsberg and related tasks. A fourth stimulated-recall interview was performed using episodes from the last paired interview. Classroom observations and interview discourses were open coded for themes, structure, and function to analyze the norms developed within the classroom and by each pair as shaped by their social interactions. Tentative findings include: 1) norms of consensus, autonomy, and argumentation produced within the classroom, 2) varying metaphors across interview contexts, and 3) reliance on empirical strategies rather than structural reasoning. In this preliminary report, evidence from collected data is shared and a brief discussion how these results could help inform IBL teaching methods is included.

Keywords: Active Learning Strategies, Cooperative Learning, Inquiry-based Learning, Socio-Cultural Theory, Transfer

The White House has issued a call to action for incorporating active STEM learning strategies in K-12 and higher education (White House Office of Science and Technology Policy, 2016). Some studies have shown the effectiveness of inquiry-based learning as an active learning strategy for all mathematics students and especially minority groups (Kogan & Laursen, 2014; Laursen, Hassi, Cogan, & Weston, 2014). Almost no literature can be found, however, on the socio-cultural theoretical underpinnings of the transfer of inquiry-based learning to individual work.

The purpose of the dissertation study shared in this preliminary report was to explore the social and socio-mathematical norms of classroom using inquiry-based learning and the reproduction (or non-reproduction) of those norms in an interview setting. The research questions of this ongoing study are:

1. What were the social and socio-mathematical norms of the classroom?
2. How were these norms reproduced (or not) by the students in the interview settings?
3. In what ways did changes in the social context of the interview settings affect the mathematical practices produced by the students?

Methods

The setting of the study was at a four-year university in the Rocky Mountain region in an upper level mathematics course. In this inquiry-based learning geometry course students worked in small groups on projects and submitted written reports, either as a group or individually. The instructor of the course, Dr. Jackson (pseudonym), had taught the course using inquiry-based learning on more than twenty occasions. All class sessions were observed using written notes, video recording, and audio recording. During these observations, the researcher (first author) described the propositions used by students and the instructor, as well as the perceived sources of authority for those propositions. Descriptions of propositions and sources of authority were then open coded for themes.

The students in the course were a mixture of elementary education majors with an emphasis in mathematics, and mathematics majors with emphases in liberal arts, applied mathematics, or secondary education. Six students, Leo, Jemma, Skye, Melinda, Phil, and Grant (pseudonyms) agreed to participate in interviews, which were conducted as a mixture of individual and paired settings, the first three being task-based and the fourth being a stimulated recall interview (See Figure 1 for a full description of the interview structure). Interviews were then transcribed in full and each utterance was coded for structure. Open coding was used to describe the function of each utterance. Examples of functions included expressing beliefs, proffering hypotheses, and making conjectures. In this report, interview analysis from only one pair, Leo and Jemma, is shared.

Interview	Setting	Purpose
Interview 1	Paired, Task-Based	To investigate reproduction or non-reproduction of social and socio-mathematical norms of the classroom while performing a novel task as a pair.
Interview 2	Individual, Task-Based	To investigate influence of paired setting on individual cognition.
Interview 3	Paired, Task-Based	To investigate the influence (or non-influence) of individual cognition on discourse of the paired setting.
Interview 4	Individual, Stimulated-Recall	To gain insight into the covert thoughts of participants during Interview 3.

Figure 1. Stages of the interviews

The Interview 1 Task was the traditional Seven Bridges of Königsberg. Pairs were prompted with a map and tasked with providing a path that crossed every bridge once and only once, or provide an explanation as to why no such path existed. The Interview 2 Task was an amendment to the Interview 1 task, in that the individuals were instructed to: 1) construct a bridge such that one could create a path that crossed each bridge once and only once starting in the Red District and ending in the Gold District but it was not possible to construct such a path starting in the Blue District and ending in the Gold District (see Figure 2), 2) construct a second bridge such that one could create a path starting in the Blue District and ending in the Gold District, but no such path could be created starting in the Red District and ending in the Gold District, and 3) construct a third path such that one could create paths that crossed each bridge once and only once, starting and ending in both the Red and Blue Districts.

The Interview 3 Task was to create a continuous curve that crossed each edge of a figure (See Figure 3) once and only once or provide an explanation as to why such a curve was not possible.

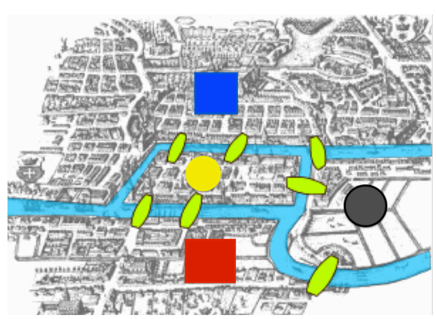

Figure 2. Seven Bridges of Königsberg with locations of Red District (southern square), Blue District (northern square), Gold District (central circle), and Grey District (eastern circle).

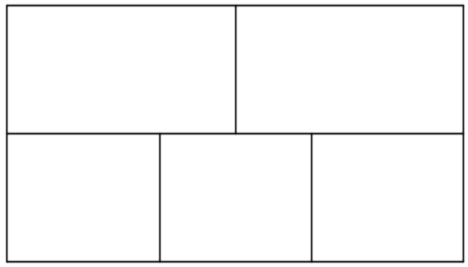

Figure 3. Figure of the Interview 3 Task

The Interview 4 was a stimulated recall interview using episodes video recorded from Interview 3. Episodes were chosen based on the propositions made during Interview 3. Participants were instructed to explain any thoughts or feelings they had during each episode, and could pause or rewind if they felt compelled to do so. After each episode, the interviewer (first author) would ask follow-up questions if the participant had not already addressed them.

Preliminary Results

Classroom Observation Findings

Three themes emerged in observing the classroom: *consensus*, *autonomy*, and *argumentation* (see Figure 4 for a summary of the themes and subthemes). Propositions were sorted into three categories: *beliefs*, *hypotheses*, and *conjectures*. Beliefs were defined as propositions that were made without prior evidence, hypotheses were defined as propositions made with unverified (by the participants) evidence, and conjectures were defined as propositions made with verified evidence. Categories of sources of authority were *group consensus*, *prior group consensus*, *authority figure*, *implicit*, *preference*, and *logic*. *Group consensus* was evidenced by a small group or the whole class reaching a sense of agreement. *Prior group consensus* was evidenced by a reference to consensuses that had been reached previously. *Authority figure* was evidenced by an appeal to either Dr. Jackson or the researcher (first author). *Implicit* was evidenced by no overt appeal to external authority, implying implicit appeal to the norms established within the classroom such as prior group consensus. *Preference* was evidenced by an appeal to personal preference.

In analyzing these themes and their interactions with one another, I could describe the evolution of the classroom could be described as follows: Students, in general, began the course lacking direction and authority to make and evaluate their own propositions. Dr. Jackson was able to source their authority in group consensus by holding whole-class discussions and building group consensus, as well as referencing these consensuses at later times. This afforded students with the opportunity to transition from lacking autonomy, to tentative autonomy, to free expression. With each new topic or discussion, however, this sense of autonomy could reset and students could revert back to lacking autonomy. By focusing on stylistic and structural aspects of argumentation, Dr. Jackson could then rebuild the students' autonomy by allowing them to express preferences and validate those preferences with logic. This cyclic process of building-referencing-losing authority continued throughout the course, even after the final project had been completed.

Theme	Subtheme	Propositions	Authority Sources	Student Quote
Consensus	*Building Consensus*	Beliefs, Hypotheses	Group Consensus	"Do you think that's a good direction? Looking at straight lines in terms of angles?"
	Referencing Consensus	None	Prior Group Consensus	"So we said that Axiom 4' is saying that there can't be two lines that share the same two points."
Autonomy	*Lacking*	None	None	"So where do we start?"
	Tentativity	Beliefs, Hypotheses, Conjectures	Authority Figure	"Does this make sense? Is it ok to do this?"
	Free Expression	Beliefs, Hypotheses, Conjectures	Implicit, Preference	"It's just saying that if we have two triangles that are the same, then the sides and the angles will be the same", "I guess we decide because it's our definition"
Argumentation	*Stylistic*	NA	Preference	"I don't think 'evenly on itself' is a very clear definition."
	Structural	NA	Logic	"If we define straight as being the shortest distance between two points, that doesn't work on the sphere."

Figure 4. Summary of observation themes of the classroom.

Interview Findings

Leo and Jemma began Interview 1 by recalling that they did something similar in Discrete Mathematics, a course they took before, albeit separately. Leo recalled the terms *Euler path* and *Euler circuit*, but was unable to use them on the task. Both recalled that the solution involved the number of even or odd vertices. Jemma then suggested that they "… know it, with like, doors?" They began using a *door-and-room* metaphor, implying that each section of the Task 1 map was a room and each bridge was a door between rooms (see Figure 5). The pair concluded eventually that there was no such path, because there could be at most two odd sections. They also claimed that if there were all even sections, the path would start and end in the same section.

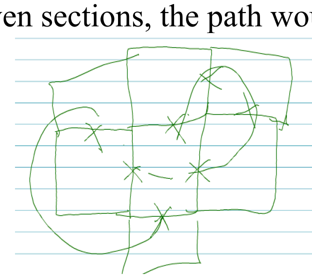

Figure 5. Leo and Jemma's picture depicting the *door-and-room* metaphor.

During Interview 2, Leo used a diagram that was more similar to a mathematical graph than a *door-and-room* diagram (see Figure 6). Leo eventually concluded, "With exactly two odds, you must start in one and end in the other." Jemma, however, used a diagram that more closely resembled the map given in the prompt (see Figure 6). Jemma eventually concluded, "If you start in an odd section, you can end elsewhere."

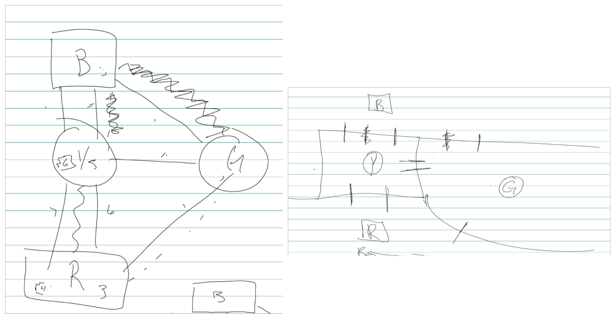

Figure 6. Leo's Interview 2 diagram (left) and Jemma's Interview 2 diagram (right).

For Interview 3, Leo initially asked if the "outside" needed to be considered. Jemma did not respond, and instead began path-tracing, claiming, "Each of these is like our space […] and there is a door on every single one of them." The pair then labeled the degree of each "space" with Leo accounting for three, five-degree sections on the "inside" and Jemma stating that, on the outside, "there would be nine." They then concluded that the curve was not possible, since they knew "three" parts of the figure had an "odd number of edges, and you can't have more than two."

In summary, Leo and Jemma built consensus around their prior understanding of the problem from Discrete Mathematics, including their use of the *door-and-room* metaphor. Individually, neither participant used the *door-and-room* metaphor, instead opting to use other diagrams. For Interview 3, the pair reverted back to using the *door-and-room* metaphor and successfully completed the task. During stimulated recall, Leo lamented that they relied so heavily on path-tracing and in-out strategies and not relying on their conjectures. He also said that he was uncertain initially as to how the previous tasks were related to the Interview 3 task. Jemma also lamented their use of path-tracing. She said that she viewed all the problems as *doors-and-rooms*, and that enabled her to solve the Interview 3 task.

Conclusion

The analysis of the classroom indicated the norms of the inquiry-based, geometry classroom as *consensus*, *autonomy*, and *argumentation*. Through the cyclic process of building and referencing consensus, Dr. Jackson was able to help the students develop a sense of autonomy in making choices regarding both stylistic and structural argumentation. During interviews, it seems that the pair of Leo and Jemma reproduced the norm of building consensus by agreeing upon their usage of the *doors-and-rooms* metaphor to solve the task. Both participants, however, did not use their agreed upon metaphor to complete the Interview 2 task. They later used the *doors-and-rooms* metaphor to complete the Interview 3 task, with Jemma feeling fully autonomous to apply the *door-and-room* metaphor, while Leo felt less sure.

These results indicated that while classroom norms may be reproduced in interview settings, they might not necessarily be reproduced when students work individually. As such, further study is required to assess the transfer of inquiry-based learning to an individual's own work.

Instruction in Precalculus and Single-Variable Calculus: A Bird's Eye View

[1]Dana Kirin, [1]Kristen Vroom, [1]Sean Larsen, [2]Naneh Apkarian, & the Progress through Calculus team*
[1]Portland State University, [2]San Diego State University

Improvement of mathematics courses in the first two years of college has recently become a priority in the United States. This is evidenced by multiple calls to enhance undergraduate education in the mathematical sciences and by funding allocated to related research and instructional improvement projects. As stakeholders make decisions to invest in the improvement of these courses, it is critical that these decisions be informed by reliable information regarding how these courses are currently being taught. The work described here is an effort to lay this groundwork by painting a comprehensive portrait of instruction in precalculus and single variable calculus (P2C2) in the United States. In this report we address two research questions; 1) What instructional formats are currently in place in the P2C2 sequence? and 2) How common are these instructional formats nationally?

Key words: Precalculus, Calculus, Census Survey, Instructional Approaches

Improvement of mathematics courses in the first two years of college has recently become a national priority. This is evident from multiple calls to enhance undergraduate education in the mathematical sciences (e.g., *A Common Vision for Undergraduate Mathematical Science Programs in 2025,* Saxe et al., 2015) as well as from available funding allocated to related research by the NSF, through several programs. Given its key role in most STEM fields, the precalculus and single variable calculus courses (Precalculus to Calculus 2, P2C2) are of particularly importance and are the focus of this report.

The request for improvements of introductory post-secondary mathematics courses in general, and courses in the P2C2 sequence in particular, is warranted by the educational research in the area. It is well documented that within these courses, student learning outcomes lack rich conceptual understanding (Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Carlson, 1998; Tallman, Carlson, Bressoud, & Pearson, 2016; Thompson, 1994). In addition, research indicates that students in calculus have difficulties leveraging their knowledge to solve non-routine problems (Selden, Selden, & Hauk, 2000) and students' impoverished understanding of pre-calculus concepts can influence their understanding of concepts found later in the sequence (Thompson, 1994).

Perhaps most problematic is the retention rate of STEM-intending students; less than 40 percent of STEM-intending majors actually complete the degree (PCAST, 2012). Moreover, PCAST predicts there will be economic implications if this rate persists. Research indicates that many lose interest in STEM after taking courses in the calculus sequence (e.g., Bressoud, Mesa, & Rasmussen, 2015; Seymour & Hewitt, 1997). The literature repeatedly points to a relationship between retention and instruction. For instance, Ellis, Kelton, and Rasmussen (2014) found that some pedagogical activities (demonstrating how to work specific problems, preparing extra material to help students understand calculus concepts or procedures, holding a whole-class

* The Project through Calculus PI team consists of Linda Braddy, David Bressoud, Jessica Ellis, Sean Larsen, Estrella Johnson, and Chris Rasmussen. Graduate students include Naneh Apkarian, Dana Kirin, Kristen Vroom, and Jessica Gehrtz.

discussion, and requiring students to explain their thinking on exams) were significantly related to STEM intending students persistence. Additionally, Seymour and Hewitt (1997) found students who transfer from a STEM major often cite traditional and uninspiring instruction as reasons for their switch.

The AMS noted that "no single pedagogical method will be suitable for every classroom… Success in education is not achieved by simple formulas: there are many different successful ways of teaching mathematics, techniques adapted to the variation of talents of both students and teachers" (Friedlander et al., 2012, p. 1205). Thus, successful P2C2 sequences may come in a variety of forms involving a variety of instructional techniques. As we work towards the future of P2C2 instruction, it is important to understand how things stand now. This is important because the current situation represents the starting point of potential improvement efforts and likely will provide significant affordances and constraints as these efforts unfold. The work described here is an effort to lay part of the groundwork for improvement efforts by painting a comprehensive portrait of the instruction that is currently being implemented in the P2C2 sequence across the United States. In this report we address the following research questions:

1. What instructional formats are currently in place in the P2C2 sequence?
2. How common are these instructional formats nationally?

Methods

The data reported here comes from a census survey undertaken as part of a larger, multiphase project. The survey was administered to all institutions across the country whose mathematics departments offer a graduate degree in mathematics between April and August 2015. We focused on institutions with graduate degrees in mathematics because they produce the vast majority of STEM graduates and because such institutions typically have significant research missions resulting in a challenging need to balance the demands of research and teaching. In the United States, there are 330 departments which offer graduate degrees in mathematics; 178 of the 330 are PhD-granting institutions and 152 of the 330 offer Master's degrees. The overall response rate was 67.6% (223/330); 75% (134/178) of the PhD-granting institutions and 59% (89/152) of the Master's-granting institutions participated in the survey.

The survey was designed to gather information about each department's P2C2 program as well as the individual courses that comprise the sequence. In particular, the survey identified programs that are currently in place and their prevalence, revealed initiatives to improve current programs, and assessed degrees of implementation of the seven features of successful programs identified in the CSPCC project (Bressoud et al., 2015). The survey itself had three main parts. Part 1 asked the participants to name the courses that make up the mainstream P2C2 sequence in his or her department. Part II asked for information about departmental practices in regards to the P2C2 sequence. Part III asked for information about specific courses in the P2C2 sequence, including number of course offerings per term, total enrollment per term, DFW rates, contact hours, instructors, instructional approaches, recitations sections, and coordinated aspects across sections. This study reports on a subset of the data collected from Part III of the survey, where participants provided information about the individual courses that make up the P2C2 sequence.

The following section includes descriptive statistics (i.e., frequencies, proportions, etc.) gathered from questions related to instruction in the P2C2 sequence. Our aim is to identify instructional patterns of existing P2C2 programs by analyzing the aggregated data as well as zooming into the individual components by stratifying the data based on institutional type (PhD vs. MA/MS), course (precalculus vs. calculus vs. calculus 2), and course type (honors vs. regular).

Sample Results

The census survey collected information about the primary instructional format used in regular course meeting and that used in recitation sections (where applicable). In this report we focus on the format of the regular course meetings, and leave analysis of recitation sections for future work. We begin with a question where participants were asked, for each course, to identify whether the course is normally taught using 1) *mostly lecture*, 2) *some active learning alongside lecture*, 3) *mostly active learning*, or 4) *computer assisted instruction with lecture*. Participants were also provided with the opportunity to report that there was too much variation in the instructional format of that course across sections or allowed to indicate that a course was taught using an instructional format that was not listed. If a participant indicated either of these last two options they were asked to provide additional explanations. In this report we do not consider these written-in responses, but that information will be discussed in our presentation.

Two hundred institutions provided information about the instructional format for 881 courses. Of these, 66% were identified as being taught using mostly lecture, 16% used some active learning in tandem with lecture, 2.5% of courses were taught using mostly active learning, and 3.6% of these courses used computer-based instruction alongside lecture. When these data were stratified by course (PC, C1, and C2), we see that the use of lecture increases throughout the P2C2 sequence, while the use of active learning decreases. The data also indicates that computer-based instruction coupled with lecture is most prevalent in Precalculus courses. These results are shown in Figure 1.

	Lecture	Lecture + Some AL	Mostly AL	Lecture + Computer
PC	0.59	0.18	0.04	0.06
C1	0.65	0.17	0.03	0.02
C2	0.74	0.13	0.01	0.03

Figure 1. P2C2 courses with selected primary instructional format. N_{PC}=256, N_{C1}=327, N_{C2}=298.

Figure 2 shows the prevalence of these instructional approaches across the P2C2 sequence for Master's-granting and PhD-granting institutions. These results indicated that Master's-granting institutions are more likely than PhD-granting institutions to teach Precalculus using mostly lecture, while PhD-granting institutions rely slightly more on lecture within the single-variable calculus courses. For both Master's- and PhD-granting institutions, courses taught using some active learning concurrently with lecture were more prevalent in Calculus 1, followed by Precalculus, with Calculus 2 employing this instructional format the least. Very few P2C2 courses are being taught using mostly active learning techniques in regular course meetings - 22 out of the 881 reported. The majority of these (19/22) come from PhD-granting institutions, and it was only at PhD-granting institutions that courses past Calculus 1 are taught in such a way. Furthermore, we note that the proportion of courses being taught using mostly active learning decrease along the P2C2 sequence at PhD-granting institutions. Additionally these results indicated that PhD-granting institutions are more likely than Master's-granting institutions to teach both Precalculus and Calculus 2 using computer-based instruction alongside lecture, while Master's-granting institutions rely slightly more on computer-based instruction coupled with lecture to teach Calculus 1.

	Lecture ALL	Lecture MA	Lecture PhD	Lecture + Some AL ALL	Lecture + Some AL MA	Lecture + Some AL PhD	Mostly AL ALL	Mostly AL MA	Mostly AL PhD	Lecture + Computer ALL	Lecture + Computer MA	Lecture + Computer PhD
PC	0.26	0.34	0.22	0.33	0.30	0.36	0.45	0.33	0.47	0.50	0.45	0.60
C1	0.37	0.31	0.39	0.40	0.43	0.37	0.41	0.67	0.37	0.22	0.27	0.10
C2	0.38	0.34	0.39	0.27	0.27	0.27	0.14	0.00	0.16	0.28	0.27	0.30

Figure 2. P2C2 courses with selected primary instructional format for MA- and PhD-granting institutions. Sample sizes for lecture: N_{ALL}=583, N_{MA}=183, N_{PhD}=400. For lecture incorporating some active learning: N_{ALL}=141, N_{MA}=63, N_{PhD}=78. For mostly active learning: N_{ALL}=22, N_{MA}=3, N_{PhD}=19. For lecture incorporating computer-based instruction: N_{ALL}=32, N_{MA}=22, N_{PhD}=10.

For courses that were identified as incorporating at least some active learning as part of their instructional format, participants were asked to provide additional information about the type of active learning strategies used during instruction. In particular, participants were asked whether these courses incorporated 1) *POGIL*, 2) *IBL,* 3) *clicker surveys*, 4) *group work*, or 5) *flipped instruction*. Participants were also provided with the opportunity to indicate that an active learning strategy other than those provided was used and prompted to provide additional information. As before, we will focus on courses that incorporated one of the provided responses for this question and discuss other active learning strategies identified by participants in our presentation.

	POGIL	IBL	Clicker Sureveys	Group Work	Flipped
PC	0.05	0.16	0.19	0.75	0.25
C1	0.05	0.15	0.22	0.78	0.22
C2	0.03	0.18	0.25	0.83	0.15

Figure 3. Selected types of active learning strategies within the P2C2 sequence. N_{PC}=57, N_{C1}=65, N_{C2}=40. Options are not mutually exclusive.

Of the 881 total courses, 163 were identified as incorporating at least some active learning. Of these, the most prevalent active learning technique was group work, reported in 78% of these courses. Additionally, 4% identified POGIL as a strategy used in these courses, 10% IBL, 21% clicker surveys, and 21% flipped (note that these options are not mutually exclusive). Figure 3 shows the prevalence of the various active learning strategies across the P2C2 sequence. These results indicate that the proportion of courses that use POGIL and flipped instruction decrease throughout the sequence. In contrast, both the use of group work and clicker surveys increase throughout the P2C2 sequence.

Conclusion

The results reported here provide some insight into the prevalence of instructional formats currently in place in the P2C2 sequence. In particular, we reported on the types of instructional approaches used in the regular course meetings. While the majority of courses are taught in a traditional lecture format, our analysis reveals that alternative instructional formats, such as active learning, are also currently present within the P2C2 sequence. Approximately 19% of courses within the P2C2 sequence are currently taught using at least some active learning, while 3.6% of courses are being taught using computer-based instruction alongside lecture. However, we note that the proportion of courses being taught in traditional lecture format increases through the sequence (from 59% to 74%), while all other formats decreased in frequency. Our analysis also reveals that courses being taught using at least some active learning employ a variety of active learning strategies. The most popular active learning strategy be used during regular class meetings is group work, followed by clicker surveys and flipped.

In addition to these results, we will present a similar analysis of the instructional formats being used in recitation sections accompanying P2C2 courses (when applicable). We will supplement the analyses presented here with information from the open-ended responses, explaining some of the variation in instructional format across instructors and identifying instructional approaches (e.g., emporium model) that were not included in our original set of options.

This preliminary report and subsequent analyses lay out the landscape of instructional format and course delivery for P2C2 courses across the country. We believe that the information in this report and presentation will be useful to those studying pedagogy at the undergraduate level, presenting a starting point and indicating the relative frequency of usage of different approaches. This information may be informative for stakeholders whose decisions affect improvement efforts in P2C2 courses.

Students’ Inclination to Use Visual Images during Problem Solving

Mile Krajcevski
University of South Florida

Karen Keene
North Carolina State University

This is a preliminary report on a study to investigate the inclination of Calculus III students to use visual reasoning in problem solving situations. One of our research hypotheses was that there is a correlation between students’ inclination towards visual representations when taking notes and their use of visual representations in problem solving situations. Surprisingly, preliminary analysis of the results suggests that there may not be a correlation, although work is ongoing.

Key words: Visual representation, visualization, problem solving, calculus

Introduction

Even though the development of computer graphics and educational software with its ubiquitous penetration into educational practice, may lead some to believe that the days of using free hand sketching in the teaching process are over, research demonstrates that the use of free hand sketching in classroom practice has significant impact on students’ learning. (Walker, Winner, Hetland, Simmons, & Goldsmith, 2011) The very process of sketching involves powerful hand-mind coordination; one reason for this is that the concretization of abstract mathematical objects as creations of our own hands is subject to easy manipulation or transformation.

Research into the role of imagery in the cognitive process has been intensified in the last two decades. The usefulness of visual representations of mathematical objects in the process of learning mathematics has been described as a vehicle that promotes abstraction and generalization. (Zimmerman & Cunningham, 1991; Arcavi, 1999; Presmeg, 2006).What do we mean by visualization? Phillips, Norris and Macnab (2010) published an overview of educational literature about visualization published between 1974 and 2009; they found 23 explicit definitions of visualization and related terms, such as “imagery” or “visual aid”, and point out that some of these are even contradictory. For our theoretical framework, we will utilize their definition of a “visualization object”:

> Visualization objects are “physical objects that are viewed and interpreted by a person for the purpose of understanding something other than the object itself. These objects can be pictures, 3D representations, schematic representations, animations, etc. Other sensory data such as sound can be integral parts of these objects and the objects may appear on many media such as paper, computer screens and slides. (Phillips et al.,2010, p.26)

Traditional calculus content is particularly suitable for implementation of visual pedagogy. In a Calculus III class taught by the first author, we strived to create a learning environment in which the main ideas about three dimensional coordinate systems, classification of quadratic surfaces, and min-max problems involving multivariable functions would first be taught focusing on a visual point of view and then from an algebraic or analytic point of view. We also followed Inglis and Mejia-Ramos’s (2009) suggestion that students are more inclined to accept figures as evidence for the claim when descriptive text explaining the claim accompanies the figure. In this study, we focused on students’ ability to reproduce the images during enacted lessons but did not evaluate students’ sketches for the basic requirements of perspective, visibility or line intersections.

The purpose of this research was to study students' desire and ability to reproduce three-dimensional images of the mathematical objects presented during instruction and how this desire and ability correlates with their use of images in solving test questions. The research questions for this work are:

1. How do students use sketches and other visual representations when taking notes in a Calculus III class?
2. What is the relationship between students' inclination and ability to hand sketch visual images and their use of visual imagery when problem solving?

Methods

Research Context and Participants

In a Calculus III class of 45 students, 30 students agreed to participate in this research project. The book used for this course was Stewart's *Essential Calculus, Early Transcendentals*. Designed as a one semester, four credit hours course, the class met three times a week with the first two class sessions for an hour and 15 minutes each and the last session meeting for 50 minutes. Students' class assessments consisted of a final exam, two one hour and 15 minutes tests, four 15 minutes quizzes, web-assigned homework, and handwritten homework each being adequately weighted. Students were encouraged to take notes for each class in a separate notebook and promised extra points for this activity. Their notebooks were examined twice during the semester and we collected copies of the notes for two particular class periods, which were also videotaped for research purposes.

The first recorded lecture was "Double integrals in polar coordinates" and the second recorded lecture was entitled "Triple integrals in spherical coordinates". We focus only on the videotaped lecture about triple integrals in spherical coordinates. The teaching style of the instructor was a traditional lecture, with occasional questions asked to students in the class in order to gage their understanding of the concepts discussed. The change of coordinate system and questions associated with this notion in the Calculus III curriculum is rich with concepts that can easily be illustrated on the whiteboard: segments, lines, cylinders or spheres in 3-D coordinate system most of the time do not present a challenging sketching task for the instructor.

Coding

Visual images from class. We first carefully watched the video recording of the lecture presented during the 50-minute class and identified all images that were presented on the whiteboard; these were typical visual representations of the Cartesian, cylindrical and spherical coordinate systems to visualization of the infinitesimal volume element in the spherical coordinate system.

The imagery presented during the enacted lesson, was subject to a natural classification. We distinguished three categories of images: primary image, secondary image, and second-layer image. We define *primary image* as an image on which the derivation of the analytical portion of the presentation, related to a justification (proof) of a proposition relies. This image may also play an essential role in the explanation of a new mathematical concept. Usually this image will stay on the board during an enacted lesson for a substantial amount of time. In Figure 1, we provide two examples of primary images that were used in the lecture about triple integrals in spherical coordinates.

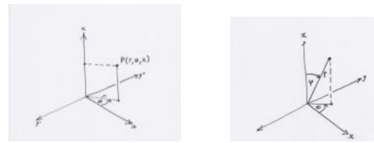

Figure 1. Primary Images

A *second-layer image* (SLI) is an image that has been superimposed on a primary image later in the exposition, bringing new aspects of the presented notion, or illustrating a portion of the proof of a proposition. Most of the time, during the enacted lesson, students are inclined to sketch a completely new illustration rather than revisiting a primary image and superimposing on this image a new one. Illustrative elements that have been superimposed on the primary images given in Figure 1 are indicated as shaded areas.

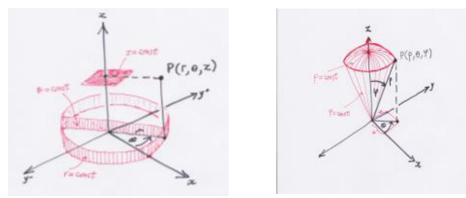

Figure 2. Second-Layer Image

Our third category of images is *secondary images*. These are images that have been used to clarify a particular argument related to the primary image, illustrate a particular point in the analytical portion of the argument, or used as a review of a specific notion used in the exposition. Usually these images will stay a short time on the board, serving its purpose and not interfering with the primary image. We illustrate this category in Figure 3.

Figure 3. Secondary Images

The left picture from Figure 3 helps students recall the definition of sine and cosine function and the right picture illustrates four graphs of the equation $\varphi = c$ (c is a constant) in the spherical coordinate system, for four different choices of c all between 0 and π.

There were 16 images presented on the whiteboard during the class period (Lecture entitled "Triple integrals in spherical coordinates"), with one of the images appearing twice in the lecture, at the beginning and towards the end, and being counted as two separate images. Out of these, 4 were counted as SLI and 5 were counted as secondary images as far as the instructor's drawing.

The researchers then coded each of the 30 notebooks by identifying which of the 16 images from the whiteboard were recorded by the students. This resulted in one tally for each of the students, which was the number of primary, SLI, and secondary images that the students had reproduced in their notebooks.

Coding visual images for problem solving. In order to investigate students' use of visual reasoning when problem solving, we chose to consider two problems from the exams given in the class. Each of these problems were designed so that visual representation of the problem would reveal a short path towards its solution. In the first problem (T1), we asked for unit vectors that make an angle of 30º with the vector < 2015, 2015 >. In the second problem (F), we ask students to evaluate an iterated integral, with its domain of integration given in cartesian coordinates by converting it to polar coordinates.

Table 1.

Code	**Description**
No code	No attempt at problem
1	No drawing used in solution
2	An attempt at sketch for some notions
3	Good sketch not used in solution
4	Sketch was essential and provided insight for student
Multiply code by 2	*Student was successful*

Students' use of images was coded as shown in Table 1. We were interested not only in the use of images when solving problems, but also in a successful use of visual information and so codes were multiplied by 2 if the solutions were correct. We are trying to quantify the instant when a logical sequence of analytical expressions is guided by the visual information.

In Table 2, we present a portion of the table with the students' full coding. This table was used to analyze quantitatively the data to answer the research questions. In the next section, we discuss some of the results.

Table 2.

Student	**Codes for notebooks**				**Codes for problem solving on exam**			
	Primary	SLI	Sec.	Primary + +SLI +Sec.	T1	F	T1+F	
7	7	1	1	9	-	1•1	1	
8	7	2	0	9	1•1	4•2	9	
9	9	1	0	10	1•1	1•1	2	
10	8	2	0	10	1•1	4•1	5	

Preliminary Results

Bold horizontal segments in Figure 4 show the total number of images that each student reproduced in their notebooks (Primary + SLI + Sec). The triangular diagrams show the total score (T1+F). Visual inspection shows that the relationship between the two is low. Due to space constraints, we have not shown graphs that break out the differences between image types.

Statistical analysis of the results reveal that the correlation index for the columns (T1+F), that measures how successful are students in producing visual information in problem solving situations and column (Primary+SLI+Sec) that indicates students' ability and inclination to hand-sketch is 0.05. In other words, there is no a correlation between these two variables. The comparison of other variables reveal similar trends. For example, 30% of the students successfully completed prblem (F), but there is not a correlation between their success in this problem with their tendency to give a visual representation of this problem (correlation index in this case is 0.334).

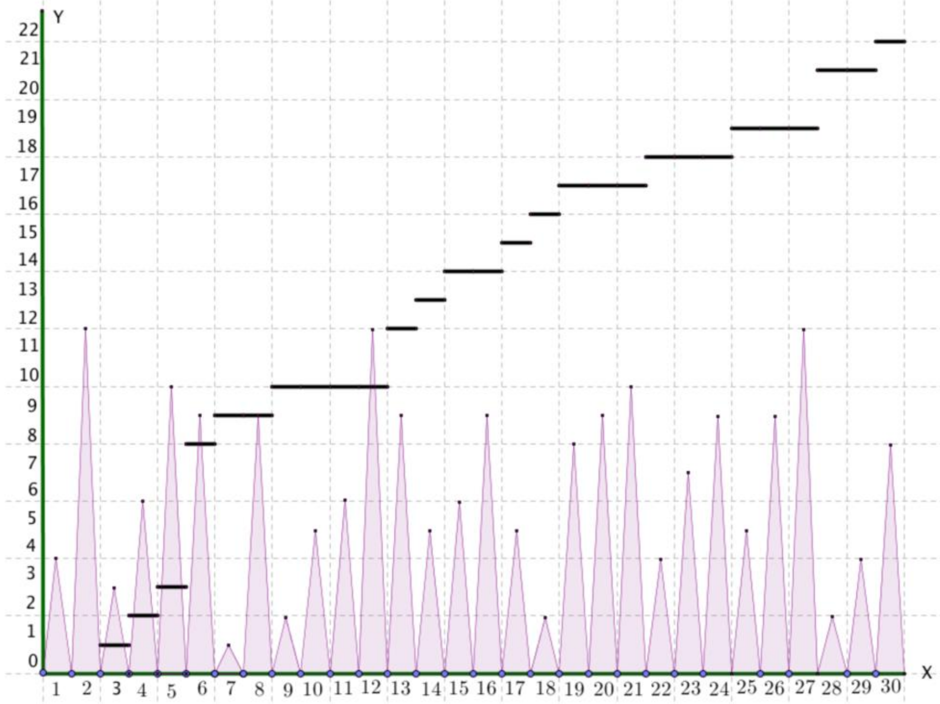

Figure 4.

Even though throughout the course the instructor exhibited a preference for visual explanations followed by analytic aspects of problem solving, it is surprising how little of this way of reasoning was accepted by students. Only four students (13%) successfully answered this question, all using the visual information in the most substantial way. A higher number of students using visual representation in the second problem (67%) may be explained by the way the polar coordinate system is introduced in all calculus books and in enacted lessons. A picture depicting how polar coordinates relate to the familiar Cartesian coordinates always accompanies it in the book.

Conclusion and Questions

These preliminary results indicate that just asking students to sketch visual representations in their notebooks is not sufficient for them to begin using more diagrams and graphs to problem solve in exams. Instructors need to consider additional ideas to encourage the use of visual methods. This might include homework that requires sketching, or using group work to have students talk and work together, with visualization as a focus.

Intended Questions for the Audience

1. What other coding ideas might help us move forward on connecting visualization and problem solving in a classroom setting?
2. Is it important to give value to getting a correct answer? How might we address this in other ways than doubling the scores?
3. What other data might be useful to collect in order to continue investigating visualization in problem solving?

Students' Epistemological Frames and Their Interpretation of Lectures in Advanced Mathematics

Victoria Krupnik	Tim Fukawa-Connelly	Keith Weber
Rutgers University	Temple University	Rutgers University

In this paper, we present a comparative case study of two students with different epistemological frames watching the same real analysis lectures. We show the general point that students with different epistemological frames can interpret the same lecture in radically different ways. We also identify epistemological frames that are useful or counterproductive for understanding a lecture on how the rational numbers are constructed from the integers. These results illustrate how different students interpretations of a lecture are not inherently tied to the lecture, but rather depend on the student and that student's perspective on mathematics. Thus, improving student learning may depend on more than improving the quality of the lectures, but also changing student's beliefs and orientations about mathematics and mathematics learning.

Key words: epistemic frames, student understanding of lecture, real analysis

In recent years, there has been a substantial increase in research into how proof-oriented university mathematics courses are traditionally taught. This research has led to important insights into what transpires in lectures in advanced mathematics (e.g., Fukawa- Connelly, 2012; Fukawa-Connelly & Newton, 2014; Hemmi, 2010; Lew et al., 2016; Mills, 2014; Pinto, 2013; Weber, 2004; Weinberg et al., 2016) and mathematics professors' motivation for their pedagogical behavior (e.g., Alcock, 2010; Lew et al., 2016; Nardi, 2007; Weber, 2012).

While the nature of lecturing in advanced mathematics is now better understood, there has been comparatively little research into how tertiary students interpret the advanced mathematics lectures that they observe. The goal of the current paper is to address this gap. In particular, we aim to shed light on the issue: When professors provide lectures in advanced mathematics that are clear to other mathematicians, why are these lectures often confusing to the students who attend them? Why do *some* students learn from a lecture while other students find the same lecture less clear? What dispositions prepare students to learn from lectures in advanced mathematics?

To address these broad issues, we adapt the notion of *epistemological frame*. We elaborate on the nature of epistemological frames shortly, but an epistemological frame can be thought of as a person's tacit answer to the question, "what sort of activity is this?" (c.f., Goffman, 1997; Redish, 2004). In this paper, we present a comparative case study of two students with different epistemological frames watching the same real analysis lectures. The first goal of this paper is to illustrate the general point that students with different epistemological frames can interpret the same lecture in radically different ways. The second goal of this paper is to identify epistemological frames that are useful or counterproductive for understanding a lecture on how the rational numbers are constructed from the integers.

Theoretical Perspective

In this paper, we adapt the notion of *epistemological frame*, as it is used in the physics education literature (e.g., Redish, 2004). Goffman (1997) introduced the notion of *frame* to describe how individuals develop expectations to help them make sense of the complex social spaces that they inhabit. For instance, most adults in the Western world have a "restaurant frame" (Schank, 1990). When individuals enter a restaurant, they carry with them numerous assumptions: for instance, the individual will eat a meal, the staff at the restaurant will prepare the meal, the items listed on the menu list are what the individual may order, the prices next to the item denote how much the food will cost, the individual will be expected to pay for their meal using cash or a credit card, and so on. Such expectations are valuable in that they enable us to cope with the enormous complexity of most situations that we regularly encounter. However, occasionally our frames can be problematic in cases where they are inaccurate or when two different individuals frame the same situation in different ways. For instance, a visitor to the United States might not be aware of the expectation to leave a 20% tip on the bill, which could lead her to inadvertently insult the waiter by not leaving the presumed gratuity.

In an educational situation, we refer to an individual's epistemic frame as consisting of their epistemological expectations. These consist of an individual's responses to questions such as "what do I expect to learn?", "how do I build new knowledge?", and "what counts as knowledge or an intellectual contribution in this environment?" (cf., Redish, 2004). Physics educators have illustrated how when a teacher and her students approach an activity with different epistemological frames, the students may not reap the educational benefits that the teacher intended. For instance, Redish (2004) described one student in a physics tutorial who was given a prompt to make a qualitative prediction using her conceptual understanding of physical principles. However, this student viewed intellectual contributions in a physics classroom as consisting of deriving numerical answers from textbook formulas. As a result, she participated in the activity by engaging in computations, thereby avoiding the conceptual considerations the activity was designed to elicit. Hammer (1995) illustrated how epistemological frames can explain how some students successfully learn physics in a traditional classroom while other students do not.

In this paper, we use epistemic frames to account for two students' interpretations of a lecture in advanced mathematics. Although the phrase "epistemic frame" is not often used in mathematics education, mathematics educators have used similar constructs to highlight students' classroom participation and identify differences in how teachers and students sometimes frame mathematical activity. For instance, Thompson (2013) described a secondary algebra teacher, Sheila, whose discourse with students was saturated with references to the conceptual meaning of the operations that were being discussed and performed, and a student, Mindi, who struggled in Sheila's course. Through his interviews with Mindi, Thompson found that Mindi believed that doing algebra consisted of applying rules and learning algebra consisted of memorizing rules; Mindi saw little value to having a conceptual understanding of these rules. As a result, she ignored the frequent references to meaning in Sheila's discourse.

In advanced mathematics, Solomon (2006) and Alcock and Simpson (2004, 2005) have explored the relationship between students' epistemologies and their learning in advanced mathematics classrooms, with both emphasizing that students who believe mathematical knowledge comes from external sources have a difficult time in these environments. Similarly, many mathematics educators have documented how the types of arguments that students found convincing influenced their proof-related behavior (e.g., Harel & Sowder, 2007; Stylianides, Stylianides, & Weber, in press). In this paper, we consider a more fine-grained epistemological distinction than the ones discussed above. The two students that we considered both showed evidence of having a desire to understand the material that they were learning, an internal loci of control and deductive proof schemes. Nonetheless, their different epistemological frames led them to interpret the same real analysis lecture in very different ways.

Methods

Rationale

The goal of this study was to understand individual student's interpretations of a real analysis lecture at a fine-grained level. Doing this in an authentic manner posed significant methodological difficulties. If we observed students in an *actual* real analysis lecture, it would be infeasible for us to know how a student was interpreting a professor's comments *in the moment* since we would be unable to interrupt the lecture to probe the student's thinking. We could follow Lew and colleagues (2016) in using cued recall by interviewing a student about a lecture they attended shortly after the lecture had occurred. However, by that time, much of the student's initial impressions would be forgotten. To manage this difficulty, we interviewed two students as they watched real analysis lectures that had previously been posted on YouTube. Here, the students can act as if they were attending an actual lecture yet the interviewer or student could pause the video to discuss their in-the-moment impressions of what was being discussed.

In this paper, we report a comparative case study (Yin, 2013) in which we attempt to illustrate how a particular phenomenon unfolds within a given context. There are some particular nuances of the study, such as the individual students' backgrounds or the content of the lecture, that may not generalize to other situations. What we contend is representative is the phenomenon of how an individual student's epistemological frame can influence his or her understanding of a mathematics lecture.

Participants

Two participants, Alan and Brittany (pseudonyms), agreed to participate in this study. Both participants were mathematics majors at a large state university in the northeast United States. Both students had completed a transition-to-proof course in the previous semester. At the university in which this study occurred, mathematics majors were required to complete a course in real analysis, for which the transition-to-proof course was a prerequisite. Some mathematics majors enrolled in real analysis in the semester after completing their transition-to-proof course while others, like Alan and Brittany, did not. Like many mathematics majors, Alan and Brittany elected to take an abstract algebra course immediately after their transition-to-proof course, choosing to postpone their real analysis requirement to a subsequent semester. Hence, while neither had, both participants could have taken a real analysis course in the semester of this study.

Procedure

The materials consisted of the first two 60 minute class meetings from a real analysis course taught by the president of the Mathematics Association of America and award winning professor Francis Su at Harvey Mudd University[1]. The lectures consisted of Professor Su beginning the real analysis course by first constructing the rational numbers and then the real numbers from the integers. Prior to conducting the study, the research team studied the lecture and parsed the lecture into five to ten minute segments in which coherent mathematical content was being

[1] Videos can be found at: http://analysisyawp.blogspot.com

presented. The research team also identified points in the lecture where important content was being conveyed.

Each participant met weekly with the first author for four weeks. Each of the four interviews was audio-recorded. The first interview was a one-hour interview in which the participant discussed the content from the transition-to-proof course to get a sense of their understanding of the relevant content (particularly with number theory, functions, and proof) as well as their learning strategies and dispositions. The next three interviews were two-hour interviews conducted in the style of a constructivist teaching experiment (Steffe & Thompson, 2000) in which the research team attempted to build and refine the mental schemes, which we termed epistemological frames, that each participant was using to interpret the real analysis lectures. During each interview, the participant watched the lecture and was instructed to stop the tape to discuss anything that they observed to be important, interesting, confusing, or otherwise noteworthy. The interviewer would also stop the tape to probe the participant's thinking when the professor had stated something that the research team had identified as important or at the end of a segment. The interviewer would then ask the participant to describe their impressions at that point.

After each interview, the members of the research team would engage in concurrent analysis by listening to the recordings of the interview and forming initial hypotheses about the schemes that the participants were using to interpret the lectures. They would then meet to synthesize these hypotheses and develop prompts to assess the viability of their hypotheses. These prompts were designed such that if a participant held a particular epistemological frame, we could expect them to respond in a particular way. We began the next interview segment by providing participants with these prompts, which was then followed by them resuming watching the lecture videos.

After all four interviewers were conducted, we transcribed all four interviews and clarified our initial hypotheses of participants' epistemological frames from the prior concurrent analysis. We then engaged in the following cyclic retrospective analysis: For each aspect of a participant's hypothesized epistemological frame, each member of the research team individually read the transcripts, identifying all instances that either supported or disconfirmed that the participant held this frame. The research team then met to determine how well the proposed epistemological frame was supported by the data. When there were aspects of the hypothesized frames that were not supported by the data (i.e., there were few confirming instances or significant disconfirming instances), we either removed this aspect from the epistemological frames that we attributed to the students or we revised the epistemological frame and repeated our analysis. The result of this retrospective analysis were epistemological frames for Alan and Brittany that were grounded in our data.

Results

Epistemological Frames

For the sake of brevity, we briefly discuss four aspects of Alan and Brittany's epistemological frames. In our presentation, we will elaborate on these and provide supporting evidence. We first note two aspects that Alan and Brittany had in common: (i) Both participants appreciated, understood, and enjoyed mathematical proof and (ii) both exhibited an internal locus of control. We also note two areas in which they differed: (iii) Alan valued definitions of terms that were unambiguous while Brittany preferred definitions that were comprehensible and relatable to her prior ways of knowing, and (iv) Alan viewed the purpose of these lectures as making his understanding of the rational numbers more reliable by basing it on a more secure footing (the reliability of the integers) while Brittany viewed the purpose of the lectures as providing a common base of knowledge shared by all students in the class from which real analysis can be built.

Differing interpretations of the lecture. We note that Brittany's epistemological frames, while sensible and productive in some situations, led her to interpret some aspects of the lecture in unproductive ways. For instance, when Professor Su deduced common properties of the real numbers (e.g., the integers were contained in the rationals), Brittany became frustrated because this was obvious and "everyone already knew this". By contrast, Alan claimed that the point of the lecture was to illustrate how Professor Su's construction of the rational numbers was sufficient to prove these important properties (cf., Weber, 2002). Brittany found many of Dr. Su's proofs of common facts about the rational numbers to be unnecessarily complicated, since she was aware of simpler proofs of these statements that were appropriate for middle school students. For instance, Professor Su defined rational numbers as equivalence classes of ordered pairs and defined addition as $(a, b) + (c, d) = (ad + bc, bd)$. Professor Su then proved this operation was well-defined. Brittany thought that the simple proof that $a/b + c/d = ad/bd + bc/bd = (ad+bc)/bd$ was superior to Professor Su's formal demonstration. In contrast, Alan abhorred the suggestion of using such a proof, since we had no right at this stage to say $a/b = ad/bd$. To Alan, the point of this exercise was to ignore everything we knew about the rational numbers. In general, Brittany wanted to apply her robust understanding of the rational numbers to the content that Professor Su was discussing and was annoyed that Professor Su did not do so. Alan continually reminded himself that he was only allowed to consider what he knew about the integers, the definitions Professor Su had provided, and the deductions made from them.

Discussion and significance

We use the general finding that students' epistemological frames can enable or prevent students from interpreting mathematical lectures in a productive manner to make two points. First, previous research on lectures in advanced mathematics has generally focused on what the professor says but did not consider student's interpretation of what was said. Our results illustrate how students' interpretations of a lecture are not inherent in the lecture itself but also depend on the student doing the interpreting. Consequently, we argue that ignoring students' interpretations of lectures is a significant shortcoming of most studies on lectures in advanced mathematics. Second, our results suggest that the key to improving students' learning from lectures does not consist only of improving the quality of the lectures. Rather, it is important to attend to their epistemological frames as well, a point that Solomon (2006) and Dawkins and Weber (in press) argue has received limited attention in the mathematics education literature.

Mathematical Modelling and Mathematical Competencies: The case of Biology students.

Yannis Liakos
University of Agder, Norway

The research aims at introducing modelling tasks in order to engage students more actively into learning mathematics through tasks that are biologically 'colored'. My focus is on the individual progression (if there is any) of students' mathematical competencies during a sequence of modelling sessions that will be part of a regular course of their first year calculus. My ultimate goal is to construct a dynamic competence profile for every student that will participate in the project. Taking the above into consideration, my research suggests a number of interventions in a standard freshmen mathematics course for biology students, interventions that offer a fruitful didactical environment where students can sharpen their mathematical competencies.

Key words: mathematical modelling, mathematical competencies, tasks, progression

Introduction

There is an increasing amount of literature which provides documentation for the learning benefits associated with engaging students in mathematical modeling. There is a 'red thread' among many researchers who, through the description of mathematical modelling processes, displayed the variety of many opportunities for educational benefits (Kaiser et al., 2006). Students engaged in modeling may develop a deep understanding of the content and an ability to solve novel problems (e.g. Wynne et al. 2001, Lehrer & Schauble 2005). Other studies (Schwarz & White 2005; Windschitl et al. 2008) have shown that modeling curricula can bring students into alignment with the epistemic aims of science and help them develop more sophisticated ideas about the scientific enterprise as a whole. Sriraman et al. (2009) blended the notion of interdisciplinarity with modelling, highlighting the necessity for creativity and giftedness across disciplines. It comes as no surprise that

> Both the National Research Council (NRC) and the National Science Foundation (NSF) in the U.S is increasingly funding universities to initiate inter-disciplinary doctoral programs between mathematics and the other sciences with the goal of producing design scientists adept at using mathematical modeling in interdisciplinary fields (Sriraman & Lesh, 2006, p.247).

Theoretical Stance

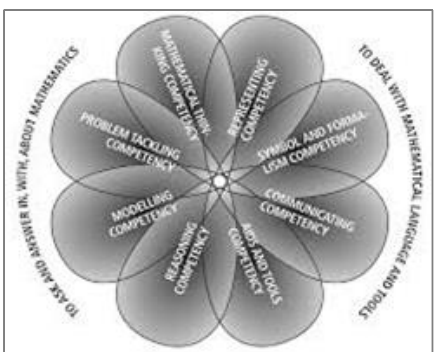

Figure 1. The KOM model (Blomhøj & Jensen, 2007)

A long-lasting and ongoing discussion among researchers and members of Educational Institutes centers on students' assessment and the need for a solid and valid evaluation (e.g. Galbraith 2007, Haines and Crouch 2007, Vos 2007). A different approach though occurred by an important number of researchers when they turned their view on students' competencies and mathematical competencies (e.g. Greer and Verschaffel 2007, Henning and Keune 2007, De Bock et al. 2007, Houston 2007, Blomhøj and Jensen 2007).

The Danish KOM (Kompetencer og matematiklæring) project (Fig. 1) Niss (2003) focused on basing the description of mathematics curricula primarily on the notion of mathematical competence. The framework they proposed could apply at any educational level. Niss and Højgaard (2011) managed to combine assessment and competence by introducing a three-dimensional model of progression of each competence, which I describe in the *Data Analysis* section. This model will be part of my set of tools for my data analysis since it focuses on the progression of students' development of a certain competence. It is possible that one mental, verbal or written action may describe two different competencies (overlapping); therefore it is important to locate discrete elements that characterize every competence even though in mathematical modelling activities students need to combine mental process in terms of combined competency profiles. We can find some attempts towards this direction from Andersen et al. (2001) and OECD (1999, 2001) focusing on the PISA investigations. These studies include an international comparison of secondary school students' competence profiles. The research reported here contributes to this research program by extending such analyses to university students.

The competence framework in my research will be based on the general term of mathematical literacy which combines the development of mathematical concepts and terms while dealing with real-world (realistic) tasks.

In my research I will use the notion of mathematical competence as something that students must bring into action in order to meet the challenges of the future. I consider this future-directedness rather important in educational terms because I am interested in the ways in which a student puts his or her mathematical knowledge to functional use. This will also give a strong connection to what Blum et al. (2002) considered as vital elements of modelling competences. He described a student, who is competent in modelling, as one who is able to structure, mathematize and solve problems. Furthermore in line with what Maaß (2004) considered as modelling competencies it is important to understand that knowledge alone is not sufficient for a student to develop his/her mathematical competencies. A student has to use and direct his knowledge with a suitable and specific way in order to be successful in modelling and this is where my study focuses on: observing, monitoring and analyzing that process.

Besides the competence theoretical framework I will adopt the theory of Didactical Transposition. Bosch and Gascón (2014) refer to four different bodies of knowledge (see Figure 2) where the transformations applied to a "content" or a body of knowledge since it is produced and put into use, until it is actually taught and learned in a given educational institution.

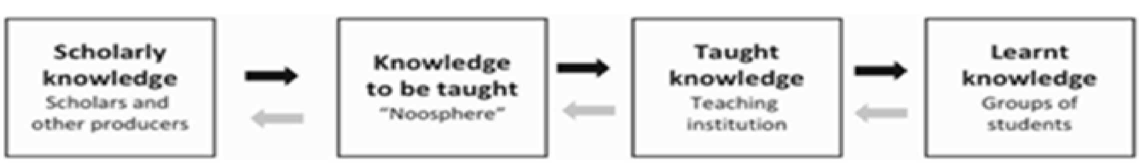

Figure 2. The didactical transposition (Bosch & Gascón)

Research Questions and Design

In this report I address the following two research questions:

1) What is the dynamic of a student's competence profile through the course of the mathematical modelling unit?
2) What competencies are deemed necessary for a student in a biology department?

By the term dynamic in the first research question I include the notion of progression (of a student's competence) from the very beginning of the project and also focus on identifying the initial set of competencies that a student brings when he or she enters the tertiary level.

In this study I make use of a design based research approach (Kelly & Lesh, 2000) in which an iterative process of design, implementation, and analysis takes place. More specifically, this study takes place in two phases. In Phase 1 (already completed), I investigated students' mathematical competencies during their engagement with a series of modelling tasks. These students were on their first year in a university's Department of Biology and the modelling session followed up a regular first year calculus course.

Phase 2 is ongoing and takes place with first year students in biology at the Norwegian university where this study takes place begin with a standard 10 week mathematics course on calculus. The modelling sessions occur weekly during their first semester. Approximately 100 students are organized in 3 separate classrooms where there is a 50 minute modelling session where students engage with modelling tasks. The students in each classroom are organized in small groups of three or four. One small group from every classroom is chosen to be monitored with audio and video devices. Every two sessions are considered to be a single modelling block where a new mathematical tool will be introduced. By the end of every session, a modelling task will be assigned to the students as part of their obligatory assignments for their mathematics course. Every modelling block will be designed in respect to the competence theoretical framework that I adopted. In addition the sessions will provide new knowledge that is also necessary for the successful engagement of students with the home assignments.

Methods for Data Generation

Data for Phase 1 and 2 consists of students' written work (tasks and assignments) and recordings (video and audio) which capture all kinds of discourses that are taking place during the sessions. In Phase 2 a questionnaire will also be given to the students at the beginning and at the end of the project. Discussions between the students and with the lecturer will be recorded both in video and in audio form. In every classroom separate cameras and audio devices will record the focusing on the group and to the whole classroom. In addition, the selected groups will be provided with a special device (LiveScribe 3 Smartpen) for more accurate and secured data collection. The same equipment will be used in all interviews with the task designer.

Data Analysis

Data from RQ_1 and RQ_2 will allow me to address the four bodies of knowledge proposed by the ATD, the first two from a detailed task-design analysis, the third from the above mentioned recordings and the last from a general assessment (formal exams and general performance in the classroom during the sessions). A task-design analysis, for example, can provide what the existing literature (mathematical biology) provides on population dynamics and exponential growth (scholarly knowledge) but also which task was finally decided to be presented (knowledge to be taught) and this will happen for every different modeling block.

The multi-dimensional model functions in such a way that whenever one or more dimensions may display a change (progression) then the volume (student's competence profile) of the cuboid changes. At this point a better analysis of these three dimensions is necessary.

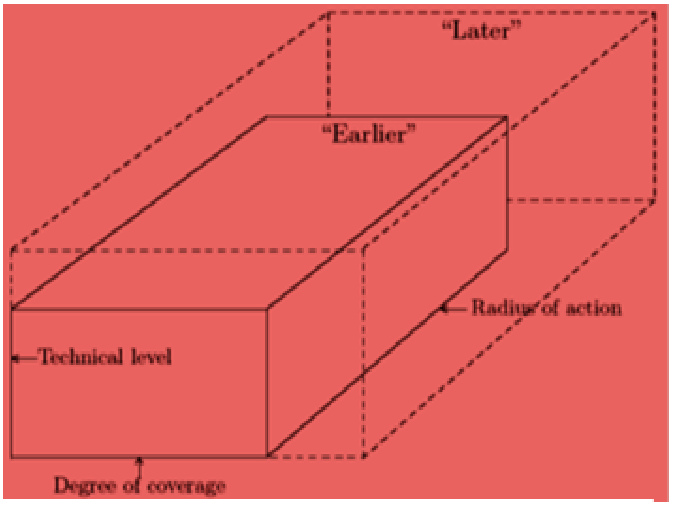

Figure 3.The three dimensional model (Niss & Højgaard, 2011)

- **Technical Level**: indicates how and to what degree (how advanced) a student may use his/her tools and mathematical entities which belong to his/her cognitive set of knowledge in order to activate a certain competence.
- **Radius of Action**: illustrates the range of action a student may take in terms of context and didactical situations. It shows where a student can activate a specific competence.
- **Degree of Coverage**: indicates to what extent a student is developing a competence in terms of its specific characteristics.

For the needs of this analysis I constructed a coding system which breaks down into smaller parts the verbal, mental and written actions of every single competence. This system, which is illustrated with data from Phase 1, functions as a decoding tool that assigns every student's discourse action to specific parts of a certain mathematical competence. In order to be successful in this attempt I need strong indicators that correspond to a specific competence and the frequency of appearance of these codes can be an indicator of progression (or stagnation) of a specific competence. It is in my intention to improve the reliability of this coding system by grading every code depending on the different tasks the students encountered during the modelling sessions.

Abstract from my coding system: the Reasoning Competence

- When a student is able to follow and assess a chain of arguments.
  Code: Flw. Arg.

- Knowing the difference between a formal mathematical proof and other kinds of mathematical reasoning. Code: Pr. ≠ Math. R.

- Separating main lines from details and ideas from technicalities during a line of arguments posed by anyone in the classroom. Code: Sep.

- When a student has the skill to devise formal and informal mathematical arguments. This may differ from a typical mathematical proof in our study therefore we could include the term: proving statements. Code: Pr. St.

Data from Phase 1

At the extract below we can see a discussion, between the members of Group2 in a university department of Biology about a modelling task. The students should come up with a solution in a time frame of 15 minutes and then present their possible solutions on a whiteboard in front of the other groups. The colored parts of the extract are based on the coding system above.

The task

Uncontrolled geometric growth of the bacteria Escherichia coli (E. coli) is the theme of the best-selling Michael Crichton's science fiction thriller, The Andromeda Strain. At some point the author claims that: ''**In a single day, one cell of E. coli could produce a super-colony equal in size and weight to the entire planet Earth.**'' If a single cell of the bacterium E. coli divides every 20 minutes, how many E. coli would be there in 24 hours? The mass of an E. coli bacterium is 1.7×10^{-12} g while the mass of the Earth is 6.0×10^{27} g.

- Is Crichton's claim accurate?
- If not, how much time should be allowed for this statement to be correct?

The students are trying to find a way to mathematize the assumption: if a single cell of the bacterium E. coli divides every 20 minutes. They should come up with this expression: 2^{3x}

1. A: what about 24x8 (checking calculator) and then I get…oh we have to compare it with, we can take 10 to the power of…isn't that very close to Earth's mass?
2. B: close is not enough for mathematics.
3. A: yes but we have something to compare it with. Is 8 our ground number (meaning base) or is it 24? I don't know what power I should put.
4. B: we have 2, 4, 8 … (almost silent)
5. C: so it's always double.
6. B: so it goes 16, 32, 64…
7. A: it may be 2^x ? Since it's always changing.
8. C: But our ground number?
9. A: Our ground number is 2, when we have 4 it is 2^2 then 2^n=8
10. B: No you have to put 3 to get 2^3=8
11. C: You have 8, 16, 3, 64… so is there …? How is it called?
12. A: (writes 2^3, 2^4…) Is this the first line with 2^1? The starting point? Oh we can take just 2^{25} and then we have (a huge number appears at the calculator)

The Reasoning Competence is not the only one that appears in the text but for the interests and page restrictions of this report I included only this specific type of mathematical competence. It is quite possible that episodes of overlapping competencies may occur but this is not an obstacle when it comes to identifying the progression of a specific competence.

Goals & Addressed Questions

My main goal is to create a dynamic competence profile for every student and it is in my intention to redefine the term good student by that of competent and try to find a way to identify students' learning skills, which in this study are considered as mathematical competencies. I therefore consider that the didactical environment of mathematical modelling is a suitable one for my research interests.

It would be more than helpful for my dissertation, if I could have some feedback on the following questions that are closely related with my data analysis:

1. What statistical tool would be ideal for my code analysis?
2. Is there a solid connection between ATD, mathematical competencies and mathematical modelling tasks?

A Preliminary Investigation of the Reification of "Choosing" in Counting Problems

Elise Lockwood
Oregon State University

In a recent combinatorics-focused teaching experiment with two undergraduate students, the students developed a robust understanding of a three-stage counting process that provided a solution for problems involving combinations. So strong was the students' three-stage process, they did not seem to naturally conceive of the singular process of "choosing," which is an important aspect of understanding combinations. In this preliminary report, I question whether or not the students engaged in reification, which Sfard and Linchevski describe as "our mind's eye's ability to envision the result of processes as permanent entities in their own right"(1994, p. 194). I raise questions about what aspects of the student work might have fostered or hindered their ability to reify choosing, as well as what might be taken as evidence that reification has occurred in the context of combinatorics.

Key words: Combinatorics, Reification, Discrete Mathematics, Counting Problems

Combinatorial enumeration, or the solving of "counting problems," is increasingly relevant in our computerized age, and counting has applications in a variety of mathematical and scientific areas. Recent research in undergraduate mathematics education has investigated a variety of aspects of counting, including examining productive ways of thinking about counting in general (e.g., Halani, 2012; Lockwood, 2014) and student reasoning about various facets of counting (Lockwood, 2013; Lockwood & Gibson, 2016). Following such research, in this paper I explore one particular aspect of counting: two students' work toward the reification of the notion of "choosing." By examining this phenomenon, I hope to both bring to light insights about the teaching and learning of the essential combinatorial construct of choosing, and also to speak to the nature of the broader mathematical practice of reification.

In this preliminary report, I share results from a paired teaching experiment that was designed to examine the students' generalization within a combinatorial context. The students were quite successful in their generalizing activity and their combinatorial problem solving, but a surprising phenomenon emerged regarding their development of solutions to problems involving combinations. Specifically, I was surprised to find that conceiving of "choosing" as an action was not something that seemed natural to them, and, interestingly, it was difficult to motivate them to reify this choosing process. By describing their work and exploring potential reasons for their resistance to reifying, I seek to answer the following questions: *What factors affected (limited and facilitated) these two students' reification of the process of choosing? What does this say about the nature of reification in the context of combinatorics?*

Literature Review and Theoretical Perspective

Reification. Sfard and Linchevski (1994) describe reification as "our mind's eye's ability to envision the result of processes as permanent entities in their own right" (p. 194). In other words, reification occurs when someone can conceive of the result of a process as something that may be operated on or with. Sfard and Linchevski elaborate this phenomenon in algebra especially, as the following example suggests. They offer the algebraic expression of $3(x + 5) + 1$, and they notice that we could view this expression in a variety of different ways. First, it may be a computational process that is "seen as a sequence of instructions: Add 5 to the number at hand, multiply the result by three and add 1" (p. 191). It could, however, also be viewed as an object in its own right – as a function that could itself be operated on or treated as the input of another function. This dual way of thinking about an expression like $3(x + 5) + 1$ is in line with Sfard's (1991) distinction between structural and operational conceptions, in which "the same representation, the same mathematical concepts, may sometimes be interpreted as processes and at other times as objects" (Sfard & Linchevski, 1994, p. 193).

Sfard and Linchevski (1994) go on to argue that reification can help promote relational understanding (or conceptual knowledge). Generally, they convey that reification is difficult, saying that their data "provided sufficient evidence that reification is inherently very difficult. It is so difficult, in fact, that at a certain level and in certain contexts, a structural approach may remain practically out of reach for some students" (p. 220). The importance yet difficulty of reification is one motivating factor for this study, and by exploring the data in depth I hope to gain insight both into the nature of reification (especially within a combinatorial context) and also how reification might be fostered for students. Additionally, I have previously noted the ways in which Sfard's (1991) structural versus operational duality naturally applies to combinatorics (e.g., Lockwood, Reed, & Caughman, in press), and I believe that there is much more to be investigated about this dual relationship in combinatorics, especially regarding combinations. The results from this study provide but one preliminary perspective of a more complex and complete picture of structural and operational conceptions in combinatorics.

Combinations. I now offer a brief mathematical discussion of combinations. I use Thompson's (2008) notion of a conceptual analysis, which he describes as a method to "describe what students might understand when they know a particular idea in various ways" (p. 42). One reason that Thompson (referencing Glasersfeld, 1995) gives for developing a conceptual analysis is to "generate models of knowing that help us think about how others might know particular ideas" (p. 43). This reason aligns with the purposes of this paper, and I highlight a couple of key aspects of what it may entail to come to know combinations.

"Combination" problems have as outcomes combinations, or sets, of distinct objects (as opposed to permutations, in which outcomes are ordered sequences). To count combinations, one may go through a three-stage process (this three-stage process describes a typical way in which the formula for combinations is taught – start with permutations and then divide by duplicate outcomes). If we consider the number of ways to choose k people from a set of n distinct people, we can first arrange all n people in a line, say. We can then note that we only care about the first k people, and thus arrangements of the last n-k people all yield duplicate outcomes. Thus, b $\frac{n!}{(n-k)!}$ yields permutations of k people from n people. Then, to count combinations, because any k! arrangement of the k people are but one combination we wish to count, we can divide that product by k!. This three-stage counting process is reflected in the formula for combinations, which is given by $\frac{n!}{(n-k)!k!}$.

While it is important to be able to explain this formula, another aspect of conceiving of combinations is to understand that although this three-stage process can effectively explain the formula, it is sometimes useful to be able to think about choosing as one reified process that can itself be a stage in the counting process. In particular, the result of choosing can itself be viewed as something that can be acted upon. When I say the act of "choosing," then, I mean conceiving of a single, particular act in which I can choose some subset of objects from a set of distinct objects. The reification of choosing is an important feature of successful combinatorial enumeration because there are many problems in which choosing itself becomes a stage in the counting process. Two previous results point to this phenomenon and highlight the importance of being able to conceive of and use choosing as a stage in the counting process. In Lockwood, Swinyard, & Caughman (2015), we highlighted an episode in which students struggled on one particular problem that involved combinations as a stage in the counting process. In Lockwood, Wasserman, & McGuffey (2016) we also demonstrated that certain combinations are particularly difficult for students, who view such problems as qualitatively different than other combination problems. The results from that study also indicate that solving counting problems that involve combinations as a stage in the counting process are difficult. Both of these studies point to the fact that choosing can be a stage in the counting process is an important but difficult idea for students to understand.

Methods

The data in this study is part of a larger project intended to explore students' generalizing activity in a variety of mathematical domains. For the part of the project described in this paper, we conducted a 15-session teaching experiment with two calculus students (Rose and Sanjeev, pseudonyms). Each videotaped session was ~60 minutes in length, and we met approximately three times a week for five weeks. We covered a variety of material in the teaching experiment, including having students generalize formulas after solving counting problems, and initially explore combinatorial proof. In this paper I focus on a particular phenomenon regarding the students' conceptions of combinations. During the teaching experiment, I started to observe that the students were solving problems involving combinations in a way that suggested they were not reifying the process of choosing. In response, I gave students tasks with the aim of examining their conceptions of choosing and to attempt to foster the reification process.

For data analysis, I had the interviews transcribed. My research team and I then took a pass through the data in which we created enhanced transcripts, which involves adding screen shots and relevant nonverbal cues to the transcript. In reviewing the videotapes and creating enhanced transcripts, we flagged situations and episodes in which students were using the choosing formula, and we returned to those episodes. We tried to use those episodes to articulate a narrative (Auerbach & Silverstein, 2003) of the students' understanding and use of combinations.

Results

In the limited space provided, I describe a handful of key episodes that demonstrate the students' development and use of the formula for combinations. I argue that their initial conceptions likely affected the ways in which they later reasoned about combinations. I try to point out that the students had such a strong conception of a particular counting process that they did not naturally seem to view choosing as a single, reified counting process. I also raise questions about whether the approach I took in teaching these concepts (starting with permutations and deriving combinations) had some unintended consequences in terms of the students' ability to reify the process of choosing.

Students' development of the formulas for permutations and combinations. A noteworthy aspect of the students' initial work is that the students developed a surprisingly strong sense of equivalence, which they used to derive the formula for permutations. We asked the problem, *How many 3-letter sequences are there using the letters A, B, C, D, E, F if no repetition of letters is allowed?*, and they understood their formula of 6!/3! as dividing out by equivalent arrangements in the three elements of the "tail" – or the three positions they did not care about.

In the exchange below, Rose suggested an answer of 6!/3!, which Sanjeev had not previously considered. As he reasoned through and ultimately explains the process, this argument became his key way of reasoning about this kind of problem.

Rose: *Well, I divide it by 3 factorial, because the last 3 spots can be in any order, and they don't matter. It doesn't really –*

Sanjeev: *Are you saying hypothetically – if you were to continue adding spots – like if you were to go all the way up to 6.*

Rose: *Yeah, if you wanted combinations with all 6 letters that means when you get the last 3, and you'd get how many combinations there are with all 6 letters.*

Sanjeev: *Oh, I see. So if you have 6 letters then 6 factorial represents the total number of arrangements you can make with 6 letters. Because you're only looking for a sequence of 3. Then you can take out that last 3, because it doesn't matter. That order these last 3 would be in. And so when you divide that out, and this part this gets divided out here, you're left with (inaudible).*

In developing the formula for combinations, the students understood that if they considered combinations (as opposed to permutations) they needed to account for duplicates, and they realized that they needed to divide by an additional factor. Ultimately, they arrived at the correct formula for combinations.

The students had thus established a strong understanding of division and equivalence in determining the formulas for both permutations and combinations. We saw subsequently that this became their go-to way of solving combination problems. This can be from Session 4 with a problem about iPhones that says, *In a shipment of 1,000 iPhones, 25 are defective. How many ways can we select a set of 50 non-defective iPhones?* Figure 1 demonstrates exactly their three stage counting process – arrange all of the distinct elements, divide by the "tail" that you "do not care about," and then additionally divide (or multiply by 1 over the reciprocal) in order to account for duplicates again.

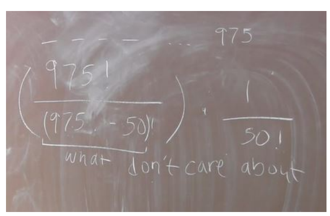

Figure 1 – The students' response to the iPhones problem

I want to emphasize that it was impressive that Rose and Sanjeev had such a solid understanding of the division and of the counting process, and especially that they had an understanding of how combinations and permutations are related. Almost more than any students I had worked with before, they had a particularly solid sense of division and equivalence and of how to make that work out in terms of the set of outcomes. However, at the same time I started to notice that every time they explained or thought about or talked through a combination problem, they always referred to that three-stage process. I began to wonder if they *necessarily* went through this process as an inherent part of their understanding of combinations.

As further evidence of their conception of this three-stage process for solving combination problems, and for the relationship between permutations and combinations, consider the students' description of four key problem types in Table 1. After the students solved some initial problems we had them characterize and group the problems according to type and to articulate a formula for each one. Their formulas and written responses for factorials, permutations, and combinations are given in Table 1. Note that they actually defined the definition of combinations as building on the formula for permutations, providing further evidence for the nature of the process for counting combinations. Subsequently, there were surprising episodes in which the students seemed to focus on their process rather than implement a single act of choosing.

Formula	Problem Type	Students' Written Description
$n!$	Arrangements	How many ways to arrange a given number of elements.
$\frac{n!}{(n-k)!}$	Permutations	How many ways to arrange a given number of elements into a given number of spots without reusing any elements
$\frac{n!}{(n-k)!k!}$	Combinations	[continue from permutations]…and divide by the factorial of the given spots to delete repeated sequences because any arrangement of the same given elements is considered the same combination.

Table 1 – The students' descriptions of what they were trying to count

Eventually, after more prompting and work with the students, they did perhaps demonstrate that they could consider the result of their three-stage process as an object in and of itself. For example, they were solving a problem in which they were making a committee with 3 men from 7 men. As they had the following exchange they wrote $\left(\frac{7!}{4!}\right)/3!$.

Rose: *So that means for this scenario, we have what was it, seven men. I'm going to write it over here. We have seven men, and it looks like we're going to isolate the three persons by 4 factorial.*

Sanjeev: *Which are the ones we don't care how they're arranged.*

Rose: *Yeah. And then, within this group of 3, there's 3 factorial ways to arrange them.*

This again emphasizes their attention to the three-stage process. However, they then did seem to be able to think about operating on the result of that expression, as Rose indicated .

Rose: *Because this will tell us how many ways you can arrange the men. And for every way you can arrange the men, it goes with one of the three arrangements of the women. So if there are three arrangements for women, then, that's three times this [the expression for the men].*

Discussion and Conclusion

Although I could provide only a limited number of examples due to space, the results presented in this preliminary report are intended to raise questions about what it takes to provide evidence that reification has taken place. There did seem to be evidence that the students could think of their combination expression as "how many ways you can arrange the men," which suggests being able to conceive of the results of their three-stage process. And yet, such utterances came only after the students clearly articulated this process. Some lingering questions, then, include, *What is evidence for reification in the context of combinatorics?* and *Do the utterances such as "this will tell us how many ways you can arrange the men" count as evidence that they conceive of "choosing" as a reified process?* In addition, I wonder what role symbolization plays in reification, as I had not prompted the students to express the formula for combinations using a single symbol. Also, I wonder if the way in which the tasks were sequenced hindered their reification process in any way. A final question is whether or not it is necessary for students to reify the process of choosing in order to be successful counters. I hope to facilitate discussion about such questions through the presentation of this preliminary report.

Outcomes Beyond Success in a Problem Centered Developmental Mathematics Class

Martha Makowski
University of Illinois at Urbana-Champaign

Low success rates in the pre-college level, or developmental, curriculum at many community colleges has resulted in the creation of classes that use problem solving and group work to help students become more mathematically empowered. This preliminary report describes one such class at a Midwestern community college and then outlines the results from a pre- and post-survey of students taking the class, focusing on whether students' attitudes towards mathematics changed while enrolled in the class. Further analysis will examine how students evaluated the class and ranked the class structures. Generally, males, younger students, and Black students were less likely to complete the course. Students who came close to completing the class had an overall positive shift in their attitudes towards mathematics.

Keywords: developmental mathematics, community college, problem solving, attitudes

Each year over 1 million students invest substantial time and money to take pre-college level classes that do not count towards a degree (Parsad, Lewis & Greene, 2003). Often called "developmental," such classes provide *all* students with the chance to be *college ready* (McCabe, 2000). However, as many as 67% of students who start developmental classes do not finish (Bailey, Jeong & Cho, 2010), which is particularly concerning given that developmental students disproportionately come from minority and low socio-economic backgrounds (Attewell, Lavin, Domina, & Levey, 2006). Despite the volume of students in developmental programs, research has rarely examined individual classes and students. Given this, an acute need exists for research on developmental math that looks beyond success rates (Mesa, Wladis & Watkins, 2014).

Developmental math tends to be taught using lecture with an emphasis on procedural knowledge (Grubb et al., 1999; Mesa, Celis, & Lande, 2014). The low success rates, combined with the fact that community college students have high levels of math anxiety (Sprute & Beilock, 2016) and appreciate knowing how what they learn relates to their lives (Cox, 2009), suggests that the traditional ways of teaching developmental math do not provide sufficient opportunities for students to change their opinions about mathematics or themselves as doers of mathematics. This study examines the outcomes beyond success of one developmental math implementation that attempts to better meet the needs of the developmental population.

Mathematical Literacy: Streamlining the Curriculum

Low success rates in developmental mathematics has led community college educators to create curriculum pathways that accelerate students through their required pre-college-level course work while promoting more real world connections. *Mathematical Literacy* at Fields Community College (FCC; all names are pseudonyms) is one such initiative. Rather than learning through lecture, students engage in group work. The teacher primarily acts as a facilitator while the students work on real world problems. The course is designed to be completed in one semester, which fulfills the students' developmental needs in a shorter time frame than the traditional algebra sequence.

The *Mathematical Literacy* movement is fairly new, but early results from national initiatives suggest students are more successful than students taught in traditional classrooms (Strother & Sowers, 2014; Yamada, 2014). Less understood is how students' relationship to math changes after taking classes like this and students' experiences in these classes. Developmental classes offer one of the last opportunities for students to explore mathematics and challenge their ideas about math, so it is important to investigate whether and how students' attitudes towards math change in these new developmental classes. In particular, I investigate:

- Who finishes *Mathematical Literacy* at FCC?
- Do the attitudes of students who finish *Mathematical Literacy* change during the course of the semester? How do attitudes vary between students with different characteristics?
- Is there a relationship between the magnitude of students' attitudes towards mathematics and their background characteristics?
- How are students' evaluations of the class related to their attitudes towards mathematics?

Methods

Sample

In total, 150 *Mathematical Literacy* students from eight surveyed sections at FCC participated. All FCC *Mathematical Literacy* instructors were invited to participate. Sections were surveyed in all instances when the instructor agreed to participate. Three sections occurred in the in fall (n = 53) and five sections in the spring (n = 97). The number of students participating from a particular section ranged from 15 to 24 students.

Data Sources

Data for this study come from a pre- and post-survey given to students during the first and last week of the semester, respectively. Both the pre- and post-survey included the Attitudes Toward Mathematics Inventory (ATMI; Tapia & Marsh, 2004) to measure mathematics attitudes along four dimensions related to mathematics performance: enjoyment of mathematics (8 items), motivation (9 items), self-confidence (15 items), and value (8 items). Students answered items using a 5 point Likert scale on items. The pre- and post-surveys also include single item questions asking about the nature of mathematics (i.e., "learning math is mostly memorizing facts") and about students' level of comfort with certain types of class structures (i.e., "I learn mathematics best when I get to work in a group"). In addition, both surveys contained free-response items asking about students' mathematical backgrounds (pre-survey), demographics (pre-survey), educational plans (pre-survey), expected grades (post-survey), and course evaluation (post-survey).

Analytic Methods

To determine who completes *Mathematical Literacy* I ran descriptive statistics on the pre-survey sample and compared these to the descriptive statistics of the post-survey sample.

To examine whether or not the attitudes of students' towards mathematics changed over the semester, I conducted a confirmatory factor analysis on the ATMI scales. For brevity, in this proposal I report only the results from the original scales. Analysis using the attitude scales were run on both the original scale and the scales created after the confirmatory factor analysis. The general trends of the findings discussed in the results section are the same for both sets of scales.

Using the attitude scales, I performed paired sample t-tests to determine whether attitudes of those who come close to completing the class changed significantly over the 16 week class. To test for differences in attitudes growth between different sub-populations, I ran independent sample t-tests between different sub-populations of interest.

To examine the relationship between the changes in attitudes and students' background characteristics, I performed two-level Hierarchical Linear Models (HLM) with teachers as a level-two variable and students as level one. Separate models were run for each of the four attitudes, with the post-survey attitude scores as the dependent variable. Independent variables were students' pre-survey attitude score, gender, race, age, anticipated grade, whether or not they had taken previous developmental math classes, and the highest degree they intended to earn.

I will use descriptive statistics, basic qualitative coding, and HLM modeling to examine the attitude scales and class evaluation data and their relationship to students' backgrounds.

Results

Who Completes Mathematical Literacy

Although eight sections took the pre-survey, one class section did not take the post-survey because the survey schedule did not work out for the instructor. Within the students who had the opportunity to take both the pre- and post-survey resulted in a 63.3% retention rate between the pre- and post-survey. Students in this group who did not take the post-survey were, for the most part, no longer actively pursuing the course for personal or academic reasons. All of the students who took the post-survey reported that they expected to pass the class.

Descriptive statistics for participants who took only the pre-survey, compared to those who took both surveys are summarized in Table 1. Notably, the whole survey sample is more female than male and majority white, which is consistent with the developmental population at FCC. Those who only took the pre-survey were more likely to be male, more likely to be Black, and were a couple years younger than the students who took both surveys.

Table 1. Demographics of Survey Samples

	Whole sample		Pre-survey only		Took both surveys	
	n	%	*n*	%	*n*	%
Gender						
Male	65	45.14	34	52.31	31	47.69
Female	79	54.86	27	34.18	52	65.82
Race						
White	52	56.52	8	15.38	44	84.62
Black	29	31.52	21	72.41	8	27.59
Hispanic	5	5.43	1	20.00	4	80.00
Asian	5	5.43	0	0.00	5	100.00
Other	1	1.09	0	0.00	1	100.00
Taken prior developmental	93	35.86	44	47.31	49	52.69
No prior developmental	52	64.14	21	40.38	31	59.62
Age (years)	150	22.71 (7.88)	69	21.59 (7.31)	81	23.66 (8.26)

Note: Age reports the mean age of the participants in years followed by the sample standard deviation.

Changing Student Attitudes in *Mathematical Literacy*

Students who took both surveys had average positive gains on all four of the measured attitudes towards math. The shift in their enjoyment of math was significant. Students who were enrolled in their first developmental class had an overall positive increase in their value of mathematics, compared to those who had taken previous developmental math (Table 2).

Students were significantly more likely to disagree with the statement "there is only one way to solve a mathematics problem" at the end of the semester than they were at the beginning of the semester (Table 3). On other nature of math items there were no significant differences. They were also likely to shift whether or not they thought they learned mathematics best in a group or not, but these results were not significant. The high mean pre-post difference combined with the high standard deviation for these items ($\overline{x}$ = -0.185, sd = 1.246) suggests, however, that students were changing their mind about whether they agreed with these statements or not.

Table 2. Attitude Change Results for Selected Sub-populations

	Comparison of pre-post-survey attitude scores (complete data on both surveys)				Average growth in attitude scores of those with no prior developmental math compared to those that did				
					N		Pre-post difference		
Attitude	*N*	Pre-score	Post-score	*t*-stat	No prior devel. math	Prior devel. math	No prior devel. math	Prior devel. math	*t*-stat
Confidence	61	2.859	2.986	1.562	36	23	0.174	0.064	0.638
Enjoyment	74	2.941	3.093	2.406*	44	28	0.202	0.076	0.943
Motivation	73	2.830	2.925	1.637	44	27	0.073	0.136	-0.502
Value	68	3.756	3.813	1.064	40	26	0.144	-0.082	2.047*

*p<0.05

Note: Attitude scores were scaled to be on a 5 point scale with 1 corresponding to "Strongly agree" and 5 corresponding to "Strongly disagree."

Table 3. Attitudes Shifts towards Math and Classroom Structures

Item statement	N	Mean post-pre difference	Standard deviation
Learning mathematics is mostly memorizing facts.	77	-0.039	1.032
There is only one way to solve a mathematics problem.	80	-0.288*	1.171
I enjoy working in small groups in math class.	78	-0.077	1.066
I learn mathematics best when I get to work in a group.	81	-0.185	1.246
I learn mathematics best when I work by myself.	81	0.185	1.205
The math I learn in school rarely helps me when I use math in my daily life.	78	-0.115	1.032

*p<0.05

Note: Items were scored on a 5 point Likert scale, with 1 corresponding to "Strongly agree" and 5 corresponding to "Strongly disagree."

The Relationship between Attitude Change and Background Characteristics

For each of the measured attitudes, the biggest significant predictor of how attitudes changed was their pre-survey attitude score. However, intending to earn a Masters or higher significantly predicted an increase in the value of mathematics. Expecting to earn a grade of A in the class significantly predicted an increase in their mathematical confidence. The full results of the HLMs using the original scales on the ATMI are presented in Table 4.

Discussion & Conclusions

The results presented in the previous section highlight many positive outcomes beyond success rates in a *Mathematical Literacy* classroom. A 63% retention rate may seem low, but this number is higher than many developmental math instructors experience when teaching using traditional methods. That the students who completed the class experienced an average positive growth in their attitudes towards and views of mathematics also warrants excitement. Although only enjoyment showed a significant increase, several others were close to being significant. A larger sample could produce more robust results. Given that community college students do

experience a lot of mathematics anxiety, these results are certainly worth investigating further to determine which parts of *Mathematical Literacy* contribute to the students' shift in attitudes.

That said, some results suggest that *Mathematical Literacy* does not reach everyone equally. The overall rate of persistence in *Mathematical Literacy* is higher than for traditional classes, but the students who did not complete the class were more likely to be Black and male than the students who did. Community college mathematics classrooms are an important and under-examined area in mathematics education. Given that Black students disproportionally enroll in developmental math, understanding the issues that keep these students from succeeding in *Mathematical Literacy* deserves a closer look.

Underrepresented Students Succeeding in Math: The Challenges and Coping Strategies of Mathematically Talented Post-secondary Students

Martha Makowski & Randi Congleton
University of Illinois at Urbana-Champaign

Retaining mathematically talented underrepresented students in mathematics programs requires understanding the challenges the face during their post-secondary mathematics education. Using Swail's framework (2003), this study investigates the self-identified challenges undergraduate and graduate mathematics students face and the coping mechanisms that helped them navigate and overcome those challenges. The vast majority of the challenges both groups of students encountered were cognitive in nature, suggesting that programs wishing to retain students should focus on providing social and institutional supports to provide balance.

Key words: Underrepresented students, mathematics, post-secondary programs

In the United States, completing a graduate program in mathematics was, until recently, primarily the domain of white American citizens and international students. In 2012−2013 the U.S. awarded 1,843 doctoral degrees in mathematical science, with 46.5% going to U.S. citizens. Of domestic students, only 24 graduates were African American and 25 Latino (AMS, 2013).

The reasons for low numbers of underrepresented students in math stem from many causes. Underrepresented undergraduate students generally have lower rates of degree attainment than the general college student population (Gladieux & Swail, 1998; Mortenson, 2005) and mathematics based fields (Bonous-Harmarth, 2000). At both the undergraduate and graduate level, underrepresented students pursuing STEM degrees face challenges related to their identity (Fries-Britt & Turner, 2002; Gildersleeve, Croom, & Vasquez, 2011; Malone & Barbarino 2008). At the graduate level academic challenges have been documented for students of color (Cooper, 2004; Herzig 2002). Cooper (2004) found that black graduate reported differences between graduate and undergraduate culture related to studying. Although they felt comfortable in the program, some reported hostile and competitive climates. Students of color who eventually earned a graduate degree in a mathematics based field reported frequently being judged by the color of their skin while earning their degree (MacLachlan, 2006).

Many students earning advanced degrees face adversity, but the unique and compounding challenges underrepresented students face means it is particularly important to understand their challenges and how they overcome them at both the graduate and undergraduates levels. Few studies have examined successful underrepresented students in mathematics. Expanding this knowledge base can help inform services that support students pursuing math. Towards this end, we compare the challenges to success and the subsequent coping strategies mathematically talented underrepresented undergraduate and graduate students identify. In particular we ask:

1. What are the self-reported challenges the mathematically talented underrepresented students face?
2. What are the strategies utilized by students to help them manage and persist through these challenges?
3. How do the challenges faced and coping strategies used vary between undergraduate and graduate students?

To help answer these questions, we focus on student participants in the National Alliance for Doctoral Studies in the Mathematical Sciences (henceforth referred to as "the Alliance"). The

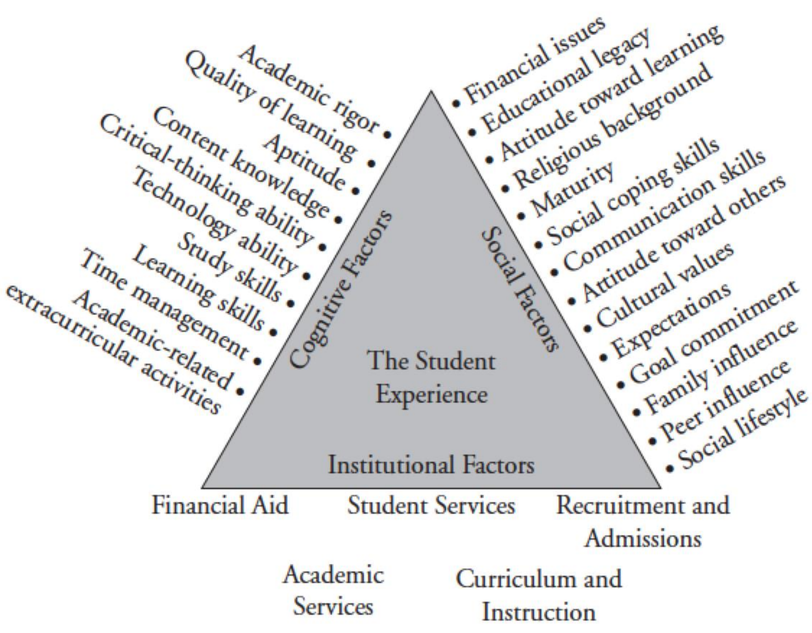
Alliance is a nationwide program seeking to facilitate the recruitment and retention of talented, underrepresented domestic students in mathematics disciplines through the doctorate.

Conceptual Framework

This study uses Swail's (2003) Framework for Retention of Minority Students, which captures the interplay of the many factors affecting student persistence and achievement by categorizing them into three main components: 1) Social; 2) Cognitive; and 3) Institutional. These constructs are presented around a triangle, with each component forming one edge (Figure 1). The graphical representation signifies that the three components impact one another while also influencing a students' persistence or achievement; persistence optimally occurs when equilibrium exists between the three factors. For example, a student facing large institutional challenges must have social and/or cognitive supports that compensate for the deficiency. Swail's framework, although underutilized in research, accounts for both students' personal attributes and the contextual factors related to an institution's role in persistence (Swail, 2003).

While Swail's (2003) retention framework is most commonly utilized by institutions to improve student retention, the Alliance's goal to retain students in mathematics is comparable. Alliance students are currently persisting towards a mathematics degree and have access to many of the factors the literature suggests cultivate success. This unique set of circumstances makes the Alliance population uniquely suited to understand the challenges of STEM pipeline persisters and the ways in which they overcome those challenges.

Figure 1. *Swail's Framework of Minority Student Persistence*



Source: Swail (2003), p. 77

Data and Methods

Sample

Participants at the 2014 Alliance conference were asked to complete an anonymous survey during lunch of the main day. Of the approximately 300 conference attendees, 210 individuals took the survey, which included students, faculty mentors, and university representatives. We focus on the responses of the participating undergraduate (*n*=127) and graduate students (*n*=25). Table 1 provides basic demographics on these students. The two page survey consisted of both free-response items asking about various dimensions of success and quantitative rankings of various influences on success.

In this study, we draw the data from four of the questions: two free-response and two ranking questions. The free response items asked:

1. *Among the various experiences you've had in your program, please describe one that you consider to be the most challenging.*
2. *If applicable, why did you think this was a challenging experience and how did you overcome this challenge?*

The first ranking question asked students to order the influence of various individuals on their success. The options were: faculty/teachers, advisors, mentors, peers, family, or others. The second ranking question asked students to assign a percentage to different people and structures that indicated how much of their success was attributable to that entity, so that the sum of the percentages assigned was 100%. Their choices were: mentors, financial aid, the Alliance, natural ability, hard work, peer relationships, and other.

Table 1. Demographics of Survey Sample

	Undergraduate		Graduate		
	Male	Female	Male	Female	Total
White	9	9	1	2	21
Black	9	25	5	1	40
Hispanic	34	23	6	4	67
Asian	0	2	0	0	2
Other/Multiracial	3	10	2	3	18
Total	55	69	14	10	148

Methods of Analysis

The analysis of the items from this survey used qualitative coding combined with statistical tests for the two free response items and statistical methods for the two ranking questions. We discuss each, in turn, below.

Free response items. The free response items asked students to identify the biggest challenge faced during their program and then describe how they overcame that challenge. We read the responses and identified the challenge and the coping strategy using Swail's (2003) Framework for Retention of Minority Students. The authors each coded all the responses separately. Discrepancies were discussed until consensus was achieved.

One hundred twelve undergraduates and 23 graduate students described the challenges they faced while in school. In comparison, only 74 undergraduates and 19 graduate students answered the follow-up question. For this preliminary analysis, each challenge and each coping strategy was coded as social, cognitive, or institutional. If a student mentioned more than one challenge or coping strategy, both codes were assigned. When the student identified a challenge but not their coping strategy, or the student indicated that the challenge had not been resolved, the coding for the coping strategy was left blank.

After coding we ran Pearson Chi-squared tests to determine whether the undergraduate or graduate students varied significantly in the types of challenges they faced. We ran similar tests to determine whether graduate students were more likely to resolve challenges with both social and cognitive coping strategies.

Quantitative items. The first quantitative item asks students to rank which individuals were critical to their success. The second asks students to assign a percentage indicating how much particular sources contributed to their success. Responses that did not sum to 100% were removed from the analysis. Data from these questions were analyzed using independent sample *t*-tests to determine if the rank or weight of each source varied significantly between the undergraduate and graduate students.

Preliminary Results

The results presented in this section represent the initial analysis done on the research questions discussed above. By the time of the conference we plan to have explored these findings in more detail, as discussed in each of the results sub-sections.

Challenges and Coping Strategies

Both undergraduate and graduate students experienced similar challenges and the majority of the challenges they faced were cognitive. For example, a female undergraduate stated that for her "balancing all aspects of life was hard. Finding the right balance between school, family, social, and sleep is hard to find so that none are ignored." A male graduate student noted that "…trying to learn anything when I wasn't prepared for the stuff" was his biggest challenge. Both of these statements received a cognitive code they mention need for balance and academic background respectively, both of which are cognitive factors in Swail's (2003) framework. The first statement also received a social code because she notes social obligations as a challenge, which falls under the domain of social in the framework.

Graduate students did use coping strategies from multiple domains significantly more often than undergraduate students. They were also more likely to draw on social coping strategies than undergraduates. Table 2 documents the relevant test statistics. In our next steps we will code the cognitive responses into the secondary cognitive categories of Swail's framework to see whether graduate and undergraduate students face different types of cognitive challenges.

Table 2. Nature of Challenges and Coping Strategies by Student Status

		Nature of Conflict						
	N	Social	Cognitive	Institutional	Social & Cognitive	Social & Institutional	Cognitive & Institutional	All three
Undergraduate	112	36	76	12	11	0	1	0
Graduate	23	5	16	3	1	0	0	0
Pearson Chi-squared		0.977	0.026	0.105[a]				
		Nature of Coping Strategy						
Undergraduate	74	24	44	11	2	1	2	0
Graduate	19	11	12	5	4	4	2	1
Pearson Chi-squared		4.176*	0.769	0.238				

*p<0.05

[a] Cell sizes in this analysis were smaller than is technically required for a reliable Person Chi-squared estimate.

Factors Students Attribute to Success

Undergraduate and graduate students agreed on the relative rank of various individuals on their success: both groups felt that the person most important to their success was themselves.

Families and peers were the least important. Graduate students did rank their family and peers a bit higher than undergraduate students, but the difference was not significant.

Of those surveyed, 23 graduate and 114 undergraduate students completed the question asking students to assign a percentage indicating how much various influences impacted their success. The only significant difference was that graduate students attributed less of their success to natural ability (9.78% compared to 16.52% for the undergraduates). Table 3 shows the means for each of the tested influences and the relevant test statistics.

Table 3. Average Percent of Influence on Student Success

Influence on Success	Student Level	*N*	Mean	Std. Deviation (s.e.)	*t*
Mentor	Graduate	23	19.13	14.05 (2.93)	.446
	Undergraduate	114	17.81	12.74 (1.19)	
Financial Aid	Graduate	23	15.61	11.54 (2.41)	1.068
	Undergraduate	114	12.96	10.74 (1.01)	
Natural Ability	Graduate	23	9.78	7.16 (1.49)	-2.764*
	Undergraduate	114	16.52	11.21 (1.05)	
Hard work	Graduate	23	30.00	17.58 (3.67)	-.269

Significance

This study provides insight into the types of challenges persistent underrepresented undergraduate and graduate students face in their mathematics programs. The fact that most of their challenges were cognitive is suggestive. Swail's (2003) framework argues that to persist students must have balance between the three domains. Because students in mathematics programs face overwhelming cognitive challenges at both the undergraduate and graduate level, programs focused on retaining underrepresented students should strive to balance the necessary cognitive challenges with rich, meaningful social and institutional supports.

The fact that graduate students were more likely to cope with the challenges they faced using structures from multiple domains of Swail's framework is also suggestive. Although undergraduate and graduate students face similar challenges, graduate students are more likely to resolve those challenges using multiple types of support. The quantitative data from the survey speak to this—graduate students believe their natural ability is not as important to their success as undergraduates, suggesting they look outside of themselves for support. Conversely, the key to promoting undergraduate retention in STEM may require encouraging underrepresented undergraduates to take advantage of the opportunities many diversity offices provide. More generally, the findings presented in this study provide support for previous research positing that an awareness of the environmental factors that exist for underrepresented students and how they perceive those factors is integral to their successful transition and persistence.

Student Gesture Use When Explaining the Second-Derivative Test and Optimization: Mimicking the Instructor?

Tim McCarty
West Virginia University

Nicole Engelke Infante
West Virginia University

The Second-Derivative Test and optimization can naturally evoke gestures from an instructor while he or she is teaching. We wanted to establish how student learning might be affected by an instructor's use of gesture. Students viewed either a gesture-rich or gesture-free video of an instructor solving an optimization problem, and were interviewed a week later to assess both their understandings of optimization and how they used gesture to support their explanations. Very few gestures were used when the students explained how they solved the optimization problem. However, when describing the second derivative test separate from optimization, students used a number of gestures. We conclude that further study should be undertaken, but such study should be focused on the Second-Derivative Test without the context of optimization problems.

Key words: Gesture, Calculus, Optimization, Instruction

Background

Gesture use in the classroom may be used to increase student interest and foster student success in calculus. Recent studies suggest that instructors' use of gesture promotes student learning, and that instructors can intentionally alter their gesture production during instruction (Alibali, et al., 2013a; Alibali, et al., 2013b; Cook, Duffy, & Fenn, 2013; Hostetter, Bieda, Alibali, Nathan, & Knuth, 2006). As calculus can be considered the study of motion, it is a natural place to examine gesture. There are several types of calculus problems that require students to visualize or imagine situations involving changing rates, with optimization being one example. LaRue (2016) studied student responses and approaches to optimization problems, while classifying each action in a student's problem-solving process using Vinner's (1997) conceptual, analytical, pseudo-conceptual and pseudo-analytical definitions. We use these definitions, along with Tall and Vinner's (1981) concept image, to describe student understanding.

We seek to answer the following questions: Will students who view a gesture-enhanced lesson demonstrate a greater understanding of the presented concept than students who view a gesture-free lesson? How do students use gesture when explaining their work? Do they mimic any gestures used by their instructor? We present a pilot study that attempts to answer these questions.

Methods

Data collection was completed in two phases. The first phase included eleven students, each of whom were currently enrolled in a second-, third-, or fourth-semester Calculus class. The average amount of time it had been since each student had taken first-semester Calculus was about three-and-a-half years. These students were asked to take a short pretest, watch one of two possible videos, and then complete a short posttest. The second phase, which occurred a week later, involved semi-structured interviews in which students were asked questions to assess their understanding and recall of the first phase's material.

The six-question pretest had students determine if points on a function were maxima, minima, neither, or “can’t tell,” using three of the standard function representations: algebraic, graphical, and verbal. The verbal problem was an optimization problem in which they were asked to maximize the area of a rectangle for a given perimeter. After completion of the pretest, students were shown one of two videos in which a similar perimeter/area optimization problem was presented, solved, and verified using the Second-Derivative Test. Both videos followed essentially the same script, but one video contained instruction that was given without any of the categories of gesture outlined in Engelke Infante (2016), while the second video contained instruction that utilized such gesture. After watching and taking notes on the video, the students were given a three-question posttest consisting of three optimization problems: the first was very similar to the one in the video, the second was an extension of the first, and the third was a different type of optimization problem. In the interest of space, we consider only the optimization problems that were similar to what was presented in the video. Six students viewed the gesture video, and the other five viewed the gesture-free video. Rubrics were created for each problem, and tests were graded and scored.

For the second phase, we requested interviews with all participants. Three students agreed to participate and were asked to 1) tell us what you know about the Second-Derivative Test, and 2) solve a simple perimeter/area optimization problem. As students reached three specific points in their solution process, they were asked “How do you know that the functions you have chosen represent area and perimeter?”, “How do you know to take the derivative at this step?”, and “How do you guarantee that the answer you obtained was a maximum?” Follow-up questions were asked to clarify responses and ascertain that we had gained as much student knowledge as possible. The interviews were videotaped and an analysis of subject gesture use was begun.

Data and Results

To assess the extent that the gesture-rich video influenced student understanding, we compared the student scores of the last item on the pre-test (the only optimization problem) with the average scores of the two similar optimization problems in the posttest. The initial results suggest that the students who viewed the gesture-rich video improved their scores on the optimization problems more than the students who watched the gesture-free video, as shown in Table 1.

Table 1
Scores of the Optimization Problems, Pre- and Post-video

Students	Pretest Problem	Posttest Problems	Improvement
All Students	26%	52%	26%
Gesture-rich video	22%	55%	33%
Gesture-free video	32%	48%	16%

During the interviews, we expected students to recall statements and solution methods that were shown to them in the video. However, of the three students interviewed, none could give an accurate description of the Second-Derivative Test, and while two students completed the initial optimization problem correctly, they did not verify their answers using the Second-Derivative Test, which was the method of verification in the video. The third student also obtained a correct answer to the initial optimization problem, but he did so without using calculus. When given an additional optimization problem to solve, he was unable to solve it. Further discussion of the interview responses is given below.

The Pretest and Posttest

The pretest suggests that the students had poor mastery and recall of first-semester calculus objectives that required the use of more abstract algebraic representations of functions. The first question (Pre #1) asked students to determine extrema of a function, f, given its graph. The next four problems (Pre #2-5) asked students to determine extrema of f given either the graph of f' or a list of algebraic information about f, f', and f'' (e.g., $f(1) = 8, f'(1) = 0, f''(1) = 2$.) The final pretest problem (Pre #6) asked students to solve an optimization problem requiring them to maximize the area of a rectangle for a given perimeter. Table 2 lists the scores for all problems on the pretest and posttest and shows this drop in scores after the pretest's first problem. We were not totally surprised by this score decrease, given that the literature indicates that the function concept takes a long time to develop, and that students have difficulty moving between different function representations (Carlson, 1998; Carlson, Oehrtman, & Engelke, 2010).

We found a similar score decrease across the posttest optimization problems. The posttest problems asked the students to: 1) solve a problem similar to the example problem in the video, 2) solve a problem with a slight extension of the example problem, and 3) solve an optimization problem with a different context. It was our goal to determine the extent to which they could make extensions from the example that had been presented. As seen in Table 2, students scored well on the most similar problem (Post #1) and scores decreased as extensions needed to be made.

Table 2
All Pre- and Posttest Scores

Students	Pre #1	Pre #2-5	Pre #6	Post #1	Post #2	Post #3
All Students	75%	24%	26%	67%	36%	20%
Gesture-Rich Video	87%	25%	22%	70%	40%	12%
Gesture-Free Video	60%	23%	32%	64%	32%	22%

The Interviews

During the interviews, no student accurately described the Second-Derivative Test. Each student gave responses that were a mixture of correct statements, pseudo-conceptual and pseudo-analytical ideas (Vinner, 1997), and statements that were incorrect or off-topic. Two of the three students were able to complete an optimization problem correctly, but neither of them used a version of the Second-Derivative Test to verify their answers, like had been done in the video example. We present case studies of each student's responses that focus on their gesture use and what they said about the Second-Derivative test.

Students Who Watched the Gesture Video

Student 105. Student 105 initially stated that the Second-Derivative Test was "concavity." His first use of gesture occurred when he began discussing a sign chart which was part of his concept image of the test. While stating that one must find critical points, he used his hands to signal a hierarchy of derivatives by moving them lower at each step while saying "… [given a] function, you find the first derivative, and then you find the second derivative." He seemed to show confusion between f, f', and f'', stating that one must "plug [critical number] back into the original function and that will tell you exactly where it changes … it will change concavity" and later compounding this error by drawing a sign chart that involved plugging critical values into f, claiming that the signs of those results determined decrease and increase, and stating incorrectly that "from decreasing to increasing is concave down, and … from increasing to decreasing is concave up." Thus, while his concept image includes this sign chart, his reasoning behind the creation of this chart is pseudo-conceptual. Nevertheless, he used many gestures during this explanation, indicating concavity by using five "U"-shaped hand positions and two "U"-shaped tracing motions within a span of about 40 seconds during the explanation of his sign chart.

He was able to solve the optimization problem correctly, using the method shown in the video minus the verification step. However, when asked about why we take the derivative of our area function, he noted because "The first derivative tells us the maximum and minimum, the second derivative tells you the concavity." While this statement is technically correct, it is pseudo-analytical as it is not an explicit reason as to why we take a derivative, and he did not include any of the "U"-shaped gestures he used before. When asked how he knew that his final answer led to a maximum, he did not invoke the Second-Derivative Test. Instead, he constructed a table by testing at least one value larger and one value smaller than his critical point; the areas resulting from those numbers were calculated and found to be less than the area resulting from his answer. Here, we see evidence of pseudo-analytical reasoning and the absence of gesture use. Aside from a few general hand motions given to emphasize certain words, he invoked minimal gesture during these particular explanations.

Student 109. Student 109 mentioned that the Second-Derivative Test was "to determine the point at which the (first) derivative changed direction," while positioning his index finger higher than his middle finger and then switching their positions to signify this change. When recalling the Second-Derivative Test, he invoked the image of a bell curve, and used gestures in his description, using two hand motions to trace, first upward, then downward, an imaginary bell curve in the space in front of him while saying, respectively, "climbing up the bell curve," and "it would not start to go negative, but start decreasing," and finishing with the same finger gesture as before while stating "it's the change of the first derivative."

Like Student 105, Student 109 was able to solve the optimization problem using the method shown in the video, and used a similar table instead of the Second-Derivative Test to show that his answer led to a maximum. Student 109 did not use much gesture during the explanation to his solution of the optimization problem; his gesture use consisted primarily of tracing elements of the many diagrams he drew to compliment his words. For example, after drawing a bell curve with a small horizontal tangent line at the top, he said "at this point, slope should equal zero, and the tangent line would be flat," while tracing over the horizontal tangent line.

Student Who Watched the Gesture-Free Video

Student 106. Student 106 initially said that the Second-Derivative test told us "rate of change" and "maximum and minimum." With that latter statement, he presented simultaneously a raised and lowered horizontal, flattened hand to delineate the ideas of maximum and minimum. He later said the test is "where the first derivative is equal to zero …," at which point he seemed to trace a small horizontal segment with his pencil, maybe to represent an image of a horizontal tangent line. He continued "… and it tells you the maximum and minimum, or maybe the local maximum and minimum of the first derivative," while making the same flattened-hand gesture during both times he said "maximum and minimum." Thus, it appears that Student 106 has at least a partial conceptual understanding of the second derivative.

He answered the perimeter/area optimization question by quickly stating that the shape had to be a square. When asked how he knew this to be true, he stated that "I know that circles have probably the largest area, then I think the square, in my mind is next … so I just figured that I'll just make a square out of the rectangle." Since this answer did not take up much time, the interviewer gave him a second optimization problem to consider. He talked through several possible ways to approach the problem, but finally settled on constructing a graph. He drew two increasing segments followed by three decreasing segments and did not have an explanation as to why he drew this shape. While he was describing how he was interpreting his graph, he made a downward pointing motion when describing a function as decreasing, moved his hand in a precise straight line when saying that a function was linear, and held up his pencil horizontally then moved a finger down at the appropriate time while saying that the first derivative equaling zero can give us a maximum because the "slope tells us where it levels off and starts to go back down."

Ongoing Work

The fact that students who viewed the gesture video showed more improvement when solving optimization problems on the posttest appears to be a promising area to explore. The interviews given a week later provided mixed results. While the students were describing their understanding of the Second-Derivative test in the interview, they used several gestures, some of which were similar to what they had seen in the video (Student 105) and some that were distinctly different (Student 106, who viewed the gesture-free video). However, students' performance on similar optimization problems was not as strong as indicated on the posttest. Students did not verify that their answers were extrema. When asked how they knew their answer was a maximum, they did not invoke the second derivative as had been presented in the video. This leads us to believe that we were potentially asking them to recall too much mathematics. Analysis of the interviews is ongoing.

Since the amount of mathematics in our script and tests seemed too much for these students, our next stage of research will be done on a smaller scale. We plan to devise a smaller, 4-5 minute script that only defines the Second-Derivative Test, eliminating the surrounding context of an optimization problem. This script will be filmed in four ways: with no gesture at all, with only tracing and pointing gestures at the board, with only hand gestures in the space between the instructor and the student, and with both of the preceding types of gesture. It is our hope that a simplified script, with more focused pre- and posttests, will allow for greater student success. With this success, we hope to not only have a greater understanding of how instructor use of no gesture, limited gestures, or many gestures might affect student learning, but also see students using more gesture to augment the explanation of their mathematical processes. Hence, we will be able to make suggestions for how instructors can incorporate gesture into their teaching to facilitate student understanding and success. As our work progresses over the next several months, we are certain several interesting questions will arise that we will bring to the conference.

Experts' Varied Concept Images of the Symbol dx in Integrals and Differential Equations

Tim McCarty
West Virginia University

Vicki Sealey
West Virginia University

The mathematical symbol "dx" is a symbol for which there can exist different views about its characteristics, purposes, and roles. We wished to see how experts viewed the dx in a variety of settings. We chose four mathematical contexts and interviewed four mathematics professors in order to understand their various concept images of the dx. While there was little agreement among the experts' responses, most of them did have a strong concept image that remained consistent throughout their interviews, despite our attempts to create cognitive conflict between the different mathematical contexts. We conclude that the existence of a range in the experts' opinions is noteworthy, and that further study should be conducted in order to more fully explore this range and any implications for instruction that may result from it.

Key words: Calculus, Integrals, Differential Equations, Concept Image

In this preliminary report, we examine instructors' views of some of the various roles of the symbol dx. This symbol can be found in a variety of mathematical settings, including definite and indefinite integrals, the formal definition for differential of a function, Leibniz notation for derivatives, the process of integration by substitution, and several types of ordinary differential equations. We wanted to see whether instructors' concept images (Tall & Vinner, 1981) of this symbol would be consistent throughout all of these settings, or if different concept images would manifest given different settings.

Research has been done on how students perceive the dx in a definite integral. Sealey and Thompson (in press) summarized four such perspectives noted in the literature: a marker that points out the variable of integration (Artigue, Menigaux, & Viennot, 1990; Hu & Rebello, 2013; Jones, 2013; Nguyen & Rebello, 2011), a graphical width of a rectangle (Bajracharya, Wemyss, & Thompson, 2012; Wemyss, Bajracharya, Thompson, & Wagner, 2011), a small amount of a given physical quantity (Artigue et al., 1990; Hu & Rebello, 2013; Roundy, Manogue, Wagner, Weber, & Dray, 2015), or a difference or change in a quantity (Von Korff & Rebello, 2012). López-Gay, Martinez, & Martinez (2015) gave other concept images found in physics, including dx as an infinitesimal increment or linear estimate. While Hu and Rebello (2013) emphasized the importance of conceptualizing the dx as a width, Sealey and Thompson (in press) noted the importance of conceptualizing it as a difference in other mathematical contexts.

The purpose of our research is to explore further concept images of the dx in some additional mathematical contexts. Specifically, we chose to investigate experts' perspectives of the dx in definite and indefinite integration, the formal definition of the differential of a function, integration by substitution, and separable and exact ordinary differential equations. To create beginning points of reference, two surveys of textbooks were conducted. The first survey included nine books (Barnett & Ziegle, 1989; Breusch, 1969; Ellis & Gulick, 1988; Fisher & Ziebur, 1965; Hughes-Hallet, et. al., 2006; Mizrahi & Sullivan, 1982; Rees & Sparks, 1969; Stein, 1967; Stewart, 1987) which contained material found in traditional first- and second-semester calculus courses. We analyzed and compared any sections of these books in which definite integrals, indefinite integrals, differentials of functions, and integration by substitution were introduced and/or defined. The second survey included three books (Boyce & DiPrima, 2012; Stewart, 1987; Zill, 1997) that contained information on basic ordinary differential equations, with which we compared and contrasted the sections that introduced separable and exact differential equations.

We found that only Hughes-Hallet et al. (2006) presented the idea that the dx in the definite integral comes from the factor Δx found in a Riemann Sum, while the other books stated that the dx in a definite integral was merely notation with its only purpose to serve as a dummy variable that indicated the variable of integration. All of the books clearly stated the definition that, if y were a function of x, the differential of y is given by the formula $dy = y'(x)dx$, with all but one book stipulating that x and dx were independent variables, x is any number in the domain of y, and dx is any real number. Every book approached the evaluation of an integral that required substitution by the usual method of determining a $u(x)$ and using the relation $du = u'(x)dx$. However, there was no discussion as to the nature or roles of the various dxs that were seen throughout this process. Similarly, no matter the solution methods offered for separable or exact ODEs, no book explained the roles of the dx, nor discussed the permissibility of multiplying or dividing by dx throughout the solution process.

Theoretical Perspective and Methods

Tall and Vinner's (1981) concept image and definition were used to structure the design of the study and the analysis of the data. Because of the discrepancies and varieties of concept images and definitions found in the existing research and collections of textbooks, we wanted to interview experienced mathematics faculty to see if their concept images would be different, not only from the books' images, but also from each other's. We wanted to determine if their individual concept images would be more well-formed and align more closely to a formal concept definition than what the textbooks seemed to provide. Assuming the existence of well-formed concept images, we also wanted to see whether we might find some instances of potential cognitive conflict.

During a series of clinical interviews, four professors were shown a series of mathematical symbols, definitions, and situations in which the symbol dx was present. Faculty members were chosen so that there was some variety in their research areas. Participants Sonya, Johnny, and Jackson each had research and/or teaching experience in analysis and differential equations, while Kurtis' research areas included combinatorics and graph theory.

Prior to the interviews, we created an interview protocol, listing the order in which the aforementioned mathematical symbols, definitions, and situations would be presented to the subjects. Thirteen such symbols, definitions, and situations were divided into four categories, listed in Table 1. In addition to the question of how the subjects perceived the role of the dx in each category, follow-up questions were posed if the subject stated something that differed markedly from the surveyed textbooks or other subjects' responses. Johnny requested that his interview not be videotaped; thus his impressions have been taken from the authors' notes. All of the other interviews were videotaped and later transcribed.

Data and Results

Since we were interviewing experienced instructors, it was possible that their individual concept images might have converged to a formal concept definition. But, as the textbooks did not show one formal definition but a variety of ways in which to think about the dx, we anticipated that the professors might not all have the same concept image. Data analysis is ongoing, but

Table 1
A Summary of Our Categories and Uses of dx

Categories	Symbols, Definitions, or Situations Containing dx
Integrals	$\int f(x)\boxed{dx}$, $\int_a^b f(x)\boxed{dx}$, and $\int_b^a f(x)\boxed{dx}$
Definitions and Notation	If $y = y(x)$, the notation $\frac{dy}{\boxed{dx}}$ and definition $dy = y'(x)\boxed{dx}$ If $x = x(t)$, the notation $\frac{\boxed{dx}}{dt}$ and definition $\boxed{dx} = x'(t)dt$
Integration by Substitution	$\int_1^4 \frac{\cos\sqrt{x}}{2\sqrt{x}}\boxed{dx}$ versus $\int_1^2 \cos x\boxed{dx}$, after $\int_1^4 \frac{\cos\sqrt{t}}{2\sqrt{t}}dt$ used the substitution $dx = \frac{1}{2\sqrt{t}}dt$
Two ODEs	1) The separable equation $\frac{dy}{\boxed{dx}} = g(y)h(x)$, and the solution steps $\frac{1}{g(y)}dy = h(x)\boxed{dx}$ and $\int \frac{1}{g(y)}dy = \int h(x)\boxed{dx}$ 2) The exact equation $(2xy - 9x^2)\boxed{dx} + (x^2 + 2y + 1)dy = 0$

preliminary analysis indeed shows that while all four interview subjects were very consistent within their personal concept image, these images differed from one another, and did not align with a single formal concept image. Summaries of the subjects' responses for each of our four contexts and some of the subjects' personal concept images are given below.

The dx in Definite and Indefinite Integration

Sonya and Jackson stated that the dx in a definite integral comes from a limiting process applied to the width represented by the bases of Riemann Sum rectangles. Kurtis seemed to have a similar idea but was not as specific, saying that "it [the dx] comes from the Δx [in a Riemann Sum]" without mentioning the image of rectangle widths. Johnny initially described the dx as arising from the limit of "cuts in the interval between a and b on the *x*-axis," but later changed his answer to "dummy variable" after some thought. All subjects except Kurtis also claimed that they viewed the dx in an indefinite integral no differently than they viewed the dx in a definite integral. Kurtis, however, claimed that the indefinite integral's dx had no meaning beyond being half of a notation (the other half being the integral sign) which signaled antidifferentiation.

The dx in Definitions and Leibniz Notation

Kurtis said that $dy = y'(x)dx$ if and only if $\frac{dy}{dx} = y'(x)$, but did not feel that this meant that one could simply multiply or divide by dx to go from one form to the other. Sonya agreed that such multiplication or division was not possible, while Johnny and Jackson had no problem with multiplying or dividing by dx in this way. Another area of contention was that part of Johnny's initial response when presented with the four notations and definitions in this section was to state an idea also found in Rees and Sparks (1969): the dx in $dy = y'(x)dx$ could be either an independent variable or a function of two other variables, and that this definition of the differential of a function would still hold. Sonya and Jackson initially thought instead that dx was strictly a dependent or independent variable depending on its position in the definition, but Sonya came around to Johnny's view after that view was presented to her. Kurtis only went so far as to claim that the relationship between the dy and dx in $dy = y'(x)dx$ was the same as the relationship between the dx and dt in $dx = x'(t)dt$.

The dx in Integration by Substitution

All subjects except Sonya seemed to feel that even though the substitution process began with the "$dx = x'(t)dt$" definition of the differential of a function, once the substitution was made, the dx had transformed into a simple dummy variable, and was therefore now bereft of any deeper meaning. Jackson additionally mentioned that while the initial dummy variable (in $\int_1^4 \frac{\cos\sqrt{x}}{2\sqrt{x}}\,dx$) and the transformed dummy variable (in $\int_1^2 \cos x\,dx$) had similar roles as infinitesimal widths, we could still think of them as different, since one was the limit as *n* goes to infinity of $\frac{4-1}{n}$ while the other was the limit as *n* goes to infinity of $\frac{2-1}{n}$. This idea that the two versions of dx have different sizes was also expressed by Sonya, but her image included an idea that both dxs were on different levels; specifically "macroscopic/microscopic" levels.

The dx in Separable and Exact ODEs

Sonya felt that even though it may appear that we could multiply by dx in order to separate variables in the separable equation, what is really happening instead is that we are multiplying by Δx and then passing through the limit. Kurtis agreed with the idea that we are not really multiplying by dx, but seemed to think that it was always fine to proceed as if that is what were really happening. Johnny and Jackson, as before, had no problem with multiplying or dividing by dx. Similar responses occurred during the explanations of the exact ODE. Sonya was still uncomfortable with the idea of "moving the dx around" but admitted that it is how solving differential equations is usually taught. Johnny and Jackson did not have this discomfort, and Kurtis declined to answer, stating that he was not as familiar with exact differential equations.

Personal Concept Images

While analyzing all of the subjects' responses, it was found that Johnny, Kurtis, and Sonya seemed to have central images that ran throughout all of their answers. Johnny's overall view seemed to be summarized by his initial response when presented with the two notations and definitions: "in some ways, they are all the same." He noted that even though the traditional definition $dy = y'(x)dx$ came with the idea that *x* and dx were independent variables, there was nothing stopping us from assuming that dx could also be a function depending on other independent variables (for example, $dy = y'(x)dx$ while $dx = x'(s)ds$), a view shared by Rees and Sparks (1969). If one were to continue this chain down to the last link, then the last differential in this chain can also fit that definition, as in our example: $ds = 1 \cdot ds$, since the derivative of s with respect to s is 1. He repeatedly said that these relations between differentials were "meaningful only in their relation to one another." Thus, for example, one can multiply or divide by a dx while manipulating an ODE, since that ODE also contains a dy, but in the "integration by substitution" process, once the substitution has been made, the dx becomes a dummy variable, since we no longer have a second differential.

Johnny's central view of all dxs outside of integration having a numerical basis seems to run counter to Kurtis' central view, which was that every instance of dx or dy was merely a product of a "useful notation" and had no mathematical meaning as a numerical entity. Kurtis said many times that all of these manipulations were products of a "perfectly good notation," and thus easy for educators use when introducing concepts like the Chain Rule or integration by substitution, but while it may appear that mathematical operations with a dx might be implied, Kurtis was adamant that this was not the case.

An image of Sonya's was that she was uncomfortable multiplying or dividing by dx, since it was an infinitesimal quantity created by "passing Δx through the limit." To her, no matter the situation in which a dx was being used in algebraic manipulations, the "real story" was that we were instead manipulating Δx (a measureable quantity) and then passing through the limit, turning all Δxs into dxs. She noted that the convenience of simply saying "multiplying by dx" was helpful for instruction, but that we should be more careful about telling our students "we can multiply by dx." Yet when it was presented to her, she seemed to accept Johnny's and Rees and Sparks (1969) view that dx could be an independent variable no matter the presentation. This might seem to contradict her idea that dx was only some infinitesimal quantity unable to be manipulated. Further research will explore whether these two views are an example of cognitive conflict, or whether deeper questioning will lead to a more complete view of her total concept image.

Discussion

Many of the subjects' responses suggest possible areas for future research. It is possible to use differentials to develop implicit differentiation (Mizrahi & Sullivan, 1982; Rees & Sparks, 1969) or generate derivatives by using differentials instead of taking the limit of a difference quotient (Dray, 2013; Dray & Manogue, 2010). Additional data collection could tell us if any of the subjects' concept images allow or conflict with these developments. Sonya mentioned that the convenience of multiplying by dx would not be appropriate with higher-order differentials; additional data collection could tell us if any of the subjects' concept images agree or disagree. Several books gave differential rules that parallel derivative rules (an example being $d(uv) = u\,dv + v\,du$), and there are also proofs of the Chain Rule and various methods of finding the solutions to separable differential equations in which it appears that differentials are being multiplied, divided, or canceled. The belief in whether one could perform such manipulations with dx divided our subjects equally; additional data collection could tell us what percentage of other experts will feel that such manipulations are acceptable.

This preliminary report also suggests implications for teaching. Even though only four subjects were interviewed, their concept images had some variety to them. One could say that there was a continuum of answers, from Johnny's central thought that all differentials outside of integration were really the same and had analytic properties, to Kurtis's assertion that all differentials were only part of a really good notation, with Sonya's and Jackson's views falling somewhere in the middle. Further research might further define spaces on this continuum or perhaps show a greater concentration of images at one or both ends. Whatever the dispersion of concept images on this continuum, the fact that such a dispersion exists perhaps begs the question of how the existence of different views of differentials held by textbooks and instructors might affect student learning.

Locating a Realistic Starting Point for the Guided Reinvention of Limit at Infinity With Community College Students Prior to Pre-Calculus

Will McGuffey
Teachers College, Columbia University

In this paper, I describe a teaching experiment conducted with a pair of undergraduate students at a two-year community college. My primary goal was to explore a realistic starting point for the guided reinvention of the concept of limit at infinity for students who had not yet studied limits. The teaching experiment included 5 weekly hour-long sessions in which the two students were presented with tasks that involved describing the behavior of certain real-world phenomena. The initial analysis revealed that these students showed ways of thinking that anticipate the formal concept of limit at infinity. Further analysis will be used to develop an appropriate instructional sequence with a realistic starting point to be used in future teaching experiments in which students will be engaged in the guided reinvention of a formal definition of limit at infinity.

Key words: Calculus, Guided Reinvention, Limit at Infinity, Two-Year College

The limit concept is notoriously difficult in learning (and teaching) Calculus. Prior research has documented common student misconceptions and models of how students might understand the limit concept (Tall & Vinner, 1981; Williams, 1991). Most, if not all, research on students' understanding of the limit concept has involved participants who had previously studied Calculus or were enrolled in Calculus at the time of the study. If we aim to improve instruction on limits by understanding what can cause difficulties for students, there are two potential issues with this approach to participant selection. First, it is difficult to discern whether cognitive obstacles are imposed by traditional instruction on limits or are natural products of the mathematical concepts themselves. In other words, what if the difficulties students face when learning limits could be avoided by using alternative instructional or curricular approaches? Second, by nature of making it through a Calculus course (or even making it *to* a Calculus course), the students in such studies have already demonstrated a certain level of mathematical ability (or determination). A different approach is needed in order to examine how students think about limits, without them first having been taught explicitly about limits. In this paper, I aim to describe how two students reasoned about limits prior to formal instruction on limits by engaging them in the guided reinvention of the concept of limit at infinity using their informal understandings of realistic situations with asymptotic behavior as a starting point.

Background and Related Literature

Guided Reinvention

Guided reinvention has often been used in undergraduate mathematics education research in order to develop instructional sequences that aim to make advanced mathematics content more accessible to students (Cook, 2014; Larsen, 2009; Oehrtman, Swinyard, & Martin, 2014; Swinyard, 2011). Guided reinvention is a teaching approach that is aligned with Hans Freudenthal's Realistic Mathematics Education (RME) philosophy, which proposes that mathematics instruction should focus on the activities of doing mathematics rather than the products of those activities (Freudenthal, 1973; 1991). The starting point for instruction should be a context that is realistic relative to students' experiences so that it will be within their reach to develop ways of reasoning related to the mathematical concept(s) that are to be learned. From that starting point the instructor guides students to reinvent the desired piece of mathematics.

The Limit Concept

The limit concept has a fairly complicated structure, which includes many advanced concepts. In order to make the definition accessible to first-time Calculus students, it is often described informally. The most rigorous informal description (of limit at infinity) is usually given in textbooks, such as "$\lim_{x\to\infty} f(x) = L$ means that *f(x)* can be made *arbitrarily close* to L (or as close as desired) by making *x sufficiently large*," where the terms *arbitrarily close* and *sufficiently large* have technical mathematical meanings.

Through the APOS framework, Cottrill et al. (1996) described how students might learn the limit concept through a coordination of these two processes. Swinyard & Larsen (2012) added that student understanding of the formal limit concept could potentially be hindered by two obstacles: (1) a tendency to take a domain-first perspective in reasoning about limits and (2) the difficulty of thinking about an infinite process as being completed. Swinyard (2011) demonstrated that students can be guided to reinvent a formal definition of limit from the starting point of a strong informal understanding of limit. I am not aware of any previous attempts to examine how or if students can be supported to reinvent any aspect of the limit concept from a starting point that does not require prior understanding of the limit concept itself.

Research Question and Methods

The purpose of this study was to gain insights into how students – who have not had instruction on limits in Pre-calculus or Calculus – might come to understand the concept of limit at infinity in the context of guided reinvention of limit at infinity. In particular, the goal was to explore one potential starting point from which the concept of limit at infinity could be reinvented. I aimed to answer the following research question: Can instructional tasks in the context of describing functional behavior evoke ways of thinking that anticipate desired ways of reasoning for understanding the concept of limit at infinity?

This study involved a teaching experiment (Steffe & Thompson, 2000) with a pair of students (Zelda and Tetra, pseudonyms) who were recruited from a College Algebra course at a two-year community college. The participants were selected based on the fact that they had not previously taken a course in Precalculus or Calculus (verified by the student on a preliminary questionnaire) and on their ability and willingness to discuss their thoughts about mathematics with others (verified through a conversation between myself and the students' College Algebra instructor). The teaching experiment consisted of five 60-minute instructional sessions. All instructional sessions were video- and audio-recorded for analysis. Before each instructional session, I conducted a thought experiment to imagine a possible hypothetical learning trajectory (Simon, 1995) for the upcoming session. Between each pair of sessions, I conducted ongoing analysis (Strauss & Corbin, 1998), which involved comparing the proposed hypothetical learning trajectory to what actually took place during the sessions, and then planning instructional tasks for the next session. After the conclusion of the teaching experiment, I conducted an initial reflective analysis (Cobb, 2000) of all five sessions together. The focus of this initial analysis was to identify events during the teaching experiment in which the students showed signs of reasoning about the instructional tasks in ways that anticipate the concept of limit at infinity.

Overview of the Teaching Experiment

For this preliminary report, I will highlight a few key moments from the first three sessions of the teaching experiment related to the development of the concept of limit at infinity. In Session 1, participants described how the quantities changed in each of the realistic situations in Table 1 (among others that were dropped after Session 1). Then, during Session 2 the students looked for similarities and differences among the situations in Table 1. During this session the students indicated that they wanted to be able to use graphs and formulas to solve these problems. So, I gave them formulas (for Situations 1 and 5) and graphs (for Situations 2 and 3) to work with in Session 3. When students indicated that the limit (or "end value") would not be reached based on the formulas or graphs, I posed the question of how close the quantity would get to it. In Sessions 4 and 5 I asked students to predict a value of the quantity at some future time that was not displayed on the graph. I introduced two new situations (involving exponential growth and circular motion) in order to contrast the other examples in which their predictions were getting better as I asked them to predict values of the quantity after longer periods of time.

Situation 1	Imagine taking a pie out of the oven after it has been baking at 350 degrees. Describe how the temperature of the pie changes as time passes.
Situation 2	Imagine a person bungee jumping over the side of a bridge that is 200 ft. in the air. Describe how the height from the ground of the bungee jumper changes as time passes.
Situation 3	Imagine dropping a tennis ball from the roof of a tall building and watching it hit the sidewalk below. Describe how the height of the ball from the ground changes as time passes.
Situation 5	A group of scientists store 10 g of a radioactive substance. Every 30 days half of the substance decays (breaks down into other substances and energy). Does the substance ever completely decay?

Table 1. Realistic situation prompts from Session 1

Results

I organize the results to discuss 3 such examples from the first three sessions, where students' dialogue about these situations seemed to lead them to discuss 3 important aspects for reinventing limit: infinite process, closeness, and coordinating domain and range.

Dealing With an Infinite Process

When comparing the four situations in Session 2, one of the main observations the students focused on was how the quantities in Situations 1-3 eventually reached a constant value whereas in Situation 5 the quantity never reached zero. For Situations 1-3, the students were only concerned with a finite timeline, as demonstrated by Zelda's description of Situation 1: "…it's just like really hot… and then over time it will just cool off gradually and then eventually, I guess, turn into room temperature." Then, when the students were first describing Situation 5 in Session 1, they spontaneously began to write out a list of values, believing that they would determine when the mass reached zero. The students paused after calculating the first eight values and had the following exchange:

Tetra: *This is what I was trying to say about the infinite numbers between zero and one. That's what I was trying to say. It'll keep going.*
Zelda: *So, would it never decay?*
Tetra: *It's just not going to decay.*
Zelda: *Ever? [with a tone of surprise]*

At this point Zelda was struggling with the idea of an infinite process. In Session 2, she decided to use her calculator to continue the process that they had started in Session 1, saying "because I do feel like it comes to zero at a point." She ended up dividing by two over forty times before giving up and saying "It will just always have a number to divide in half, like always. Even if it's like zero-point-one or zero-point-something." Engaging in this task allowed the infinite process to become experientially realistic to her.

Anticipating Arbitrarily Close

Since the students had determined that the mass of the radioactive substance in Situation 5 would never completely decay, I posed the question: "How close would the mass get to zero?" The following dialogue transpired.

Tetra: *I can't comprehend that number because, like, every time you would divide it, the decimal just keeps getting longer and longer and longer and longer and longer and longer. So, it would be like some crazy, never-ending decimal.*
Zelda: *I don't know how to figure that out. Unless you give us a number that's like to you that's close enough to zero.*

The students' comments indicate that any comprehensible number is insufficient in describing how close the mass gets to zero. Tetra's comment about the decimal just getting longer demonstrates the students' struggle with seeing an infinite process as being completed. In addition, Zelda's comment "Unless you give us a number…" was connected to her knowing that for any given value, they could use the formula to identify the corresponding number of days needed to reach that number. In other words, there was a sense of "arbitrariness" to the "give us a number that's close enough to you, and we can figure it out" idea.

Coordinating Domain and Range

Another interesting interaction occurred near the end of Session 3. Prior to giving the students a graph for Situation 2, I asked them to recall their prior description of the situation from Session 1, and Tetra sketched a graph (Figure 1).

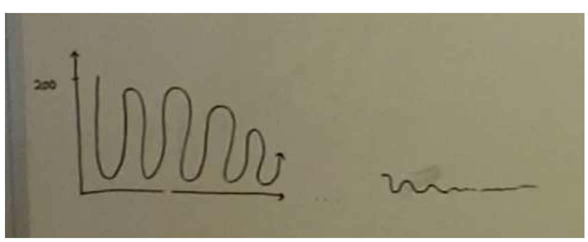

Figure 1. Students' graph of the height of the bungee jumper (Situation 2)

Based on our previous discussions, the students seemed to believe that the bungee jumper would eventually stop bouncing. So, I asked them how long it would take.

Tetra: *I feel like all of these are the same. They just never end.*
Zelda: *No, I think he'd stop bouncing. I think he'd just like stay. I don't think it would take that long to stop bouncing completely.*
Will: *So, on the graph, what would it look like?*
Tetra: *Just taper off.*
Will: *But, like, how would you draw it?*
Tetra: *So, let's say after a point it would be really, really small. Like, I could draw it bigger, but like, on the other bounce, it would keep getting smaller until it's kind of like… [draws the portion on the right in Figure 2]*
Zelda: *And then he's just still, or like swinging at the same height.*
Tetra: *And then just get smaller.*

Relying on her intuition that the bungee jumper would eventually stop bouncing, Zelda saw the stopping point as an end to the situation. On the other hand, Tetra was open to the idea that the bungee jumper would continue to bounce forever. As a result, she was able to focus on the quantity *approaching* a limit rather than simply *reaching* it. This perspective also fostered a shift in her language. Where she had previously used language like "at a point" to refer to some moment in the future when the limit was reached, she began to say "after a point" to indicate that she was also considering what happened beyond the moment when she considered the quantity to be close to the limit. Moreover, she coordinated her notion of "after a point" (similar to *sufficiently large*) with the bounces being really small and continuing to get smaller.

Discussion

The two students in this study were able to reason about these realistic situation contexts in ways that indicate that these contexts and tasks could potentially be used as a starting point for the guided reinvention of the concept of limit at infinity for students who have not previously learned about limits. In particular, describing a situation in which the students believed that the limit (or "end value") would not be reached could provide a context for discussing the completion of infinite processes. The task of determining how close the changing quantities could get to the limit (Task 3) supported discussions in which the notions of *arbitrarily small* and *sufficiently large* were present in the students' comments.

These findings come with several limitations. Although the students were able to reflect on an infinite process, it was not in the context of the infinite processes involved in the limit definition in which students think of values in the range becoming successively closer to the limit value and values in the domain becoming successively larger (Cottrill et al., 1996). Moreover, there was no indication that the students were able to resolve the idea of an infinite process being completed, which is one of the student difficulties with the limit concept described by Swinyard & Larsen (2012). Lastly, although Tetra showed signs of coordinating the notion of sufficiently large in the domain with the notion of small variations in the range, she seemed to be taking a domain-first perspective. Overall, important issues related to the concept of limit at infinity, including potential student difficulties, were evoked during these students' engagement in the instructional tasks; however, more insight is needed to help the students overcome and resolve these difficulties in future implementations of the teaching experiment.

Exploring Student Conceptions of Binary Operation

Kathleen Melhuish
Texas State University

Binary Operations are essential to many undergraduate mathematics courses. However, little is known about student conceptions around binary operation. This report presents preliminary results from nine student surveys about the topic. The question set was developed in response to Group Concept Inventory (GCI) results. We look at three activities closely related to binary operation: identifying when an instantiation is a binary operation, identifying when two instantiation are the same binary operation, and generating an original binary operation instantiation. We use the lens of variation theory to make sense of student responses. We found that students' concept image of binary operation may be missing key attributes (such as requiring two inputs) and contain unnecessary attributes (requiring a general rule.)

Key words: Group theory, variation theory, abstract algebra, binary operation

Students begin working with binary operation in elementary mathematics classes. However, binary operation is not defined abstractly until advanced mathematics courses such as abstract algebra. Well-known operations such as addition and multiplication provide the examples of binary operations for much of mathematical education. Taking a variation theory approach, student conceptions of binary operation are built from the examples they encounter and particularly what variations exist across this space. This may lead to overgeneralizing properties such as operations always having a formal name or symbolic rule to describe them. Furthermore, critical attributes of binary operation may remain hidden such as the necessity for binary operations to be defined on two elements of a set. By giving nine modern algebra students a set of non-routine binary operation prompts, we identify critical aspects of binary operation that may be hidden in routine contexts.

Concept Understanding in Advanced Mathematics

There are a number of ways researchers have made sense of concept understanding in advanced mathematics. In this study, we use the concept image/concept definition framework (Tall & Vinner, 1981) and variation theory (Marton & Booth, 1997) to make sense of the snapshot data collected about students' conceptions of binary operation. Tall and Vinner's work on concept image and definition introduced a way of discussing all of the cognitive associations with a given mathematical concept. Concept definitions exist formally, but also personally for each student. Concept image captures all associations such as examples, applications, and representations of a concept. Tall and Vinner's work was especially powerful in its ability to capture a lack of coherence that often exists in novice's concept images and definitions. The definitions may not be cohesive with images, and different parts of a concept image may not align with itself.

Variation Theory (Marton & Booth, 1997, Watson & Mason, 2006) provides one lens for making sense of potential lack of coherence. The theory posits that learning occurs in contexts where variations occur. Experiences with examples of a concept, such as binary operation, may expose a learner to different attributes to eventually become part of their greater conception around a topic. Marton and Booth likened this process to a jigsaw puzzle where "the parts need to be found and then fitted into place" (p. 180) to understand the whole. Through exposure to varying aspects, the learner can then determine which aspects are parts of the whole or the structure of a mathematical concept and which are allowed to vary, *dimensions of possible variation* (Watson & Mason). A students' concept image reflects the attributes that they have been exposed to (and assimilated) in varying situations.

Prior Research on Student Conceptions of Binary Operation

Informally, a binary operation can be thought of as a rule for combining two elements of a set to produce a single element (from this same set.) Addition is a binary operation on the set of real numbers because any two real numbers can be added to another real number. Formally, binary operations are defined as a function from the Cartesian product of some set *S (SxS*) to *S*. In this way binary operation brings together two concepts that may have been seen as disjoint in prior situations: operations and functions. Research on the specialized case of arithmetic dominates the operation literature with framework such as Slavit's (1998) *operation sense* framework. This framework builds formal operations from standard processes (such as combining groups developing into addition), but does not extend to the abstract notion of binary operation. To adopt the language of variation, until university courses, variation in operations are likely limited to these well-developed arithmetic operations.

Because binary operations are a special case of functions, student conceptions around functions may play an additional role in their understanding. Students have been documented as struggling with functions across grade levels (Oehrtman, Carlson, & Thompson, 2008). For example, students may prefer a certain representation such as a written symbolic rule (Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Vinner & Dreyfus, 1989). This may reflect students typically being exposed to functions that can be defined in that manner leaving students to overgeneralize that a written symbolic rule is a structural aspect of function.

Existing frameworks on binary operation have taken a number of approaches. Brown, DeVries, Dubinsky, and Thomas (1997) presented a genetic decomposition of binary operation where students may have an action conception (explicitly combining two inputs to arrive at an output), a process conception (a general process for combining inputs to arrive at outputs), or an object conception (seeing binary operations as things that can be acted on as objects themselves.) Novotná, Stehlíková, and Hoch (2006) provided a structure sense framework capturing the transition from familiar operations to unfamiliar. Ehmke, Pesonen, and Haapasalo (2011) presented a framework leveraging different representations to distinguish students with procedural and conceptual understandings. Each of these frameworks in some way captured going from concrete to abstract understanding. The variation theory approach in this paper aims to compliment these process frameworks with a more nuanced view of exactly what attributes of binary operation may be influencing student conceptions.

Some of these ideas have been broached in misconception literature in other subject areas. Mevarech (1983) found statistics students overgeneralized properties onto binary operations such as associativity. Zaslavsky and Peled (1996) had pre-service and in-service teachers generate examples of binary operations resulting in a number of issues including defining unary operations rather than binary operations.

The study presented below serves as a follow-up to initial results from the Group Concept Inventory (Melhuish & Fasteen, 2016). We conjectured that student conceptions of binary operation accounted for performance on questions targeting subgroups, the associative property, and groups themselves. For example, in results from the GCI, over half of students surveyed felt that the set {0,1,2} was a subgroup in $\mathbf{Z}_6$. Follow-up interviews reflected that the students might not think that the addition modulus 3 was different than addition modulus 6. These students' responses raised questions regarding student conceptualizations about what makes two binary operation instantiations the same or different.

Methods and the Question Set

The nine surveys analyzed herein come from two modern algebra classes at a large, public university. The students were surveyed at the end of their course. In order to make sense of student thinking around binary operation, we identified three activities that are tightly linked to understanding of mathematical concepts:

1. ***Is or is not***. Determining if a given instantiation is an example of a concept (Ehmke, Pesonen, and Haapasalo, 2011)
2. ***Same or different.*** Determining if two instantiations are mathematical the same
3. **Generating**. Creating an instantiation meeting some criteria (Zazkis, & Leiken, 2007)

The survey questions prompted students to engage in one of those activities. We looked at what attributes of binary definition students might attend to, how students determine if two binary operations are the same, and if students can generate a non-standard binary operation. For each question, students were also prompted to explain their reasoning. The surveys were then analyzed with the lens of variability: which attributes of binary operation seemed to guide student solutions.

Results and Analysis

The Binary Operation Concept Attributes

Each student was asked to determine if functions were binary operations including: addition mod 3 on {0, 1, 2}, division on the reals, x^2 on the reals, and a binary operation defined element-wise on the set {1, 2}. The responses to these prompts had two notable patterns: 1) students attended to closure over other attributes; 2) students did not always attend to binary requirement.

Closure seemed to the primary attribute attended to across all prompts. The eight students who elaborated on their responses either used the term closure or provided an explanation such as: "Yes. When you add any two numbers in the set it produces another in the set." However, this closure manifested differently depending on whether the student had integrated the attribute of binary. When evaluating addition mod 3, one approach was to take all six combinations of three elements, add together the pairs, and determine the result was still in the set. However, two of the students looked at the elements and appeared to treat the modulation as the operation. For example, one student stated: "Yes, 0 mod3=0, 1 mod3=1, 2 mod3=2. All the elements of the operation are in the set." Similarly, all eight students who responded to the prompt about x^2 claimed that this was in fact a binary operation. I conjecture this is for one of a two reasons 1) a unary approach, 2) restricting the domain of a known binary operation: multiplication. For example, see the students' response in Figure 1.

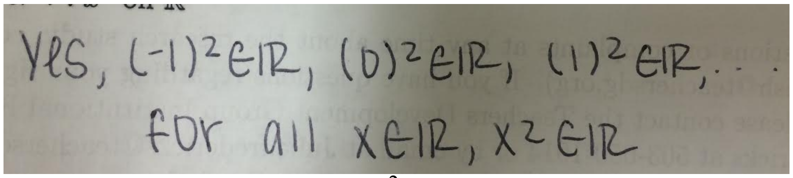

Figure 1. Unary approach to x^2

In this case, the student appeared to be inputting members of the reals rather than ordered pairs or two inputs. As in the modular addition case, this student illustrated that the attribute of binary may not be realized as structural to binary operation. Alternately, some students rewrote x^2 as $x*x$ then explained that it "gives you another number that is [sic] ***R***." In this case, the students seemed to unintentionally be restricting the domain from all sets of two elements, to only ordered pairs of the form: (x, x). These students may not be attending to the necessity of domain to include all combinations of two elements from the corresponding set.

Attributes of the Same Binary Operation

The students were also given four pairs of operations to determine if they were the same or different respectively. These prompts were intended to probe what attributes of the binary operation instantiations determine if they are unique. Of the nine students, five thought that division and multiplication were the same operation on ***R***. (One student provided the caveat that 0 had to be removed for division.) The arguments generally relied on the relationship between division and multiplication: they are inverse operations, or alternately, division can be rewritten as a multiplication statement. ($a/b = a*(1/b)$). There are similarities across multiplication and division; however, the commonalities are not sufficient attributes to be the same operation. Students also argued that addition modulo 3 and addition modulo 6 are the same. Half of the eight students felt these were the same operation with reasoning such as: "Yes, because op 1 is addition under mod 3, whereas, op 2 is also addition under mod 6." In the third of these tasks, students were given a binary operation defined on a table and a second defined element-wise. The elements were named the same, but had had a differing output for one combination. Of the seven students who addressed this prompt, all seven appropriately matched elements and used the rationale to declare the operations different. Yet, these same students used different rationale to declare multiplication and division the same operation and addition modulo 3 and 6 as the same operation. Table 1 contains a breakdown of attributes that students allowed to vary when determining if two binary operations are the same.

Table 1. Sameness Attributes.

Name	**Description**	**Permissible Variation**
Superficial Sameness	Students attend to attributes that provide similarities disconnected from the definition of binary operation.	element names, domain of operation, output for given pair of elements
Literal Sameness	Students attend to attributes connected to binary operation requiring a literal sameness	none
Isomorphic Sameness	Students attend to attributes up to isomorphism	names of elements

Attributes when Generating Binary Operations

The final question in the survey stemmed from a GCI question. Students were prompted to generate a binary operation such that the set {1,2,4} forms a group. Five students indicated it was impossible to construct such an operation, one student did not know how to approach the prompt, two students provided a familiar binary operation not meeting criteria, and one student provided no rationale for their response. One sample student response was, “No. Because the finite set does not hold enough elements to have the properties necessary when performing an operation on the set to form a group.” Another student listed the four arithmetic operation putting, “No?” next to them. These students’ approaches reflected student responses from the GCI (Melhuish & Fasteen, 2016). Through generating an unfamiliar example, students are limited to a set of examples with what they perceive as permissible variations. If students were to create a binary operation on this set, they would need to create one that had no pre-set name or explicit symbolic rule. This may not be a variation that students have experienced and aligns with other research on how students conceive of functions.

Discussion

Looking across the three activities highlights 1) binary operations are not trivial structures for students in introductory group theory, 2) variation theory provides a lens for making sense of what variations are permissible in students’ concept images. The students in this study seemed to include some form of closure as a structural attribute of binary operation. The desire for closure was found in the *is or is not* question set and the *creating* question. However, binary, the need for two inputs, appeared to be lacking across several of the surveys. To take a variation-based approach, it is unlikely these students are ever presented with a function that does not take two inputs as typical textbook treatments do not include operations that are not binary (Gallian, 2016; Fraleigh, 2003). Without varying this attribute to illustrate non-examples, students may not realize that two inputs are a structural aspect of the binary operation concept. Going a step further, we can look at what attributes students attend to when differentiating between members of the set of binary operations. In this case, students looked at a number of attributes ranging from superficial similarity to deep, structural similarity. The student responses reflected their understanding of binary operation on a whole. Particularly, the students often shifted from the defining attribute of a binary operation being the elements and the way they are operated on to other aspects such as both belonging to a similar family. We argue that the notion of identity (or sameness) amongst elements of a set is essential to understanding the attributes of greater concept. Furthermore, across first and second question sets, students often altered the domain such as restricting to (x,x) inputs in the x^2 question. The notion of binary operation as function (with a particular domain) may not be prioritized as an attribute when approaching such tasks.

Understanding binary operation is essential to appropriately addressing any number of tasks and concepts in group theory. This preliminary analysis shows that students’ concept image of binary operation may overlook key attributes (such as two inputs) and pick up unnecessary attributes (such as requiring a symbolic name.) The consequences of exploring student understanding using variation theory are largely pedagogical in nature. Studies have started looking at dimensions of variability available for students in abstract algebra courses in terms of groups and rings (Cook & Fukawa-Connelly, 2015; Fukawa-Connelly, 2014). Pairing such studies with student responses can provide a powerful impetus towards consciously varying examples and non-examples to best bring attention to structural attributes.

The Lead TA Influence: Teaching Practices Focused on for an Active Learning Classroom

Hayley Milbourne
San Diego State University

Susan Nickerson
San Diego State University

Across the nation, there is increased national interest in improving the way mathematics departments prepare their GTAs. In particular, this research focuses on how the mentor GTAs in the graduate teaching assistant program under consideration share effective teaching practices and how this effects changes in the teaching practice of GTAs. I report preliminary results on how the focus of particular teaching practices of mentor GTAs (known as lead TAs) change over the period of one term through their participation in professional development. With an understanding of the differences and the similarities between the focuses of the lead TAs, an analysis of the differences between the Calculus I and II GTAs will become more apparent. The research presented here represents the start of an increased understanding of how GTAs form their own teaching practices.

Key words: Graduate teaching assistants, professional development, teaching practices

Across the nation, mathematics departments have begun to change the way they structure the teaching of the Calculus sequence. One of the seven recommendations that emerged as a result of the MAA sponsored study of successful Calculus programs (Bressoud, Mesa, & Rasmussen, 2015) was to improve the professional development offered to the Graduate Teaching Assistants (GTAs) involved in the teaching of Calculus. Though the departments have the common goal of improving the teaching practice of GTAs, the structure of the professional development programs for GTAs varies greatly among mathematics departments (Belnap & Allred, 2009). The research has been on the various structures of professional development programs or on the outcomes of the program. While it is important to know what the outcomes of the program are, it is equally important to understand how those changes occurred so as to improve our professional development programs. Little work has been done investigating the process GTAs go through in their evolving understanding of effective instructional practice and, ultimately, improving their practice.

At a large southwestern university, several changes were made to the calculus program, including to the structure of the professional development program for the GTAs. Before the changes were implemented, the GTAs had no training before they began to work. Currently, the GTAs participate in a three-day seminar before the semester begins. They also meet with a professor in mathematics education in a professional development course that meets throughout the academic year and with a mentor GTA, or lead TA. The focus of the seminar, the course, and the mentoring is on effective teaching practices and developing ways to reflect on one's instructional practice.

This paper discusses preliminary results of analysis on the nature of the discussions regarding effective teaching practices in the various debriefing sessions between the lead TA and their fellow GTAs. In addition to these debriefs, the GTAs participate in weekly meetings with their course coordinator to prepare the activity for the following week. When coupled with analysis of debriefs, the differences between the two lead TAs will help provide insight into the ways the lead TAs have possible influence over the ways the teaching practices of their fellow GTAs is shaped throughout the term.

Background

In many ways, professional development can feel like a complex game of telephone. The leaders and creators of the professional development have certain ideas of effective instructional practice that they are attempting to convey to the teachers or the facilitators with whom they are working. However, the facilitators and teachers are appropriately going to interpret it in their own way and share and use their transformed version of their ideas of effective practice. This particular phenomenon has been well documented in the K-12 literature. Research on the Standards movement reform of the 1980's and 1990's documented only a modest impact of the initiative on teachers' practice. What the research did document was that teachers selectively took up reform ideas and adopted only the surface-level features (Spillane & Zeuli, 1999). Researchers explained the adaptation in terms of teachers' learning processes and suggested that implementation varied because teachers drew on prior knowledge and practices when interpreting the message about the new standards and instructional practices (Coburn, Hill, & Spillane, 2016; Coburn, 2001; Cohen & Ball, 1990). Additionally, the interpretation created by the teachers sometimes did not align with the professional development and messages from school districts and school administrators and so resulted in inconsistent instructional guidance (Coburn, 2001).

Though the K-12 research focuses on how standards are adopted or polices are implemented at the state level and then interpreted by district and local administrators (and, in some cases, content coaches), the context is still similar to the process of changing teaching at the university level. I argue that when faculty and graduate students undertake reform teaching, all of those involved, including the department chair, course coordinators, faculty who take on professional development of teaching assistants, and the teaching assistants, co-construct the message of the reform. It begins with a small group of faculty with the goal to promote high-quality instruction and its success ultimately, in large part, depends upon the learning of the teaching assistants who interact with the college students most frequently. In the K-12 literature, focus has been placed on the ways in which the teachers themselves are interpreting instructional policy and the ways in which their communities affect their interpretations (Coburn, 2001; Stein & Coburn, 2008). Through these studies, researchers have been able to record the significant impact on understanding that discussion with other teachers has on an individual teacher's learning of the instructional policy. My particular study focuses on something similar at the undergraduate level, where I am interested in gaining a better understanding of how GTAs make sense of and interpret what they learn about how to lead a student-centered classroom.

Within the various studies done on the range of professional development programs available for GTAs, most studies can be described by three main themes: temporal, structural, and topical. In temporal, the duration of the professional development is discussed and how it varies across the nation (e.g. Belnap & Allred, 2009). In structural, the focus is on the various ways the programs for professional development of GTAs is structured across the nation (e.g., Ellis, 2015; Palmer, 2011). In topical studies there is an effort to create a list of standard topics focused on within each of the professional development programs described in previous studies (e.g. McDaniels, 2010). Finally, outside of the three topics described above, there are a group of studies on the efficacy of particular professional development programs (e.g. Griffith, O'Loughlin, Kearns, Braun, & Heacock, 2010).

There have been only a handful of studies done exclusively on the state of professional development of GTAs across the nation (Belnap & Allred, 2009; Ellis, 2015; Kalish et al., 2011; Palmer, 2011; Robinson, 2011). Outside of the national studies, there are also a handful of articles on particular programs at specific institutions, with a focus on the structure of the program or the efficacy of the program (e.g. Griffith, O'Loughlin, Kearns, Braun, & Heacock, 2010; Marbach-Ad, Shields, Kent, Higgins, & Thompson, 2010). So, while there have been studies that describe the various forms of professional development or that give an idea of what GTAs have learned from their experiences in professional development, little to no work has been done on the ways in which the GTAs are actually taking-up and implementing what they have gleaned from the professional development. In other words, the focus has been on the product and not the process. This research contributes to understanding how the GTAs are appropriating and transforming various teaching practices to fit their own needs over time.

Setting

At the large, public southwestern university, several significant changes have been made to the Calculus I and II courses, with professional development on teaching for GTAs who lead the break-out sections taking a central role. The professional development for the GTAs focuses on supporting the enactment of student-centered instruction so the GTAs are prepared to lead group work and whole class discussions around challenging problems. The GTAs are being asked to lead the Calculus homework and problem-solving sessions in a manner different than the instruction they likely experienced. Some have never taught before and among those who have, the paradigm is likely new to them.

In addition to a professional development program, the structure of the GTA program has been changed to include a lead TA. The lead TA position is filled by a more experienced GTA providing support to his or her fellow GTAs with a professional development aspect that occurs both before the term begins and throughout the term (Ellis, 2015). At the university in the study, the lead TAs for Calculus I and II were chosen based on their prior experience with teaching or participating in an active learning classroom. Throughout the semester, the lead TA visited the activity day sections of his fellow GTAs to observe the class and met with the GTAs after to debrief about how the class went. The lead TA attempted to make these visits about three times a semester for all of the other GTAs that he was able to observe. Finally, the lead TA served as a liaison for the other GTAs to the coordinator of the course, the mathematics education researchers involved in the professional development, and occasionally the head of the department.

With the lead TA holding such a centralized position within the program, capturing the ways they have influence over how the professional development on leading a student-centered classroom is appropriated and transformed is important to research. What role does the lead TA play in shaping the information provided through the various professional development meetings? To begin answering this question, the analysis compares the teaching practices discussed by each lead TA during the debriefings. In the next section, I go into more detail on how this was done.

Methods of Analysis and Initial Results

To contribute to the research base, I collected data for one term at a large, southwestern public university with two groups of GTAs, one for Calculus I and the other for Calculus II. The mentor GTAs who performed the observations and debriefs are known as the lead TAs and they have more experience with student-centered instruction than the other GTAs. The data used in this study includes the discourse in the various formal professional development settings in which they were involved and the debriefings between the lead TAs and the other GTAs for Calculus I and II.

I transcribed each of the videos and audio recordings, creating a new utterance (Bakhtin, Emerson, & Holquist, 1986) each time the topic changed within each speaker's turn. The utterances are open coded (Strauss & Corbin, 1994) for the various teaching practices discussed. With this list of teaching practices, the instructional practices the lead TAs deemed important enough or relevant to discuss with their fellow GTAs during the debrief sessions is evident for a comparison between the two lead TAs. With this analysis, I will have the basis for understanding how the lead TAs shaped the teaching practices of their fellow GTAs over the course of the term and how the communities of Calculus I and II GTAs differ in their focuses over the period of a term.

For the final analysis of how the lead TAs shaped the teaching practices of the GTAs over the term, I am be using a framework known as the Vygotsky space (Harré, 1983). In this framework, a particular teaching practice can be tracked as it is appropriated and transformed by the GTAs throughout the term. A representation of the Vygotsky space can be seen below in Figure 1. Since the analysis of the data in this preliminary report will not be using the Vygotsky space framework, a detailed explanation of the framework is beyond the scope of this proposal.

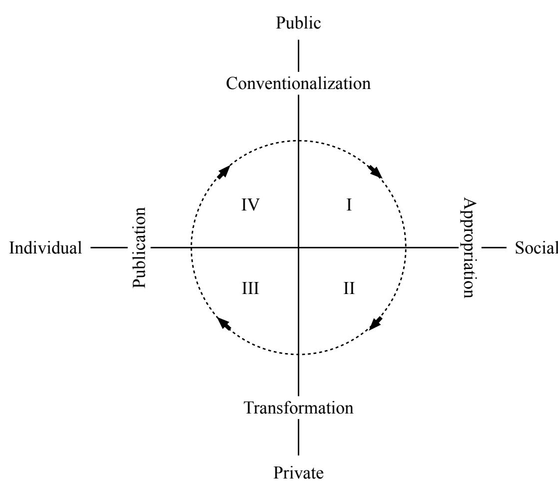

Figure 1: The Vygotsky Space

Preliminary Analysis

Each of the lead TAs met with their fellow GTAs approximately three times throughout the term. In these debriefings, the lead TA would discuss both things he found positive in the class and things he felt could be improved. The lead TA for Calculus I observed his fellow GTAs over the period of two weeks, twice during the term. He conducted his debriefings after the observation in his office and the meetings lasted between 20 and 40 minutes. In contrast, the lead TA for Calculus II conducted two observations a week and rotated the GTAs so that he observed each of them two times throughout the term. He conducted his debriefings directly after his observation so as to give the GTAs the information before they went to their next class and the meetings lasted between 5 and 10 minutes. Each of these debriefings were audio recorded and transcribed.

The teaching practices focused on in the debriefs by the two GTAs did differ in some ways but there were several main similarities. What differed the most between the two lead TAs were the ways they discussed particular teaching practices. For instance, both lead TAs focused on the ways to launch a task at the beginning of a class but there were distinct differences in the ways they talked about the launch. The lead TA for Calculus I tended to focus on the goal aspect of launching a task:

> So one thing that you did do that we want to stress is like at the beginning, you really want to outline their goal. What they should be doing. And I thought you did that well. You said the goal is to match the limits and then create a limit sentence so you can say it in English and you know exactly what it means. So that was really good. And you want to try and do that every activity, like, make sure they know what they're working towards because if they don't then they think that they're done really fast and you're like, what about this? They're like, oh I didn't know we had to do that. Just typical student stuff.

In contrast, the lead TA for Calculus II focused more on the wording and the tone of the launch:

> You did a really quick launch. You did a nice quick launch… Yeah. Um, so in your intro, sort of avoid saying things like the professor's says or the professors wanted me to say. It sort of exudes that you don't really care what you're doing. You're just doing it because you have to.

The difference between the two lead TAs could possibly come from the differences between the focuses of the course coordinators. For Calculus I, the weekly meetings with the course coordinator do involve a discussion about the activity for the coming week but the lead is mostly taken by the lead TA. In contrast, the comment from the Calculus II lead TA illustrates how the lead TA appropriated the use of the word 'launch.' The lead TA also adopted the professor's message that they were to convey that this was a most interesting mathematics problem. The lead TA chose to discuss the GTA's reference to the professor as deflection of autonomy, authority, and, consequently, conveying a lack of personal interest in the problem. With the focus on the way the activity was introduced to the students, the lead TA made sure to focus and comment on those particular practices during his first two observations. These differences between the interpretations and weekly meeting discussions have the potential to highly influence the lead TAs and, as a consequence, the other GTAs. With an analysis of the rest of the data, we can better understand the GTA's interpretation and whether or not the practices of the GTAs changed over the course of the term based on these suggestions.

Conclusion

The study discussed in this proposal is still within the preliminary stage of analysis. However, with a better understanding of the teaching practices focused on by the lead TAs, there will be a better understanding of what practices were deemed important by the community of GTAs and how those practices changed over the course of the term. With this information, the field can begin to understand how GTAs change their practice over time and improve the professional development offered to graduate students who are new to the practice of teaching.

Professional Development Linking the Concept of Inverse in Abstract Algebra to Function Inverses in the High School Curriculum

Melissa Mills
Oklahoma State University

Cara Brun
Oklahoma State University

*Pre-service and in-service high school teachers often do not leverage their experience with abstract algebra when interpreting the notation of inverse functions. For this study, we have designed a professional development activity in which teachers can explore inverses in different sets with different binary operations to elicit pseudo-empirical abstraction of the relationship "element * inverse = identity." We used a scripting task found in previous literature to measure the impact of the activity on both the teacher's understanding of inverses and how the teacher would explain the inverse function notation to students. We claim that emphasizing the role of the identity element when discussing inverses can help pre-service teachers overcome misconceptions about inverse functions.*

Key words: teacher education, abstract algebra, horizon content knowledge

Introduction and Literature Review

Students in high school or college algebra classes commonly misinterpret the notation $f^{-1}(x)$ as $\frac{1}{f(x)}$. From an advanced mathematical perspective, we understand that the root of this issue is that the student is not attending to, or is not aware of, the fact that the notation $f^{-1}(x)$ generally refers to the inverse with respect to function composition and not function multiplication. Really, the fact that function composition is the binary operation at hand is merely a convention and the student's interpretation, while it does not conform to standard mathematical interpretations, is not unreasonable.

As instructors who have had experiences with students at this level, we realize that the student is probably not thinking about binary operations at all and is merely generalizing from their experiences with negative exponents of real numbers. But how do high school teachers, who have presumably had training in abstract algebra, think about such a situation? Zazkis & Mamolo (2012) report that they informally asked ten in-service teachers how they might respond to a student who has this confusion. Eight of the ten responded that the meaning of the $\square^{-1}$ is context-dependent. For example, a teacher may explain that the meaning of the symbol $\square^{-1}$ changes depending on what it is "next to." Only two of the ten teachers referenced an inverse with respect to an operation.

Continuing this line of research, Zazkis and Kontorovich (2016) crafted a scripting task for pre-service teachers to investigate how they would respond to a student's question about the symbol $\square^{-1}$ in a classroom setting. The pre-service teachers were given the beginning of a script between a teacher and a student (see Figure 1) with directions to finish writing the dialogue between the teacher and student (or several students). Their analysis divided the 22 scripts into two groups: those that explained the symbol $\square^{-1}$ as always meaning inverse with respect to an operation and those that explained that the symbol $\square^{-1}$ changes meanings (inverse or reciprocal) depending on the context. Fourteen of the 22 pre-service teachers fell into the latter category.

T: So today we will continue our exploration of how to find an inverse function for a given function. Consider for example $f(x) = 2x + 5$. Yes, Dina?
S: So, you said yesterday that f^{-1} stands for an inverse function.
T: This is correct.
S: But we learned that the power (-1) means 1 over, that is, $5^{-1} = \frac{1}{5}$, right?
T: Right.
S: So, is this the same symbol, or what?
T:

Figure 1: *Scripting Task (Zazkis & Kontorovich, 2016)*

We have developed a professional development activity designed to help pre-service and in-service teachers make connections between inverses as they appear in the school curriculum and inverses with respect to binary operations in a group theoretic context. To measure the impact of our professional development activity, we utilized the same scripting task (Figure 1) as a pre- and post-test. From our results from the pre-test we will identify two misconceptions held by pre-service teachers: an "opposite" scheme for inverse, and a "get to one" scheme for inverse. We present evidence that group theoretic activities designed to help teachers pseudo-empirically abstract the generalized property "element * inverse = identity" can help them move from a "same-symbol different meaning" understanding to a "same symbol same meaning" understanding. In particular, an emphasis on identifying the identity element with respect to an operation <u>before</u> discussing inverses can help teachers overcome a "get to one" scheme.

Theoretical Perspective

The data from this study will be analyzed through the lens of Piagetian genetic epistemology and von Glasersfeld's radical constructivism. According to these theories, "…what [people] are able to observe about the world is more dependent on what they already know – that is, on their own special system of thinking - than it is on what actually exists" (Gallagher & Ried, 1981, p. 1). These structures of knowing are referred to as schemes or "units of generalized behavior (or actions) that provide the basis for mental operations" (Driscoll, 2005, p.192). When a learner encounters something that does not fit into an existing scheme, the learner must accommodate this new object by expanding his existing scheme or by creating a new one (vonGlasersfeld, 1995). Piaget used theories of abstraction to describe how assimilation and accommodation can occur. Pseudo-empirical abstraction can be defined as, "abstraction based on the observation of perceptible results, with coordination drawn from activities exerted on objects, reflection on the products of activity" (Ellis, 2016). The process of acting on objects, reflecting on these activities, and coordination of those actions can cause perturbation, which can lead to the learner accommodating their current scheme to encompass this new element.

Horizon content knowledge is one part of mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008). While some view horizon content knowledge as a connection between the mathematics that students are doing and more advanced mathematics that the *students* will encounter (Ball, et. al, 2008; Fernandez & Figueiras, 2014), others perceive it as connected to the *teacher's* knowledge of advanced mathematics (Wasserman, 2013; Zazkis & Mamolo, 2011). Our working definition of HCK is the teacher's advanced mathematical knowledge and the threads that connect it to the students' mathematical understanding that guide a teacher's planning and in-action instruction.

Task Design

The professional development tasks were designed to give teachers experience with several different sets and operations. We chose three sets: the Real Numbers, the integers modulo 12 (the numbers on a clock), and the set of functions. We chose the first two sets because the teachers have experience doing calculations in both of those settings, and the latter set because it was relevant to the discussion about inverse functions. We used colloquial language whenever possible so that the activities are accessible to those who were not familiar with group theory.

For the real numbers, the participants were asked to begin with the binary operation of addition. We gave the following definition: "The *additive identity* element is the element that 'does nothing' when you add it to another element," and asked them to identify the additive identity. Then we gave them the definition: "An *additive inverse* for an element in the set is the element that you must add to get back to the additive identity," and asked them to find additive inverses of several different elements and then to write a statement describing additive inverses in the real numbers in general. We then asked corresponding questions regarding multiplication.

For the set of integers modulo 12, we chose to use only the numbers appearing on the face of a clock, because we wanted them to have experience with a set in which the additive identity is represented with something other than zero. Since they may not be as familiar with computing in this context, we first gave them some true statements (i.e. 8+9=5) and asked them to explain why each one is true and to generate some of their own statements. Then they were asked to identify the additive identity element, find additive inverses of several elements in the set, and write a general statement describing additive inverses in this set. The tasks for clock multiplication were similar, but before we talked about multiplicative inverses we gave them a completed multiplication table and asked them to circle all of the times that the multiplicative identity appears in the table. Then they were asked to identify some of the elements that had multiplicative inverses.

At this point, we had the participants make a table in which they described the different sets, operations, identity elements, and types of inverses that they had seen in the exercises. The goal of this activity was for them to begin to abstract the notion: element * inverse = identity.

The final set was the set of functions. We began with function addition. We gave them a few functions to work with and had them practice adding functions. We then asked them to identify the additive identity function, and asked them to graph it. We had a discussion about why this function was the additive identity, and asked them to find the additive inverses of the given functions. Then we moved on to function composition, asking them to compose some given functions and think about an identity function with respect to composition (most groups were able to figure it out). We then proposed the function $i(x) = x$, and asked them to compose the given functions with the function *i.* They then found inverses for the given (injective) functions with respect to composition and composed the given functions with their inverses to see that that composition results in the identity function $i(x) = x$.

Methods

Participants were recruited via email and word of mouth from a mathematics department at a large Midwestern public university and a local high school. Participant groups included two graduate students in mathematics who piloted the activities, three senior level pre-service secondary teachers who were doing their student teaching, three sophomore level pre-service secondary teachers, and three in-service teachers from a local school district. We implemented the professional development in groups of two or three. The activity took approximately two hours. First, we gave the participants the scripting task (Figure 1) and had them write a script individually. Then we collected the scripts and went directly into the professional development activities, which they worked on in groups. At the end, we gave their scripts back and had them individually write a reflection on their script, identifying things they might change in their script and areas in which their own understanding had changed as a result of the activities. All groups were video recorded and their written work was collected.

Results

The results reported here will focus on an analysis of the scripts that the participants wrote before they did the group theory activity, and the reflections on the scripting task that they wrote after the activity. We found, similar to Zazkis's previous work, that only a few of our participants (3 out of 11) explained the notation $\square^{-1}$ as referring to an inverse with respect to an operation: both of the graduate students and one in-service teacher. The scripts also revealed that several of the participants held misconceptions about inverses. We identified two schemes that displayed underdeveloped understandings: the *opposite scheme* and the *get-to-one* scheme.

The *opposite scheme* is characterized by the vague idea that "inverse means opposite." They pay no attention to the identity element at all in this scheme. When asked to find an inverse of an element, they will do something to make it an "opposite," whether that is changing the sign or finding the reciprocal, and often cannot move smoothly between the "two types of opposites." One participant fixated on the symmetry that additive inverses have on the number line. He then had difficulty thinking about multiplicative inverses because he couldn't construct a visual representation. Others referred to the inverse of an operation: "An inverse means opposite, so the opposite (if you're thinking about multiplication) is division. So 5^{-1} means you would divide by five. An inverse function is different, but it still essentially means opposite."

The *get-to-one* scheme is characterized by the idea that "the inverse is what gets you to one." Participants who displayed this scheme began to attend to the role played by the identity element, but incorrectly generalized that the identity is always 1. One participant, Ben, showed in his script that composition of a function and its inverse results in x. Ben seemed to be unsatisfied with the x, so he wrote that $x = 1x$ and drew a box around the coefficient 1. We interpret this action as his way to assimilate this result into his get-to-one scheme (see Figure 2).

T: So, the inverse of an object, be it a fraction or a function, is the thing that turns the thing into 1.
S: Okay?
T: Remember when we found the inverse of a fraction? We got the reciprocal, which was the flipped fraction and when we multiplied it with the original fraction we got one.
S: Yeah…
T: So, that is what the inverse fraction does. And I will show you exactly what I mean by this.

So, for $f(x)$ the inverse is $\frac{1}{2}x-\frac{5}{2}$. Now… plug it in $2(\frac{1}{2}x-\frac{5}{2})+5=x-5+5=x=1x$

Figure 2: *Ben's Scripting Task Exhibiting a Get-to-One Inverse Scheme*

Five of the six undergraduates and two of the three in-service teachers reported that they think differently about inverses after the group theoretic activity. All but two mentioned that their understanding about the identity changed. Dan said, "I had forgotten how to find the inverse of a function because I hadn't done them in so long and I was only taught the process, not the reasoning." Markus also reported, "Yes, this session was a good refresher for me on what inverse was." Sloan explained, "Before this session, I never really realized how many different types of inverses were possible depending upon the operations and sets. Seeing the relationships between the various inverses and correlating identities is enlightening…"

It is interesting that although they had found inverse functions in the past and had likely encountered the computation $f(f^{-1}(x))=f^{-1}(f(x))=x$, the pre-service teachers didn't know how to interpret this result. Jane said, "I now think of inverses as connected to the identity" and Kim notes "the composition of functions having the identity x is very interesting and I hadn't thought of the idea of the operation actually having an identity."

Dan, Sloan, and Ben all showed evidence of a get-to-one scheme in their first scripting task. After the exercises, both Sloan and Ben said that they had never thought about different types of identity elements and had expanded their understanding of inverses.

Six of the eleven participants said that they would change how they talked about inverse functions to students. Sloan said, "I would make an effort to clarify which operation [and] identity I would use as I explain." Kim said, "The word 'identity' would be used much more. However, the same concept regarding 'neutralizing' the function I believe I would continue to use. When the composition [gives] x, the composition is neutral."

Discussion

Previous research has shown that many pre-service teachers do not leverage their understanding of abstract algebra when interpreting the notation $\square^{-1}$. Because of teacher shortages, it is quite possible that many teachers have never had a course in abstract algebra at all. Thus, professional development activities designed to broaden teachers' mathematical experiences can be beneficial. Zazkis and Mamolo (2011) suggest that a teacher could make use of her horizon content knowledge by explaining the situation in terms of an inverse with respect to an operation. Our work contributes by incorporating professional development tasks aimed to help teachers make these connections. Our tasks emphasize the role of the identity element when thinking about inverses. This emphasis seems to help teachers overcome the misconception that an inverse is the element that "gets you back to 1." Having the teachers experience finding identity elements and inverses in different sets with different operations helped many of them to generalize the relationship "element * inverse = identity" which can lead them to interpret the notation $\square^{-1}$ as meaning an inverse in general. This study is limited by the small number of participants, however, the goal of this work was to design and conduct a professional development activity focusing on a particular connection between an advanced mathematical concept and secondary school mathematics in a way that teachers can leverage in their classrooms. Future research is needed to continue the development of such professional development activities.

Textbook Formations of Independence

Steven Edalgo — Oklahoma State University
Adam Molnar — Oklahoma State University

The noun independence and adjective independent are applied in multiple mathematical contexts. In probability, independent events do not affect each other, but in algebra and regression, an independent variable has a non-symmetric effect on a dependent variable. Further complicating matters, independence in everyday language represents something in between. Prior research has shown that students and professors struggle to apply concepts of independence. As part of an investigation into curriculum about independence, textbook definitions about independence were examined. Across nine books, a mix of algebra and statistics texts, substantial variations existed in definitions of independent events and independent variables. Variations included the register of representation, verbal against algebraic, and the strength of the dependent effect. Little written guidance was provided to help learners navigate across the multiple formations.

Key words: Independence; Probability; Variable; Semiotics; Lexical Ambiguity

Independence is an old concept in probability. Over 250 years ago, De Moivre defined independent events in *The Doctrine of Chances*; two events are *independent* when "the happening of one neither forwards nor obstructs the happening of the other" and *dependent* if the "probability of either's happening is altered by the happening of the other" (1756, p. 6). The concept is symmetric; either event can serve as the "one" or the "other". In probability, the term maintains that definition today. Independent events are sufficiently common that the authors of the Common Core State Standards chose to include the definition in the high school standards (National Governors Association [NGA] Center for Best Practices & Council of Chief State School Officers [CCSSO], 2010, p. 82).

Despite 250 years of history—or perhaps because of 250 years of history—people have trouble determining if events are independent. Manage and Scariano (2010) surveyed 219 college students in US introductory statistics classes; only 23% correctly answered a multiple-choice question on the definition of independence. Molnar (2016) surveyed 25 US high school mathematics teachers; only 3 (12%) correctly solved a problem about two events in a table. Outside the USA, D'Amelio (2009) wrote about students' and professors' challenges in Argentina; about half the French pre-service teachers surveyed by Nabbout-Cheiban (2016) incorrectly solved problems about independent events.

One potential reason behind the trouble is that the colloquial non-probabilistic definition of independence differs from De Moivre's statement. According to the Oxford English Dictionary, the adjective *independent* refers to something "not depending on the authority of another, not in a position of subordination or subjection; not subject to external control or rule; self-governing, autonomous, free" ("Independent," 2015). In everyday language, independence and dependence are not necessarily symmetric. For instance, when choosing where to live, young children are usually dependent on their parents' decisions, but parents have more autonomy.

Another complication arises from the labeling of *independent* and *dependent* variables when describing algebraic functions. In Common Core standards, Grade 6 students should "write an equation to express one quantity, thought of as the dependent variable, in terms of the other quantity, thought of as the independent variable" (NGA Center for Best Practices & CCSSO, 2010, p. 44). With defined sides, this definition is never symmetric, although closer to the sometimes-symmetric everyday definition than the always-symmetric probability version. Incomplete textbook explanations do not assist students. Leatham (2012) gathered 10 school mathematics textbooks containing problems on independent and dependent variables. Of 73 total problems, 32 (44%) provided absolutely no information to determine the independent variable; others provided only partial information. Leatham concluded that most textbook problems sent mixed messages, "implicitly impeding students from developing a robust understanding of independent and dependent variables" (p. 357).

Some statistics textbooks tag on an additional non-symmetric definition of independent variables in regression models, where the independent variable controls the value of the dependent variable. Because the regression definition is similar to the algebraic one, and the definition does not appear in state standards, it is less crucial. Besides, between colloquial, algebraic, and probabilistic definitions, ample opportunities exist for confusion.

Our entire investigation will consider the curriculum around independence through multiple lenses as defined in Gerhke, Knapp, and Sirotnik (1992). In this preliminary report, we examine planned textbook curriculum in algebra and statistics textbooks. Later, we will interview teachers to ask about intended curriculum and analyze student artifacts of experienced curriculum.

Theoretical Framework

Independence is a non-physical mathematical concept. As Duval wrote in 2006, mathematical objects are never physically visible. Humans comprehend mathematics only through symbols and signs, "but the mathematical objects must never be confused with the semiotic representations that are used" (p. 107). Therefore, our framework for understanding mathematical confusions about objects labeled independent is semiotic.

For example, a mathematical object that can change between more than one value, dependent on circumstances, receives the representation *variable* in written English. In college algebra, the object receives a single letter representation such as X. In either setting, the object could have been expressed with another semiotic representation, such as changing-number or ϖ or 변수 (the Korean representation for the concept of variable).

In Duval's (2006) framework, systems of representations are called *registers*; earlier, variable was presented in the registers of written English, algebra, and Korean. Explanations for mathematical objects, known as *formations*, are designed to help students connect a concept with its representation in a register. Students are expected to learn formations. For instance, in the Common Core probability standards, students are asked to explain the formation of "independence in everyday language and everyday situations" (NGA Center for Best Practices & CCSSO, 2010, p. 82).

When authors write textbooks, they generate written formations for mathematical objects. Some authors include formations in other registers or ask students to convert between registers. Our textbook research uses the semiotic framework to ask the following questions.

1. For independent events, what formations and registers are used in definitions?
2. For independent variables, what formations and registers are used in definitions?

We had also proposed a third question, about explanations provided to distinguish applications of the semiotic symbol *independence*, but we did not find many of these explanations. We comment more about this in the section on questions for the audience.

Method

Encyclopedic search of pre-algebra, algebra, and probability textbooks would be very long, given the abundance of available textbooks. For this RUME report, we decided to concentrate on a small sample of books we knew had recent college-level use, similar to how Cook and Stewart (2014) examined recently-published textbooks on linear algebra. We selected three college introductory statistics textbooks (Bluman, 2014; Bowerman, O'Connell, & Murphee, 2014; Diez, Barr, & Cetinkaya-Rundel, 2015) and three college algebra textbooks (Bittinger, Beecher, Ellenbogen, & Penna, 2013; Crauder, Evans, & Noell, 2014; Miller, 2014). For comparative purposes, we added three US secondary school algebra textbooks (Benson, Dodge, Dodge, Hamberg, Milauskas, & Rukin, 1991; Bittinger, 1999; Brown, Dolciani, Sorgenfrey, and Kane, 1990). In each textbook, we recorded the initial formative definition involving *independent* or *independence* and examined problems in the text related to independence.

Results

Each introductory statistics textbook had a different definition of independent in regards to events. One college algebra textbook and one secondary school algebra textbook also contained formations because the books included sections on probability. The initial definitions are presented in Table 1, with statistics book definitions first.

Table 1
Initial Textbook Definitions Related to Independent Events in Probability

Textbook	Definition
Bluman (2014, p. 213)	Independent Events – Two events A and B are independent events if the fact that A occurs does not affect the probability of B occurring.
Bowerman et al. (2014, p. 171)	Independent Events – Two events A and B are independent if and only if 1.) $P(A\|B) = P(A)$ or, equivalently, 2.) $P(B\|A) = P(B)$ Here we assume that P(A) and P(B) are greater than 0.
Diez et al. (2015, p. 85)	Independent Process – Two processes are independent if knowing the outcome of one provides no useful information about the outcome of the other.
Brown et al. (1990, p. 756)	Independent Events – Two events A and B are independent if and only if: $P(A \cap B) = P(A)P(B)$.
Miller (2014, p. 779)	Independent Events – If events A and B are independent events, then probability that both A and B will occur is P(A and B) = P(A)*P(B).

The authors of a statistics textbook, Bowerman et al. (2014), presented the most challenging definition, using both the probability algebra register $P(A|B) = P(A)$ and conditional probability. The two algebra textbooks also contain formulations in the probability algebra register, varying slightly in the semiotic sign for and (and versus $\cap$), but do not require another mathematical concept. Relying on an additional concept complicates the structure. If a student cannot convert $P(A|B)$ into a mental concept, the student will not comprehend independence. Research results, summarized by Falk in 1986, have shown that conditional probability confuses many students.

Asking learners to construct a mental formulation of independence through another challenging concept, plus a conversion from the algebra register, is highly demanding.

On the other hand, Diez et al. (2015) and Bluman (2014) avoided conditional probability and the algebra register, relying only on written English. The computational formula appears later. Placing the written definition first reduces cognitive load by requiring less symbolic conversion. Nevertheless, despite language similarities, their definitions are not alike. A process is a larger concept than an event; events are sets of outcomes inside random processes. By defining independence on processes, not two events inside a process, Diez et al. (2015) have offered a different conception than the other authors. Interestingly, Diez et al. later refer to independent events, writing "if two events are independent, then knowing the outcome of one should provide no information about the other" (2015, p. 94). The shift between larger processes and smaller events may not appear notable, but for a concept with demonstrated problems, all shifts in formulation matter. Bluman's (2014) definition is the clearest.

Turning to variables, four algebra books and two statistics books contained a definition for independent variables. We do not know why the other two algebra books did not; perhaps the authors considered the concept a prerequisite. Initial definitions are presented in Table 2, with college algebra textbooks first, then secondary school algebra textbooks, then statistics books.

Table 2
Initial Textbook Definitions Related to Independent Variables

Textbook	Definition
Bittenger et al. (2013, p. 62)	Independent Variable – In the equation $y = \frac{3}{5}x + 2$, the value of y depends on the value chosen for x, so x is said to be the independent variable.
Miller (2014, p. 17)	Independent Variables – One type of mathematical model is a formula that approximates the value of one variable based on one or more independent variables.
Benson et al. (1991, p. 346)	Independent Variable – In a function, the variable whose value is subject to choice. The independent variable affects the value of the dependent variable.
Bittenger (1999, p. 156)	Independent Variables – Write an equation like $y = x^2 – 5$, which we have graphed in this section, it is understood that y is the dependent variable and x is the independent variable, since y is calculated after first choosing x and y is expressed in terms of x.
Bluman (2014, p. 19)	Independent Variable – In an experimental study, the one that is being manipulated by the researcher. … The resultant variable is called the dependent variable.
Bowerman et al. (2014, p. 487)	Independent Variable – Regression analysis is a statistical technique in which we use observed data to relate a variable of interest, which is called the dependent (or response) variable, to one or more independent (or predictor) variables.

As with the independent event definitions, we see multiple registers in Table 2. Both books with Bittenger (1999, 2013) as an author initially used the algebraic register. Although the letter x is a common algebraic formulation for an independent variable, writing in two registers complicates the concept. In other surveyed books, the symbolic x appears later.

Both Bittenger books (1999, 2013) introduce independence through the verb choose; independent variables have values selected, but dependent variables do not. The noun choice appears in Benson et al.'s (1991) definition; Bluman's (2014) definition of manipulation in experiments has synonymous language. The other two books do not mention choosing a value for independent variables. Both Miller (2014) and Bowerman et al. (2014) utilize a word related to prediction. Only Miller's 2014 mathematics book—not a probability and statistics text—describes the connection as approximate, although *affect* in Benson et al.'s (1991) definition is not as strictly causative as the other books or the Common Core formulation. Overall, free choice versus control appears to be the dominant formulation. The two statistics books that use the term independent variable do not vary much from algebra formulations, a slightly surprising result.

Questions for the Audience

The third probability and statistics textbook made a type of distinction we had hoped to see frequently. When discussing regression modeling, Diez et al. add in a footnote that applying the words independent and dependent "becomes confusing since a *pair* of variables might be independent or dependent, so we avoid this language" (2015, p. 18, emphasis in original). The other books do not make distinctions or connections between formations involving the word independent. One possibility for the paucity of connections we saw is our sample size. Although our recollections of other texts include few connecting and distinguishing statements, a larger search could identify more. Alternatively, we could interacting with more teachers and students.
1. Would a more comprehensive textbook search be fruitful?

The three concepts are unalike in the direction of the relationship. As described earlier, the probability relationship is symmetric; the algebra relationship is not symmetric; the colloquial relationship is sometimes symmetric. In an earlier discussion, one person suggested that relationships be defined in terms of causal direction, bi-directional versus uni-directional.
2. What research could be done to investigate this idea? Given the untested nature of any new causal definitions, the investigation would likely have to occur outside standard classroom flow.

This leads into another question, the primary one in the minds of teachers—and us.
3. What are other possible solutions to the misconceptions and lexical confusion?

Connecting Secondary and Tertiary Mathematics: Abstract Algebra and Inverse

Eileen Murray
Montclair State University

Matthew Wright
Montclair State University

Debasmita Basu
Montclair State University

This study explores how practicing teachers make connections between secondary and tertiary mathematics. Using three frameworks for teacher knowledge of mathematics, coupled with key developmental understandings (KDUs) (Simon, 2006) as related to teacher knowledge (Murray & Wasserman, 2016), we observe how a professional development workshop focused abstract algebra impacts teachers' understanding and teaching of secondary mathematics.

Key Words: mathematical connections, professional development, teacher knowledge

Within the mathematics and mathematics education communities, ongoing consideration has been given to the knowledge secondary mathematics teachers require to provide effective instruction. At the focus of this debate is what mathematical content knowledge secondary teachers must have in order to communicate mathematics to their students, evaluate student reasoning, and make informed curricular and instructional decisions. Many believe that mathematics teachers should have a solid base of mathematical knowledge and mindfulness of how tertiary mathematics is connected to secondary mathematics (Papick, 2011). But some have shown how more mathematics preparation does not necessarily improve instruction (Darling-Hammond, 2000; Monk, 1994). Thus, questions endure about what connections are between secondary and tertiary mathematics are important and how knowledge of these connections may impact classroom practice. While there are many who support the notion that mathematics preparation for secondary teachers must involve knowledge of vertical connections, less is known about how inclusion of courses such as abstract algebra in teacher preparation programs may bring this about.

Framework

In order to explore the nature of vertical connections in mathematics, we draw on three areas of teachers' knowledge of mathematics research: Mathematical Knowledge for Teaching (MKT) (e.g., Ball, Thames, & Phelps, 2008), Advanced Mathematical Thinking (AMT) (e.g., Zazkis & Leiken, 2010), and Knowledge of Algebra for Teaching (KAT) (e.g., McCrory, Floden, Ferrini-Mundy, Reckase, & Senk, 2012). These frameworks, along with the research on key developmental understandings (KDUs) (Simon, 2006) as related to teacher knowledge (Murray & Wasserman, 2016), provide a way to think about how understanding of tertiary content may impact teachers' understanding of the teaching and learning of secondary mathematics.

Building on Shulman's seminal work on teacher knowledge (1986, 1987), Ball and colleagues (2008) conceptualized the domains of MKT according to elementary mathematics. Although there exist many challenges in translating the definition of these domains in a secondary context (Baldinger), our current work utilizes MKT constructs to better understand the nature of knowledge needed for secondary teaching. In particular, we consider the development of horizon content knowledge (HCK) as it pertains to secondary mathematics through exposure to tertiary mathematics. According to Ball, Thames, & Phelps (2008) HCK is "an awareness of how mathematical topics are related over the span of mathematics in the curriculum" (p. 403), but this construct varies considerably from the elementary to secondary level (Howell, Lai, &

Phelps, 2008). For the purpose of the current work, we use the definition of HCK as rendered by Jacobson et. al., (2013), as "an orientation to and familiarity with the discipline (or disciplines) that contribute to the teaching of the school subject at hand, providing teachers with a sense for how the content being taught is situated in and connected to the broader disciplinary territory" (p. 4). We use this definition to consider how instruction in abstract algebra coupled with secondary tasks prompting teachers to apply this knowledge may develop an awareness of connections between abstract algebra and secondary mathematics. We believe that knowledge of specialized content such as abstract algebra may provide secondary teachers with a better understanding of the mathematical horizon as it pertains to their teaching of secondary algebra.

Even with more students taking algebra, the preparation of algebra teachers is still not well researched (Stein et. al., 2011 in McCrory et. al., 2012). This lack of research on teacher preparation and shortcomings of existing frameworks serves as motivation for the development of KAT. This framework contains three domains of knowledge believed to be essential to the teaching of secondary algebra: s*chool algebra, advanced mathematics,* and *algebra for teaching* (McCrory, et. al., 2012). Knowledge of advanced mathematics is pertinent as this is the knowledge that provides teachers with "some perspective on the trajectory and growth of mathematical ideas beyond school algebra" (McCrory et. al., 2012, p. 597), much like HCK. This knowledge is of special significance because many students experience difficulty transitioning from high school to college mathematics and many teachers perceive the undergraduate mathematics that they themselves learned as immaterial with regard to their teaching practice. For these reason, and because secondary teachers are typically required to graduate with an undergraduate degree in mathematics, we also draw upon AMT, defined as "knowledge of the subject matter acquired in mathematics courses taken as part of a degree from a university or college" (Zazkis & Leiken, 2010, p. 264).

Finally, in order to better understand how exposure to abstract algebra content may impact secondary teachers' knowledge of teaching mathematics, we consider mechanisms by which teachers develop awareness of connections and how this awareness may impact instruction. To accomplish this, we utilize the construct of KDUs (Simon, 2006). The essential characteristics of KDUs to teachers and teaching are that a KDU must involve a conceptual advance on the part of the teacher, and that without the knowledge, teachers must build their understanding through activities and reflection rather than explanation or demonstration. We posit that through awareness of connections between secondary and tertiary mathematics, it is possible for secondary teachers to develop KDUs, thereby furthering their understanding of and ability to teach secondary mathematics.

Our current work explores how in-service teachers make connections between secondary mathematics and abstract algebra. This work builds on the results of a smaller pilot study, which revealed an interesting change in participants' understanding of various mathematics concepts, including inverse. In the previous and current work, frame participants' understanding of inverse using the APOS framework (Asiala, Brown, DeVries, Dubinsky, Mathews, & Thomas, 1997). The APOS framework conceptualizes an individual's understanding of mathematical content according to four levels - *action*, *process*, *object*, and *schema*. At the action level, inverses are used algorithmically to perform mathematical tasks such as solving equations, e.g., multiply both sides of an equation by the multiplicative inverse. As a process, inverses are viewed as both an operation and mathematical property of equality. At the object level, inverses are understood as elements within a set defined with respect to a binary operation. Finally, at the schema level, a comprehensive understanding of inverse is attained and the operational/elemental duality of inverse is understood as well as its utility as a mathematical property of equality (Wright, Murray, & Basu, 2016).

In our pilot, we found that some participants initially discussed inverses through an action or process-level of understanding. After engagement in activities focused on the algebraic structures of groups, rings and fields, participants began to consider inverses as objects. We used this finding to further explore how an extended professional development workshop highlighting the connections between abstract algebra and secondary mathematics may not only change teachers' ideas about the inverse concept, but also influence their thinking about mathematics teaching and learning. The research questions for this study are: (1) How does understanding of tertiary mathematics change teachers' knowledge and teaching of secondary mathematics concepts? (2) How does exposure to and instruction in tertiary content, specifically abstract algebra, change the way teachers understand and teach the concept of inverse?

Methods

To answer these research questions, we conducted a four-day professional development (PD) workshop with four in-service teachers (Conor, Dylan, Orlaith, and Aidan) from an urban high school in northern New Jersey. The workshop consisted of four three-hour sessions held on consecutive days prior to the beginning of the school year.

Data Collection

During the workshop, participants worked through three packets of activities that included scripting tasks (Zazkis, 2013) (e.g., extend an imaginary interaction between a teacher and students in a form of dialogue, including explanations and/or examples), secondary content activities (e.g., describing the mathematical properties used to solve a multistep linear equation), and tertiary content activities. The tertiary activities focused on abstract algebra content including algebraic structures (groups, rings, and fields) and formal definitions of binary operations, inverse relation and function. The first two packets prompted participants to consider mathematical properties used when solving equations in a secondary classroom and how these properties relate to algebraic structures. The third packet focused on connecting the content on algebraic structures to functions. The purpose of these activities was to unpack how discussions about inverses through an abstract algebra lens might help participants reconsider functions as objects rather than actions or processes. Additionally, we sought to challenge conventional thinking about what a function is and common problems distinguishing between additive, multiplicative, and compositional inverses for functions.

Participants engaged in these tasks individually and as a group. One researcher engaged participants in group discussions, which were audio and video taped. We collected all written artifacts containing participants' responses and reflections for future analysis. Future data to be collected is classroom observations and participant interviews that will allow us to further explore how exposure to and instruction in abstract algebra content impacts instructional practice.

Data Analysis

In our initial analysis, each researchers independently isolated episodes from the video recordings that highlight teachers' understanding of inverse and identity. Once the significance of these episodes was mutually ratified, we transcribed and analyzed the audio using an initial or "open" coding method, searching for words or phrases that showed evidence of participants' making connections between secondary and tertiary mathematics. Open coding was the preferred method for our initial analysis as it allows for the development of tentative codes that may lead to further inquiry, thereby allowing the study to take direction naturally (Saldana, 2009).

Preliminary Results

We focus our results on the fourth day of the workshop to explore how abstract algebra impacts secondary teachers' understanding of inverse. Similar to our pilot, we found participants moved from an action/process level toward an object level of understanding of inverse. To highlight how the participants' understanding evolved, we divide our results into three sections: understandings of the concept of inverse and inverse function as action/process, the transition in understanding towards object, and impact on instructional practice.

Initial Understanding of Inverse

At the beginning of the session, participants read and responded to a scripting task capturing the conversation between a teacher and three students regarding the inverse of the function $f(x) = x^2$. Students in the task provided three answers for the inverse of this function: $1/x^2$, $-x^2$, and $\sqrt{x}$. After considering this scenario, Dylan, commented, "Only one of them [$1/x^2$, $-x^2$, or $\sqrt{x}$] is the inverse of the function $f(x) = x^2$, but they all have different thinking. For example, x^2 and $-x^2$. When you combine them it is 0 but does that mean that that's an inverse?"

Conor viewed the inconsistency of responses as a lack of "conciseness in mathematical vocabulary" rather than "just students' misconceptions". Based on this discussion, we see participants beginning to understand why there are inconsistencies in students' understandings of inverse functions. In trying to unpack this ambiguity, participants exhibited an understanding of inverse at the action/process level. For example, when participants were asked to communicate their understanding of inverse, Conor referred to multiplication and division as inverse operations, while Dylan asserted, "my definition of the inverse of a function is something that undoes another function." In providing this definition, Dylan overlooks the binary operation with respect to which the inverse is defined. He references an algorithmic approach to "undoing" without considering the operation that is being undone or the product of this undoing, arriving at the identity, thereby evidencing action-level understanding.

Transition in Inverse Concept Understanding

During the discussion of abstract algebra in connection with the inverse and identity function, participants transition from action/process to object level understanding. In the introductory scripting task described above where participants realize the ambiguity in their conception of inverse, they discuss the importance of clearly defining the term *inverse*. Orlaith states, "What does it mean that we are asking them for the inverse? So define the term inverse. I think that's where we would have to start." She also notes how inverse is different for functions, but expresses her inability to provide a specific definition for this concept. Through this reflection, we posit that Orlaith's HCK might not include the understanding of functional inverse. Specifically, she seems to be aware of how her inability to provide an accurate definition of a function's inverse is indicative of a gap in her knowledge of the broader mathematics territory of inverses in algebraic structures. We interpret this as evidence of a transition in her understanding of the concept of inverse.

We also observe transitioning through participants' written responses to reflection questions posed at the end of the four-day workshop. In particular, Conor writes, "You think about them in terms of other definitions/properties that contain the words inverse or identity." In addition, Aidan reflects on his transitioning knowledge by stating, "It is important to emphasize what operations we are working with." Through these reflections, we claim that participants have developed a deeper awareness of inverses as either a mathematical property (process level) or as an element within a set of objects that must be defined with respect to an explicit mathematical operation (object level). Furthermore, we posit that this advance in conceptual understanding may signify the development of a KDU with regard to the higher-level mathematical underpinnings of inverse.

Impact on Instructional Practice

At the conclusion of the workshop, participates seemed more aware of the connection between tertiary and secondary mathematics than they had been at the beginning. This awareness prompts teachers to reconsider their own practice in different ways. For example, during one conversation, Dylan mentions how he will integrate newfound understanding of inverse, particularly in regard to defining inverses with respect to their identity under composition, into this year's lessons. Upon realizing that the identity of a function under composition is the function "y=x" Dylan states, "I never taught it like that" and "I'm one-hundred percent using that this year!" When asked to reflect upon future instruction, he further states, "I will be lesson planning completely different. Our first unit is all about solving and inverse operations. I must change how I approach my introduction throughout this unit because I want my students to not have misconceptions as they approach higher levels." In so stating, Dylan is considering how this new knowledge impacts his teaching of secondary mathematics as it may help prepare his students for higher-level mathematics, showing an awareness of the mathematical horizon.

Applications and Implications

Based on our pilot findings in which participants' understanding of the mathematical concept of inverse evolved from action/process to object understanding, we created an extended PD workshop to push teachers' thinking about inverse, identity, and solving equations. This extended workshop allowed us to present classroom scenarios and scripting tasks and to delve more deeply into abstract algebra content.

In the current study, participants' understanding of inverse evolved in a similar way as our pilot participants. That is, participants began to think about inverses as objects within an algebraic structure, rather than as an action or process. The difference between the current work and the pilot came from the participant's connection to their classroom practice. Similar to the pilot, the participants reported a newfound appreciation for being precise and consistent with their language in the classroom, especially around definition of identity, inverse, and binary operations. In the current work, the participants went even further by connecting their experiences in undergraduate mathematics classes to their teaching. As Conor stated, "I left it all in the floor in college, but it's so important for Algebra II as well!"

As we continue our data collection and analysis, we will use classroom observations and interviews to verify that the teachers' reports of how this new understanding of content might impact instruction. The implications of this work are a first step in helping us understand how knowledge of mathematics is related to being an effective secondary mathematics teacher. We hope to engage mathematicians and mathematics teacher educators in discussions about how this data might provide confirming or disconfirming evidence for teachers' reports on instructional impact of the knowledge of connections between secondary and tertiary mathematics.

Self-assessment Behaviors of College Mathematics Students: A Preliminary Report

Kedar Nepal	Kailash Ghimire	Ramjee Sharma	Manoj Thapa
Mercer University	Georgia SW State University	University of North Georgia	Georgia SW State University

Research shows that low-achieving students are less able to accurately assess their own weaknesses. As a result, many might fail to see the need to explore the subject matter more deeply, in order to improve their conceptual understanding and procedural fluency. This study investigates undergraduate mathematics students' self-assessment behaviors. Students from a broad range of courses at three universities were asked to predict their expected grades on assignments, and these predictions were compared with the grades assessed by their instructors. They were also asked to justify their self-assessments if they did not give themselves full points. Preliminary results showed that students overall overestimate their grades. There was a significant difference between expected and actual grades. As test scores increased, the difference increased from negative to positive. Students in the B-range (between 80-89%) were the most accurate predictors.

Key words: [Self-assessment, Undergraduate Mathematics Teaching, Metacognition]

Studies suggest that higher-ability students also have better metacognitive skills (Chi et al, 1989; Recker & Pirolli, 1992; Shute & Gluck, 1996; Wood & Wood, 1999), and that low-achieving students are less accurate when assessing their own weaknesses (Langendyk, 2006). One implication of these findings is that many low-achievers may not see the need to explore the subject matter more deeply, in order to improve their conceptual understanding and procedural fluency. Students think that they are doing "just fine" even if their knowledge and performance are weak (Kruger & Dunning, 1999). This over-confidence could be a factor contributing to students' lack of success (Langendyk, 2006). Students often do not know when they need help or what form of support is appropriate (Aleven & Koedinger, 2002), and low-achieving students need external support in order to link assessment to learning (Langendyk, 2006).

Undergraduate mathematics courses have one of the highest dropped, failed or withdrawn (DFW) rates (Gardner Institute, 2013). However, little research has investigated mathematics students' self-assessment of performance, or the reasoning for their self-assessments. This study addresses these gaps in the literature by investigating the following research questions: 1) How accurately do undergraduate mathematics students self-assess their performance? 2) How do self-assessments of successful and unsuccessful performers compare? 3) What reasons do students give to justify their self-assessment of their performances? 4) How does students' self-assessment accuracy affect their self-regulated learning behaviors?

At this point, we only have information pertaining to the first two research questions.

Literature Review

This study is based on the theoretical framework of "meta-ignorance," also referred to as the Kruger-Dunning effect (Dunning & Kruger, 1999; Kruger & Dunning, 1999). This framework asserts that people's ignorance is often invisible to them, because "lack of expertise and knowledge often hides in the realm of the "unknown unknowns" or is disguised by erroneous beliefs and background knowledge" (Dunning, 2011, p. 248).

Research shows that good students have better metamemory (a conscious awareness of ones own processes with respect to memory) accuracy than do poor students, and are better able to predict what they know and do not know (Sinkavich, 1995). Dunning and Kruger (1999) found that when asked to rank their performances relative to peers, bottom-quartile students overestimated their performance, while top-quartile students underestimated. Self-assessments are more likely to be inaccurate on difficult tasks for which people lack requisite knowledge (Lichtenstein & Fischhoff, 1977). If the task is too difficult or the person is unskilled, there is a greater likelihood of overconfidence (Dunning & Kruger, 1999).

Dunning and Kruger (1999) assert that people unaware of their incompetence suffer a dual burden, as "not only do they reach erroneous conclusions and make unfortunate choices, but their incompetence robs them of the ability to realize it. Instead, they are left with the mistaken impression that they are doing just fine" (p. 1121). They further argue that such people are likely to get stuck and become unaware of their incompetence, because "the skills that engender competence in a particular domain are often the very same skills necessary to evaluate competence in that domain" (p. 1121). Incompetent individuals are unlikely to recognize correct judgment if they cannot produce correct judgment. In other words, they lack metacognition skills (Everson & Tobias, 1998).

Research shows that good students are more successful in the metacognitive task of evaluating their own performances, such as anticipating which test items they will get right or wrong (Austin, Gregory, & Galli, 2008; Sinkavich, 1995). A survey of 15-year old students across 34 countries showed that higher performance and more accurate self-perceptions of math skills are associated with each other (Chiu & Klassen, 2010). However, good students also underestimate their abilities when comparing themselves to peers (Dunning, 2011), a behavior known as the "false consensus effect" (Ross, Green, & House, 1977). Below-average students, on the other hand, falsely believe that they are above-average (Ferraro, 2010). When students are given their peers' work to grade, good students improve their ranking accuracy much more than their weaker peers (Dunning, 2011).

Dunning and Kruger (1999) found that students are willing to rate themselves more negatively if they are equipped with intellectual resources. They showed that even a short 20-minute lesson to solve a certain task improved students' logical reasoning and self-assessment accuracy. Research also shows a link between self-assessment and learning if students use their knowledge to formulate new strategies and learning goals (Boud & Falchikov, 2006). However, making people aware of their limitations does not necessarily induce them to overcome their limitations (Prasad et al., 2009). Many of them are unwilling to anticipate their incompetence even if they receive feedback on their work (Hacker, Bol, Horgan, & Rakow, 2000; Ferraro, 2010). Such unwillingness may be caused by self-esteem, self-defensiveness, or the difficulty they experience when trying to improve (Sheldon et al., 2014).

Little research has investigated undergraduate mathematics students' self-assessment behaviors, how they justify their self-assessments, and whether their self-assessment accuracy impacts their self-regulated learning behaviors. We hope that the results of this study would inform future mathematics instruction and the design of professional development activities for instructors to help students become better learners.

Methodology

Four faculty researchers collected data in their respective universities: a private university in central Georgia, and two public universities in north and southwest Georgia. Data were collected from 229 students in a broad range of undergraduate courses taught by the researchers: introduction to mathematical modeling, college algebra, elementary statistics, calculus I, II, and III, differential equations, and mathematical probability and statistics.

Students in these courses were given an initial survey asking their self-reported readiness to take the course and their expected end-of-semester grades. Students were asked to write their expected grades for all in-class quizzes and exams, which were graded based on the instructors' grading rubrics. Students were also asked to justify their self-assessment if they did not give themselves full points in those problems. Since they were asked to write their expected grades at the bottom of each assignment, they were able to compare the two scores after the assignments were returned to them.

Students' self-evaluation of their performances was also measured through a short survey after each exam. Toward the end of the semester, a purposeful sample of students (those who consistently overestimated, underestimated, or made almost accurate predictions of their scores) was asked to voluntarily participate in a few semi-structured interviews. They were reminded of the differences between the two scores and asked to explain their perceived reasons for the inaccuracy (or accuracy) of their assessment. This report is based on data from the spring 2016 semester, but does not include qualitative data from the interviews. Data will also be collected in the fall 2016 semester and a comprehensive study of the combined data will be made.

Based on existing research and our personal experiences, we hypothesized that top performers would be more accurate predictors of their scores, bottom performers would overestimate themselves and be less accurate predictors, and students would become better predictors as the semester progressed.

Results

This paper reports preliminary results from quantitative analysis pertaining to only the first two research questions. We have used both descriptive and inferential statistics. An independent t-test was used to determine the statistical significance of the average difference between the students' expected grades and the grades assigned by the instructor. Pearson's correlation test was used to determine the significance of the relationship between the students' predicted and actual grades. We found that students overall overestimated their scores. The test shows a statistically significant difference between their expected and actual grades ($t\ (1799)=-6.89$, $p < 0.01$), with a mean difference of 5.85 on a 100-point scale. For A students (scoring 90-100%), the difference was still statistically significant ($t\ (381)= 7.84$, $p < 0.01$), but they underestimated their performances by an average of 5.22 points on the 100-point scale. B students (scoring 80-89%) slightly overestimated themselves, but the difference between predicted and actual grades was not statistically significant. The mean difference was only 1.42 points.

For C students only (70-79%), the difference was statistically significant ($t\ (150)=-6.58$, $p < 0.01$). They overestimated themselves on average by 8.43 points. Students in the D range and below (69% and less) were the most miscalibrated, overestimating their performance ($t\ (500) = -14.4$, $p < .001$) by 20.25 points on a 100-point scale. The line graph (see Figure 1) shows how the difference between instructors' average grade and students' expected grade changes in relation to the average instructors' grade. This shows that bottom performers tend to overestimate themselves, and top performers tend to underestimate. The graph suggests that students in the B-range (80-89%) were more accurate predictors of their performances.

Preliminary test results did not support our initial hypothesis that top performers are more accurate predictors, as B students actually proved to be the most accurate. But the results supported the hypothesis that bottom performers are less accurate predictors than others.

The regression line in Figure 2 shows the relation between average grades vs. average differences. The two variables are strongly correlated, $r\ (89) = 0.67$, $p < 0.01$. This shows that as the test scores increase, the difference between the instructor's grade and students' predicted grade increases from negative to positive.

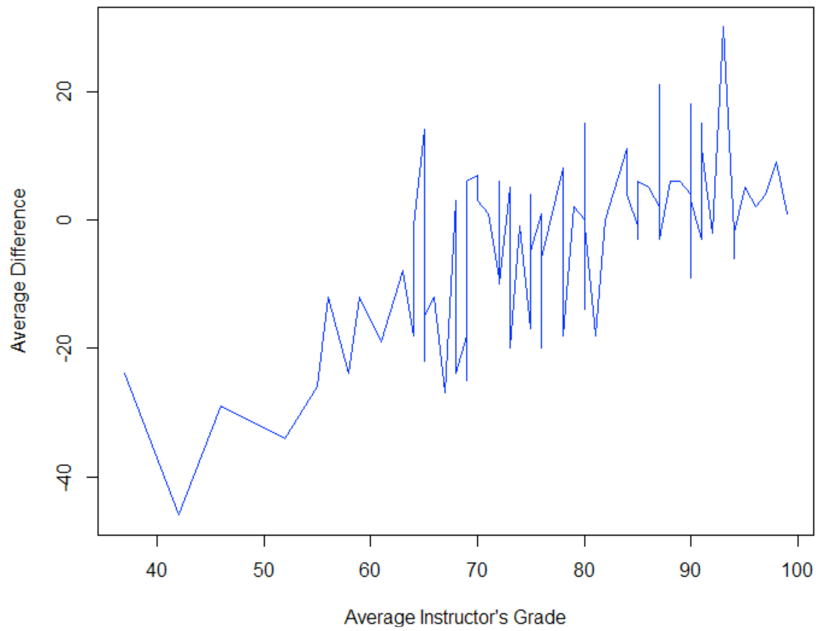

Figure 1. Average Instructors' Grades vs. Average Differences

We also looked at how the differences between predicted and actual grades changed as the semester progressed. Students overestimated their performance by 5.58 points on the first quiz, then underestimated by a mere 0.74 points on the second. Interestingly, they then overestimated by 5.7 and 6.3 points on the third and the last assignments (quizzes or tests). This did not validate our initial assumption that students would be more accurate predictors of their performances as the semester progressed.

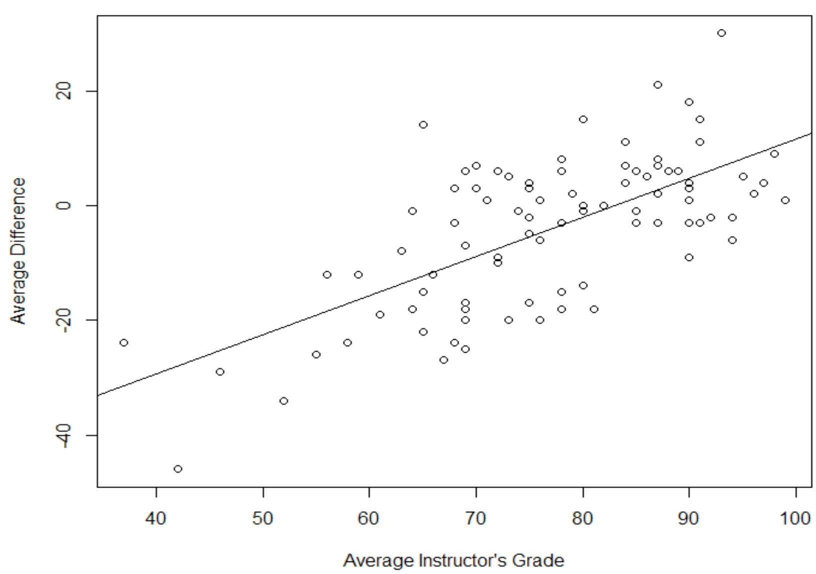

Figure 2. Average instructors' grades vs. average differences

Discussion

We had little information about college math students' self-assessment behaviors prior to this study. The results show that they are likely to be more miscalibrated when they either perform well or do not perform well, as also found in existing research (Kruger & Dunning, 1999; Langendyk, 2006). Both top (A students) and bottom performers (C and below) were inaccurate predictors. Top performers slightly underestimated their scores, while bottom performers overestimated by a huge margin. More interestingly, B-range students turned out to be the most accurate predictors, as the difference between their expected and actual grades was not statistically significant. This was in agreement with previous findings that students in between the top and bottom performers are more accurate predictors (Langendyk, 2006). We do not know why this group was able to better predict their performances, but we will have better insight once we finish analyzing our qualitative data.

Existing research shows that top performers in general underestimate their performance when comparing themselves to their peers (Dunning, 2011). Our study showed that top-achievers in college math courses still underestimate themselves, even when they are not comparing themselves with their peers. Since we haven't analyzed our qualitative data yet, we do not know why this group of students underestimate themselves. Either they are not completely confident that their solutions are correct, or they think they have not met instructors' expectations. The false consensus effect (Ross, Green, & House, 1977) in this group of students might be encouraging them to always work harder.

Lack of knowledge may prevent poor performers from knowing what they have done wrong (Dunning, 2011; Kruger & Dunning, 1999). If they had the ability to recognize right or wrong solutions, they probably would have been able to better predict their scores. Since they did not know that their solutions were incorrect, they might have been overly optimistic about their performances because they were hoping for a passing grade. Because of their mistaken belief that they know the subject matter, they might not even realize that they need to work harder to gain deeper understanding of the subject matter and gain procedural fluency.

We did not find studies that investigated college math students' self-assessment behaviors as we did in this study. One implication of our findings is that both low- and high-achievers need instructor support. Low-achievers need help figuring out conceptual and procedural gaps in their knowledge. They often do not know when they need help and what kind of support they need (Aleven & Koendinger, 2002). High-achievers, on the other hand, need help figuring out that what they know is actually correct. Preliminary findings show that they know the content but still lack confidence in their knowledge, as evident from their predicted scores. Since the students in between these two groups know, in general, whether they did right or wrong, it shows that these in-between students (mostly B students) have potential to improve. We will have better understanding about students' self-assessment behaviors once we finish analyzing their justifications for their self-assessments.

Results from this study showed that our initial assumption that students would become more accurate predictors of their performances as the semester progresses was not necessarily true. Even though they made almost accurate predictions of their scores in the second assignment (a quiz or a test), they then overestimated their performances on the next two quizzes or tests. Seeing the difference between their expected and actual grades on the first assignment might have made them more cautious about expecting higher scores on the second assignment. But why the students then became overly optimistic on the next assignments is unknown. We need to analyze interviews and collect more data to make any conclusions about this student behavior. This can be a good topic for further investigation.

Identification Matters: Effects of Female Peer Role Models Differ By Gender Between High and Low Mathematically Identified Students

Susan D. Nickerson Katie Bjorkman Sei Jin Ko David Marx
San Diego State University

We investigated a peer role model intervention designed to alleviate underrepresentation of women in STEM. Half of the Calculus break-out sections at a large university were visited by a peer role model and half served as controls. The female peer role models were expected to increase the sense of belonging and mathematical self-efficacy of women highly identified with mathematics. Our results show that peer role models have the intended effect on women highly identified with mathematics, but also have a positive effect on men with low mathematical identification.

Key words: Calculus, Gender, Experimental, Self-Efficacy, Mathematical Belonging

In spite of the need for more workers with training in science, technology, engineering, and mathematics (STEM) (PCAST, 2012), retention in STEM majors and programs of study is a persistent problem in the United States (e.g., Bressoud, Mesa, & Rasmussen, 2015; Chen, 2013; Seymour & Hewitt, 1997). It is particularly troubling that under-represented groups such as women and ethnic minorities are disproportionately affected (Ellis, Fosdick, Rasmussen, 2016; Hill, Corbett, & St. Rose, 2010; Lewis, Stout, Pollock, Finkelstein, & Ito, 2016). The Calculus sequence is critical to student success in a STEM major, and students' experience in Calculus has been shown to dissuade students from continuing. At the site of our study, a large, urban, southwestern university, women are almost twice as likely as men to opt out of taking Calculus II after completing Calculus I. This is similar to national data showing that even after controlling for academic preparation, career intention, and instruction, women are one and a half times more likely than men to leave after Calculus I (Ellis et al., 2016). We need to better understand how different populations are differentially affected by their Calculus experiences.

Several factors have been suggested to be potential causes for the retention disparities between men and women. One factor that researchers in the laboratory have identified as important in the performance of women highly-identified with mathematics is stereotype threat (Steele & Aronson, 1995). Stereotype threat is a concern stereotyped individuals have about confirming a negative ability stereotype that exists about their group. For instance, women routinely contend with the stereotype that they are inferior in math and this concern lowers their math performance below their actual math ability (Spencer, Steele, & Quinn, 1999). Among these women, exposure to female peer role models enabled positive performance and psychosocial outcomes, such as greater self-efficacy (Marx & Roman, 2002). Peer role models are inspiring in-group members who defy negative ability stereotypes about their group (i.e., mathematically-capable female students) (Marx & Roman, 2002). Researchers have suggested that the lack of mathematical confidence, or self-efficacy, is a potential deterrent to women's persistence (Ellis et al, 2016). Furthermore, stereotypes contribute to the perception that gender and ethnic minority students do not fit with being a STEM major leading to the minority students' feeling of not belonging, greater insecurity, and greater expectation of dropping out of STEM (London, Rosenthal, Levy, & Lobel, 2011). The absence of female peer role models in the classroom contributes to feelings of not belonging (Lockwood, 2006). For under-represented students, including women, belonging is crucial (Good, Rattan, & Dweck, 2012;

Hill, Corbett, & Rose, 2010; Walton & Cohen, 2007).

Wilson et al. (2015) conducted a 5-institution study linking belonging with academic engagement among STEM majors. Students filled out surveys containing measures of belonging at multiple levels (class, major, and university) as well as measures of behavioral and emotional engagement in their academic pursuits. The results were that class and major belonging correlated with greater behavioral and positive emotional engagement and lower negative emotional engagement. Belonging remained a significant predictor even when other measures such as self-efficacy were included in the models. Furthermore, while belonging and self-efficacy are correlated, they also have distinct aspects that contribute separately to positive outcomes for students. While Wilson et al. (2015) looked at correlates for a single point in time, Walton and Cohen (2011) demonstrated that a short intervention can result in long term stabilization of feelings of belonging and raise the GPA of minority students who participated.

In Calculus classrooms, women are aware that their gender is in the minority and this contributes to a feeling they do not belong and this can feel threatening for STEM-intending students. In numerous past laboratory studies, researchers have found that exposure to similar others who represent success in STEM (i.e., math-talented peer female role models) can alleviate the negative effect on women's math performance (e.g., Marx & Ko, 2012; Marx & Roman, 2002; Marx, Stapel, & Muller, 2005). Because female peer role models defy the stereotype and highlight women's presence in STEM, more exposure to these peer role models may also has the potential to foster women's belief that they do belong in STEM and that they have the ability to succeed in math. The results presented here are part of a larger study that seeks to examine the effects of peer role models on sense of belonging and self-efficacy in the setting of university mathematics classrooms, as well as long-term effects such as a higher percentage of women continuing in higher level mathematics courses.

Setting & Participants

Participants were undergraduates of all racial/ethnic groups in Calculus I at a large university in the southwestern U.S. All were eligible to participate. The Calculus I classes are conducted in large lecture halls with graduate teaching assistants (GTAs) leading two 50-minute break-out sections each week. There were 16 break-out sections that were typically about 35-40 students. We recruited and trained 4 female upper-division STEM majors to serve as near peer role models (2 Hispanic and 2 non-Hispanic white STEM majors). These near peers made 2 in-class role model presentations in half of the breakout sections of the Calculus I classes. The other half of the Calculus I class served as the control. The role model presentations closely followed the structure that we have found through laboratory studies to be key components of a role model. Half of the break-out sections were visited by one of four female near-peer role models twice during the semester. These smaller sections supported the opportunity for students to form a more personal connection with the peer role model. The focus of past work on role models has been conducted among under-represented minorities who were pre-selected to be highly STEM identified. Those who are most likely to experience threat are those who are most vested or identified with the domain (i.e. STEM) (Schmader, Johns, & Forbes, 2008). In a Calculus classroom with high and low math identified students, we have the opportunity to test whether role models can be beneficial to minority students at all levels of math identification.

The role model presentations consisted of:

1) an introduction establishing the role model's similarity to students and aptitude in

mathematics

2) a presentation of a mathematical topic, each topic related to helping people/the environment and was directly tied to mathematics being taught in the class but presented within some mathematical setting that was mathematically unfamiliar

3) explicit encouragement to persist in mathematics/STEM in order to understand the unfamiliar mathematics

The particular topics were chosen in effort to combat the notion that STEM careers are less likely than careers in other fields to fulfill communal goals (e.g., working with or helping other people) (Diekman, Brown, Johnston, & Clark, 2010).

Methodology

Following the second in-class role model presentation, all students (both intervention and control groups) filled out a questionnaire containing the *Mathematics Identification Questionnaire* (Brown & Josephs, 1999) and a modified version of Walton and Cohen's (2007) *Social Fit Measure* to assess sense of belonging in STEM. This measure contains questions such as, "I would feel comfortable in a math field" and "I feel that I would belong in a math field." We also combined Marx and Roman's (2002) Self-Appraised Math Ability Scale and a modified version of Schwarzer and Jerusalem's (1995) General Self-Efficacy Scale (GSE) to measure self-efficacy. The self-appraised math ability scale contains items such as "I deal poorly with challenges in math". All items in the GSE were worded to reflect mathematical self-efficacy (e.g., "I can always manage to solve difficult math problems if I try hard enough"). Responses were recorded on 1 (strongly disagree) to 7 (strongly agree) scale. Students then provided basic demographic information. In our analysis the sense of belongingness and self-efficacy dependent variables were regressed separately onto role model (yes vs. no), student sex (female vs. male), and the continuous variable math identification (centered).

Results

Sense of Belonging

Sense of belonging yielded a main effect of math identification, F (1, 120) = 41.73, $p <$ .001, showing a positive relation between math identified and sense of belonging in math. Of more interest was the significant 3-way interaction between role model, student sex, and math identification, F (1, 120) = 14.06, $p < .001$. Among low identified female students, those exposed to role models indicated feeling just as low a sense of belonging in math ($M = 4.12$) as those in the control ($M = 4.42$), $F < 1$. Whereas among high identified female students, those exposed to role models indicated a higher sense of belonging in math ($M = 5.60$) than those in the control ($M = 4.93$). The benefit of role model exposure among high math identified female students was further confirmed by comparisons with male students. Specifically, among high math identified students in the control condition, we observed the classic lower sense of belonging for female compared to male students ($Mfemale = 4.93$ vs. $Mmale = 5.59$). In contrast, among high math identified students in the role model condition, female students had a higher sense of belonging in math than male students ($Mfemale = 5.60$ vs. $Mmale = 4.95$). These results suggest that role models are not as beneficial for low as compared to high STEM identified female students. Interestingly, however, low math identified *male* students seem to derive benefit from female role model exposure such that those who were exposed to the role model had higher sense of belonging than those in the control (*M* = 4.02 vs. *M* = 4.62).

Self-Efficacy

Self efficacy also yielded a positive relation with math identification, F (1, 120) = 33.29, $p <$ .001. There was also a role model by student sex interaction, F (1, 120) = 4.75, $p < .05$. This demonstrated that in the control condition female students had lower self-efficacy than male students (*Mfemale* = 4.47 vs. *Mmale* = 5.17). In contrast, this gender difference in self-efficacy closed in the role model condition (*Mfemale* = 4.97 vs. *Mmale* = 4.95).

This 2-way interaction was subsumed under a 3-way interaction between role model, student sex, and math identification, F (1, 120) = 10.82, $p < .01$. A closer look at this interaction showed a remarkably similar pattern of effects as that found for sense of belonging. Specifically, low identified female students, those exposed to role models indicated about the same level of self-efficacy (*M* = 4.18) as those in the control (*M* = 4.28), $F < 1$. Whereas among high identified female students, those exposed to role models indicated higher self-efficacy (*M* = 5.76) than those in the control (*M* = 4.66). Comparisons between female and male students within the high math identified students further confirmed the beneficial effect of role model exposure on female students. Specifically, in the control condition, we observed the classic gender gap in self-efficacy (*Mfemale* = 4.66 vs. *Mmale* = 5.80). In contrast, in the role model condition, female students had self-efficacy than male students (*Mfemale* = 5.76 vs. *Mmale* = 5.14). Again, mirroring what we found for sense of belonging, role models seem to have an opposite impact among those in with low math identification. In particular, whereas role models did not seem to benefit female students (*Mrole model* = 4.18 vs. *Mcontrol* = 4.28), role models seem to have some benefit for male students (*Mrole model* = 4.75 vs. *Mcontrol* = 4.54).

Discussion

We posited that female students' career trajectories would benefit from exposure to female peer role models who, through their own success in mathematics, illustrate that women do belong in STEM. The female peer role models were expected to increase the sense of belonging and mathematical self-efficacy of women highly identified with mathematics. Our results show that peer role models have the intended effect on women highly identified with mathematics, but also have a positive effect on men with low mathematical identification. We will discuss possible reasons for the positive effect in men. The results are being analyzed for a second semester to see whether role models can alleviate female students' negative mathematics experiences in order to increase their interest and persistence in mathematics.

Considerations for Explicit and Reflective Teaching of the Roles of Proof

Jeffrey D. Pair
Middle Tennessee State University

Sarah K. Bleiler-Baxter
Middle Tennessee State University

In a previous study we sought to understand the classroom activities that provided students the opportunity to engage in the five roles of proof described by Michael de Villiers (1990). In conducting the analysis for that study, we noticed that students' views of proof were sometimes not aligned with de Villiers' views. This led us to the current investigation, where we explore alignment between undergraduate students' views of the nature of proof and de Villiers'. We hypothesize that an explicit and reflective (ER) approach to instruction may be important if students are to learn about the nature of mathematics (in general) and the nature of proof (more specifically). We offer implications for both research and practice, with respect to the explicit and reflective instruction on roles of proof.

Key words: Roles of Proof, Nature of Mathematics, Nature of Proof, Transition-to-Proof

Researchers in mathematics education have made several efforts to understand the disciplinary practices of mathematicians (e.g., Burton, 1999; Nardi, 2008; Weber, 2008; Weber & Mejia-Ramos, 2011). As a result of such studies, the field benefits by gaining a deeper understanding of the nature of mathematical knowledge and inquiry. Proponents of situated learning theory (ourselves included) would argue that in order to learn mathematics, students must engage in authentic mathematical practices (Greeno, 1997; Lave & Wenger, 1991). From this perspective, understanding the work of experts in a field (such as mathematicians in mathematics) is an important aspect of instructor knowledge, allowing instructors to design learning environments that engage students in authentic disciplinary practices and thus aid in their learning of mathematics. But, do students need to go beyond engagement in legitimate mathematical practices within the classroom, and actually hold an understanding of the nature of mathematician's practice and the nature of mathematical knowledge? It is widely acknowledged that most students know very little about what mathematicians do (Hersh, 1997). Yet little research has been conducted regarding students' understanding of the nature of mathematics as a discipline (Jankvist, 2015). Perhaps an understanding of the nature of mathematical knowledge and inquiry may lead undergraduates to have a greater appreciation of mathematics or even lead to greater learning gains. But until systematic research is conducted into this area, these remain untested hypotheses.

Within science education, researchers have studied how students learn about the nature of scientific inquiry and scientific knowledge and the benefits of such knowledge (Lederman & Lederman, 2014). One of the main findings of that work is that engagement in authentic scientific practice alone is not sufficient for students (or teachers) to learn about the nature of science (Bell, Blair, Crawford, & Lederman, 2003). Although teachers often perceive that their students will *implicitly* learn the nature of science through engaging in scientific practice, research shows that students need *explicit and reflective* (ER) instruction on the nature of science in order to develop a sophisticated understanding (Bell et al., 2003). To teach the nature of science explicitly and reflectively means that students engage in authentic scientific practice, have that practice brought to their attention explicitly (e.g., by the instructor), and have the opportunity to reflect on the ideas that have been explicitly addressed (Lederman et al., 2014). Researchers in mathematics education sometimes claim that students have developed "desirable beliefs about the nature of mathematics" (Rasmussen & Kwon, 2007, p. 192) after participating in inquiry-oriented courses. However, these claims about student beliefs are made in regards to what it means to do mathematics within the particular classroom settings, and generalizations are not made about what students may believe about the nature of mathematics as a discipline (e.g., Fukawa-Connelly, 2012; Yackel & Rasmussen, 2002).

We believe there may be an implicit assumption possessed by some scholars that if students participate in inquiry-oriented classrooms and engage in mathematical practices similar to those of research mathematicians, then the students may come away from such classes with informed conceptions of what it means to know and do mathematics in the discipline. The authors of this paper admit to being guilty of this assumption in the past. We believed that undergraduates' understanding of the nature of proof in the discipline could be developed implicitly by engaging students in the five roles of proof described by de Villiers (1990). One of the learning objectives in our transition-to-proof course, taken from the course syllabus, was that students "Gain an appreciation of the many roles of proof and reasoning in the discipline of mathematics (e.g., verification, explanation, systemization, discovery, communication)." In a previous study, we identified the (classroom) activities that engaged students in those five roles of proof. Our implicit assumption was that by engaging in the five roles of proof, the students would gain a sophisticated understanding of those roles in the discipline. However, we found that even when students were engaged in a role of proof, this did not always lead to their understanding of the role in the broader discipline. Even after reading de Villiers' (1990) paper on the roles of proof, their written summaries of these roles suggested they had naïve conceptions that did not align with de Villiers'. This leads us to the hypothesis, based on the findings in science education, that an explicit and reflective (ER) approach to instruction may be important if we want students to learn about the nature of mathematics (in general) and the nature of proof (more specifically).

In this preliminary report, we intend to explore the following questions:

- What do undergraduate students in a transition-to-proof course understand about the nature of proof in the discipline? What do they not understand?
- Which roles of proof are in need of further explicit and reflective (ER) instruction?

By exploring these questions, we hope to gain a better understanding of the considerations necessary when teaching the nature of proof in a more explicit and reflective (ER) manner.

Conceptual Framework

A key construct in our research is the notion of the nature of proof as it is experienced by research mathematicians. We conceptualize the nature of proof using de Villiers' (1990) five roles of proof: verification, explanation, systematization, discovery, and communication. A mathematician engages in *verification* when a proof convinces the mathematician of the truth of a mathematical statement. The reason why the mathematical statement is true may be illuminated as a mathematician engages in the *explanation* role of proof. *Systematization* refers to proof's role in organizing and creating a deductive system of axioms, definitions, and theorems. A mathematician engaged in *discovery* may deduce an unanticipated result during the completion of a proof. Proof also provides a means for *communication* among mathematicians as they transmit mathematical knowledge and negotiate meaning and validity. We frame our work from the following assumption: Students have a sophisticated understanding of the nature of proof if their ideas surrounding the roles of proof align with those of de Villiers (1990).

Methodology

The data for this study were taken from an undergraduate transition-to-proof course at a southeastern university in the United States. The instructor (also one of the authors on this paper) designed the course with an aim toward broadening students' understanding of proof and providing experiences for students to engage with proof in ways similar to mathematicians in the discipline. There were thirteen students in the course: nine mathematics majors (seven of whom were prospective secondary mathematics teachers), and four mathematics minors. At the end of the semester the students took a two-part final exam. The second part (20% of the exam grade) of the final required students to read de Villiers (1990) paper, describe in their own words each of the five roles of proof, recall an instance during the course in which they engaged in one of the five roles (or describe an activity that might be used in the future for engaging students in such a role) and rank order their engagement in each role of proof throughout the semester.

The researchers used open process coding (Saldaña, 2009) to analyze the written descriptions of the 65 student recollections (five roles and thirteen students) of the instances in which they recalled being engaged in the roles of proof during the course. During subsequent analysis the researchers discussed the following questions:

1) How do students perceive that a certain activity engages them in a specific role of proof?
2) How do student perceptions align with the role of proof as articulated by de Villiers?
3) What are some implications for teaching such a course in the future?

When completing initial work related to the project, we focused on the first question. Here we concentrate our efforts on the second question related to comparing student perceptions to de Villiers' perceptions. After completing the introductory analysis, the first author went back to the data and reviewed each students' summary of the five roles of proof as well as their description of an activity which engaged them in the role of proof. He noted if the students' ideas were aligned with de Villiers, identified evidence for this determination, and noted any implications. He then reviewed these notes and identified several preliminary discussion points regarding student understanding of the roles of proof and the nature of mathematical knowledge/inquiry.

Results and Discussion

Verification

When describing the verification role of proof, de Villiers' (1990) challenged the naïve view that proof provides mathematicians with absolute certainty. While acknowledging that proof does indeed provide conviction, especially in the case of non-intuitive claims, lack of quasi-empirical falsification also plays a role in conviction. Our data suggest that reading de Villiers' arguments was not enough for students in the course to understand this position. Several students summarized de Villiers' description of verification using the language of "absolute certainty." David wrote, "Verification by proofs is to show the absolute certainty of a mathematical computation by proving it in every case." Similarly, Tina claimed,

> The verification of a proof is most often a way of knowing what you already know. By that I mean the things that we are most sure are true the verification makes us absolutely certain. If mathematicians had not verified the proofs of some of the greats from ancient times we still would not know that some of them were incorrect.

Students such as Tina and David may benefit from classroom discussions regarding the nature of proof and absolute certainty. Perhaps reading *and discussing* relevant philosophy of mathematics

(Hersh, 1993) or mathematics education literature (Weber & Mejia-Ramos, 2015) may prove useful in challenging students' absolutist conceptions of proof.

Explanation

We have noticed that the term "explanation" may be confusing for students. While the occasional student understood this role, many students interpreted explanation in a colloquial sense, e.g. explaining why one step follows from another within a proof. Jared claimed,

> Explanation is the reasoning behind the proof. It shows how steps are logically taken to get to the conclusion of the proof and why we take them. Overall, it is saying why we can go from the statement to the conclusion.

Similarly, Stephanie wrote,

> Proofs may provide more or less explanation and still be a valid proof. Explanation is just how much detail the writer of the proof goes into. If your audience doesn't know as much about mathematics you may want to give a full explanation of your proof.

Perhaps it would be beneficial for an instructor to specifically draw attention to how proving can provide *insight* or *understanding.* Hersh (1993) claimed that in teaching, the primary role of proof is for explanation. However, without explicit and reflective instruction, students ultimately may fail to understand that proofs serve this important function. Instructors may ask students to compare and contrast proofs in regards to the insight or understanding they provide.

Systematization

In general, the students in the course under study did not understand the systematization role, that proof may play a role in the organization of a theory. They viewed systematization as the use of established theorems, axioms, and definitions within a proof. Jeb wrote,

> Systemization is taking several smaller true statements and arranging them into one large true statement that is the proof. It is organizing or ordering the smaller sections of a proof to flow in such a way that they look like a single statement.

De Villiers (1990) noted that the systematization role is only understandable at an advanced stage of mathematics. It is the first author's opinion that in a course in which systematization has already been conducted by the organization of course materials, it will be difficult for students to understand systematization as a role of proof. Perhaps in a course in which the organization of materials is not predetermined (e.g. Fawcett, 1938), students may better understand this role.

Discovery

De Villiers (1990), in describing the discovery role of proof, described how mathematicians may prove an unexpected result when they realize, through deduction, that a proof generalizes from a specific case to a larger class of mathematical objects. Students in the course recalled times when they experienced discovery in this manner, but also wrote about additional ways they came to discovery during the course. For instance, Millie recalled a problem that asked her to "Prove, or disprove and salvage" a given mathematical statement:

> I decided [for all integers a, b, and c, if bc is divisible by a, then either b is divisible by a or c is divisible by a] was a false statement, and I provided a counter example. Then, I made a conjecture that the converse was true: for all integers a, b, and c, if either b is divisible by a or c is divisible by a, then bc is divisible by a. I proved my conjecture, and that conjecture was my own personal discovery.

Although not aligned with de Villiers' description of the discovery role of proof, we believe that Millie's learning experience was valuable. For instance, Susan explicitly mentions how classroom discoveries led her to develop a new conception of the nature of mathematics.

> Discovery came to me when working on a truth table to test possible outcomes of a proof. This truth table led to "Susan's conjecture." I also think this class, in general, led to a broader "discovery" that mathematics is a living, changing, developing thing. Unlike my former perspective that it had all been discovered many years ago and we are just reviewing and learning those truths.

We contend, that although these two students did not describe an instance in which they discovered a new result through deduction (as de Villiers described), their classroom discoveries were valuable. It is important that students come to realize that mathematics is a dynamic field in which new discoveries are made rather than a static body of knowledge. Explicit and reflective instruction related to the discovery role of proof should enable students to be aware of the variety of ways discovery may occur in mathematics (in addition to discovery as de Villiers described).

Communication

De Villiers describes the communication role of proof as being related to the negotiation of meaning and validity amongst mathematicians. We are encouraged that students seemed to understand this role. Krissy wrote,

> Our inability to come to a consensus among three people when evaluating a particular argument also demonstrated how difficult it might be for the global community of mathematicians to achieve agreement when it comes to proof style and validity.

The instructor designed several course activities with the goal of helping students understand the social nature of proof. For instance, students designed a course rubric that outlined what makes a valid mathematical argument and were constantly asked to critique the arguments of others. The instructor frequently made the social nature of proof an explicit part of classroom discussions and we believe this contributed to students' understanding of the communication role of proof.

Conclusions

Reading de Villiers' (1990) article may be a first step towards explicit and reflective (ER) instruction on the nature of proof, but it is not enough. The students submitted their reflections as part of a final assignment, and there was no subsequent class discussion related to the assignment. Our findings may have been different if students had the opportunity for discussion. We judge that if any role of proof was discussed explicitly and reflectively most often in class, it was the communication role. Students seemed to possess a clear understanding of how validity is negotiated within the community of mathematicians through proof.

In moving forward with this work, we would like to gain feedback from RUME conference participants on the following questions:

1. How important is it that students understand the nature of mathematics (in general) and the nature of proof (more specifically)? Why?
2. How can what we know from science education research (about explicit and reflective teaching of the nature of a discipline) transfer to mathematics education?

Perturbing practice: The effects of virtual manipulatives as novel didactic objects on instruction

Krysten Pampel
Arizona State University
United States
krysten.pampel@asu.edu

Abstract: *The advancement of technology has significantly changed the practices of numerous professions, including teaching. When a school first adopts a new technology, established classroom practices are perturbed. These perturbations can have both positive and negative effects on teachers' abilities to teach mathematical concepts with the new technology. Therefore, before new technology can be introduced into mathematics classrooms, we need to better understand how technology affects instruction. Using interviews and classroom observations, I explored perturbations in mathematical classroom practice as an instructor implemented novel didactic objects. In particular, the instructor was using didactic objects designed to lay the foundation for developing a conceptual understanding of rational functions through the coordination of relative magnitudes of the numerator and denominator. The results are organized according to a framework that captures leader actions, communication, expectations of technology, roles, timing, student engagement, and mathematical conceptions.*

Key words: Virtual manipulative, Didactic objects, Rational functions

The advancement of technology over the past twenty years has significantly altered the practices and routines found in numerous professions. When school districts adopt a new technology, teachers experience immediate changes, or perturbations, in their existing practices. These perturbations in practice can have small or large, short- or long-lived, and positive or negative effects on teachers' ability to accomplish the work with the new technology. In mathematics education, new technology is regularly being introduced into instruction (Pope, 2013). This technology comes in many forms such as hardware (e.g., computers or graphing calculators), software (e.g., Geometer's Sketchpad), or educational website licenses (e.g., Nearpod).

The goal associated with the implementation of new technology in instruction is to facilitate instruction and improve student achievement and understanding. However, in order to achieve this goal, we need to better understand the process of adopting new technology in instruction. In particular, we need to account for teachers' current mathematical meanings of concepts, the perturbations experienced by teachers when implementing a new technology, and the effect these perturbations have on the instruction of mathematical concepts.

As a step along this path, this paper identifies perturbations that occur in mathematical classroom practices (MCPs) when an instructor uses novel virtual manipulatives to teach a concept for which there are already established instructional practices. In order to connect with the goal of introducing technology to improve student understanding, virtual manipulatives designed to support reflective mathematical discourse were chosen for the study. The observed perturbations in MCPs are organized in a framework based on perturbations from industry when a new technology was adopted (Edmondson et al., 2001; Pickering, 1995). Additionally, assimilation and accommodation (Piaget, 1967), cognitive conflict (Lee, Kwon, Park, Kim, Kwon, & Park, 2003), and covariational reasoning (Carlson et al., 2002), were used to tailor the framework to a mathematics classroom.

Virtual manipulatives as didactic objects. Manipulatives are physical objects or concrete models that can be touched and moved around by the learner (Durmus & Karakirik, 2006). In mathematics instruction, manipulatives afford opportunities for learners to interact with abstract mathematical concepts and procedures through visualization and movement. However, we now recognize that the benefits of using manipulatives do not necessarily require the sense of touch, e.g., moving around physical objects. Now, a new class of computer-based manipulatives has been created (Durmus & Karakirik, 2006; Moyer-Packenham, Salkind, & Bolyard, 2008), where a virtual manipulative is defined as a "web-based visual representation of a dynamic object that presents opportunities for constructing mathematical knowledge" (Moyer, Bolyard, & Spikell, 2002,p.373).

Research on the use of objects (physical or virtual) in mathematics instruction has traditionally focused solely on how the tool itself supports student learning and understanding in terms of cognition (Lee et al., 2003). However, there has been a shift to expand the focus beyond the object itself to include the accompanying discussion (Thompson, 2002). Accordingly, Thompson (2002) defines *didactic objects* (DOs) as tools or objects that are created with the intent of supporting reflective discourse (p.198) and considers them to have two components: first, the object itself, and, second, the classroom discussion that engages students in constructing mathematical understandings. This study explores DOs designed to scaffold a conceptual understanding of rational functions.

Practices in and out of the classroom. Practices or routines are ways of doing things that are known and shared by a group of people as they engage in some activity. They are established over time and emerge as a group works together repeatedly to accomplish an activity. Changing the tools that are used in an activity, therefore, changes the associated practices, both in the long and short term. In the long term, tools can transform practices and significantly change the very nature of an activity. In the short term, the introduction of a new tool or technology can perturb established practices and lead to the adoption of new practices. For example, Pickering (1995) noted multiple disruptions in established practices on the labor floor and within management due to the adoption of numerically controlled machine tools by General Electric's (GE) Aero Engine Group in the early 1960's. Similarly, Edmondson, Bohmer, & Pisano (2001) discovered disruptions in routines that occurred when minimally invasive cardiac surgery equipment was introduced to cardiac surgery in an emergency room. Table 1 contains a framework categorizing, summarizing, and providing examples of the perturbations in practice informed by research in industry.

Table 1. *Framework summarizing perturbations in practice in industrial contexts*

Aspects of practice	Description	Example
Leader Actions	Leader's interpretation of the technology and how the leader implements the technology	Edmondson et al. (2001) demonstrated how the surgeon's beliefs in the technology correlated with how the ER team adapted to the technology.
Communication	The discourse and environment	In Edmondson et al. (2001), the discourse in the ER changed from the surgeon being the only speaker to every member of the team needing to communicate.
Expectations of Technology	Predicted outcomes for the implementation process	In Pickering (1995), prior to implementation GE management expected the technology to increase production.
Roles and Responsibilities	The individual's original responsibilities are altered during the implementation process	In Pickering (1995), the role of workers evolved from button pushers to integral members in the success of the machines.

If we consider a mathematics classroom, then the teacher and students together represent a team of individuals with a shared, collective goal of learning, and with the teacher as the team leader. The teaching practices that have been established over time in the context of the classroom by the teacher and her or his students in the course of their ongoing interactions (Cobb, Stephan, McClain, & Gravemeijer, 2001) and that may be disrupted by the implementation of new technology include pacing, student engagement, communicative norms, etc. For mathematics classrooms, such practices also include the emergent mathematical conceptions of the students as well as the mathematical understandings the teacher plans to cultivate within students (Thompson, 2013). MCPs, once established, are maintained through reflection and consistency. When a teacher reflects on the effectiveness of a practice, he or she is assessing whether the practice is effective in helping attain the goal of learning. Maintaining established MCPs relies on the consistency of the teacher. Teachers continually reinforce MCPs (for example through selecting tasks and activities) that engage students in productive ways and help them to build mathematical understandings.

Establishing and maintaining classroom practices is arduous work and takes a fair amount of time, effort, and coordination to accomplish, which makes changing practices difficult as well (Thomson, 2004). If a practice is disrupted or forced to change, there may be an accompanying experience of discomfort. Teachers, like every working professional, easily fall into a comfort zone that is made up of carrying out established practices. When these established classroom mathematical practices are perturbed by a new technology, such as a virtual manipulative, the teacher might well experience disequilibrium or discomfort (Schwartz, 1999). Furthermore, the teacher beliefs of how the mathematics classroom should function, what mathematics concepts are important, and what resources are to be used for instruction can affect how the established practices are changed (Cobb & Yackel, 1996).

Rational Functions. Students are first introduced to rational functions in algebra courses, usually taken in high school. Traditionally, rational function instruction centers on finding the asymptotes algebraically. However, this calculational orientation does not provide students with a conceptual understanding of how rational functions behave. In particular, simply setting the denominator equal to zero does not capture the covariational relationship that exists between the two polynomials that make up the rational function. It does not support students' ability to see the relative magnitude of the numerator in terms of the denominator as a single quantity. This issue sets the stage for the adoption of a virtual manipulative that allows students to explore rational functions more dynamically and to construct a covariational understanding of how the functions behave near vertical asymptotes.

Methods

I focused on a single instructor (Elaine) and a pair of novel DOs for teaching rational functions. Elaine was a graduate student teaching Pathways Pre-calculus (Carlson et al., 2013) and had taken a technology and visualization course, but was unfamiliar with teaching rational functions with the DOs used in this study. Therefore the DOs are considered novel to Elaine. The DOs (Rat Bar and Rat Graph) were accompanied by teacher guides, containing display setting and questions to ask students to foster a discussion around four phases, as summarized in Table 2.

Table 2. *Phases of didactic objects*

Phase	Didactic Object	Purpose of the Activity	See Figure
1	Rat Bar	Assist students in conceptualizing and representing relative magnitude as a quotient of functions by comparing the relative lengths of the red and blue bars.	1a
2	Rat Bar	Assist students in internalizing relative magnitude as a quantity by no longer just seeing *two separate magnitudes* but instead seeing the relative magnitude of these magnitudes *as its own quantity*.	1b
3	Rat Bar	Assist students in coordinating the change in parameter values with the change in the relative magnitude.	1c
4	Rat Graph	Assist students in graphing the rational function by attending to changes in the relative magnitude of its numerator and denominator.	1d

In order to study the perturbations caused by the novel DOs, I used two pre-interviews, classroom observations, and a post-interview with the instructor. In the first pre-interview, which took place one week prior to the observations, I explored the participant's current understandings of rational functions and gathered descriptions of the participant's instructional practices prior to the introduction of the novel DO. In the second pre-interview, which took place two days prior to the observations, I guided the participant through an exploration of the DOs. The instructor was provided with a journal to record instructional preparations made following the second pre-interview. Two days after the pre-interviews, I conducted three real-time classroom observations covering the instruction on rational functions to identify moments of perturbations from my perspective. Using stimulated recall methodology (Stough, 2001), video clips of the moments I identified during the observations were then shown to Elaine during a post interview two days later so she could give a retrospective analysis of the instances that I had flagged as perturbations.

Figure 1 depicts the implementation of the DOs for each phase shown in Table 2. In Phase 1, the teacher displays various lengths of two bars and asks students to provide a numerical guess of their relative magnitude (Figure 1a); in Phase 2, the teacher changes the length of the two bars and asks students to use the distance between their fingers to represent the changing magnitude (Figure 1b); in Phase 3, the teacher changes the length of the two bars and asks students to use their fingers to coordinate the change of one magnitude relative to the other (Figure 1c); in Phase 4, the teacher shows students a graph of the numerator and denominator of a rational function and asks students to graph the resulting rational function (Figure 1d).

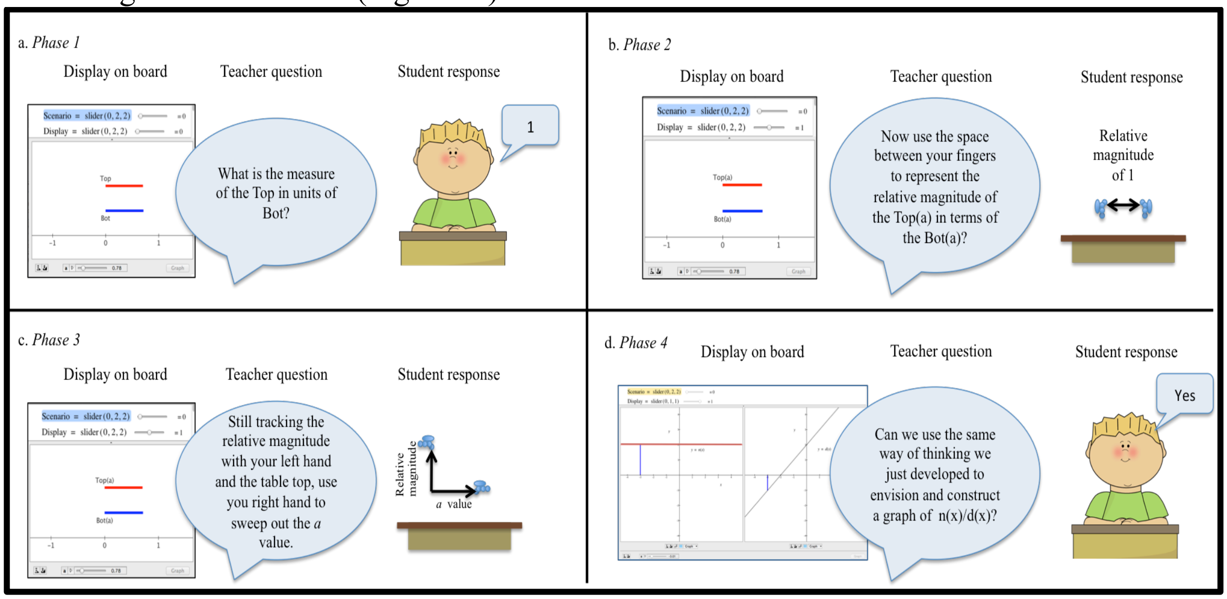

Figure 1. Four phases of using didactic objects for teaching rational functions

Preliminary Results

The preliminary results of the study provided converging evidence for the aspects of practice that are perturbed when novel technology is introduced in the context of industry, e.g. leader actions, communication, expectations of technology, and roles/responsibilities (Table 1). However, there were also ways in which the novel DOs perturbed practices in the classroom that were not observed in industry. These included student engagement and mathematical conceptions, as shown in Table 3 which describes and provides examples of the aspects of practice that were perturbed as a result of the introduction of novel DOs.

Table 3. *Framework summarizing perturbations in practice in mathematics classroom*

Aspects of practice	Description	Example
Leader Actions	How instructor perceives novel DO and how the instructor uses the technology in the classroom	Elaine's introduction to the DO demonstrated her uneasy feeling toward trying something new.
Communication	Classroom discourse surrounding the novel DO	Elaine's students no longer relayed exact answers but instead they explained the behavior of the function.
Expectations of Technology	What understandings the teacher expects students to develop	Elaine had expected the novel DO to take the exact amount of time as her previous lesson.
Roles and Responsibilities	Responsibility for assimilating conceptual and procedural	Elaine's role was altered from lecturer to discussion facilitator.
Student Engagement	Student participation while the DO is being used	Elaine's students became more active in the lesson through the activities that accompanied the virtual manipulatives.
Mathematical Conception	How students perceive the mathematics addressed by the novel DO	The novel DO change the emphasis of rational functions to behaviors rather than symbolic manipulation.

A possible reason for these additional perturbations in classroom practice (student engagement, mathematical conceptions) stems from differing expectations of technology. Industry adopts technology with the intent of increasing productivity and efficiency. In contrast, the purpose of using technology in a mathematics classroom is reorganizational (Sherman, 2014) and supports the development of deeper understandings (Thompson, 2002). All sources of data collected in this study point to the difficulties of accomplishing this task. Figure 2 displays two examples drawn from the classroom observations showing how two of the six aspects of practice, namely leader actions and mathematical conceptions, were affected by the implementation of the novel DOs.

Leader actions. In industry, it was noted that the introduction of new technology impacts the actions of the leader, which in turn affects how the team operates. This was also true in the observed classroom environment. In this case, the novel DOs caused Elaine to adopt a hesitant, foreboding approach to the upcoming lesson on rational functions. As seen in Figure 2, her introduction of the DOs to the students sounded much like a parent trying to explain to a child that vegetables may not taste good but that they are good for your health. Thus, as the leader, she gave students plenty of reason to be wary of the upcoming lesson and mathematics, instead of exuding confidence and a belief in the value of conceptual understanding. This is noteworthy because teachers, as classroom leaders, profoundly influence student beliefs in both the short and long term and thus ultimately shape the perception of what it means to understand and do mathematics (Thompson, 2013).

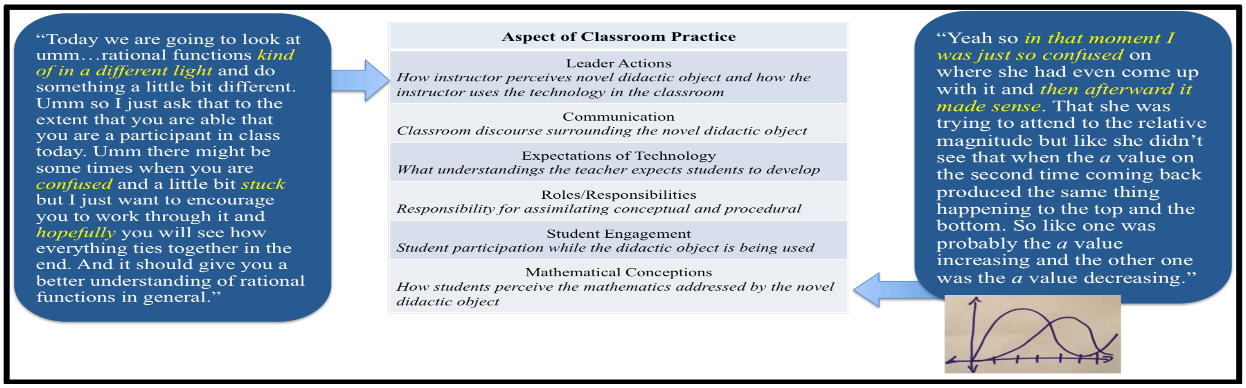

Figure 2. Examples of perturbations in mathematical classroom practices

Mathematical conceptions. However, unlike what was observed in industrial contexts, in the classroom the introduction of novel DOs also perturbed the conceptions of those involved, causing new conceptions to emerge and unexpected conceptions to surface. Thus, as seen in Figure 2 (right) Elaine was baffled by the mathematical conception of one of her students when working with the class through Phase 3. In this phase, the students are asked to construct a graph of the relative magnitude of the numerator in terms of the denominator. Elaine admitted to being stumped in the moment when the student drew a graph on the board of two functions on the board. After the class session ended, Elaine figured out the student's conception and how this was reflected in the presentation on the board. This is an example of how perturbations can lead to additional practices, in this case the practice of anticipating student responses (Stein, Engle, Smith, & Hughes, 2008).

Discussion and Conclusions

This preliminary work found converging evidence of perturbations found in industry (Edmondson et al., 2001; Pickering, 1995). Evidence from the study confirmed that novel technology caused perturbations in classroom practice with regard to leader action, communication, expectations of technology, and roles and responsibilities. Additional perturbations in student engagement and mathematical conception were found supporting the tailoring of the framework.

Although this study has limitations in scope, but sets the stage for delving more deeply into the ways in which novel DOs perturb classroom practices so that we can find ways to foster productive perturbations (e.g., supporting cognitive conflict and conceptual understanding) and mitigate the effects of less productive perturbations (e.g., transmitting a lack of confidence to students through the instructor's actions). The framework can guide development of interventions to smooth the path of using technology in classrooms. If teachers are more comfortable introducing and making use of new technology, we will be one step closer to improving student achievement and understanding.

In this study we focus on the use of graphical representations to find similarities and differences regarding how graphs are used in mathematics textbooks and how they are used in STE textbooks and journals. After highlighting the need for our study and summarizing the results of related studies, we present our methods. We then present key preliminary findings comparing how a selected pre-calculus textbook and certain textbooks and journals in various STE fields use graphical representations. We conclude with preliminary implications and questions.

Keywords: Graphs and graph use; STEM; Precalculus

The changing nature of the global market has highlighted the need for improving STEM education in the U.S. In order for the U.S. to compete with other nations, U.S. students need to enter STEM fields. However, currently U.S. STEM education is surpassed by other nations at the elementary and secondary levels (Holdren, Lander, & Varmus, 2011). Further, mathematics often plays the role of a "gatekeeper" for students' continued study and future success in STEM fields (Crisp, Nora, & Taggart, 2009; Gasiewski, Eagan, Garcia, Hurtado, & Chang, 2012). Given this role, we focus on college level mathematics, particularly precalculus and calculus. These levels are particularly important because more than one third of students intending to pursue a STEM major in the U.S. enroll in mathematics remediation (e.g., precalculus) (Radford, Pearson, Ho, Chambers, & Ferlazzo, 2012) and students interested in STEM majors are more likely to declare a non-STEM major after introductory calculus (Bressoud, Carlson, Mesa, & Rasmussen, 2013).

In the larger study we aim to explore the mathematics presented at these levels as it connects to the demands of science, technology and engineering (STE) fields. Our research question is, "How are graphical representations used in precalculus and calculus textbooks similar to and different from the graphical representations used in STE textbooks and practitioner journals?" Specifically, we focus on nuances of graphical representations of two covarying quantities in mathematics textbooks and in STE textbooks and journals. We note that at the time of submission we have examined one precalculus text and have not had the opportunity to examine any calculus textbooks, although this is our intention.

Literature Review

Rybarczyk (2011) and Roth, Bowen, and McGinn (1999) analyzed several textbooks and research journals in biology and ecology respectively, examining every visual representation in these sources (e.g., diagrams, photographs, graphs, tables, etc.). The researchers identified a mismatch in the types of visual representations used in science textbooks compared to journals. For instance, journals used graphical models to represent statistical data more frequently than textbooks. Because these researchers focused broadly on the different visual representations used across science textbooks and journals, they did not address nuances in how these sources represent two covarying quantities. Such nuances can impact students' interpretation of graphs (e.g., if graphs follow conventions commonly maintained in school mathematics) (Moore, Paoletti, Stevens, & Hobson, 2016; Moore, Silverman, Paoletti, & LaForest, 2014). Hence, in this study, we attempt to close this gap by producing a fine-grained analysis of how STE textbooks and journals use graphs to represent two covarying quantities and compare these to introductory college level mathematics textbooks.

Methods

To address our question, we have begun to gather data from textbooks and journals in STEM fields to explore how graphical representations are used in these different sources. To date, we have analyzed the five sources described in Table 1. We used the Open Syllabus Project (OSP, opensyllabusproject.org) to determine which textbooks were frequently used in STE courses.

Table 1

The Source Title, Author or sub-journals and reasons for including the source, by source.

Source Title (Short name)	Author or sub-journals	Reason for including
Glencoe Precalculus (Precalculus text)	*Glencoe Precalculus* 2014	Precalculus textbook from a major publisher.
Chemistry: The Central Science (Chemistry text)	Brown, LeMay, Bursten, Murphy, and Woodward (2012)	3rd ranked textbook in OSP under search for “chemistry”.
Engineering Mechanics: Statics (Statics text)	Hibbeler (2013)	1st ranked textbook in OSP under search for “statics”.
IEEE Journals and Physics Today (IEEE/Physics)	IEEE Electron Device Letters IEEE Network IEEE Communications Magazine IEEE Photonics Journal IEEE software IEEE Journal of Selected Topics in Quantum Electronics Ten IEEE “Transactions” journals Physics Today	IEEE is the world’s largest technical professional organization for engineers and scientists. They publish a variety of journals and magazines aimed at providing a venue for these professionals to share their knowledge. Physics Today, with a circulation over 100,000 is the membership magazine of the American Institute of Physics.
Journal of the American Medical Association (JAMA)		The most widely circulated medical journal in the world, JAMA publishes original research, editorials and reviews within the biomedical sciences.

With respect to the three textbooks, we focused on the graphical representations that the authors emphasized. As such, we analyzed all graphical representations that were included in the body of the text and did not analyze the graphs in the problem sets as it is up to instructor to assign these problems. With respect to the journals, for JAMA, we started with the most recent issue available through our university library (July 5, 2016) and backtracked through May 2016, identifying all articles with at least one graphical representation. For IEEE/Physics, we identified journals whose stated purpose seemed to align with informing practitioners. We then scoured these journals for articles with at least one graphical representation. For every article we found, we coded any graphs we observed in the article. As our coding of the graphs is both a method and result, we elaborate on how we coded each graph in the results section.

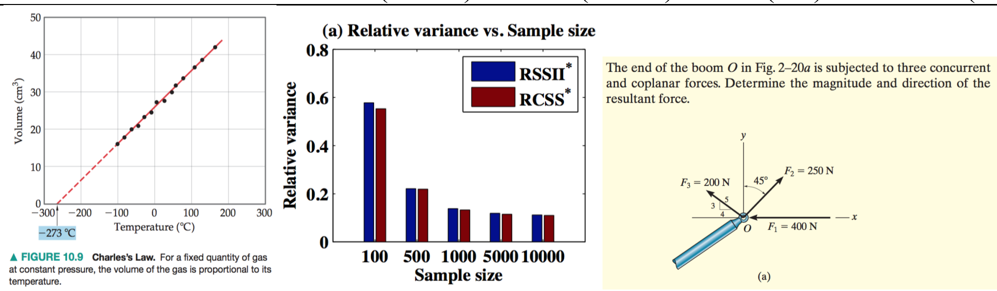
Results

We coded a total of 850 graphs across the five sources (Table 2). Our initial goal was to code the extent to which these sources used graphs to represent relationships between covarying quantities (Covarying Quantities in Table 2, Figure 1a). However, because certain sources used graphs for other purposes, we also coded the number of graphs in each source that were used for these purposes. For instance, and as reported by Rybarzyk (2011) and Roth, Bowen, and McGinn (1999), several sources often presented statistical graphs (Statistical Graphs in Table 2, Figure 1b). Other sources (specifically the Statics text) overlaid a coordinate system over an object or phenomena to help mathematize the situation (Imposing Axes in Table 2, Figure 1c). Table 2 presents the number of each type of graph we observed in each source. We highlight the prevalence of graphs representing two quantities in the precalculus text, chemistry text and IEEE/Physics journals. Statistical graphs played a smaller but still significant role in journal articles when compared to textbooks. Further, we note that the Engineering Statics text almost exclusively used graphs to impose axes on a given object or phenomena.

Table 2

The total number of graphs (N) as well as the number of graphs representing two quantities, statistical graphs, imposing axes, and imaginary planes versus the source.

Source	N	Covarying Quantities	Statistical Graphs	Imposing Axes	Imaginary Plane
Precalculus text	299	273 (91.3%)	23 (7.7%)	0 (0%)	3 (1.0%)
Chemistry text	74	74 (100%)	0 (0%)	0 (0%)	0 (0%)
Statics text	255	3 (1.2%)	0 (0%)	252 (98.8%)	0 (0%)
IEEE/Physics	166	144 (100%)	22 (13.3%)	0 (0%)	0 (0%)
JAMA	56	35 (62.5%)	21 (37.5%)	0 (0%)	0 (0%)



(a) (b) (c)

Figure 1. An example of a graph representing (a) two covarying quantities from Brown et al. (2012, p. 390), (b) statistical information from Li, Yu, Mao, and Jin (2016, p. 13) and (c) imposing axes on a situation from Hibbeler (2013, p. 37).

Because our main focus was on how these sources use graphs to represent the relationship between covarying quantities, all further analysis focused on graphs that fit this subcategory. We were interested in how frequently graphs represent two decontextualized quantities (typically x and y), one contextualized and one decontextualized quantity, or two contextualized quantities (e.g., Figure 1a) (Table 3). We note the significant differences across these sources in regards to using graphs to represent contextualized quantities. Unsurprisingly, STE textbooks and journals almost exclusively used graphs to represent two contextualized covarying quantities. In contrast, graphs in the precalculus textbook rarely represented two contextualized quantities. We found the lack of contextualized examples in the precalculus textbook surprising, and conjecture that we may obtain a different result when we examine calculus textbooks and possibly precalculus textbooks from other publishers.

Table 3

The total number of graphs representing two covarying quantities (CQ), the number of graphs representing two decontextualized, one contextualized one decontextualized, and two contextualized quantities versus the source.

Source	CQ	Two decontextualized	One contextualized one decontextualized	Two contextualized
Precalculus text	273	270 (98.9%)	1 (0.4%)	2 (0.7%)
Chemistry text	74	2 (2.7%)	1 (1.4%)	71 (95.9%)
Statics text	3	0 (0%)	0 (0%)	3 (100%)
IEEE/Physics	144	0 (0%)	0 (0%)	144 (100%)
JAMA	35	0 (0%)	0 (0%)	35 (100%)

Another aspect of graphs representing two quantities that we examined across these sources was the frequency with which conventions with respect to the location of the intersection of the coordinate axes was maintained (Table 4). We coded graphs representing two quantities as either having axes intersect at (0,0), as having axes intersecting at a value other than (0, 0) (e.g., Figure 1a), or if the graph had no scale and we were unable to infer the coordinate values of the intersection of the axes. We note that all graphs in the precalculus and chemistry textbooks had axes that intersected at (0, 0). However, practitioner journals followed this convention with less frequency; it was typical for the intersection of the axes in these sources to not be at (0, 0).

Table 4

The total number of graphs representing two covarying quantities (CQ), the number of these graphs with the intersection of the axes at (0, 0), not at (0, 0) and no scale versus the source.

Source	CQ	Axes intersect at (0, 0)	Axes do not intersect at (0, 0)	No Scale
Precalculus text	273	273 (100%)	0 (0%)	0 (0%)
Chemistry text	74	74 (100%)	0 (0%)	0 (0%)
Statics text	3	0 (0%)	0 (0%)	3 (100%)
IEEE/Physics	144	40 (27.8%)	89 (61.8%)	15 (10.4%)
JAMA	35	19 (54.3%)	16 (45.7%)	0 (0%)

We conjectured that mathematics textbooks used time as a quantity under consideration frequently and wanted to compare how frequently other sources used time. Hence, for all graphs representing covarying quantities with at least one contextualized quantity, we coded if time was represented on the graph (Table 5). Articles in JAMA represented time in a majority of their graphs representing contextualized quantities. The chemistry text and IEEE/Physics journals had significantly more graphs in which time was not a quantity under a consideration.

Table 5

The total number of contextualized graphs, graphs in which time is a quantity under consideration, and time is not a quantity under consideration by source.

Source	Contextualized Graphs	Time is a quantity under consideration	Time is not a quantity under consideration
Precalculus text	3	1 (33.3%)	2 (66.7%)
Chemistry text	72	10 (13.9%)	62 (86.1%)
Statics text	3	0 (0%)	3 (100%)
IEEE/Physics	144	35 (24.3%)	109 (75.7%)
JAMA	35	25 (71.4%)	10 (28.6%)

Preliminary Discussion, Implications, and Future Research

One important preliminary implication of our results is the importance of preparing students who may enter STE fields to use coordinate systems both to represent two covarying quantities and to mathematize a situation or phenomena. Although researchers have focused on students' understandings of representing relationships between covarying quantities (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu 2002; Kozhevnikov, Motes, & Hegarty, 2007; Thompson, 2011) there has been less focus on students' use of coordinate systems to help mathematize an object or phenomena. There have been some efforts to examine the mental operations that students' use when imposing axes onto a situation or phenomena (Lee, 2016; Lee & Hardison, 2016; Piaget & Inhelder, 1967), however, the extent to which the Statics textbook uses coordinate systems to mathematize a phenomena or situation reinforces the need to continue to examine students' understandings of this use of coordinate systems.

A second implication relates to previous researchers' findings in regards to students' interpretations of graphs. There is a large body of research examining individuals' struggles interpreting graphs in both mathematics and the sciences (e.g., Glazer, 2011; Leinhardt, Zaslavsky, & Stein, 1990; Shah & Hoeffner, 2002). For instance, several researchers have indicated students make iconic translations, interpreting graphs intended to represent two covarying quantities as an image of the situation (Carlson et.al., 2002; Leinhardt et al., 1990; Monk, 1992). We conjecture the lack of contextualized graphs in precalculus curriculum may help explain some of the observed struggles students encounter when interpreting contextualized graphs. Consistent with Shah and Hoeffner's (2002) argument, if graphs are presented only abstractly, students are likely to struggle translating this knowledge to graphs in contextualized situations; future research is needed to examine the validity of this conjecture.

A third implication relates to graphing conventions. Researchers (Gattis & Holyoak, 1996; Moore et al., 2016; Moore et al., 2014) have indicated that students often maintain what are conventions to teachers and researchers as inherent aspects of their mathematics. These findings reflect what students experience with their textbooks. If students repeatedly experience graphs in which these conventions are maintained, they may develop mathematical understandings that are constrained by such conventions. Hence, it may be unsurprising when students struggle to make sense of situations in which these conventions are not maintained.

A final implication relates to the extent to which different sources represent time as a quantity under consideration. Entering the study, we conjectured time would be a predominant quantity used in mathematics textbooks but found this was not the case in the precalculus textbook. In JAMA time was a quantity under consideration in a majority of graphs but in the chemistry textbook and IEEE/Physics journals time was a quantity under consideration in less than a quarter of the graphs. The extent to which time is used as a quantity under consideration in various STEM fields requires further examination.

Intended Questions

We intend to examine more precalculus and calculus textbooks. What other sources (both mathematics or sciences textbooks or journals) would be good to consider in this study? Why? What other data would be worth analyzing within the graphical representations? Why?
What do you see as some other possible implications of a study like this? What could we do to make our implications stronger?

Student Conceptions of Three-Dimensional Solids

Stepan Paul
UC Santa Barbara

Monica Mendoza
UC Santa Barbara

In the study presented in this paper, the authors aim to construct a model for the processes by which students in a multivariable calculus class conceptualize solid regions in three dimensions. We designed and recorded student work from several tasks in which students must decode a description of a solid figure and answer questions assessing the strength of their conception of the figure. Presented here are findings from the analysis interviews and group work on one of these tasks in which students are asked to build a clay model of the solid region described by a set of inequalities in three variables.

Key words: multivariable calculus, spatial reasoning, three-dimensional solid

Introduction

As motivation for our study, we consider the following problem, variations of which appear in many multivariable calculus textbooks.

Let E be the solid region in $\mathbb{R}^3$ defined by the following set of inequalities.

$$\begin{array}{ccccc} 0 & \leq & x & \leq & 1-z \\ z^2 & \leq & y & \leq & 1 \\ 0 & \leq & z & & \end{array} \tag{1}$$

Find the volume of E.

In anecdotal observations of student work, the authors found that students would attempt to solve this problem, apparently without attempting to conceptualize the solid figure E as a subset of $\mathbf{R}^3$. While this observation calls into question the validity of such problems in building and assessing students' understanding of volume, it also raised the question, through what process would students decode sets of inequalities such as (1) as a solid figure?

In the present study, we use data from 76 undergraduate multivariable calculus students (split into 29 response groups) collected in individual interviews and recorded group work, to identify common strategies and obstacles in decoding, processing, and communicating representations of solid figures.

Theoretical Background

There is a rich history of studying student conceptions of three-dimensional solids in the context of spatial reasoning. Much of the work in this area relies on methodology in which subjects must interpret a two-dimensional drawing of a solid figure and then perform some spatial task such as rotation (Bodner, Guay, 1997) or identification of cross-sections (Cohen, Hagerty, 2007). However in studies where a two-dimensional drawing is used, Gorgorió (1998) warns, "individuals' demonstration of their spatial orientation ability depends also on their abilities for interpreting and communicating spatial information." Indeed it has been shown that student misconceptions can lead to errors both during interpretation (Parzysz, 1988; Hallowell, et al, 2015), and communication (Ben-Chaim, Lappan, & Houang, 1989; Hershkowitz, 1990). Thus, building on the paradigm set forth by Parzysz (1991), we model student responses to the tasks as information which has passed through three phases: decoding, processing, and communication.

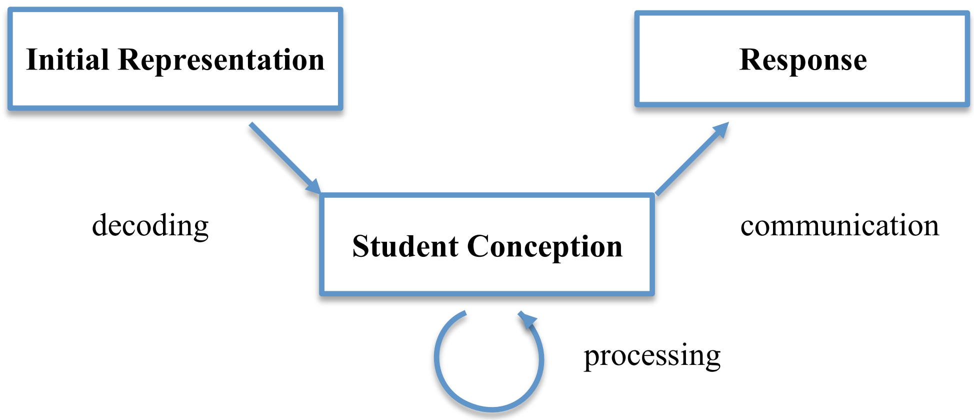

Figure 1: Model for student responses. This figure illustrates the flow of information resulting from students' response to a task. Errors or loss of information may occur in each phase.

The *decoding* phase encompasses interpretation of the given representation. The *processing* phase includes any mathematical or visuospatial treatments the subject performs, as well as conversions between registers. Finally, in the *communication* phase, subjects encode their responses to the task. Included in the communication phases are written work, drawings, conversation with other students, and building physical models.

In a multivariable calculus class, students are asked to become fluent in interpreting descriptions of figures in $\mathbf{R}^3$ which come in a variety of forms: written descriptions, equations or inequalities in three variables, two-dimensional drawings, and combinations of these. Viewed from the theoretical framework of semiotic representation theory, this requires students to coordinate representations in several registers (Duval, 1993), and perform conversions from one register to another (Duval, 2006). Trigueros and Martínez-Planell (2010) investigate how students use this coordination of registers to perform tasks related to surfaces and equations in multivariable calculus. Our study builds on this work by applying the same theoretical framework to solid figures in three dimensions.

Methodology

We designed several tasks meant to elicit responses which would give insight into the strategies students use and the obstacles they face in decoding and processing representations of solid figures. For this preliminary report, we will discuss results from Task 2 below.

Task 2: Let G be the solid region described by the inequalities

$$\begin{array}{ccccc} 0 & \leq & x & \leq & 1 \\ 0 & \leq & y & \leq & 1 \\ 0 & \leq & z & \leq & x+y \end{array}$$

a Build the region G out of clay

b Write 2–4 sentences explaining how you determined the shape of the solid region from the inequalities.

Like many of the tasks in our study, Task 2 pairs a *close* representation of the solid (Parzysz, 1988)—a three-dimensional model—with the representation type we wish to study—in this case, a set of inequalities. Underlying the rationale behind this pairing is the hypothesis that students will face little difficulty in decoding the close representation, nor in communicating a robust enough conception of the figure into the medium of a clay model. Under this assumption, errors in student work on Task 2 could be attributed to misunderstandings or miscalculations related to the decoding and processing of the sets of inequalities[1].

We used a grounded theory approach to collect and analyze the data from participants in the study. Data collection involved video-taping students working in groups on the tasks during nine class sections from two different instructors in the spring and summer of 2016. We also collected students' written work and photographed clay models produced by the students. Additionally, we conducted individual interviews with four students. Through axial coding (Glaser & Strauss, 1967), we established categories for responses to the task, and identified several distinct strategies used by the students.

Preliminary Results

Here we present preliminary findings from analysis of Task 2 above. Four categories of clay models emerged from the coding of student responses: rectangular prism (P), tetrahedron/pyramid (T), conflicted (C), and accurate (A); examples of each are shown in Figure 2 below.

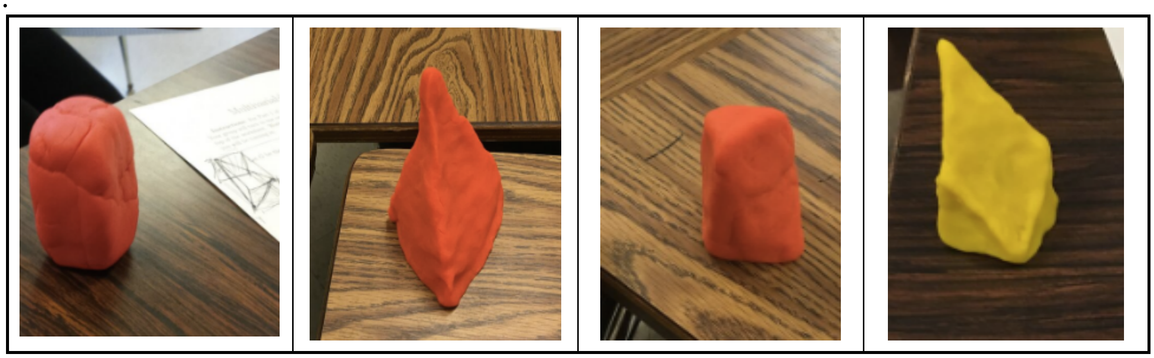

Figure 2: Examples of the four categories of responses. From left to right: rectangular prism (P), tetrahedron/pyramid (T), conflicted (C), and accurate (A).

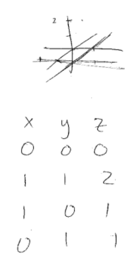
[1] This assumption was not entirely accurate since some students who demonstrated a robust conception of the solid made errors in the model the produced related to the relative scaling in the *x*, *y*, and *z* variables.

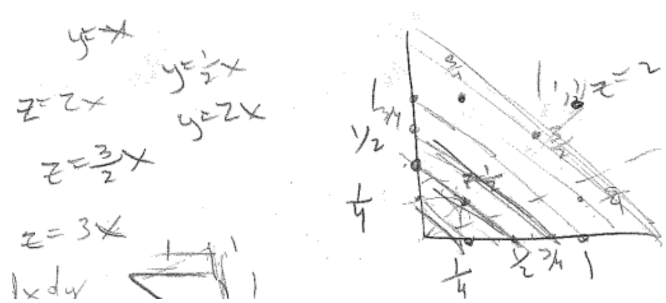
The categories of (P) and (T) are self-explanatory. A clay model was classified as accurate (A) if it reflected all the correct faces and edges of figure described by the given inequalities; models in which the x, y, and z variables were scaled differently could still be considered accurate. Models which fell into none of the other three categories were classified as conflicted (C); in all cases, these models were some hybrid between a pyramid and an accurate model.

Additionally, we identified several distinct strategies that were used by students while completing the tasks, which are described below.

1. Maximum/Minimum: Identifying the maximum and minimum values for each variable—in this context, this amounts to identifying that $z \leq 2$. Example: "The first two inequalities are the same, so we concluded that the base of the region is a square. The third inequality is dependent on x and y, and the largest value is 2, so the region can range from a rectangular prism to a 2d square."
2. Covariation/Path: Using language that invokes an image of two variables changing at the same time, often to describe an edge of the figure or a path along a face. Example: "the z starts at zero and the origin corner at the square then goes to 2 at the (1,1) corner."
3. Finding Vertices: Locating extremal points of the figure by converting some subset of the inequalities to equalities and solving. Example: see Figure 3.
4. Level Curves: Sketching level curves of $z = x + y$ in order to understand the top face of the figure. Example: see Figure 3.



Finding Vertices



Level Curves

Figure 3: Examples of Finding Vertices and Level Curves.

We organized strategies by response category, as shown in Table 1. The most notable trend is that response groups which produced an accurate model seemed to use a wider range of strategies than those which produced other models.

Applying our model for interpreting student responses from Figure 1, we can attempt to infer in which phase information was lost or mishandled from both the response type and the strategies used. For example, we hypothesize that for students who responded model type (P), most of the information never made it past the decoding phase—that students did not correctly interpret the meaning of the inequalities taken as a set. For students who responded with model type (T), it seemed that some information was lost in the decoding phase, and that only minimal processing had taken place. For model type (C), a hybrid between (T) and (A), the mishandling of information seemed to occur in the processing phase; these students had a conception of the figure in one representation register, but failed to accurately convert it to another.

Table 1: Strategies used, organized by response category. Responses submitted by a group of students were treated as a single response. In many cases, groups reported using more than one strategy, which is reflected in the table.

Student's Strategies	Rectangular Prism (P)	Tetrahed-ron/Pyramid (T)	Conflicted (C)	Accurate (A)
Responses in this category	5	2	7	15

Conclusions

We plan on analyzing the rest of our collected data in a similar vein. We remain interested in using this information as a base line to flesh out the three phases of decoding, processing, and communication in further analysis of student's thinking on solid regions in $\mathbf{R}^3$.

Questions for Audience

1. For those who teach multivariable calculus: How do you communicate solid figures to students in the context of triple integrals and volume? What big ideas do you hope your students will get out of this part of your course?
2. The use of three-dimensional models of unfamiliar three-dimensional solids, constructed using 3D printing or clay, is somewhat novel to our research. What other lines of inquiry could we investigate with this medium?

The Effects of the *Epsilon-N* Relationship on Convergence of Functions

Zackery Reed
Oregon State University

Much work has been done in recent years to study students' formulations of formal limiting processes. One of the most common goals is to foster a productive understanding of the relationship between the error bound epsilon and the domain of the convergence; what is called a range-first perspective. My study examined an advanced calculus student's understanding of the relationships involved in convergence of functions, and how his prior experience with limits influenced his concept image. I unpack his cognitive organization of the dependence relationships between epsilon, N, and x in functional convergence. This case study demonstrates the effects of a persistent understanding that ϵ depend on N in the convergence of sequences.

Key words: Sequences of Functions, Formal Definition of Convergent Sequences, Advanced Calculus

Mathematics students study convergent sequences throughout their college career. Formalizing sequential convergence provides an important yet difficult stage in the development of students' reasoning about advanced mathematics. A vital component of the formal definition of sequential convergence is the relationship between ϵ (*epsilon*) and the critical index N. I call this the *epsilon-N* dependence relationship, which mirrors the *epsilon-delta* dependence relationship within the formal definition of continuity of a function.

In advanced analysis courses, sequences take on forms beyond just real numbers. In particular, advanced calculus students encounter sequences of continuous functions towards the end of their instruction. The convergence of such functions is defined in a manner that is structurally similar to the familiar convergence of real numbers, but it has the added complexity of also accounting for variation within the domain of the function. Thus, keeping track of the definition's quantifiers becomes vitally important to understanding the different types of convergence and their implications on the functions themselves.

While conducting a larger study involving student conceptions of metric spaces, I interviewed two students to examine their concept images and definitions (Tall & Vinner, 1981) pertaining to convergence of function sequences. A case study of one student's interview demonstrates how reversal of the *epsilon-N* relationship may persist beyond convergence of real numbers to affect the convergence of functions. In this preliminary report, I will discuss this case to demonstrate the effect of this reversal on convergence of functions, and I will go into detail about some cognitive conflicts that seemed to arise within the student's concept image. I seek to answer the following research questions: 1) How does the addition of the domain value x into the definition for functional convergence affect student understanding of convergence?, and 2) Does reversal of the *epsilon-N* dependence relationship in real number convergence affect the dependence relationships for functional convergence?

Literature Review

There is an abundance of research on student initial understanding of limits, the potential difficulties that arise and initial interpretations of limit definitions (Bezuidenhout, 2001; Cornu, 1991; Cottrill et al., 1996, Davis & Vinner, 1986; Roh, 2008; Roh, 2009; Tall, 1992; Tall &

Vinner, 1981; Williams, 1991). There have also been investigations into students' intuitions about the nature of limits (Oehrtman 2003; Oehrtman 2009). Much of these investigations, however, pertained to students' intuition and reasoning with informal limits rather than formal understanding.

Targeted glimpses of student understanding of formal limit definitions began with Swinyard (2011). In his teaching experiment, two students successfully reinvented the formal definition of the limit of a function. Swinyard and Larsen (2012) also suggested some strategies for fostering productive generation of formal limit definitions such as a focus on the error bounds. This strategy is called adopting a range-first perspective as opposed to a domain-first perspective where the control of the convergence is given to the variation in x values. This was adapted to sequences by Oehrtman et al. (2014) to also include the index n in the domain-first perspective for purposes of sequential convergence study where students reinvented the definition of formal sequence convergence.

Other efforts have also been made to investigate student understanding of the formal definition of limits with special attention paid to the relationships between the variables controlling the limiting process (Adiredja, 2013; Adiredja & James 2013; Adiredja & James 2014).

This study will continue the literature on student understanding of formal limit definitions with specific attention to the relationships of the variables within convergence of sequences in advanced settings.

Theoretical Perspectives

Concept Image and Concept Definition

Formal mathematics often entails understanding a particular concept via its definition. Accompanied with each concept, however is also a collection of cognitive organizations beyond just the definition. This calls for a distinction to be made between the collection of cognitive objects that are brought to bear upon recollection of the concept, and the words that compose the definition of the concept. This is the distinction between a thinker's concept image and concept definition (Tall & Vinner, 1981).

Tall and Vinner define the concept image as the "total cognitive structure that is associated with the concept". This includes examples, graphs, images, relationships, and even the concept definition. The concept definition is the formal language that the student uses to identify the concept. This definition may be a personal definition given by the student, or it might be the formal definition accepted by the mathematical community. In this report, I use the notions of concept image and concept definition to characterize the student's conceptions.

Domain-First and Range First Perspectives

Informal limit notation is usually written in a manner such as $\lim_{n\to\infty} a_n$ or $a_n \to a$. In accordance with this notation, students transitioning from informal to formal notions of the limit may focus first on how the variation of the index affects the sequence entries. This is called a domain first perspective. Swinyard and Oehrtman (2014) suggest that focusing on the behavior of the range values before focusing on the domain values will foster correct interpretation and generation of the quantifiers within the formal limit definition.

Mathematical Discussion

I now briefly offer a discussion of the mathematics involved in this study to situate the subsequent discussion of the data. The convergence of a sequence of functions is an advanced concept that is encountered by mathematics students towards the end of the advanced calculus sequence. There are two types of convergence, however we will only be discussing point-wise convergence.

Because of the nature of convergence in metric spaces, the formal structure of functional convergence is very similar to that of the familiar convergence of real number sequences. A sequence of real numbers (a_n) converges to a real number a if $\forall \epsilon > 0$, $\exists N \in \mathbb{N}$ such that $\forall n \geq N$ we have $|a_n - a| < \epsilon$. For this type of convergence, the error bound ϵ controls the behavior of the sequence, since as ϵ decreases, a critical index N must be found.

A sequence of functions(f_n) converges point-wise to a function f on a domain D if $\forall \epsilon > 0$ and $\forall x \in D$ $\exists N \in \mathbb{N}$ such that $|f_n(x) - f(x)| < \epsilon$. Note that at each x value in the domain of convergence we have the sequence of functions forms a convergent sequence of real numbers, thus the critical index N is controlled by both x and ϵ.

Methods

The episode reported on was part of a larger study exploring student's reasoning about metric spaces. This involved conducting teaching experiments with two students, each teaching experiment consisting of six hour-long sessions (Steffe & Thompson, 2000) with a single student. The particular episodes being explored in this report were semi-structured and task based (Hunting, 1997) so that student activity could be observed.

The participants in the study were both mathematics majors at a large northwestern university who had completed the advanced calculus instructional sequence and were studying real analysis applied to finite dimensional vector spaces at the time of the interviews. Both students demonstrated proficiency in their advanced calculus courses and had seen functional convergence before.

Each interview was video recorded, and the sessions have been reviewed multiple times highlighting episodes illuminating aspects of the students' concept images as well as sources of cognitive conflict and their resolution. The particular episodes reported on are transcribed along with time stamped pictures highlighting diagrams or writing done by the students.

Results

The goal of this interview was to explore Kyle's concept images and definitions pertaining to different types of convergent function sequences. This set the stage for a new metric space to be explored, and I was able to examine Kyle's concept image for convergence of functions.

The first step of the interview was to establish Kyle's concept definition for point-wise convergence of functions. This type of convergence would have been Kyle's first experience with functional convergence of any kind in the classroom. Kyle's first concept definition, the formulation I claim that is most relevant to his understanding, is given here: A sequence of functions $\{f_n\}$ converges pointwise to f if $\forall x \in D$, $\lim_{n\to\infty} f_n = f$. Kyle soon corrected this to add in $f_n(x)$ and $f(x)$.

This is significant because Kyle first chose to use the conventional limit notation given in a calculus setting instead of incorporating the ϵ-N definition. Kyle demonstrated a domain-first focus throughout the majority of the interview, and this focus on N controlling the limiting process was first displayed in his personal concept definition.

After a brief discussion about what the elements of his definition meant, I prompted Kyle to write a formal definition. When asked to discuss what the definition means, he said:

Kyle: When we are trying to show point-wise convergence we are trying to find some ϵ that will always be greater than the difference between our sequence and our function, however because we are selecting our ϵ and then selecting our x then this ϵ will actually be a function of x and the N from the naturals.

As he said this he wrote out $\epsilon(x, N)$. As we began to unpack the nature of the dependence of ϵ on N and x, he made the following statement:

Kyle: N plays the same role that it always plays when we're talking about convergence. It's the last index such that every index past this you're going to have this property $[|f_n(x) - f(x)|]$ be true, so in so much as that ϵ is pretty much always dependent on that natural because you want to say that past this natural N, you know this ϵ is always going to be true.

As we continued discussing the nature of the ϵ dependence on N and x, we discussed some typical examples of functions that converge in a point-wise manner such as x^n and x/n. In each of these examples Kyle would draw an ϵ window around the values of the functions at a particular point x, reinforcing that a different ϵ window was necessary as N increased without bound and as x varied across the domain. Kyle continually demonstrated that the index increasing without bound was the driving force of the convergence of the functions, verifying that he had adopted a domain-first perspective.

This domain-first perspective, which I infer had carried over from his experience with convergence of real numbers, now had an added complexity of incorporating the domain of the function as well into his scheme for convergence. As an example of this, Kyle described the following *x-N-epsilon* relationship as we examined the sequence of functions x/n:

Kyle: but if we think about what n is, like if we think about the Archimedian property. If you are thinking about $1/n$ as being less than ϵ, then that means that $2/n$ would imply that $1/n$ is less than $\epsilon/2$. So if you're increasing the values of these x's, your ϵ is going to get smaller and smaller.

This of course is not the case as there is no inherent relationship between ϵ and x. As we further discussed the effect of fixing an x value, Kyle had a moment of cognitive conflict where he commented that he didn't really mean ϵ was a function of x, just that if you changed the x you would change the ϵ, but then since we do this for all positive $epsilon$ maybe "$\epsilon/2$ is just as good as ϵ". Here I think he has a moment where he is considering the universal quantification of ϵ, but his reversal scheme is still his dominant stance.

His reversal was evident later when Kyle wrote out that to show x^n converges at $x = 1/2$ we needed to bound $(.5^n)$ by ϵ, and so we take the "nth root of *epsilon*" . This would happen if we had already found a critical index N and needed to find an error bound that worked for that N. This task then illuminated Kyle's potential sources of cognitive conflict which allowed a resolution to be found. When he could not verify the convergence in the manner he wanted, I suggested using the fact that 2^n is greater than n for all n, and so then he tried bounding $1/2^n$ by $1/n$ which could then be bounded by ϵ. When trying to prove the convergence of $1/n$, he recalled the Archimedean property, and after trying to find the ϵ using the property, I reminded him that the Archimedean property works for a fixed ϵ and showing that there exists some N that bounds $1/N$ by ϵ. This served to reorient Kyle's stance on the dependence.

By resolving that the N is found for a fixed ϵ, he immediately restructured his construct on not only the convergence of $1/2^n$ but also for all of his previous claims of dependence. This was then reinforced by showing x^n converged for different values of x, which altered the ciritcal index even with a fixed ϵ. After realizing that varying x and ϵ could potentially change the critical index, he claimed that N was doing all the work of convergence, thus reorienting his understanding of the dependence relationships.

Discussion and Conclusion

This episode is meant to serve as an example of the persistence of ϵ dependence within more advanced mathematical settings and the effect it can have on the understanding of more complicated processes than just convergence of real numbers. I argue that because the informal perspective on a limit was so ingrained in Kyle's concept image, it caused him to project the dependence of ϵ on the domain values x as well, even though no relationship should exist at all between ϵ and x. While Kyle could readily recall the formal concept definition of functional convergence, and even reason through a few examples, his personal concept definition dictated the contradictory *epsilon-N-x* relationship that seemed to permeate his concept image.

I contend that the main source of his interpretation of the dependence relationship was his previously held notion that ϵ depended on N for convergent real-number sequences. This demonstrates a lack of attention to the use of quantifiers since he correctly understood the need to fix an x value in evaluating the convergence. His proficiency of fixing x played a vital role in his cognitive re-organization when he observed the convergence of x^n at different fixed values of x and ϵ after the discussion about the Archimedian Property. This suggests a potentially strong instructional point to make is that point-wise convergence of functions is the convergence of a continuum of real-valued sequences all at once.

One final observation is that his understanding of the limiting process was robust enough to adjust upon integrating the Archimedean Property into his concept image. Kyle was secure in the convergence of a few key examples of function sequences so that he could experiment with his process of proving the functions converged to the limit he knew them to have. This case study highlights the complex relationships that exist between the different variables involved in functional convergence and the potential compounding of the *epsilon-N* reversal. An instructional takeaway from this is the importance of original instruction of formal convergence, as well as the need for attention to quantification in the interpretations of formal definitions. This study also serves as a first look into student understanding of convergence beyond that of real numbers.

Questions and further directions

This of course was a first glance at student reasoning with function convergence, and so there is still much to explore in this area. Clearly there is a natural relationship between understanding of convergence of real numbers and convergence of functions. Thus an extension of this study is to introduce function convergence to students with a robust understanding of real number convergence.

The following are for further discussion: 1) Are there ways in which we can investigate the relationship between the types of convergences? 2) Are there ways to specifically target universal quantification that might elicit useful understanding of the need to vary x and *epsilon* in functional convergence? 3) As pointwise convergence is the evaluation of a continuum of real-valued sequences, is there a way to leverage this natural connection to sequential convergence of real numbers in future investigations?

The Effect of Attending Peer Tutoring on Course Grades in Calculus I

Brian Rickard
University of Arkansas

Melissa Mills
Oklahoma State University

Tutoring centers are common in universities in the United States, but the effects of tutoring on student success are often not examined statistically. This study utilizes multiple regression analysis to model the effect of tutoring attendance on final course grades in Calculus I. Our model predicted that every three visits to the tutoring center would increase a students' course grade by one percent, after controlling for prior academic ability. We also found that for lower achieving students attending tutoring had a greater impact on final grades.

Keywords: Calculus I, multiple regression, peer tutoring, undergraduate mathematics

Introduction and Literature Review

Although many institutions across the nation offer free tutoring to students (Johnson & Hansen, 2015) with the goal of improving lower division instruction, there have been few published studies investigating the impact of attending tutoring on performance (Xu, Hartman, Uribe & Mencke, 2001). A common approach is to simply look at success rates for students who attended peer tutoring versus success rates for students that did not attend tutoring (e.g. Garcia, Morales & Rivera, 2014; Jimenez, Acuna, Quiero, Lopez & Zahn, 2015). While this may provide some evidence that tutoring had a positive impact, we argue that this type of analysis is over-simplified. Unfortunately, reporting on student performance and retention in an in-depth manner requires resources in terms of staff time and collaboration with other disciplines that many tutoring centers simply do not have (MacGillivray, 2009).

Quantitative measures of the impact of tutoring on grades can be difficult because students tend to self-select and students of different mathematical abilities may attend tutoring for different reasons (Topping, 1996). One way to account for these factors is to use multiple regression. Regression models have been used to show that attending Peer Assisted Learning sessions can improve the grades of mathematics majors (Duah, Croft & Inglis, 2013) and that attending optional tutoring can improve the grades of college algebra students while controlling for students' mathematical abilities (Xu, et. al, 2001). This study will add to the literature by using multiple regression to measure the impact of attending optional tutoring sessions at the Mathematics Learning Success Center on course grades for Calculus I students at Oklahoma State University.

The research questions for the study are:

1. What is the effect of attending optional drop-in tutoring offered by the MLSC at Oklahoma State University on Calculus I students' course grades, after controlling for their high school math GPA and ACT math sub-score?
2. Do we see that attending optional drop-in tutoring at the MLSC benefits students of lower mathematical ability more than stronger students?

Method and Data

To evaluate the effectiveness of mathematics tutoring in calculus, student academic and tutoring data were collected from a public 4-year research university in the Midwest with an enrollment of approximately 25,000 students. Study participants include all 640 students enrolled in Calculus I for the fall 2015 semester. Since attending tutoring sessions is voluntary and students receive no credit for participation in tutoring, self-selection bias is acknowledged as a limitation of this study.

Data collected for the study includes: student course grade (percentage) in Calculus I, high school math grade point average, ACT math score, number of visits to the tutoring center, and duration of visits at the tutoring center. For visits with a missing duration, the average of the student's other visit durations is used as an estimate. Of the 640 students enrolled in Calculus I, there were 390 students who visited the tutoring center a total of 5193 times.

Table 1. Descriptive Statistics

	Mean	Standard Deviation	Minimum	Maximum
Final Course Grade (Percent)	73.93	22.49	3.44	101.46
High School Math GPA	3.51	0.58	1.63	4.75
ACT Math	26.55	3.60	14	36
Visits	8.11	13.75	0	102
Estimated Total Time (Minutes)	738.45	1435.43	0.00	11549.03

Of the 640 students in the study, 390 (60.9%) visited the tutoring center at least one time. For the students who did visit the tutoring center, the average number of visits was 13.3 per student with an average visit length of 78 minutes. These students had slightly higher prior academic achievement scores with an average high school math GPA of 3.58 and math ACT of 26.8 compared to 3.38 and 26.2 respectively for those who did not visit the tutoring center. The average course grade earned for students who attended tutoring was a B (80.4%) while the average for those who did not attend tutoring was a D (62.0%). There were 534 students who completed the final exam and 78 (12.2%) withdrew from the course.

Overall, as the number of times a student visits the tutoring center increases, so does the course grade. However, on average, students with a higher frequency of visits also had a higher high school math GPA, so it is unclear at this point whether the increase in exam score is a result of increased tutoring visits or prior math ability (see Table 2).

Table 2. Scores by Tutoring Visit Category

	Number of Students	Average Final Exam Score	Average High School Math GPA
0	250	62.0	3.38
1-5	169	78.2	3.52
6-10	64	80.3	3.54
11-20	72	82.3	3.65
21+	85	83.3	3.68
Overall	640	73.9	3.51

Results

To investigate the relationship between the variables, Pearson r correlations were computed (see Table 3). The correlation between visits and estimated total time is close to 1 which indicates possible multicollinearity and that likely only one of these variables will be needed in the final model.

Table 3. Correlation Matrix

	Final	High School Math GPA	ACT Math	Visits
High School Math GPA	0.50*			
ACT Math	0.42*	0.42*		
Visits	0.26*	0.15*	-0.03	
Estimated Total Time	0.23*	0.12*	-0.05	0.94*

Note. * significant at $p < 0.05$

Simple linear regressions using each independent variable separately as a predictor of the dependent variable indicate that each independent variable individually is a significant predictor of course grades. The initial multiple regression model will therefore include all four independent variables. Analysis of this model indicates significant overall statistical predictive ability, $F(4, 455)=60.63$, $p<0.0001$. The R^2 of this model is 0.348, which indicates that approximately 34.8% of the variance in course grades can be explained by the predictor variables. In this model, Estimated Total Time has a large p-value of 0.9016 indicating it is unlikely to be a meaningful predictor. Removing this variable and analyzing the subsequent model with predictor variables of high school math GPA, math ACT, and visits results in a significant overall model, $F(3, 485) =85.27$, $p<0.0001$, and an R^2 of 0.345. Each independent variable was found to have a p-value of less than 0.0001 indicating a they are all likely meaningful predictors. The R^2 values indicate the proportion of variance in course grades that can be uniquely accounted for by that predictor variable. Coefficients, correlations and collinearity statistics are found in Table 4.

Table 4. Multiple Linear Regression Results

	Parameter Estimate	P-Value	Partial R^2	Tolerance
Constant	-21.677			
High School Math GPA	12.993	<0.0001	0.13	0.81
ACT Math	1.782	<0.0001	0.10	0.83
Visits	0.333	<0.0001	0.06	0.97

The parameter estimates in Table 4 indicate the change in predicted course grade for each unit change in the predictor variable. As such, the parameter estimate of 0.333 for visits indicates that a student's course grade is predicted to be approximately one percentage point higher for every three visits to the tutoring center. The prediction equation for this regression is: Final Course Grade = -21.677 + 12.993(High School Math GPA) + 1.782(ACT Math)+0.333(Visits).

Interaction

It is also of interest to determine if students of lower mathematical ability, determined by high school math GPA, benefit more from tutoring than students with higher mathematical ability. In Table 5, mean course grades are compared between those who did attend tutoring and those who did not at different categories of high school GPA. From this table, it does appear that lower mathematical ability students benefit more from tutoring with a decreasing difference in mean course grades with increasing mathematical ability.

Table 5. Mean Final Exam Score by HS GPA and Tutoring Participation

HS GPA Category	No Tutoring	1+ Tutoring Visits	Mean Difference
2.00-2.49	25.9	66.6	40.7
2.50-2.99	56.4	72.7	16.3
3.00-3.49	58.1	74.2	16.1
3.50-3.99	71.6	86.4	14.8
4.00+	78.5	87.2	8.7

To investigate this analytically, a regression with an interaction between high school GPA and number of visits is analyzed. The results from this analysis are found below in Table 6. It should be noted that the independent variables in this analysis have been centered to mitigate multicollinearity due to the inclusion of both GPA and Visits and the interaction term between those variables.

Table 6. Multiple Linear Regression Results

	Parameter Estimate	P-Value	Partial R^2	Tolerance
Constant	74.105	<0.0001		
High School Math GPA	12.929	<0.0001	0.13	0.83
ACT Math	1.798	<0.0001	0.10	0.81
Visits	0.365	<0.0001	0.07	0.89
High School Math GPA/Visits Interaction	-0.203	0.0555	0.01	0.93

In this analysis the predictors of high school math GPA, ACT math, Visits and the interaction term all have very low p-values indicating they are likely meaningful predictors of the final course grade. However, it is worth noting that the partial R^2 of the interaction term of 0.01 indicates that the interaction is only able to account for an additional 1% of the variation in course grades over that of the other dependent variables. The overall R^2 of this model is .350 compared to .345 for the model without interaction which indicates that the predictor variables are able to account for 35.0% of the variance in course grades.

The sign of the coefficient of the interaction term suggests that visits for students with lower high school math GPA result in a larger increase in course grade than for students with a higher high school math GPA. The predicted increase in course grade per visit to the tutoring center of a student with a high school math GPA one standard deviation above the mean is 0.25 points. This increase is 0.37 points for students with an average high school math GPA and 0.48 points for students with a high school math GPA one standard deviation below the mean. In other words, students with lower prior math academic achievement see a larger increase in course grade per tutoring visit than students of higher prior math academic achievement. The prediction equation for this regression is: Final Course Grade = -27.752+ 14.576(High School Math GPA) + 1.798(ACT Math)+1.077(Visits)-0.203(Visits*High School Math GPA). The coefficients of this equation have been simplified from the centered form of the equation and therefore differ from those in Table 6.

Discussion

We attempted to control for students' prior mathematical ability by using high school GPA and ACT math sub-score as variables in the multiple regression model. We found that high school math GPA, ACT math sub-score, and the number of tutoring visits were all significant factors in predicting course grades. The model predicts that each visit to the tutoring center raises the student's grade by 0.33%. A student with the mean high school math GPA and the mean ACT math sub-score who does not attend tutoring is predicted to make a 60% in the course. If that same student attends tutoring twice a week for the whole semester (30 visits), the predicted course grade is raised to 70%.

To determine if tutoring attendance benefits low achieving students more than high achieving students, we developed a new regression model that includes the interaction between high school math GPA and tutoring visits. This interaction model has slightly better predictive power than the previous multiple regression model. The model predicts that a low achieving student (with high school math GPA and ACT math score each one standard deviation below the mean) would score 56% without tutoring, and would need to attend tutoring 28 times to raise their score to a passing grade (70%). In contrast, a high achieving student (with high school math GPA and ACT math score each one standard deviation above the mean) would score 86% without tutoring, and 28 visits to the tutoring center would only raise the student's grade 7 percentage points. Thus, for the lower achieving student, each visit to the tutoring center has more of an impact on his or her course grade.

There are several limitations to this study. We acknowledge that the students had the option to attend tutoring, so there is a self-selection bias that we attempted to control by using prior mathematical ability scores in the multiple regression model. We also have no data about whether or not students made use of other support services, such as office hours or independent study groups.

Mental Constructions Involved in Differentiating a Function to a Function Power

Rachel Rupnow
Virginia Tech

Catherine Ulrich
Virginia Tech

Functions of the form $f(x) = (g(x))^{h(x)}$*, including constant functions, power functions, and exponential functions, are fundamental examples of functions that differential calculus students should be able to differentiate. Yet students often struggle to distinguish between these forms. Drawing on APOS (Action-Process-Object-Schema) theory as well as Piaget and Garcia's triad of schema development, this paper offers a genetic decomposition of the schemas students build for determining the derivative of a function to a function power. In particular, we analyze how students determine which differentiation rules to use with different function structures of a function to a function power and how students construct a conception of logarithmic differentiation. An initial genetic decomposition informed by existing literature was refined using the results of a series of three clinical interviews with each of two calculus students. Findings include the necessity of a strong background in functions, logarithms, and other differentiation rules.*

Key words: Logarithms, Differentiation, Function, APOS, Schema

Purpose and Background

Logarithmic differentiation is useful when differentiating non-constant functions to non-constant powers. For example, consider the function $y = x^x$. To find the derivative of this function, a student would need to realize that neither the power rule nor the exponential rule applies so the function equation must be transformed into an equation to which standard differentiation rules apply. Taking the natural logarithm of both sides of the equation and implementing a property of logarithms yields $\ln y = \ln x^x = x \ln x$. This function can then be differentiated using standard differentiation rules, resulting in $\frac{dy}{dx} = x^x(\ln x + 1)$. When either the base or exponential function in a function to a function power (FFP), $f(x) = (g(x))^{h(x)}$, is constant you can, in contrast, use the appropriate rule for differentiating polynomial or exponential functions.

Therefore, appropriately carrying out logarithmic differentiation requires students to coordinate all other differentiation rules and properties of logarithms. Additionally, students who know when to apply the technique demonstrate recognition of differences between types of FFPs. Because of this, we felt that differentiating FFPs provided a rich context for studying how students construct and utilize their differentiation rules. In this paper, we examine the necessary mental constructions for students to differentiate FFP expressions and to distinguish between situations where the constant rule, power rule, exponential rule, and logarithmic differentiation are appropriate.

Theoretical Framework

We use both APOS theory (Dubinsky, 1991) and Piaget and Garcia's (1989) triad of schema development to analyze the mental constructions necessary to address problems like the one above. APOS theory is an extension of Piaget's work with reflective abstraction in which student concepts are categorized as Actions, Processes, Objects, or Schemas. An *action* is an external transformation of objects (Asiala, et al., 1996); for example, a student with an action concept of the derivative could directly apply the power rule to find the derivative of $f(x) = x^4$. A *process* is an interiorized action; for example, a student with a process conception of the derivative could find the derivative of $f(x) = (x^3 + 2)^2$ by expanding the binomial and then taking the derivative by using the power rule or by applying the chain rule and power rule. An *object* is an encapsulated process; for example, a student can think about the result of applying the power rule to an appropriate, arbitrary function as producing another function, not just as a series of steps to find a solution. A *schema* coordinates a student's objects and processes; for example, a student could recognize that finding the derivative of $f(x) = (x^3 + 2)^2$ could be accomplished by expanding the binomial and then taking the derivative by using the power rule and could be accomplished by applying the chain rule and power rule, but then decide which was simpler and differentiate accordingly.

Researchers such as Clark et al. (1997) have found categorization using APOS theory difficult in cases where students will be at different levels of abstraction for different elements of study: action concepts of some composite functions and process for others when studying the chain rule. In these cases, the triad of schema development can help look in more detail at how schemas develop (Dubinsky & McDonald, 2001). Three stages, Intra, Inter, and Trans, describe the development and coherence of connections made within a student's schema. At the Intra stage, a student focuses on individual objects rather than looking for connections between them. A student at the Inter stage recognizes some relationships between different actions, processes, objects, and schemas, but cannot explicitly connect all of the relationships. A student at the Trans stage has created a coherent structure that connects appropriate relationships and recognizes what is and is not within the scope of a schema.

Preliminary Genetic Decomposition

Students with only an action conception of function need to substitute specific values into a function and receive outputs to make sense of a function. Students with a process conception of function recognize that a function receives inputs and gives outputs without explicitly needing values with which to calculate, but still consider a function in terms of a dynamic activity (Arnon et al., 2014). A student with an object conception of function recognizes the set of outputs of a function as an entity, recognizes the relationship of the inputs to the outputs, and can distinguish between different types of functions. We hypothesize that an object conception is necessary when differentiating FFPs in order to distinguish between types of functions and choose applicable differentiation rules and techniques.

An action conception of logarithms requires logarithms to be calculated with specific values to have any meaning. At the process level, students can recognize logarithms are functions that obey specific properties and use those properties of logarithms appropriately because they recognize the process that has been applied to compute solutions. For many students, it takes a long time to attain a process understanding of logarithms, as they tend to overgeneralize algebraic rules as they "factor out" logarithms (i.e., $\ln x + \ln y = \ln(x + y)$) or "cancel" logarithms (i.e., $\frac{\ln x}{\ln y} = \frac{x}{y}$), (Liang and Wood, 2005). This process knowledge is necessary for logarithmic differentiation because complex equations involving the chain rule, such as $f(x) = (x^3 + 2)^{4x^3}$, require awareness of what can and cannot be separated using logarithmic properties.

A differentiation scheme at any level of development, from action conception to full schema development, includes many subschemes including a graphing scheme and separate schemes for determining derivatives according to different differentiation rules. In order to address finding the derivative of an FFP, all differentiation rules must be at least at a process level for derivatives requiring more than one rule to be coordinated in a new process, much as Maharaj's 2013 study concluded. However, each differentiation rule need not be viewed as a static object, because coordinating the rules and completing the procedure for finding the derivative could be viewed as a few more steps in a dynamic process.

Finally, students must develop a logarithmic differentiation scheme as a subscheme of their differentiation schemes. The logarithmic differentiation scheme coordinates their function scheme, logarithm scheme, and various differentiation rule subschemes in order to determine a derivative of an FFP when the functions in both the base and exponent are non-constant. Because this scheme must coordinate so many other schemes, decomposing students' mental constructions with the triad of schema development is useful.

Students at the Intra level of logarithmic differentiation would struggle with coordinating the constituent schemes described above, either because they had not developed all of them to a sufficient degree or because they would not recognize that their other differentiation schemes could not be applied to a situation. For example, students may not recall their logarithmic properties and therefore take the natural logarithm of the equation, but then use the power rule to differentiate the resulting logarithm rather than applying properties of logarithms, which was the point of performing logarithmic differentiation (i.e. $y = x^x$ yields $\ln y = \ln x^x$, but then the student incorrectly concludes $\frac{1}{y}\frac{dy}{dx} = \frac{x^{x-1}}{x^x}$). Alternatively, students might be able to perform the steps of logarithmic differentiation but would need to be told to apply it. Another possibility is that they might indiscriminately perform the process to find the derivative of any function, whether useful or not (i.e. determining the derivative of $y = \sin^{-1} x$ through logarithmic differentiation because it appears to contain a power).

Students at the Inter level would have organized the constituent differentiation rule subschemes sufficiently to recognize which functions require logarithmic differentiation. However, they would not recognize why logarithmic differentiation works or why functions with constant base and non-constant power and functions with non-constant base and constant power require different differentiation rules or why logarithmic differentiation might be applied to equations like $f(x) = x\sin(2x^3)\cos(3x^2 + 2)$.

Students at the Trans level would recognize that logarithmic differentiation is useful because it allows previously inaccessible functions to be transformed into functions that can be addressed with other differentiation rules. A secondary use of logarithmic differentiation, simplifying functions requiring multi-part product rule application like $f(x) = x\sin(2x^3)\cos(3x^2 + 2)$, would also be assimilated at this time, though a student may not choose to use logarithmic differentiation in this way. Moreover, students might recognize that changing the position of the constant in FFP situations (i.e. $y = e^x$ versus $y = x^{\mathrm{e}}$) alters the set of outputs of the function, so it also alters the rate of change of the function.

Methods

The participants for this study were two entering freshmen taking a differential calculus course in a six-week summer session. Both students had previously seen differential calculus in high school, participant A through AP Calculus AB and participant B through a pre-calculus course that also included calculus topics. Participants were recruited from the same section.

Each participant engaged in three semi-structured interviews (Fylan, 2005) lasting 30-50 minutes. The interview questions are listed in Figure 1. The first interview occurred after both students had been taught how to find derivatives of constants, power functions, e^x, and to use the product, quotient, and chain rules. The second interview occurred after students had been taught logarithmic differentiation. The last interview occurred within a day of the final exam for the course, approximately three weeks after the second interview. The interviews were video-recorded and participants' written work was collected. To analyze the data, participants' interviews were examined for evidence of the construction of processes, objects, and schemas relevant to developing a schema for logarithmic differentiation.

Interview 1	Interview 2	Interview 3
$f(x) = e^x + 3x$	$f(x) = 5\sin(x^2) + xe^x$	Sketch the graph of the derivative of the given function (which was $f(x) = 2.82x + 1.37$).
$f(x) = 4x^5 - 2e^x$	$f(x) = \ln(2x^2 - 1)$	
$f(x) = x^x$	$f(x) = 4^{2x} - \cos^3 x$	Sketch the graph of the derivative of the given function ($f(x) = 2.9(x + 2.6)^2 - 2.1$).
$f(x) = (x^3 + 1)^2$	$f(x) = x^x$	
$f(x) = \dfrac{7e^{2x}}{e^x}$	$f(x) = \dfrac{\cos x}{x}$	Sketch the graph of the derivative of the given function ($f(x) = e^{-x} + 2$).
$f(x) = e^\pi$		Sketch the graph of the derivative of the given function ($f(x) = 3x^3 + 2x^2 + 1$).
$f(x) = xe^x$	$f(x) = x\sin(2x^3)\cos(3x^2 + 2)$	
$f(x) = \pi x^2$		Sketch the graph of $f(x) = x^x$ and connect to the derivative of the function. (The derivative is $f'(x) = (1 + \ln x)x^x$.)
$f(x) = (x^3 + 2)^{4x^3}$	$f(x) = (x^3 + 2)^{4x^3}$	
$f(x) = (x^3 + 4)\sin x$	$f(x) = \sin^{-1}\left(e^{(1-x)^3}\right) + e^{2.4}$	Differentiate: $f(x) = \pi^2 + 2^x + x^2 + x^{1/x}$

Figure 1: Interview questions

Results

Both participants demonstrated at least an object conception of function; they could fluently distinguish between constant, x^n, and n^x forms when asked to identify what type of function each was. Participant A was also able to identify graphs of quadratic and cubic polynomials and exponential functions, though Participant B struggled to identify the graph of an exponential function. Additionally, when Participant A was asked to find the derivative of $f(x) = x^x$ in the first interview, before learning logarithmic differentiation, he noted similarities to $f(x) = e^x$, but also noted the base x, "was not a constant, or a number. It's just weird."

Participant B displayed a process conception of logarithms. He applied logarithm properties appropriately in all but one problem and actively avoided the error he had made in the second interview in the last interview. Specifically, in the second interview he chose to use logarithmic differentiation on $f(x) = 4^{2x} - \cos^3 x$, which led him to say that $\ln y = 2x \ln 4 - 3\ln(\cos x)$. However, in the last interview, he recognized directly applying logarithmic differentiation to $f(x) = \pi^2 + 2^x + x^2 + x^{1/x}$ "wouldn't help because it's not multiply or divide; it's the sum. They are different [functions] so that's not going to work."

Participant A was less comfortable with the use of logarithms, displaying process level conceptions intermittently. In interview 2, when asked to differentiate $f(x) = \ln(2x^2 - 1)$, he questioned aloud whether or not $f(x) = \ln(2x^2 - 1) = \ln(2x^2) - \ln(1)$. When asked if he could determine if this was true or not, the only method he could determine was to compare their derivatives. While this method worked, he could not construct an argument based on properties of exponents. In interview 3, when asked to differentiate $f(x) = \pi^2 + 2^x + x^2 + x^{1/x}$, he took the natural logarithm of both sides, but wrote each piece separately as $\ln y = \ln \pi^2 + x \ln 2 + 2 \ln x + \frac{1}{x} \ln x$. While he knew some procedures for working with logarithms, he did not display understanding of why the procedures worked.

Both participants had full schema conception for all of their differentiation rule subschemas. They were both very comfortable with differentiating using the product, quotient, chain, and basic differentiation rules. In many instances, they demonstrated multiple ways of approaching problems, including recognizing the derivative of $f(x) = (x^3 + 1)^2$ could be found by using the chain rule directly or by expanding the binomial and then applying the power rule.

Bringing together these constituent subschemas, Participant A had an Inter stage and Participant B had a Trans stage of logarithmic differentiation schema development. By the end of the course, neither participant tried to apply his logarithmic differentiation schema to functions where it was not helpful (like $f(x) = \sin^{-1}\left(e^{(1-x)^3}\right) + e^{2.4}$) and both recognized when it was necessary ($f(x) = x^x$) or helpful ($f(x) = x \sin(2x^3) \cos(3x^2 + 2)$). However, in interview 3, Participant A could not successfully differentiate $f(x) = \pi^2 + 2^x + x^2 + x^{1/x}$ because his logarithm schema was not sufficiently developed, whereas Participant B could and realized why his previous "factoring" of the logarithm was inaccurate.

Discussion

Because both participants struggled at times to process how a logarithm works and what properties it possesses, having a process conception of logarithms does appear to be necessary to address logarithmic differentiation problems. Despite expecting development of a Trans stage schema for logarithmic differentiation to be necessary for students to consider apply logarithmic differentiation to three-part product rule situations, Participant A, who only attained Inter stage, applied this ably. Thus we revise the genetic decomposition, claiming students recognize all possible opportunities to use logarithmic differentiation at the Inter stage, even if they do not understand exactly why it works.

The present genetic decomposition of a logarithmic differentiation schema requires an object level conception of function and a process level conception of logarithms and each differentiation rule. A student's logarithmic differentiation schema then coordinates these subschemas. The level to which a student is able to coordinate these subschemas is characterized as being at the Intra level if the student cannot coordinate them and does not realize when logarithmic differentiation should be performed, at the Inter level if the student recognizes when to apply logarithmic differentiation but does not understand why, and at the Trans level if the student recognizes the underlying structure of the functions and can therefore answer why logarithmic differentiation should be used.

By describing the mental constructions necessary to perform and know when to apply logarithmic differentiation through APOS theory and the triad of schema development, instructors may be better equipped to teach in a manner that encourages the development of students' mental constructions. Specifically, encouraging students to distinguish between different types of functions may assist students in strengthening their function schemas and differentiation rule schemas. This will then enable them to construct a logarithmic differentiation schema and a richer understanding of calculus.

Some mathematics education publications highlight the importance of fostering students' mathematical creativity in the undergraduate classroom. However, not many describe explicit instructional methodologies to accomplish this task. The authors attempted to address this gap using a formative assessment tool named the Creativity-in-Progress Rubric (CPR) on Proving. This tool was developed to encourage students to engage in practices that research studies, mathematicians, and students themselves suggest may promote creativity in processes of proving. Three instructors in different institutions used a variety of tasks, assignments, and in-class discussions in their proof-based courses centered around the CPR on Proving to explicitly discuss and foster mathematical creativity. These instructors' actions are explored using Levenson's four teacher roles of fostering mathematical creativity. In this report, preliminary results indicate that each of the three instructors assumed at least three of the four roles.

Keywords: Mathematical creativity, teaching practices, proof-based courses

Mathematical creativity has been emphasized by the MAA's Committee on the Undergraduate Program in Mathematics in its latest guidelines (Schumacher & Siegel, 2015). The guidelines state that "[a] successful major offers a program of courses to gradually and intentionally leads students from basic to advanced levels of critical and analytical thinking, while encouraging creativity and excitement about mathematics" (p. 9). Under *Cognitive Goals and Recommendations*, the guidelines also state "major programs should include activities designed to promote students' progress in learning to approach mathematical problems with curiosity and creativity and persist in the face of difficulties" (p. 10). In support, Nadjafikhah, Yaftian, and Bakhshalizadeh (2012) claim that one of the goals of any educational system should be to foster mathematical creativity. Mathematical creativity is discussed as an important aspect in undergraduate mathematics (e.g., Zazkis & Holton, 2009), but pedagogical actions that support its explicit fostering in classrooms are rarely mentioned or studied. Ervynck (1991) stated, "[W]e therefore see mathematical creativity, so totally neglected in current undergraduate mathematics courses, as a worthy focus of more attention in the teaching of advanced mathematics in the future" (p. 53). In this project, the authors attempt to explore this issue further by attempting to address the research question: ***What teacher actions or practices in the proof-based undergraduate classroom might foster students' perceptions of mathematical creativity?***

To explicate mathematical creativity with undergraduate students, three instructors from different universities in the U.S. implemented various practices such as designing assignments, creating tasks, and structuring class discussions in their courses. One common feature of these practices was that all three instructors centered their implementations around a tool created to enhance research-based actions for mathematical creativity in the proving process, the Creativity-in-Progress Rubric (CPR) on Proving (Savic et al., 2016; Karakok et al., 2016). This rubric was developed considering certain theoretical aspects of mathematical creativity, which is discussed in the following section.

Theoretical Perspective and Background Literature

There are over 100 different definitions of mathematical creativity (Mann, 2006) and multiple theoretical perspectives (Kozbelt, Beghetto, & Runco, 2010). In developing the CPR on Proving, the authors considered mathematical creativity as a *process* that involves different modes of thinking (Balka, 1974) rather than looking at the creative end-product (Runco & Jaeger, 2012). Mathematical creativity in the classroom often considers a *relative perspective*, similar to Liljedahl and Sriraman's (2006) description of mathematical creativity at the K-12 level: a process of offering new solutions or insights that are unexpected for the student, with respect to his/her mathematics background or the problems s/he has seen before. This particular definition acknowledges students' potential for creativity (both in process and product) in the mathematics classroom. Often literature cites this as “little-c” creativity (Beghetto, Kaufman, & Baxter, 2011), as opposed to “big-C” or an absolute perspective (Feldman, Csikszentmihalyi, & Gardner, 1994). Finally, the authors focus on creativity in the domain of mathematics, instead of exploring creative endeavors in general (Torrance, 1966). Many researchers (e.g., Baer, 1998; Milgram, Livne, Kaufman, & Baer, 2005) also stressed this distinction and the importance of domain-specific creativity: “creativity is not only domain-specific, but that it is necessary to define specific ability differences within domains” (Plucker & Zabelina, 2009, p. 6).

Creativity-in-Progress Rubric (CPR) on Proving

The CPR on Proving was rigorously constructed through triangulating research-based rubrics (Rhodes, 2008; Leikin, 2009), existing theoretical frameworks and related studies (Silver, 1997), conducting studies exploring mathematicians’ and students’ views on mathematical creativity (Tang et al., 2015), and investigating students' proving attempts (Savic et al., 2016).

There are two categories of actions that may help a student foster mathematical creativity: *Making Connections* and *Taking Risks*[1]. Making Connections is defined as the ability to connect the proving task with definitions, theorems, multiple representations, or examples from the current course that a student is in or possible prior course experiences. Taking Risks is defined as the ability to actively attempt a proof, demonstrate flexibility in using multiple approaches or techniques, posing questions about reasoning within the attempts, and evaluating those attempts. Making connections has three subcategories (between definitions/theorems, between examples, and between representations), and Taking Risks has four subcategories (tools and tricks, flexibility, posing questions, and evaluation of a proof attempt) that are designed to have students explicitly think about ways to develop aspects of their own mathematically creative processes.

Teaching for Development of Creativity

The literature for teachers’ actions to develop mathematical creativity at the undergraduate level is scarce. Zazkis and Holton (2009) cite a few implicit instances or strategies for encouraging mathematical creativity, including learner-generated examples (Watson & Mason,

---

[1] For a final version of the CPR on Proving, see Karakok et al. (2016).

2005) and counterexamples (Koichu, 2008), multiple solutions/proofs (Leikin, 2007), and changing parameters of a mathematical situation (Brown & Walter, 1983). From the K-12 literature, there are quite a number of articles of fostering mathematical creativity through problem posing (e.g., Silver, 1997; Knuth, 2002) or open-ended problems (e.g., Kwon, Park, & Park, 2006). However, there is still a need to understand what teacher actions in the classroom could foster mathematical creativity, especially in undergraduate mathematics courses.

Methods

Participants

Three different instructors, Drs. Eme, X and Omar, from three different institutions (two located in Western US and one located in Northeastern US) participated in this study. Each instructor used the CPR in Proving; Drs. Eme and X removed the word "creativity" from the rubric in an attempt to minimize the explicit influence of the rubric on students' development of ideas on mathematical creativity. They also both implemented IBL teaching pedagogies, whereas Dr. Omar also included lectures. Dr. Eme introduced the CPR on Proving mid-semester in her Transition to Advanced Mathematics course in Spring 2016. Dr. X's implementation was in a seminar on Elementary Number Theory during Fall 2015 where he introduced the rubric in the third week. Dr. Omar implemented the CPR in his Combinatorics course in Spring 2016 and used it in Portfolio Assignments.

Data

Prior to the start of the semester, all instructors discussed their course goals with the researchers and shared their CPR on Proving implementation plans with the researchers. Drs. Eme and X were involved in the development of the CPR on Proving where as Dr. Omar approached the authors to utilize the CPR on Proving in a course that he was designing. All three instructors met with the authors regularly to discuss the process of their utilization of the CPR on Proving throughout the semester. All three instructors collected their students' work and utilization of the CPR on tasks. Dr. Eme also audio-recorded in-class sessions. Students in the three courses were invited to participate in interviews at the end of the semester. In this preliminary report, we share our analysis of notes from instructors' self-reported actions in class and implementation plans, along with recorded implementations of the CPR in their courses.

Three instructors had different ways to introduce the idea of mathematical creativity and implementation of the CPR on Proving. Two months into the course, Dr. Eme started a class period showing the class their own exam solutions: "...That's the exam 2 'solutions' and I say solutions in quotes because they're not all 100% correct, okay, but it doesn't matter. You know there are still really good ideas in there and that's what I want you to see." Dr. Eme had students practice using the CPR on a former student's scratch work in the same class period. The scratch work was for theorem: "If $3|n$, then n is a trapezoidal number (a number that can be decomposed into a sum of two or more consecutive integers)" The discussion below ensues:

1 Dr. Eme: What did you guys get for the first one?
2 Stephanie: Advancing
3 Dr. Eme: Advancing? Why?
4 Stephanie: Because they were able to utilize multiple theorems and
5 definitions…Definition Q, the consecutive integers, Definition test 3.
6 Dr. Eme: Good. Good. Other people agree? Disagree?
7 Tony: Agree.

Dr. Eme: Agree? Ok. How about "between representations?"
…
Cargo: That "The Between Representations" still confuses because I'm not sure exactly what it means? Is it supposed to be like using the notation or what?
Dr. Eme: Yeah, that's a good question. Does anybody have an answer?
Stephanie: I would say it's anyway you can rewrite it, or draw a picture, or anything you can do to represent that same concept but in a different way.
Cargo: OK.
Dr. Eme: That helps?
Cargo: Yeah.
Penny: That "concept" being.... the if $3|n$, let be trapezoidal number or any like any definition?

At another institution, Dr. X asked the students to use the CPR on five occasions throughout the semester, during homework as an evaluative tool, and during the final exam as extra credit. For example, in a homework problem, a student provided some scratch-work in his proof, bracketed the scratch-work, and wrote the reason why this scratch-work was not leading to a correct proof (in the student's words, "a mistake"). The student then promptly proved the theorem, utilizing the evaluation subcategory of the CPR on Proving.

Finally, Dr. Omar utilized the rubric while handing out problems labelled as "portfolio problems," which are, quoting from the syllabus, "much more involved, and the intention is to allow freedom to roam with it in any direction you wish." The students were required to use the rubric in a minimum three-page write up summarizing the proving processes they used. Unbeknownst to the students, many of these portfolio problems were open in mathematics, and the one portfolio problem had the same weight as the other three problems in the assignment which Dr. Omar viewed as "exercises". Dr. Omar stated that these three additional problems could be done by directly implementing ideas from class lectures or discussions.

Analytical Framework

To explore these three instructors' teaching actions, the authors adapted the work of Levenson (2011, 2013), who investigated fifth- and sixth-grade classes with the intention of explicating collective creativity and its effects on an individual's mathematical creativity. She described four teacher roles in fostering mathematical creativity:

1. choosing appropriate tasks,
2. fostering a safe environment where students can challenge norms without fear of repercussion,
3. playing the role of expert participant by providing a breakdown of the mathematics behind a process, and
4. setting the pace, allowing for incubation periods. (Levenson, 2013, p. 273)

The authors conducted preliminary analysis on instructors' actions during implementation of the CPR on Proving in their courses using these four roles. In particular, this preliminary analysis focused on how the CPR on Proving was utilized to foster mathematical creativity in their classroom, and using student interview data to support that fostering occurred.

Preliminary Analysis Results

The authors observed that all three instructors reported utilizing tasks that would encourage the mathematical creativity (property 1). For example, all three instructors choose tasks that were not all “Type 1” tasks, i.e. “proofs…can depend on a previous result in the notes” (Selden & Selden, 2013, p. 320), but rather either “Type 2:” “require formulating and proving a lemma not in the notes, but one that is relatively easy to notice, formulate, and prove” (p. 320) or “Type 3,” which is hard to notice a lemma needed. Moreover, Dr. Omar assigned open-ended tasks, and Drs. Eme and X had their students analyze solutions or proof processes of others as part of classroom discussions, which we view as an action related to choosing appropriate tasks since students were required to think analytically about both a solution and proving process.

The authors noticed from Dr. Eme’s classroom data that this instructor explicitly tried to foster a safe environment (property 2). As seen in the above episode, she carefully stated that the “solutions” the instructor was sharing out were not correct, but contained ideas that were “still really good.” This teacher action challenged the common norm of “only correct solutions should or would be valued” in this course. In addition, this action may also allow the students to challenge norms themselves without repercussion, since their instructor modeled such an action.

In the dialogue above, the students looked at another student’s proof of the trapezoidal number theorem. The authors claim that both the theorem and the evaluation of a student’s proof using the rubric are two examples of choosing appropriate tasks (property 1) for fostering students’ perceptions of creativity. Also, Dr. Eme is setting the pace to allow for incubation periods (property 4) in the course by letting students wrestle with how to interpret the CPR on Proving by analyzing the student’s scratch work (see lines 8-18).

Property 4 is more apparent in the “appropriate tasks” that Dr. Omar assigned during class, since he knew those tasks were open, and therefore necessitated incubation time. The tasks themselves are a form of property 1, since they had the necessary elements for mathematical creativity to occur (through the lens of CPR). That is not to say that mathematical creativity can only occur in open math problems; tasks that both Dr. Eme and X provided can also elicit relative mathematical creativity.

Finally, each of the four properties of teachers fostering mathematical creativity (Levenson, 2013), seemed to appear in different forms in these instructors’ implementations of the CPR on Proving. For example, even though Dr. Omar did not have regular in-class discussions about the CPR on Proving in class, his approach to assignments encouraged the students to experience his “role of expert participant” (property 3).

Discussion/Conclusion

Creativity in mathematics is important for both mathematicians and students' development of mathematical actions. Three instructors of this study used the CPR on Proving differently. However, all three had a shared goal: a recognition or awareness of students' own proving processes and the actions that could lead to the development and enhancement of students’ perceptions of mathematical creativity. Drs. Eme and X had explicit discussions related to rubric categories, which are important to “increase student learning, motivate students, support teachers in understanding and assessing student thinking, shift the mathematical authority from teacher (or textbook) to community” (Cirillo, 2013, p. 1). Discussions can lead to student reflections of their own work. Dr. Omar asked students to utilize the CPR on Proving to reflect on their portfolio problem assignments. The CPR on Proving seemed to facilitate the explicit valuing of such meta-cognitive practice. As Katz and Stupel (2015) stated, “Creative actions might benefit from meta-cognitive skills and vice versa, regarding the knowledge of one’s own cognition and the regulation of the creative process” (p. 69).

The Saga of Alice Continues: Her Progress With Proof Frameworks Evaporates When She Encounters Unfamiliar Concepts, but Eventually Returns

Ahmed Benkhalti Annie Selden John Selden
New Mexico State University

This case study continues the story of the development of Alice's proof-writing skills into the second semester. We analyzed the videotapes of her one-on-one sessions working through our inquiry-based transition-to-proof course notes. Our theoretical perspective informed our work and includes the view that proof construction is a sequence of mental, as well as physical, actions. It also includes the use of proof frameworks as a means of initiating a written proof. Previously, we documented Alice's early reluctance to use proof frameworks, followed by her subsequent seeming acceptance of, and proficiency with, them by the end of the first semester (Benkhalti, Selden, & Selden, 2016). However, upon first encountering semigroups, with which she had no prior experience, during the second semester, her proof writing deteriorated, as she coped with understanding the new concepts. But later, she began using proof frameworks again and seemed to regain a sense of self-efficacy.

Keywords: Transition-to-proof, Proof construction, Proof frameworks, Coping, Self-efficacy

This case study reports how Alice, in one-on-one sessions, after adopting the technique of proof frameworks (Selden, Benkhalti, & Selden, 2014) and completing several real analysis proofs, apparently hit a "brick wall" when she encountered a new concept, semigroups, in the second semester. However, after some time spent acquainting herself with semigroup concepts, such as ideals, idempotents, and homomorphisms, she "regained her footing" and started once again to use the technique of proof frameworks. Amongst other things, this case study illustrates the fragility of newly acquired proving skills, in the context of the acquisition of new mathematical concepts. It appears that Alice's proof-writing knowledge was initially, but not permanently, context bound.

Theoretical Perspective

We consider proof construction to be a sequence of mental and physical actions, some of which do not appear in the final written proof text. Such a sequence of actions is related to, and extends, what has been called a "possible construction path" for a proof (Selden & Selden, 2009). For example, suppose that in a partly completed proof, there is an "or" in the hypothesis of a statement yet to be proved: "If A or B, then C." Here, the situation is having to prove this statement. The interpretation is realizing the need to prove C by cases. The action is constructing two independent sub-proofs; one in which one supposes A and proves C, the other in which one supposes B and proves C.

When several similar situations in proof construction are followed by similar actions, an *automated link* may be established between such situations and actions. Subsequently, such a situation can be followed by the corresponding action, without the need for any conscious processing between the two (Selden, McKee, & Selden, 2010). When students are first learning proof construction, many actions, such as the construction of proof frameworks (Selden, Benkhalti, & Selden, 2014; Selden & Selden, 1995), can become automated. A *proof framework* is determined by just the logical structure of the theorem statement and associated definitions. (For some examples, see Selden, Benkhalti, & Selden, 2014).

Related Research

Proof Frameworks

The idea of proof frameworks was introduced by Selden and Selden (1995), who stated:

> By a *proof framework* we mean a representation of the "top-level" logical structure of a proof, which does not depend on detailed knowledge of the relevant mathematical concepts, but which is rich enough to allow the reconstruction of the statement to be proved or one equivalent to it. A written representation of a proof framework might be a sequence of statements, interspersed with blank spaces, with the potential for being expanded into a proof by additional argument. (p. 129).

Selden and Selden (1995) went on to connect the ability to unpack the logical structure of mathematical statements with the ability to construct proof frameworks and with proof validation. They also pointed out that mental skills were involved (p. 132). The learning and mastering of such mental skills can involve much mental energy and considerable working memory. While Selden and Selden (1995) did not state this explicitly, in their sample validation in the Appendix, they did note that sometimes checking a sufficiently complex part of a proof might overload working memory and potentially lead to error. (p. 146).

Working Memory

It has been said that the "two major components of our cognitive architecture that are critical to [thinking and] learning are long-term memory and working memory" (Kalyuga, 2014). *Working memory* makes cognition possible but has a limited capacity that varies across individuals. It is associated with the conscious processing of information within one's focus of attention. However, working memory can only deal with several units, or chunks, of information at a time, especially when working with novel information (Cowan, 2001; Miller,1956). In contrast, *long-term memory* can be thought of as a learner-organized knowledge base that has essentially unlimited capacity and can be used to help alleviate the limited capacity of working memory (Ericsson & Kintsch, 1995). However, when working memory capacity is overloaded, errors and oversights are likely to occur.

Coping with Mathematical Abstraction and Formality

While the mathematics education research literature does not seem to have considered working memory overload during learning per se, there are a few studies of coping with abstractions. These could be reinterpreted as related to working memory overload causing confusion. For example, Hazzan (1999) investigated how Israeli freshman computer science students, taking their first course in abstract algebra in a "theorem-proof format", coped by "reducing the level of abstraction". Specifically, she found that they tended "to work on a lower level of abstraction than the one in which the concepts are introduced in class." (p. 75).

Leron and Hazzan (1997) pointed out that students in mathematical problem-solving situations “often experience confusion and loss of meaning.” (p. 265), and that students attempt to make sense of the problem situation “in order to better *cope* with it.” (p. 267). While this coping perspective occurs at all levels, they stated that “the phenomena of confusion and loss of meaning are even more pronounced in college mathematics courses.” (p. 282). They also suggested that more work on the coping perspective in mathematics education is needed. Pinto and Tall (1999) also considered university students’ coping mechanisms when confronted with formal definitions and proofs in real analysis. However not many university level mathematics education studies have specifically considered students’ coping perspectives.

Methodology: Conduct of the Study

In the second semester, as in the first, we met regularly for individual 75-minute sessions with Alice, a mature working professional, who wanted to learn how to construct proofs. Alice followed the same course notes previously written for an inquiry-based course used with beginning mathematics graduate students. As previously reported (Benkhalti, Selden, & Selden, 2016), Alice had a good undergraduate background in mathematics from some time ago and also had prior teaching experience. Further, she only worked on proofs, at her own pace, in front of us during the actual times we met. Because of this, we gained greater than normal insight into Alice’s mode of working and its development. Altogether, we met with Alice for 39 sessions.

We met in a small seminar room with blackboards on three sides, and Alice constructed original proofs at the blackboard, eventually using the middle blackboard almost exclusively for her evolving proofs. We videotaped every session and took field notes on what Alice wrote on the three boards, along with her interactions with us. For this study, we reviewed the second semester videos and field notes several times, looking for signs of Alice’s progress. However, somewhat to our surprise, after continued progress with her proof writing when dealing with real analysis proofs, she seemed to hit a “brick wall” upon beginning the abstract algebra (semigroups) section of the notes.

Alice’s Progression Through the Second Semester

At the end of the first semester, we (Benkhalti, Selden, & Selden, 2016) left our 19th meeting with Alice, feeling that she was making great progress, both with writing proof frameworks and with the problem-centered parts of proofs, and was developing a sense of self-efficacy (Bandura, 1994, 1995). She had just completed the proof of the theorem that the sum of continuous functions is continuous. This proof has a rather complicated proof framework that necessitates leaving three blanks spaces -- one for using the hypothesis appropriately, one for specifying a □, and one for showing that the chosen □ “works”, by showing the relevant distance is less than □.

Upon resuming in the second semester, Alice continued proving real analysis theorems, first attempting to prove that the product of two continuous functions, f and g, is continuous[1] in our first three meetings (i.e., our 20th-22nd meetings). She set up the proof framework correctly and explored the situation in scratch work. During this proving process, Alice made some astute

[1] Due to space limitations, we do not provide Alice’s proof.

observations, for example, having gotten to $|fg(x) - fg(a)| = |f(x)g(x) - f(a)g(a)| \leq |f(x)|\ |g(x) - g(a)| + |g(a)|\ |f(x) - f(a)|$, and having dealt with term involving $|g(a)|$, she noted that the former term was the "hard part" because $|f(x)|$, unlike $|g(a)|$, is not a constant. Somewhat later, Alice exhibited some self-monitoring, noting that she needed to move her sentence about the bound on $|f(x)|$, prior to setting δ equal to the "minimum of [the] three" deltas she had found. She also noted, in the 22nd meeting, that it seemed "weird" to write the restrictions on $|f(x) - f(a)|$ and $|g(x) - g(a)|$ without immediately explaining why she had chosen the bounds $\frac{\varepsilon}{2|g(a)|}$ and $\frac{\varepsilon}{2M_f}$, respectively, when applying the definition of continuity to f and g. Next, Alice proved polynomials are continuous with only a small amount of help from us.

By our 25th meeting, Alice had completed the real analysis section of the notes, and was ready to begin the abstract algebra (semigroups) section that starts with the definitions of binary operation and semigroup, followed by requests for examples. She provided only the most obvious of examples, such as the integers under addition or multiplication, and when asked for something "stranger", she said she could use the real numbers. When asked for another "strange" example "with no numbers at all", she suggested union as the binary operation, and with help, wrote up the example of the power set of a set of three elements. Next, when it came to providing examples of semigroups, she suggested the natural numbers with subtraction, but had to be prodded to check associativity; for this she considered (3 - 7) - 2 versus 3 - (7 - 2) and correctly inferred this was not a semigroup. To provide examples of left and right ideals, Alice needed to come up with a noncommutative semigroup, but she drew a blank. We suggested the semigroup of 2×2 real matrices under multiplication, and for an ideal, the subset of matrices of the form $\begin{bmatrix} x & y \\ 0 & 0 \end{bmatrix}$. After some calculation, Alice concluded the subset is a right ideal, but not a left ideal.

Alice continued considering examples for the first 35 minutes into the next (26th) meeting, after which she came to the first semigroup theorem to prove: "Let S be a semigroup. Let L be a left ideal of S and R be a right ideal of S. Then $L \cap R \neq \emptyset$." She first wrote the definitions of semigroup, left ideal, right ideal, and ideal on the left-hand board, as she had done many times before. Then she wrote the first-level framework on the middle board, after which she went to the right-hand board and began doing some scratch work, which included drawing a Venn diagram of two overlapping circles, L and R, with an arrow pointing to the intersection. She wrote in her scratch work "$L \cap R = \emptyset$" and "there exists an element $a \in L \cap R$". It seemed that Alice was trying to clarify the theorem statement for herself, however, she had not yet attended to the second-level framework. We pointed this out. During the rest of her proving attempt, we seemed to need to remind Alice of relevant actions, such as considering what she knew about ideals (i.e., that they are nonempty), and hence, concluding that each of L and R contains an element, which she labeled l and r respectively, and using those, to try to "explore" to find an element in $L \cap R$, in order to conclude it was not empty. With our guidance, Alice finished the proof, but her sense of self-efficacy seemed shaken. Indeed, at the next (27th) meeting, Alice wanted to reprove the theorem before continuing. We now feel that she had been somewhat overwhelmed, or confused, by the new content, perhaps causing working memory overload. She had tried to cope as best she could by concentrating on the new concepts, while “forgetting” her prior proof writing skills. Alice’s hesitant behavior continued for eight more sessions.

Then, during the 35th meeting, Alice considered the theorem, “If S and T are semigroups and f: $S \rightarrow T$ is an onto homomorphism and I is an ideal of S, then $f(I)$ is an ideal of T”. She wrote the definition of homomorphism on the left board, wrote “What I know” on the right board, constructed the first-level proof framework, unpacked the conclusion, wrote the second-level proof framework, and decided to do a two-part proof (for left and right ideal). She seemed to have regained “her footing”. At the next meeting, she finished the proof, with some help from us.

Discussion

Alice began the second semester with the construction of additional real analysis proofs and seemed to be making very considerable progress, both with writing proof frameworks and with the harder problem-centered parts of proofs. By the end of the real analysis section of the course notes, we felt that she had developed greatly in her proving ability and had developed a sense of self-efficacy (Bandura, 1994, 1995) about proving. However, the subsequent introduction of unfamiliar, abstract content in the form of several definitions and theorems about semigroups at the 25th meeting seemed to cause her confusion, and she constructed the most obvious examples somewhat hesitantly. Also, when asked to prove the first theorem about semigroups, she did not begin by producing a proof framework, as she had previously done with the real analysis proofs, but rather began writing what she knew or could find in the notes, on the right-hand blackboard. Her proof construction, while not top-down, seemed to consist of first trying to gather as many semigroup ideas as she could, followed by trying to arrange them into a final proof. We feel that concentrating on understanding the unfamiliar abstract content was Alice’s initial way of coping. It was not until the 35th meeting, almost at the end of the second semester, that Alice seemed to have regained her sense of self-efficacy, and she again constructed proofs using the technique of proof frameworks that she had learned and perfected previously.

Implications

It seems that coping with newly introduced abstract concepts is not easy, even for someone as experienced as Alice. It also seems that one cannot expect, having learned the skill of constructing proof frameworks in more familiar settings, that this skill will be easily invoked while new abstract content is being learned, perhaps due to working memory overload. Amongst other things, this case study illustrates the fragility of recently acquired proving skills, in the context of the acquisition of new abstract mathematical concepts. It also suggests the difficulty due to such fragility can be overcome. Our own experiences as mathematicians suggests that one can (tacitly) learn not to be greatly disturbed by the introduction of several new abstract ideas. However, some school curricula avoid certain introductions of concepts, such as the Bourbaki definition of function, because they are considered too abstract (Tabach & Nachlieli, 2015). Further, as Hazzan (1999) found, students sometimes cope by “reducing the level of abstraction.” Yet Alice’s case suggests that, with time and effort, students can learn to cope with abstraction.

Studying Pre-Service Teachers' Selection of Representations in a Technologically Enhanced Environment

Robert Sigley — Texas State University
Muteb Alqahtani — SUNY Cortland
Victoria Krupnik — Rutgers University

This paper reports the results of four groups of three pre-service teachers working on a task that had them investigate the fairness of dice. The teachers used an online collaborative environment to sample from six different dice and the environment provided them with various representations, which they used to support their arguments. All four groups preferred the frequency table over bar and pie charts representations. After working on the task, they evaluated the work of students on the same problem. They viewed students' work that used other representations as not convincing regardless of the correctness of their solution and showed preference to the students only using one representation. Implications for pre-service teacher training in statistics and how to promote the use of multiple representations are discussed at the end.

Keywords: statistics education, probability, representations, technology

Statistics and probability are important to understand everyday phenomena. Technologies allow us to efficiently collect, organize, and present our data. Other technologies allow us to simulate phenomena and explore the likelihood of different events. Starting in early grades, students are encouraged to learn concepts of statistics and probability. The National Council of Teachers of Mathematics (NCTM) suggests that students in elementary grades learn how to collect and present some basic data and make decisions using them (NCTM, 2000). Similarly, the Common Core State Standards (CCSS) recommends that students starting from sixth grade to learn about the likelihood of events and to use simulations to generate frequencies of events (CCSS Initiative, 2010). This indicates that mathematics teachers in all levels need to acquire a deep understanding of statistic and probability in order to teach the topic effectively. Though groups such as NCTM have identified the importance of teachers preparing their students to be statistically literate, little is understood about teachers' knowledge of the subject (Jones, Langrall, & Mooney, 2007). Externally provided visual representations such as bar graphs have been shown to aid in the development of student understanding by providing a model of the situation (Schwartz & Black, 1996). By studying the external representations teachers use as evidence in problem solving may provide insight into their knowledge. In this study, we report on the work of four groups of pre-service teachers who collaborated online to solve a probability task and evaluate middle school students' solutions of the same task. The main goal of study is to understand how PSTs use and analyze multiple representations while investigating the fairness of dice and how they evaluate middle school students' justifications for their solutions.

Overview of the Literature

Teaching statistics and probability are disciplines that require different knowledge to that needed to teach mathematics, such as non-mathematical activities like building meaning in data and choosing appropriate study designs (Groth, 2007; Cobb & Moore, 1997). Groth (2007, 2013) developed a hypothetical framework for the knowledge of teaching statistics, acknowledging in the framework the differences that statistics and mathematical knowledge. Due to the difference between the disciplines, investigating teachers' knowledge of statistics and probability is relatively a new direction in mathematics education (Garfield & Ben-Zvi, 2008; Garfield & Ben-Zvi, 2007). Nonetheless, multiple studies investigated the challenges students and teachers face when learning statistics and probability and how to deal with some of these challenges (Garfield & Ben-Zvi, 2007; Groth and Bergner, 2006). Other studies showed that incorporating technological tools in learning and teaching probability can support collaborative learning of probabilistic concepts effectively (Garfield et al., 2008; Lee & Hollebrands, 2011).

Researchers have shown the benefits of eliciting multiple representations when engaging in problem solving tasks (e.g., Shaughnessy, 2007). Computer programs have become useful in statistics education since they can quickly sample from a data set multiple times and provide multiple representations of the data. Beihler (2013) emphasized the benefits of technological environments as a pedagogical tool for learning elementary probability. Ben-Zvi and Arcavi (2001) used virtual environments to study students' use and construction of data representations to understand their way of thinking and found that in these environments students were able to learn in unique ways that promoted understanding compared to traditional environments. While multiple representations are beneficial and computer environments can quickly construct them, a study by Schnell and Prediger (2014) concluded that connecting different representations for students is complex, and if taught properly can foster deep understanding for patterns and variability.

Methodology and Data Source

Twelve pre-service teachers (PSTs) participated in the study. All of the PSTs were in their last semester of a two-year teacher education program at a large Northeastern university. The study consisted of the PSTs working in groups of three to solve three open-ended mathematics problems in a collaborative online environment, Virtual Math Teams with Geogebra Tool (VMTwG). The VMTwG tool integrates Geogebra with a white board and a chat box for synchronous discussion.

During each problem-solving session, the PSTs would meet in their group and work together to solve a task. The goal of the tasks was to have the PSTs not only come to a solution, but to form arguments to justify their solutions. After the PSTs worked on and discussed the task, they then watched together a video of children working on the same task as them. Discussion prompts for the video were provided that had the PSTs contrast and compare their problem-solving experience with those of the children in the video. Finally, individually, the PSTs would look at samples of work of students who worked on the same problem as them. The teachers were asked to review the student's representations and work and specifically address: (1) the correctness of the solution provided, (2) description of the strategy used, (3) the validity of the reasoning, and (4) whether or not they find the solution convincing and, if so, why. If they did not find the solution convincing, they were asked to indicate from studying the student work what pedagogical moves they might take to help the student develop a convincing argument. The data for this paper focus on the probability task which had the PSTs investigate the fairness of different dice using interactive simulations of each die. This module was chosen for analysis since the VMTwG software provided a variety of representations for the data and the PSTs were to choose which representations they wanted to support their argument whereas other modules had them construct their own representations. We were interested in studying which representations they chose for their argument and how it influenced their analysis of student work.

The PSTs were provided with simulations for six dice that were weighted differently. They could roll each dice between 1 and 1,000 times to determine whether the dice are fair. The

VMTwG environment provided them with three different representations of the data; a frequency table, a pie chart, and a bar graph (Figure 1). As a group, the PSTs were to determine which data representations they wanted to use as evidence to make an argument about the fairness of the dice. The video they watched contained a group of eight seventh graders engaged in a debate about how many times one would have to roll the dice to determine if the dice were fair or not. The student work, that was analyzed individually, was a series of charts produced by the same group of students. The charts contained screenshots of the tool, which the students used as evidence to support their conjectures about which set of dice were fair.

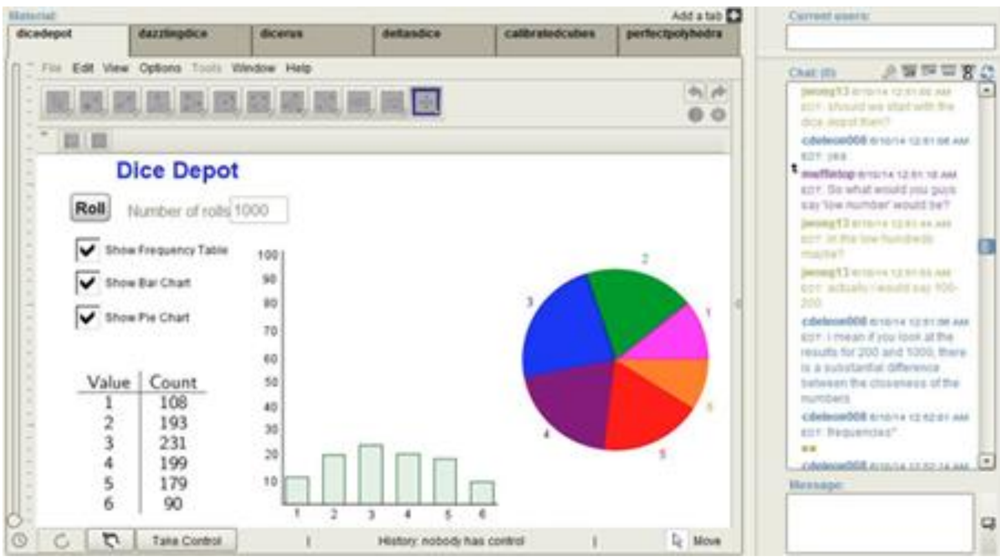

Figure 1. The VMT environment the PSTs worked in.

The VMTwG software contains a replay tool that allows a user to replay all actions that occurred in the tool. For analysis, two researchers openly coded the actions of the teachers inside of the tool, their chat logs, their group write up about which dice company they thought was fair, and their individual analysis of student work. Altogether, four groups of three teachers were analyzed.

Preliminary Results

Analyzing the chat logs and reports submitted by the PSTs revealed that while the groups saw benefits in using the bar graph and pie chart, all four groups chose to use the frequency table as evidence for their selection of dice in their reports. During the problem-solving session, all of the groups chose to use the frequency table to calculate the range of the distribution and used that to determine the fairness of the dice regardless of the sample size they used. The groups discussed selecting the dice that had “less range in the numbers” and dismissed dice with a “much wider range”. One teacher elaborated on her use of the frequency table. She reported that she “used this fraction [one sixth] with the frequency table to compare numbers.” She used the numbers provided in the frequency table to test whether the outcome for each side of the dice is more or less that one sixth of the sample size.

Furthermore, when responding individually to the student work produced by the middle school students, the PSTs indicated that they were not as convinced by the students who used bar graphs and pie charts as their evidence even though the students’ arguments were correct. Several of the PSTs also expressed that the children should only use one type of representations to make their argument and that multiple representations were “not appropriate”, “confusing”, and “made it difficult to decipher [their argument]”. In responding to a student who used both a bar chart and a pie graph, one of the teachers remarked, “The pie graph did not represent this argument as well as the other two types of data because the visual contrast is not as present in the pie as it is in the bar graph”.

Discussion and Questions

Though all four groups of PSTs had multiple representations available to them, all four groups chose to focus on the frequency table to support their own arguments. Their chat logs and write ups of the problem indicate that they found that representation as more convincing. When analyzing students’ work, the PSTs were dismissive of arguments by students who used the other representations. The preference for one type of representation by the PSTs may be problematic as researchers (e.g., Shaughnessy, 2007) have shown that multiple representations are a learning goal for statistics education and that various representations can help aid students in different ways. When the students whose work was evaluated by the PSTs used multiple representations, the PSTs suggested that they only use one to make their argument less confusing. While environments like the VMTwG have the ability to construct multiple representations of the same data, just providing the representations are not enough since it seems that learners tend to prefer and focus on one representation. Further work is needed to understand how to engage PSTs in environments like the VMTwG where they have to consider the affordances and constraints of different representations so they can foster a classroom environment that invites and uses multiple representations to support arguments.

Questions for the audience:

1) Do you see any benefits in having students construct their own representations instead of having them generated by the software? Dynamic representations have shown to be useful in statistics education, but the process of creating a representation seems important.
2) Any feedback or suggestions about the structuring of the study (participants engaging in the task, viewing videos, evaluating student work).

Mathematicians' Interplay of the Three Worlds of the Derivative and Integral of Complex-valued Functions

Hortensia Soto
University of Northern Colorado

Michael Oehrtman
Oklahoma State University

We engaged five research mathematicians in describing their images of differentiation and integration for functions of complex variables. Analyzing the data in terms of Tall's three worlds, we explore the connections between the physical embodiments of the mathematicians' reasoning, their descriptions for students, and their formalizations of these interpretations. For differentiation, the mathematicians relied heavily on direct application of concepts and analogies from differentiation of real-valued functions and employed rotation and stretching as a local linear description of the action of the function, corresponding to repeated mental imagery and physical gestures. For integrals, the mathematicians employed reasoning about line real-valued integrals, but acknowledged that they struggled to conceptually interpret what was being accumulated in the complex case. Instead, they all developed more personal meanings through a process of reconciling various aspects across their own conceptual-embodiment, operational-symbolic, and axiomatic-formal reasoning.

Key words: complex-valued function, derivative, integral, reasoning

Introduction and Literature Review

Authors of complex analysis texts introduce the definition of the derivative of a complex-valued function f at the point z_0 as the complex limit: $f'(z_0) = \lim_{z \to z_0} \frac{f(z)-f(z_0)}{z-z_0}$ if it exists. Although this algebraic inscription is introduced as early as chapter 2 of many texts (Brown & Churchill, 2009; Paliouras & Meadows, 1990; Saff & Snider, 2003) authors claim, "geometric interpretations of derivatives of functions of a complex variable are not as immediate as they are for derivatives of functions of a real variable" (Brown & Churchill, 2009, p. 59). Such interpretations are then delayed until after conformal mappings are introduced which generally appear towards the end of the text. Similarly, integration of complex-valued functions is generally introduced using algebraic inscriptions similar to those employed in a multi-variable calculus course. If $w: [a, b] \to \mathbf{C}$ is a complex-valued function of a real variable such that $w(t) = u(t) + iv(t)$, where u and v are are real-valued, then $\int_a^b w(t)dt = \int_a^b u(t)dt + \ i\int_a^b v(t)dt$, provided the integrals exists. A contour integral over a path $\gamma: [a, b] \to \mathbf{C}$ of a function $f: \mathbf{C} \to \mathbf{C}$ is further defined as $\int_\gamma \ f(z)dz = \int_a^b f(\gamma(t))\gamma'(t)dt$. If any geometric representations are provided for these integrals, they are often for the integrals of *u* and *v* in Euclidean space rather than leveraging any complex geometry to visualize *w* or *f* and γ. Given complex variables textbooks do not offer introductory geometric interpretations of either differentiation or integration on the complex plane, it is possible that students enrolled in complex analysis courses may not have opportunities to develop rich visualization of either of these notions. As such, we felt it worthy to explore the research question: What geometric interpretations do mathematicians use to reason about differentiation and integration of complex-valued functions? Such research has the potential to contribute to the creation of design experiments and new curricula as well as to extend the literature on teaching and learning of complex variables which is scarce.

Much of the literature on the teaching and learning of complex variables is limited to exploring undergraduates' and inservice teachers' geometric reasoning of arithmetic and algebraic concepts of complex numbers (Danenhower, 2000, 2006; Harel, 2013; Karakok, Soto-Johnson, & Anderson-Dyben, 2015; Nemirovky, Rasmussen, Sweeney, & Wawro, 2013; Panaoura, Elia, Gagatsis, & Giatlilis, 2006; Soto-Johnson, 2014; Soto-Johnson & Troup, 2015). Much of this work illustrates undergraduates' and inservice teachers' tendency to prefer algebraic reasoning even when geometric reasoning simplifies the task. On the other hand, Nemirovsky et al. demonstrated how undergraduates' geometric reasoning of the arithmetic of complex numbers could be developed through the use of physical activities. These activities entailed using a tiled floor, string, and stick-on dots representing the complex plane, vectors, and points respectively. As a result of these activities the research participants were able to make connections between algebraic and geometric reasoning. Soto-Johnson (2014) and Soto-Johnson and Troup (2015) found similar results with high school students and undergraduates, who used a dynamic geometric environment (DGE) to explore the geometric meaning of the arithmetic of complex numbers. The dynamic movement of the string or dragging elements in the DGE allowed the research participants to reconcile their algebraic and geometric reasoning and to view the arithmetic of complex numbers as transformations on the complex plane.

Some researchers have begun to explore analytical concepts related to complex variables (Soto-Johnson, Hancock, & Oehrtman, 2016; Troup, 2015) but the work in this area remains scant. Troup (2015) showed how DGEs can assist in developing undergraduates' geometric reasoning of the derivative of complex numbers. Specifically, with the aid of technology the research participants abandoned their belief, which stemmed from their calculus experiences, that the derivative of a complex function represents the slope of the tangent line. They also came to recognize the derivative of a complex function as the dynamic notion of an *amplitwist* (Needham, 1997). While Troup focused his work on undergraduates, Soto-Johnson et al. focused their research on mathematicians' conception of continuity of complex-valued functions. Using Schiralli and Sinclair's (2003) framework of *conceptual* and *ideational mathematics*, the authors found that the participating mathematicians' ideational mathematics manifested itself via metaphors which appeared to stem from their prior physical embodied experiences. Furthermore, these metaphors did not tend to fully capture the mathematicians' conceptual mathematics. For example, although the concept of continuity accounts for the co-domain first, several of the metaphors accounted for the domain first and thus had a *domain-first* quality. Given the role that metaphor and embodiment played in the participants' responses, we decided to employ Tall's (2013) Three World of Mathematics Framework (discussed below) in this research project.

Although there is abundant literature on both students' understanding of derivatives and definite integrals in introductory calculus of real variables, little of it touches on interpretations that are likely foundations for generalization to geometric interpretations of the corresponding concepts in complex variables. Neither standard curricula nor research tend to address the derivative of a function from $\mathbf{R} \rightarrow \mathbf{R}$ as a linear map (multiplication by the value of the derivative at a point) in any representation as a potential precursor to the amplitwist idea. Introductory multivariable calculus also does not typically provide such a foundation and instead frames the derivative in terms of partial derivatives or equations of tangent planes. Even more, most texts (quite reasonably) rely on the independence of codomain functions for real-variable derivatives to simplify the situation to multidimensionality only in the domain. Although line integrals provide a possible foundation for contour integrals, little education research has focused on the related concepts. Multiplication in the integrand of a contour integral by a complex-valued $\gamma'(t)$, however, introduces a rotation of the real and complex components of *f* that does not have a convenient real-valued analog.

Theoretical Perspective

Tall (2013), coined the term *met-before* after the word metaphor and defined it as “a structure we have in our brains *now* as a result of experiences we have met before” (p. 23). These met-befores can be supportive or problematic in a new situation, such as in the case of Troup’s (2015) research participants’ initial notion of the complex-valued derivative as the slope of a tangent line. A natural counterpart to met-befores are *set-befores* which consist of “a mental structure that we are born with, which may take a little time to mature as our brains make connections in early life” (p. 23). Tall identified *recognition*, *repetition*, and *language* as the primary set-befores, which promote categorization, encapsulation, and definition which in turn foster mathematical knowledge through three worlds of mathematics.

The three worlds of mathematics are: *conceptual-embodiment*, *operational-symbolic*, and *axiomatic-formal* and though distinct, they are very much interrelated. Tall (2013) explained how the world of conceptual-embodiment is a result of our perceptions and actions which create mental imagery which are perfected via verbal communication. The second world, operational-symbolism, stems from embodied human actions which transform into symbolic procedures that in turn are compressed into procepts (Tall, 2008). The third world, axiomatic-formal builds on formal axiomatic systems whose properties are established through mathematical proof. It is important to note knowledge expressed in the axiomatic-formal world can be conveyed via the conceptual-embodiment world. This is especially evident in teaching abstract notions and this was evident in the work of Soto-Johnson et al. (2016). Given that Tall (2013) clearly states that these three worlds are intertwined, we will seek to document mathematicians’ interplay between the three worlds as they convey their geometric reasoning of the derivative and integral of a complex-valued function.

Methods

This research is part of a larger study where we explored mathematicians’ geometric reasoning of the arithmetic of complex numbers and analytic concepts of complex-valued functions. Five Ph.D. mathematicians from three different institutions, within the same state, participated in a 90-minute, video-taped, structured interview. Becky, Judy and Rafael’s area of expertise was complex analysis, Luke’s area of expertise was differential geometry, and Andrew’s background was in differential equations (names are pseudonyms). All five of the mathematicians have taught complex analysis on a regular basis and four of the mathematicians have published in this area. In this preliminary report, we focus on the participants’ responses to the questions about their interpretation of differentiation and integration. As part of the interview, the participants had access to a black or white board and were encouraged to use it as they saw fit. We also probed in instances where the response seemed unclear or in instances where we knew that the response was not a complete geometric representation of the concept.

Our data analysis is similar to the analysis conducted by Soto-Johnson et al. (2016), including time-lines which depict the interplay of the three worlds. At this time, we have transcribed all the interviews and began using a scheme similar to Soto-Johnson et al., while attempting to tease out conceptual mathematics into either operational-symbolic or axiomatic formal. We also provide rich descriptions of gesture as this is a prominent source of evidence for the conceptual-embodiment world. Below we provide a glimpse of the mathematicians' responses.

Preliminary Results and Discussion

We categorized segments of the mathematicians' responses to the differentiation questions into comparisons to differentiation of real-valued functions, amplitwist models, and a variety of idiosyncratic images. While interpreting the complex derivative, all of the mathematicians relied heavily on met-before comparisons to differentiation of functions from $\mathbf{R} \to \mathbf{R}$, $\mathbf{R}^2 \to \mathbf{R}$, and $\mathbf{R}^2 \to \mathbf{R}^2$. Especially when describing how they explain the ideas to students, they emphasized operational-symbolic reasoning as they stressed the need to write out the complex function in coordinates $f(x+iy) = u(x,y) + iv(x,y)$ and examine the limit definition of the derivative, paths along coordinate axes, partial derivatives, level curves, matrix representations of linear maps, and single and multi-variable Taylor series expansions. Judy, for example, acknowledged the need for real differentiability of f as a function from $\mathbf{R}^2 \to \mathbf{R}^2$, but asserted she believed most people do not understand the geometry of this well. Instead, she consistently pursued approaches involving the separate tangent planes of u and v in her arguments, ultimately attempting to work out the geometric relationship between the tangent planes of the component functions u and v. Luke and Rafael agreed that there was no significant geometric insight to be gained from interpretations of continuous partials implying real differentiability, but both connected images of real-valued linear functions to the complex case. Andrew and Becky resisted drawing geometric interpretations of derivatives when talking about them apart from specific examples.

Four of the five mathematicians relied heavily on geometric interpretations consistent with Needham's description of an amplitwist, drawing several pictures and making consistent and repeated physical gestures of the action. As such, they integrated conceptual-embodied reasoning. All of the participants emphasized aspects of dependence on the domain point, local behavior of the function, linear approximation of this behavior, errors approaching zero "more quickly" than $|z|$, relating to multiplication by $f'(z)$, and decomposing the action into a rotation and a stretch. All of the mathematicians represented these actions algebraically and graphically in Cartesian coordinates, but several either commented that polar representations are more appropriate or deliberately switched to using polar coordinates in their descriptions. They all drew coordinate grids in a domain plane and their images in a codomain plane to illustrate the local stretch and rotation in the mapping. These decisions reflected conceptual-embodied and operational-symbolic reasoning. Repeatedly they would either move their hands from one to the other on the board or an imagined version in space spreading their fingers apart to indicate stretching and twisting their wrist to indicate rotation, often doing so seemingly subconsciously as they were thinking about other tasks. When focusing directly on conveying these ideas, their gestures became more exaggerated, often involving both arms or their whole body.

The responses to the integration task tended to combine various met-befores from real-valued calculus, but for the most part, the mathematicians were uncertain about a clear geometric interpretation for integration of complex-valued functions. For example, Andrew, Luke, and Judy applied the met-before notion of line integrals from multi-variable calculus. Andrew immediately responded that he would not think of integration geometrically and followed up by saying that he would have to think about it. After some pause he started using operational-symbolic reasoning as he wrote $\int_C (u+iv)(dx+idy) = \int_C (udx - vdy) + i\int_C (vdx + udy)$ and indicated that one could easily determine an answer but that he didn't know how to make sense of it. Although, hesitant to interpret such symbolism, he attempted to reconcile operational-symbolic reasoning with conceptual-embodiment of contexts such as work and flux but concluded, "It just means if I would compute the integral this is what I would get. I don't think I have any deep insight. Is there deep insight?" Luke's initial response to the integration question was similar to Andrews, as he stated, "Wow, what does that mean? (long pause). Okay, so this is a hard question. If you're integrating (long pause). This is hard." Although starting with conceptual-embodiment to reason about a path in the plane, Luke shifted to reconciling operational-symbolic reasoning with axiomatic-formal reasoning as he wrote mathematical inscriptions and cited several theorems. He uttered that these theorems would allow him to "get some number," but did not "know what that number means," and concluded, "I don't have a good feel for it."

In contrast, Judy immediately remarked that she teaches integration of complex functions as integrating along the x-axis for the function $f(z) = u(z) + iv(z)$. Thus, she employed operational-symbolic reasoning but transitioned to conceptual-embodiment as she mentioned that "it's geometrically more helpful for students to think about an application like work done along the curve … imagine there's a force field and I'm traveling through it." As she uttered these these words she traced a curve in the air with her hands together. One aspect of Judy's response that was quite different from the other responses was that she discussed tangent planes in conjunction with the Cauchy-Riemann equations and as such appeared to be combining conceptual-embodiment reasoning with axiomatic-formal reasoning.

Rafael's response mimicked Needham's (1997) description the most, but through a creative and well-developed story regarding an early explorer on an ocean ship, who has a route on a map that is incorrect. Rafael mentioned that the route represents the path of integration and in order to determine the correct route one has to break up the incorrect route "into little line segments … [and] each one of these [segments] is a displacement vector." Each of these displacement vectors are then rotated and dilated and all summed in order to determine the true path. Rafael's response combines symbolic-operational and conceptual-embodied reasoning via diagrams that come to life with his gestures.

Discussion and Questions for the Audience

Besides contributing to the literature on the teaching and learning of complex numbers we hope to contribute to Tall's framework. For example, he provides rich theoretical examples that illustrate these three worlds for the derivative and integral of real-valued functions. Our work will provide further empirical evidence but for complex-valued functions. We anticipate this can be adopted for real-valued functions, which might create non-problematic met-befores. We anticipate posing questions to the audience about ways to analyze and present the evolution of the interplay between the mathematicians "three worlds" in time. We will also seek critical feedback on our coding scheme, especially from the community whose research adopts embodied cognition or Tall's Three Worlds of Mathematics.

Evaluation of Graduate Student Professional Development and Instruction by Mathematics Departments: Results from a National Survey

Natasha Speer, University of Maine
Jessica Deshler, West Virginia University
Jessica Ellis, Colorado State University

Findings from a recent national survey indicate that two thirds of graduate-degree-granting mathematics departments provide some form of teaching-related professional development to their graduate students. Despite the prevalence of such programs, little is known about how departments evaluate the quality of the graduate students' instruction or the efficacy of their professional development. We present a mixed-method analysis of data to shed light on both of these topics. We found that graduate students and their professional development are most often evaluated based on student evaluations. Other research indicates the ineffectiveness of student evaluations as measures of teaching, and so this finding indicates a need for research-guided evaluation tools for graduate student professional development.

Key words: Graduate Student Teaching Assistants, Professional Development, Institutional Change, Evaluation

In the United States (U.S.), graduate student teaching assistants (GTAs) play a large role in undergraduate mathematics education (Belnap & Allred, 2009; Ellis, 2014), though typically have little to no prior teaching experience and receive minimal teaching preparation. It is well documented that more rigorous teaching preparation can result in expert-like beliefs, knowledge, and practices (Alvine, Judson, Schein, & Yoshida, 2007; Hauk et al., 2009; Kung & Speer, 2009; Luft, Kurdziel, Roehrig & Turner, 2004), making up for the lack of teaching experience of graduate student instructors compared to other types of instructors. In particular, a recent national study found the presence of a robust GTA professional development (PD) program to be characteristic of departments with successful undergraduate calculus programs (Ellis, 2015). Given the need for effective preparation of GTAs in teaching, there is also a growing need to understand how these PD programs are, and can be, evaluated.

A primary goal of GTA PD is to help ensure that high quality instruction is provided to undergraduate students. Consequently, it stands to reason that departments would (or could) utilize some measures of teaching effectiveness in the evaluation of their programs. Unfortunately, assessing teaching practices presents many challenges. As noted recently:

> "…even with widespread national investments, education researchers, administrators, and faculty do not yet have shared and accepted ways to describe and measure important aspects of teaching. Developing the language and tools necessary to describe teaching practices in undergraduate education is crucial to achieving productive discussions about improving those practices" (American Association for the Advancement of Science (AAAS), 2013, p. 1).

The work reported on in this Preliminary Report is part of a longer-term effort to understand and support department change related to GTA PD. To help departments improve their GTA PD programs first we need to understand their current evaluation practices and what they take as evidence of effective instruction. Here we present findings from a U.S. national survey of graduate-degree granting (Master's and Ph.D) institutions to answer the following questions: *How are mathematics departments currently evaluating the success of their GTA PD programs?*

What data do departments gather related to teaching effectiveness? Answers to these questions provide insights into the current context. The findings presented here are the first phase of the larger, longer-term effort. These findings and the discussions that will occur as part of this Preliminary Report presentation will inform the design of the next phase that will include case studies and interviews. These sources will provide detailed data to further inform answers to the research questions that are the focus of our current presentation of findings from survey data.

Theoretical Background

As noted by others, "Documenting an existing practice is often the first step in improving it" (AAAS, 2013, p. 4). With our longer-term goals of supporting change to GTA PD programs, our initial efforts are focused on obtaining and analyzing baseline data about current practices of GTA PD program evaluation and assessment of teaching practices.

Typically a PD program for teachers is marked as successful based on a positive change in teachers' knowledge, beliefs, instructional practices, or their students' success (Sowder, 1997), and thus evaluating a PD program often involves evaluating at least one of these measures. A number of researchers have (separately) assessed multiple K-12 PD programs and determined common characteristics of successful ones (Elmore, 2002; Garet, Porter, Desimone, Birman, & Yoon, 2001; Hawley & Valli, 1999; Kilpatrick, Swafford, & Findell, 2001). These characteristics include, but are not limited to, programs occurring over long periods of time, a focus on content-specific understanding and student thinking and an opportunity for enactment of practices through teaching activities. Currently, there exists no comparable set of characteristics identified as common to successful GTA PD programs. We anticipate that frameworks used in these other studies of PD programs can inform our efforts and thus our survey question design was informed by the common characteristics identified by these researchers.

With the long-term goal of analyzing factors that influence how and why departments change (and supporting such efforts), we approach this work with an eye towards *change strategies*. Henderson, Beach, and Finklestein (2010) conducted a large-scale meta-analysis of research on facilitating change in undergraduate science, technology, engineering, and mathematics (STEM) instruction. They found that the least successful change strategies were developing and testing "best practice" curricular materials and then making these materials available to other faculty as well as other "top-down" policy-making meant to influence practices. Successful strategies involved shifting the focus from approaches with exact intended outcomes before implementation to those that acknowledge that the final outcomes will be shaped by the individuals and/or environment involved in the system. To leverage these findings in the context of mathematics departments' GTA PD program change we need rich data and insights into the "system" in which program and teaching practice evaluation occur. That information can then be used to help support departments to pursue what Henderson et al. (2010) characterized as one of the most effective change strategies: seeking to understand the system that one wishes to change and designing a strategy that is compatible with that system.

Methods

A survey was sent to department chairs at all graduate-degree granting mathematics departments in the U.S. (n = 330). The survey was designed to document a variety of features of current departmental efforts including their calculus program, planned changes related to this program, and their GTA PD program.

Department chairs were encouraged to have local departmental experts answer components of the survey with which they were most knowledgeable. For instance, in the case of questions about GTA PD programs, facilitators of the programs would be ideal for answering that section of the survey. The survey was administered using Qualtrics and distributed by the Mathematical Association of America (MAA) with follow up emails and phone calls to encourage participation. Response rate was 68% (n=223) of all institutions, 75% (n=134) of Ph.D.-granting and 59% (n=89) of Master's-granting institutions. For this report we present combined data from Ph.D.- and Master's-granting institutions. Results presented here come from analysis of survey data from the 148 departments (two-thirds of all responding institutions) that reported having a department-specific GTA PD program.

Here we discuss responses to a subset of questions related to GTA PD, as shown in Table 1.

Table 1: Overview of questions used for analysis.

#	Question (and multiple choice options)
3.	Which of the following activities, related to **evaluating** GTAs' teaching, does your program FORMALLY include? Mark all that apply. • GTAs are observed by a faculty member while teaching in the classroom • Student evaluations required by the university or department • Student evaluations are gathered specifically for the purpose of evaluating GTAs (in addition to or separate from the student evaluations required by the university or department)
3e.	• Other (please explain):
4.	How well does your teaching preparation program prepare new GTAs for their roles in the precalculus/calculus sequence? Very well Well Adequately Poorly Very poorly
4e.	• Please elaborate on your answer above.
5.	• Is the department generally satisfied with the effectiveness of the GTA teaching preparation programs currently in place?
5e.	• Yes • The programs are adequate, but could be improved (please explain) • No (please explain)
6.	What best characterizes the current status of your GTA teaching preparation programs? Mark all that apply. • No significant changes are planned • Changes have recently been implemented or are currently being implemented • Possible changes are being discussed

These questions focus on how departments evaluate graduate students in their roles as GTAs, how they assess success of their GTA PD program, and what data they use as evidence in their program assessment. This subset of questions includes both multiple choice questions and open-ended responses questions, asking responders to explain or elaborate their choices to the main questions. In elaborating their selections to the multiple-choice questions, many institutions pointed to specific aspects of their GTA PD program as evidence for their statements. From these responses we are able to gain insight into how departments currently evaluate their GTA PD programs. We conducted basic descriptive analyses on the multiple choice question data and thematic analyses on open-ended responses (Braun & Clarke, 2006). Thematic analysis is a bottom-up qualitative approach, where themes are data-driven.

Results

Analysis of data from Question 3 provides insights into the various ways departments evaluate GTA's teaching. Over 90% of departments with a GTA PD program use university/department-required student evaluations to evaluate their GTAs' teaching, while about three-quarters use teaching observations by faculty members and one-quarter use additional student evaluations that are specific to GTAs. Note that these percentages do not add up to 100% because responders could indicate the use of multiple evaluation methods.

Questions 4-6 provided information on the evaluation of the departments' PD programs. Findings show that 57% of respondents report that their program prepares graduate students well or very well for their roles, 66% of departments are satisfied with their programs, and there are no changes underway at 63% of the schools. This indicates that roughly 40% of graduate degree granting mathematics departments in the U.S. are less than happy with the current state of their GTA PD programs. It is these programs that will be especially in need of good evaluation tools as they move forward with changes to their programs.

Ninety-six respondents provided elaborations for responses to Question 4 (regarding how well the GTA PD program prepares GTAs). Thematic analysis revealed 11 themes in these responses related to what departments use to evaluate their programs. These themes are named and described in Table 2, along with their frequencies. Each department's response was coded with as many themes as were present and appropriate.

Table 2: Description of themes from open-ended responses and their frequencies.

Theme	Description	Frequency
Student evaluations	Department or university student evaluations used as data to rate GTA PD.	7
Prevented from teaching	GTAs are prevented from teaching if they are not already determined to be prepared. This may be based on performance in teaching a lower level class, being a recitation leader, through an interview, or through practice teaching.	6
Compared to others	The GTA PD program is evaluated in comparison to other departments in the same university or other university, the program is	4
Common Exams	GTAs' students' performance on common exams is used as data to rate GTA PD.	4
Student Grades	GTAs' students' course grades (or pass/fail rates) are used as data to rate GTA PD.	4
Observations	GTAs are observed teaching or leading recitation and these observations are used as data to rate GTA PD.	3
Complaints	The amount of complaints about the GTA is used as data to rate GTA PD.	2
Teaching Award	GTAs' receiving Department or University teaching awards is used as data to rate GTA PD.	2
Other	This included alumni surveys, listening to the advice experienced GTAs give to new GTAs, reviews from faculty, retention of students, and student performance in subsequent courses.	4
Too vague	Response included an evaluation of the program with no reference to data, with answers such as "could be improved" or "is a well oiled machine."	48
Description of program only	The response included a description of the program without mention of evaluation or other kinds of data.	28

As shown in Table 2, 76 of the 96 responses were coded as being either a description of the program without information about evaluation, or an indication of evaluation but with no description of the data related to the evaluation. This finding suggests that either program evaluation is not a prominent part of these programs, or the design of the survey question did not provide us access to this information, or both. This indicates that further investigation is necessary to obtain richer and more definitive answers to this question. Of the remaining responses, the most often used data were student evaluations, followed by student performance on common exams, student grades, comparison to other known programs, teaching observations, teaching awards, and complaints. Four responses involved "other" data, including alumni surveys, listening to advice experienced GTAs give to new GTAs, faculty reviews, student retention, and student performance in subsequent courses.

Discussion and Next Steps

Our findings indicate that although the majority of mathematics departments run a PD program for their GTAs, evaluation of these efforts is limited. This is not especially surprising given that it would be somewhat unusual for most mathematics faculty to possess the specialized knowledge and skills needed to engage in program and other types of evaluation. This points to a significant need for our field if we wish to leverage GTA PD to improve the teaching and learning of undergraduates and increase enrollment and retention rates in STEM majors. Of course, this situation is not unique to GTA PD programs and other researchers have noted the unique skill set required for this work: "Institutional and departmental policies affect everyone, yet most investigators researching undergraduate STEM teaching practice lack the tools and expertise to document institutional change" (AAAS, 2013, p. 47).

In addition, the above analysis shows that a primary means of evaluation of graduate students as teachers and of their professional development is student evaluations. An abundance of research indicates issues with using student evaluations as an evaluative tool (Basow, 1995; Centra & Gaubatz, 2000; Krautmann, & Sander, 1999). Influences on student evaluations are diverse and include gender, perceived enthusiasm and other factors. Therefore, it is problematic that student evaluation data is the primary source used to evaluate novice instructors. Relying exclusively on such data may provide incomplete and/or inaccurate information that, in turn, may provide inaccurate information about the GTA PD program's impact on the effectiveness of the instruction being provided to undergraduate students.

The results presented here reveal a number of additional measures that mathematics departments are or could use to evaluate GTA's teaching and GTA PD. These include measures of student performance, such as course grades, grades on common exams, and grades in subsequent courses, as well as more direct measures of teaching performance, such as observations and teaching awards. This finding is an initial insight into what approaches are being pursued in the particular context of a mathematics departments and as such, this information suggests practices to leverage when encouraging and supporting change in other departments. Our planned interview and case study investigations can augment these findings and provide additional insights into what mathematics faculty see as relevant and meaningful ways of examining programs and what they take as evidence of the effectiveness of those programs.

An Explicit Method for Teaching Generalization to Pre-Service Teachers Using Computer Programming

Cynthia L Stenger Janet T Jenkins James A Jerkins Jessica E Stovall

University of North Alabama

As colleagues in a Mathematics/Computer Science department, we found that many of our undergraduates were not able to participate successfully in the full range of STEM course offerings. In response to this need, we developed a strategy for explicit instruction in mathematical generalization. Our instructional design is grounded in a theory of mathematical learning that uses computer programming to induce students to build the mental frameworks needed for understanding a math concept. The design includes writing mini programs to explore a mathematical concept, finding general expressions in the code, making conjectures about the relationships among general expressions, and writing logical arguments for the conjectures. We share results from a study of 18 undergraduate math/secondary education majors. Our results indicate most pre-service teachers showed improvement in their level of abstraction over the concept of direct variation.

Key words: Generalization, Computer programming, Pre-Service teachers

Introduction

Abstraction and generalization are critical skills for navigation through the computer science and mathematics curriculum. Any effort to improve instruction should take into consideration how students learn. It is widely believed that teaching proof writing as a solitary activity may not provide students the building blocks to become proficient in reasoning about mathematical concepts. Stylianides claims that the four essential components of 'reasoning-and-proving' are 'identifying patterns, making conjectures, providing non-proof arguments and providing proofs' (Stylianides, 2008). Jenkins, et al., developed an explicit approach to teaching abstraction and generalization that considers the mental processes by which abstract concepts are acquired and utilized (2012). In developing the instructional treatment, close attention was paid to the theory of learning called APOS theory (Dubinsky, 1984). APOS is an acronym that stands for Action, Process, Object, and Schema. Each level denotes a cognitive classification of the learner's conception. APOS theory is an outgrowth of Piaget's theory of Reflective Abstraction (Piaget, 1971). As a constructivist theory, the basic tenet of APOS theory is that an individual's understanding of a mathematical topic develops through reflecting on problems and their solutions in a social context and constructing or reconstructing certain mental structures, then organizing these mental structures into schemas to use in dealing with problem situations. Specifically, in APOS theory, the process of reflective abstraction is the key to cognitive construction of logico-mathematical concepts (Dubinsky & McDonald, 2001, Beth & Piaget, 1966).

Programming as a Vehicle for Building Abstraction in the Mind of the Learner

Researchers in APOS theory have long employed computer programming as a means to teach undergraduate mathematics. In numerous studies, spanning several countries, and applied to a spectrum of mathematical topics, APOS theory has been applied to the use of computer experiences to encourage the construction of mental processes that lead to mathematical concepts (Asiala et al., 1998, Weller et al., 2008). The computer treatments have consistently yielded an increase in likelihood that students acquired the desired concepts. It is a commonly held belief among this substantial group of researchers that computer constructions are an intermediary between concrete objects and abstract entities (Dubinksy, 1997, Asiala et al., 1998).

Instructional Treatment: Building Mental Structures with Computer Programming

Applying this theoretical framework, an instructional treatment was developed using computer programs to push students to build the mental frameworks for abstraction and generalization. This instructional treatment consists of four stages as shown in Figure 1. In the first stage essential characteristics (ESS) of a problem are identified. Next, mini programs (PROG) are written to explore the essential characteristics. General expressions (GEN) are found in the programs. Participants are taught to write these generalizations as mathematical statements. Further exploration with computer programs (PROG) leads to more generalizations, and general expressions (GEN) are collected as participants conjecture about relationships between concepts. Participants are taught to write convincing arguments (CA) for some of the conjectures, using the general expressions (GEN).

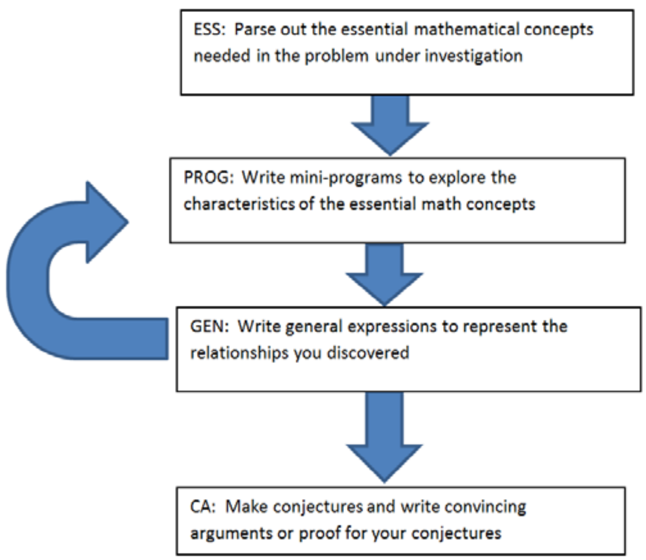

Figure 1. The four stages of the instructional treatment

Methodology

The participants were 18 undergraduate math/secondary education majors who were enrolled in a mathematical methods class. At this regional state university preservice teachers earn a bachelor of science in education and, in addition, complete all of the coursework for a mathematics major. This course is offered the fall semester before their internship.

Procedure Description

The instruction took place over a three day period. Each class session was 75 minutes. The format for the lessons included writing mini-programs using Python to explore concepts and make conjectures about relationships among concepts. For example, participants were asked to produce a table with columns consisting of distance, rate and time, then insert additional columns to show what happens when the rate is doubled while time is unchanged. From program output, they observe that distance doubled as rate doubled. They were taught to find the general expression for this relationship in their code and then to write it in mathematical language. After sufficient time exploring the relationship between increasing rate and resulting distance, they were led to make conjectures about relationships between distance, rate and time, in general. For example, they might conjecture that when the rate was multiplied by *k*, then the resulting distance was *k* times the original distance or "If $r_2=kr_1$, then $d_2=kd_1$." This was followed by instruction constructing convincing arguments for some of the conjectures. The proof writing activity was designed to push students to progress to the next level of cognition by affording them the opportunity to apply their conceptual knowledge in a different setting.

Data Collection/Analysis

All participants were pre-tested and post-tested to determine their level of abstraction for the concept being explored. Throughout the lessons, response sheets were also collected. This allowed the conceptual knowledge to be evaluated at multiple points to determine how mental frameworks were being built. Based on this data, each participant was assigned scores representing their level of abstraction over the concept before and after each lesson.

APOS analysis was used to assign level of abstraction demonstrated by a participant. Scores ranged from 0 to 3 representing No abstraction, Action, Process, or Object. Each entry was scored by at least three trained data analysts with a rubric developed for that particular concept and based on responses elicited on the pre- and post-tests and the response worksheets. Triangulated scores were tested for inter-rater reliability using Randolph's Kappa and assigned to each participant for each lesson, before and after instruction.

Results

Table 1 lists the item text associated with each scored response on the pre-test, response sheet, and post-test. Table 2 shows student scores for responses on the pre-test, participant response sheets, and post-test. Participant U0065 was not viable because they did not participate on the second day of the study. Twelve of the eighteen participants improved at least one level of abstraction in the direct variation lesson.

Response Item	Item Text
Pre-test 2,3	What happens to distance when time is fixed and you triple the rate? Write a convincing argument.
Computer 3,4	What happens to distance when time is fixed and you double the rate? Write a convincing argument.
Math 7,8	What happens to distance when time is fixed and rate is cut in half? Write a convincing argument.
Math 9,10	What happens to the distance when time is fixed and rate decreases? Write a convincing argument.
Post-test 2,3	What happens to distance when time is fixed and you triple the rate? Write a convincing argument.

Table 1. Question text on pre-test, response sheet, and post-test

Participant Code	Pre-test 2,3	Computer 3,4	Math 7,8	Math 9,10	Post-test 2,3	Change
U0018	1	1	3	3	3	2
U0064	0	1	3	3	2	2
U0065	0	1	N/A	N/A	1	1
U0066	0	1	3	3	3	3
U0067	1	1	3	3	3	2
U0068	1	1	3	3	3	2
U0069	2	1	3	3	2	0
U0070	1	1	3	3	2	1
U0071	1	1	3	3	1	0
U0033	0	0	2	3	0	0
U0038	0	0	3	3	2	2
U0041	0	0	2	3	2	2
U0042	1	1	2	3	3	2
U0045	0	0	2	3	2	2
U0047	0	1	2	3	2	2
U0048	0	0	2	3	3	3
U0049	0	1	2	3	2	2
U0051	2	1	2	3	2	0

Table 2. Scored participant responses on pre-test, response sheet, and post-test

The following snips from participant U0068 are representative of how the students' convincing arguments improved over the course of the instruction.

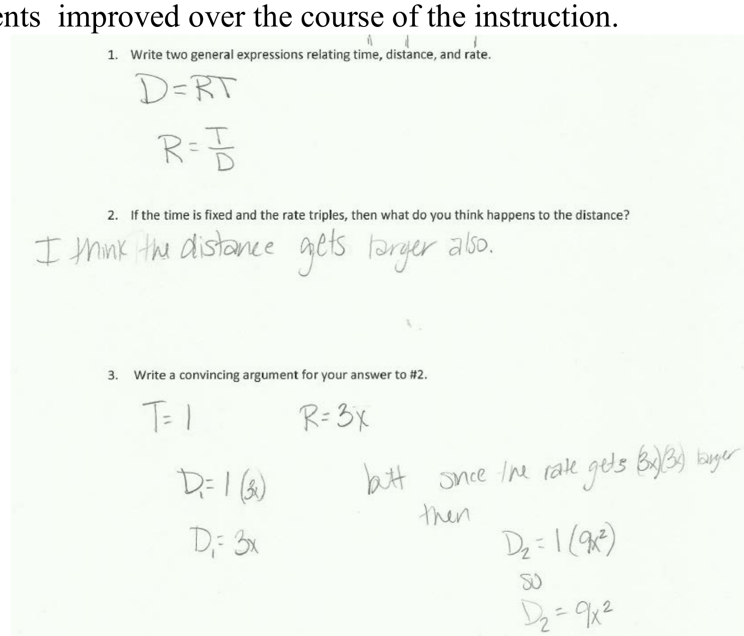

Figure 2. Pretest for participant U0068

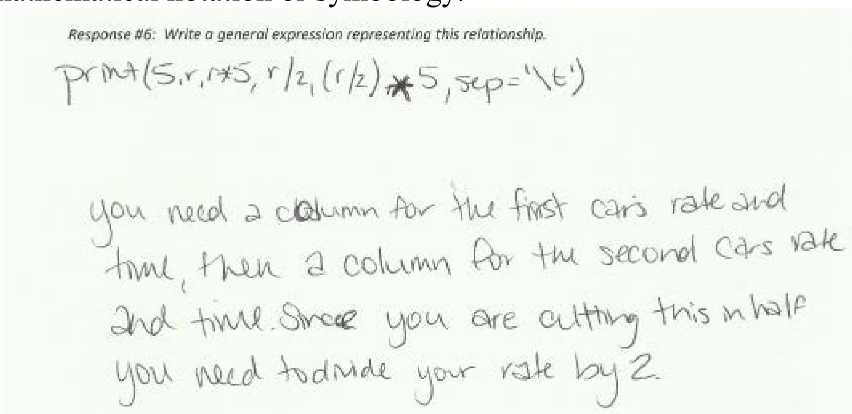
In the pretest, participant U0068 was able to recall the correct formulas to express the relationship between distance, rate and time. They had a correct "intuition" concerning the result, "distance gets larger also" (Figure 2). After the computer programming instruction, participant U0068 could state the effect of the increase specifically, rather than saying "the distance gets larger". When asked to give a general expression for the relationship, they referenced their computer code. In addition, they wrote a description of the output of the code and described the relationship in terms of the columns of data produced as output (Figure 3). The mathematics portion of the lesson taught students to find general expressions in their code and write them in mathematical notation or symbology.

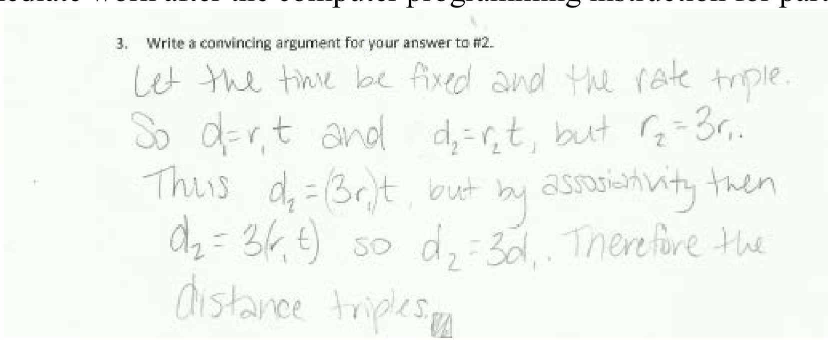


Response #6: Write a general expression representing this relationship.

```
print(5,r,r*5, r/2,(r/2)*5, sep='\t')
```

you need a column for the first cars rate and time, then a column for the second cars rate and time. Since you are cutting this in half you need to divide your rate by 2.

Figure 3. Intermediate work after the computer programming instruction for participant U0068



3. Write a convincing argument for your answer to #2.

Let the time be fixed and the rate triple. So $d_1=r_1t$ and $d_2=r_2t$, but $r_2=3r_1$. Thus $d_2=(3r_1)t$, but by associativity then $d_2=3(r_1t)$ so $d_2=3d_1$. Therefore the distance triples.

Figure 4. Post test participant U0068

In the post-test, participant U0068 gave a convincing argument that used general expressions to express the relationship between distance, rate and time (Figure 4).

Conclusion

In this study we have described an explicit method for teaching generalization. We have reported results from a pre-service teachers in a mathematical methods course. We have shown that most participants' level of abstraction or ability to apply generalizations for direct variation increased. This is a strong indication that generalization can be taught explicitly. It suggests that further research into computer programming as an effective tool for teaching mathematical thinking is warranted.

The Use of NCTM Articles as Reading Assignments to Motivate Prospective Elementary Teacher Engagement in Mathematics Courses

Krista Strand
California State University, Chico

Eva Thanheiser
Portland State University

In this study, we examine the use of assigning articles published in NCTM's practitioner journals as readings in mathematics content courses for prospective elementary teachers (PTs). In particular, we study the articles' roles in motivating PTs to engage in their content courses. As a conceptual foundation, we characterize NCTM articles as having potential to (1) increase PTs' "buy-in" of pedagogical approaches used in content courses, (2) challenge PTs' unproductive beliefs about mathematics, and (3) address mathematics content via children's thinking. We plan to analyze an existing dataset of PTs' online typed responses to assigned NCTM articles to identify whether and how their responses reflect increased motivation to engage in their content courses. We anticipate that our results will lead to an increased understanding of PTs' actual experiences related to the assigned article readings.

Key words: Prospective elementary teachers, subject matter knowledge, student motivation

Elementary teachers must have deep *subject matter knowledge* (Hill, et al., 2008) in order to teach mathematics well (Ball, 1990; Conference Board of the Mathematical Sciences, 2001; Kilpatrick, Swafford, & Findell, 2001; Ma, 1999). Thus it is of critical importance that PTs engage fully in their preparatory mathematics content courses in order to maximize their learning. This is particularly true in light of the fact that prospective elementary teachers (PTs) in the U.S. typically enter their content courses with limited subject matter knowledge (Ball, 1990; Ma 1999; Thanheiser, 2009; Thanheiser et al., 2014). And yet, it has been shown that PTs do not enter their content courses motivated and ready to learn (Kurz & Kokic, 2011; Moyer & Husman, 2006; Philipp et al., 2007; Thanheiser, 2009; Thanheiser et al., 2013).

Accordingly, mathematics teacher educators have developed pedagogical techniques and interventions that work to motivate PTs to engage in their content courses (Philipp et al., 2007; Thanheiser, 2009; Thanheiser et al., 2013; Thanheiser & Jansen, 2016). A recent example of one such intervention is the use of one-on-one content-based interviews that instructors can implement with their PT students (Thanheiser et al., 2013). Thanheiser and her colleagues showed that interviews can motivate PTs to learn by changing their beliefs about mathematics, and by increasing their awareness of their own unpreparedness to teach mathematics.

In this study, we investigate ways in which having PTs read and reflect on articles from NCTM's practitioner journals (e.g., *Teaching Children Mathematics* and *Mathematics Teaching in the Middle School*) might also motivate PTs to learn mathematics, according to the perspectives of the PTs themselves. As instructors of mathematics content courses for PTs, we find these reading assignments to be indispensable. Prior to this study, though, we know of no research specifically examining the use of NCTM articles in PT content courses and how such article assignments might support PTs in engaging in their content courses, promoting their development of subject matter knowledge for teaching mathematics. Our work addresses this, and moreover, our work illuminates PTs' own experiences and reactions to NCTM articles.

Conceptual Framework: Three Types of NCTM Articles to Motivate PTs' Learning

Below, we introduce three types of NCTM articles according to how we, as instructors of PT content courses, believe the articles boost PTs' motivation to learn mathematics. Further, we point to previous research literature to support these notions. Note that our discussion of each type of article is not intended to imply that every NCTM article can be categorized as being only one type. In other words, we see these three article types are interconnected, and indeed, many articles are two or three types simultaneously.

Type 1: Potential to increase PTs' "buy-in" of our pedagogical approaches

In our content courses for PTs, we strive to develop a collaborative, discussion-heavy learning environment that is built upon PTs' own ideas (Thanheiser, Browning, Moss, Watanabe, & Garza-Kling, 2010), and that fosters an orientation towards mathematics as a sense-making and problem-solving activity (Lampert, 2001). We do so not only to model for PTs how we hope they will someday conduct their own classrooms, but also because we believe this type of environment is necessary for PTs' own learning of mathematics. However, such an environment can differ drastically from the types of environments PTs experienced as K-12 students (Beswick, 2005; Comiti & Ball, 1996). For example, we ask PTs to share their thinking often in class, yet one study recently found that 85% of PTs had little to no experience being asked to share their thinking during any previous mathematics class prior to taking their first PT content course (Thanheiser & Jansen, 2016).

Because PTs hold preconceived notions about the teaching and learning of mathematics based on their own prior experiences as learners (Anderson, White, & Sullivan, 2005; Charalambous, Philippou, & Kyriakides, 2008), they are often skeptical about the unfamiliar style of teaching they are experiencing in their content courses. We believe NCTM articles that discuss the potential effectiveness of certain pedagogical approaches can help PTs make the transition to participating in class in ways that are new to them.

An example of this type of article is "Techniques for Small Group Discourse" (Kilic, et al., 2010). The authors open this article with a brief discussion of the importance of having children engage in discourse in a mathematics class. Then, the authors present two scenarios of teachers engaging elementary students in discourse, and they examine how the teachers' facilitation of student discourse promoted students' reasoning about the content. Although the intended audience of this article is practicing elementary teachers, we believe that having our PT students read about a classroom of children who deepened their understanding of a mathematical concept through dialogue might motivate them to similarly engage in dialogue during their content courses. We believe articles like this one can help PTs understand the rationale behind the teaching methods that we use in class, potentially decreasing their skepticism and increasing their willingness to engage with them.

Type 2: Potential to challenge PTs' beliefs about mathematics

A second type of article serves to challenge unproductive beliefs that PTs commonly have about mathematics (Philipp et al., 2007). For example, many PTs believe that mathematics consists entirely set of procedures or rules to be memorized (e.g., Ball, 1990; Thanheiser, 2009). Such PTs might not see the value in understanding why the procedures make sense, or that there is more than one correct way to solve a problem, thus potentially shutting down their motivation to learn the content, that they believe they already know, more deeply. Articles that push against PTs' commonly-held beliefs about mathematics might help them be more open to learning.

An example of this type of article is "Multicultural mathematics and alternative algorithms" (Philipp, 1996). This article opens with a child's invented algorithm for long division, introducing the idea that there is more than one way to solve a mathematics problem and that even young children can invent effective mathematical procedures. Then, the article presents and discusses examples of algorithms for multi-digit computation used around the world. None of the algorithms are the same as the standard algorithms traditionally taught in the United States. We believe that having our PT students read this article might help them recognize and re-think their beliefs centered on the idea that mathematics consists of one fixed set of procedures developed by somebody else. Additionally, this article might help challenge PTs' belief that the procedure that they are most familiar with is the only one, is used by everyone worldwide, and is the easiest. Our intention is that articles of this type help PTs think through beliefs that might restrict their motivation to learn mathematics that is new to them.

Type 3: Potential to address mathematics content via children's thinking

Prior research has pointed to the fact that PTs' analysis of children's mathematical thinking can be a motivator for PTs' own learning of content. For example, the use of artifacts of children's thinking (e.g., videos of children doing mathematics, or children's written work) has been linked to gains in PTs' mathematical understanding (Jacobs, Lamb, & Philipp, 2010). Our use of NCTM articles that discuss the mathematical details of children's ideas and strategies follows directly from this work. We believe that PTs are motivated to understand the mathematics more deeply themselves when they are confronted with artifacts of real children's mathematical thinking (e.g., via an article discussing a child's invented algorithm for long division).

An example of this type of article is "Tuheen's thinking about place value" (Wickett, 2009). This short article gives an account of a third-grader, Tuheen, who suggests that the regrouped "1"s in the multi-digit addition problem 59 + 67 be written as "10" and "100" instead of "1"s, to show their true value. The author then discusses how Tuheen's insight seemed to help strengthen his peers' understandings of place value in multi-digit addition. Because many PTs do not know the true value of the regrouped "1"s when they enter their content courses themselves (Thanheiser, 2009), we assign this article with the intention of helping them deepen their own understanding of place value and see that children can and do make sense of mathematics and come up with their own algorithms. As PTs work to follow the account of Tuheen's mathematical reasoning in the article, we believe they strengthen their own mathematical reasoning as well.

Research Questions

The above potential benefits of assigning NCTM articles are derived from our perceptions as teacher educators and may or may not be actualized, according to the perspectives and experiences of our students. And so we wonder whether there is evidence within PTs' written reactions to articles to support that they are, in fact, serving to motivate PTs' learning of mathematics. Further, we wonder what PTs' article responses tell us about the ways in which the ideas in the articles support their learning of mathematics. Therefore, in this study, we specifically ask the questions:

(1) Do PTs experience increased motivation to engage with the course material in mathematics content courses as a result of reading NCTM articles, according to PTs' responses to the articles?

(2) If so, how do PTs experience increased motivation to engage with the course material in mathematics content courses by reading NCTM articles, according to their responses?

Methods

Participants

Participants in this study were 42 PTs enrolled in the first course in a sequence of three quarter-long mathematics content courses for undergraduate PTs at a large, urban state university in the Pacific Northwest of the United States. The content of the course focused on whole numbers and operations. Thirteen of the participants were enrolled in the course in the Summer, and the class met for 140 minutes every weekday for three weeks (equivalent to four credits in one quarter). Twenty-nine of the participants were enrolled in the course in the Fall, and the class met for 110 minutes twice per week for ten weeks, which is also equivalent to four credits in one quarter.

Data Collection

As part of the homework assignments for the course, students were asked to read NCTM articles and respond online via a discussion forum in Desire2Learn (a course platform similar to Blackboard). Specifically, students were asked to: (1) type and post their initial summary and reaction to the article, and then (2) respond to at least one other person's post. There was no specific requirement for post lengths, yet the students were asked to make their responses substantive enough to convince the instructor that they read the article.

The dataset for the analyses below consists of all students' first summary/reaction discussion forum posts for each of three articles (one article representative of each type introduced above). Specifically the three articles are: "Techniques for Small Group Discourse" (Kilic et al., 2010, representative of a Type 1 article); Beliefs About Mathematics for "Multicultural Mathematics and Alternative Algorithms (Philipp, 1996, representative of a Type 2 article); and Content via Children's Thinking "Tuheen's Thinking About Place Value" (Wickett, 2009, representative of a Type 3 article).

Data Analysis Plan

This study is ongoing. At the time of this preliminary report, all data has been collected and analyses are in beginning stages, according to the plan outlined below.

In our first research question, we wonder whether the intended reasons for assigning NCTM articles appear within PTs' reactions to the articles. For example, for a Type 1 article, we ask, "Is there evidence to suggest that PTs actually experience increased buy-in to our pedagogical approaches, in response to reading this article?" Accordingly, all PTs' initial responses to each of three articles (one representative of each type) will be coded "yes" or "no", according to whether they made a statement relating to the type of the article. The percentage of "yes" and "no" responses will be reported. Further, if a response is coded "yes," the section(s) of the PTs' response that addressed the purpose of the article will be pulled out for analysis pertaining to the second research question. Figure 1 shows sample excerpts from our dataset that would be coded "yes" for each type of article.

Type of Article	Sample "Yes" Excerpt from a PTs' Response
Type 1: Potential to increase PTs' "buy-in" of our	"While the article primarily addresses the teacher's role in small-group facilitation, it provided me with an opportunity to reflect on my own experiences of working in small groups. The math classes that I have

pedagogical approaches	taken in high school were primarily lecture format, so working and collaborating with my peers is a new experience. Although I was tentative at first, I enjoy the collaborative atmosphere.”
Type 2: Potential to challenge PTs’ beliefs about mathematics	“Before reading the authors final comments I was thinking the alternative methods introduced in the article seemed much harder than the methods I was taught as a youngster but then the author recognized the fact that “people have the tendency to believe that the algorithm they use is easiest, regardless of what it is." I was shaking my head yes and then revisited the alternative methods with a more open mind.”
Type 3: Potential to address mathematics content via children’s thinking	“Wow! I never would have thought to do math that way, how very interesting. I think that that is a good way to do math in the beginning to show them what it means to carry and that the number (lets say 1) is actually a ten or hundred when carried over to that column.”

Figure 1. Sample PT responses that will be coded “yes” as evidence of the PT experiencing increased motivation, for each type of article.

In our second research question, we wonder how each type of article might motivate PTs to learn mathematical content, according to their own perspectives (as opposed to our own notions about how this might happen). For example, for a Type 1 article, we ask “In what ways (if any) do PTs’ responses suggest they are experiencing increased buy-in to our pedagogical approaches?” Here our goal will be to identify patterns in PTs’ open-ended responses to articles, and so we will use thematic analysis (Braun & Clarke, 2006) on the marked, relevant sections identified in our analyses for the first research question. Specifically, we will identify themes that illuminate the PTs’ perspectives on how an article’s intended purpose connects to their own motivation to learn. In this way, our use of thematic analysis will be focused on developing a deeper understanding of PTs’ perspectives pertaining to themes, using a narrow lens. This is in contrast to a more broad application of thematic analysis that would seek to capture all themes within the entirety of the PTs’ responses.

Discussion Questions for the RUME 2017 Audience

Because this is a preliminary report, we encourage feedback from the RUME 2017 audience to help shape the future directions of our work, as well as clarifying the community-wide implications of our findings. We specifically plan to pose the following questions to inspire discussion:

1) In our report, we introduce three types of NCTM articles according to the way in which they motivate PTs’ learning of mathematics content. What other “types” of NCTM articles might we consider including in future research?

2) For teachers of elementary mathematics content courses for PTs: What implications (if any) do the themes within our PTs’ responses have with respect to your own teaching?

Analysis of Teachers' Conceptions of Variation

Gabriel Tarr
Arizona State University

April Strom
Scottsdale Community College

The CCSSM emphasize statistical concepts for grades 6-12. A key factor in thinking statistically is to reason about variation and variability. This paper will present the analysis of survey questions and tasks given to in-service middle school teachers. The paper will attempt to answer the following question: "To what extent do middle school math teachers consider variation and variability when thinking about statistics and reasoning through statistical tasks?"

Key words: Statistics, Professional Development, Teacher Education

Organizations such as the American Statistical Association [ASA] (GAISE, 2005) and researchers (Gal, 2003; Gould, 2004; Davidian & Louis, 2012) have discussed the need for and importance of citizens' statistical literacy. Since 2010, many states across the United States have adopted the Common Core State Standards for Mathematics [CCSSM] (National Governors Association, 2010). These math standards explicitly contain statistics[1] standards for each grade band starting with the sixth grade. This emphasis on statistics in CCSSM is much greater than in previous standards (Tran, Teuscher, Dingman, & Reys, 2014). As a result, math teachers in the middle grades must now attend to statistical concepts as well as solely mathematical concepts.

However, peoples' prior experiences with statistics in formal educational settings are usually limited to ideas of center where ideas of variation are not emphasized until later grades, if at all (Pereira-Mendoza, 1986; Shaughnessy and Pfankuch, 2002; Noll & Shaughnessy, 2012). In order for teachers to teach statistics in a manner their students might find useful, the teachers themselves must first have productive beliefs, meanings, and ways of thinking about statistics. These productive meanings, beliefs, and ways of thinking about statistics must, by necessity, include productive ideas about variation and variability (Garfield & Ben-Zvi, 2005).

In this paper the researcher will answer the following question: *To what extent do middle school math teachers consider variation and variability when thinking about statistics and reasoning through statistical tasks?* This paper will include a preliminary analysis on the beliefs and conceptions that middle school math teachers participating in a professional development program hold about ideas of variation and variability. The beliefs and conceptions will be analyzed through the use of open-ended survey questions, and free-response statistical content questions.

Literature Review

Salisbury (1996) discusses variability and variation in data as the differences among people, among environments, and among things. Cobb and Moore (1997) describe statistics as a methodological discipline that arises from the omnipresence of variability. According to the GAISE (2005) framework, statistical thinking "must deal with this omnipresence of variability; statistical problem solving and decision making depend on understanding, explaining, and quantifying the variability in the data" (p. 6). Though the CCSSM (National Governors Association, 2010) does not formally define statistics, there is an implicit theme of variability

[1] Statistics used in this paper will mean the discipline of statistics, unless otherwise stated.

that is essential to this idea of statistics. The first 6th grade statistics standard in the CCSSM is for students to develop an understanding of statistical variability. A person who understands statistical variability will be able to recognize that statistical questions anticipate variability in data and considers its role in the answers (National Governors Association, 2010).

Several researchers have studied students' and teachers' conceptions of statistics as they relate to variability and variation (Shaughnessy et al, 1999; Torok & Watson, 2000; Saldanha & Thompson, 2002; Liu, 2005; Noll & Shaughnessy, 2012). For example, Saldanha and Thompson (2002), Liu (2005), and Noll and Shaughnessy (2012) discussed productive meanings for individuals to possess about sampling that involved individuals being able to envision variability of sample attributes between outcomes from repeatedly sampling from a population. Thus, the first 6th grade statistics standard is a large part of the foundation for a much more sophisticated statistical concept.

Methodology and Framework

The data collected for this study were gathered through the efforts of a large-scale professional development and research program. This program focused on middle school teachers in a Southwestern state in the United States. Each teacher in the program was asked to participate in professional development activities for two years. The project focused on promoting the mathematical and pedagogical development of its participants.

At the beginning of the second year, the researcher gave two assessment instruments to 50 teachers prior to formal professional development on statistical ideas. The first instrument was a set of mathematical tasks, both multiple choice and free-response, that related to statistical content the teachers were expected to teach in middle school (grades 6-8). The second instrument was an open-ended beliefs survey with seven questions about statistics and statistics teaching.

The researcher performed an initial examination of the teachers' survey responses by conducting several passes through the data. During each pass, the researcher examined the response for each question from each teacher before moving on to the responses for subsequent questions. The researcher created themes in teacher responses while using the lens of the GAISE (2005) framework in conjunction with CCSSM (2010) for statistics. Using this lens, the researcher examined the two survey questions and two content tasks where teachers had the most opportunity to consider variability as they thought about statistics and reasoned through statistical tasks.

Questions and Task Description

The focus of this paper is on the analysis of two of the beliefs survey questions and two of the tasks. The researcher analyzed the following two questions. Q1: Briefly give a definition for *statistics*. What do you take this to mean? What comes to mind when you see or hear the word *statistics*? Q2: To you, what are the differences, if any, between *statistics* and *mathematics*? What are the similarities, if any, between *statistics* and *mathematics*?

In addition to these survey questions, two tasks were analyzed: The Sampling Task and The Calorie Intake Task. The researcher designed The Sampling Task (Figure 1) to determine what teachers believed to be important aspects of sampling, as well as to determine which aspects of sampling that teachers would give evidence of noticing in their arguments for or against one of the choices.

You give your class a task to determine the average height of all the students in your school. Due to various time and logistic restrictions, your students are unable to measure each student at the school and instead must use sampling to determine the average height. Three of your students each come up with their own way to sample the school's population.

Chi's method: Assign the students in each class at her school a number. Randomly select one number of the numbers from each class. Record the height of the student that corresponds with that number.

Kendra's method: Wait until after-school clubs and sports start. Select one boy and one girl of each grade level (6th, 7th, and 8th) for each club or sport. Record their heights.

Diego's method: Pick an entire class from each grade (6th, 7th, and 8th) and record the heights for each student in each class.

Based only on the sampling method, whose conclusions would you be most willing to accept? Why would you be willing to accept this student's conclusions more than the other students' conclusions?

Figure 1: The Sampling Task

Each of the choices in The Sampling Task has a designed strength and weakness pertaining to sampling methodology. Chi's method is the only sampling method that includes random sampling. However, the number of classes in the school are not given in the prompt, thus the size of Chi's sample may be too inadequate to accept her conclusions. Kendra's method is the only sampling method that accounts for gender[2] in the sample. However, Kendra's sample may not be representative of the students at the school due to the existence or composition of certain sports. Diego's method has the potential for having the largest sample. However, Diego's sample, while large, may not be representative of the population at the school due to how he picked the classes. From the prompt, the teacher had to determine that Diego's method is not a census.

The histogram presented in The Caloric Intake Task (Figure 2) depicts a collection of calorie (kcal) counts.

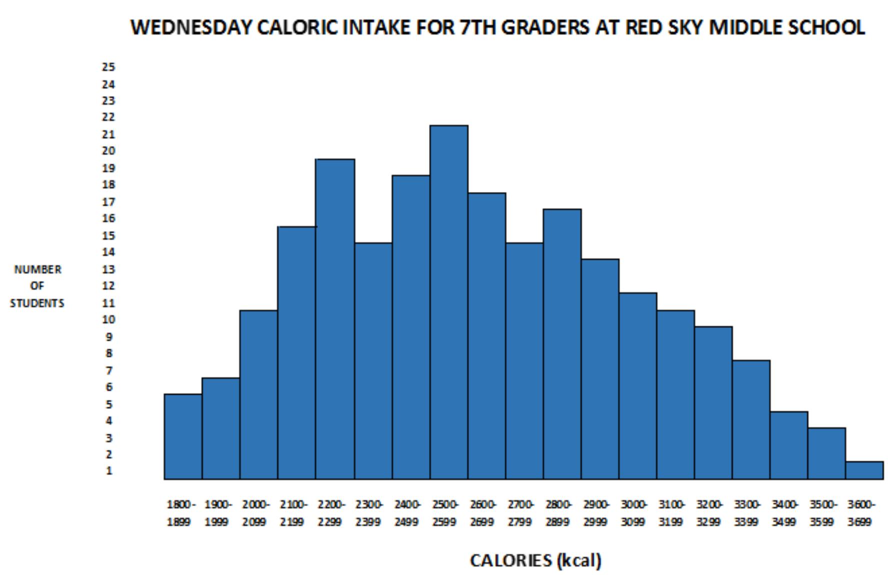

Figure 2: Histogram from The Caloric Intake Task

[2] Assuming gender as being dichotomous.

Using the histogram in Figure 2, the teachers were tasked with describing the data, developing questions to ask their students about the data, and explaining the statistical concepts underlying these questions. The researcher designed this task to determine what teachers believed to be important enough aspects of a distribution of data to ask their students. The researcher wanted to examine the ideas and language relating to the data's shape, center, and variability that the teachers would (or would not) use in posing questions to their hypothetical students.

Preliminary Results and Discussion

The new standards unambiguously state variability as a necessary condition for statistical thinking. However, the preliminary data from the teachers in this study suggest that teachers rarely consider the notion of variability when thinking about statistics or engaging in statistical tasks. In the beliefs survey, only one of the 50 teachers responded to Q1 with anything pertaining to variability.

An important difference between statistics and mathematics is that people who do statistics are focused on the variability of data. Thus, Q2 is a natural question to probe teachers' thinking about variability. Several teachers responded to the question with statements about utility, subjectivity, or practicality of statistics when related to mathematics. Several teachers also responded with the notion of statistics as a subset of mathematics. None of the teachers responded to Q2 by mentioning anything about variability being a key difference between the two, not even the teacher who had mentioned variability in her response to Q1.

Q1 and Q2 provided the best opportunity for teachers to discuss variability's role in statistics in the survey format. With only 1% of the total responses mentioning variability, the teachers seem to indicate that they do not consider variability when thinking about statistics. To strengthen this argument, analysis of the statistical tasks is presented below.

The Sampling Task and The Caloric Intake Task provided the teachers with opportunities to reason about statistics both personally and pedagogically. Of the 44 respondents to The Sampling Task, 31 selected only Deigo's method, 12 selected only Chi's method, and one selected Kendra's method or Diego's method. None of the teachers selected only Kendra's method, in fact, the teachers overwhelmingly selected against Kendra's method. As Table 1 shows, many teachers picked out the potential for sampling bias in Kendra's method as a weakness. None of the teachers (including the lone teacher who picked Diego and Kendra) mentioned the designed strength of Kendra's method.

Table 1: Teacher Responses to Kendra's Method

Sample of Teacher Responses to Kendra's Method	Kendra's method will undoubtedly be skewed because of clubs and especially sports.	Kendra is only athletes which could be biased to tall people.	Kendra's only samples a certain demographic and is not representative of "normal"	Kendra or Diego because their samples would be random vs biased. You must take into account not only the sample space but the direction the question at hand is leading you to a conclusion.

The variability in middle school students' heights due to gender[3] is familiar to middle school teachers. However, based on the responses, it seems to have gone unnoticed by the teachers that

[3]The height differences due to gender in middle school are obvious, but these claims can be corroborated by The Center for Disease Control. http://www.cdc.gov/nchs/data/series/sr_11/sr11_252.pdf

Kendra deliberately accounted for gender in her sampling. If some teachers did notice it, accounting for gender did not seem to be important enough for the teachers to give comment. Given this context that is near to the teachers, the researcher speculates that teachers who attend to the necessity of variability for statistics would have had no problem mentioning this strength of Kendra's design, even if the teacher did not choose Kendra's method.

The Caloric Intake Task was more open-ended than The Sampling Task. As stated previously, it was designed to allow the teachers to share what they felt might be salient statistical concepts for their students. A surface-level analysis revealed that 19 of the 31 teachers responded to the task with language or calculations that were related to variability. A deeper analysis of the teacher responses showed that only four of the 31 teachers asked meaningful questions about variability. Of these four teachers, two asked questions of their students about why the caloric intake between students could potentially vary. The other two teachers gave examples of how the caloric intake could potentially vary due to students' socioeconomic statuses, students' athlete statuses, and students' health statuses (Table 2).

Table 2: Teacher Responses to The Caloric Intake Task

Sample of Variability Language Responses	"Range of intake, mean, median, mode, MAD..."	"Students are between 1800 and 3699 calories which is a range of 1899 calories."	"What's the mean? What's the range?"	"I would ask my students about the spread and shape of the data as well as the skew."
Meaningful Variability Responses	"Why do you think the data varies?"	"What was the variation of the number of calories consumed?"	"Which groups of students might be in different categories? (athletes, poor who wouldn't get dinner at home, etc"	"There is a large range is calorie intake. I wonder how many students play sports - this could affect the needed calorie intake.

Based on the fact that the variability response rate for Q1 and Q2 was so low, it is safe to assume that the four teachers are atypical of the teachers in the program at-large. Most of the teachers do not seem to consider variability when thinking about statistics or reasoning through statistical tasks.

Future Work

Teachers responded to Q1 and The Caloric Intake Task with language that relates to variability. However, the teachers' responses to all four assessment items do not indicate that they are considering how variability influences statistical thinking. In the future, the researcher plans to 1) collect task-based interview data to assess the meanings that teachers have when they use variability language and 2) interact with teachers during lesson-planning activities to focus their attention on attending to variability while planning tasks and activities for their students.

Implementation of Pre and Post Class Readings in Calculus

Salam Turki
Rhode Island College

Houssein El Turkey
University of New Haven

Active learning practices highly depend on students' preparation for class in advance. However, reading Calculus can be a challenging task to students. We address this concern by assigning targeted pre-class readings and reading quizzes in two Calculus II classes. To study the effectiveness of these, we also provided them as post-class readings in two other classes. We report on our implementation and we discuss students' feedback about the readings and quizzes.

Key words: pre and post class readings, reading quizzes, exit quizzes, Calculus

Introduction

In recent years, Flipped Classroom and Inquiry-Based Learning pedagogies have emerged as methods of active learning. These active learning practices highly depend on students' preparation for class in advance. To prepare for class, professors often ask their students to read the textbook before they come to class. However, most faculty report that students rarely do this (Felder & Brent, 1996). We believe that this concern is even more evident in mathematics education. Reading mathematics texts before the class can be a challenging task to students especially in introductory classes such as Calculus. In this proposal we attempt to address this issue by implementing active learning practices (Prince, 2004) in four classes of Calculus II.

Our study is divided into two themes: students in two sections had access to short typed targeted notes before class combined with reading quizzes at the beginning of the class period. In two other sections students had access to the same notes after the class and the same reading quizzes were given to them as exit quizzes at the end of the class. After presenting a literature review, we describe the methods of this study. In particular, we describe the structure of these classes, the nature of the readings and quizzes, and the collected data. We report preliminary quantitative and qualitative results on students' usage of textbooks and these notes. We provide some of their feedback about the pre/post class readings and the respective reading/exit quizzes.

Literature Review

Many science education articles discuss reading assignments and reading quizzes. Hodges, Anderson, Carpenter, Cui, Gierasch, Leupen, and Wagner (2015) discussed different formats of reading quizzes in different STEM areas. We found in (Heiner, Banet, & Wieman, 2014) an implementation of targeted pre-reading assignments with an associated online quiz in two science classes, physics and biology. In an introductory physics course, Henderson and Rosenthal (2006) used reading questions instead of reading quizzes where students posed questions on the assigned readings to the instructor via email before class.

On the other hand, there have been numerous research articles demonstrating the difficulties students have with reading mathematics texts. For example, Shepherd, Selden and Selden (2009) believe that "many, perhaps most, first-year university students do not read large parts of their mathematics textbooks effectively, that is, they cannot work straightforward tasks based on their reading. Whether this is because they cannot read effectively, or choose not to do so, seems not to have been established" (p. 1). Shepherd (2010) also states that "the textbooks for many first-year university courses, such as college algebra, precalculus, and calculus seem to be written with the assumption that they will be read thoroughly and precisely" (p. 3). She also refers to a brief survey (JMM presentation, Exner & Shepherd, 2008) of Calculus I students where they found that few read the textbook at all. The authors of this presentation (as cited in Shepherd, 2010) provide a typical student comment: "When I think there is a formula I need, I'll go back and look if there is a formula, otherwise… there is very little chance that I'm going to read any of it. "

In addition, we refer the reader to Weinberg, Wiesner, Benesh, and Boester's study (2012) in which they surveyed 1156 undergraduate students in introductory mathematics classes about their textbook usage. Students reported that they used the examples instead of the expository text. Weinberg et al. results show that "instructors may play a role in students' textbook use. When students perceive that they are asked to use their textbook, they report that they are more likely to do so…Although the conclusions that can be drawn from these results are limited, they suggest that instructors may be able to increase students' use of their textbooks by asking their students to use their textbooks" (p. 23).

The aforementioned student's comment from (Exner & Shepherd, 2008) and Weinberg et al.'s results (2012) probably describe the attitude of the majority of Calculus students towards their Calculus textbooks. This motivated us to provide students with targeted summarized typed notes that can serve as a tangible resource for students' learning of Calculus concepts. By going through a literature search, we have found little evidence on the usage of targeted reading assignments in Calculus courses. In this preliminary report, we discuss the implementation of pre and post class targeted readings in Calculus classes. We also report on using quizzes that served as both "reading" (beginning of class) and "exit" (end of class) quizzes. Preliminary results from an end of the semester survey are presented in which we address the questions: *How much time do students spend on pre-class readings; how often do they use post class readings? How do they perceive these readings? How do they perceive reading and exit quizzes?*

Study Design

The study was conducted in four sections (Sections 2, 8 am; 4, 10.50 am; 6, 4.30 pm; 8, 8 am) of Calculus II classes at a comprehensive Northeastern university that has emphasis on sciences and engineering. At this institution, Calculus II covers integral Calculus and Series. The classes had a total of 90 students where a total of 69 students consented to participate in the study (26 females and 43 males). The majority of them were Engineering and Forensic Sciences majors. The classes met in Spring 2016 semester, three times a week for one hour and fifteen minutes.

To answer the questions above, we designed the study to have two sections (4 & 6) with pre-class readings where students took a quiz on new concepts and techniques at the beginning of the class period. Two other sections (2 & 8) had access to the same readings after the material was discussed in class and the same quizzes were taken as exit quizzes at the end of the class.

The readings were targeted in the sense that they were brief and prepared (typed) by the instructors. A typical note is a 1 page (at most 1.5 pages) long that has a short discussion about a concept followed by two or three examples. Fig. 1 is a sample note on Integration by Parts. We omit the second part of this note that included the two examples $\int \boldsymbol{xe^x dx}$ and $\int \boldsymbol{xlnx\, dx}$ followed by a brief generalization to any power of x. We designed the quizzes to be very similar to the examples in the readings that included any new formulas and multiple steps to guide the student's answers. In Fig. 2 we see a sample quiz question on Integration by Parts. It is worth noting that the quizzes constituted only 5 % of the final grade and hence did not have a huge impact on students' final grade.

Calculus-II
Integration by Parts

We have seen so far how to use the substitution rule. It is worth noting that the substitution rule for integrals is the opposite of the chain rule for derivatives:

- Chain Rule: $\big(f(g(x))\big)' = f'(g(x))g'(x)$,
- Substitution Rule: $\int f'(g(x))g'(x)\,dx = f(g(x)) + C$ using $u = g(x)$.

Now we will find the opposite of the product rule of derivatives. It is called **integration by parts**.

- Product Rule: $\big(uv\big)' = u'v + uv'$,
- Integration by Parts: $\int u\,dv = uv - \int v\,du$.

To get this formula, we rewrite the product rule as $\frac{d}{dx}(uv) = \frac{du}{dx}.v + u.\frac{dv}{dx}$, then we integrate both sides to get

$$uv = \int v\,du + \int u\,dv,$$

which can be written as $\int u\,dv = uv - \int v\,du$.

Figure 1: A sample note

To find $\int x^2 \ln x\,dx$ we need to use the formula $\int u\,dv = uv - \int v\,du$.

use $u = \ln x$ then $du = \ldots\ldots\ldots\ldots\ldots\, dx$

use $dv = x^2\,dx$ then integrate to get $v = \ldots\ldots\ldots\ldots$

Thus $\int x^2 \ln x\,dx = (\ldots\ldots\ldots)(\ldots\ldots\ldots) - \int \ldots\ldots\ldots\ldots\, dx =$

Figure 2: A sample quiz

The collected data for our study include two surveys, the first was given in the second week of classes and the second was given in the last week of classes. Our data also include the reading/exit quizzes, an early quiz on the first day of classes and a retention quiz at the end of the semester. The grades for these two quizzes were not counted towards students' grades but the students were not informed of this till after the quizzes were taken. For this report, we only present data from the two surveys.

Preliminary Results

In the early survey we asked students about their study habits and, in particular, how often they read the textbook prior to the next class. We found that about 65 % of the students who took the survey reported that they never or seldom read the textbook before coming to class, about 22 % of them said they read the textbook about half the time, and about 13 % said they read it usually or always. This shows that most students did not spend time outside the classroom to reinforce the learning of the concepts that were discussed in class before they come to the next class period. These results served as a motivation for assigning pre-class readings or providing targeted readings for an after-class reinforcement of concepts.

We now present some preliminary results from the end-of-semester survey. We analyzed two questions from the survey. In sections 4 and 6, we asked the students: How much time (on average) did you spend on each pre-class reading assignment while in sections 2 and 8, we asked the students: Did you use the typed notes when you worked on your homework or studied for tests (did not use them, sometimes, frequently, all the time). In all sections, students were asked to rate the usefulness/effectiveness of the typed notes. In sections 4 and 6, 59 % of students spent between 20 and 40 minutes, 16 % spent more than 40 minutes, while 25 % of students spent less than 20 minutes on the typed notes. The survey analysis showed that 69 % of students in these two sections found the notes either effective or very effective. In sections 2 and 8, 76 % of students either used them sometimes or frequently when they worked on homework assignments or studied for tests and 68 % of students found them either effective or very effective.

In the following, we support these positive students' perceptions by providing some of their feedback on the notes and the quizzes**.** Even though the quizzes constituted only 5 % of the final grade, they had a relatively high impact on students' pre-class reading efforts in sections 4 & 6, and on students' attention span in sections 2 & 8. We will support this claim via students' qualitative data from the end-of-semester survey.

We start with comments from students in sections 4 and 6 who had pre-class readings. We refer to students from these sections as S-number. Student S1 reported:

> The notes and quizzes constantly forced us to actively learn outside of class which I thought was very effective.

Student S2 found that:

> The typed notes and the quizzes are great additions to the class is probably why this class has not been as stressful as previous math courses.

Student S3 pinpointed the main purpose of having pre-class readings:

> The typed notes and quizzes made us have an understanding of the topic before class but left room for further understanding during class discussions.

Student S4 had a concern about the grades when s/he said:

> The notes are helpful but don't give the same understanding like doing it in class does which effects the grades since we do the quizzes in the beginning.

Student S5 commented:

> The typed notes were very helpful because they helped me have some understanding of the material before it was taught to me. There were only a few that were hard to understand but then the lecture was able to help me get a better grasp of the material. The quizzes were also very helpful because they pushed me to actually read the notes.

We also provide some feedback from students who had access to the typed notes after class and we present their feedback on the exit quizzes. We refer to students from these sections as T-number. The main theme of students' feedback was that the typed notes were helpful in doing the homework and that the quizzes kept the students' attention at a high level. For instance, student T1 said:

> The provided typed notes were a great help in doing the HW. They should of however, been uploaded before class instead of after. The quizzes were good to make sure that you are actually understanding the lesson that day.

Student T2's feedback was:

> The typed notes helped with the typed homework and the quizzes helped reinforce what I learned that day.

Student T3 found that:

> The notes, quizzes, & the assigned typed HW helped me comprehend the content even more than what I had expected.

While Student T4 commented:

> I liked the typed notes, but for the last few classes of the semester the typed notes did not cover everything we did in class. I like the way the quizzes are (right after the lesson)….I think that quizzes sometimes took away from the lecture when we could have used that time to finish the lecture.

Student T5 gave the following comment:

> Typed notes: I find it hard to understand math written out on a piece of paper. Quizzes: a nice grade booster and opportunity to show what I learned.

Discussion/Future Research

Our preliminary data analysis shows that the majority of the students reported that the typed notes and quizzes were helpful and conducive to learning. Some students went even further and recommended some changes. For example, Student T1, from a post-reading section with a final C+ grade in the course, expressed her/his preference to having access to the typed notes before class rather than after. Her/his feedback basically encapsulates instructors' hope of increased exposure to concepts outside the classroom. It is indeed our goal to assign these readings before class in every course, but for the purpose of this study, this was not the case in Spring 2016.

As pointed out by some students, there were a few notes that were technical and harder to read. We definitely agree and we will surely modify these notes as we implement these readings in the future. However, we do not plan to increase their size as we want to intentionally keep them short and concise. The purpose of the notes is not to replace the classroom mini-lectures or discussions, and consequently they will not cover everything that is discussed in class.

To address student T4's concern about the time taken by the quizzes (typically about 5 minutes), we looked into other alternatives such as online quizzes but we believe that in class quizzes give a better hands-on learning experience for students. We also claim that they provide a better assessment method of students' reading efforts and attention span.

For future research we hope to have a more in depth analysis of our data. In particular, we would like to have:

- A comparative analysis of the grades on quizzes and/or exams of the 4 sections through the lens of the targeted notes' usage,
- A study of the effect of these notes on students' content retention using the retention quiz,
- A study of the effect of pre-class readings on the classroom environment as reported by the instructors' observations, and
- An exploration of the shortcomings of this study such as the different meeting times and lack of instructions on how to read mathematics.

Preliminary Report Questions

1. Do the different meeting times of classes impact students' learning and performance?
2. What does existing research suggest for instructions to read mathematics?
3. What is the correlation between students' GPA and their motivation to read mathematics textbooks/notes?

Opportunities to Learn from Teaching: A Case Study of Two Graduate Teaching Assistants

Nathan Wakefield
University of Nebraska-Lincoln

Erica Miller
University of Nebraska-Lincoln

Yvonne Lai
University of Nebraska-Lincoln

Graduate students teach many first year undergraduate mathematics courses, such as College Algebra and Calculus. In this report, we focus on the opportunities to learn to teach that graduate student teaching assistants (GTAs) construct from reflecting on their teaching experiences. Research in professional development suggests that although reflection is absolutely essential to improving one's teaching, teachers have the greatest opportunity to learn from their teaching when they can mobilize their interpretations of teaching to inform specific and nuanced future actions. Yet, there are few studies addressing the ways in which GTAs develop opportunities to learn from reflection. In this case study, we examine how two graduate students developed the ability to link observations of student work to hypotheses about student thinking and then connect these hypotheses about student thinking to future teaching actions. These reflections were generated as a part of a professional development program for GTAs.

Key words: Post-Secondary Professional Development, Graduate Teaching Assistants, Student Work, Student Thinking, Teaching Actions

Providing and studying professional development programs for teachers has become a norm in K-12 education. Since instruction is the primary responsibility of K-12 teachers, the need for professional development is commonly accepted. In higher education, the need for professional development is gaining acceptance. While the primary function of colleges and universities is to provide students with an education, the instructors and professors who teach the classes often have responsibilities that extend beyond instruction. This is especially true at research universities, where a professor's appointment is often split between teaching and research. In a similar way, a graduate student's responsibilities are often split between the two. While it may be true that many graduate students are training to become researchers, their secondary role as an instructor is important. It is often the case that graduate students are the primary instructor of a course for the first time as a graduate teaching assistant (GTA), which is an assignment that mathematics departments should not take lightly. As providers of education, one of our primary goals should be to help our teachers provide high quality instruction. It is for this reason that we believe it is necessary and important to study not only *how* to provide professional development to graduate students, but also the *impact* that professional development has on their development as teachers and their future teaching actions.

Purpose and Relationship to Research Literature

While there are many important differences between teaching in K-12 and higher education (Speer, King, & Howell, 2015), there is also much that we can take from K-12 professional development when designing and studying professional development programs for GTAs. One thing that research has shown is that an instructor has more opportunities to learn when they plan future teaching actions by reflecting on previous instructional experience (Thompson, 1984). In the K-12 literature, studies have shown these opportunities to learn are impacted by both the clarity of the teacher's reflections on the nature of student's understandings and the amount of time available for the teacher to construct a response to student thinking (Horn, Kane, & Wilson, 2015). If the model from K-12 holds, then one would expect that graduate teaching assistants' opportunities to learn will also be more meaningful when they are given time to reflect.

However, providing time for reflection alone is not enough. The other important variable in the process is the clarity with which the teacher has the ability to reflect. While clarity could be measured in various ways, one potential means of measuring the clarity with which a teacher reflects is by studying the arguments the teacher makes. Since our study involved analyzing several reflective essays on teaching in which the GTAs made arguments to explain student thinking and propose future teaching actions, this measurement seemed best suited to our purposes. Toulmin (1958) developed an argumentation model for legal arguments using the components of grounds, claims, and warrants. In this model, grounds are the evidence underlying a claim and a warrant justifies the relationship between the grounds and the claim. More recently, Toulmin's model has been applied to other fields, including mathematics education (Inglis et al., 2007).

In Lai, Smith, Wakefield, Miller, St. Goar, Groothius, Wells (2016), a modified version of Toulmin's model was used to analyze the connections GTAs made between what they observed their students doing and their future plans for teaching. Lai et al. performed a qualitative analysis of 16 final papers written by mathematics GTAs and developed a coding scheme that categorized papers as low connectivity, medium connectivity, high connectivity with low coherence, and high connectivity. The researchers concluded that even when GTAs are teaching the same course, participating in the same professional development, and completing the same task, the clarity of their reflections on the nature of student thinking varies widely. Further, there is a wide variation in the GTAs apparent ability to connect student thinking to future actions. However, in this previous study, no attempt was made to look at the growth GTAs experienced. For example, while the authors found examples of GTAs with high connectivity in their final papers, there was no indication of what growth may have occurred over the course of the professional development program. An important question that resulted from this is whether or not these cases of high connectivity are representative cases of individuals who entered the professional development program with these reflective skills.

The purpose of this intrinsic case study (Stake, 1995) is to better understand the growth experienced by two mathematics GTAs over the course of their involvement in a professional development seminar. These two GTAs were selected because they have been identified as strong teachers and pedagogical leaders in the department. At this point in the research, growth will be generally defined as increase in coherence over time. The central question that is guiding our inquiry is: How did the GTAs grow over the course of the professional development seminar? We decompose the central question as follows:

1. How might the opportunities to learn afforded over the course of the professional development seminar help the GTAs to make changes in their teaching?
2. How might the GTAs' ability to clearly reflect on the nature of student thinking change over the course of the professional development seminar?

Our intention is to use Lai et al.'s research methods on a set of papers collected from GTAs over the course of an entire semester of professional development. Conducting this type of longitudinal case study will allow us to examine the growth of the GTAs, as opposed to just examining the final paper. Although the context of this case study makes it hard to generalize, this analysis will help identify what GTA growth looks like and provide one possible measure by which professional development programs for GTAs could be evaluated.

Theoretical Frameworks

This paper utilizes the coding framework discussed in Lai et al. (2016), which examines the connections between student data, student thinking, hypothesis, and future teaching actions. *Data* is defined to be the written student work collected by the instructor with the addition of any memory-recalled communication as observed by the instructor and recorded in their writing. After collecting data, the instructor interprets this data in the form of *student thinking*. That is, student thinking is the instructor's expression of how he or she believes the data should be interpreted as a reflection of the student's work. Instructors may hypothesize likely reasons for a student to think in the way in which the instructor has argued. This *hypothesis* depends upon the underlying origin of student thinking. Finally, an instructor may plan a *future teaching action* based upon any or all of the previous elements. These four elements, and the connections between them, form the framework used to analyze GTA work.

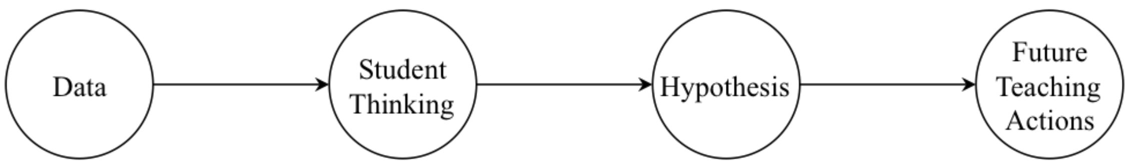

Figure 1. Model for GTA arguments

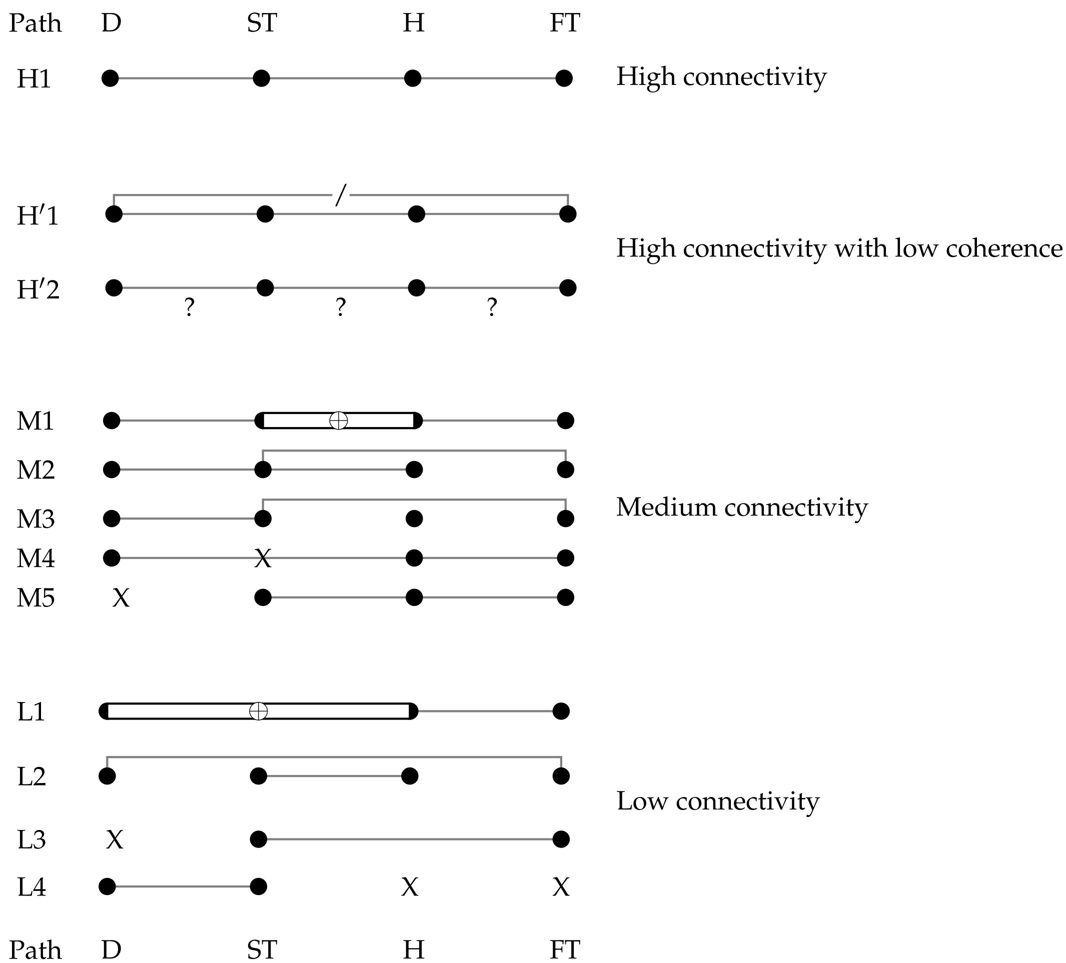
Using this framework, a GTA's work may be coded by looking for the presence or absence of any of the four elements and the connections between them. When looking at connections, coding captures not just the presence or absence of a connection but also the plausibility of a connection. Using this technique, a work may be categorized as having *low connectivity* if explicit reference to two or more of the four elements was missing, or the connections between these elements are not present. On the other hand, a work is said to have *high connectivity* if the GTA clearly articulates all four elements and makes explicit links between these elements. The tag *low coherence* is added when the four elements are articulated, but weak, implausible, or implicit links are present. A final category of *medium connectivity* is marked by the presence of at least three of the four elements, and attempted links between all of the components. A visual representation of these various types of connectivity is included in Figure 2.

Data and Methods

Using this framework, we plan to study the growth that we observed in the works of two particularly strong GTAs over the course of the fall 2015 semester when they were enrolled in the department's pedagogy seminar. At the university in the study, every graduate student who is assigned to be the primary instructor of a course for the first time is required to enroll in a seminar titled "Teaching and Learning Mathematics at the Post Secondary Level." This seminar meets for two hours a week in the fall semester and one hour a week in the spring semester. To help develop their ability to reflect, the graduate students in the course read educational literature, including articles ranging from Erlwanger's (1973) discussion of Benny to expository articles like Tsay and Hauk's (2013) explanation of constructivism.

While enrolled in the seminar, the graduate students enrolled in the course are primary instructors for their own mathematics course (either intermediate or college algebra). The typical enrollment in these courses is between 34 and 40 students. Graduate students are the sole instructor of record and, for most, this is their first experience teaching. Their experience teaching together with the articles they read provide the backbone of weekly discussions in which graduate students are given the opportunity to reflect on their own teaching, utilizing the vocabulary of mathematics education.



Key: D = data, ST = student thinking, H = hypothesis, FT = future teaching actions, X = component absent, ⊕ = conflated components, •—•= link was attempted and satisfied criteria, •$\overset{?}{—}$•= no consensus from research team on whether link is plausible, •-/-•= future teaching actions do not plausibly address student thinking identified in data.

Figure 2. Categories of connectivity of GTA arguments

The data for this study, which has already been collected, includes three assignments completed by the GTAs throughout the semester course. All three assignments asked the GTAs to write papers in which they analyze student performance on a quiz or exam question and provide both an interpretation of what went wrong for a student or a group of students and evidence supporting their interpretation. GTAs were also asked to form a hypothesis about what underlying experiences and beliefs may have contributed to this performance and ultimately develop an “intervention” to try and help the student overcome these experiences and beliefs in order to move into a more productive way of handling this type of problem. Data from 16 GTAs was collected and analyzed using the above-mentioned argumentation framework. The results of the final paper were previously analyzed and reported in Lai et al. (2016). This purpose of this paper is to discuss the growth observed in two GTAs who have been identified by the math department as particularly strong teachers. By comparing their three papers to each other, this study will allow us to analyze how these GTA's teaching may or may not have changed throughout the semester. In other words, while Lai et al. (2016) looked broadly at the work of all GTAs on a single assignment with the purpose of characterizing opportunities to learn, this study will look narrowly at the work of two GTAs across multiple assignments, so as to understand better how these opportunities to learn were utilized.

Significance

Even though providing professional development for GTAs is a rather new phenomenon, exemplary models of GTA professional development programs do exist (Bressoud, Mesa, & Rasmussen, 2015) and some studies of GTA professional development have been conducted (Hauk et al., 2009; Kung 2010; Kung & Speer, 2009; Speer, Gutmann, & Murphy, 2005). Yet, there is much that we have to learn. Ellis (2014) suggested that one means of better understanding how to prepare post-secondary mathematics instructors is to look at methods employed in the K-12 environment and use those methods to study the post-secondary environment. This study takes that approach by focusing on the clarity of reflections, as suggested by the K-12 literature. Also, this work provides an opportunity for further testing and refining of the framework proposed by Lai et al. (2016). Since this work is in its early stages, we believe that a case study is the right methodological approach. In order for researchers to better study GTA training, researchers need to better understand what is happening to the individuals in GTA training programs. Since the two subjects of this study were identified by as being particularly strong teachers, it would be useful to understand what this means and whether or not the framework suggested by Lai et al. (2016) identifies any features of their strength.

Questions for the Audience

To refine our ideas, we pose the following questions to our audience:

1. Are their areas of our framework that you think would be hard for you to utilize in analysis of GTAs in your program?
2. Is there something missing from our framework that would add a significant contribution to our understanding of the reflective process a GTA uses?

Factors Influencing Instructor Use of Student Ideas in the Multivariable Calculus Classroom

Aaron Wangberg	Tisha Hooks	Brian Fisher	Jason Samuels	Elizabeth Gire
Winona State U.	Winona State U.	Lubbock Christian U.	CUNY – BMCC	Oregon State U.

Despite overwhelming evidence of the effectiveness of student engagement in instruction, practicing mathematics instructors often use instructor-centric practices even if they value student engagement. Answering a call by Henderson and Dancy (2007) to study the implementations of researched-based curriculum in the classroom, this paper looks at the change in practices and values of instructors utilizing active-engagement activities in multivariable calculus classes. This curriculum incorporates context and multiple representations, and we look for evidence that addresses whether these features facilitate instructor use of student ideas in instruction.

Key words: Curriculum adoption, Student-centered Instruction

Despite an abundance of research highlighting the benefits of actively engaging students in the classroom, many practicing undergraduate mathematics instructors still utilize lecture and a host of non-student-centric practices. This often occurs even if instructors value student engagement.

We examine how two features of a research-based curriculum – contextualized problems and an emphasis on multiple representations (MR) – may or may not support instructors in attending to and using student ideas in instruction. In this study, we look at two guiding questions:

- What features of instructional materials support instructors in attending to and incorporating student ideas in instruction?
- Do contextualized problems and an emphasis on MR support instructors in valuing student contributions and incorporating them in their instruction?

Theoretical Framework

Activity theory (Engeström, 1987; Cole, 1996) notes that many factors influence change in any new activity. Instructors adopting a new curriculum have to navigate many new factors with the existing factors in the classroom. This might involve new roles of both students and instructors in the classroom, new agreements about how these populations interact and new rules for each of the new groups. In particular, instructors adopting a student-centered curriculum have to re-evaluate their expectations for how students and the instructor contribute toward the course. Instructors often have to settle into new roles while still being familiar with their prior roles.

There is reason to believe that context and MR might support an increase in the use of student ideas. For context, students may find contextualized problems more relevant to their interests and be more engaged with the task than for more abstract problems. Additionally, students can contribute conceptual and intuitive knowledge connected to the problem context. The use of MR could increase the possibility of finding multiple solution paths. Different groups can use different representations, providing opportunities for students to identify and discuss the connections and differences between them.

The instructional materials in this study incorporate context and MR so that students are able to touch, point at, and work with mathematical objects and explore properties even before these concepts have been introduced formally by the instructor. The contextualized activities present students with a meaningful scenario, effectively changing how they interact with math concepts:

Instead of asking how the mathematics they've learned is related to the real world, they're instead solving real-world problems and learning how the mathematics they discovered is connected to multivariable calculus. Lastly, the use of MR allows students to choose which way they want to solve a problem. They may choose to use a familiar representation, even if it is not the best choice for that problem. Natural questions exploring the connections between representations arise when their peers present similar or contradictory solutions using a different representation.

Methods

Instructional Context

Raising Calculus to the Surface (RC), an NSF (DUE-1246094) project funded in 2013, utilizes small group activities and open-ended questions designed to help students *discover* important multivariable calculus concepts prior formal introduction by their instructor. The *Raising Calculus* materials highlight four main features: physical manipulatives, open-ended prompts, contextualized problem situations, and an emphasis on MR. We focus on the relationship between the instructor's attention and use of student ideas in instruction and (1) how much they value the contextualized nature of the problems and (2) the extent to which they emphasized the use of MR.

Instructors rarely approached the *RC* project because the materials utilized inquiry. To facilitate adoption, instructors could modify the activities and choose which activities to incorporate into their course (Henderson and Dancy, 2007). All 11 activities utilized MR; Nine made meaningful use of context.

Data

Data for this paper comes from 16 of the 38 instructors who used the *RC* materials during one or two terms of the 2014-2015 academic year. The chosen 16 instructors completed anonymous open-response pre/post surveys. The paired surveys focused on the instructor's practices as well as their attitudes and beliefs about student learning in multivariable calculus. The pre-survey was completed prior to a professional development workshop in Summer 2014, and the post-survey was completed after each term of using the materials. Instructors completing the post-survey were shown their pre-survey responses, thus helping them identify and address changes in their course.

Categorization Process

The first two authors independently read and identified over 160 categories contained in all 23 instructor's survey responses. After comparing notes, the authors revised the categories, independently re-categorized instructor responses then met again and collapsed categories into four main themes. These themes were the instructor's instructional method, their use of students' ideas, their value and use of MR, and their value of context. We now describe how instructors were classified within each theme.

Instructor's use of instructional methods. No one question asked about their specific practices, but instructors often reported their instructional practices on the pre-survey or changes to their typical practices on the post-survey questions. An instructor was categorized as *Lecture* if they made no mention of having students engaged in *Small Group Skill Activities*, *open-ended Small Group activities*, or *Inquiry Activities*. Instructors could be categorized under the last three categories even if they still utilized lecture as the primary instructional method.

Instructor's use of students' ideas. Pre-survey questions asked instructors to describe the contributions an average student made to their classroom under the ideal setting (and to describe the actual contributions, if it differed from the ideal). A paired post-survey question allowed instructors to describe any changes in the contribution of the average student to the course. The post-survey also asked if (and how) students were more likely to explore their ideas with each other than in the instructor's previous course.

Instructors use student ideas in courses in a multitude of ways, making any one-dimensional representation of that data difficult. Nevertheless, subcategories chosen progress from no use of student ideas all the way to expecting or noticing students are contributing new content to the course. Responses such as using Think/Pair/Share or activities involving practice of previously introduced skills are sub-categorized under *Peers*, while responses involving group work with presentations to the class or whole-class discussion are sub-categorized as *Whole Class*. Instructors are categorized under the *Add New Content* category if they report their students contribute new ideas to the course.

Instructor's value and use of multiple representations. Survey questions asked instructors about the role various representations played in their course (pre-survey) and how this role changed after using the materials in the course (post-survey). Instructors often reported representations played a minimal role or a significant role in their course on the pre-survey, and frequently indicated it increased on the post-survey. The category Low indicates the instructor primarily emphasized symbolic and/or visual (height) features of graphs. The High category indicates the instructor utilized many representations, including contour plots, throughout the course. In the graphs that follow, pre-survey data points are marked to the left of the Low and High categories; the vector points toward the right of Low or High if the instructor noted that their use increased. The final category (Connecting Representations) indicates the instructor noted they value that students are making connections between different representations.

Instructor's Value of Context. No survey questions asked about context, yet many instructors mentioned their use and value of context or units increased on the post-survey question focused on MR[1]. For this category, Low indicates an instructor pays attention to units and quantities. High indicates an instructor is describing how context helps students understand mathematical concepts. Several instructors are categorized as No Context, indicating that their surveys contained no references to the value of context.

Limitations and Representation of the Data

The categories listed above contain multiple factors and dimensions; we have deliberately collapsed and ordered the data to assist us in visualizing changes contained within the data. Although the data is not ordinal, we present the data using graphs and vectors. Each of the 16 instructors are represented by a vector, with the tail (round circle) and tip (arrow) representing data from the pre-survey and post-survey, respectively. An instructor using the materials for two terms has a multi-segmented arrow. All sub-categories described in the previous section are included on the graphs, although not every sub-category is labeled. Small perturbations were added to the data points to keep nearby data points from overlapping.

[1] Context can be an important representation of a mathematical problem, but the survey questions directed instructors toward contour plots, graphs, symbolic, and verbal representations of functions.

Data Analysis

More Inquiry-Like Instructional Methods Corresponds to Increased Use of Students' Ideas

Figure 1 compares the change in the instructor's use of student ideas to their change in instructional methods. The data shows instructors utilizing *RC* materials incorporated open-ended small group activities into their course, although only 8 of the 16 instructors (those in group A) described using them in ways which let students discover concepts prior to formal introduction. Six instructors in group B changed from using primarily lecture-based practices where students engaged in instructor-led questions to using practices in which students shared their results with the whole class. One instructor in this group noted that he "liked the interactive atmosphere that took place in the classroom. There was a lot of student-led activity, including making conjectures, measurements, etc. that lead to sometimes heated debates about concepts.". He further stated that "using the surfaces made [him] re-think what [he] emphasize[d] in the course as an instructor." Although he wasn't expecting students to contribute new ideas as a result of adopting the materials, he used the experience to reflect upon his teaching practices.

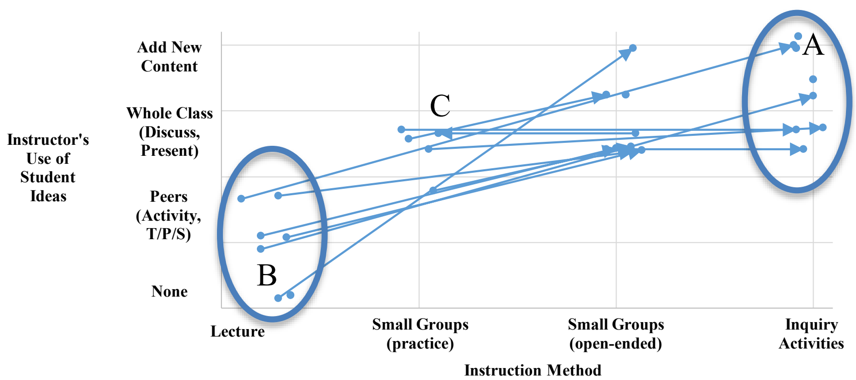

Figure 1: Instructor's value of context compared to their value of MR

These results are not surprising, as the *RC* materials include small group activities and use open-ended questions. Instructors could change and modify the activities, and those which landed outside Group A often indicated their changes made the materials more clear or less confusing for their students. Earlier work (Wangberg et al., 2016) suggests such modifications can make the activities easier to implement but could also unintentionally limit the conversations within the small groups. In the most extreme case, an instructor (just below C) typically taught his course using small group practice activities with whole-class discussion. He used the *RC* open-ended activities in small groups for one term, but modified the materials in the subsequent term so that his students could use them to practice previously learned concepts. Henderson and Dancy suggest that providing instructors with the freedom to modify materials can improve adoption. Instructors sometimes modified materials in order to align them with their more familiar instructional practices. Never the less, instructors tended to increase the use of student ideas as they incorporated open-ended activities into their course.

Valuing Multiple Representations Corresponds to Valuing Problem Context

Figure 2 compares changes in the instructor's value of context to their reported value and use of MR. It suggests instructors using *RC* materials report increased use of context or representations in their course, with 11 of the 16 instructors increasing one or both categories. We note four instructors never mentioned the value of context on their surveys[2].

Valuing Multiple Representations Corresponds to Increase in the Use of Student Ideas

Figure 3 compares changes in the instructor's use of student ideas in the classroom to the change in the instructor's value and use of MR[3]. Nine of the 16 instructors reported an increase in the use of student ideas, and six of these nine reported that the use or value of MR increased in their course. Two other instructors reported they had previously expected students to contribute ideas in the form of new content to the course.

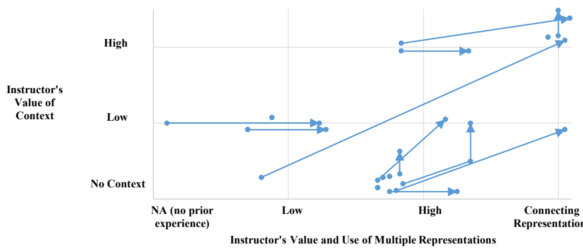

Figure 2: Instructor's value of context compared to their value of MR

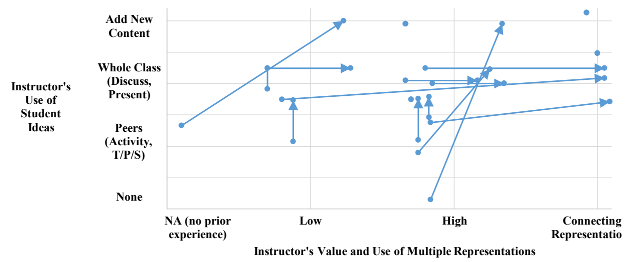

Figure 3: Instructor's expectation of student engagement and value of MR

Conclusion and Implications

Instructors rarely approached the *RC* project because the materials utilize inquiry, yet half of the instructors increased the use of student contributions in their course. While instructors could modify the materials to eliminate features like open-ended questions, which promote discussion, or utilize the activities after introducing the mathematical ideas, we note that is was much more difficult, given the nature of the activities, for instructors to remove the context from the activities or to limit an activity to a single representation of a function.

This paper investigates the connection between the instructor's use of student ideas in a course and the use of a research-based curriculum carefully incorporating MR in context-rich activities. Overall, we see increases in the use of students' ideas, the degree to which instructors value and use contextualized problems, and the degree to which instructors value and use MR. These corresponding increases support a hypothesized relationship between these aspects of instruction. Curriculum developers might consider incorporating contextualized problems and emphasize MR to support instructors in using and valuing student contributions in class.

Knowledge About Student Understanding of Eigentheory: Information Gained from Multiple Choice Extended Assessment

Kevin Watson	Megan Wawro	Michelle Zandieh	Sarah Kerrigan
Virginia Tech	Virginia Tech	Arizona State University	Virginia Tech

Eigentheory is a conceptually complex idea whose application is widespread in mathematics and beyond. Herein we describe the development and use of an extended multiple choice assessment that gives us further insight into the ways students think about and understand eigenvectors, eigenvalues, and their related concepts.

Key words: linear algebra, eigenvector, eigenvalue, student understanding, assessment

The purpose of this preliminary report is to share results regarding student understanding of eigentheory that were gained from a multiple choice extended assessment instrument. We chose to focus on eigentheory because (a) it is a conceptually complex idea that builds from and relies upon student understanding of multiple key ideas in mathematics, and (b) its application is widespread in mathematics and beyond. Our aim to create an assessment instrument that captures nuances of students' conceptual understanding of eigentheory exists in tandem with our pursuit to frame what it might mean to have a deep understanding of eigentheory. As such, in this report we offer results both about student thinking and about possible affordances and constraints of various assessment instrument question formats.

Background and Literature

Research into people's understanding of eigenvectors and eigenvalues has had several different focuses**,** such as identifying the various processes and objects students need to understand in eigentheory (Stewart & Thomas, 2006; Thomas & Stewart, 2011), studying how mathematicians use gesture, time and motion to describe the concepts of eigenvector and eigenvalue (Sinclair & Gol Tabaghi, 2010), examining how dynamic geometry software can encourage students to think geometrically about eigentheory (Gol Tabaghi & Sinclair, 2013), and investigating the use of modeling problems and APOS theory to teach students the concepts of eigenvectors and eigenvalues (Salgado & Trigueros, 2015). Our current research into students' understanding of eigenvectors and eigenvalues has been influenced by the above work, but we endeavor to extend this growing body of knowledge in two ways. First, we hope to share further insights into how students think about and understand eigenvectors and eigenvalues that has not been reported on previously. Second, we are working towards the development of a framework for student understanding of eigentheory that ties together the work others have done in this area of research. We further discuss this framework within the next section.

Theoretical Framework

There exists a small collection of previous research into students' understanding of eigentheory towards developing a theoretical framework for what it means to have a deep understanding of eigenvectors and eigenvalues (Salgado & Trigueros, 2015; Thomas & Stewart, 2011). Although this research has merit, specifically pointing out the processes, objects, and coordinations necessary for understanding eigentheory, we feel there is more to understanding eigenvectors and eigenvalues than is conveyed therein. Our framework for student understanding of eigentheory aims to include the following ideas: (a) A distinction between the equations $A\boldsymbol{x} = \lambda\boldsymbol{x}$ and $(A - \lambda I)\boldsymbol{x} = \boldsymbol{0}$ and how these constitute two different ways to think about eigenvectors and eigenvalues; (b) the importance of eigenspaces, diagonalization, and their connection to the concepts of eigenvectors and eigenvalues; (c) how the concepts of eigentheory can be thought of within different modes of thinking (Sierpinska, 2000), modes of description (Hillel, 2000), or contexts (Zandieh, 2000); and (d) the various processes (e.g., matrix multiplication, scalar multiplication), entities (e.g., matrices, vectors), and theorems (e.g., invertible matrix theorem) needed to understand eigentheory and the calculations involved therein. While this framework is still under development, it informed our decisions about the creation and refinement of the assessment instrument, and, cyclically, the results of the assessment continue to inform the development of the framework. We describe the assessment more fully in the following section.

Methods

In this section, we describe the development and format of our multiple-choice extended (MCE) assessment instrument. We then describe the data collection and participants for the portion of the study presented in this proposal, followed by a description of our analysis.

Instrument Development

The MCE assessment instrument for eigentheory development grows from our prior work in student understanding of span and linear independence (Zandieh, Plaxco, Wawro, Rasmussen, Milbourne, & Czeranko, 2015) in which we developed the MCE-style question format. During this development, we considered literature on conceptually oriented assessment instruments in undergraduate mathematics and physics (Bradshaw, Izsak, Templin, J. & Jacobson, 2013; Carlson, Oehrtman, & Engelke, 2010; Epstein, 2013; Hestenes, Wells, & Swackhamer, 1992; Wilcox & Pollock, 2014). Questions written in a MCE style begin with a multiple-choice element and then prompt students to justify their answer by selecting all statements that could support their choice, a format based on a concept inventory in Upper-division Electrostatics created by Wilcox and Pollock (2014).

To develop the assessment instrument questions, we compiled a database of questions about eigenvectors, eigenvalues, and related concepts from literature on student understanding of eigenvectors and eigenvalues, online resources for clicker and classroom voting on linear algebra (Cline & Zullo, 2016), and previous linear algebra homework assignments, exams, and interview protocols used by research team members (e.g., Henderson, Rasmussen, Sweeney, Wawro, & Zandieh, 2010). The most promising questions that collectively addressed various aspects of our working framework were edited into the MCE format. The instrument has been administered in student interviews and as written homework twice and subsequently refined. This current proposal relies on a third administration of the assessment, described in further detail below.

Data Collection

In this proposal we present data from written assessments collected from three linear algebra classes taught by the same instructor at a large, research-intensive public university in the mid-Atlantic United States. Each class worked on one version of the MCE assessment for 20-25 minutes during the last day of class. All three versions consisted of the same six multiple choice question elements, with varying justification sections. Class 1 received a version in which students indicated if each of six given justifications were true and relevant, true but not relevant, or false (see Figure 1a). Class 2 received a version in which students only selected justification choices that were true and relevant (see Figure 1b). Lastly, Class 3 received an open-ended version in which they wrote their own justification for their choice.

The matrix $A = \begin{bmatrix} -2 & 4 \\ 2 & 5 \end{bmatrix}$ has $\lambda = 6$ as one of its eigenvalues. Which of the following vectors is an eigenvector of A with corresponding eigenvalue $\lambda = 6$?

(a) $x = \begin{bmatrix} 4 \\ -1 \end{bmatrix}$ (b) $x = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$

Because … (indicate if the choice is true and relevant, true but not relevant, or false)

True & relevant	True not relevant	False	Statement
			(i) This vector $\boldsymbol{x}$ makes $A\boldsymbol{x} = 6\boldsymbol{x}$ a true statement.
			(ii) This vector $\boldsymbol{x}$ is the only vector in $\mathbb{R}^2$ for which $A\boldsymbol{x} = 6\boldsymbol{x}$.
			(iii) This vector $\boldsymbol{x}$ makes $(A - 6I)\boldsymbol{x} = \boldsymbol{0}$ a true statement
			(iv) Subtracting 6 from the diagonal of A yields this vector $\boldsymbol{x}$ as a column vector of the resulting matrix.
			(v) The vector $A\boldsymbol{x}$ is 6 times the magnitude and in the same direction as this vector $\boldsymbol{x}$.
			(vi) The matrix A also has $\lambda = -3$ as an eigenvalue.

(a)

The matrix $A = \begin{bmatrix} -2 & 4 \\ 2 & 5 \end{bmatrix}$ has $\lambda = 6$ as one of its eigenvalues. Which of the following vectors is an eigenvector of A with corresponding eigenvalue $\lambda = 6$?

(a) $x = \begin{bmatrix} 4 \\ -1 \end{bmatrix}$ (b) $x = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$

Because … (select ALL that could justify your choice)

(i) This vector $\boldsymbol{x}$ makes $A\boldsymbol{x} = 6\boldsymbol{x}$ a true statement.

(ii) This vector $\boldsymbol{x}$ is the only vector in $\mathbb{R}^2$ for which $A\boldsymbol{x} = 6\boldsymbol{x}$.

(iii) This vector $\boldsymbol{x}$ makes $(A - 6I)\boldsymbol{x} = \boldsymbol{0}$ a true statement

(iv) Subtracting 6 from the diagonal of A yields this vector $\boldsymbol{x}$ as a column vector of the resulting matrix.

(v) The vector $A\boldsymbol{x}$ is 6 times the magnitude and in the same direction as this vector $\boldsymbol{x}$.

(vi) The matrix A also has $\lambda = -3$ as an eigenvalue.

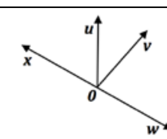
(b)

Figure 1. Comparison of (a) Class 1 MCE and (b) Class 2 MCE.

Analysis

After each class's written assessments were digitally scanned and grouped by question, spread sheets were designed to enter the data from Class 1 and Class 2. From the spreadsheets, the research group examined trends within each class before looking for trends across formats. Some basic percentages were calculated for the justification choices for Classes 1 and 2, as well as students' multiple-choice answers for all three classes.

2. Suppose the vector $\boldsymbol{x} \in \mathbb{R}^2$, in the two-dimensional sketch below, is an eigenvector of a 2x2 matrix M with real-valued eigenvalues. Which of the vectors $\boldsymbol{u}, \boldsymbol{v}$ or $\boldsymbol{w}$ illustrated below could be the result of the product $M\boldsymbol{x}$?



(a) $\boldsymbol{u}$ (b) $\boldsymbol{v}$ (c) $\boldsymbol{w}$
(d) Not enough information is given to know a possible result of the product $M\boldsymbol{x}$

3. Suppose A is a $n \times n$ matrix, and $\boldsymbol{y}$ and $\boldsymbol{z}$ are linearly independent eigenvectors of A with corresponding eigenvalue 2. Let $\boldsymbol{v} = 5\boldsymbol{y} + 5\boldsymbol{z}$. Is $\boldsymbol{v}$ an eigenvector of A?

(a) Yes, $\boldsymbol{v}$ is an eigenvector of A with eigenvalue 2.
(b) Yes, $\boldsymbol{v}$ is an eigenvector of A with eigenvalue 5.
(c) No, $\boldsymbol{v}$ is not an eigenvector of A.

Figure 2. Multiple Choice Stem to Questions 2-3 of the Eigentheory MCE.

The open-ended data was analyzed through multiple iterations of open coding. First, each team member individually summarized the key aspects of each student's justification process. Next, the team came together to develop a coding scheme for the student work to be used in the second iteration of coding. Each team member then individually coded the student responses with the new coding scheme before collectively determining a set of codes for each student. Lastly, the larger themes from the finalized coding were identified by examining common patterns across multiple students' solutions and justifications.

The focus then shifted to an analysis of identifying patterns in how students selected or supported their work in their justification for each question and what insight each format provided us about the students' reasoning. Currently the research team is focusing on the first three questions from the assessment (see Figures 1 and 2), with plans to analyze all six later.

Results

Table 1 shows the general performance of the three classes on the multiple-choice portion of the three questions. We make a few observations. First, classes performed similarly on all three questions, so comparing students' justifications across the three classes is reasonable. Second, Question 1 and Question 2 may seem somewhat uninformative because a majority of the students chose the correct answer. However, in the results and discussion to follow, we share how the MCE gives more information about student thinking through the justification portion of each question. Third, linear combinations of eigenvectors with the same eigenvalue, in other words, elements of an eigenspace, is a difficult topic. For sake of space, we focus on the student understanding we discover through the justifications of Question 1 in this proposal.

Table 1
Class Percentages for Answers Chosen on the Multiple Choice Portion

		Class 1 Judgment MCE (27 Students)	Class 2 Original MCE (29 Students)	Class 3 Open-Ended (28 Students)
Question 1	*Choice (a)*	14.8	24.1	7.1
	Choice (b)	81.5	75.9	92.9
	No Answer	3.7	0.0	0.0
Question 2	*Choice (a)*	0.0	0.0	0.0
	Choice (b)	0.0	6.9	0.0
	Choice (c)	92.6	82.8	96.4
	Choice (d)	3.7	10.3	3.6
	No Answer	3.7	0.0	0.0
Question 3	*Choice (a)*	25.9	48.3	21.4
	Choice (b)	3.7	6.9	21.4
	Choice (c)	55.6	31.0	53.6
	No Answer	14.8	13.8	3.6

NOTE: Correct answers are shaded.

Evidence of a Distinction Between the Equations $\boldsymbol{A}\boldsymbol{x} = \boldsymbol{\lambda}\boldsymbol{x}$ and $(\boldsymbol{A} - \boldsymbol{\lambda}\boldsymbol{I})\boldsymbol{x} = \mathbf{0}$

Justification choices (i) and (iii) on Question 1 (see Figure 1) could be seen as the same statement (to an expert), with a rearrangement of the terms within the equations and an important use of the identity matrix. One might expect that students who selected choice (i) would also select choice (iii), and vice versa. However, four of the 27 students in Class 2 who selected justification choice (iii) did not select justification choice (i), and of the 26 students in Class 1 who said justification choice (i) was true and relevant, three said that justification choice (iii) was true but not relevant. Furthermore, 24 of the 28 students in Class 3, when writing down their justification, focused on some form of only one equation (10 used $A\boldsymbol{x} = \lambda\boldsymbol{x}$, and 14 used $(A - \lambda I)\boldsymbol{x} = \mathbf{0}$), as opposed to the remaining 4 who wrote or used both equations. This gives us evidence that there are two distinct ways to think about eigenvectors and eigenvalues, encapsulated within the two equations, as we had conjectured in our framework development.

Geometric Reasoning on Question 1

Although all 27 students of Class 1 and 28 of the 29 students in Class 2 indicated that at least one of the symbolic justification choices (i) and (iii) were true and relevant, only 12 of the 27 students in Class 1 and 14 of the 29 students in Class 2 indicated that the geometric justification choice (v) was true and relevant. With only the Original MCE, we cannot know why the other 15 students in Class 2 did not select justification choice (v). However, with the MCE given to Class 1, we get more information, as 9 of the 15 students said this choice was true but not relevant, and 5 said this choice was false. We feel this either indicates that students tend to think about eigenvectors and eigenvalues symbolically more than they do geometrically, or that students see symbolic justifications as more acceptable to their teacher or the larger mathematics community. This is further corroborated by the data from Class 3, where none of the 28 students gave any geometric argument when justifying their answer.

Open-Ended Results

Results from the open-ended data consisted of identifying common strategies in students' justifications and possible refinements to the MCE justification choices based on these. From the open coding, two main strategies emerged in how the students approached the problem, namely based on the equation the student chose to focus on, as mentioned above in the section on the $A\boldsymbol{x} = \lambda\boldsymbol{x}$ or $(A - \lambda I)\boldsymbol{x} = \boldsymbol{0}$ equations. Within these two larger strategies, several sub-strategies presented themselves in student work. For example, of the 10 students that used the $A\boldsymbol{x} = \lambda\boldsymbol{x}$ approach, 8 also used a "plugging in" strategy to find the eigenvector, by simply multiplying each vector choice by the given matrix, and seeing which satisfied the $A\boldsymbol{x} = \lambda\boldsymbol{x}$ equation. We classified this approach as the "Eigenvector Definition Check" (EDC) approach.

These classified student solution strategies are also being considered in future refinement to the MCE justification choices. For example, 16 of the students used some form of solving a system of equations in their justification work; however, currently there is no justification choice that deals with this idea. Additionally, in previous work on the MCE, we had identified a solution strategy wherein students calculated the coefficient matrix $[A - 6I]$ and concluded incorrectly that a resulting column vector from the matrix was an eigenvector. Justification choice (iv) was added to the MCE to capture this solution method. However, disconcertingly, only two students in Class 3 wrote down this strategy, whereas in Class 1, 10 students selected (iv) as true and relevant and three students selected it as true and not relevant, and in Class 2, six of the 29 students selected it as true and relevant. Thus, further modification of this justification is needed to only tempt students who think of this strategy as the only way to find eigenvectors.

Discussion

One might posit we would learn more about student understanding of eigentheory through open-ended questions than other forms of written assessment. However, we have shown how the MCE format can provide rich information regarding how students think about and understand eigenvector and eigenvalue problems; in particular, we can gain more information about the aspects and contexts of eigentheory students see as connected and relevant in justifying their solutions. As we pursue research in this area, we ask for feedback on the following questions:

1. What nuances of student understanding of eigentheory do we learn from the various MCE formats, and which format do you think would be most promising in future use?
2. With the MCE data, what ideas for analysis (statistical tests or otherwise) do you believe would be useful and informative?

Meta-Representational Competence with Linear Algebra in Quantum Mechanics

Megan Wawro, Virginia Tech
Kevin Watson, Virginia Tech
Warren Christensen, North Dakota State University

In this report we shared our preliminary analysis of one student's meta-representational competence as he engages in solving a quantum mechanics problem involving linear algebra concepts, namely basis, eigenvectors, and eigenvalues. We provide detail on student A25, who serves as a paradigmatic example of a student's power and flexibility in thinking in and using different notation systems. This preliminary work lends credence to and inspires our conjecture that strong meta-representational competence (MRC) is necessary not only to be fluent and proficient in the mathematics involved in solving quantum mechanics problems but also to develop a robust understanding of the quantum mechanics content.

Key words: *linear algebra, physics, matrix notation, Dirac notation, symbolizing*

The National Research Council's (2012) report, which charges the U.S. to improve its undergraduate STEM education, specifically recommends "interdisciplinary studies of cross-cutting concepts and cognitive processes" (p. 3) in undergraduate STEM courses. It further states that "gaps remain in the understanding of student learning in upper division courses" (p. 199), and that interdisciplinary studies "could help to increase the coherence of students' learning experience across disciplines … and could facilitate an understanding of how to promote the transfer of knowledge from one setting to another" (p. 202). Our work contributes towards this national need for basic research by investigating students' understanding, symbolization, and interpretation of eigentheory and related key ideas from linear algebra in quantum physics.

In this preliminary report, we focus on one student's reflection on explicit symbolization choices he makes while solving quantum mechanics problems that involve linear algebra. In particular, we inspect data of one student solving an expectation value problem and his reasons for how and why he chooses a specific symbol system – either Dirac notation or matrix notation – for that particular situation. We align our analysis with the framework of meta-representational competence (diSessa, Hammer, Sherin, and Kolpakowski (1991), as well as the delineation of structural features of algebraic quantum notations offered by Gire and Price (2015). We conjecture that strong meta-representational competence (MRC) is necessary not only to be fluent and proficient in the mathematics involved in solving quantum mechanics problems but also to develop a robust understanding of the quantum mechanics content.

Background and Theoretical Framework

In this section, we give an overview of research conducted on student understanding of symbols and representations in mathematics and physics, as well as our theoretical orientation. We conclude with a brief introduction to eigentheory in Quantum Mechanics and Dirac notation.

Student Understanding of Symbols and Representations

The recognition of the importance of students having an understanding of the symbols used in mathematics and physics has grown over the past few decades. Arcavi (1994, 2005) coined this as "symbol sense," which includes (a) being "friendly" with symbols, (b) reading through symbols, (c) engineering symbolic expressions, (d) understanding different meanings based on equivalent expressions, (e) choosing which aspects of a mathematical situation to symbolize, (f) using symbolic manipulations flexibly, (g) recognizing meaning within symbols at any step in the solution process, and (h) sensing the different roles symbols can play in various contexts. Many researchers along this vein have examined the ways students learn, make sense of, and use mathematical symbols and notations (e.g., Kaput, 1998; Meira, 2002; Van Oers, 2002).

Research into students' competence with symbols, inscriptions, and representations is not limited to K-12 studies. For example, Harel and Kaput (2002) describe how mathematical notations play a key role in forming conceptual entities in higher mathematics. Additionally, in linear algebra research, Hillel (2000) described three modes of description (abstract, algebraic, and geometric) of the basic objects and operations in linear algebra and pointed out that "the ability to understand how vectors and transformation in one mode are differently represented, either within the same mode, or across modes is essential in coping with linear algebra" (p. 199).

Extending even further, research into students' understanding in quantum mechanics has looked at how students make sense of and use a novel notation, called Dirac notation (explained in the subsequent section). Singh and Marshman (2013) showed that even after graduate level instruction in quantum mechanics, students still struggle with Dirac notation, showing inconsistencies in its use among contexts and problems. More closely related with this current study, Gire and Price (2015) looked at four structural features of three different notation systems used in quantum mechanics (Dirac, matrix, and wave function) and how students' reasoning interacts with these features. The features identified by the authors are: (a) individuation, or "the degree to which important features are represented as separate and elemental" (p. 5); (b) externalization, or "the degree to which elements and features are externalized with markings included in the representation" (p. 7); (c) compactness; and (d) symbolic support for computation. Using problem-solving interviews with students as insight into these features, Gire and Price found that students readily used Dirac notation, and that the structural features vary across the different notations as well as among several contexts within quantum mechanics.

Relatedly, diSessa et al. (1991) importantly discovered that students have a great deal of knowledge about what good representations are and are able to critique and refine them, which the authors defined as Meta-Representational Competence (MRC). diSessa and Sherin (2000) explained that MRC includes inventing and designing new representations, judging and comparing the quality of representations, understanding the general and specific functions of representations, and quickly learning to use and understand new representations. Furthermore, diSessa (2002, 2004) offered a list of critical resources students possess as part of their MRC for judging the strength of representations, such as compactness, parsimony, and conventionality. Iszák and his colleagues (Iszák, 2003, 2004; Iszák, Çağlayan, & Olive, 2009) extended this research by looking at students' MRC with the creation and critique of algebraic representations, and demonstrated students and teachers have criteria for good algebraic representations, though the criteria may not align between teacher and student.

Brief Introduction to Eigentheory in Quantum Mechanics and Dirac Notation

In quantum mechanics, certain physical systems are modeled and made sense of using eigentheory. To a physical system we associate a Hilbert space (such as $\mathbb{C}^2$), to every possible state of the physical system we associate a vector in the Hilbert space, and to every possible observable we associate a Hermitian operator (usually given in its matrix form). The only possible result of a measurement is an eigenvalue of the operator, and after the measurement the system will be found in the corresponding eigenstate.

Dirac notation, also known as bra-ket or just ket notation, is a common notational system in quantum mechanics. A vector representing a possible state is symbolized with a ket, such as $|\psi\rangle$. Mathematically, kets behave like column vectors, such as $|\psi\rangle \doteq \begin{bmatrix} a_1 \\ a_2 \end{bmatrix}$, $a_1, a_2 \in \mathbb{C}$, and are usually normalized. To each ket is associated a bra, such as $\langle\psi| \doteq [a_1^* \quad a_2^*]$, its complex conjugate transpose that behaves like a row vector. The eigenvalue equations for observables are central to many calculations. For instance, the eigenvalue equations for S_x (the operator measuring the intrinsic angular momentum along the x-direction of a spin-½ particle) are $S_x|+\rangle = \frac{\hbar}{2}|+\rangle$ and $S_x|-\rangle = -\frac{\hbar}{2}|-\rangle$, where $|+\rangle$ and $|-\rangle$ represent the orthogonal eigenbasis of S_x. Because of the orthonormality of eigenbases of Hermitian operators, the inner products yield $\langle+|+\rangle = 1, \langle-|-\rangle = 1, \langle+|-\rangle = 0$, and $\langle-|+\rangle = 0$. An elegant use of Dirac notation involves change of basis; because the eigenbasis of one operator is often well known in terms of another, such as along the z-direction of a spin-½ particle, Dirac notation is seen to make basis change calculations efficient.

Methods

Participants for this study were junior physics majors at a large, public, research-intensive university in the Pacific Northwestern United States. They were drawn on a volunteer basis from a class of 35 students in a Spin and Quantum Measurements course; this course met for 7 class-hours per week for three weeks and involved many student-centered activities and discussions. Data for this report were collected during individual, semi-structured interviews (Bernard, 1988) conducted with 8 students at the end of the course.

To begin our analysis, we viewed the video and observed how students navigated the interview problems, with no set ideas ahead of time of what we would analyze, while keeping in mind the overarching research focus of students' understanding, symbolization, and interpretation of eigentheory in quantum physics. We looked for correct, incorrect, and unique reasoning approaches. Throughout our viewing, we noticed two students were particularly fluent in how they talked about and worked with both matrix and ket notations. This compelled us to investigate the literature about student use of symbols and notations, the most relevant of which were discussed above. As such, we began an analysis drawing on the work of diSessa and colleagues, Iszák and colleagues, and Gire and Price (2015). We reviewed the video data through this lens, coding for instances of students mentioning structural features of the mathematics or students making explicit meta-commentary on the representations they were using.

In this preliminary report, we focus on one student: A25, a double major in physics and nuclear engineering who had completed two quarters of linear algebra. The purpose for focusing on this participant is his demonstrated ability to articulate his thinking. During the interview, he demonstrated flexibility in reasoning about the concepts we were probing, and through his explanation a great deal of MRC was visible and analyzable.

Preliminary Results

In the beginning of the interview, student A25 volunteered that he sometimes explicitly chooses between doing calculations in matrix notation or in Dirac notation:

I: So how do you feel like, using eigenvectors and eigenvalues, in spins has been similar to and different from how you've experienced those in other classes?

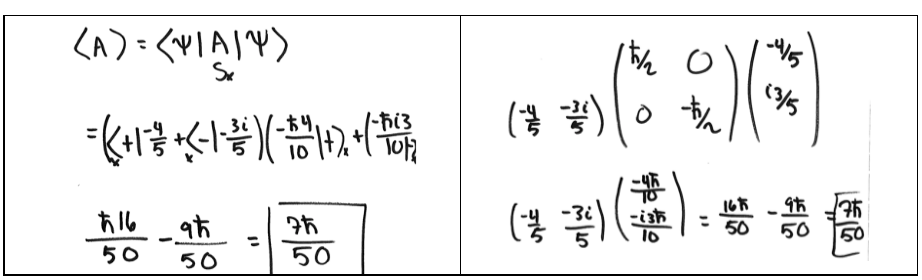
A25: Uh, well, it's very similar because you're doing a lot of the same math …the difference especially in physics, you're looking at kets. In, in at first I was kind of jarring, like to- to

> try to do the math in kets. But now, it's kinda- it's kinda easier, there's problems, there certain problems…where there's two ways to do them, they're kind of parallel, you can do it and you can expand the- the- the state in- in like as a- and expand them as- as kets in a different basis, or you can write that state as a- as a, as a vector, in that basis, and you can either do the matrix math for the like expectation values for example, you can do the matrix math or you can do the ket math, and sometimes it's, I'm finding that I, rather expand something in the ket.

From the transcript we see that A25 was aware that there exist multiple legitimate ways to solve the problem, seemingly understanding the various mathematical nuances and implications of his notational choices. His brief explanation highlights sentiments that are consistent with Arcavi's characteristics of symbol sense, such as being "friendly" with symbols and using them flexibly. We add, however, a metacognitive aspect of symbol sense here, noting that A25 was engaged in self-reflection rather than a researcher analyzing A25's engagement with symbols.

Because A25 volunteered expectation value problems as a situation in which he could use either notation, the interviewer had him work on such a problem right away, even though it was prepared to be at the end of the interview: "Consider the state $|\psi\rangle = -\frac{4}{5}|+\rangle_x + i\frac{3}{5}|-\rangle_x$ in a spin-1/2 system. Calculate the expectation value for the measurement of S_x." A25 immediately worked on the problem within Dirac notation, saying, "basically to find the expectation value… it's like denoted that way [writes $\langle A\rangle$] but really what you're doing is you're taking the, the bra of the state, and then you're putting the operator [writes $= \langle\psi|A|\psi\rangle$] in the middle of the inner product…" He continued to explain his work as he went, arriving at the correct answer of $7\hbar/50$ (see Figure 1a). Note that his work in Figure 1a involved the state's expansion and use of eigenvector equations for S_x in ket notation. In addition, this notation was first introduced to the students during this course; as such, A25 was clearly quick to use and understand this representation (a quality of MRC, diSessa & Sherin, 2000).

After discussing his work and solution, the interviewer asked: "Before you were telling about bra-ket versus matrix notation, you brought up an expectation value as an example of like, either or both, so can you, now that you had this problem, kinda revisit that?" A25 immediately solved the problem completely within matrix notation (see Figure 1b), explaining his steps. For instance, in line 1 in Figure 1b, he wrote the complex conjugate transpose of the vector representation of the state in the x basis, the matrix representation of the S_x operator in the x basis, and the vector representation of the state in the x basis. He also stated his process for computing the matrix times the column vector before he did the computation, and again in line 2 he explained "then I do it again, so, um, this time you're gonna get a number out," meaning he anticipated that a row vector times a column vector would be a number. We see this as flexibly using symbolic manipulations (Arcavi, 1995) and an anticipation of results.



(a) (b)

Figure 1. A25's expectation value problem, in ket notation (a) and matrix notation (b).

The interviewer then asked A25 to reflect on his preference between the two notations:

A25: Uh...To be honest, I don't really, I don't really know why I prefer this [Figure 1a], I think it's just because, um, I like this notation. This- this specific notation [Figure 1a line 1] like this to me is like a cleaner way of writing that [Figure 1b line 1] because that- I mean this and that [touching lines 1 in both figures] I feel like are your starting points, so you, you start here with this nice, like, looking thing [traces his finger under $\langle\psi|A|\psi\rangle$], or you start here with this big array of numbers [puts open hands around Figure 1b], and I prefer this [Figure 1a line 1], even though you have to expand this into basically the same amount of information [Figure 1a line 2]. And also, the nice thing about, about this [Figure 1a line 1], is it—actually this is really why it's better—is because you can, you can say ok S_x works- acts directly on these kets, you can just get rid of the matrix altogether...

We see his use of "nice looking thing" and "big array of numbers" in comparison to one another are an example of compactness. He also compares line 1 in 1(a) and line 2 in 1(b) regarding the "amount" of information they convey, which involves reflection on the physical and mathematical content expressed in the compared notations. Finally, acting directly on the expansion in terms of the eigenstates of the operator allow him to forego the matrix calculation entirely, which speaks to A25's view of compactness, parsimony, and symbolic support for using ket notation for this problem.

When asked about his notation preferences if the basis expansion of a given state vector and the operator "didn't match," A25 recalled a problem from their last homework that was "actually easier…to do the matrix multiplication," stating "you don't want to have to change these kets into different bases all over the place 'cause they're already all written in the same basis and you know what the operator is in that basis so you might as well just, do the matrix multiplication." This speaks to his awareness of symbolic support as well as using symbols flexibly. Finally, when asked if the notions of basis or eigenvectors/eigenvalues come up more in one notation than the other, A25 stated, "certainly…every time you write down a ket you're, you're very conscious of what basis you're in. In this one [points to Figure 1(b)] it's just kinda implied…all this [is] in the same basis, so you're just, you're just writing out numbers, an arrays of numbers, but here [in Figure 1(a)] you're thinking ok, this is the S_x operator, this is the x plus ket, this is the x minus bra…so I think that you're definitely more aware of what basis you're in when you're using this, because you have to be." This explanation is consistent with Gire and Price's (2015) notion of externalization, in that the ket notation allows features of the problem, namely basis, to be externalized in a way that the matrix notation did not provide for A25.

Conclusion

In this report we shared our preliminary analysis of one student's meta-representational competence as he engaged in solving a quantum mechanics problem involving linear algebra. This is a paradigmatic example of a student's power and flexibility in thinking in and using different notation systems. During our presentation, we will provide additional data and analysis on A25 and other students regarding observed MRC during their interviews. We would benefit from discussion with the audience regarding the following: (1) what aspects of MRC seem most important to success in solving quantum mechanics problems involving linear algebra, and (2) how tied to a robust understanding of the quantum mechanics content might MRC be, and how could that be explored through analysis?

An Investigation of the Development of Partitive Meanings for Division with Fractions: What Does It Mean to *Split Something into 9/4 Groups*?

Matthew B. Weber
Arizona State University

Amie Pierone
Scottsdale Community College

April Strom
Scottsdale Community College

In this paper we describe a study involving twelve preservice elementary teachers who were attending a community college. The design and implementation of this study were guided by the research question: In what ways do students reason through a sequence of tasks which progressively become more abstract, and which challenge primitive intuitions regarding partitive division? We highlight students' ways of thinking involved with division that are not easily generalizable, that favor numerical procedures over quantitative reasoning, and which are obstacles to the development of more robust meanings for division.

Keywords: Fraction Division; Partitive Division; Preservice Elementary Teachers

Discussion of the Literature

Researchers (Fischbein, Deri, Nello, & Marino, 1985; Harel, Behr, Lesh, & Post, 1994; Rizvi & Lawson, 2007; Simon, 1993; Thompson & Saldanha, 2003; Tirosh, 2000) have long acknowledged some primitive ways of thinking about partitive and quotitive division. Partitive division is when $a \div b$ is interpreted as the amount of the quantity referenced by a per one unit of the quantity referenced by b, given that the quantities are proportionally related. One primitive model for partitive division identified by researchers is *fair sharing*, which is characterized by thinking about splitting a into b equal parts. This primitive model requires the divisor to be a whole number, and thus the value of the quotient should be less than the value of the dividend; in other words, division makes smaller. Quotitive division is when $a \div b$ is interpreted as the number of copies of b that make a, which can also be interpreted as the measurement of a in units of b. Concerning quotitive division, the primitive model of *repeated subtraction* requires the divisor to be smaller than the dividend. These primitive models for division are rooted in reasoning with whole numbers and they continue to influence the reasoning of students and teachers, even after they are exposed to more sophisticated models (Fischbein et al., 1985). In particular, these primitive models obstruct sensible reasoning pertaining to division involving fractional values.

In a study of preservice elementary teachers, Simon (1993) noticed that the subjects could accurately execute procedures for long division of whole numbers, but that these procedures were not well connected to the subjects' meanings for division. He stated that "their lack of conceptual understanding given their algorithmic competence seems to challenge the idea that procedural practice eventually leads to understanding (Simon, 1993, p.249)." In a study of preservice elementary teachers, Tirosh (2000) investigated the impact of primitive models on division involving fractional values. She observed that the subjects heavily relied on procedures, such as *flip and multiply*, instead of relying on meanings for division. She introduced the subjects to formal justifications for the flip and multiply algorithm, but these formal arguments were based largely on symbolic manipulation of non-contextualized variables, and it was unclear whether these justifications would be accessible to elementary students. Rizvi and Lawson (2007) noticed that none of the 17 preservice teachers from their study could explain the flip and multiply algorithm, nor could any of the subjects initially pose a word problem that required division by a fractional value. The researchers attributed these deficiencies to a reliance on the primitive fair sharing and repeated subtraction models for division.

We have found little research on partitive meanings for division when the divisor is a fractional value. A quick survey of textbooks and online resources is likely to reveal that many attempts to connect numerical division of fractional values to a meaning for division are based on the quotitive division model. However, some researchers and educators (Beckmann, 2011; Gregg & Underwood Gregg, 2007; Kribs-Zaleta, 2008; Ott, Snook, & Gibson, 1991) have illustrated partitive models for division with fractions, but they do not discuss the development of these meanings. This paper reports on a study designed to investigate the development of partitive meanings for division with fractions.

The Partitive Model: What Does it Mean to *Split Something into 9/4 Groups*?

The design of this study assumed the subjects had existing meanings for fair sharing with whole numbers of groups, as well as meanings for fractions as operators. As such, we intended to build on these meanings by introducing the subjects to situations that require partitive division with whole divisors, followed by situations with non-whole divisors. Let's consider a learning progression that begins with primitive meanings for partitive division with whole divisors, and ends with robust meanings that accommodate non-whole divisors. Consider 6 cups of water fitting perfectly in 3 equally-sized whole containers. The relative size of one container's capacity to the total amount of water is critical – if 6 cups fit into 3 equally-sized containers, then one container holds 1/3 of the 6 cups. This way of thinking forms a meaningful foundation for the numerical equivalence of the expressions $6\div3$ and $1/3\times6$. Next, suppose 6 cups of water fit perfectly in 9/4 containers. Interpreting 9/4 containers as 9 quarter-containers allows one to reason that 1/9 of 6 cups will be in each quarter container with four copies constituting the capacity of one whole container (see Figure 1). Thus a whole container's capacity would be $4\times1/9\times6$, or $4/9\times6$ cups. This idea yields a numerical equivalence between $6\div9/4$ and $4/9\times6$. As another example, consider a situation where 6 cups of water fit perfectly in 2/3 of a container. Thus, 1/3 of the container holds 1/2 of 6 cups, and the whole container holds 3 times as much as 1/2 of 6 cups (see Figure 2). This way of thinking yields a numerical equivalence between $6\div2/3$ and $3/2\times6$. The study described in this paper investigates the development of these schemes for partitive division involving fractions.

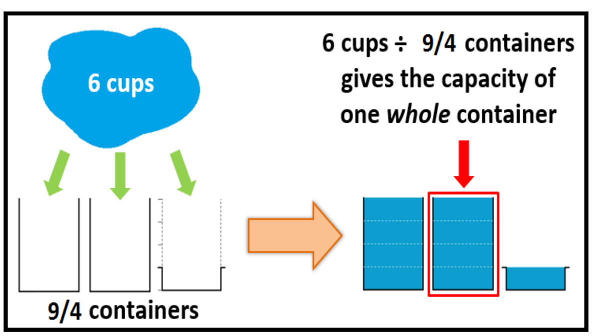

***Figure 1*. 6 cups in 9/4 containers.**

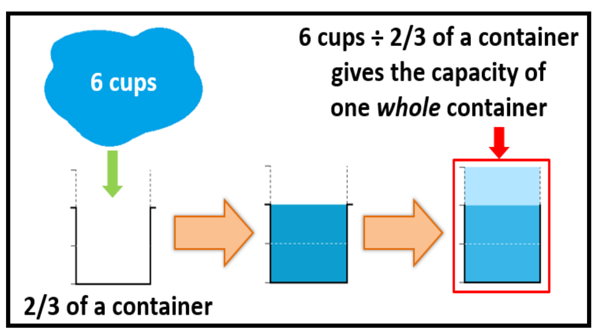

***Figure 2*. 6 cups in 2/3 of a container.**

Methodology

This study focused on twelve elementary education students in a *Mathematics for Elementary Teachers* course at a community college. An instructional unit, focused on the meanings of division, was implemented in the course and spanned three class sessions. Of the five learning objectives for this unit, two are the focus of this paper: (1) Use partitive and quotitive meanings for division (instead of algorithms) to divide by rational numbers and (2) Make sense of the *flip and multiply* procedure by using the partitive meaning for division. We issued a total of four assignments to each of the twelve students in the class. The first assignment preceded any formal class discussion on division and the remaining three assignments were given out after each class session. Two students, one higher-performing and one lower-performing, were selected to participate in videotaped interviews while they worked through the assignments. Leveraging Goldin's (2000) principles, the interviews with these two students were semi-structured and task-based, with the purpose of investigating their thinking. We asked the other ten students to each work on their assignments alone and without resources, to do the tasks from each assignment in order, and to clearly present their solutions in writing. The design of this investigation and subsequent data analysis were guided by the research question: *In what ways do students reason through a sequence of tasks which progressively become more abstract, and which challenge primitive intuitions regarding partitive division?*

Discussion of the Data

During this study, the subjects participated in a variety of tasks. In this paper, we narrow our discussion to the data from the following three tasks:

Task 1: Divide 27 gallons of water into 9/4 containers. How much water is in one whole container?
Task 2: Suppose an unknown amount of water is divided into 9/4 containers. What could you say about how much water is in one whole container?
Task 3: Explain why it is that when you divide by a fraction, you can multiply by the reciprocal of the fraction instead. In other words, explain the following: $a \div \frac{b}{c} = a \cdot \frac{c}{b}$

We designed these tasks to be successively more abstract. For Task 1, we considered a response to be correct if it was *12 gallons of water in one whole container*. For Task 2, we considered a response to be correct if it was conceptually equivalent to saying *4/9 of the water is in one whole container*. For Task 3, we considered a response to be correct if it was a generalization of valid thinking from Tasks 1 and 2, or some other valid explanation. Table 1 summarizes our analysis of the subjects' responses to these three tasks, and it reveals that as the tasks become more abstract, the students became less successful overall. We now discuss the thinking of the two students who were videotaped. We will refer to them as Adam and Sue.

Table 1. Summary of Results of Tasks 1 through 3.

	Task 1	Task 2	Task 3
Number of students with a correct response	8	4	1
Number of students with an incorrect response	3	5	4
Number who said "I don't know" or gave no response	1	3	7

The Case of Adam

Adam was the only student out of the twelve subjects who demonstrated valid reasoning during all three tasks. For Task 1, he drew 9/4 containers, then decided to procedurally compute 27÷9/4 by inverting and multiplying to get 108/9, which he reduced to 12 through procedural division. He admitted to using the numerical operation of division because the word *divide* was in the prompt. Once he calculated that the answer should be 12, he decided to find the amount in each quarter-container, by dividing 12 by 4 to get 3. He did not indicate that he could have also divided 27 by 9 to get 3. In fact, his calculation of 27×4/9 by first multiplying 27 by 4 is indicative that he was operating numerically and not thinking quantitatively about partitioning and iterating. He then confirmed that a total of 27 gallons was in the 9/4 containers by saying that 12 gallons were in each of the two whole containers and 3 more gallons were in the remaining quarter-container (see Figure 3).

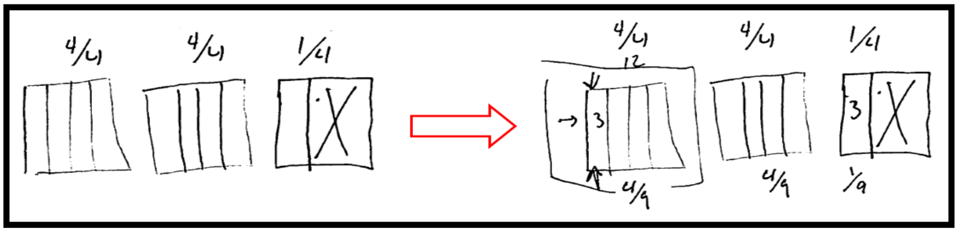

***Figure 3*. Adam's response to Task 1.**

During the interview, Adam's language was not consistent. He sometimes referred to each quarter-container as a whole container, as well as misspeaking about other referents. However, we suspect that his language was simply misrepresenting his valid thinking. Figure 3 also reveals that Adam labeled one container as "4/9", and he said that "4 out of the 9" pieces make one whole container. As such, and not surprisingly, for Task 2 he wrote that "4/9 of the whole" corresponded to one whole container. For Task 3, Adam demonstrated that he was beginning to generalize his thinking. He attempted to explain the algorithm by describing division by 7/2, as depicted in Figure 4. When pressed to speak in terms of *a*, *b*, and *c*, Adam responded by describing partitive thinking, but then gave a quotitive example. He said "The whole thing is the *a*...and I'm cutting it up to a certain amount of pieces. I don't know how many… abstract… but let's say it's one third. And I want to know how many one thirds fit into it [referring to the whole]." Ultimately, Adam was unable to generalize the partitive division models that he had earlier demonstrated using specific fractional values for the divisor.

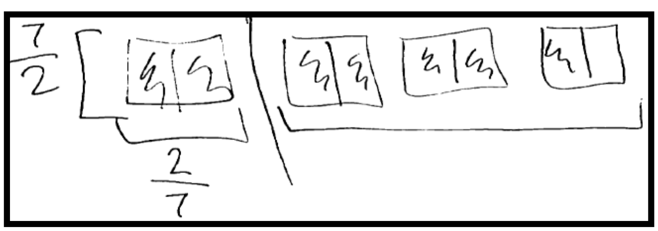

***Figure 4*. Adam uses division by 7/2 to illustrate the invert and multiply procedure.**

The Case of Sue

Sue appeared to have no trouble with Task 1. She drew nine contiguous boxes, marked "3" on each, indicated that four such boxes made a whole container, and concluded that 12 gallons were in one whole container. This is depicted in Figure 5.

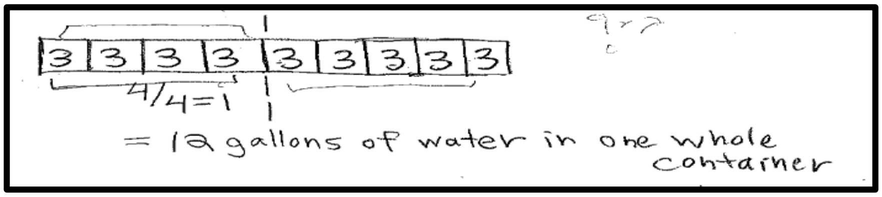

***Figure 5.* Sue's work on Task 1.**

On Task 2, Sue was immediately perturbed. She said she didn't know what to do, pointing out that the amount of water was not provided like it was in Task 1. The researcher asked what she would do if the amount of water was 18 cups. She proceeded to answer this question in the same way that she did for Task 1. The researcher then asked her to consider what she would do if "*x* cups" were the total amount of water, but she was ultimately unable to respond. Since Sue was stumped, the researcher returned to Task 1 and asked her how she knew to put a "3" in each box. She explained that she knew the total had to be 27 gallons and that there were nine boxes. She mentioned that each of the nine boxes had to have the same amount of water and mentioned a guess and check strategy. Two gallons per box was too little ("nine times two is only 18"), but nine times three gives the correct 27 gallons. The researcher then asked her why she answered that 12 gallons were in one whole container. She said that each box was one fourth of a container, so she added the four copies of three gallons to get 12 gallons. The researcher then drew nine contiguous boxes, shaded in four of them, and asked Sue how much of the entire collection was shaded. Sue promptly answered "four ninths". The fact that Sue answered "four ninths" so quickly in the latter situation indicates that Sue's meanings for fractions are likely limited to the *out of* model and that she does not have developed meanings for fractions as operators. As such, her schemes for solving Task 1 were not generalizable to the point where she could sensibly talk about Task 2. For Task 3, Sue did not know how to respond.

Conclusion

Primitive ways of thinking about division continue to be pervasive in mathematical thinking. This research explored the development of more robust meanings for partitive division, which are not thwarted by non-whole divisors. The initial data reveals that underdeveloped meanings for fractions are impediments to the maturation of robust meanings for division. For example, Sue mentioned "four ninths" when she saw 4 out of 9 boxes shaded, but she did not appear to think of four ninths as an operator on the total amount of water. The data also suggests that quantitative operations, such as partitioning and iterating, are often neglected in favor of procedural approaches to division. This was illustrated by Adam, in Task 1, when he procedurally calculated that 12 gallons were in each whole container; yet, there was no indication that he partitioned the total amount of water into 9 equal pieces. Additionally, we see examples of schemes for division that are not generalizable to more abstract levels of meaning. For example, Sue's guess and check scheme in Task 1 was dependent on knowing the total amount of water. It is evident that the development of partitive meanings for division with fractions depends on more robust meanings for both fractions and division. Additional research is needed to better investigate this claim.

Corequisite Remediation and Math Pathways in Oklahoma

Matthew Wilson
Oklahoma State University

Michael Oehrtman
Oklahoma State University

We examine the current progress of implementing both corequisite remediation and math pathways in the state of Oklahoma. In this paper, we discuss the details of these effort and the underlying needs while providing a national perspective about the reforms. We present preliminary data from pilot sections of a corequisite College Algebra course and a new math pathway for degrees that require significant quantitative literacy but do not require engineering calculus. We also present statewide data on student course-taking patterns, degree requirements, and existing institutional efforts that will inform state-level decisions.

Key words: corequisite remediation, mathematics pathways, reform

Introduction

The state of Oklahoma is currently in the process of reforming introductory post-secondary mathematics options and curriculum across all 27 public higher education institutions with the goal of increasing success in college mathematics courses and therefore increasing degree attainment across the state. To accomplish these goals the Oklahoma State Regents for Higher Education, the governing body for all public higher education institutions in Oklahoma, adopted the Complete College America agenda (Complete College America, 2013). The main focus of the state reforms are 1) supplementing the current system of remedial courses with a corequisite model and 2) creating multiple introductory mathematics pathways better aligned to diverse degree programs.

Traditionally, to ensure preparation of entering students, colleges assess students using various criteria (e.g. SAT scores, ALEKS, etc.) then place them into college courses using these measures. Under-prepared students are placed in a remedial course sequence designed to fill in deficiencies from secondary mathematics and prepare them for college-level courses. Once a student completes the remedial course sequence, they are allowed to take credit-bearing math courses required for a degree. However, this remedial system often fails in its ultimate goal. In 2010, Bailey et al found that only 31% of community college students referred to a remedial courses sequence in mathematics completed it often due to a failure to enroll. Even more troubling, only half of the students completing the remedial course sequence enrolled in the gatekeeper college-level course passed (2010). Meaning only 15% of students referred to remediation passed the subsequent college credit-bearing course, which is significant as 58% of entering students community college students enrolled in a remedial mathematics course (Attewell et al., 2006). Overall, 28% of college students from two or four-year colleges enroll in remediation (Attewell et al., 2006). Furthermore, delaying enrollment in college-level courses in favor of remedial courses has the consequence of extending students' time to degree, meaning both an increased cost and decreased persistence toward a degree (Complete College America, 2011).

Alternatively, in corequisite remediation, underprepared students are placed directly in college-level courses with targeted assistance. The aim of the model is to allow under-prepared students to earn college credit upon entering while still providing the students with necessary perquisite material, thereby eliminating often multiple semesters of remedial courses and enabling students to progress to through their degree programs. Corequisite remediation has been successful in several pilot programs across the country, which will be briefly discussed in the next section.

The second focus of the reforms are creating mathematics pathways beyond the standard College Algebra/Calculus sequence. Creating additionally pathways provides students in non-STEM disciplines basic mathematics courses more relevant to their interests and needs. The reforms seek to increase collaboration between math departments, other academic degree programs, and employers as to the necessary mathematical knowledge and skills for students in their chosen field. For many, courses in statistics, quantitative literacy, or mathematical modeling are more applicable to future collegiate and career needs. The need for increasing such diverse mathematical competencies has been highlighted by several reports from professional associations including: the *Common Vision 2025* report by the Mathematical Association and America (Saxe, 2015), the *Guidelines for Assessment and Instruction in Statistics Education (GAISE): College Report* endorsed by the America Statistical Association (Aliaga, 2005), and the *Beyond Crossroads* Report of the American Mathematical Association of Two-Year Colleges (Foley, 2007). Additionally, by creating clearly defined mathematics pathways at the state level, Oklahoma is aiming to increase transferability of mathematics courses between public institutions.

In this paper, we address the following research questions:

1. What are the primary national trends and lessons in corequisite remediation and math pathways relevant to the goals and structures of the Oklahoma higher education system?
2. What are the primary obstacles in implementing corequisite remediation and math pathways in Oklahoma, and what factors can local and state leaders influence to address these challenges?

A National Perspective of the Reforms

Several states have either implemented or are in the process of implementing the reforms outlined above. We briefly describe progress in two of the states to lead these reform efforts, Georgia and Tennessee.

Currently, Georgia has two pathways: the traditional College Algebra/Calculus pathway and a non-algebra pathway which focuses on either quantitative reasoning or modeling. In Fall of 2014, Georgia piloted corequisite remediation for both pathways. 67% of the 2919 students in the non-corequisite sections passed the gateway course. In the corequisite sections, there was a total 1,132 students 64% of whom passed. Comparably, only 21% of students referred to remedial education in 2010 passed their gateway course within two years (Complete College America, 2015).

Beginning in Fall of 2014, Tennessee conducted a pilot corequisite program for an introductory statistics courses with 1,019 students at 9 different campuses. Tennessee saw similar results to Georgia, 63.3% of students assessed as being underprepared pass introductory statistics whereas under the previous remediation model only 12.3% had pass the introductory statistics course.

Similar results can been see in other states (Complete College America, 2016). We will continue to examine the progress and challenges of the reforms across the country and how their efforts can inform the reforms in Oklahoma.

Progress in Oklahoma

Corequisite Remediation

In fall of 2015, Oklahoma State University began piloting corequisite courses. The ALKES test is used to assess entering student college readiness. Normally, to place into College Algebra a score of 45 out of 100 is required. OSU ran three pilot sections consisting of 87 students scoring between 30 and 44 on the ALEKS test. The students in the corequisite sections attended class five days a week. Three days were dedicated to regular instruction, similar to the standard three-hour College Algebra class. During the other two days, an undergraduate learning assistant engaged students in active learning sessions designed by an experienced course coordinator to improve students' prerequisite knowledge. Students in the corequisite sections completed the same homework and took the same exams as students in regular College Algebra sections. Table 1 shows the percentage of the students in these courses earning a D and F, or withdrawing (D/F/W rate).

Table 1
Data from pilot sections.

	Enrollment	Proportion of first-generation students	Overall D/F/W rate	First-generation D/F/W rate
All sections	820	20.7%	31.6%	35.9%
Regular sections	733	18.8%	31.2%	37.0%
Pilot sections	87	36.8%	34.5%	31.3%

While the D/F/W rate overall for the pilot corequisite sections was slightly higher than for regular sections, the D/F/W rate for first generation was significantly lower. Traditionally only a small fraction of students enrolling in remedial courses succeed in that course, continue to College Algebra, and further succeed in College Algebra. Equally important is student persistence to and success in subsequent mathematics or statistics courses which is shown in Figure 1.

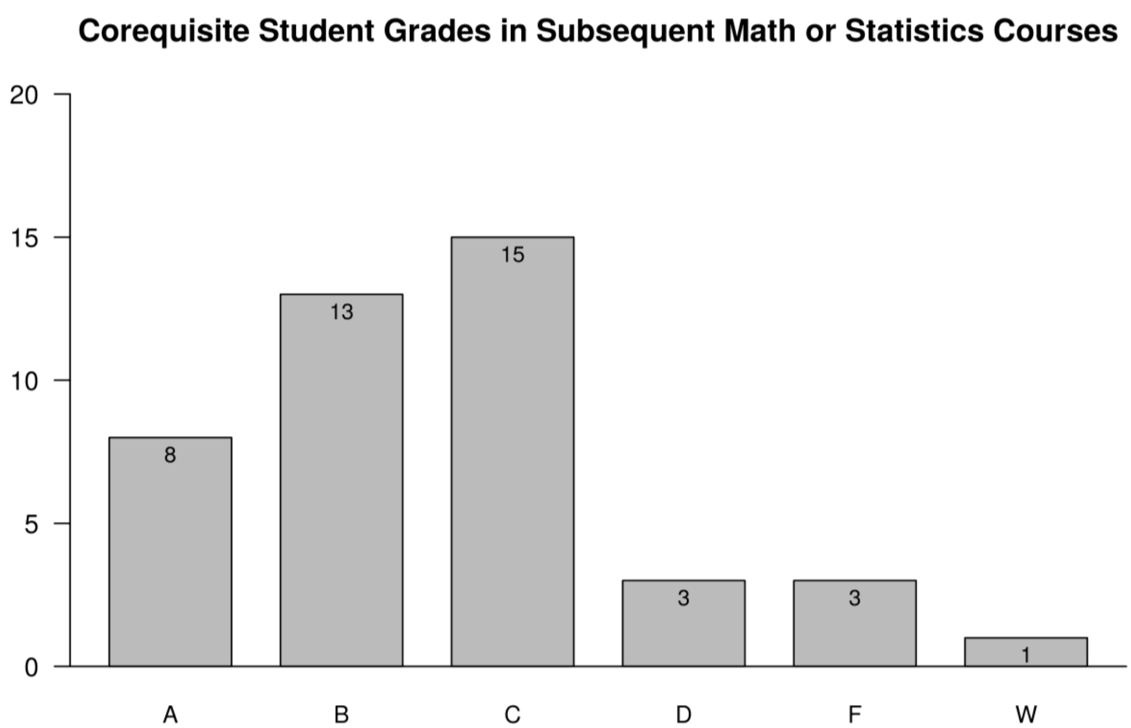

Figure 1. Corequisite students' grades in subsequent mathematics or statistics courses.

With regard to the state wide reforms, we have collected surveys from all public institutions in the state on their implementation of corequisite courses. We are in the process of analyzing this data, which will provide a useful baseline for comparison as the state reforms unfold.

Math Pathways

Oklahoma State University has also created a course *Mathematical Functions and Their Uses* (MATH 1483) which is being offered as an alternative to College Algebra for many business, social science, health, and agriculture degrees that do not require an engineering calculus course. The course emphasizes quantitative reasoning by modeling data with a calculator and/or excel and serves as an equally successful preparation for Business Calculus as College Algebra. The D/F/W rates are typically 15% and 25% for the fall and spring respectively. As degree requirements shift away from college algebra, we are in the process of analyzing D/F/W rates from subsequent gateway courses. Moreover, the shift to functions has led to an increased success in College Algebra. Additionally, in Fall 2016, the university began piloting a corequisite section of the functions course allowing traditionally underprepared students another pathway to earn college credit upon entering.

Statewide, we collected detailed information on the mathematics requirements for every major at 26 of the 27 state public institutions (we are still seeking information from the last institution) and complete statewide data for student enrollment and success in math courses by major. The aim is to better understand the current math pathway options available and clusters of majors that might benefit from shifts to new math pathways. As we continue our data analysis, we will be conducting interviews with individuals involved in the reforms in Oklahoma and individuals involved in the national reforms to better understand the data and process.

Discussion Questions

During our presentation, we will present a more complete analysis of the data described in this proposal with implications for state-level reform decisions. We seek a discussion on the primary challenges to a successful implementation of corequisite remediation and math pathways at-scale and productive theoretical perspectives on institutional and systemic change to guide ongoing research and evaluation.

Instructor-Generated Concepts Framework for Elementary Algebra in the College Context

Claire Wladis
Borough of Manhattan Community College at the City University of New York
Graduate Center at the City University of New York

Kathleen Offenholley, Susan Licwinko, Dale Dawes, Jae Ki Lee
Borough of Manhattan Community College at the City University of New York

The long-term aim of this study is to develop a conceptual framework outlining the concepts necessary for college students to be able to successfully complete fundamental tasks of elementary algebra. This paper is a preliminary report of one part of this research, which focuses on instructor perceptions of what concepts are fundamental to successful completion of elementary algebra tasks. The framework presented here is the result of an action research project conducted by five college instructors in the U.S. who teach elementary algebra.

Keywords: Elementary algebra, conceptual understanding, algebra concepts, tertiary education.

Elementary algebra and other developmental courses have consistently been shown to be barriers to student degree progress and completion in the U.S.. There is evidence that only as few as 20% of students who are placed into developmental mathematics ever successfully complete a credit-bearing math course (see e.g. (Bailey, Jeong, & Cho, 2010). At the same time, elementary algebra has higher enrollments than any other mathematics courses at U.S. community colleges (Blair, Kirkman, & Maxwell, 2010).

Significant research has been done in the primary and secondary context to explore which types of student thinking lead to more successful or less successful outcomes in student algebraic problem-solving, but little research has been conducted with students enrolled in elementary algebra courses in the tertiary context, despite the fact that there is significant evidence to suggest that mathematics learning is likely somewhat different in this context (Mesa, Wladis, & Watkins, 2014). One approach to investigate this setting is to conduct participatory action research in the tertiary context in order to explore how instructor experiences, including cyclical investigations of their own practice, can shed light on some ways that tertiary students learn elementary algebra concepts, and on which types of student understandings are important for successful completion of elementary algebra tasks.

Conceptualizations of algebra and fundamental algebraic concepts

There are a number of different conceptualizations of algebra that have been explored in the research literature. Usiskin (1988) laid out four conceptualizations of algebra: generalized arithmetic; the set of all procedures used for solving certain types of problems; a study of relationships among quantities; and a study of structure. Kaput (1995) in contrast identified five conceptualizations of algebra, the first four of which mirror somewhat closely those of Usiskin: generalization and formalization; syntactically-guided manipulations; the study of functions, relations, and joint variation; the study of structure; and a modeling language.

A number of different important algebraic concepts have been studied previously, typically in the primary or secondary context. A complete review of the literature is not possible due to space constraints, but we outline here briefly some of the major categories of research on algebra that are relevant to elementary algebra in the tertiary context and cite one or two key references for each:

- Variables and symbolic representation (Dubinsky, 1991; Kuchemann, 1978; Sfard, 1991)

- Functions and covariation (Blanton & Kaput, 2005; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Goldenberg, Lewis, & O'Keefe, 1992)
- Equivalence (Kieran, Boileau, Tanguay, & Drijvers, 2013; Knuth, Stephens, McNeil, & Alibali, 2006)
- Algebraic structure sense (Hoch, 2003; Hoch & Dreyfus, 2006; Linchevski & Livneh, 1999)

For an excellent and systematic review of historical developments in the conceptualization, teaching, and learning of algebra, see (Kieran, 2007). Some researchers have developed frameworks for organizing algebra as a subject, typically in the primary and secondary context (see e.g. (Nathan & Koedinger, 2000; Sfard & Linchevski, 1994). In addition, various national standards regarding the teaching of algebra exist, such as the Mathematical Association of America college algebra standards (Mathematical Association of America, 2011), the National Council of Teachers of Mathematics Standards (National Council of Teachers of Mathematics (NCTM), 2000), and the American Mathematical Association of Two-Year Colleges Beyond Crossroads standards (Wood, Bragg, Mahler, & Blair, 2006). However, while these standards stress the importance of conceptual understanding, their detailed explication of what students should learn tends to focus on computational tasks (e.g. being able to perform function composition) rather than on the specific conceptual ways of thinking that underpin those tasks (e.g. having a process view of function).

Teacher beliefs and expertise

The relationship between teacher beliefs and practice is complex; for example, teachers do not always employ teaching practices that strongly reflect their professed beliefs about how students learn. However, despite this complexity, there is significant research suggesting that teacher beliefs are often strongly related to the teaching practices that teachers implement in the classroom, and therefore are also related to student beliefs and learning experiences (see e.g. (Fang, 1996; Maggioni & Parkinson, 2008). So understanding teacher beliefs is one critical component of understanding instructor practice and its impact on student learning.

On the other hand, teacher expertise also has the potential to benefit the research community by contributing important information about what teachers have learned while teaching; this knowledge can then be used by researchers to generate and test new theories about how students learn and about what is effective in the classroom. As Schulman (1987) explains, "One of the more important tasks for the research community is to work with practitioners to develop codified representations of the practical pedagogical wisdom of able teachers" (p. 11).

This study uses a *teacher-as-researcher* interpretation of *action research*, as originally coined by Stenhouse (1975) and later expanded conceptually by Elliot (1991) and then Cochran-Smith and Lytle (1993; 2009). In this framework, teacher-practitioners investigate research questions not only to improve their own practice, but also to add to a larger body of knowledge than can be implemented by other teachers in similar contexts. This is a more inclusive view that includes practitioner experiences as a valid foundation for knowledge production.

Theoretical Framework

This study uses Vygotsky's (1986) theory of concept formation as a framework for investigating student understandings in elementary algebra. According to Vygotsky, algebraic symbols, graphs and other representations of mathematical objects and concepts mediate two interconnected processes: 1) the development of a mathematical concept in the individual; and 2) the individual's interaction with an external mathematical world where these representations are rigorously codified. Learners begin to use these representations before they have “full” understanding of their meaning, and it is through this experimentation and attempts at communication with “more knowledgeable” others over time that they internalize more formal and correct meanings for the objects that the representations symbolize.

Methodology

Five elementary algebra instructors collaborated on this action research project, some of whom are also active educational researchers. The group included faculty with doctorates in both mathematics and mathematics education, who have taught at the high school, community college, and university levels. Faculty came from varied backgrounds, and included both men and women, several different racial/ethnic, national, and immigrant backgrounds, and reflected a variety of different teaching styles.

Conceptual Framework

This study used the *Action Research Spiral* Framework (Kemmis & Wilkinson, 1998) to guide the process of collaborative exploration into student thinking about elementary algebra concepts. This framework outlines a cyclical practice in which practitioners cycle through the following steps repeatedly in a spiral: 1) plan; 2) act and observe; 3) reflect; 4) revised plan, etc.

First each instructor independently created a list of concepts that they saw as fundamental to elementary algebra. After all instructors had created their own list, all lists were combined. Then a series of discussions ensued, during which various topics and sub-topics on the original master list were combined, rephrased, removed, added, and otherwise revised. Instructors used the framework to inform the creation of assessments and classroom activities, used these in their classes, and then used their experiences to inform revisions in a cyclical process over four separate semesters.

In deciding on what concepts to explore, instructors were asked to think not just about the current elementary algebra course that they were teaching, but about tertiary elementary algebra in general, including variations in what might be included on the syllabus at different colleges. The syllabi of elementary algebra courses at a number of different colleges in the U.S. were consulted to give instructors an idea of the range. Several framing questions were used both during initial independent selection of topics and the subsequent discussions:

- What concepts would we want students to still understand a year after they have completed an elementary algebra course?
- What fundamental algebra ideas are necessary for future mathematics courses (e.g. college algebra, pre-calculus, calculus)?
- What fundamental ideas are of significant value in other liberal arts math courses (e.g. statistics), or necessary in order to be able to apply algebraic thinking in “real” life (e.g. financial calculations, risk calculations)?
- For which particular concepts might you conclude that students had missed the “whole point” of elementary algebra if they were to finish the course without understanding them?

Results

In the process of identifying a conceptual framework for elementary algebra, the group first identified a list of four broad types of tasks that they felt all successful elementary algebra students should be able to complete, whatever the differences across elementary algebra curricula (see Table 1). Then, using these tasks as an initial frame, the group developed a list of concepts that, based on their cyclical experience interacting with students in elementary algebra classes, they felt to be fundamental in order for students to successfully complete these tasks (see Table 2 for a partial reporting of that framework).

Table 1. Fundamental Elementary Algebra Tasks
1. Expressing and correctly interpreting relationships, patterns, and properties in expression or equation form, through correct use of algebraic symbols
2. Simplifying expressions by replacing them with equivalent expressions
3. Solving an equation/inequality or system of equations and correctly interpreting the solution set
4. Relating an equation, or properties of an equation, to a graph, and vice versa
This list of tasks was not intended by the instructors to include all of those that might be relevant to any elementary algebra class given in any context.

The instructors theorized that the fundamental elementary algebra tasks in Table 1 could only be completed if students understand the following concepts in the Framework given in Table 2.

Table 2. Elementary Algebra Concept Framework (selected topics presented in detail)
1. **Algebraic Symbolism:** Understands how to express relationships and patterns in expression or equation form, and can explain in words the pattern or relationship expressed by a given expression or equation *(The sub-concepts in this concept are not outlined here because of space constraints.)*
2. **Algebraic Structure:** Recognizes algebraic structure, with respect to the relevant context of a particular problem-solving goal a. Understands the role of a variable: i. That it can take on a wide variety of values; ii. That its value can vary or that it can represented a fixed unknown; iii. That any expression can be substituted in for a variable; iv. That a variable functions as a set of parentheses around whatever is substituted into its place; v. That every instance of a variable stands in for the same value; vi. That any repeating expression can be replaced by a variable, as long as that variable is defined to take on the original value that it replaced. vii. That during substitution, the structure of the expression outside the part being replaced remains independent of and unchanged by whatever is being substituted into it b. Is able to view expressions or equations with respect to a particular context, and in this context identify the relevant properties *(The sub-concepts for 2.b. are not outlined here because of space constraints.)*
3. **Properties/Generalizing Arithmetic Operations:** Understands the definitions of basic arithmetic operations and can use those definitions to describe general patterns and properties (in words and using equations). For example, understands basic definitions of addition, subtraction, multiplication, division/fractions, positive whole exponents and square roots and can use these definitions to determine when these operations (or combinations of these operations) have certain properties. *(The sub-concepts in this concept are not outlined here because of space constraints.)*
4. **Equality/Equivalence:** Understands equality/equivalence a. Understands what it means for two expressions to be equal i. Understands that two expressions are equal if and only if they are equal for all possible (combination of) values of (each of) the variable(s) ii. Understands that if two expressions are equal, one expression may be substituted for the other in any other expression or equation 1. Understands that simplifying (or otherwise rewriting) expressions is a process by which one expression is replaced by another equivalent expression b. Understands what it means for two equations to be equivalent *(The sub-concepts in 4.b. are not outlined here because of space constraints.)*
5. **Equations as Relationships between Variables:** Understands equations with two variables as something that describes the relationship between two variables, describing how one variable varies with respect to changes in the other variable. *(The sub-concepts in this concept are not outlined here because of space constraints.)*
6. **Thinking Graphically:** Understands how one and two-dimensional graphs describe the relationship depicted in

a particular equation or inequality and vice versa, and can describe how different operations will impact a graph. *(The sub-concepts in this concept are not outlined here because of space constraints.)*

In a cyclical process of experimentation, instructors developed assignments and assessment questions intended to either 1) assess the extent to which students understood one or more concepts listed on the framework; or 2) confront students with tasks that would require them to directly engage with a common misconception or a type of productive struggle that might better reveal their current understandings related to one of the concepts on the framework, or how they use those understandings to complete specific elementary algebra tasks.

An example of one question in the first category is below:

Assume that $a \neq 0$. Dale simplifies the expression a^3a^{-2} and gets the correct expression a. Which of the following must be true? There may be **more than one** correct answer—select **ALL** that are true.

a. $a^3a^{-2} = a$
b. If Dale lets $a = 10$ in both the expressions a^3a^{-2} and a, he will get two different answers.
c. Dale can substitute a for a^3a^{-2} anywhere it appears.
d. If Dale lets $a = 20$ in both expressions, he will get the same value for each expression.
e. Dale needs to know the value of a before he can say whether a^3a^{-2} and a are equal.

This question was designed to test the extent to which students understand the items listed under 4.a. in the framework in Figure 2. Based on the answers that students gave, instructors could then engage with students about their understanding of specific components of item 4.a. in order to better understand what those are and how they relate to one another. Based on conversations with students as a result of this question, the framework was revised: The first framework draft contained only item 4.a.ii.1; after repeated cycles of the research process the additional items under 4.a. were added and structured hierarchically.

An example of a task that falls into the second category is the following question, which one of the instructors used for an in-class activity:

Suppose there is a new algebraic operation called the bow tie, defined this way: $\bowtie a = \frac{1}{a} - a^2$
Use this definition to rewrite the following expressions (no need to simplify afterwards!) so that they no longer contain a bow tie symbol:

a) $\bowtie (-2)$
b) $\bowtie (x^2)$
c) $\bowtie \left(\frac{1}{y}\right)$

Instructors expected students to make the following mistakes somewhat frequently: $\bowtie (-2) = \frac{1}{-2} - 2^2$, $\bowtie (x^2) = \frac{1}{x^2} - x^2$, $\bowtie \left(\frac{1}{y}\right) = \frac{1}{y} - \left(\frac{1}{y}\right)^2$. The expectation was that students who made these mistakes did so through oversight—for example, they might forget to write both negative signs when substituting in -2 for $-a^2$. However, in one-on-one discussions with students, it became clear that many students did not forget to write the negative sign in this case; rather, they believed that because the -2 already had a negative sign, that this negative sign took the place of the one that was already in the expression $\frac{1}{a} - a^2$. This led to a revision of Framework item 2.a. to include sub-item vii.

Discussion and Plans for Next Steps

This framework reflects only the experience of one group of elementary algebra instructors at the college level and may not reflect the experiences of all tertiary elementary algebra instructors. This is also just one step of data collection in our larger goal of developing a conceptual framework for elementary algebra at the college level. Another ongoing study that is a part of this larger project is an extensive literature review synthesis whose goal is to develop a comprehensive research-based conceptual framework for elementary algebra that is based on existing literature from primary and secondary settings. The next step will then be to compare that framework to the instructor-generated framework in order to identify areas where they overlap and where they do not. Areas where the frameworks differ will then be used as a starting point for future research projects investigating how the algebraic understandings and learning processes of tertiary students in elementary algebra may differ from the experiences of primary and secondary students learning similar content.

Abstract: Students who have persisted in mathematics coursework long enough to be present in calculus or who enter mathematics at the level of calculus would be expected have more robust notions concerning their career choices than those who enter developmental mathematics. In the current work, we give a preliminary comparison of data generated by a career decision making survey administered to students in a developmental mathematics course and to students in a first semester calculus course at a large research university during the fall 2015 semester. We consider some initial results for students who switch majors after a semester of mathematics coursework.

Keywords: Career Choices, Persistence, Calculus, Developmental Mathematics

Introduction

Students at most institutions of higher education will begin their studies with a mathematics course of some kind, and students who choose science, technology, engineering and mathematics (STEM) careers usually take mathematics courses during their first term. In addition, STEM intending students will typically eventually take calculus. These students have a variety of motivating factors for their choice of major and their career goals. During their mathematics course experiences, they may or may not make changes to their plans. In the current work, we present a preliminary study of career and major choices of students in developmental mathematics courses and first term calculus and provide some initial data from a study of how those intentions change over the course of a semester in those classes.

Theoretical Perspective

In this project, we surveyed students about a number of factors related to career exploration and career identity theory as part of a larger project to build models of developmental mathematics and calculus students who have declared a STEM major and career intentions. This work builds on early work on self-identity situated in disciplines (Marcia, 1966; Nosek, Banaji & Greenwald, 2002; Du, 2006; Hazari, Sadler & Sonnert, 2013) as well as some affective factors such as anxiety (Alexander & Martray, 1989) and personality constructs identified by the Big Five Inventory (John, Naumann & Soto 2008). This effort explores relationships between mathematics anxiety, personality, coursework and both persistence and identity. The data generated from a collection of five surveys is used to analyze when and why developmental mathematics and calculus students change majors. In this preliminary report we summarize the results from one of these surveys.

Methodology

In the fall semester of 2015 a series of surveys were administered to a cohort of students enrolled in both types of courses (developmental and calculus) to assess their anxiety levels, personality traits and career decision-making strategies. The survey consisted of a series of Likert-response questions combined with open answer questions intended to assess a student's methodology and reasons for choosing a major and career. This data and student demographic information were analyzed in an effort to begin to identify differences between the responses of these two groups. Identifying patterns in responses will help us begin to develop profiles of students in each cohort, but particularly in developmental mathematics, who will be successful in STEM majors. The survey was given in the second week of class and again in the final week of the semester. There were 458 calculus students and 80 developmental mathematics students who completed both pre- and post-surveys. Both surveys asked students about their thoughts on changing majors, therefore we have data about intentions to change majors both before and after a semester of mathematics coursework.

Results

Demographic data for each population are presented (Table 1). Developmental mathematics students were primarily female, non STEM intending. Calculus I students were more mostly male and STEM intending. We asked students their reasons for selecting a major and about the attractiveness of their field in a pre- and post-survey by providing the following two open-ended questions: "What seems attractive about your current major or career goals?" and "How did you come to decide on your current major?" Responses (pre and post) to these questions from both the developmental mathematics and calculus groups were coded for themes by two members of the research team. Codes were compared until there was total agreement among the researchers and each response was assigned up to three codes. Surprisingly, we do not note changes on these two statements from a pre and post comparison for both developmental mathematics and calculus groups. Even more unexpected, the summarized responses to the questions (Figure 1) show a parallel between factors influencing both groups of students. The majority of students chose their major based on personal interest and future career expectation. Many students also indicated that they were influenced by some external factors such as family and friends when making their decisions.

Table 1. Demographic information for Developmental Mathematics and Calculus I groups.

	Developmental Mathematics			Calculus I Groups		
	STEM	Non-STEM	Total	STEM	Non-STEM	Total
Female	8	50	58	102	48	150
Male	10	12	22	283	25	308
Total	18	62	80	385	73	458

In addition to the open ended questions that were coded, students were asked eight additional questions to be rated on a Likert scale. The questions are given in Table 2 and student response rates are given in Figure 2. We observe that most students in the two groups are confident in choosing their major, feel satisfaction with their selected major and are seriously committed to their current occupation. These characteristics of decision-making are consistent with the reasons for choosing their major. Moreover, the response rates for each category in the Likert scale are remarkably similar for both groups, indicating that student thinking about major and career choices is similar for both developmental mathematics students and calculus level students. This result contradicts the intuitive notion that students at the calculus level would have different reasoning about their career and major choices than those not ready for college level mathematics.

Figure 1. Student responses to open ended questions about factors affecting choice of major and attractiveness of major or career goals.

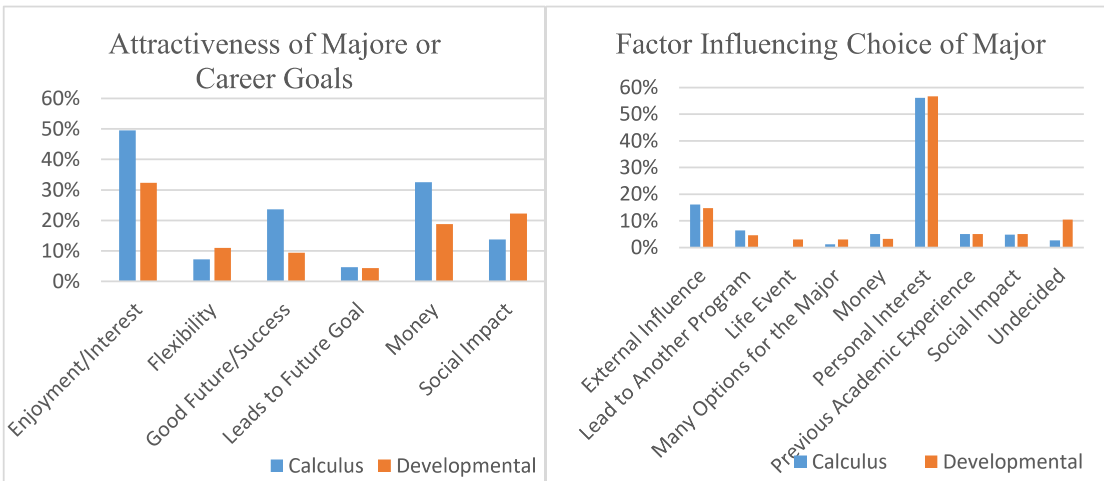

Table 2. Likert-scale questions asked in career decision making survey.

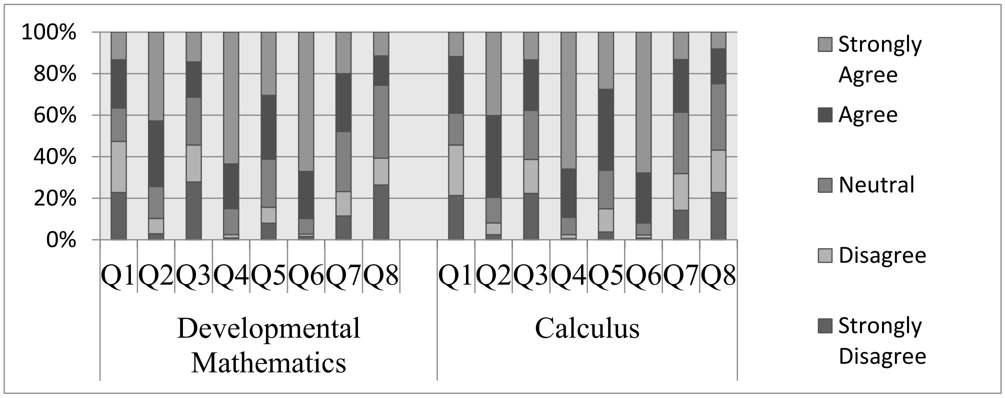
Q1	I had difficulty choosing a college major and a future career path.
Q2	I feel good about my current position with respect to my major.
Q3	Most parents have plans for their children, things they'd like them to do or go into. My parents have plans like that for me.
Q4	My parents feel good about what I'm doing now.
Q5	I would be willing to change my current plans if something better came along.
Q6	I see my occupation as being important to me in my life.
Q7	My family's opinion was very important in helping me choose my current major.
Q8	If my family were supportive, I would be likely to change my major.

Comparisons between pre- and post-survey responses, however, within the groups as well as between groups show that a substantially higher percentage of developmental mathematics students are deciding to change their major (18.12%) after a semester in a mathematics course than those in calculus (12.81%). We designate these students as “switchers” (Bressoud, Carlson, Pearson, Rasmussen, 2012). In addition, we asked students if they planned to change their major both at the beginning of the semester and at the end of the semester. At the beginning of the semester, 13.92% of developmental mathematics students indicated they planned to change majors, while 25.32% indicated that they planned to at the end of the semester. For calculus students, 21.27% planned to change majors at the beginning of the semester while 19.74% indicated they planned to change at the end of the semester.

Figure 2. Characteristics of career decision making processes



Students from the both courses who indicated an intent to change majors at the beginning of the term described different reasons for doing so (Table 3). Developmental mathematics students experienced a significantly lower level of confidence coming into the course, affecting their decision to switch, but few calculus students stated such a reason. On the other hand, the critical reason for change for calculus students at the beginning of the term was a loss of interest in their current major. Both groups of students also indicated their new major would be more interesting and be a better fit for their talents.

Table 3. Reasons for change-population indicating major change intention during pre-survey.

Statements	Developmental Mathematics	Calculus
I don't find my current major very interesting anymore	35.00%	26.67%
I found another major that is more interesting	30.00%	47.78%
I found another major that better fits my talents	35.00%	30.00%
My current major really wasn't what I expected	25.00%	22.22%
I just don't feel I belong when I am with other students in my major	15.00%	16.67%
My current department does not seem interested in me	10.00%	4.44%
I am not sure I can be successful in my current major	50.00%	16.67%

Specifically, examining the reasons for changing majors at the end of the term for both groups, we discovered a similar but more prominent pattern along with one exception (Table 4). A decrease in confidence appeared as an equally important reason for switchers in the calculus population (as well as in developmental mathematics). More importantly, some of the reasons that are not emphasized by students in the pre-semester survey results became critical for switchers in the calculus group at the end of the semester.

Table 4. Reasons for change-population indicating major change intention during post-survey.

Statements	Developmental Mathematics	Calculus
I don't find my current major very interesting anymore	30.77%	19.57%
I found another major that is more interesting	23.08%	47.83%
I found another major that better fits my talents	23.08%	56.52%
My current major really wasn't what I expected	30.77%	41.30%
I just don't feel I belong when I am with other students in my major	0.00%	17.39%
My current department does not seem interested in me	7.69%	8.70%
I am not sure I can be successful in my current major	46.15%	45.65%

Considering students in both groups by gender and by major (STEM or non-STEM), we found that in developmental mathematics courses there is an increase in number of students changing their major in all categories from the beginning to the end of the semester: male, female, STEM intending and non-STEM intending. The increase is greater for females (~+14%) than for males (~+5.5%) and greater for non-STEM intending (~+12%) than for STEM intending (~+5.5%). Conversely, for the calculus population, there was an increase in the number of non-STEM intending and female switchers, while the numbers of STEM intending (~-2%) and male (~-4%) switchers decreased. Rates for female and non-STEM intending students switching increased by approximately 2.5% and 4% respectively.

Conclusions

Despite the fact that there are several parallel patterns and no pre- and post-test differences in students' reasons for choosing their major, beliefs towards the attractiveness of their major, and the characteristics of how they chose their major between students in the developmental mathematics and calculus courses, we discovered differences in the reasons for switching between the course populations as well as differences in the switch rate between gender and the classification of STEM intention.

By comparing the overall rate of students' changes in their majors, we found that there are more students from the developmental mathematics courses changing their majors. This may be a preliminary indication that students who are taking the developmental mathematics course are comparatively more negative affected by mathematical experiences. In addition, the developmental course delivery format is significantly different than the calculus course delivery. The effect of the format of the course on the specific factors measured in this study has not yet been investigated. Losing interest and confidence are the two most critical explanations for changing their major in both groups, especially for the switchers. On the other hand, the developmental mathematics course and calculus courses perform similarly in keeping STEM intending students, since the decline in STEM intending students are significantly lower than the decline in non-STEM; the Calculus courses are doing comparatively good job retaining STEM intending students. This could inform the instruction in both courses so that we can retain more and increase the number of students who pursue a STEM degree.

The work reported in this paper is part of a study aimed at characterizing the processes and identifying the ways in which different kinds of expertise (mathematics vs. mathematics education) unfolded in the planning and teaching of an undergraduate course on Mathematical Proof and Proving (MPP), which was co-taught by a professor of mathematics and a professor of mathematics education. More specifically, the study aimed at unpacking the affordances and drawbacks of this collaboration. The collected data includes all 13 videotaped lessons in the 2012 semester, the second time the course was taught. The content of the course consisted of topics that were familiar/accessible to the students, e.g., high school level algebra, geometry, and basic number theory. In this paper we focus on how the views held by each instructor regarding what constitutes an acceptable proof and how it should be presented, are reflected in his/her teaching.

Key words: Mathematical Proof and Proving; Undergraduate Course; Problem-based Learning; Community of Practice

Introduction

The study reported herein was carried out in the context of an undergraduate course on Mathematical Proof and Proving (MPP)[1] that was designed in collaboration between mathematicians and mathematics educators, and was co-taught by a professor of mathematics (Jim) and a professor of mathematics education (Olga)[2]. A small portion of the study appeared in Zaslavsky, Sabouri, & Thoms (2013). The present paper is a preliminary report on work in progress - a qualitative analysis of the actual teaching of both instructors, viewed through a variety of lenses and guiding questions. The overarching goal of our study is to characterize the processes and to identify the ways in which the different kinds of expertise (mathematics vs. mathematics education) unfolded in the actual planning and teaching of the MPP course; in particular, we are looking for instances that could help understand how each expertise contributed to the course and complemented the other. In terms of student learning, the course was assessed by a special evaluation team. Their report indicated a gain in students' understanding of the notion of proof and their ability to prove. Thus, for the purpose of the study reported herein, we do not address questions regarding student learning; rather, we look at the teaching of both instructors and the interactions between them as they taught.

The MPP Course

Two assumptions led to initiating this MPP course: 1. Mathematical proof and proving are fundamental to mathematics; and 2. Many undergraduate students struggle with the notion of formal proof and the activity of mathematically proving (e.g., Harel and Sowder, 2007).

The notion of proof is often incorporated in mathematical content courses, and typically does not constitute the focal topic of a single undergraduate course. There are many transitional courses in mathematics, most of which combine learning about proof with learning unfamiliar fundamental topics in mathematics. Consequently, the cognitive load on students is high and they encounter more difficulty than necessary, since they need to deal with many issues

[1] This material is based upon work supported by the National Science Foundation under Grant No. 1044809.
[2] The names in this paper are pseudonyms.

concurrently: advanced mathematical ideas as well as proof and proving. The intention of the MPP course was to build on students' existing mathematical knowledge, and to draw on learning activities that involve familiar topics such as high school level algebra and geometry and basic number theory (e.g., familiar properties of integers such as divisibility).

The challenge of attending to students' learning difficulties, and at the same time maintaining an appropriate level of sound mathematics, led to a collaboration between mathematicians and mathematics educators. Moreover, the MPP course was designed and co-taught by two instructors – a full professor of mathematics and a full professor of mathematics education. The goal of this collaboration was to capitalize on each of the instructors' expertise. The mathematics educator brought her expertise on teaching mathematics, and in particular the teaching of proof and proving. She also brought expertise on students' difficulties in learning to prove. The mathematician brought his expertise in the discipline of mathematics and the knowledge and understanding of MPP that students will need for successful participation in more advanced undergraduate mathematics content courses. This collaboration was grounded in a mutual respect for each other's role and potential contribution, and on the recognition that the instructors had much to learn from each other.

While sharing the same concerns and long-term goals for the course, each instructor brought a different perspective on how students should be learning MPP and on how to attend to their difficulties. From the outset it became clear that although the structure and syllabus of the course were pre-determined in full agreement between the two instructors, each instructor had his/her own views and interpretations, and that the joint efforts to produce an MPP course to address the above concerns would require ongoing dialogue and reflection. The challenge was to bridge the different perspectives and use them as a springboard to enhance the course.

Conceptual Framework

The following perspectives on learning and teaching guided the design of the MPP course: 1. Students' interactions and classroom discourse contribute to learning [to prove] (Yackel, Rasmussen, and King, 2000; Zaslavsky and Shir, 2005; Smith, Nicholas, Yoo, and Oehler, 2009); 2. Tasks play a significant role in learning (Henningsen and Stein, 1997); 3. Uncertainty could promote the need to prove (Dewey, 1933; Fischbein, 1987; Harel and Sowder, 2007, 2009; Zaslavsky, 2005; Zaslavsky et al, 2012); 4. Class discussions and activities should address students' anticipated/manifested preconceptions and difficulties (Harel and Sowder, 2007, 2009; Weber, 2001; Reid, 2002; Buchbinder and Zaslavsky, 2009).

The decision to design and co-teach the course collaboratively, assigning two full professors as the MPP course instructors, is in a way a response to issues raised by Harel and Sowder (2009). Their study indicates that while mathematicians who teach undergraduate courses in mathematics have a broad and deep mathematical knowledge/understanding, many are not necessarily fully aware of students' difficulties in learning to prove, or of effective ways to scaffold their learning. In addition to the instructors, three mathematicians were involved in the design of the course, two doctoral students served as TAs and one served as a research assistant. The team members varied with respect to their expertise and experience, as well as their roles, which is one of the characteristics that Roth (1998) considers essential for a community. Theories of communities of practices provide us with tools for analyzing the various kinds of learning of the members of the community as well as the contribution of each member to the shared goals of the community (Rogoff, 1990; Roth, 1998; Lave & Wenger, 1991). These theories consider knowledge as developing socially within communities of practice.

An integral characteristic of our community of practice is associated with the notion of reflective practice (Dewey, 1933; Schön, 1983). The notions of reflection on-action and reflection in-action have been recognized as effective components that can contribute to the growth of teachers' knowledge about their practice. In our study, reflection was a key issue for the development of the instructors' awareness and understandings related to teaching and learning to prove.

Data Sources and Analysis

The data for the large scale study consists of video-tapes and field notes of all the classes in the semester (13 sessions), audio-records and field notes of weekly meetings held a day after each class, and email conversations between the team members. In addition, students' written homework and TA's comments and grades were scanned and documented.

The methodology employed in the analysis followed a qualitative research paradigm in which the researcher is part of the community under investigation. It borrows from Strauss and Corbin's (1998) Grounded Theory, according to which the researcher's perspective crystallizes as the evidence, documents, and pieces of information accumulate in an inductive process from which a theory emerges. The researcher acts as a reflective practitioner (Schön, 1983) whose ongoing reflectiveness and interpretativeness are essential components (Erickson, 1986). In our case, the researchers were members of the community of practice that they investigated.

For the purpose of this paper, we identified excerpts that reflected the instructors' views on what constitutes an acceptable proof, and analyzed how these views were exhibited.

Views on what is an acceptable proof

One of the main goals of the MPP course was to establish what constitutes an acceptable proof and how to produce and present a proof that is acceptable. At this point we restrict the discussion to what the instructors considered acceptable in the context of the course (we acknowledge that for different communities, the requirements of a proof could vary; e.g., mathematicians who present their proofs to colleagues, experts in the field, may not be expected to go into much detail from one step to another, as it is clear that the presenter as well as the audience can easily follow and fill in the gaps).

While Jim repeatedly insisted on the need to explicitly state the Given and the RTP (Required to Prove), Olga insisted on the need to back each step in the proof with a valid explanation for the inference that is made. Jim explained his stance mainly as a helpful strategy for constructing a proof, when this is not straightforward for the student. Olga supported her stance mainly from a metacognitive perspective. She distinguished between the way we think, e.g., in a draft version of a proof, and the way the proof should be presented formally.

How to Present It?

We illustrate the above views through an excerpt from the 6th session (of 13), that aimed at implementing the equivalence between a claim and its contrapositive for proving.

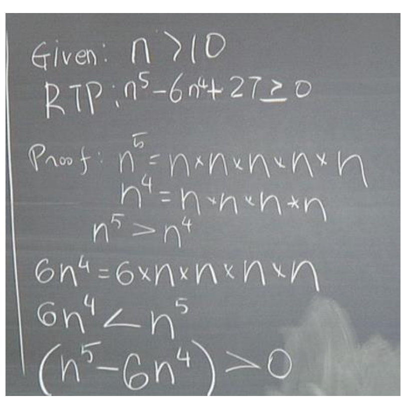

Figure 1. A student's proof of the contrapositive

Olga began the lesson with a review of some homework assignments, which included the following: "Prove that for any rational number n, if $n^5 - 6n^4 + 27 < 0$, then $n \leq 10$." Most of the students had proven the equivalent contrapositive claim, i.e.: "if $n > 10$, then $n^5 - 6n^4 + 27 \geq 0$. " The episode begins as a student is writing her proof on the board, explaining her reasoning as she goes. Her proof, as presented on the board, is shown in Figure 1.

Student: So if we know that n is greater than 10 and this number [expression] can be written... Since 6 is less than n, because we know that n is greater than 10, then we can say that... and then if we subtract ... we know that that would be a positive number. [writes on the board].. if we add 27 it would be greater than 0 also.

Olga: [turning to the class] What do you say? I see a lot of nodding. You agree with the proof? With the arguments, building the proof? How about the presentation?

Jim: I want to write that last line. She said it verbally without writing.

Olga: Ya, there are a few problems.

Jim: Just write the last line you said.

[Student adds the following line at the end: "$n^5 - 6n^4 + 27 > 0$"]

In Olga's feedback to the student she says:

> "This maybe makes it clearer, but still in order to present the proof very logically, it's important to write how we move…. in terms of presentation of the proof, it's still lacking. We look at it, it's not clear what follows from what and why. This was said orally. But the proof has to stand alone in writing. So all these missing parts should be written... Everything you write you have to account for…".

To make her point, Olga asks: "is n^5 always larger than n^4?"; this question pushed the students to realize that this holds only because of the Given, that is, because we know that $n > 10$." She uses this as an example of a missing justification in the proof.

Olga distinguishes between the way we think about a proof and the way we present it, as follows:

> "… we often think in less organized ways, but once you write a proof, we really want to make it flow…. So this, I think, is a good example of the slight difference between how we think and how the proof in the end has to look…"

In a different lesson, following Jim's emphasis on the need to clearly state the Given and the RTP, Olga says:

> "… It's more than writing what's given and what you have to prove. It's also accounting in each line you write, what is the status of what you wrote. Is it given, is it a known fact that you bring from some other place, which is fine. You have to annotate and write where it comes from, how you got to there... We need these words to make sense of what the status of each line is. … It's also a means of communication, but it's also a means of sort of control of what you're doing."

Interestingly, Jim was less worried about accountability for each line of the proof. He was more concerned with stating and using the Given and the RTP to come up with a valid proof. He repeatedly made utterances like the following:

> "…What's missing here completely is what's given and what do you have to prove. One thing I told you in the very first lecture is to do what? Write the Given and write RTP. …So notice here that this line is the implication, is assuming this is what's given and this is your conclusion.... This is a mistake that is commonly made because people confuse what is given and what you need to prove. If the people who wrote this proof started by GIVEN... then there will be no confusion of what should the last line be, verifying this.... When you cannot organize your thoughts... and tell me what's given, and what do you have to find, then there is

a serious issue…."

In response to an impasse a student expressed regarding a claim he could not think of a way to prove, Jim said:

> "… You construct the proof by playing. ok? ... You just start to play... How do you play intellectually? You take the object that is not recognizable to you and you start to play with this object. … You work with the "required to prove" to make it look more and more like the given. That should be your strategy. That's the only strategy that you have. There is no other strategy to follow. Ok? You should always think of playing with what you have to prove …".

The status of examples

Much has been written about the roles and status of examples for proving (e.g., Buchbinder & Zaslavsky, 2009; Ellis et al., 2013). Views vary from reluctance to rely on examples for proving to acknowledging the merits of example use for proving, particular the use of generic examples in proving (Leron & Zaslavsky, 2013).

Both Jim and Olga frequently used examples in their teaching of how to prove. Moreover, they accepted some proofs that relied on examples, as demonstrated in Figure 2 - a proof provided by one of the students.

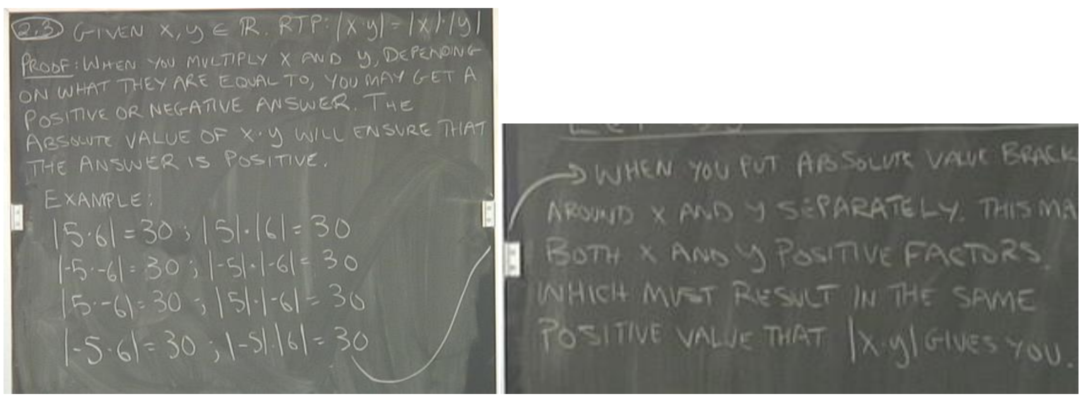

Figure 2. A student's proof by cases, with numerical examples

This proof can be seen as a generic proof, as each numerical case represents a general case. Both instructors accepted it as a valid proof, but Jim criticized its form of presentation, saying: "It's a badly written proof, but it is a proof. "

Concluding Remarks

This preliminary report captures some of the views that were expressed throughout the MPP course by the instructors regarding what a proof should consist of and how it should be presented. It highlights common views as well as differences in emphases between the two instructors, and suggests reasons for these differences. What we have presented is work-in-progress. In the oral presentation of our work we will provide a deeper and more comprehensive analysis, and will discuss implications of our findings for teacher preparation.

STUDENTS' THINKING IN AN INQUIRY-BASED LINEAR ALGEBRA COURSE

Sarah Hough
University of California, Santa Barbara

Monica Mendoza
University of California, Santa Barbara

Elizabeth Thoren
Pepperdine University

William Jacob
University of California, Santa Barbara

This evaluation study compared the mathematical thinking of undergraduate students (as they responded to class work and interview prompts) who participated in an inquiry-based linear algebra course to a comparison group of students who participated in a traditional course.

Keywords: Linear Algebra, Inquiry-Based-Learning

The research literature shows that in traditional linear algebra classrooms students often memorize algorithmic methods that "work" even when not properly understood. Students develop understandings of matrix algebra and solving systems of linear equations using the Gaussian elimination, yet have problems with the more abstract notions of spanning set, linear independence and linear transformation (Stewart & Thomas, 2007). In the language of Sierpinska's modes of thinking (2000), the student dependent upon reducing a matrix to echelon form to determine whether vectors are linearly independent are thinking in *arithmetic mode*, whereas a student who is able to think more generally about objects in a system, by applying a definition or theorem when appropriate, is thinking in *structural mode.*

In this poster session we will share results from an evaluation study conducted in a large public research university, that examined how an inquiry-based linear algebra course supported the development of student mathematical reasoning from actions in the embodied world to formal structural thinking (See Figure1). Our framework, used to guide analysis of student work/interview responses, is adapted from Stewart & Thomas (2009, 2010), incorporates three mathematical worlds (embodied, symbolic and formal) and depicts a progression in the development of mathematical thinking (Tall, 2004).

	Embodied world/Synthetic Geometric Thinking	Symbolic World/ Arithmetic Thinking	Formal World/ Structural Thinking
Action	Adds multiples of two given vectors in R^2 or R^3 to visually determine whether a third is a linear combination of the given vectors.	Tests if a set of vectors is LI by constructing a matrix with the vectors as columns and row reducing it.	
Process	Generalizes this visualization process to two arbitrary vectors v_1, v_2, v_3 in R^2 or R^3.	Thinks about the action above without actually carrying it out.	
Object	Operates on this visualization of LI vectors (eg. Transforming them via reflection, rotation, etc)	Understands process as above and can operate on the resulting matrix (eg. knows that if matrix has a pivot in every column the original set of vectors is LI.	Shows set of given vectors is LI by definition by considering the vectors space that the vectors are in (eg. Gives a dimensional argument)

Figure 1. Framework of Progression of Mathematical Thinking (with Linear Algebra examples)

The Influences of a Teacher's Mathematical Meaning of Constant Rate of Change on His Classroom Practices

Sinem Bas Ader
Istanbul Aydin University

Marilyn P. Carlson
Arizona State University

We investigated how a teacher's meaning of constant rate of change influenced his teaching practices. Findings revealed that a teacher with a strong mathematical meaning of constant rate of change was able to provide conceptually coherent explanations and pose questions that are based in his understanding of constant rate of change and his models of students' thinking.

Key words: Teacher Knowledge, Rate of Change, Teacher Questioning, Decentering

Introduction and Theoretical Framework

Many researchers have identified links between a teacher's mathematical knowledge and her teaching practice (Ball, Thames, & Phelps, 2008). However, few researchers have characterized how a teacher's meaning of a specific mathematical idea is expressed when teaching.

Steffe and Thompson (2000) described decentering in the context of teacher-student interactions as the mental actions involved in building a model of students' mathematical thinking. The teacher is acting in a decentered way when she adjusts her explanations and questions, based on her model of a student's thinking.

An individual's meaning for constant rate of change (*CROC*) might be a calculation for the slope of a line, without realizing that CROC describes how two quantities change together. An individual possessing a more robust meaning of CROC sees x and y changing together with the restriction that: i) the ratio of the changes in the two quantities remains constant (e.g., $m = \frac{\Delta y}{\Delta x}$) and ii) the changes in the two quantities are related by a constant multiple (e.g., $\Delta y = m\Delta x$).

Select Results

In the below excerpt the teacher is discussing the meaning of the statement $\Delta d = 6\Delta t$ with a student. The teacher began by prompting the student to explain the statement. The student responded by saying that the change in y is always 6 (lines 1 and 3). The teacher then poses a question (line 4) that is rooted in his meaning of CROC and his assessment of his student's expressed meaning. This short except reveals how the teacher's strong meaning for CROC enabled him to react productively (lines 4, 6, 8) to the thinking the student expressed. We claim that the teacher's ability to decenter was possible because of his strong meaning for CROC.

1 **Student:** *As the values of x and y change together the change in y is always 6.*
2 **Teacher:** *Say that again?*
3 **Student:** *Basically, this whole thing with 6.*
4 **Teacher:** *Is it? What if the change in t is ½? Then, what would the change in d be? 6? Or, what?*
5 **Student:** *Then it would be ½ times 6.*
6 **Teacher:** *Yeah but then that says that the change in d is 3, which isn't 6.*
7 **Student:** *So it's something times 6?*
8 **Teacher:** *What's that something?*
9 **Student:** *The change in t times 6?*

Supporting Math Emporium Students' Learning Through Short Instructional Opportunities

Andrea Alt
Bowling Green State University

This study focuses on the concept of including traditional math classroom experiences in a math emporium course. The aim of the study is to gain an insight into the opinions of students about which emporium structure they prefer as well as which they believe they can be more successful in. Also, this study will analyze emporium students' academic success in both scenarios. To accomplish these goals, two sections of Algebra II in the math emporium were offered the option to attend short instructional opportunities led by the instructor.

Key Words: Math Emporium, Classroom Research, Student Opinions, Algebra 2

A math emporium is a self-paced math course that is completed with the aid of an instructional software package, which includes computational exercises, videos, practice exercises, and online quizzes (Twigg, 2011). Students work on math problems and ask for help when needed. Virginia Tech pioneered the first math emporium and studies have shown positive effects in terms of attendance, pass rates, and performance on end-of-course exams (Taylor, 2008; Twigg, 2011). In general, math emporiums follow the Virginia Tech model with three major places of variation; attendance, weekly traditional meetings, and size of facility (Twigg, 2011). The idea of having weekly traditional classroom meetings is not one that all schools adopt. As previously stated Virginia Tech does not offer traditional classroom meetings, while other schools, such as the University of Idaho, have weekly focus meetings (The Polya, 2016). This study focuses on the differences between a fully computer based instruction emporium and an emporium offering traditional classroom experiences. The U.S. Department of Education reported that there are advantages for blended learning and that "it was the additional opportunities for collaboration that produced the observed learning advantages" (U.S. 2010). An emporium that offers traditional classroom experiences is a type of blended learning and this study may be able to further support the claim that blended learning gives students an advantage.

The purpose of this study is to gain an insight into the opinions of emporium students at a public university in the Midwest as to which emporium structure they prefer, as well as which they believe they can be more successful in. In addition, this study will analyze the emporium students' academic success when they become involved in traditional classroom experiences, called short instructional opportunities, versus those who continue to use the fully computer based emporium system. The research questions for this study are:

1. What is the nature of students' perspectives of the benefits of incorporating short instructional opportunities into their emporium experiences?
2. How does attendance at the short instructional opportunities change over the course of the study?
3. What differences, if any, in student achievement were there between and among students who participated in short instructional opportunities and their peers?

Although the study is in the data collection stage, preliminary analysis suggests that at least sixty percent of students reported that having the opportunity to attend the hear the course material in a short instructional opportunity would aid in their success in the emporium.

Mathematics Affirmations

Geillan Aly
Hillyer College, University of Hartford

This poster reports on an action research project set in a developmental mathematics classroom in a community college. Students at the beginning of the semester expressed mathematics anxiety and did not believe they could succeed in the course. To help support students' learning, the instructor and students co-created a list of ten statements that became the prevailing philosophy in the class. These statements helped students alter their view of their own mathematics learning.

Key words: Developmental mathematics, student beliefs, mathematics anxiety

The first day teaching a developmental mathematics course, I distributed a self-efficacy survey and questionnaire to give me insight into my students' previous experiences learning mathematics and the challenges they foresaw which could affect their success. Several students discussed their responses personally and that based on their prior experiences, they did not believe they even had the *capability* to succeed in my class. Several mentioned mathematics anxiety. It was clear that if I wanted to help these students see themselves as mathematical beings (Nasir, 2002), I would have to find a creative solution to alter their perspective on their potential for success. These conversations had a sense of urgency; my impression was that their negative self-talk needed to be addressed before students would be open to learning mathematics.

Inspired by The Definite Dozen (Duncan-Andrade, 2010), my students and I co-created a list of ten *Math Affirmations* to increase students' self-efficacy (Bandura, 2008; Zientek, Yetkiner Ozel, Fong, & Griffin, 2013), reduce their anxiety (Dowker, Sarkar, & Looi, 2016), and develop a growth mindset (Dweck, 2006). The *Affirmations* included statements such as "I am capable of learning and doing math," "Hard work is often mistaken for luck or natural ability," and "Success comes from not being afraid to ask questions," and were recited every day. The norms of the course centered on reinforcing the *Affirmations* so that they were not an empty set of statements read aloud, but the foundation for the pedagogical structure of the course.

When the *Affirmations* were initially presented, many students felt optimistic that the *Affirmations* would help them be successful in this class. One student wrote, "I believe that *Math Affirmations* will help me to sharpen my math skills and also help me a be a confident student" Another supported this sentiment; "I think they [the *Affirmations*] can all benefit us in many ways". One student supported reading the *Affirmations* only once per week. Overall, student feedback at the beginning of the semester and during mid-semester feedback indicated a belief in the potential of the *Affirmations* to help improve students' mathematics performance or attitude.

These students were successful compared to other developmental mathematics classes, (Bahr, 2010; Bonham & Boylan, 2011; Boylan & Nolting, 2011; Waycaster, 2001). Twenty-nine students enrolled in the course. Eighty one percent of the students completed the course by taking the final exam; 57% passed the common final exam. Students were also highly satisfied with the course with 95% of students stating they would recommend the course and instructor to others and felt the instructor motivated them to do their best.

The *Math Affirmations* could be introduced to reduce any trepidation students may have about their ability to succeed. Future research will explore whether the *Affirmations* reduce anxiety, increase self-efficacy, and how they may contribute to student success.

DEVELOPING AND TESTING A KNOWLEDGE SCALE AROUND THE NATURE OF MATHEMATICAL MODELING

Reuben S. Asempapa
Penn State Harrisburg

This study explored efforts to design and empirically test measure teachers' knowledge of the nature of mathematical modeling. The author begins by reviewing the literature on teachers' content knowledge and mathematical modeling, noting the effect of content knowledge on teachers' professional competence. Next, the author discusses the items used on the questionnaire to represent knowledge of the nature of mathematical modeling. Results from reliability, factor analysis, and scaling work with the items showed teachers' knowledge of the nature of mathematical modeling was unidimensional. The construct indicated by factor analysis formed psychometrically acceptable scale for measuring teachers' knowledge of the nature of mathematical modeling.

Key words: [modeling, mathematical knowledge for teaching, teacher knowledge, and teacher education]

Mathematical modeling strongly influences what mathematics students learn and how they learn it. Likewise, mathematical modeling has gained increased focus in standards and assessments for school mathematics—both nationally and internationally (NGA & Center, 2010; OECD, 2003). Consequently, there is much emphasis on the need to address the skills and understanding of mathematical modeling in school mathematics (Blum & Borromeo Ferri, 2009; NCTM, 2000; NGA & Center, 2010). However, most teachers have misconceptions about mathematical modeling and the modeling process (Gould, 2013) and lack knowledge about the nature of mathematical modeling (Blum & Borromeo Ferri, 2009). Therefore, this study investigated teachers' professional knowledge about the nature of mathematical modeling.

Significance and Related Literature

Ball, Thames, and Phelps (2008) emphasized the importance of teacher's content knowledge and explained that teachers of mathematics need certain knowledge domains to teach mathematics effectively. The practice of mathematical modeling is consistent with the Common Core standard: model with mathematics, and echoes the effective teaching practices and productive dispositions as explained in NCTM's principles to action (NCTM, 2014). Therefore, teachers' knowledge of the nature of mathematical modeling is worth investigating.

Methodology and Results

To achieve this, the author developed a Mathematical Modeling Knowledge Scale (MMKS) and pilot tested it with 71 practicing teachers of mathematics. The MMKS comprised 12 true or false items and an open-ended question. The scale development phases included item writing, experts' reviews, cognitive interviews, item analysis, and factor analysis. The overall internal consistency reliability of the MMKS for this sample was .80, indicating a relatively good reliable scale. Analysis on the open-ended item revealed that most teachers in this sample have misconceptions about the phrases *mathematical modeling* and *modeling process*.

Conclusion and Implications

Overall, the psychometric properties of the MMKS show promise in mathematics education research. The MMKS has the potential to benefit teacher education on mathematical modeling education. Results from this study and other published materials indicate a need for mathematical modeling education with both practicing and pre-service teachers of mathematics.

Exploratory Activities with Dynamic Geometry Environment in Axiomatic Geometry

Younggon Bae
Michigan State University

In this study, I designed and implemented an instructional sequence of exploratory activities using a Dynamic Geometry Environment (DGE) in an axiomatic geometry course. The tasks in the sequence aimed at providing students with opportunities to encounter cognitive conflicts between their prior knowledge on Euclidean geometry and new observations on non-Euclidean geometry. However, some did not appear, some did appear and students recognized them, but could not resolve or just passed by. The conflict between what I intended in designing tasks and what I found in student responses seems to result from several aspects of design and implementation of the tasks.

Key words: Dynamic Geometry Environment, Axiomatic Geometry, Non-Euclidean Geometry

Researchers have addressed that exploration on non-Euclidean geometry can foster students' development of axiomatic reasoning by providing with informal experience of resolving cognitive conflicts toward their prior knowledge of Euclidean geometry (e.g., Hollebrands, Conner, & Smith, 2010). The purpose of the study is to investigate an effect of students' interactions with a Dynamic Geometry Environment (DGE) on developing axiomatic reasoning in terms of how they manipulate the geometric construction given in the DGE and how the corresponding responses from the DGE affect students' discussions.

I designed and implemented an instructional sequence of exploratory activities using Geometry Explorer (GEX) in an axiomatic geometry course at a large public university. For each of the tasks in the sequence, the students were asked to record their exploration using a screen-casting software. This form of data can capture the students' verbalized observations and arguments in the discussion synchronized with the visual representation. I analyzed the data to determine overall student performance and success or failure in the task design. The last activity of the sequence was coded to describe student use of GEX with analytic framework for student use of drag feature in relation to theories of variation (Leung, 2008).

In this study, I found several issues that resulted in success or failure of the task design as follows; (1) understanding of valid and robust geometric construction in DGE; (2) limitations of mathematical models in DGE; (3) concurrent multiple conflicts; (4) limitations of task design; (5) lack of strategic use of drag feature of DGE. The early experience of exploration brought into the issues on validity and robustness of geometric constructions in GEX. It embarked on discussing what it means to generalize figures by dragging activities in DGE and what they are expected to produce in the following investigations. On the other hands, the task designs in the activities have limitations in facilitating student's productive use of drag feature of GEX that resulted from several aspects involved in the design and implementation of the tasks. The spherical model of GEX constrained the students' wandering dragging across the entire surface of the sphere so that they could not successfully recognize the conflicts as planned in task design. Also, the geometric constructions given in the tasks was not robust enough to allow student to involve in guided dragging to find a particular example, the counter example of the exterior angle theorem in spherical geometry. The analysis on the students' use of drag feature indicated that the task design for exploratory activities need to take into consideration appropriate intervention to support developing systematic dragging strategies.

STEM Major Mindset Changes During Their First Undergraduate Mathematics Course

Laura Beene
Texas A&M-Commerce

Rebecca Dibbs
Texas A&M-Commerce

One of the reasons for the exodus in STEM majors is students' experiences in their first undergraduate mathematics course, usually introductory calculus. However, students with a growth mindset are more likely to persist past these initial courses. Although there is evidence that curricula like CLEAR calculus promoted gains in students' growth mindset, it is unclear how this curriculum compares to traditionally. The purpose of this quasi-experimental study was to investigate to what extent students enroll in CLEAR calculus become more growth mindset orientated than those that are enrolled in traditionally taught courses. The Patterns of Adaptive Learning Scale was used to measure the mindset of students in pre-calculus, calculus I, and calculus II. The analysis of the pilot data indicated CLEAR calculus students experience a small positive shift towards a growth mindset, while students in traditionally taught courses have a significantly more fixed mindset by the end of the semester.

Keywords: Calculus, mindset, transition to college

The initial transition course for STEM majors is calculus; most students who take this gateway course overestimate their preparation for the experience (Bressoud, Carlson, Mesa, & Rasmussen, 2013). One potential challenge in the post-No Child Left Behind era in the United States is that although students believe they are well prepared, the emphasis on standardized testing has placed a significant amount of emphasis on surface learning. This focus on surface learning leaves students unready to make connections between concepts in their initial undergraduate mathematics courses (Gueudet, 2008; Selden, 2005; Selden & Selden, 2002).One possible solution to help students transition smoothly to undergraduate mathematics is the use of formative assessments such as exit tickets; such assignments show promise in helping students to perceive their instructor as more approachable and caring about their success (Black & Wiliam 1998, 2009; Dibbs & Patterson, 2014).

However, the number formative assessments completed are a far stronger predictor of students' success than their weight in the course grade would indicate (Dibbs, 2015). One possible explanation for this effect was that students who completed more post-labs had different mindsets about learning mathematics than those that did not. Mindsets play a significant role in the overall success of calculus students. Dweck (2006) defines mindset in two different ways: fixed mindset and growth mindset. Students classified under the fixed mindset, if not immediately successful in introductory calculus often leave the STEM field. However, growth mindset students can persist and succeed, even after failures as severe as failing a course (Dweck, 2006). The hypothesis for this study was:There is no significant difference in the mindset changes between students enrolled in CLEAR Calculus and students enrolled in traditional calculus.

Participants were recruited from STEM majors enrolled in first-semester calculus (150 students enrolled) or second-semester calculus (100 students enrolled) courses at a rural Hispanic-serving research university in the South during the Fall 2016 semester. A modified version of the Patterns of Adaptive Learning Scale (PALS) was used to assess students' mindset. Data was analyzed via ANOVA and Tukey tests.

Building a Cognitive Model for Symmetry: How Well Does an Existing Framework Fit?

Anna Marie Bergman
Portland State University

Ben Wallek
Portland State University

Symmetry has been found to be a rich and natural context for developing group theory (Larsen, 2009), yet the existing literature offers little insight on the complex cognitive processes in this domain. This poster will describe an attempt to use a pre-existing cognitive model of a student's understanding of symmetry, to help analyze the data from a recent teaching experiment aimed at exploring the development of one undergraduate student's understanding of symmetry. We share the ways in which the existing model accurately describes the student's cognitive processes associated with symmetry and also the places in which the model fell short in capturing the complexity of the student's thinking.

Keywords: Symmetry, Abstract Algebra, Cognitive Model, Teaching Experiment

Abstract algebra is an essential part of undergraduate mathematical learning and yet this subject is also known for its high level of difficulty at the collegiate level. Larsen has found the context of geometric symmetry proves to provide a 'rich and natural context for developing the concepts of group theory' (2009, p. 136), since the ideas of symmetry and equivalence are fundamental concepts in group theory (Burn, 1996). A recent teaching experiment (Steffe & Thompson, 2000) was conducted to identify a student's cognitive processes related to symmetry as they develop a mathematically robust definition of symmetry. This experiment explored how one undergraduate student, Birdie, developed an understanding of symmetry over a series of 5 task-based interviews. The student worked through the Measuring Symmetry Task (Larsen & Bartlo, 2009), which is designed to build on the student's aesthetic sense and intuition to help the development of formal ideas of symmetry. Asiala et al. (1998) offer a framework 'useful for understanding the mental constructions made by students learning about permutations and symmetries' (1998, p. 13), which utilizes the APOS perspective (Breidenbach, Dubinsky, Hawks, & Nichols, 1992). This framework includes a genetic decomposition of an individual's understanding of symmetries. While the authors admit it is a 'very simple genetic decomposition' (1998, p. 18), they still found it to be very useful describing student conceptions of symmetry; when considering only rotation and reflection symmetries of fairly simple geometric objects.

In an initial attempt to use the APOS framework for symmetries as offered by Asiala et al. (1998) to describe Birdie's developing understanding of symmetry, we have found that it is fairly easy to illustrate that very often in the interviews Birdie is working with a "process" conception as described by Asiala et al., "A process conception of symmetry might be indicated by the subject's ability to imagine performing the symmetry without actually doing it." (1998, p. 18). However during our experiment, we also found that Birdie was able to articulate multiple processes for finding/identifying symmetries, some of which were mathematically accurate and some of which were not. For example she offered 2 distinct versions of what she called "line symmetry" one as a true reflection and the other as an iterative deformation of the figure based on Birdie's ability to fold, where Birdie performed both of these processes mentally. In this poster we challenge the ability of a simple genetic decomposition to accurately capture the complex ideas students associate with symmetry, especially in contexts when students are encouraged to rely on their intuition and aesthetic sense.

Student Understanding of the Product Layer of the Integral in Volume Problems

Krista Kay Bresock
West Virginia University

Vicki Sealey
West Virginia University

Research has shown that students have difficulties attending to the underlying product and summation structure of the integral when solving application problems. This study examines student conceptions of the product layer when solving volume problems. Participants were second-semester calculus students enrolled in a large, public university. Task-based interviews consisted of students working through and discussing volume problems. Preliminary results show that a majority of students' volume integral setups are highly formulaic and linked to memorized patterns and methods seen in class, as opposed to having a true understanding of the underlying structure of the problem. We plan to conduct more interviews of this type with additional volume problems and investigate other aspects such as visualization and gesture.

Key words: Calculus, definite integral, solid of revolution, volume

Some of the first types of definite integral application problems that students encounter are volume problems. Previous research has found that when solving definite integral application problems, students often rely on formulas, patterns, and previously encountered methods for setting up integrals (Yeatts & Hundhausen, 1992; Grundmeier, Hansen, & Sousa, 2006; Huang, 2010). Other studies have shown that students have very little idea of the dissecting, summing, and limiting processes involved in integration (Orton, 1983; Sealey, 2006, 2014; Jones, 2015). The goal of this study is to explore and analyze how students conceptualize volume of solid of revolution problems, and in particular, how they attend to the product layer (integrand and differential) during integral setup.

Our research is built on the foundation of the constructivist learning theory (Piaget, 1970), and the framework guiding our analysis of student understanding of definite integral concepts is based on Sealey's (2014) integral framework. We will also be discussing student's responses using Vinner's (1997) conceptual framework that describes and analyzes mathematical behaviors of students as conceptual/analytical or pseudo-conceptual/pseudo-analytical.

Clinical interviews were conducted with four students who were enrolled in second-semester calculus during Summer 2016. The video-taped interviews involved the participants working through three routine volume problems and talking aloud about their thought processes and problem-solving strategies. The interviewer asked several questions throughout the interview in order to determine if the students could unpack their methods to explain why they worked. The videos were transcribed and data analysis is ongoing.

Preliminary data analysis suggests that students have a very superficial understanding of integral volume problems. After some probing, it becomes clear that participants' responses are based on memorized formulas and not linked to the underlying structure of the definite integral. Almost all of the participants exhibited a strong connection between the axis of rotation and the variable of integration, but could not explain that connection.

In future studies, we plan to create volume problems that better expose the inconsistencies between students' integral setup and their conceptual understanding of integration, and develop activities that discourage students' pseudo-actions and foster more meaningful learning. Other avenues we would like to explore are how students use their visualizations when solving volume problems, and how gesture is incorporated into their understanding of these types of problems.

Mathematics Education as a Research Field: Reflections from ICME-13

Stacy Brown
California State Polytechnic University, Pomona

Hortensia Soto
University of Northern Colorado

Spencer Bagley
University of Northern Colorado

Abstract: In an effort to broaden knowledge within the United States, the National Council of Teachers of Mathematics, with support from the National Science Foundation, funded multiple scholars' participation in the 13th International Congress of Mathematics Education. Working in NCTM theme groups these scholars met, discussed, and provided reports to various American educational organizations, so as to bring back findings related to a variety of ICME Topic Study Groups. The purpose of this poster is share findings from the "Mathematics Education as a Research Field" NCTM theme group.

For several decades mathematics education has been referred to as a rapidly expanding field of scholarly inquiry (Sierpinska & Kilpatrick, 1997; Artigue, 1999; Schoenfeld, 2000; English & Kirshner, 2015). Evidence of this growth can be seen in the significant increase in scholarly journals focused on mathematics education research and in the increasing number of areas of scholarly inquiry. As areas of inquiry have grown so has the diversity of the theories and research methods employed. With increasing diversity comes both opportunity and challenge. New theories, methods, and areas of inquiry offer not only opportunities to pursue novel phenomena but also the promise of fresh perspectives on persistent problems. However, diversification can also hinder communication and understanding among researchers – a point prophetically made in Thompson's (1982) article, *Were lions to speak, we wouldn't understand*.

To foster professional community among American researchers during this rapidly expanding period of growth, it is important (perhaps more than ever before) to seek out and understand diverse perspectives. Indeed, there is a need not to only to seek out those whose work and professional lives differ from our own but also to seek out and understand the ways in which our work is understood by others. It was with these aims in mind that a cadre of American scholars was sent to the *13th International Congress of Mathematics Education* (ICME 13) by the National Council of Teachers of Mathematics (NCTM), with funding from the National Science Foundation. The purpose of this poster is share findings from the reports of those scholars, who as part of the NCTM envoy participated in the *"Mathematics Education as a Research Field"* NCTM theme group: Hortensia Soto (group leader), Spencer Bagley, Stacy Brown, Jinfa Cai, Molly Keaton, Debra Junk, Robert Ronau, and Brandy Wiegers. Specifically, the poster will share questions and insights from a variety of ICME 13 topic study groups and do so with a focus on understanding distinct perspectives, new horizons, and shared domains of inquiry that may inform research on undergraduate mathematics education.

Connecting Reading Comprehension Research and College Mathematics Instruction

Melanie Butler
Mount St. Mary's University

The poster will have three parts. The first is a literature review of reading comprehension research. Connections will be drawn between different research studies that apply to college mathematics instruction. In addition, common themes from research will be used to motivate the need for reading comprehension instruction in college mathematics. The second part will give results of a new research study involving interviews about reading comprehension strategies and instruction with interdisciplinary faculty from several institutions. The third part will describe proposed methodology of future research on reading comprehension in college mathematics instruction. It is hoped that during the poster session, participants will have a chance to brainstorm about possible future directions and methodologies for research in this area.

Keywords: reading in mathematics, clinical interviews

Faculty comment that students don't use the textbook. Students complain that the textbook wasn't useful. Courses have shifted from pure lecture to flipped classrooms, the Moore method, and other student-centered, constructivist approaches. In addition, there are more online courses. Often people don't know how to read newspapers or other articles that contain technical information and evaluate the accuracy. What is the missing piece that weaves through all of this? The ability to read and comprehend mathematics.

Several years ago I was given the opportunity to teach a freshman symposium course, taught by instructors from different disciplines, but with a focus on reading and writing. Instructors for the course undergo intensive summer training. I soon realized that the techniques from faculty across campus would be valuable when modified for my mathematics courses, and I began to research reading comprehension literature.

The first part of this poster will be an overview of reading research literature on literacy, on content area literacy, on disciplinary literacy, and on teaching reading in mathematics. Unfortunately, there are not a lot of resources for teaching reading in mathematics at the college level. Taking advantage of the poster format, this section will draw connections between different reading comprehension research studies that pertain to college mathematics instruction. Through this literature review, the need for college mathematics reading instruction will also be illustrated.

Due to the need for increased study of reading comprehension in college mathematics instruction, a new exploratory research study was completed that included open-ended, clinical interviews with ten faculty from mathematics, foreign language, philosophy, education, English, history, theology, and K-12. The second part of the poster will give details on the interpretive analysis of the interviews.

There is a need for additional research on this subject. A research study is planned, and the third part of the poster will give details on the proposed methodology of this study. It is hoped that participants during the poster session will have the opportunity to discuss future directions and methodologies for this research.

Diagrams for the Reasoning and Proof of Amortization Formula

Kuo-Liang Chang, Utah Valley University
Hazel McKenna, Utah Valley University
Thomas Mgonja, Utah Valley University

Many liberal arts or humanities students who are required to take quantitative reasoning in college have mathematics anxiety. One cause is a lack of symbolic skills for reasoning. Learning style theories suggest that different people learn in different ways. This study constructs a diagrammatic reasoning model for the concept of amortization to help students learn quantitative reasoning. The model also connects the basic concepts to the proof of the mortgage payment formula.

Key words: Diagrammatic Reasoning, Quantitative Reasoning, Amortization, Proof, non-STEM

Many non-STEM major students (e.g., liberal arts and humanities) have negative attitudes towards and fear college mathematics classes such as quantitative reasoning (Henrich, 2011). This math anxiety is due in part to a lack of skills in symbolic and propositional calculations or manipulations of mathematics (Ashcraft, 2002; Hembree, 1990). The question that must be asked is, "Are there other alternative ways to help the students learn quantitative reasoning and appreciate mathematics?".

Learning style theories suggest that different people learn in different ways (Coffield et al., 2004; Pashler et al., 2009). In particular, diagrammatic reasoning has been tested as an alternative method for mathematical inference and proof (Jamnik, 2001; Kulpa, 2009). Diagrams allow richer properties and relations among elements in presenting mathematical structures and their meanings. They may significantly reduce the encoding process and make it easier for students to understanding and reason.

The purpose of the study is to construct a diagrammatic model for helping non-STEM major students perceive and process mathematical information visually while improving their math attitudes, and, consequently, become more effective at performing quantitative reasoning. In addition, we hope to assess the potential of the diagrammatic model in quantitative reasoning and in facilitating symbolic manipulations and proof.

We chose the concept of amortization for model construction because (1) it is introduced in the quantitative reasoning course, which is required of most liberal arts and humanities students, and (2) it involves the idea of complicated exponential growth (compounding process) and algebraic reasoning (symbolic manipulations on the mortgage payment formula $M = \frac{A\times r(1+r)^t}{(1+r)^t-1}$). We constructed two diagrammatic maps, the quantitative map and the operational map (See Figures below).

A Discussion of The Use of Excel in Statistics Teaching and the Role of Technology in Improving Teaching and Learning Statistics with a Special Focus on the 'knitr' R-package.

Sher B. Chhetri
Florida Atlantic University

We cannot imagine teaching statistics today without using some form of technology. Teaching statistics courses in the past was very challenging due to time consumption in calculation. The computation is now done by computer and other software packages but the challenge now is that understanding the results and staying mistrustful to the results. In this discussion, we will discuss how we have been teaching introductory statistics courses with or without computer and provide some typical examples in excel spreadsheet. On the other hand, due to the recent development of the power of computing, we present a dynamic documentation of computational outputs from a statistical programming language using R markdown (included in the package "knitr") which is a simple formatting syntax for authoring HTML, PDF, and MS Word documents. Hence the main goal of this presentation is to give an outline of the method used in the past, its challenges as mentioned by Christine Duller (2008) and a demonstration of an R package which recently brought a great attention to the teachers of statistics and researchers. The usefulness of the package will be presented using some data analysis and graphs using R programming language. Since R Markdown supports dozens of static and dynamic output formats including HTML, Pdf, MS Word, Beamer, HTML slides, Tufte-style handouts, books, dashboards, shiny applications, scientific articles, websites, and more, it is more popular to the researcher, teacher of statistics and collaborators.
Key words: Teaching and Learning Statistics, Excel spreadsheet, "knitr" package, R Markdown

Literature Review

After we had an access of excel spreadsheet for teaching statistics classes, a number of research work have been published about teaching statistics. Christie, D. (2004) mentioned in his paper about "Resampling with excel-teaching statistics". Similarly Doane, D. (2004) talked about "Using Simulation to Teach Distributions". In (2008), Christie D. raised some issues on his paper "Teaching Statistics with Excel: A Big Challenge for Students and Lecturers". We can find many institutions use excels spread sheet for teaching and learning statistics in classroom.

After the development of the programming language R in 1993 and the availability of personal computer and other technologies, the programming language R (an open source) and many other programming languages have been widely used. The package "**knitr"** is an engine for dynamic report generation with R. It is a package in the statistical programming language R that enables integration of R code into LaTeX, LyX, HTML, Markdown, AsciiDoc, and re-structured text documents. We can see the popularity of R markdown and its usefulness for statistic teaching and research. Markdown is a lightweight markup language with plain text formatting syntax designed so that it can be converted to HTML and many other formats using a tool by the same name. Markdown is often used to format readme files, for writing messages in online discussion forums, and to create rich text using a plain text editor.

In this discussion, we attempt to address the usefulness of excel spreadsheet in teaching and learning statistics and also will discuss the latest development and show how efficient it is to use the package R Markdown for teaching and research. The main goal of this discussion is to provide high school and college introductory statistics instructors with a scenario of teaching statistics using excel and the recent development of the power of computing.

We have the following research question for this study:

1. What is the targeted group of people who use excel sheet for teaching and learning statistics?
2. What is the label of statistics and computation knowledge we need for using the programming language R and the package "knitr"?
3. What is the cost and availability of the programming language and computers etc.?

Theoretical Framework and Methodology

We will briefly discuss the heavy use of excel in teaching and research in different disciplines. Further, we discuss the statistical software R and its usefulness in teaching and learning statistics courses.

Results of the Research

We compare the usefulness of teaching statistics using excel for one group of audience and also look at the effectiveness and popularity of the statistical programming language R with a special focus on the package "knitr".

Discussion and Conclusions

Even though the use of excel in teaching in the past was very effective, due to its capacity and challenge for special data, statistical programming language R is more popular. Especially, for research and teaching statistics courses, it looks like people are more tending to use R.

Since R Markdown supports dozens of static and dynamic output formats including HTML, Pdf, MS Word, Beamer, HTML slides, Tufte-style handouts, books, dashboards, shiny applications, scientific articles, websites, and more, it is more popular to the researcher, teacher of statistics and collaborators.

To Factorize or Not To Factorize: Novice Teachers' Struggles

Hyungmi Cho, Miyeong Na, Oh Nam Kwon
Seoul National University

Focusing on the unique factorization domain (UFD) in college mathematics and polynomial factorization in school mathematics, this study examined how teachers' factorization concepts occur in the teaching context. We conducted semi-structured interviews with eight novice teachers. The result of this study can serve as a resource for teacher educators when teaching UFD in abstract algebra in the future.

Key words: Mathematical Knowledge for Teaching, Polynomial Factorization

What role does college mathematics knowledge play as teacher knowledge for teaching mathematics? To answer this question, much research has been devoted to mathematics teacher knowledge (see e.g. Ball, Hill & Bass, 2005; Evens & Ball 2009; Buchholtz et al., 2013). However, there is a lack of specific research on how college mathematical knowledge contribute to teaching school mathematics. With regard to the concepts that intersect between college mathematics and school mathematics, we focus on the concept of UFD in college mathematics and polynomial factorization in school mathematics. The purpose of this study is to examine how teachers are utilizing their college mathematics knowledge in the context of school mathematics.

Eight novice teachers were selected as our research participants because we considered teachers with the most recent college mathematics knowledge to be the most suitable participants for understanding how related college mathematics concepts are being used to understand school mathematics concepts. Using middle school-level polynomial factorization task, we conducted semi-structured interviews. All interviews were transcribed. The teachers' answers were categorized and analyzed focusing on teacher knowledge emerged in terms of Mathematical Knowledge for Teaching framework (Ball, Thames, & Phelps, 2008). In order to ensure the validity of the analysis, three researchers crosschecked the categories of teacher interviews. The task was: If a middle school student has asked you to what extent he or she needs to factorize the polynomial $2x^2 + 4x - 6$, how would you answer?

This study shows that teachers who knew about polynomial factorization in college-level explicitly did not just follow the knowledge to teach polynomial factorization in school context. Teachers who had proper common content knowledge (CCK) sometimes modified to suit the level of secondary school mathematics, but recognized how they are treating number factors in explaining polynomial factorization in school context. Based on the results, we identified that horizon content knowledge (HCK) plays significant roles to understand secondary school mathematics from advanced viewpoint. The other teachers who did not show the proper common content knowledge did not consistently and concretely explain the basis for their explanation. So, this study implies that especially HCK and CCK should be emphasized in order to connect between college-level mathematics knowledge and school-level mathematics knowledge in preservice teacher education.

This work was supported by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2016S1A3A2925401).

Upper-division Physics Student Thinking Regarding Non-Cartesian Coordinate Systems

Brian Farlow[1], Marlene Vega[2], Michael Loverude[2], Warren Christensen[1]

[1]North Dakota State University, [2]California State University - Fullerton

As part of a larger effort to develop a research-based math methods curriculum for undergraduate physics students, results from a case study probing student thinking on plane and spherical polar coordinates are presented. Using a resources framework, a think-aloud protocol was used to elicit student thinking regarding non-Cartesian coordinates. Findings are consistent with previously published literature regarding student thinking on coordinate systems. Mark, a senior physics major, despite initially clearly identifying and defining the radial and polar unit vectors on a diagnostic 2-dimensional problem, made inconsistent assertions when asked to apply those definitions in three dimensions using spherical coordinates. Additionally, we will address content issues concerning the definition of displacement and position vectors in Cartesian and Non-Cartesian coordinate systems.

Key words: Coordinate systems, Non-Cartesian, Resources, Interviews, Physics

Using non-Cartesian coordinate systems continues to be difficult for undergraduate physics students (Paoletti *et al.* 2013, Montiel *et al.* 2009) even in the upper division where application of the concept is of significant importance (Sayre and Wittmann 2008). As part of a larger effort of PER in the upper division (Caballero *et al.* 2015, Loverude and Ambrose 2015) our collaboration has begun to develop a research-based curriculum for a mathematical methods course for undergraduate physics majors. This paper discusses a portion of that effort by investigating student thinking regarding non-Cartesian coordinates systems, specifically plane and spherical polar coordinate position vectors.

The polar coordinate system, both planar and spherical, is commonly used in a number of upper-division physics courses, including mechanics and electrodynamics (Griffiths 1999, Fowles and Cassiday 1999). Students are initially taught how to convert from the more familiar Cartesian coordinate system into polar coordinates while the expectation for most upper-division courses is that students can think in and use non-Cartesian coordinates fluently; not simply translate. Issues arise as students attempt to map Cartesian thinking into non-Cartesian coordinate systems (Hinrichs 2010). The research presented here analyzes students' in-the-moment thinking using a Resources theoretical framework in an attempt to understand a student's underlying reasoning with respect to non-Cartesian coordinate systems. The nuanced nature of students' reasoning during our interviews informs the use of a Resources Framework, wherein we attempt to identify the kinds of resources students appear to be using as they proceed through the interview.

For this poster, we present a case study of one student, Mark, who initially demonstrates outstanding understanding of unit vectors and their definitions in non-Cartesian coordinates; i.e., that $\hat{r}$ points in the direction of increasing radius. However, he has a self-described "moral dilemma" when deciding whether or not to include $\hat{\phi}$ and/or $\hat{\theta}$ terms in spherical position vectors where only a $\hat{r}$ term was needed. The content details of position vectors versus displacement vectors in three dimensions are not trivial and will be discussed alongside student data and analysis.

The Mathematics Attitudes and Perceptions Survey: New Data and Alignment with Other Recent Findings

Warren Code
University of British Columbia

Wes Maciejewski
San José State University

Student attitudes about and perceptions of mathematics influence their success and learning, and have been of interest for many years in mathematics education. The Mathematics Attitudes and Perceptions Survey is a short, validated Likert-scale instrument that measures confidence, interest, relation of mathematics to the real world, persistence in problem solving, growth mindset, use of sense-making behaviours, and the extent of other novice attitudes towards mathematics. In this poster, we share the complete instrument and its categories, a brief summary of the development process and resulting model statistics, as well as scores across different populations measured so far (3 institutions, variety of courses). The student responses include new data since the publication of the instrument as well as additional analysis of groups, in particular a comparison of attitudes between genders that matches with recent results relating STEM persistence to attitudes and beliefs (Ellis et al., 2016; Wang et al., 2016).

Key words: student attitudes, student perceptions, student beliefs, survey tool

Motivation and Development

Development of the Mathematics Attitudes and Perceptions Survey (MAPS) was prompted by interest in matching up results regarding student attitudes in mathematics to those captured via similar surveys "scored" relative to expert consensus views in physics (Adams et al., 2006), chemistry (Barbera et al., 2008), biology (Semsar et al., 2011), earth sciences (Jolley et al., 2012), and computer science (Dorn & Tew, 2015). These contain many similar statements and share aspects of development (Adams & Wieman, 2011), though for MAPS the quantitative aspects followed more conventional instrument development in terms of factor analysis and model fitting.

The survey consists of 31 Likert-scale statements scored based on alignment with expert views and reported behaviours involving mathematics. The instrument was designed iteratively with interviews of faculty and students, rounds of responses from multiple populations of students leading to factor analysis and model confirmation. Further details and preliminary population scores are available in an initial article (Code et al., 2016).

Results So Far

While our data does not have sufficient detail for comparison in some demographic variables, nor for a relation to teaching methods like Sonnert et al. (2015), we have similar findings to the recent MAA study of calculus programs, including an overall decrease in such attitudes over a first year of a calculus courses, with men overall reporting higher attitudes in most categories including confidence in their mathematical ability (Maciejewski, 2016). The drop in attitudes in introductory post-secondary courses and the gender gap are similar to results in other fields with the instruments which helped inspire MAPS (Hansen & Birol, 2013; Bates et al., 2011). This convergence of results, along with the ease of deployment, suggests the value of MAPS in measuring student attitudes and perceptions in mathematics. Our poster will present the full instrument, categories, and a variety of data from different populations so far.

Online Course Component and Student Performance

Elizabeth DiScala and Yasmine Akl
Widener University

Abstract: *A study was conducted in a small, private university in Northeastern United States in order to determine if introducing an online component to a first year Calculus course would influence student learning. An online component was presented in two sections of the calculus courses while two sections were taught using the traditional format. Preliminary data suggest a positive correlation between the online component and improved student performance in the course.*

Keywords: online learning, calculus

Online education is rapidly growing in colleges and universities. According to Allen and Seaman (2013), thirty two percent of students in higher education in the United States are taking online courses, which equates to approximately 6.7 million students taking at least one online course each year. The college student population is becoming increasingly diverse and different learning options are necessary to meet the demands of these students.

This poster reports on a study at a small, private university in the Northeastern United States. Prior to the intervention, there were very little opportunities for students to participate in online learning. There has been recent interest from the administration to remain competitive with other institutions by offering online mathematics courses. The request was to transition some mathematics courses to an online format. In order to address this concern, we incorporated an online component to two sections of a first semester Calculus course, a course which was has traditionally been taught without an online component. The remaining two sections of the course were taught in the traditional format without an online component. The research question guiding this study is: *Does an online component increase student performance rates in a first year calculus class?*

The study began in the Fall semester of 2016, and will continue in the Spring of 2016. Students in the online sections participated in weekly discussion questions through a forum using critical thinking skills to review the course material. The other sections were given the same questions, but discussed in a face to face setting during the fourth hour of the course. Themes from the student discussion have been grouped and coded for analysis. Questions from exams and the final were selected to compare results from each section. Student surveys are being distributed at the end of the semester to gather feedback on their experiences. Formal data analysis will take place in the Spring of 2016, but preliminary results indicate a positive correlation between the online component and student performance in the course. The results of the study will be used to implement changes in other courses that will be moved to an online format.

JITAR Online Modules to Improve Math Preparation of Engineering Students

Alina N. Duca, NC State University
Hatice Ozturk, NC State University
Dianne Raubenheimer, Meredith College

Engineering educators are challenged with students at greatly varying mathematical skill levels while needing to quickly bring all students up to the same mathematical mastery level at appropriate points during a semester. To address this problem our team designed a teaching e-tool in WeBWorK called Just-In-Time Assessment and Review (JITAR) to be delivered as an on-line system consisting of a series of individualized mathematics modules inserted within engineering courses at strategic points in the semester, prior to students needing those math skills. JITAR assesses the mathematical competency level of the individual student and provides formative individualized learning opportunities in time for the students to be successful in applying the necessary mathematics to the new engineering material. The new type of WeBWorK assignment was designed to support the desired presentation and flow of the module integrating assessment and e-learning assistance by offering a customized learning path to students. This project is currently funded by National Science Foundation.

Key words: Engineering Education, On-line Assessment, Just-In-Time, JITAR.

There are several factors that influence student retention and success in engineering, the most important being mathematical competency, but there is well documented knowledge gap in the preparation of engineering undergraduates. Engineering programs typically enforce prerequisites to guarantee a certain level of mathematics proficiency before the students enroll in engineering classes. Due to several factors this sequence is not completely effective at preparing engineering students so engineering educators are challenged with students at greatly varying mathematical skill levels, while needing to quickly bring all students up to the same mathematical mastery level at appropriate points during a semester. While the traditional model of integrating engineering applications into the mathematics courses and later reviewing those concepts in engineering courses has benefited the math preparation of the engineering students, it does not completely address the mathematical knowledge gap of engineering students due to its "one size fits all" approach to the problem (Manseur, Leta, & Manseur, 2010).

To address this problem, mathematics and engineering instructors designed a teaching e-tool called Just-In-Time Assessment and Review (JITAR) delivered as an on-line system through WeBWorK consisting of a series of individualized mathematics modules, to be inserted within engineering courses at strategic points in the semester. JITAR assesses the mathematical competency level of the individual student and provides formative individualized learning opportunities in time for the students to be successful in applying the necessary mathematics to the new engineering material. The structure of the modules relies heavily on the fact that the assessment and review content needs to be generated based on individual student's performance.

The first JITAR module has been developed for Complex Numbers and Complex Functions and implemented in Linear Systems for Biomedical Engineers course in the Biomedical Engineering curriculum. The module is an application in WeBWorK that allows any course instructor to import and adopt easily. In this poster, we will present results from the implementation of JITAR modules (Ozturk, Duca, & Raubenheimer, 2015).

A Framework for Characterizing a Teacher's Decentering Tendencies

Ashley Duncan
Arizona State University

Sinem Bas Ader
Istanbul Aydin University

Marilyn Carlson
Arizona State University

This poster presents a framework for characterizing teachers' decentering during teacher-student interactions when teaching. Analysis of video data of a graduate teaching assistant's (GTA's) precalculus class generated six levels of teacher-student interactions. These levels will be described and illustrated with excerpts from this video analysis.

Key words: Precalculus, Graduate Teaching Assistants, Decentering

Mathematics education policy documents (e.g., NCTM, 2000) have emphasized the importance of teachers' focusing on and using student thinking to inform their interactions with students. In our work to support teachers to consider student thinking **when** teaching, we leveraged Steffe and Thompson's (2000) description of decentering—the manner by which an individual adjusts (or does not adjust) his or her actions **to understand** another individual's thinking. In our group's early work Carlson, Bowling, Moore, and Ortiz (2007) identified five levels of decentering when analyzing teacher-teacher interactions when participating in a professional learning community.

We coded video data collected in a GTA's precalculus classroom using research based instructional materials (Carlson, Oehrtman & Moore, 2016) designed to engage students in constructing deep meanings of the course's key ideas. Our early coding using Carlson et al's (2007) framework resulted in our extending the framework to include a teacher's focus on students' answers and thinking when teaching. These levels are described (Table 1) and will be illustrated in the context of the GTA introducing his precalculus students to the ideas of constant rate of change from a quantitative reasoning perspective.

Decentering Levels	Description
0	Appears interested in student's answers but not in student's thinking.
1	Takes actions to move students to her/his thinking or perspective without trying to understand or build on the expressed thinking and/or perspectives of students.
2	Appears interested in understanding the thinking and/or perspectives of students but actions do not appear to be based on these expressions.
3	Appears interested in understanding the expressed thinking and/or perspectives of students but takes actions to move students to her/his thinking or perspective.
4	Appears to have insight into the expressed thinking and/or perspectives of students and makes general moves based on the students' expressions.
5	Takes action to understand the thinking of others (probes), appears to understand the expressed thinking and/or perspective of students and takes actions that builds on and respects the rationality of these expressions.

Table 1. Characterization of Teacher Decentering Levels (adaption from (Carlson et al., 2007)

SOME LOGICAL ISSUES IN RUME

Viviane Durand-Guerrier, University of Montpellier (France)

In this communication, we will present various arguments supporting the claim that it is worthwhile taking in account logical issues in research in undergraduate mathematics education. We will provide arguments relying on research on student's difficulties and their links with teachers' practices on the one hand; on relevance for researchers on the other hand.

Key words: logical analysis of language - syntax and semantics – truth *versus* validity

We have shown (Durand-Guerrier 2003) that predicate calculus, with concepts such as variable, open sentence, quantifiers, logical connectors, logical validity, truth in an interpretation, syntax and semantic, is a relevant epistemological reference for mathematics education. We present two sides of these logical issues in RUME: on teaching and learning, and on research.

Students'difficuties and links with teachers'practises

Undergraduates' difficulties concerning logical matters in mathematics are well documented in the research literature (Chellougui 2009; Dubinsky & Yparaki 2000; Durand-Guerrier et al. 2012; Epp 2003; Roh 2010). We hypothesize that they are linked with some teachers' practices. We will provide two examples of such links.

1) While the logical formalism could appear as a mean of conceptual clarification (Quine 1950), it appears for many fresh university students as an unbearable obstacle (Chellougui 2009), and many students are unable to unpack the logic of mathematical statements (Selden and Selden 1995). On another side, some ordinary teacher's practices tend to reinforce these difficulties by neglecting the logical side of students' mathematical difficulties (Durand-Guerrier 2003, 2008).

2) A main concern in undergraduate education is to develop competencies in proof and proving as a clue contribution to mathematical conceptualization. However, for many students, the requirement for proof is seen as a formal demand of teachers. In Durand-Guerrier (2008) we claimed that this could be related to the lack of a clear distinction between truth in an interpretation and logical validity. Durand-Guerrier and Arsac (2005) evidenced that while expert use semantic controls to check the validity of a proof it is not the case for undergraduates

Logical analysis as a tool for research in mathematics education

We claim that logical issues are also valuable for RUME. In our work we use logical tools to enrich and deepen the *a priori* analysis of didactical situation on the one hand, the *a posteriori* analysis of students' productions on the other hand (Durand-Guerrier 2013). We use *logical analysis of mathematical statements* to enlighten ambiguities likely to create difficulties that are reinforced in case of plurilinguism (Durand-Guerrier et al. 2016), and Copi's natural deduction as a tool to identify steps in a proof that could be *a priori* problematic (Durand-Guerrier 2008).

Conclusion

Although logical issues concern all the levels in the curriculum, it is clear that they become more crucial at university where logic and mathematics are closely intertwined in mathematics activities, including proof and proving. We will give examples in this communication showing that taking in consideration logical issues in research design for RUME appears to be fruitful.

A Comparison of Faculty Expectations and Student Perceptions of Engagement in a Calculus I Class

Belinda P. Edwards
Kennesaw State University

This poster describes and includes a discussion of the learning benefits and gains that students, enrolled in a Calculus I course, and their instructor reported as a result of participating in an active learning environment. The alignment between what the instructor valued and what 67 students experienced as they engaged in Calculus I activities was assessed using a survey. The results indicate a positive relationship between perceived importance and reported frequency of engagement, which resulted in benefits and student learning. Opportunities for improvement outcomes were found and can serve to support strategies that improve teaching and learning in Calculus I.

Key words: Calculus I, Engagement, Learner-centered Instruction

Learner-centered teaching is an instructional approach to teaching that is increasingly being encouraged in undergraduate gateway mathematics courses such, as Precalculus and Calculus I. Research (e.g., Fritschner, 2000; Kogan & Laursen, 2013) suggests that students learn best when they are engaged with active learning tasks that promote student thinking and lead to deeper mathematics understanding. Learner-centered teaching reflects several instructional approaches including, but not limited to, actively engaging students in group-worthy tasks, peer-learning, problem-solving, and engagement that includes student effort outside the classroom that will contribute to their academic success. While learner-centered instructional strategies have many reported benefits, research also indicates that it is not easily accomplished and there is often a mismatch between instructor and student expectations (Brophy, 2004). The congruence between what instructors value and what students report doing in their Calculus I actively learning environment is critical to understanding the value instructors place on instructional practices intended to support student learning and understanding of Calculus I concepts.

The question that guided this study was: What benefits and gains do students enrolled in a Calculus I LC course and their instructor report as a result of participating in a LC teaching environment? Student and instructor reported benefits and gains were assessed using a modified Class-Level Survey of Student Engagement (CLASSE) survey. The purpose of the study was to use the results to identify effective Calculus I instructional practices that are beneficial in promoting student success in Calculus I.

A quadrant analysis was used to analyze the data and give meaning to the relationship between perceived importance and benefits of Calculus activities by the instructor and reported frequency of occurrence and learning benefits of those activities by students. The findings indicate a high degree of congruence associated with the completion of in-class higher-order thinking tasks, student effort, and participation in in-class group worthy activities/tasks. Areas for further consideration include student engagement with the instructor (i.e., meeting with the instructor during office hours to review problem solutions) and outside-classroom activities (i.e., participating in a study group or pre-reading/problem solving). The results of the study can be used to shape/transform Calculus I teaching and learning experiences, and inform the design of faculty development activities.

Calculus Students' Meanings for Average Rate of Change

Wyatt A. Ehlke, Hamline University
Sayonita Ghosh Hajra, Hamline University

This study considers calculus students' conceptualization of average rate of change at a private liberal arts college in the Midwest. Researchers have indicated that undergraduate students do not develop productive meanings for average rate of change. In order to explore undergraduate students' meanings for average rate of change further, we conducted clinical interviews with 10 undergraduate students on a four-item test. Participants were undergraduate students taking Calculus 1 at the time of the study. Interviews were conducted towards the end of the semester to ensure students have learned average rate of change. Qualitative techniques were used to analyze data. We will present and interpret data highlighting the techniques used by the students during the tasks. We will conclude with implications from our findings and questions for future research.

Keywords: Average rate of change, calculus, mathematical meanings, undergraduate students

Mathematics students in the United States are underperforming when compared to other major world powers (Hanushek, 2010). As Byerley, Hatfield and Thompson (2012) discuss in a recent study, the underlying understandings of math concepts that students develop while studying at our schools and universities are an explanation for the gap in performance. By studying the understandings behind a major concept, we can draw conclusions about the quality of education that brings the students to this point. A previous study by Carlson, Jacobs, Coe, Larsen and Hsu (2002) showed that Calculus students have difficulties with problems that require an understanding of average rate of change.

10 undergraduate students from a Calculus 1 course from a private liberal arts college participated in this study. Interviews were conducted towards the end of the semester to ensure students have learned average rate of change. The interviews were task-based clinical interviews (Clement, 2000) and were videotaped. Participants were given a four-item test, two of which were the same that were used by Yoon, Byerley and Thompson (2015), consisting of questions that examined their meanings for average rate of change. Interviews were conducted in a one-on-one environment. Each interview was transcribed and written work was digitized.

We used open and axial coding techniques (Clement, 2000; Strauss & Corbin, 1998) and conceptual analyses (Thompson, 2008) to analyze data. Each researcher analyzed student's responses individually by noting each student's responses for working with average rate of change tasks. Then, we met to discuss our observations, looking for common patterns among the students' techniques for specific tasks. We created codes to identify these patterns we observed. Codes were revised and changed in the process to capture the similarities or differences in techniques we observed both within similar tasks and across varying tasks.

We found some students interpreted average rate of change as the difference of function values only. We also found students conceived average rate of change as the arithmetic mean of rates. We will discuss students' meanings for average rate of change in detail in the poster presentation and will present questions for future research.

Empowered Women In RUME: What Have We Been Up To?

For the past three years we have run a seminar for 60 – 75 women in RUME the day before the annual conference called MPWR: Mentoring and Partnerships for Women in RUME. Participants included graduate students, post-doctoral fellows, faculty, and researchers outside of academic positions. In this poster, we provide a window into these seminars, specifically addressing the motivation for the seminar, the structure of the seminar, topics discussed in the seminar, research related to the efficacy and transferability of MPWR, and the future of MPWR. Our hope with this poster is to both share what we have been doing and get feedback from the community for what more can be done.

Jess Ellis	Stacy Musgrave	Kathleen Melhuish	Eva Thanheiser	Megan Wawro
Colorado State University	Cal Poly Pomona	Texas State University	Portland State University	Virginia Tech

Key Words: Mentoring, Women, Support

The disproportionately low number of women in STEM fields in academia at all stages of a career is well documented (Hill, Corbett, & St. Rose, 2010), as is the role of mentoring, both vertically and laterally, in bringing (and keeping) more women in these positions (Beede et al., 2011). However, mentoring is underutilized (Preston, 2004). As female mathematicians whose expertise is in research in undergraduate mathematics education (RUME), we identified a need in our community for increased support and mentorship. Prior to 2014 (when this seminar began) there was no formal mentoring structure for women specifically, or RUME participants in general. Some women were getting mentoring because of their personal or academic networks, but this was not equitably accessible, especially for women coming from universities with no other RUME researchers, or for women coming into RUME from mathematics or non-undergraduate mathematics education. We need to ensure that support exists for all women at all career stages in their academic development. The MPWR seminar, which stands for Mentoring and Partnerships for Women in RUME, was created to address this need, and, based on participant feedback, is succeeding in doing so.

In this poster we describe the MPWR seminar, including motivations for this ongoing seminar, a description of past seminars, and our vision for future MPWR seminars. We also address the beginning stages of researching what aspects of MPWR are most effective and why, with an eye towards what aspects of MPWR could be adapted by other organizations.

Designing and Developing Likert Items That Capture Mathematical Problem Solving

James A. Mendoza Epperson[(1)] Kathryn Rhoads[(1)] R. Cavender Campbell[(1)]
[(1)]The University of Texas at Arlington

The Mathematical Problem Solving Item Development Project is designing and developing Likert items that capture students' capacity in mathematical problem solving (MPS). The project, now in year two, continues to refine items that capture aspects of MPS. The refinement process included piloting items on over 1000 students in College Algebra and Calculus, hour-long think-aloud interviews with 26 students, and review by experts. The goal of this poster presentation is to provide information about the item development and design and gather feedback and suggestions on further design and development.

Key words: mathematical problem solving, mathematics assessment, gateway courses

Research has identified key prerequisite procedural knowledge and conceptual knowledge linked to foundational preparation for gateway mathematics courses (e.g. Carlson, Oehrtman, & Engelke, 2010); however, there is limited research on connections between foundational MPS capacity and success in gateway mathematics courses (Schoenfeld, 2013). The *Mathematical Problem Solving Item Development Project* aims toward eventually developing an instrument that provides a profile of an undergraduates' MPS capacity.

Research Questions

This project has created and tested over 100 Likert items linked to research-based aspects of MPS such as sense-making, justifying, representing and connecting, and looking-back (Epperson, Rhoads, & Campbell, 2016). Discussion with RUME attendees will assist us in determining future item development as well as in identifying any issues in research design and methods. This will help us address the questions: (1) What design issues need to be resolved to create items intended to minimize the effects of domain knowledge while bringing MPS capacity to the forefront in measurement? (2) To what extent can Likert items linked to research-based MPS behaviors capture undergraduates' MPS capacity?

Discussion

The refinement process has been informed by results from pre- and post-tests consisting of five open-ended problems and 25-30 associated items to over 1000 students over three semesters of College Algebra and Calculus at a large urban university in the Southwest, analysis of 26 hour-long think-aloud student interviews, and expert review. This poster will provide details on item development and refinement as well as the methods used in item analysis.

Reducing Abstraction in the Group Concept Inventory

Joshua B. Fagan
Texas State University

Kathleen M. Melhuish
Texas State University

In this poster we report on results from the Group Concept Inventory (GCI), a conceptual assessment for introductory group theory students. Over 400 students from thirty institutions took the inventory. We use the framework of reducing abstraction (Hazzan, 1999) to situate student responses. We found that students frequently reduced abstraction (in a multitude of ways) when dealing with fundamental concepts in group theory.

Keywords: Abstract algebra, Reducing abstraction, Concept inventory

Abstract algebra is often one of the earliest courses where students "cop[e] with the difficult notions of mathematical abstraction and formal proof" (Weber & Larsen, 2008, p. 139). Hazzan (1999) introduced the framework of *reducing abstraction* in an effort to "describe the mental processes of undergraduate students as they solve problems in abstract algebra" (p. 71). She introduced three ways students cope with abstraction; by (1) retreating to familiar mathematical structures, (2) using canonical procedures, or (3) adopting a local perspective.

We used this framework to situate students' responses to an inventory designed to measure conceptual knowledge in an introductory undergraduate group theory course (Melhuish, 2015). We report on the frequency of responses from 432 students spanning thirty United States institutions. We pair these results with discussion of the role of abstraction level.

Sample Results

1. Let $i = \sqrt{-1}$. Consider the homomorphism $\phi(n) = i^n$, that maps $\mathbb{Z}$ under addition to the set $H = \{1, -1, i, -i\}$ (a subgroup of $\mathbb{C}$ under multiplication). What is the kernel of this homomorphism?

Table 1
Distribution of Responses for Question 1

Response	Frequency (n=432)
a. {1}	120
b. {4}	41
c. multiples of 4	223
d. empty set	48

In this prompt, students are asked to reason about the kernel of an unfamiliar homomorphism. Most students chose the correct answer of 'multiples of 4,' exhibiting an adequate understanding of the concept. From follow-up interviews we found that students who selected the response of $\{1\}$ often relied on an incomplete process of first identifying the identity in the co-domain group. For students who chose $\{4\}$, they were most often adopting a local perspective in recognizing an element in the kernel, not all elements of the kernel. Finally, students who opted for the *empty set* typically did so because 0 was not an option, which to them was a familiar identity for $\{\mathbb{Z}, +\}$.

Engaging in Abstract Algebra through Game Play: Group Theory Card Game *Groups*

Patrick Galarza
Teachers College at Columbia University

In this presentation, I discuss the viability of a mathematical game as a learning tool for abstract algebra—specifically, the groups of order four. Throughout 2016, I designed and tested variants of my group theory card game, Groups, *among individuals ranging from no post-secondary mathematics experience to current or prior graduate level mathematics study. Here, I review the design choices and challenges central to working in a game space drawing heavily on abstract algebra, and assess alterations to the game's mechanics influenced by my interactions with players.*

Keywords: Abstract Algebra, Group Theory, Educational Game

Salen and Zimmerman (2004) define a game as a "system in which players engage in an artificial conflict, defined by rules, that results in a quantifiable outcome" (p. 80); this definition is often argued to hold natural parallels to that of mathematical exploration, and a wealth of individuals have already begun designing and utilizing games for mathematical learning both inside and outside of the classroom (Ke, 2008; Kebritchi, Hirumi & Bai, 2010; McCue, 2011; Wijers, Jonker & Drijvers, 2010). However, the majority of these games target adolescents at the elementary and secondary level. In the literature on instruction in abstract algebra, Weber and Larsen (2008) advocate building a strong *informal* knowledge base for student reflection, and later introducing students to the corresponding *formal* mathematical concepts (p. 147). In this regard, Weber and Larsen's approach via mathematical reinvention lends itself to exploring groups and group theory through a game-based lens as a means of preempting formal content treatment. Hoping to evoke a similar sense of reinvention, I detail the ongoing development—design, testing, and critical review—of my group theory card game, *Groups*.

Methods

Participants played several video-recorded rounds of *Groups* in pairs, in a novice-novice, novice-expert, or expert-expert match, participated in a recorded interview, and completed a written questionnaire that facilitated a transition to formal mathematical thinking. Preliminary data shows participants had a strong understanding of inverses and identities within groups, but required further clarification on associativity and closure.

Significance

Game-based approaches to mathematics instruction are an innovation worth exploring in undergraduate mathematics education, and can align with reinvention approaches. Refinement of *Groups* may lead to a classroom-viable group theory learning tool that could extend the accessibility and appeal of abstract algebra—and university-level mathematics, in general—to a broader audience, including secondary-level students. From the data, I plan to further explore the following: (i) the utility of *Groups* for new group theory learners; (ii) the utility of *Groups* for current or prior group theory learners; and (iii) how to improve *Groups* for all students.

Research on Concept-based Instruction of Calculus

Xuefen Gao

Mathematics Department, Zhejiang Sci-Tech University, China

Abstract: This study, involving 254 college-level calculus students and 3 teachers, investigated the misunderstanding of concepts in calculus and designed concept-based instruction to help students understand concepts. Multiple achievement measures were used to determine the degree to which students from different instructional environments had mastered the concepts and the procedures. The midterm examination and the final examination results showed that the students enrolled in the concept-based learning environment scored higher than the students enrolled in the traditional learning environment and the investigation at the end of the semester showed that most of students like the concept-based learning environment.

Key words: Concept-based Instruction, Misunderstandings, Teaching design

In the context of mass higher education, the ability of college freshmen is generally in a lower level than before. Many college students can do simple works on calculus, but they cannot understand the idea behind the concept, and as a result, usually have fuzzy understanding of the relationship between concepts. Therefore, to find the cognitive difficulties of the students on the concepts of calculus and to design the concept instruction are the keys to the reform of the teaching on Calculus.

This research presented a study on calculus course in three freshmen classes by carrying out the teaching design and teaching experiment. Research methods such as design research, questionnaires, interviews and classroom observation were adopted. There were 3 teachers and 254 students participated in the practice. Based on the findings of this study, the following conclusions could be drawn:

Firstly, college students' concept image of the fundamental concepts of calculus was one-sided, and some even wrong. Some students couldn't define the limit by correct words. Most of the students usually thought of the slope of the tangent when seeing the derivative, rather than the rate of change. There was confusion in the understanding of the geometrical meaning of differential and linear approximation. Some students know that the definite integral can express the area, but they can't make sure the area of what region; some students did not know which amount was sliced when they calculated the integral.

Secondly, we constructed principles on concept instruction in calculus as follows: (1) Concepts were introduced and demonstrated in a genetic way. (2) To help students understand the concepts by means of geometric or intuitive examples. (3) Paying attention to the elaboration of the relations of the concept between them. The results of teaching experiment showed that the students enrolled in the concept-based learning environment scored higher (M=34.42) than the students enrolled in the traditional learning environment (M=30.27) on the 40 point Conceptual Understanding Subscale and the students enrolled in the concept-based learning environment scored significantly higher (M=48.68) than the students enrolled in the traditional learning environment (M=42.65) on the 60 point Procedural Skill Subscale in the examination.

Equity Issues That (May) Arise in Active Learning Classrooms

Jessica Gehrtz Richard Sampera Jess Ellis
Colorado State University

There is an overwhelming amount of evidence that the incorporation of active learning in the classroom benefits all students and can be especially beneficial for women and underrepresented populations. However, our work is not finished when it becomes an integral part of teaching and learning across the nation. Classroom settings that foster group interaction and collaboration may result in an environment that is even more undermining to underrepresented populations. In this poster we illustrate these potential issues that arose in an abstract algebra course.

Key Words: Equity, Abstract Algebra, Inquiry Oriented Learning

Research clearly indicates that active learning is beneficial for students in undergraduate mathematics courses, especially for students from traditionally underrepresented populations (Freeman et al, 2014; Laursen, Hassi, Kogan, & Weston, 2014). There are a number of evidence-based reasons that active learning classes may support a more equitable classroom. For instance, active learning classes often center around "low floor, high ceiling" tasks which allow for multiple entry points and for students to share their thinking (rather than only correct answers). This provides opportunities for students to see each other struggle and emphasizes the process of learning as well as allowing for a "broadened notion of competence" (Esmonde, 2009). In this poster we present on an Inquiry Oriented Abstract Algebra (IOAA) class that employed these strategies. In addition, the instructor was conscientious concerning equity issues and took active measures to create a classroom in which all students were valued contributors. Despite this, the teacher, a participant observer (TA), and an additional observer became acutely aware of differences in the class relating to participation and the nature of the contributions. In the poster, we use observer field notes and reflections to identify and describe issues related to equity that arose in the IOAA class, and consult video of the class for triangulation. We then consider reasons why such issues arose *despite* the active learning environment and conscientious teaching. Specifically we consider two questions: (1) Were there aspects of this execution of active learning that can account for the equity issues, such as shorter class periods, the teacher's lack of experience with this material, the specific students, etc., or (2) Are there more general aspects of active learning classes that expose equity issues that may not be exposed by lecture?

Conceptual Understanding of Differential Calculus: A Comparative Study

The research community shares a concern for students' conceptual understanding of calculus and commonly advocates for student-centered approaches as a way to promote it. In this study, we investigated the effect of different instructional approaches on 151 undergraduate students' conceptual understanding of differential calculus in context-specific, natural settings. We collected data on the pre- and posttest of the Calculus Concept Inventory in three classes. In one class, most of the time was dedicated to conceptually oriented problem solving, another class implemented practice problems for students, and the third class was a traditional lecture class. The results showed that there was no difference in students' conceptual understanding of differential calculus controlling for their initial understanding. Thus, our findings do not support the research that advocates for student-centered instruction suggesting that the approaches' implementation and contextual differences may be sources of variation in their effectiveness.

Key words: Calculus, Conceptual Understanding, Active Learning, Instruction, Concept Inventory

Mastery of calculus, a desired and necessary student learning outcome (Sofronas et al., 2011), needs to include not only mastery of procedures but mastery of concepts, as well (Zerr, 2010). Multiple attempts have been made to identify instructional approaches that lead to greater conceptual understanding of STEM disciplines (Freeman et al., 2014; Prince, 2004) and specifically of calculus (Laursen, Hassi, Kogan, & Weston, 2014; Rasmussen, Kwon, Allen, Marrongelle, & Burtch, 2006), typically advocating for student-centered instruction. However, those calculus studies either used measures with limited evidence of validity and reliability or aggregated data across classrooms, potentially different in instruction implementation or contextual factors. With our ex post facto study, we aimed to overcome these limitations and investigate students' conceptual understanding of differential calculus (measured by a validated instrument) in three calculus classes with distinct instructional approaches taking contextual factors into account.

Literature Review

The education research community has been working on identifying instructional approaches effective for students' learning and specifically for their conceptual understanding of content for a long time (Prince, 2004). Many researchers have advocated for student-centered instruction as an effective one, typically contrasting it with the teacher-centered instruction. For example, in physics, one of the largest studies was conducted by Hake (1998) where he compared student conceptual understanding in interactive engagement classes and traditional classes. The results of that study suggested that students in the former classes had higher conceptual understanding than students in the latter.

In undergraduate mathematics, several studies exist that explored the influence of student-centered instruction - specifically inquiry-based learning (IBL) - on student conceptual understanding. One of such studies is a study of Laursen et al. (2014) where learning gains of students in IBL mathematics classes were compared to those of students in non-IBL mathematics classes. The results showed that students' cognitive gains in understanding and thinking, among others, were greater in IBL classes than in non-IBL. However, the measurement of learning gains in this study is important to note. The learning gains were self-reported by students, i.e., the gains were students' subjective perceptions of their learning. Perceived learning, though it has its advantages, might not always be an accurate estimation of actual learning.

Another relevant study was conducted by Rasmussen et al. (2006) where students conceptual understanding of differential equations was explored in IBL and traditional classes. The results also supported the effectiveness of IBL. However, several notes need to be made about the measurement of conceptual understanding in this study, as well. First, the validity evidence for the instrument used was limited (Kwon, Allen, & Rasmussen, 2005). Second, the measure was administered only as a posttest assessment (without a pretest) and only to volunteers after the final exam.

Both studies also used data that were aggregated across classrooms. While data aggregation has its pros in terms of increasing sample sizes and, therefore, increasing the power of statistical comparisons, it may have cons, as well. Our main concern is that by considering students from different classes as one sample, important class-level differences may be overlooked. These differences, may contribute to differences in learning outcomes between classes. Examples of such class-level differences may include different quality of teaching of different instructors or different implementation of the same teaching approach.

Due to the limitations of the studies of Laursen et al. (2014) and Rasmussen et al. (2006) discussed above, we decided to explore the effects of student-centered instruction on student conceptual understanding using a validated content instrument, administered during class time at the beginning and end of the semester. We specifically focused on differential calculus as (1) it is one of the fundamental college mathematics courses, and (2) the content measure for this material was already developed and validated. We also decided to consider each class individually to explore the effects of instructional approaches holistically. In this study, we examined two different student-centered instruction types and one traditional instruction type. The decision to study two different student-centered instruction types instead of one is consistent with the suggestions drawn from the meta-analysis of Freeman et al. (2014). This meta-analysis encouraged further research to focus on "second-generation research," which compares courses that differ in active learning implementation, rather than on "first-generation research," which compares active learning courses with traditional ones. The three studied classes are described in the next section.

Methods

Context

Course. The study was conducted in the three course sections of Calculus I, the first course in the calculus sequence. This mainstream course has the traditional material on limits, derivatives, the integral, and culminates in the fundamental theorem of calculus. All three sections met twice a week for a lecture with a professor (1 hour and 50 minutes each) and once a week for a recitation with a graduate teaching assistant (50 minutes). The study was conducted during the same academic year with the data collection in the first two classes done in the fall semester and in the third class in the spring semester.

Lectures. The lecture portion of the first class was taught in an active learning classroom with most of the class time dedicated to conceptually oriented problem solving (COPS) and whole class discussion (the COPS class). The ALT classroom has 8 round tables with 9 seats at each table (a total room capacity is 72). The room also contains flat screen displays (one per table), and whiteboards that cover the walls. In the COPS class, class periods typically started with resolving any questions or problems that students encountered doing homework or that remained from the last class period. The professor would ask students to write their concerns on a whiteboard, and then have a whole class discussion to address the concerns. Then, the professor would lecture for a short period of time (10-20 minutes), followed by student active work that would take the majority of the class time. The active work typically included student group work on worksheets that consisted of conceptually oriented problem sets. The groups were self-selected and included 4-5 students each. The students were also encouraged to work on whiteboards to show their solutions. During this part of the class, the professor and undergraduate learning assistants walked around the classroom and talked to students to monitor their progress and answer or pose questions. If a common question or misconception arose, the professor would often address it via a whole-class discussion. To wrap up the active work, the professor would ask students to do a gallery walk and/or would hold a whole class discussion. At the end of the class, students typically turned in their completed worksheets.

The lecture portion of the second class was taught in a traditional lecture hall and implemented practice problems (PP) during lectures (the PP class). Similar to the COPS class, this class also started with the professor answering student questions. Then, the professor would present new material and work through an example problem. Next, students were asked to solve a similar problem in groups (i.e., their neighbors) or individually, as they preferred. During this part of the class, the professor and learning assistants circulated around the classroom to monitor student progress and answer questions. After most students finished, the professor would write down the solution suggested by the students and then discuss it with the whole class.

The lecture portion of the third class was also taught in a lecture hall but utilized primarily direct instruction (DI), the DI class. This professor prepared handwritten notes of the material (typically, proofs) and projected them on the screen in class. He/she would talk through the projected notes and then show an example problem on the board. This professor also incorporated graded quizzes in class which usually consisted of true-false questions (typically conceptual) to check student understanding of the material. Answers to the quizzes were discussed during the following lecture. In this class, no group work was utilized.

Recitations. Recitations for the COPS and DI classes were taught by the same teaching assistant in a primarily lecture style. This teaching assistant would typically answer student questions, if any, conduct quizzes if required by the professor, and then explain the material and show solutions for example problems. Recitations for the PP class were taught in an active style with most of the class time dedicated to answering students' questions, addressing their concerns, and clarifying misconceptions.

Participants

The three professors who participated in the study were experienced mathematics faculty members with similar goals for Calculus I classes. All of them aimed for students to have a mastery of both concepts and procedures by the end of the course. In addition, all of them wanted students to be actively involved in class and ask questions. The teaching assistants – recitation instructors – were both graduate students studying mathematics. The recitation instructor for the PP class was an experienced teaching assistant; the recitation instructor for the COPS and DI classes was a new teaching assistant at the university where the study was conducted, though he/she had teaching experience at a different institution.

A total of 151 undergraduate students participated in the study (49 in the COPS class, 64 in the PP class, and 38 in the DI class). The students were enrolled in the Calculus I course at a large, suburban public university located on the east coast of the U.S. Student demographic information is presented in Table 1. In the COPS class, most participants were sophomores; in

Table 1
Sample Demographic Information

Characteristic	COPS (N=49)		PP (N=64)		DI (N=38)		Overall (N=151)	
	Frequency	%	Frequency	%	Frequency	%	Frequency	%
Student classification	N=47		N=63		N=37		N=147	
- Freshman	14	29.8%	43	68.3%	16	43.2%	73	49.7%
- Sophomore	21	44.7%	11	17.5%	14	37.8%	46	31.3%
- Junior	5	10.6%	5	7.9%	6	16.2%	16	10.9%
- Senior	7	14.9%	4	6.3%	1	2.7%	12	8.2%

- 3.5 or better	15	32.6%	22	39.3%	6	17.1%	43	31.4%
- 3.0 up to 3.5	17	37.0%	23	41.1%	10	28.6%	50	36.5%
- 2.5 up to 3.0	11	23.9%	9	16.1%	11	31.4%	31	22.6%
- 2.0 up to 2.5	3	6.5%	2	3.6%	8	22.9%	13	9.5%
Gender	N=45		N=63		N=37		N=145	
- Male	23	51.1%	40	63.5%	25	67.6%	88	60.7%
- Female	22	48.9%	23	36.5%	12	32.4%	57	39.3%
Race/Ethnicity	N=44		N=62		N=37		N=143	
- White	23	52.3%	33	53.2%	18	48.6%	74	51.7%
- African-American	2	4.5%	4	6.5%	7	18.9%	13	9.1%
- Hispanic	4	9.1%	4	6.5%	2	5.4%	10	7.0%
- Asian	13	29.5%	16	25.8%	7	18.9%	36	25.2%
- American Indian or Pacific Islander	0	0%	0	0%	1	2.7%	1	0.7%
- Other/Mixed	2	4.5%	5	8.1%	2	5.4%	9	6.3%
Age	M=20.33 (SD=3.46); N=45		M=19.02 (SD=2.06); N=61		M=20.11 (SD=3.04); N=37		M=19.71 (SD=2.87); N=143	

the PP class, the majority were freshman; in the DI class, freshman and sophomore students were enrolled in about the same proportion. Students' GPAs (self-reported) in all classes varied greatly. In terms of gender, in the COPS class, about a half of students were male, while in the PP and DI classes, the majority of students were male. Students also varied in race and ethnicity. In all classes, about a half of students were White and about a quarter were Asian. Notably, the DI class had more African-American students than the other two classes. Lastly, in the PP class, students were, on average, 19 years old; in the COPS and DI classes, they were, on average, 20 years old.

Procedure

The Calculus Concept Inventory (CCI; Epstein, 2007), a measure of conceptual understanding of differential calculus, was administered in all three classes at the beginning and end of the semester during recitations. Additionally, at the end of the semester, students were also asked to complete a demographic form. Students received a small amount of extra credit for participating in the study. They also received their individual scores on the inventory. The instructors received only class average scores. After the semester was over, the instructors also participated in interviews, during which they were asked mainly about their teaching practices in the classes in question and their teaching philosophies.

Results

Data Exploration

We computed descriptive statistics of CCI scores for each class measured at each point of time (the beginning and end of the semester). The averages and standard deviations are presented in Table 2. First, we were interested in whether students in each class showed growth over time. To answer this research question, we conducted three dependent samples t-tests with a Bonferroni correction ($\alpha=0.017$). The results revealed a significant effect of Time for the PP class, $t(63)=3.303$, $p=0.002$, but not for the COPS class, $t(48)=2.165$, $p=0.035$, or for the DI class, $t(37)=2.371$, $p=0.023$.

Next, we wanted to know if students in the three classes differed in their conceptual understanding on the pre- and posttest. To answer this research question, we conducted two ANOVA tests with a Bonferroni correction ($\alpha=0.025$). The results showed a significant effect of Class for both the pretest ($F(2,148)=5.466$, $p=0.005$) and the posttest ($F(2,148)=5.700$, $p=0.004$). Multiple comparisons – Tukey HSD tests – revealed a significant difference between the PP and COPS classes ($p=0.013$ for the pretest; $p=0.012$ for the posttest) and between the PP and DI classes on the pretest only ($p=0.017$).

Table 2
Descriptive Statistics for CCI

	Mean (SD)			
	COPS (N=49)	**PP (N=64)**	**DI (N=38)**	**Total (N=151)**
Pretest	6.43 (3.03)	8.06 (3.18)	6.37 (2.56)	7.11 (3.08)
Posttest	7.33 (3.60)	9.28 (3.77)	7.37 (3.11)	8.17 (3.66)

Differences in Conceptual Understanding between Classes over Time

To determine whether there was a difference in student conceptual understanding of differential calculus between classes over time, we conducted a mixed design ANOVA with Time as a within subjects factor and Class as a between subjects factor (see Figure 1). The results indicated a main effect of Time (F(1,148)=19.160, p=0.000), i.e., students' conceptual understanding, averaged across classes, was higher at the end of the semester (M=7.11; SD=3.08) than at the beginning (M=8.17; SD=3.66). The results also showed a main effect of Class (F(2,148)=6.811, p=0.001). Multiple comparisons – Tukey HSD tests – revealed that students in the PP class had significantly higher conceptual understanding, averaged across time, than students in the COPS (p=0.005) or DI (p=0.009) classes. No interaction effect between Time and Class was found (F(2,148)=0.187, p=0.830). Thus, the changes in students' conceptual understanding in all three classes were not significantly different from each other.

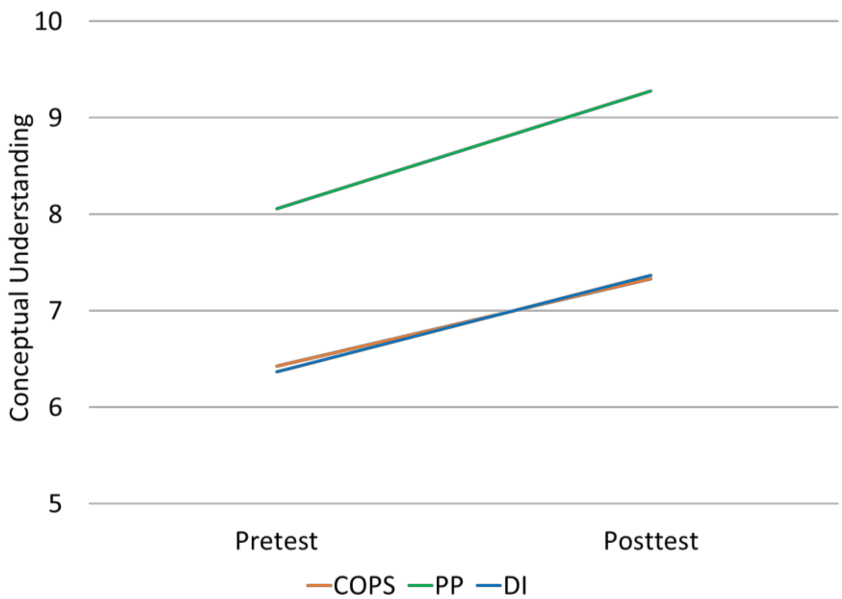

Figure 1. Pretest and posttest means for each class

Differences in Conceptual Understanding at the End of the Semester Controlling for Initial Understanding

To determine whether students differed in their conceptual understanding of differential calculus at the end of the semester controlling for their initial understanding, we conducted an ANCOVA test (see Figure 2). The results showed no difference between the classes in students' conceptual understanding at the end of the semester controlling for their initial understanding, F(2,147)=1.065, p=0.347. The adjusted means were as follows: 7.837 (SE=0.398) for the COPS class, 8.561 (SE=0.353) for the PP class, and 7.924 (SE=0.452) for the DI class.

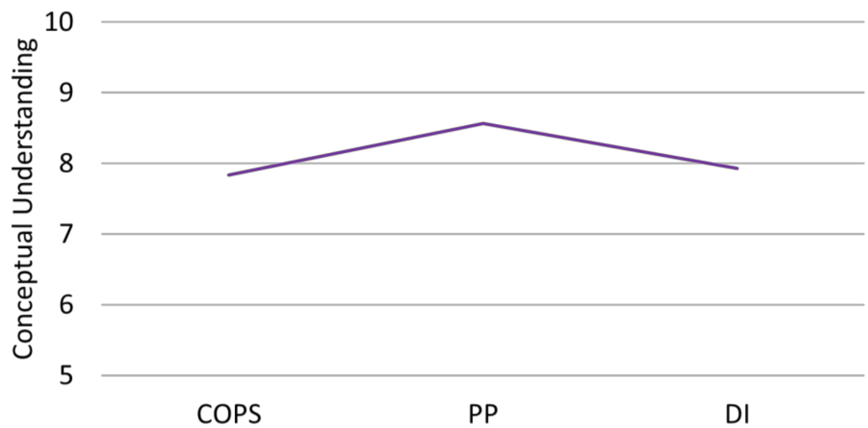

Figure 2. Adjusted posttest means for each class

Discussion

Our findings suggest that students' conceptual understanding of differential calculus is independent from the type of instruction when (1) conceptual understanding is measured by a validated, content instrument, and (2) the study is context-specific, i.e., when each class is considered individually instead of averaging across multiple classes. These nuances may explain why our results appeared to be different from the results of Laursen et al. (2014) and Rasmussen et al. (2006). In other words, implementation characteristics of a particular approach by a particular instructor in a particular course offering may lead to different levels of conceptual understanding and, therefore, need to be taken into account.

Among advantages of the study, we consider its ex post facto design, as no intervention was made. We aimed to explore the effects of teaching approaches in the most natural environment possible, and, therefore, chose to investigate the effects of the approaches typical to the instructors. Thus, this design provides a comprehensive picture of instruction implementation, where all elements of the instructional approaches are considered together. At the same time, a comprehensive picture of instruction has the disadvantage of making those elements with the most influence on the outcome challenging to identify. Therefore, future research should explore more context specific variations in approaches' implementation to determine potential commonalities between the effective ones. Another disadvantage of our ex post facto, context-specific design is a possibility for confounding variables to occur, as no control over the approaches is used. For example, the direct instruction in the recitations of the COPS class may have cancelled out the effect of conceptually oriented problem solving in the lecture periods. Finally, our study design substantially limits the generalizability of the findings.

Variations of College Algebra Instructors' Presentations of the Mathematics: The Case of Solving Quadratic Inequalities

Claire Gibbons
Oregon State University

The mathematical content presented during instruction has been shown to have an effect on student achievement. To investigate the content presented by instructors during College Algebra instruction, the Mathematical Quality of Instruction (MQI) observation protocol was applied to video recordings featuring instructors' presentations of examples of solving quadratic inequalities. Wide variation was observed in the solution methods chosen by instructors and in the rationale provided for choosing a particular procedure. This poster summarizes the variation in the mathematics that was observed and the ability of the MQI protocol to capture this variation.

Key words: College Algebra, Instructional Activities and Practices, Classroom Observations

College Algebra is cited as one of the most failed courses at universities across the country (MAA, 2007). It is difficult to pinpoint the particular causes for high failure rates in College Algebra, but the literature provides some insight into the relationship between teaching and student understanding: researchers agree that quality of the content offered during instruction is linked to student success (Porter, 2002), and how mathematical content is presented has an effect on student understanding and comprehension (Seidel & Shavelson, 2007; Weinberg, Wiesner, & Fukawa-Connelly, 2014).

Informed by previous observations of wide variation in the mathematics offered during College Algebra instruction (Beisiegel, Gibbons, & Paul, 2016), a study was designed to further investigate the qualities of the mathematics presented by College Algebra instructors. The purpose of the study was to identify what variation in the mathematics occurred in the lessons and how well the Mathematical Quality of Instruction (MQI, Learning Mathematics for Teaching Project, 2011) observation protocol captured this variation. Four College Algebra instructors' lessons at a large university were recorded regularly throughout the duration of the course. To focus on the mathematical content offered during instruction, video clips were chosen from the set of recordings that featured instructors' presentations mathematical examples. In particular, lesson clips containing teachers' presentations of solving quadratic inequalities were selected to allow for comparison between the mathematical content offered during instruction.

The MQI protocol was used as a lens and framework for observing the selected video lessons. This instrument was selected because of its attention to the interactions between the instructor and the content. In particular, one of the MQI dimensions, *Richness of the Mathematics*, is well-suited to capture the mathematics offered during a lesson. This dimension includes codes such as *Explanations, Linking Between Representations,* and *Mathematical Sense-Making*. Two researchers viewed and scored the selected College Algebra video clips using the *Richness of the Mathematics* dimension of the MQI.

Wide variation in the mathematics was observed. First, most instructors presented only one solution method, showing either the graphing method or the table/number line procedure; this was well-captured by the MQI. Second, the instructors differed in their decision of when to convert the inequality to an equality, and this decision affected their choice of solution method; the MQI did not attend to this variation. These findings, along with examples of the procedures observed for solving quadratic inequalities, will be presented in the final poster.

Investigating Prospective Teachers' Meanings of Covariation Before and After Calculus Coursework

Roser Giné
Lesley University

This study seeks to uncover prospective teachers' construction of mathematical meanings after engaging in a two semester calculus sequence. The research question for this work is: How might the learning of calculus impact prospective teachers' mathematical meanings of functions, and in particular, prospective teachers' meanings of covariation? The purpose of this study is to understand whether, and if so, how, the study of calculus is useful for prospective teachers, and to place a lens on meanings that students develop on covariation, a concept that permeates the secondary school mathematics curriculum.

Because not all secondary school teachers will teach calculus or more advanced mathematics, the importance of success in calculus remains a question for students. Even when it is accepted that calculus may be useful, learning more advanced mathematics continues to be questioned, especially as the undergraduate mathematics courses increase in levels of abstraction. At the teaching university where this study takes place, this is a relevant issue because students who major in mathematics will become middle or high school teachers. This study may contribute to our understanding of the need of calculus as prerequisite knowledge for teaching.

The courses in which this study takes place include Calculus 1 and 2. The site of this study is a small private university with a primary goal of training prospective teachers at the undergraduate and graduate levels. Students who enroll in the calculus sequence are undergraduate double majors in mathematics and in education. Because I teach both courses as well as the mathematics methods courses for middle and high school teaching, I have a unique opportunity to get to know students well as they form mathematical meanings and acquire pedagogical content knowledge in mathematics.

Research Design and Theory

The study is taking place in two calculus courses during the 2016-17 academic year (Calculus 1, Fall 2016; Calculus II, Spring 2017). The first stage of the project involves participants' completion of an assessment that measures meanings students form with respect to specific mathematics concepts related to covariation. Items in this instrument were developed by Dr. Patrick Thompson (2016) and his research team through Project Aspire (*Mathematical Meanings for Teaching secondary mathematics).* This instrument has been designed to assess pre-service and current teachers' mathematical meanings for teaching secondary mathematics.

The second part of the project consists of administering the same assessment tool at the end of Calculus I to understand whether there have been any changes in students' meanings. At this time, I will interview students to check my interpretations of their written work and to allow students to elaborate on their responses. Students will also be asked to reflect on any changes in their responses on the two completed assessments. Students who continue to Calculus II will revisit this assessment at the end of the semester in Spring 2017, as the research cycle is repeated. Theoretical lenses used to guide this work include theory of meanings (Thompson, Carlson et al., 2014), as well as the concept of backward transfer of mathematical meanings that may be productive for teaching (Hohensee, 2014).

Improving Undergraduate STEM Education Through Adjunct Mathematics Instructor Resources and Support (IUSE-AMIRS)

Amir H. Golnabi, Eileen Murray and Zareen G. Rahman
Department of Mathematical Sciences, Montclair State University

The Improving Undergraduate STEM Education Through Adjunct Mathematics Instructor Resources and Support (IUSE-AMIRS) project aims to measure the impact of course coordination and support on adjunct mathematics instructors' knowledge, instructional practices, and job satisfaction. In this project, we use the organization and coordination of Precalculus with the goals of 1) implementing best practices for learning and instruction, 2) improving instructor knowledge, and 3) creating a professional learning community. As a part of this project we measure the impact of Precalculus course coordination and adjunct support on student achievement, leading to student retention in STEM majors. We believe our initiative can be implemented in other departments and institutions that have a similar need for adjunct instructors in math courses with multiple sections.

Key words: [Adjunct, Precalculus, Course Coordination, Professional Learning Community]

Students' persistence in continuing to pursue STEM degrees is heavily influenced by their classroom experiences, especially in the first year mathematics courses (Hutcheson, Pampaka, & Williams 2011; Pampaka, Williams, Hutcheson, Davis, & Wake, 2012). In this regard, the quality of pedagogy can make a big difference in the retention of STEM students beyond beginning mathematics. There is a growing body of research aimed at graduate teaching assistants touting benefits of targeted professional development (PD) (DeLong & Winter, 2001), but much needs to be done with respect to the growing population of adjunct instructors (Austin & Sorcinelli, 2013).

To better address this challenge at our institution, we have developed the project *Improving Undergraduate STEM Education Through Adjunct Mathematics Instructor Resources and Support (IUSE-AMIRS)*. Through this project, inaugurated in summer 2016, we are creating a model for implementing best practices for learning and instruction through adjunct instructor development and support. We have incorporated instructor supports backed by research and provided course coordination of Precalculus to begin a departmental transformation that will ultimately support students in this early mathematics course. Our course coordination includes having a course coordinator, two dedicated Precalculus tutors, and a common pacing guide, syllabus, assessments and rubrics for all instructors. In addition, we provided a summer workshop for Precalculus adjunct faculty and tutors, during which the participants received a comprehensive training on our recently adapted curriculum. This workshop was part of a larger PD effort that has continued throughout the semester through online weekly meetings. These meetings form the foundation of a professional learning community (PLC) aimed to provide content and instructional support for the instructors. Adjunct faculty highly regard such supports as they help improve teaching and integrate adjuncts into their institutions (Lyons & Burnstad, 2007; Bowers, 2013). To better understand the impact of these supports, we have been collecting a wide range of data from both adjuncts and students including instructor and student surveys, instructor interviews and classroom observations. We are measuring the effects of IUSE-AMIRS on Precalculus instruction and instructors since we strongly believe they will positively impact student achievement, thus leading to increased retention in STEM majors.

Quantitative Learning Centers: What We Know Now and Where We Go from Here

Melissa Haire
University of Connecticut

Given the recent national and international events the need for developing students' quantitative literacy (QL) has taken center stage in the mathematics education community. We are interested in investigating the existing support structures and the impact they have on the development of QL. The purpose of this study is to investigate the literature on quantitative learning centers at institutions of higher education. This poster will discuss the themes that emerged from a qualitative analysis of these works, highlighting what we currently understand and identifying opportunities for growth.

Key words: quantitative learning centers, quantitative literacy, literature review

A desire for quantitative literacy (QL) in college graduates has caused institutions of higher education (IHE) to form quantitative course requirements for their students. These requirements are intended to develop QL, "the ability to adequately use elementary mathematical tools to interpret and manipulate quantitative data and ideas that arise in an individual's private, civic, and work life" (Gillman, 2011). This ability is desired across fields, not just in the sciences, and employers search for candidates who have these reasoning skills. Out of a need for student support, quantitative learning centers (QLCs) have been founded at IHEs across the country. The centers seek to provide support for students enrolled in classes with a quantitative focus through a variety of programs, including drop in tutoring (Black, 2016), scheduled one-on-one tutoring (Mayes, 2016), and review sessions (Grant, 2016). Their ability to effectively support students and their impact on quantitative literacy is something that has not been broadly assessed. The purpose of the study presented in this poster is to investigate the literature on QLCs at IHEs in order to synthesize what we currently understand and identify opportunities for growth.

Methods

In order to address our purpose, a literature review was conducted. The literature included in the review were accessed through ERIC, PsychInfo, and Google Scholar using the keywords "learning center," "mathematics," "undergraduate," "help-seeking," and "peer-tutoring," as well as variations on the term learning center, such as "support center" and "help center". Works that focused on undergraduate student use of a help center for mathematical support were included. A content analysis was performed on the resulting literature to identify emerging themes.

Findings

This poster will elaborate on the results of the analysis. Most of the literature focuses on help seeking behaviors of students, an individual center's effectiveness in meeting its' objectives, or some combination thereof. The following themes emerged: 1) the academic need of students attending the QLCs (Xu, Hartman, Uribe, & Mencke, 2001), 2) the discipline of the students attending the QLCs, and 3) the center as a physical space for students to work together (Solomon, Croft, & Lawson, 2010). Opportunities for growth will also be discussed.

Characterizing Normative Metacognitive Activity During Problem Solving in Undergraduate Classroom Communities

Emilie Hancock
University of Northern Colorado

Mathematical problem-solving research studies abound, and a significant portion express the role of metacognition as an underlying component of the problem-solving process. Unfortunately, much of the research on metacognition in mathematics does not describe the explicit role metacognition plays during the problem-solving process. Moreover, metacognitive interventions are typically disconnected from natural mathematical activity and discourse within a classroom community. The purpose of this qualitative study is to characterize sociomathematical metacognitive norms within an introductory number theory course intended for pre-service teachers. Utilizing Vygotsky's conception of language-based, mediated action and activity theory as an analytic framework, this study aims to test the use of these methods to investigate "real-time" metacognition with explicit focus on the broader classroom community. Attention is paid to the dynamic relationship between the teacher and students.

Key words: Activity Theory, Metacognition, Problem Solving, Sociomathematical Norms

There has been increased focus to develop problem-solving skills and related 'habits of mind' (e.g., CBMS, 2012; MAA CUPM, 2015). Metacognition is one such habit of mind (Costa & Kallick, 2000), and problem-solving frameworks identify metacognition as a core component of the problem-solving process (e.g., Carlson & Bloom, 2005; Schoenfeld, 1985). Although problem-solving *frameworks* have been heavily studied, research does "not yet offer a *theory* of problem solving" (Schoenfeld, 2007, p. 539, emphasis added). Particularly, metacognition remains undertheorized and under-studied in its application to classroom communities (Carroll, 2008), especially at the undergraduate level (Dumford, Cogswell, & Miller, 2016). Much of the research to date has not described the *explicit* role metacognition plays during the problem-solving *process* (Carlson & Bloom, 2005). A shift of focus to a process view of "real-time" metacognition necessitates an investigation "in the context of natural purposeful activity" (Neisser, 1976, p. 7). Specifically, there is limited research documenting the normative metacognitive behaviors during problem solving of classroom communities. Understanding how metacognition manifests itself in such an environment could help to develop techniques to foster metacognition as normative behavior within the mathematics classroom.

As such, this research aims to address the following research question: *How do sociomathematical metacognitive norms during problem solving develop in an undergraduate mathematics community of practice?* Vygotsky's (1978, 1986) social constructivism is adopted as the theoretical lens and Ernest's (2010) model of sign appropriation/use is incorporated to highlight the reflexive nature between individual and collective. Activity Theory (Engeström, 1987; Leont'ev, 1979) is utilized as a framework to investigate these interactions, as it provides concrete language to describe broader social factors potentially influencing metacognitive norms. To test the feasibility of activity theory, I conducted a qualitative pilot study in a number theory course designed for pre-service teachers. This poster will present analysis, results, and an evaluation of methodological tools. The pilot study also informed data collection and analysis for my dissertation study. Modifications and initial results of this current study will also be shared.

Research in Courses before Calculus Through the Lens of Social Justice

Shandy Hauk	Allison Toney	April Brown	Katie Salguero
WestEd	U. North Carolina Wilmington	U. Mary Hardin Baylor	WestEd

The terms equity, diversity, inclusion, and social justice have entered the research lexicon. This theoretically-focused poster presents some recent policy efforts to generate a shared meaning for "social justice" in mathematics education and offers a theoretical framework for making sense of (and making sense with) intercultural interactions as an essential component of rigorous research. The poster includes illustrations for how to use these tools for thinking through and talking about research. To anchor discussion, we focus on research on teaching and learning in the courses before calculus (e.g., algebra, mathematics for pre-service elementary teachers).

Keywords: Social justice, Research in undergraduate mathematics education

This year two organizations, TODOS: Mathematics for All and the National Council of Supervisors of Mathematics (NCSM), issued a position paper, *Mathematics Education Through the Lens of Social Justice: Acknowledgement, Actions, and Accountability*. In it, social justice includes "fair and equitable teaching practices, high expectations for all students, access to rich, rigorous, and relevant mathematics, and strong family/community relationships to promote positive mathematics learning and achievement." Underlying all of these is an understanding of how power, privilege, and oppression contribute to and maintain an inequitable learning system.

As people trained in research in undergraduate mathematics education, we know that our work is about more than identifying a problem and solving it. As citizens of a first-world country in the 21st century, we are keenly aware of societal injustice. And, as a community, we have an opportunity to guide how social justice issues are explored and addressed in collegiate mathematics education research. The opportunity has been there for a while (e.g., Aguirre & Civil, 2016; Adiredja, Alexander, & Andrews-Larson, 2016; D'Ambrosio et al., 2013; Davis, Hauk, & Latiolais, 2010; Gutiérrez, 2013; Nasir, 2016).

According to the TODOS-NCSM position paper, three conditions are necessary to establish just and equitable mathematical education for all learners: (1) acknowledge that an unjust social system exists, (2) take actions to eliminate inequities and to establish effective policies, procedures, and practices that ensure just and equitable learning opportunities for all, and (3) be eager for accountability so changes are made and sustained. How do we increase researcher capacity to do these three things? We must address our own needs – as researchers – for language, concepts, and awareness-building. This will support us in the inevitable struggle to gain and use pertinent understandings related to social justice. The poster offers key ideas and examples from intercultural development (Bennett, 1993; 2004).

Questions driving poster conversation: What is the role of social justice in research in collegiate mathematics education? When we conduct research in the U.S. we make decisions about who participants are – what would be different if decisions in the projects we are in the midst of or just finished had included overt and repeated attention to the three tenets? How might research be framed to provide evidence that supports action to eliminate an inequity? How do we do that? How might the research design or the analysis be different if the results of the work are to be held accountable by research peers *and* judged in a court of stakeholder opinion that values equity as much as excellence in mathematics education? What are some of the concepts and language from intercultural development that can help us address these questions?

Exploring the Content–Specific Mathematical Proving Behavior of Students: Opportunities for Extracting and Giving Mathematical Meaning

Sarah Hough
University of California, Santa Barbara

Monica Mendoza
University of California, Santa Barbara

Alex Sacharuk
University of California, Santa Barbara

William Jacob
University of California, Santa Barbara

Studies were conducted to explore the efficacy of a non-traditional transition to upper division proof course using Freudenthal's notion of mathematizing *as a framework. Classroom video data and student work were analyzed using grounded theory methodology. Results indicated that students in the non-traditional course developed better understandings of the role of definition and counter example in proof through engagement in meaning making activities that fostered both the semantic and structural aspects of proof writing.*

Key words: Transition to Proof, Mathematizing, Grounded Theory

These studies were conducted in a large public research university on the West Coast. Participants were 109 undergraduates enrolled in three sections of a transition to upper division mathematics course. Thirty six students were enrolled in a pilot course that had students use first-order languages and their semantics to investigate truth/falsity in a variety of structures as a basis for developing mathematical reasoning. Thirty seven students were enrolled in a traditional section of the course. The remaining students were enrolled in a revised non-traditional course.

Study 1

We asked: What landmark thinking strategies (such as acting upon definitions) occur along the way to successful proof at the collegiate level? All spring non-traditional course sessions and a sample of five traditional course sessions were observed, audio-taped and transcribed. Student work was collected. Data were analyzed using the constant comparative methods of Strauss and Corbin (1998). A learning trajectory of the ways in which students' understanding of the big ideas of mathematical proof developed over time was constructed.

Study 2

We asked: How do final exam responses of students in this non-traditional course compare to those students who took a traditional proof course? Common exam items were coded numerically and qualitatively using the understandings of proof landscape above. Non-traditional students did better on constructions of objects using operable definitions (Bills & Tall, 1998).

Study 3

We asked: In what ways did the revised non-traditional course support the development of understanding of proof? Transcripts of classroom activity and student written proofs were analyzed. Cases of student proof writing in contexts illustrated ways in which the course allowed both formal and natural strategies can be used to engage in meaning making activities (Pinto & Tall, 1999). Future research should address how such development can be fostered in a traditional setting.

Questioning Assumptions about the Measurability of Subdomains of Mathematical Knowledge for Teaching (MKT)

Heather Howell	Yvonne Lai	Heejoo Suh
Educational Testing Service	University of Nebraska-Lincoln	Michigan State University

The goals of undergraduate mathematics teacher education include developing teachers' content knowledge and pedagogical content knowledge. As a strategy for conceptualizing and assessing these forms of knowledge, researchers have further divided these domains. However, it has proven difficult for research groups to create tasks to reliably capture a specific domain without involving other domains, leading them to question these subdomains. We argue that tasks' inability to measure subdomains separately is not evidence that tasks or theory are flawed. Instead, we propose that assessment tasks are effective in measuring MKT when they represent the work of teaching, rather than when they isolate subdomains. To make this argument, we use an analysis of teachers' thinking in response to nine MKT assessment tasks. Though prior work provides evidence that the tasks measure MKT, the tasks cannot be meaningfully parsed into the subdomains of multiple established MKT frameworks.

Key words: Mathematical knowledge for teaching, pedagogical content knowledge

A common viewpoint in undergraduate mathematics teacher education is that content knowledge is the domain of mathematical knowledge for teaching (MKT) to be taught primarily in content courses and pedagogical content knowledge (PCK) is the domain to be taught primarily in methods courses. Assessment development efforts have focused on measuring content and PCK and theoretically derived sub-components of each separately, with factor analyses confirming (or disconfirming) hypothesized subdomains (e.g. Hill, Schilling, & Ball, 2004; Floden & McCrory, 2007; Herbst & Kosko, 2014; Krauss, Baumert, & Blum, 2008). This approach has yielded at best mixed results (Hill, 2016).

While category theory suggests that factor analysis is a reasonable approach for evaluating theoretical subdomains whose purpose is to inform assessment domain sampling (Kaarstein, 2014), we counter that this need not be the purpose of a theoretical framework. Failure to measure subdomains in isolation does not alone imply that assessment tasks or theory are flawed.

To illustrate this argument, we present an analysis of nine assessment tasks previously shown to assess MKT (Howell, Lai, & Phelps, 2016) across five established frameworks for MKT (Ball, Thames, and Phelps (2008), KAT, COACTIV, TEDS-M, and MUST). Prior work generated knowledge maps for each task specifying the knowledge measured, and verified their accuracy in capturing reasoning in response to the tasks. In the present study, the tasks themselves became the data; we coded them by subdomains of each of the five specified frameworks. Eight of the nine tasks measured multiple subdomains across multiple frameworks, substantiating our hypothesis that tasks that measure MKT well overall may simply not be amenable to the measurement of isolated subdomains of MKT.

Implications of this study substantiate concerns in the field of meaningful inconsistency in the conceptualization and description of MKT, but may temper critiques of theoretical frameworks based on assessments like those studied. A theorized subdomain need not be distinctly measureable in isolation from the larger construct to be useful in informing the field's thinking, pushing policy, or as a heuristic for organizing teacher supports.

Data Cleaning in Mathematics Education Research: The Overlooked Methodological Step

Aleata Hubbard
WestEd

The results of educational research studies are only as accurate as the data used to produce them. Drawing on experiences conducting large-scale efficacy studies of classroom-based algebra interventions for community college and middle school students, I am developing practice-based data cleaning procedures to support scholars in conducting rigorous research. The poster identifies common sources of data errors in mathematics education research and offers a framework and related data cleaning process designed to address these errors. I seek feedback on the framework and discussion around data cleaning techniques used by other RUME scholars in their research and in the preparation of future researchers.

Key words: Research methodology, Efficacy studies, Algebra

Screening data for potential errors and ensuring anomalies do not influence analyses is an essential step of the research cycle (Wilkinson, 1999). Despite the importance of data cleaning in rigorous research practice, most methodology courses only give cursory attention to the topic (Osborne, 2012). I am developing practice-based data cleaning processes to support scholars in implementing rigorous research in classroom settings. Specifically, I ask: (1) What are the sources of data errors in educational research studies conducted in authentic mathematics learning environments? and (2) How can a data cleaning process be designed to consistently produce accurate, reliable, confidential, and timely datasets?

The framework presented in this poster was informed by two large-scale efficacy studies. Study A was a three-year, nationwide study involving over 10,000 middle school students and 180 mathematics teachers. Study B is a two-year, statewide study of community college elementary algebra courses. During Study A, a list of data related challenges and their associated resolutions was compiled and used to inform the data cleaning process currently used in Study B. Four common sources of data errors appeared in both studies: variations in assessment administration; participant mobility; multiple participant names; and use of external vendor systems. The following data cleaning process was developed to identify and repair these issues:

1) Create visually distinct instrument forms; indicate administration format in final data sets;
2) De-identify study data as early as possible in the data collection process;
3) Compare record counts against participant lists to identify missing and extra records;
4) Check data files for missing values, missing data columns, and extra data columns;
5) Check identifier columns for duplicate values;
6) Transform categorical values into pre-determined standard values;
7) Flag records with errors;
8) Establish a review process so data cleaning work can be checked by another person.

The data cleaning process and taxonomy of common data error sources offered here can provide a framework for other researchers to evaluate their current data management strategies. Furthermore, I hope this work can spark discussion around more comprehensive methodology training for future researchers. I also seek feedback on ways to communicate the process and information on how others in the RUME community handle data cleaning issues in their work.

Calculus Instructor Beliefs Regarding Student Engagement

Carolyn James
University of Portland

Student engagement has been identified as a critical element in student learning of mathematics, yet most university math classrooms have very little active content (Olson & Riordan, 2012). Guided by Schoenfeld's (2011) framework for instructional decision-making, this study examines calculus instructor beliefs about, purposes for, and barriers against student engagement. Results indicate instructors utilize active learning primarily for formative assessment and improving student dispositions with development of understanding as a secondary, implicit goal.

Key Words: Active learning, Student Engagement, Teacher Beliefs, Calculus Instruction

The evidence is overwhelming that active approaches to mathematics instruction are more effective than traditional lecture (e.g. Bressoud et al., 2013; Freeman et al., 2014; Kogan & Laursen, 2014). However, effective instructional changes must be in alignment with teacher beliefs (e.g. Henderson, 2011). Schoenfeld's (2011) framework for instructional decision-making served as the theoretical framework to guide this study. According to this framework, a teacher's decisions are based on their goals, orientations (which include beliefs), and resources. In order to enact instructional change, it is necessary to build upon existing teacher beliefs regarding student engagement. Research questions include:

1) How do calculus instructors view student engagement in their classes?
2) What is the purpose of student engagement?
3) What are some of the barriers for student engagement? How are they overcome?

This study is the first stage of a multi-stage project aimed at shifting departmental culture toward more active mathematics instruction. In this study, four calculus instructors at a small (< 8,000) university were interviewed regarding their beliefs about student engagement, its purposes, and potential barriers for implementation. The interviews were transcribed and analyzed according to Braun and Clark's (2006) thematic analysis, which resulted in a set of themes. Results are summarized for brevity.

Results from this study indicate that this group of calculus instructors recognized the importance of student engagement, and offered many forms of student engagement, such as asking and answering questions, and group-work. All instructors recognized the limitations of lecture in terms of student engagement, but all saw it as a necessary part of teaching mathematics. They also recognized most students' discomfort while participating in whole-class relative to participating in small groups and addressed this discomfort. Purposes of student engagement included formative assessment, improved student communication, improved mathematical dispositions, and improved relationships. Notably, learning was not listed as one of the primary purposes; instead it was mentioned implicitly when describing how student engagement can be a means for improving test scores, allowing more processing time, or creating a more personal connection to the material. If reform efforts seek to increase active learning through student engagement, these beliefs will need to be addressed.

Students' Strategies When Matching a Function's Graph with the Graph of its Derivative

Nathan Jewkes
University of Missouri

Amy Dwiggins
University of Missouri

This study explores a fundamental calculus connection between a function and its derivative by examining and categorizing strategies students use when matching a function's graph with the graph of its derivative. Through interviews with four students using multiple choice (MC) tasks, we wanted to explore whether common mistakes and students' strategies when drawing the graph of the derivative of an original function are consistent with those found when using open-ended tasks. While tendency to find an equation of the graph in order to differentiate was observed, simple replication of the original function was not observed.

Keywords: Calculus, Derivative, Graph, Function

Given the graph of a function, there are several strategies students use when asked to draw the derivative. One common, correct strategy is to find points of local extrema of the function and match those points with the zeros of the derivative. Another correct strategy is to identify intervals on which the function is increasing and decreasing and match those intervals with places where the derivative is above and below the x-axis, respectively. Students often employ inefficient or altogether incorrect strategies. Some of these strategies include simple replication of the original function when asked to draw the derivative (Nemirovsky & Rubin, 1992) and students' tendency to find an equation of the graph of the function before differentiating (Ferrini-Mundy & Graham, 1994; Asiala, Cottrill, Dubinsky, & Schwingendorf, 1997). However, online assessment programs draw upon MC items to assess student understanding of the connections between graphs of functions and their derivatives creating a potentially different set of challenges. Our study explores whether common mistakes and strategies students use on MC tasks are consistent with those when given open-ended tasks.

For this study, clinical interviews (Ginsburg, 1997) using MC tasks were conducted with four current calculus students at a Midwestern university. Tasks provided students with graphs of functions, asked students to choose the correct derivative graphs, and describe their thinking about their choice. Student strategies were varied. One student focused on locations of local extrema as zeros of the derivative as well as intervals of increasing and decreasing to match places where the derivative was above or below the x-axis. A second student incorrectly attempted to use combinations of first and second derivative concepts, while consistently ruling out a simple replication option. While the two remaining students wanted to find the function's equation in order to differentiate, they were equally focused on how the end behavior of the function determines the end behavior of the derivative graph.

While some common mistakes and strategies used on these MC tasks were observed, the mistake of simply replicating the function was not observed. Common mistakes and strategies observed in this study can inform the development and evaluation of MC tasks for assessments. For university math departments that depend on MC tasks to assess student understanding of the graphical connections between a function and its derivative, using assessment items that reflect conceptual connections between functions and their derivatives rather than surface-level characteristics is essential to increasing one's confidence in student understanding.

Situational Characteristics Supporting Instructional Change

Estrella Johnson & Rachel Keller
Virginia Tech

Instructional practice and decision-making are influenced by a myriad of factors, with both individual instructor characteristics (e.g., beliefs about teaching and learning and personal experience) and departmental/institutional characteristics (e.g., resources and supports) shaping day-to-day teaching practices. However, little is known about which factors are the most influential and how those factors influence pedagogy. In this project, in an effort to identify commonalities in situational contexts and better understand how these commonalities support non-lecture instructional approaches, we look at interviews from fourteen mathematicians who volunteered to implement inquiry-oriented instructional materials.

Key words: instructional practice, contextual factors, departmental influences

There is a growing body of research indicating that traditional instructional methods (e.g., lecture) is both prevalent in undergraduate mathematics education and problematic in terms of STEM retention and student outcomes. Lecture is the most frequently reported instructional approach in undergraduate mathematics – with about 65% of mathematics faculty reporting extensive lecturing in all or most of their courses (Eagan, 2016). Such lecture-based pedagogy has been labeled problematic for undergraduate learning, persistence, and success. For instance, a meta-analysis by Freeman et al. (2014) found that in undergraduate STEM courses "active learning leads to increases in examination performance that would raise average grades by a half a letter" (p. 8410), and that students in lecture classes are 1.5 times more likely to fail than those in classes where active learning methods are used. The growing tension between the predominant instructional practices of mathematics faculty and the growing body of research on the benefits of active learning gives rise to the need to better understand the factors that contribute to pedagogical decision-making and the factors that influence instructional change.

In order to understand instructional practice and decisions, Henderson and Dancy (2007) made the argument for investigating both individual and situational characteristics. While individual characteristics are often the focus of similar research, a recent research report on abstract algebra instructors found individual factors, such as years of teaching experience and previous experience teaching abstract algebra, failed to predict pedagogical format (Fukawa-Connelly, Johnson, & Keller, 2016). Thus, here we decided to focus on situational characteristics by analyzing interviews from fourteen mathematics instructors who volunteered to implement an inquiry-oriented set of instructional materials. By identifying commonalities in departmental contexts, specifically for instructors who are actively using non-lecture pedagogies, our aim is to better understand how situational characteristics support such teaching practices. Situational factors under consideration include: class size, pre-requisite and subsequent courses, content and coverage expectations, and support/constraints expressed by colleagues and department chairs. Our analysis suggests that support for non-lecture pedagogy can range widely from passive (e.g., a department in which there is little oversight on individual courses) to active (e.g., a department in which professional development opportunities are widely circulated, department chairs who help mitigate negative student evaluations when new instructional approaches are tried).

Graphs Display Lengths, Not Locations

Surani Joshua
Arizona State University

Students are frequently asked to reason about graphs that they see as geometric shapes, instead of representations that show the relationship between two quantities. This study shows an instructional intervention, using the theory of multiplicative objects (Saldanha and Thompson, 1998) that has great potential for orienting students to the quantities involved and their relationships, by focusing on how graphs display orthogonal lengths whose magnitudes are measures of quantities.

Key words: Graphs, Magnitudes, Representations, Lengths, Covariation

Research on students' understanding of graphs show that students frequently have difficulties with interpreting, manipulating and creating graphs (Baker, Cooley, & Trigueros, 2000; Kieran, Boileau, & Garançon, 1996). Many studies have suggested instructional sequences to help students develop their skills to carry out the aforementioned tasks (Dugdale 1993; Eisenberg & Dreyfus, 1994; McDermott, Rosenquist, & vanZee, 1987) but they frequently rely on asking students to use mnemonics based on graphical shapes, or "shape thinking", that has been shown to be problematic for students (Moore & Thompson, 2015); moreover, these studies are frequently silent on the original causes of the student difficulties that they are seeking to remedy.

While teaching both Precalculus and calculus at a large southwestern university, I noticed that these college-level students had surprising levels of difficulty in reasoning with graphs. We frequently drew vertical and horizontal lengths to represent *changes* in quantities on a graph, but I soon realized these lengths were meaningless if the students did not also have an understanding of the lengths on a graph that represent *total* quantities. A graph on rectangular (Cartesian) axes expresses the relationship between two quantities (Thompson 1993) by displaying points where a point's perpendicular distance from the y- and x-axis represent paired values of the x- and y-quantities, respectively. As such, a point on a graph is what Saldanha and Thompson (1998) called a multiplicative object. I noticed when students' interacted with graphs that they saw points on a graph as locations instead of representing the values of two lengths, the magnitudes (Thompson et al. 2014) of which represented the measurement of two quantities. They must also be able to visualize the covariation of these quantities (Carlson 2002) as the graph develops.

To investigate, I carried out a research project with a single participant, a community college student studying nursing in the American southwest. We used dynamic software to investigate graphs and their properties by highlighting the vertical and horizontal magnitudes (via directed lengths, or vectors) that were paired together in the multiplicative objects that were the points on any given graph. I found that these activities provoked surprising responses from my subject about the nature of graphs and their utility. We then continued to use these dynamic visualizations to investigate transformations of graphs and the student had a significant amount of success in justifying answers that earlier she could not explain.

I feel that this study will be of great interest to math education researchers because the nature of graphs and of how students use, create, manipulate, and reason with graphs is central to our work. Focusing on this aspect of reconceptualizing graphical shapes to points as 'locations' to points as 'paired lengths' may be a strong starting point for instructional innovation and increased student learning.

Reasoning About Relative Motion: A Frames of Reference Approach

Surani Joshua
Arizona State University

In introductory physics classes, student frequently experience difficulties with relative motion problems. Previous studies have categorized student difficulties with reference frames, or used computer simulations or experiments to create seeming paradoxes that students would need frames of reference to resolve; however, these studies failed to define what they meant by a "frame of reference" in the mind of a student. In 2016 I carried out a pilot study that used our cognitive definition of a conceptualized and coordinate frame of reference (Joshua, Musgrave, Hatfield, & Thompson, 2015) as well as quantitative reasoning (Thompson, 1993) to guide an instructional intervention and analyze the difficulties the student had with relative motion tasks. Both constructs proved to have great explanatory power, as they revealed aspects of the student's thinking that were not commonly explored in previous studies. Both the results of this study and their implications will be the topic of my poster.

Key words: Relative Motion, Frame of Reference, Velocity, Physics, Quantitative Reasoning.

It is commonly acknowledged that the reason students struggle with relative motion tasks is because they fail to correctly use reference frames. Some studies have focused on categorizing student difficulties with reference frames (Bowden et al., 1992; Panse, Ramadas, & Kumar, 1994). Others have tried interventions based on computer simulation designed to have students experience different points of view (Monaghan & Clement, 1999, 2000) or to build experiences with seemingly paradoxical conclusions that students would need reference frames to resolve (McDermott, 1984; Trowbridge & McDermott, 1980). However, when I looked closely at these studies, I could not help but notice that velocity was frequently seen as an aspect of a single object. Even though students were asked to find an object's speed in "a new reference frame", the task was still framed as *the object's velocity* instead of *the rate of change of distance between an object and a reference point with respect to time*. Moreover, most of these interventions sought to simply build student intuition about velocity as an isolated quantity instead of a intensive quantity composed from distance and time.

To address this gap in the research, I investigated how a single student reasoned about tasks involving relative motion. After a clinical interview where I asked the student to work through several tasks, I used the theories of quantitative reasoning and conceptualized and coordinated frames of reference entail, to analyze the student's reasoning. Among other results, I found that the student was unusually attuned to the necessity of a reference point (though not always sure of how to utilize one) but completely unaware of the idea of a directionality of comparison. My analysis of the student's work guided the content of an instructional intervention, followed by a chance for the student to rework the original relative motion tasks. He showed great improvement in being able to both explain answers he previously thought were correct without justification, and to complete some previously blank tasks. He also used his commitment to reference point to spontaneously coordinate reference frames. I believe that my data, as well as my analysis of the data using my construct of a cognitive frame of reference and quantitative reasoning, will be of interest to the math education community as they showcase an area of applied mathematics where our students commonly struggle, as well as a potential avenue for improved instruction.

All The Math You Need:
An Investigation into the Curricular Boundaries of Mathematical Literacy

Gizem Karaali
Pomona College

This project attempts to seek out common threads and analyze discrepancies in the tertiary-level mathematical literacy / quantitative literacy curricula proposed by eight different textbooks and content-providers. Following the framework developed originally in (Harel 1987) we investigate sequencing of content, levels of generality, emphasized applications, introductory material, as well as explicitly stated learning outcomes.

Key words: mathematical literacy, quantitative literacy, textbook analysis.

Mathematical literacy, and related notions and terminologies (such as numeracy, financial / quantitative / statistical literacies), refer to the usefulness of, and ability to use or apply, mathematical and quantitative ideas, broadly viewed, in a range of different life contexts [TSG 23 Call for papers and participants]. In earlier work, researchers have analyzed the overlaps and divergences between these specific terms; for a recent overview of related work, see [Karaali et al. 2016]. In this project, we seek to clarify the boundaries of these terms using curricular materials as a guide, mainly focusing on mathematical literacy as a goal, no matter how a specific term is defined or used. In particular we intentionally avoid fixing a definition for these terms and focus entirely on delineating the boundaries described by curricular content offered.

We analyze eight different textbooks and other curricular content aimed for the tertiary-level. Following the framework developed originally in [Harel 1987] we investigate sequencing of content, levels of generality, emphasized applications, introductory material, as well as explicitly stated learning outcomes.

We summarize our results in the poster using the above framework, using visual and verbal descriptions of each dimension (sequencing of content, levels of generality, emphasized applications, introductory material, explicitly stated learning outcomes). In particular we note that the topics covered do overlap significantly among the texts analyzed, thus offering hope that curricular boundaries might be determined even if there may not be consensus on definitions of terms like mathematical literacy and quantitative literacy. We also note that curricula and textbooks mostly fall into one of two categories that can broadly be described as *pragmatic* and *idealistic*.

Student Beliefs About Mathematics in an Inquiry-Based Introduction to Proof Course

Shiv Smith Karunakaran
Washington State University

Abigail Higgins
Washington State University

James Whitbread, Jr.
Washington State University

An "Introduction to Proof" or "Transition to Proof" course is widely offered as an essential part of the undergraduate mathematics curriculum at most post-secondary institutions. This poster reports on the iterative development of one such course that used an Inquiry-based approach to the teaching and learning of mathematical proving and proof. Moreover, the changing beliefs of students, about the nature of mathematics and about doing mathematics, in this course, are discussed.

Keywords: Transition to Proof, Inquiry-based learning

The importance of proof has long been emphasized by numerous mathematics and mathematics education organizations, such as the *Mathematical Association of America* and the *National Council of Teachers of Mathematics*. Apart from the general importance placed on proof, the process of proving is also indispensable in the act of doing mathematics. At the higher academic levels (graduate and professional mathematics), proving can be considered as the definite way in which the truth of a claim is established or realized (Hanna, 2000).

In the United States of America, most undergraduate students of mathematics first encounter the process of proving and the related product of proof in an "Introduction to Proof" or a "Transition to Proof" course. Historically, the teaching of proving to students in these courses has followed the custom of presenting the statement of the theorem and following it with a presentation of the finished proof. However, research suggests that this form of mere presentation of proof may not engender understanding of the proving process for the students (Raman, 2002) and may instead promote memorization of the proofs without understanding the proving process. In an effort to correct this trend and to allow for more opportunities for undergraduate students of mathematics to gain understanding into the process of proving, the authors designed and implemented an "Introduction to Mathematical Proof" course that was built upon principles of inquiry-based mathematical teaching and learning. Other undergraduate courses, such as abstract algebra (Larsen & Lockwood, 2013) and linear algebra (Wawro et al., 2012), taught using these principles seem to have helped students gain insight into the relevant mathematical content.

This poster presents the design, development, and implementation of the various iterations of this inquiry-based course in mathematical proving and proof. It will report on the sequencing of tasks that may have helped students gain a deeper understanding of different proving strategies, such as using the Principle of Mathematical Induction. It will also present data from classroom observations and from student interviews about specific features of this course that helped students.

Students self-reported that specific beliefs about doing mathematics and about the nature of mathematics evolved during the span of this course. For instance, students modified their stances on the following beliefs: 1. There is always exactly one solution to mathematical problems and one valid way to solve mathematical problems; and 2. Mathematical proofs or arguments or justifications must adhere to a particular format. Observations of students' work in class and in interview settings provided triangulation of these espoused changes in beliefs by the students.

Bringing Evidenced-Based Practices to a Large-Scale Precalculus Class: Preliminary Results

Karen Allen Keene	Leslaw Skrzypek	Greg Downing	Brooke Kott
NCState University	U of South Florida	NCState University	NCState University

Using evidenced-based practices in a large undergraduate mathematics classroom can be challenging but results of recent research on active-learning demand investigation. Preliminary results show that students already have self-confidence upon entering the classes, but there is a slight gain in perceptions of the value and appreciation of mathematics. Additionally, activities and clickers were considered useful and important by some of the students interviewed.

Keywords: Large scale classrooms, precalculus, evidence-based practices

In general, researchers and curriculum developers have developed numerous student-centered instructional strategies which has been shown to support conceptual learning gains (Freeman et al, 2014), diminish the achievement gap (Kogan & Laursen, 2013; Riordan & Noyce, 2001), and improve STEM retention rates (Rasmussen, Ellis, & Bressoud, 2013). Our objective was to introduce evidence-based active learning practices and conduct a mixed method study to understand how these new practices are perceived and affect student outcomes. Outcomes defined were students' attitudes towards mathematics, interest in mathematics, and self-efficacy. Research questions were: 1) what are students' perceptions of the new instructional strategies? And 2) how are students' self-efficacy and attitudes towards mathematics different after participation in the evidence-based practice course compared to a comparison course?

Study Design

The participants in this study were students in two (one treatment and one comparison) large classes at a southern university. The content in the courses were the same: precalculus, including triangle and unit circle trigonometry, conic sections, and sequence and series. The course included lecture and computer labs where homework, quizzes and exams were taken. In the treatment class, the instructor introduced the use of real-world videos, team activities, and conceptual clicker questions answered in small groups. There were 5 team activities, 3 real-world videos and clicker questions in the summer treatment class. None of these were done in the fall control class.

Data included pre and post surveys of students that asked about their perceptions of themselves as mathematical learners, their perceptions of mathematics, and the course itself. Interviews at the end of the semester with approximately 20 students were conducted and video recorded. Data analysis is ongoing with quantitative methods being used on numerical questions in the surveys and qualitative methods used on the open ended questions and interview videos.

Preliminary Results and Conclusion

Students were already confident in their mathematical skills, but there were advances in their value of mathematics. Students were more engaged, positive about the social value, and showed mathematical gains from participating in the treatment class. Further research is needed to identify connections between the team activities, clickers, and changes in the students. Early results show that there may be ways to implement these strategies in a large-scale mathematics classroom.

Post-class Reflections and Calibration in Introductory Calculus

Taylor Kline
Texas A&M-Commerce

Rebecca Dibbs
Texas A&M-Commerce

One of the reasons for the exodus in STEM majors is students' experiences in their first undergraduate mathematics course, usually introductory calculus. However, students with high calibration are more likely to be aware of their deficiencies and seek assistance in time for it to be effective. Although there is evidence that students who regularly complete post class reflections are more successful than those that do not, it is not known if such assignment also improves students' calibration. The purpose of this correlational study was to investigate to what extent students enroll in CLEAR calculus become more growth mindset orientated the relationship between post-class reflections, calibration, and achievement in introductory calculus.

Key words: Calculus, calibration, formative assessment, transition to college

Most undergraduates who take calculus have some prior experience and believe they are prepared for the course (Bressoud, Carlson, Mesa, and Rasmussen, 2013). Without acknowledging the framework in which undergraduates learned mathematics in secondary school, undergraduates are more probable than any time in recent memory to struggle with the move to college. These initial struggles leave students more likely than ever to struggle with the transition to college and the advanced mathematical thinking needed to be successful beyond calculus (Kajander & Louric, 2005; Selden & Selden, 2002; Tall, 2008). One possible way to help undergraduates transition to college is the utilization of formative assessments, for example, exit tickets; such assignments can help undergraduates to see their professor as more caring and increases the probability students will seek help when they are struggling (Black and Wiliam 1998, 2009; Dibbs, 2014). However, the number of formative assessments finished is a far larger indicator of understudies' course grade than their weight in the course grade (Dibbs, 2014). One possible latent variable that could account for this impact was that undergraduates who finished more post-labs had better calibration than those that did not. The hypotheses for this study were: (1) There is no relationship between students' calibration on tests and achievement in introductory calculus (2) There is no relationship between the number of post- class reflection assignments students complete and their calibration on tests

Participants were recruited from two sections of calculus (n = 60) at a rural Hispanic-serving research university in the South during the Fall 2016 semester. Students enrolled in calculus most commonly major in engineering, physics, computer science, mathematics, or secondary mathematics education. At the time of consent, students' ACT scores (SAT scores were converted to ACT equivalents), current GPA, native language, gender, and major were collected. Data was collected during the four unit tests of the course and the final exam. At the bottom of each question, students had to circle a face on an affective Likert scale indicated their confidence in their answer. During analysis, the Likert scale was converted to a numerical score, and the difference between student's exam score and Likert score was used to obtain a calibration score for each item. A linear regression model was constructed. Based on pilot data, ACT scores, gender, and native language were all included in the initial model:

$$Score = a_1(calibration) + a_2(ACT) + a_3(gender) + a_4(native\ language)$$

Error Detection in an Introductory Proofs Course

Jason Aubrey, Tyler Kloefkorn, and Kyle Pounder
University of Arizona

We report on an exploratory quantitative study of students' error detection skills. Based on the research on "proof framework" type errors and models for proof comprehension, we classify errors in proofs as internal or external for proof validation. We then test students' ability to detect errors of both types and determine if detection is correlated with success in an introductory proofs course.

Key words: proof validation, proof comprehension

Researchers have shown that students struggle to validate proofs (Selden & Selden, 2003; Inglis & Alcock, 2012; Ko & Knuth, 2013; Weber, 2010). It is known that students are particularly prone to miss "proof framework" errors (Selden & Selden, 2003; Inglis & Alcock, 2012). Researchers have also proposed that one component of comprehension is "local" or line-by-line understanding (Mejia-Ramos et al, 2012). For use in proof validation, we propose a classification of errors as external (e.g., proof framework errors) or internal (e.g., local errors). Here we take a quantitative approach to studying students' error detection skills. That is, instead of focusing on the complex written and mental processes involved in proof validation, we focus on quantifying students' final judgments about purported proofs. We hypothesize that students are more adept at detecting internal errors over external errors and external error detection is more predictive of performance in an introductory proofs course than internal error detection.

Method

In summer 2016, we studied 23 students in a 300-level introductory proofs course emphasizing analysis at a large public university. Students were given 12 "proof feedback activities," each consisting of one claim and one purported proof. Depending on the activity, the claim was false, the proof had an error, both, or neither. The students' task was to list any errors in the claim or proof. We call an error external if it is global or structural. An internal error is not an external error. The activities included a mixture of types of errors.

Results and Conclusions

For each student we recorded identified errors and course grade. The results of a paired samples t test ($t(22) = 2.16$, $p = 0.04$) confirmed that students were more successful in identifying internal errors ($M = 35.40$, $SD = 24.69$) than external errors ($M = 22.71$, $SD = 16.23$). Logistic regression was used to predict the probability that a student would earn a grade of C or better. The predictor variables were participants' rates of success in detecting internal errors and in detecting external errors. A test of the full model versus a model with intercept only was statistically significant, with the Cox & Snell $R^2 = 0.32$. These results confirm that external error detection is more predictive of performance in an introductory proofs course than internal error detection. Ability to detect external errors had significant effect ($p = 0.049$) on success in the course. Future work includes an analysis of students' false negatives (i.e., "errors" listed in parts of proofs that were correct).

An Active Learning Environment in Introductory Analysis

Brynja Kohler and Patrick Seegmiller

December 8, 2016

Abstract

At Utah State University, the course known as 'Math 4200:Foundations of Analysis' is a requirement for all department majors, and, in addition to introducing real analysis, serves as an introduction to rigorous proof. All too frequently, courses such as these are taught with the typical lecture format: the instructor enters the classroom to deliver polished explanations of definitions, theorems, and their proofs, while leaving students to struggle to follow lectures and then struggle further on their own to make sense of incomprehensible homework problems. This poster includes descriptions of easy-to-implement strategies that change the classroom to an active learning environment, with ample opportunities for formative assessment and feedback without overloading the professor with busywork. The strategies include: name tents, group exercises and quizzes, peer-reviewing of homework, concept quizzes, individual presentations, and growth mindset reflections. We surveyed students to find their reactions to these class activities and found positive and helpful implementation hints.

1 Introduction

Here we will share the course specifics, a description of the text and instructor's experience, the classroom, students and their demographics. Our course and student population are quite typical of Land-grant research 1 universities, and we have class sizes of 40-45 students typically. The authors have researched various textbooks and course materials that encourage an active approach to analysis and these will be summarized and reviewed.

2 Methods

In this section, we will detail the course design and instructional strategies employed.

- **Peer-reviews of Homework** Using an online course organization system (CANVAS) we set up homework assignments (5 proofs each) and a peer-review system, so students could read each other's work, the instructor's solutions, and evaluate and comment on the writing.
- **Group Work** The class has tables so students are students can easily work together in groups. We assigned groups and changed them monthly. In almost every class meeting, groups were prompted to discuss and/or write about specific problems. The instructor gathered written work (only 12 groups reduces the grading load) and provided non-graded formative feedback in the following class meeting.
- Several more simple strategies for an active learning environment.

3 Results

In this final section of the poster, we will summarize comments from students regarding the implementation of these active learning approaches. Generally, students were enthusiastic about mathematics and their learning experiences in the class.

Pre-service Teachers' Use of Informal Language While Solving a Probabilistic Problem

Victoria Krupnik
Rutgers University

Robert Sigley
Texas State University

Muteb Alqahtani
SUNY Cortland

This exploratory study investigates pre-service teachers' (PSTs) collaborative discus-sions to solve probabilistic problem. The PSTs synchronously collaborated online using Virtual Math Teams with GeoGebra to investigate the fairness of a series of die by using interactive simulation to randomly sample from the die with replacement. While discussing their solution in the chat panel, the PSTs used informal, non-standard language to describe the distribution of the data. In this poster, we present examples of how the PSTs, using informal language, co-constructed their knowledge of different probabilistic concepts while solving the problem. This study contributes one of a series of tasks that were designed to elicit how PSTs build understandings of mathematical concepts without formal introductions to these concepts.

Key words: probability, pre-service teachers, law of large numbers, informal language, statistics

Mathematics is viewed as blending language, symbolism, and representations, and when working on problems, students must articulate their language of the connections between their symbolism and representations (O'Halloran, 2005). Studies (e.g., Francisco & Maher, 2011) have shown that when students engage in open-ended problem solving they tend to use informal, non-standard language as they build ideas. While solving problems in an online environment, students rely on their language to make those connections and make sense of mathematical ideas.

A study on PSTs' informal talk about variation was rich with statistical ideas of spread, modal clumps, and distribution chunks (Makar & Confrey, 2005). Makar & Confrey (2005) noted that when PSTs used the word *range* they referred to measure or location. Also, PSTs who used *spread out* would frequently accompany it with the word *evenly* for the notion of spread.

In our study, four groups of three PSTs from a large university solved an open-ended probability task in a collaborative online environment, VMTwG. The VMTwG integrates a multi-user version of GeoGebra, a dynamic geometry environment, with a shared whiteboard and a chat panel. The teachers met in VMTwG synchronously and collaborated to solve the probability task. In this task, the PSTs were provided with an interactive simulation of six dice that are weighted differ-ently. The simulation allows users to choose the number of trials from 1 to 1,000 rolls and select from three different representations of the data: a fre-quency table, a pie chart, and a bar graph to present the outcomes. The PSTs were asked to roll the dice, explore the different representation of the outcomes, and discuss in the chat panel the fairness of each die.

To analyze teachers' interactions in VMTwG, three researchers openly coded the chat logs for informal language referring to empirical and theoretical probabilistic concepts such as sampling, law of large numbers, distribution, and randomness.

Similar to Makar & Confrey's (2005) findings, PSTs used non-standard language to make sense of distributions. PSTs described various distributions as (*un)even*, *well-distributed*, *bell curve*, and *smallest range*. They justified choosing 1,000 trials to discover *patterns* of the graph such as *more equal*, *steady*, and *more accurate*, which we view as an attempt to establish connections between theoretical and empirical probability. However, our PSTs used *range* differently, to explain how close the frequency bar graphs were to a uniform graph. Our study contributes understanding of the development of PSTs' knowledge of probability and statistics. It also contributes understanding of how non-standard, informal language shapes mathematical understanding in collaborative environments.

Student Ways of Framing Differential Equations Tasks

George Kuster
Christopher Newport University

In this research presentation I utilize the theoretical perspective Knowledge In Pieces (diSessa, 1993) to identify the knowledge resources two students utilized while in the process of completing various differential equations tasks. The results provide a fine-grained description of the knowledge students consider to be productive with regard to completing various differential equations tasks. Further the analysis resulted in the identification of five ways students frame differential equations tasks and how these framings are related to the different knowledge resources students utilize while completing the various tasks. These framings did not only provide insight into the students' general approaches to completing the task; differences in the individual students' applications of knowledge across the tasks were accounted for by the different Framings. The results have direct implications with regard to the teaching of differential equations as they inform the ideas students view as productive when completing various tasks involving differential equations.

Keywords: Differential Equations, Knowledge in Pieces, Undergraduate Student Learning

In a recent review of undergraduate mathematics education literature Rasmussen and Wawro (in press) made a call for research on student learning in differential equations. In response to this call, I conducted 5 individual, problem-based interviews with each of 8 students. Two students' complete set of interviews were transcribed and analyzed using methods sharing characteristics with the iterative processes of Knowledge Analysis as discussed by Cambell (2011). Through this process I identified regularities in the language, ideas and actions utilized by the students across various tasks. One result of the analysis was the identification of five ways of framing differential equations tasks, general approaches to completing the differently framed tasks, and sets of resources regularly utilized to complete tasks of a particular framing.

Results

The five ways students framed the various differential equations tasks identified in this study are the differential equation as: a description of the behavior of the quantity of interest, as a relationship between values of quantities and the value of the rate of change of the quantity of interest, an equation that provides a model, as a relationship between values, and, as a relationship between functions.

In the poster I outline in more detail, the similarities and differences between the different framings, the general approaches to the students took with regard to the individual framings, and the regularities with regard to student usage of resources within the framings.

Implications

Based on the analysis of the students learning opportunities may be created by providing students with tasks that prompt them to focus on relationships between the variables (and functions) in the differential equations, the quantities those variables (and functions) represent, and the connections between differential equations and their solutions.

Using Evidence to Understand and Support an Educational Reform Movement: The Case of Inquiry-Based Learning (IBL) in College Mathematics

Sandra Laursen, Chuck Hayward, and Zachary Haberler
Ethnography & Evaluation Research, University of Colorado Boulder

We present a graphic review of a decade of research and evaluation work on inquiry-based learning in college mathematics. Featured studies examine student outcomes of IBL instruction, processes of change as instructors explore and adopt IBL approaches, and the workings of the faculty learning community that has formed to learn and promote IBL ideas. Collectively, these studies highlight the use of evidence to understand instructional practices and change in these practices, and to support evidence-based decision-making by instructors and change leaders.

Key words: inquiry-based learning, faculty change, evidence-based decision-making

This poster offers a graphics-oriented summary of a decade of research and evaluation studies of inquiry-based learning (IBL) in college mathematics. Our group's foray into this topic began with a large, multi-campus research study of student outcomes of inquiry-based learning as compared with primarily lecture-based instruction (e.g., Kogan & Laursen, 2014; Laursen et al., 2014; Hassi & Laursen, 2015). As IBL practitioners began to share their knowledge and experience with other instructors, we evaluated their faculty development activities and used these projects as vehicles to study the processes of faculty change (e.g., Hayward, Kogan & Laursen, 2016) and to develop better ways to measure such change. We continue to work with IBL leaders on IBL professional development and expanding community capacity to deliver skillful professional development. Another current study examines the IBL math ecosystem, seeking to understand the history, opportunities and challenges for the IBL math community as it develops strength as an educational change movement.

The poster will show the intellectual arc of our research questions and findings over time and highlights diverse research methods. The poster will also spark conversation about broader themes, such as selecting research methods, balancing scholarly and applied research, or taking a long view in developing a research program.

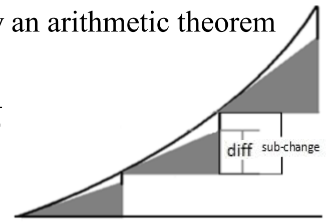
EDUCATIONAL POINT OF NEWTON-LIEBNITZ FORMULA

Author: Lin, Qun, Academy of Mathematics and Systems Science, Chinese Academy of Sciences

Presenting author: Cao, Rongrong, School of mathematics and statistics, Qingdao University



Newton-Liebniz formula has been stated by a figure and proved by an arithmetic theorem

$$0.9...9 < \frac{diff}{sub-change} < \frac{1}{0.9...9} \quad \Rightarrow \quad 0.9...9 < \frac{sum\ of\ diffs}{total\ change} < \frac{1}{0.9...9}$$

Increasing number of 9s, we get the Newton-Liebniz formula:

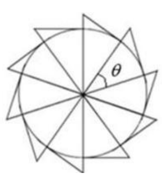
Integral of differentials = total change. See Lin's early book (Jan 1999) or recent paper in US-China Education Review A, March 2016, Vol.6, No. 3.

We discuss in this single page its educational point.

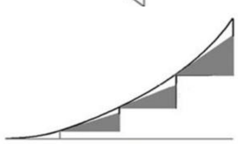
1. Tolstoy's view of history in *War and Peace*: Only by taking infinitesimally small units for observation (the differential of history, that is, the individual tendencies of men) and attaining to the art of integrating them (that is, finding the sum of these infinitesimals) can we hope to arrive at the laws of history.

2. Economy, collection of merchants, or integral of differentials of merchants, the latter are, the individual tendencies of merchants.

3. More exact examples, e.g.



$$0.9...9 < \frac{\text{Arc length}}{\text{Tangent length}}\left(=\frac{\theta}{\tan\theta}\right) < 1 \Rightarrow 0.9...9 < \frac{\text{Circumference}}{\text{Sum of tangent length}} < 1$$



$$0.9...9 < \frac{\text{Tangent length}}{\text{Sub-curve length}} < 1 \Rightarrow 0.9...9 < \frac{\text{Sum of tangent length}}{\text{Curve length}} < 1$$

Increasing number of 9s, we get the circumference and curve length.

There is a similar conclusion for the area under the curve.

The authors thank the reviewer's comments.

Any questions, please contact with presenting author Cao Rongrong, E-Mail: caorrqdu@sina.com.

Student reasoning with differentials and derivatives in upper-division physics

Michael E. Loverude, Department of Physics and Catalyst Center,
California State University Fullerton, Fullerton, CA 92834.

Abstract: *Students encounter multiple mathematical representations of change in physics courses. In addition to the complexity of the material, students must navigate mathematical notation that can seem arbitrary and can differ from conventions used in mathematics coursework. In this poster we will examine student responses illustrating the challenges of mathematical representations of change, drawn from students in upper-division physics courses in mathematical methods and thermal physics.*

Description

This work is part of a collaboration to investigate student learning and application of mathematics in the context of upper-division physics courses. Our project seeks to study student conceptual understanding in upper-division physics courses, investigate models of transfer, and to develop instructional interventions to assist student learning. Throughout, we seek to go beyond procedural skill and calculation and to probe conceptual understanding and the development of quantitative reasoning skills whose development is often left implicit.

As part of the project, we have examined several key ideas that cut across the upper-division physics curriculum, including vectors, integration, and derivatives. For this poster, we focus on mathematical descriptions of change encountered by students, including derivatives and differentials. Physics and mathematics tend to place different levels of emphasis on differentials, and students often struggle to conceptualize the distinctions between differentials, derivatives, and a finite difference indicated by a delta.

In the poster we will show data from a variety of written questions in which students reason with change. In some problems, students performed calculations of various quantities. In others they were asked for interpretations of expressions. For example, in thermal physics:

> *The definition of enthalpy can be used to derive the differential expression $dH = T\,dS + V\,dP + m\,dN$.*
> *These expressions contain differentials like dH. What does this mean?*
> *What is implied by choosing this notation instead of ΔH?*

A second question, posed in the mathematical methods course, was focused on ordinary differential equations. Students were asked to interpret quantities containing differentials:

The law of conservation of momentum give the differential equation $(M+m)dv+v_P dm=0$. Interpret the quantities dv and dm.

Student responses suggest a lack of distinction between change quantities. We will present examples of students performing inappropriate manipulations that suggest confusion between derivatives and ratios of variables, as well as written explanations. For example:

"dm is a rate that fuel mass is leaving"
"differentials imply integration"

Although this work is preliminary, we are particularly interested in presenting this to a math education research audience due to the disciplinary differences in use of change quantities.

An alternate characterisation of Developmental Mathematics students

Wes Maciejewski and Cristina Tortora
San José State University

Developmental – or the antiquated "remedial" – mathematics is a large enterprise in American colleges. For the California State University (CSU) system roughly one-third of all students require developmental mathematics. Placement in these courses in the CSU is determined by a standardized test. Those who fail are required to take some campus-specific variant of developmental mathematics. This poster addresses the question, what more can be said about students enrolled in developmental mathematics programs other than they have failed an exam? An analysis of survey instrument data will be presented that shows San Jose State University developmental mathematics students are fundamentally different, undesirably so, than their non-developmental counterparts on a range of attitudinal, affective, and dispositional measures.

Key words: developmental math, attitudes towards and perceptions of mathematics

Poster Description

Though developmental students failed an exam to be streamed into their developmental courses, this failure may be the symptom and not the cause of their under-performance in mathematics. Institutional records at San José State University (SJSU) indicate that developmental mathematics students never reach the level of academic achievement of their non-developmental colleagues, if they ever complete the developmental sequence – a result contradicting other studies (eg. (Bahr, 2008)) – putting into question the effectiveness of current developmental mathematics education practices at SJSU.

An online survey was sent in Fall, 2016 to all San Jose State University students enrolled in a freshman mathematics course. In addition to general questions about financial concerns of the students, the survey comprised two established survey instruments: the Mathematics Attitudes and Perceptions Survey (MAPS; Code, et al., 2016) and the Abbreviated Math Anxiety Scale (AMAS; Hopko, et al., 2003). The MAPS survey assesses the students on a range of factors known to impact academic achievement in mathematics: growth mindset, seeing connections between mathematics and the real world, confidence, interest, persistence in working with mathematics, sense making, and views of the perspectives on answers. Students' MAPS responses are weighed against consensus responses of mathematicians and relative-to-expert scores are reported for each factor, along with an overall expertise index. The AMAS assesses students on their level of mathematics anxiety. The survey reports an overall anxiety score, the sum of learning and assessment anxiety.

On almost all MAPS and AMAS scores, developmental math students scored less-favourably than their non-developmental counterparts. There are two notable exceptions: i) developmental math students scored higher on the "connections to the real world" subscale, and, ii) there was no statistically-significant difference between the groups on the interest in mathematics subscale. The poster presents these comparisons along with a cluster analysis that further characterises sub-groups of developmental math students.

The results of this study highlights the importance of addressing non-conceptual aspects of learning and performing mathematics in developmental mathematics courses. Doing so, we argue, is the only way to provide effective developmental mathematics education.

Student Attitudes, Beliefs, and Experiences Related to Counting Problems

Samantha McGee, Oregon State University
Sarah Erickson, Oregon State University
Elise Lockwood, Oregon State University

Mathematics textbooks and mathematics education research articles frame counting problems as requiring clever insight and being inherently challenging and especially accessible. In this study, we distributed a survey to mathematics students in order to examine student attitudes about counting problems and the extent to which these attitudes aligned with presentations of counting in the literature. In this poster, we present results from this survey that highlight some surprising ways in which the responses did and did not align with the literature.

Key Words: Counting, Student Attitudes, Combinatorics, Discrete Mathematics

Both mathematics textbooks and mathematics education research articles tend to frame counting in particular ways. For example, Tucker (2002) says that counting requires logical reasoning and clever insights (p. 169), Lockwood (2013) that counting is accessible and has a variety of applications, and Martin (2001) claims that "Counting is hard" (p. 1). While some of these characterizations are based on evidence with students, there have not been studies that measure the extent to which such perspectives about counting align with what students actually believe and experience. We think such work is important because it will allow researchers and teachers to consider students' perspectives about counting. Our research question is, *"What are students' attitudes, beliefs, and experiences with counting and combinatorial reasoning, and how do these affective factors align with how counting is presented in combinatorics education literature and textbooks?"* We developed a survey that targeted students' attitudes, beliefs and experiences about counting. We collected textbooks and mathematics education research papers, and we identified claims about the nature of counting, how counting compares to other disciplines, and applications of counting. We categorized these claims and used them to create a survey that we sent via a listserv to mathematics majors at a large public university.

We currently have approximately 40 student responses (some did not answer all questions), and the survey will continue to run in the coming months. Due to space we briefly describe just a couple of interesting findings that demonstrate the nature of our results. First, we found that students did seem to align with many of the statements in the literature. For instance, 95% of respondents agreed or strongly agreed that "Solving counting problems requires critical thinking skills," aligning with statements by Tucker (2002) and others. Also, less than 25% agree that "Solving counting problems requires prior mathematical knowledge," which aligns with the claims by many researchers that counting is accessible (e.g., Kapur, 1970; Lockwood, 2013).

There were also some surprising results. For instance, only 20% of respondents agreed or strongly agreed with the statement "Solving counting problems is difficult in general." Given the claims by many textbook authors and researchers (e.g., Tucker, 2002; Martin, 2001), we were surprised that more students did not seem to think that solving counting problems is difficult. Another surprising finding was that only 30% agreed with the statement "Solving counting problems requires memorization." Given our experience with students, we expected more students to associate counting with memorization. In our final poster, we will provide a more comprehensive report of our results and will paint an overall picture about students' attitudes, beliefs, and experiences with counting problems.

Algebra Instruction at Community Colleges:
An Exploration of its Relationship with Student Success

Vilma Mesa,[1] Irene M. Duranczyk,[2] Nidhi Kohli,[2] April Ström,[3] Laura Watkins,[4] Angeliki Mali[1]
[1] University of Michigan, University of Minnesota,[3] Scottsdale Community College,
[4]Glendale Community College

We present the research design and data collection strategies for a federally funded project (Watkins, Duranczyk, Mesa, Ström, & Kohli, 2016) that investigates the connection between instruction and student learning and performance in algebra courses at community colleges. The poster focuses on measurement issues we face in identifying the characteristics of mathematics instruction and students' learning gain, specifically we address questions encountered from the pilot data collection (six community college faculty and nearly 150 students) that need to be resolved prior to data collection.

Key words: instruction, community colleges, teaching quality research, algebra, observational measures

Although we like to think that teaching influences learning, the truth is that such connection has not been established empirically (Hiebert & Grouws, 2006). As a first attempt to establish this connection, we investigate the extent to which there is an association between what occurs in the classroom and what students learn in a one-semester course of algebra at a community college. Whereas there is some research documenting how individual and institutional characteristics (e.g., prior achievement, family support, financial aid, learning support and tutoring centers, and ratios of full- to part-time instructors) contribute to failure rates and other performance measures (Bradburn, 2002; Feldman, 1993), there is little information about the fundamental work of teachers in the classroom, and the interactions that occur between instructors, students, and the mathematical content. The Mathematics Quality Instruction (MQI) protocol a video analysis tool used in P-12 settings (Learning Mathematics for Teaching Project, 2011) and the Algebra Instruction Protocol (Litke, 2015) have been adapted to measure faculty and student interaction at the community college. The Algebra and Precalculus Concepts Readiness (APCR) test (Madison, Carlson, Oehrthman, & Tallman, 2015) was used to measure student learning. We also collected information on instructors' mathematical knowledge for teaching algebra, and instructor and student beliefs, and attitudes towards the teaching and learning of algebra which can also moderate the relationship between instruction and learning. Research in the K-12 arena documents that the association between quality of instruction and student performance on standardized tests can be moderated by instructors' knowledge and attitudes towards innovative teaching practices, knowledge of algebra for teaching, and their beliefs about mathematics, its curriculum, and students' learning (Hill, Rowan, & Ball, 2005). In this project we seek to test such relationships, in a different setting and grade level. The first phase, presented in the poster, is the testing of the instruments and initial assessments of the measures done with six instructors at three different community colleges in three states, Arizona, Michigan, and Minnesota.

Bridging the Gaps between Teachers' and Students' Perspectives of a Culturally Inclusive Classroom

Thomas Mgonja
Utah Valley University

Kuo-Liang Chang
Utah Valley University

Creating a culturally inclusive classroom has been suggested to help minority students improve their achievement in class. However, evidence shows gaps between teachers and students about what a culturally inclusive classroom should be. We propose a framework for investigating the differences between teachers' and students' beliefs on such a classroom.
Key words: Minority, Culturally Inclusive Classroom, Mathematics Achievement

Evidence shows that minority students' mathematics achievement tends to rapidly fall behind during fifth to eighth grade (Beaton et al., 1996; Schmidt et al., 1999). In the majority of the states in the U.S., there was a 30% to 50% difference in performance between White students and the largest minority groups (Hispanic and Black students) at the basic level of mathematics on the eighth-grade National Assessment of Educational Progress Exam (Blank & Langesen, 1999). One possible cause of this disparity in performance is the various forms of discrimination minority students experienced in the classroom (Dovidio, 2001; Salvatore & Shelton, 2007).

A culturally inclusive classroom is a learning space that encourages students, and especially teachers, to acknowledge, appreciate, and use diversity as a tool to enhance learning experiences (Nieto, 2004; Montgomery 2001). Unfortunately, evidence shows that there are gaps between teachers and students on what a culturally inclusive classroom is and how to construct such a culturally inclusive classroom (Tyler, Boykin, & Walton, 2006).

The purpose of this study is to develop an instrument to investigate the differences and their extent between teachers' and students' beliefs of what a culturally inclusive classroom should be. We also intend to investigate how these differences are related to teachers' and students' ethnicity, age, and gender. We hope to offer more specific recommendations to bridge the gaps once we understand the relationship between teachers' and students' demographic and their culturally inclusivity beliefs.

From the students' perspective, it has been suggested that a culturally inclusive classroom has no superiority of intelligence based on race or culture, no authentic behavior expectations on culturally different minorities, a willingness to accept a different racial reality in communications, and validating feelings of minority students in class (Sue et al., 2009). While from the teachers' perspective, a culturally inclusive classroom provides equal attention to all students (Gay, 2002), an equal expectation of high achievement for all students (Foster, 1997; Kleinfeld, 1975), and an equal opportunity of learning for all students (Oakes, 1990; Banks et al., 2001).

Based on these teachers' and students' perspectives, we constructed a framework, in tabular form, to guide the construction of the instrument. Mathematics contexts are given in each cell to help generate a questionnaire specifically for a mathematics class.

	Attention	**Expectation**	**Opportunity**
Knowledge	Math topics	Math topics	Math topics
Behavior	Problem solving	Problem solving	Problem solving
Communication	Questioning & Ans.	Questioning & Ans.	Questioning & Ans.
Emotion	Positive & Negative	Positive & Negative	Positive & Negative

Mathematical Knowledge for Teaching & Cognitive Demand: A Comparative Case Study of Precalculus Examples that Involve Procedures

Erica R. Miller
University of Nebraska-Lincoln

In 2010, Charalambous published an article that examined the relationship between mathematical knowledge for teaching (MKT) and task unfolding. As a result of this study, Charalambous found evidence to support the claim that there is a positive relationship between a teacher's MKT and the cognitive level of task presentation and enactment. Drawing upon this finding, the purpose of this case study is to utilize unfolding and cognitive demand as a lens through which to examine mathematical knowledge for teaching at the undergraduate level. While MKT has been studied extensively at the K-12 level, there are relatively few studies that focus on MKT at the collegiate level. In order to help fill this gap, this case study first identifies how Precalculus instructors unfold examples that involve procedures and then examines the MKT that is involved in this unfolding.

Keywords: Mathematical Knowledge for Teaching, Cognitive Demand, Case Study, Precalculus, Examples, Procedures

Mathematical knowledge for teaching (MKT) has been defined as "the mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students" (Ball, Thames, & Phelps, 2008, p. 399). At the K-12 level, MKT has been studied extensively, but few studies exist at the collegiate level. The purpose of this study is to examine MKT at the collegiate level from the perspective of practice while still drawing upon previous research. In particular, Charlambous (2010) found that there was a positive relationship between teachers' MKT and task unfolding. Charalambous used the MKT measurement developed by Ball for elementary teachers, the Mathematical Task Framework (Stein, Grover, and Henningsen, 1996, p. 469) to analyze the unfolding (i.e., selection, preparation, and enactment) of tasks, and the Task Analysis Guide (Stein & Smith, 1998) to analyze the cognitive demand. While it would be desirable to replicate this study to look for similar results at the collegiate level, no comparable measure of MKT exists. However, it is possible to use the Mathematical Task Framework and the Task Analysis Guide as lens to help examine what MKT at the collegiate level might look like.

Instead of examining collegiate MKT at large, this study focuses specifically on Precalculus examples that involve procedures. The larger purpose of this study is to contribute to research on Precalculus courses (Hastings, 2014; Saxe & Braddy, 2016). Examples were chosen as the specific task of teaching of interest because of their centrality to math instruction. Procedural knowledge is often characterized as superficial memorization of algorithms and therefore less important than conceptual knowledge. However, procedures are an integral part of mathematics and there is a need for students to develop deep procedural knowledge (Star, 2005) that is connected and requires high-level cognitive demand (Smith & Stein, 1998). This comparative case study seeks to answer the following research question: What mathematical knowledge do Precalculus instructors draw upon when selecting, presenting, and enacting examples that involve procedures? In order to answer this question, the Mathematical Task Framework will be used to analyze the unfolding of the examples while the Task Analysis Guide will be used to analyze cognitive demand. Finally, similar and different cases (in terms of the cognitive demand) will be compared in order to examine the MKT involved in unfolding examples.

Coping with the Derivative of an Atypical Representation of a Common Function

Alison Mirin
Arizona State University

250 calculus students were asked to evaluate $f'(2)$ when $f(x) = x^3$ *if* $x \neq 2$ *and* $f(x) = 8$ *if* $x = 2$. *Responses were coded, and eight students were interviewed about their answers. The data provide insight into students' understandings of function, derivative, and graph.*

Key words: Function, Derivative, Graph

250 students upon completion of a calculus course were given the following task: "let f be the function defined by $f(x) = x^3$ *if* $x \neq 2$ *and* $f(x) = 8$ *if* $x = 2$. Evaluate $f'(2)$ and explain your answer". This task was motivated by my experience as a calculus teaching assistant, in which students insisted that for $g(x) = \frac{\cos x - 1}{x}$, $g(0) = 0$, the value of $g'(0)$ must be 0 due to the constant rule. Harel and Kaput (1991) and Sfard (1992) share a similar anecdote and attribute students' incorrect responses to not viewing a function as an object. By working with a familiar function with a familiar graph, students might recognize that the function provided to them is the same as the cubed function, and then successfully solve the problem. This recognition is, in theory, available to students who view the derivative as no more than the slope of a tangent line.

100 of the 250 students were in a reform calculus course. 16% of the students answered correctly (including students whose explanations were incoherent or inconsistent), 64% wrote that $f'(2) = 0$, 9% wrote "undefined" or "does not exist", and only 52% of the students who acknowledged that $2^3 = 8$ arrived at the correct answer. Some students wrote that $f'(2) = 0$ *if* $x = 2$ and $f'(2) = 12$ *if* $x \neq 2$. A common way of thinking can be summarized as "take the derivative of each equation, and then plug in 2. The derivative of 8 is 0," which was indicated in students' responses to questions about other piecewise functions during the interviews.

All eight of the students interviewed were enrolled in a reform calculus course that stressed the meaning of derivative at a point as rate of change over a small "essentially linear" interval (Thompson, Bryerly, & Hatfield, 2013). Only one student correctly answered the question on the exam, but during the interview, she immediately changed her answer. The remaining 7 initially claimed that $f'(2) = 0$. In fact, many of the students who graphed *f* correctly tried to explain why their initial answer made sense with the graph. Two students claimed the graph of *f* has the same points as the graph of x^3 and is flat around $x = 2$. Some students claimed that $f'(2) = 0$ because the point (2,8) is separate, and there is no rate of change at a single point. Two students stood out in particular. By the end of the interview, they concluded that *f* has the same graph as the cubed function, but also that $f'(2)$ is not 0, since *f* is increasing around $x = 2$. However, they claimed they could not find its exact value. Each student said that she could only "approximate" $f'(2)$ by finding dy/dx for small intervals around $x = 2$. When asked "what do you think you would end up getting?," they could not provide an answer. They both claimed that it was illegitimate to use the power rule on x^3.

It was common for students to claim that they were graphing "two functions" and not know how to incorporate information about the domain. The data collected reveals that many students have weak conceptions of function, derivative, and graph. Since several of the subjects were enrolled in the reform course, these results have implications for instructional design research in the reform setting.

Speaking with Meaning about Angle Measure and the Sine Function

Stacy Musgrave
Cal Poly Pomona

Marilyn Carlson
Arizona State University

Researchers have reported on the difficulties K-12 students, pre-service and in-service teachers experience in reasoning and communicating about angle, angle measure and trigonometric functions. This work extends the existing literature to highlight that even mathematically sophisticated individuals (e.g., PhD mathematics students) often struggle to speak with meaning about these ideas sans targeted interventions to support them in doing so. We share tasks and data from semi-structured clinical interviews conducted with graduate teaching assistants to highlight differences in communication about these ideas pre- versus post-intervention.

Keywords: Graduate teaching assistants, Precalculus, Speaking with meaning

Researchers have reported on the difficulties K-16 students, pre-service teachers and in-service teachers experience in reasoning and communicating about angle, angle measure and trigonometric functions (Moore, 2013; Moore, 2010; Thompson, 2008). This work extends the existing literature to highlight that even mathematically sophisticated individuals (e.g., PhD mathematics students) may struggle to *speak with meaning* about these ideas sans targeted interventions to support them in doing so (Clark, Moore & Carlson, 2008).

We share tasks and associated data from one-hour, semi-structured clinical interviews conducted with graduate teaching assistants (GTAs) (Clement, 2000). Research participants were mathematics PhD students who had taught (either as lead instructor or recitation leader) at least one college-level course at a public, state university in the Southwestern United States. Twenty-two of the 24 research participants had undergone one or more years of an intervention designed to support them in constructing deeper meanings and speaking with meaning about the ideas in an undergraduate precalculus class. Their participation in this intervention coincided with teaching a precalculus course using research-based curriculum materials that were designed to support quantitative and covariational reasoning (Carlson, Oehrtman, & Moore, 2015). The other two research participants had no exposure to the intervention or the research-based curriculum materials, but rather they underwent the standard university GTA training and taught calculus courses (Calculus I or Calculus II, as lead instructor and as recitation leaders).

There was relative uniformity in response characteristics from participants who had undergone the intervention. As such, the data presented will showcase two representatives from that group and the two participants sans intervention experience. Our preliminary analyses of the data suggest the latter two participants struggled to communicate meaningfully about *how* certain procedures (e.g., measuring an angle using a protractor) work, *why* formulas (e.g., relating arc length, angle measure and radius length) are what they are, and *how* to think about the sine function in a way that works in different contexts (as opposed to thinking of values in a table in one context, to having a triangle-based method in another context, and a x,y-coordinate meaning in yet another). In contrast, post-intervention participants spoke with relative fluency about generating formulas from definitions and applied consistent ways of thinking about the sine function to tasks throughout the interview. Excerpts from interview transcripts and written work will be shared to demonstrate the above distinctions between the two groups in conceptual versus procedural orientation of responses, as well as coherency and consistency in reasoning from task to task.

Examining Prospective Teachers' Justifications of Children's Temperature Stories

Dana Olanoff, Widener University
Nicole M. Wessman-Enzinger, George Fox University
Jennifer M. Tobias, Illinois State University

Part of the work of mathematics teacher educators (MTEs) are to provide authentic experiences to prospective teachers. We showed four temperature story problems involving integers to prospective teachers (PTs), and asked them if the stories matched given number sentences. While each of the stories were similar to the number sentence, none of them matched exactly. We examine the reasons PTs gave for saying that the stories matched the number sentences, and discuss implications of their thinking for mathematics content courses for prospective teachers.

Key Words: Prospective Teacher Education, Integers, Mathematical Knowledge for Teaching

In working with prospective teachers (PTs), part of the work of the mathematics teacher educator (MTE) is to help them develop the mathematical knowledge that they will need for teaching (MKT) (Ball, Thames, & Phelps, 2008). This is true, even if the PTs are taking a course primarily focusing on mathematics content, rather than methods for teaching. Research has shown that providing PTs with tasks authentic to the work of teaching will help motivate them to want to learn the mathematics (Newman, King, & Carmichael, 2007). Thus, as MTEs, we try to provide PTs in our mathematics content courses with tasks that will ask them to perform activities that they will need to do while teaching. This poster focuses on a task designed around using temperature as a context to support the learning of integer operations.

Part of the MKT that PTs use in their work as teachers is being able to evaluate contextual problems that relate to the mathematics that they are teaching. The *Common Core State Standards for Mathematics* (Council of Chief State School Officers & National Governors Association, 2010) suggests using contexts for teaching integers which include temperature, elevation, credit/debits, and electron charges. However, studies have shown that students, including PTs, have difficulty using negative integers in these contexts (e.g., Whitacre et al., 2015). This study looks at the ways that PTs' evaluated temperature problems designed by children.

In this study, we provided opportunities for elementary and middle school PTs (N=100) to explore four stories written by fifth graders that were intended to correspond to given integer number sentences. We investigated the PTs' responses to the children's problems, noting what they attended to in order to decide which stories made sense with the given number sentences. Each of the four stories contained aspects that were not a perfect fit with the number sentence (e.g., changing structure of number sentence, unrealistic situations). However, a majority of the PTs in our study indicated that two of the stories matched the number sentences perfectly—neglecting some important nuances. For example, one problem fits the number sentence 17 – 13, although the given problem was 17 + -13. Many of the PTs incorrectly argued that these number sentences were equivalent, because when evaluating a subtraction problem, students are often taught to "add the opposite."

In the poster, we will share the four temperature story problems as well as the data from the PTs who said that the story matched the problem. We will discuss the reasons that PTs gave for saying that the stories matched the problems, and the implications that this has for teacher education, particular in the context of mathematics content courses for prospective teachers.

Classroom Participation as a Socialization Agent for Identity shaping of Preservice Mathematics Teachers

Janet Omitoyin
Department of Curriculum and Instruction: Mathematics and Science Education, University of Illinois at Chicago

Abstract
This study explores classroom participation as an agent of socialization for preservice elementary mathematics teachers. Each character, the teacher, student and curriculum in the classroom plays various roles in the socialization process. However, the teacher plays a major role because s/he is responsible for creating the environment where participation is possible. In this work, the analysis of data shows the teacher's teaching method(s), questioning and listening skills, as well as her background understanding of the specialized mathematics knowledge needed for teaching and the students all help to create such an environment. Also, as students explore mathematics by *doing* through group work, class discussions and individual work, they experience growth in mathematics classroom practices that results in change in the mathematics identity of the students.

Key words: Socialization agent, mathematics knowledge for teaching (MKT), and mathematics identity.

Setting the Stage

Recent educational reforms have increased the amount of attention paid to the preparation of elementary school teachers, particularly in subject areas such as mathematics. Low rankings by U.S. students in international comparisons, slow growth on national assessments such as the National Assessment of Educational Progress, and high levels of remediation among university and college students have helped to signal alarms about the ability of elementary school teachers to teach mathematics effectively. Also, research on teacher knowledge has begun to document specialized forms of mathematics knowledge that are unique to teaching (Ball, D. L., Hill, H. C., & Bass, H., 2005; Hill, Rowan, & Ball, 2005). For students who are products of schools in these contexts, and who desire to become teachers, it is important to understand how universities can support such students. Inadequate preparation in mathematics at the K-12 level should not automatically disqualify these students from the teaching profession. Principled, research-based understandings of how to best support students with less than ideal mathematics backgrounds are critically important. This study shows how university designed mathematics courses and classroom practices affect mathematics identity and socialization of preservice elementary mathematics teachers.

Findings

This poster reports the preliminary findings of classroom participation as a socialization agent for identity shaping of preservice mathematics teachers. Quantitative results include changes in identity using Martin's (2000) mathematics socialization and identity frameworks. The analysis of field notes, audio and video recordings of the classroom activities of the spring semester show consistent changes in participants' self-confidence, their use of appropriate language and a stronger mathematics identity.

Investigating Student Learning Through Team-Based Learning Calculus Instruction

Travis Peters, Iowa State University
Heather Bolles, Iowa State University
Elgin Johnston, Iowa State University
Craig Ogilvie, Iowa State University
Alexis Knaub, Western Michigan Univ.

We have a collection of ongoing studies designed to investigate the impact of Team-Based Learning (TBL) in calculus instruction on student learning. The first study involves the implementation of TBL in Calculus I and II. Initial findings suggest that TBL students have larger score gains on the Calculus Concept Inventory (CCI) than students receiving traditional instruction. However, there seems to be a gender gap as women tended to have smaller CCI gains than men. The second and third studies investigate the transfer of calculus to major courses, one by asking calculus content questions in subsequent major courses and the other through the educational setting of first-year student Learning Communities.

Key words: [Calculus, Team-Based Learning, Instructional Design, RUME]

We present a collection of studies conducted at Iowa State University on the impact of Team-Based Learning (TBL) in calculus on student learning. The project addresses three research questions: (1) Is TBL more effective than traditional instruction in Calculus I and II?, (2) Does calculus instruction using TBL promote transfer of calculus knowledge to downstream major courses?, and (3) Do calculus enrichment activities in first-year student Learning Communities (LCs) promote transfer of calculus knowledge?

In Fall 2015, three members of our group taught Calculus I in large and small lecture settings using Larry Michaelsen's TBL approach. This teaching strategy based on a constructivist learning theory involves students first engaging with introductory material individually and then at a higher level in teams (Hrynchak & Batty, 2012). The students do preparatory work outside of class using reading guides and instructional videos before completing a five question assessment individually and then again as a team. The majority of class time is spent working on application exercises in teams. We collected data to determine the impact of TBL on Calculus Concept Inventory (CCI) score gains, midterm exams, final exams, and final grades. In particular, we calculated individual normalized gains for the CCI (Epstein, 2013). The TBL group had a larger normalized gain than the traditional group. We also looked at individual gains by gender and section size. Women tended to have smaller CCI gains than men. The students enrolled in the small (under 50 students) TBL sections had the highest CCI gains. The second highest CCI gains were in the large (over 100 students) TBL sections. The midterm and final exams were not commonly graded but data for Fall 2016 and Spring 2017 will be from uniformly graded exams. Currently (Fall 2016), we are in our second implementation of TBL in Calculus I. We will implement TBL in Calculus II during the 2017-2018 academic year.

The second component of our project involves assessing students' retention and facility with calculus in downstream math, science, and engineering courses. Instructors in these courses will include a calculus based application problem on exams. The third component of our project involves the first-year student LCs. During Fall 2016, students completed discipline specific calculus projects related to concepts currently discussed in their Calculus I classes. To assess near transfer of calculus to STEM courses, we will administer a discipline specific calculus problem to Chemical Engr. and Aerospace Engr. students in Spring 2017. By transfer, we mean the ability to apply knowledge or procedures learned in one context to new contexts, with near transfer occurring when the learning situation is similar to the previous learning situation (Mestre, 2002).

Analyzing Focus Groups of an Experimental Real Analysis Course: ULTRA

Ruby Quea
Rutgers University

William McGuffey
Columbia University

As part of a larger study, we analyzed focus groups of students discussing their perceptions of an experimental real analysis course. The aim of this course was to teach real analysis to prospective and practicing teachers in a way that improved their future teaching. This poster analyzes data from four focus group interviews from 20 students after they completed the experimental course. The majority of comments from the participants' comments about the course, both in general and in regards to informing their future teaching of secondary mathematics, were favorable. We present commonalities in the participants' responses.

Keywords: secondary mathematics, focus groups, real analysis, teacher preparation

Rationale

Many secondary math teachers are required to complete a substantial number of courses in advanced mathematics. The efficacy of advanced mathematics courses for improving future teaching has been questioned (Darling-Hammond, 2000; Monk, 1994). In particular, many prospective and practicing secondary teachers see little to no value in the advanced mathematics courses that they take (e.g., Goulding, Hatch, & Rodd, 2003; Ticknor, 2012; Wasserman et al, 2015; Zazkis & Leikin, 2010).

In our current work, we helped develop a real analysis course, ULTRA (Upgrading Learning for Teachers in Real Analysis), that aimed to be simultaneously faithful to teaching the content of real analysis while also informing teachers' future pedagogical practice. The rationale for this course and sample lessons are described in Wasserman et al. (in press). We implemented this course with 32 prospective and in-service teachers in the Spring of 2016; 20 of these teachers agreed to participate in a focus group interview on the efficacy of this course and how this course can be improved.

Research Questions

The research question addressed in this proposal is: What were students' perceptions of this innovative real analysis course? To what extent did they find this course relevant to their teaching and why?

Method of Analysis

We answer these questions by exploring participants' utterances regarding the efficacy of the course in (i) learning real analysis, (ii) learning secondary mathematics, and (iii) teaching secondary mathematics, using each participant utterance as the unit of analysis. Analysis is ongoing (there were over 1000 participant utterances), but preliminary work demonstrates that (i) participants found the real analysis course beneficial to their teaching and (ii) participants could describe specific ways that particular modules used in the real analysis course would change or improve their practice. We will elaborate on these themes in our poster.

Extreme Apprenticeship

Johanna Rämö
University of Helsinki

Jokke Häsä
University of Helsinki

Juulia Lahdenperä
University of Helsinki

Extreme Apprenticeship is a novel, student-centred teaching method that is designed for teaching large courses with hundreds of students. It is based on Cognitive Apprenticeship. In this poster, we present the Extreme Apprenticeship method and data collected from courses taught with it.

Key words: Extreme Apprenticeship, Cognitive Apprenticeship, student-centred

Extreme Apprenticeship (XA) is a student-centred teaching method for organising instruction in an effective and scalable manner. The method was originally created for teaching university-level computer programming (Vihavainen, Paksula, & Luukkainen, 2011), and later employed in university mathematics education (Hautala, Romu, Rämö, & Vikberg, 2012; Rämö, Oinonen, & Vihavainen, 2016). Its theoretical background is in situated view on learning and Cognitive Apprenticeship (Collins et al., 1991). The focus is in supporting students in becoming experts in their field by having them participate in activities that resemble those carried out by professionals (Hautala et al., 2012; Rämö et al., 2016).

In XA, teaching consists of weekly tasks given to the students, course material, guidance and lectures. For each course, there is a teaching team whose members are the responsible teacher and undergraduate/graduate teaching assistants. The key elements are instructional scaffolding and continuous bi-directional feedback. Instructional scaffolding is implemented by providing constant support in the weekly tasks. The teaching team guides the students in drop-in sessions, and the students may spend there as much time as they need to. The members of the teaching team lead the student subtly towards the discovery of a solution through a process of questioning and listening. They model to the students how mathematicians work and thereby help them in gaining the kinds of skills mathematicians need. The drop-in sessions take place in a collaborative learning space that is easy to access for the students.

The tasks have been divided into small and approachable goals, which are then merged together as the students start to master a topic. This enables students to tackle tasks they are not yet able to complete by themselves. The students receive continuous feedback on their work, and at the same time the teachers receive feedback on the progress of the students. Some of the tasks are pre-lecture problems, which force the students to read the course material and prepare for the lectures. This way, the lectures can be made to support discussion and more active participation from the students, and time can be allocated for finding links between the course topics and building a broader picture of the subject.

The regular and close interaction between students and teaching staff guides the students in learning approaches and metacognitive skills used by experts (Burton, 2001). Further, it supports the students to establish relations within the communities of practice which enhances the students' integration into the community (Lave & Wenger, 1991).

Alongside the XA method, we present data collected from courses taught with the XA method. The data indicates that passing rates and student satisfaction have not dropped even though the workload has been significantly increased and the requirement level raised. In addition, students complete more coursework than before introducing the method.

Hypophora: Why Take the Derivative? (no pause) Because it is the Rate

Kitty L. Roach
University of Northern Colorado

***Abstract**: Part of a larger study of the development of teaching among novice college mathematics instructors, this report focuses on one participant, Disha, and her use of a questioning technique called hypophora. At the beginning of the observations, 25% of her questions were hypophora. After video-case based activities during weekly coordination meetings her use of hypophora decreased to about 10% of questions. Although Disha rejected the idea that her teaching had changed in any way, she acknowledged that she began "breaking things into smaller pieces" to help students understand.*

Keywords: questions, calculus, hypophora, professional development

Background. This study examined the teaching of five novice instructors (four graduate student Teaching Assistants (TAs) and one Ph.D. graduate) teaching calculus when their weekly course coordination meetings included video case-based professional development activities. For each instructor, research data gathering included audio and video capture of four class sessions, short surveys about practice, and multiple interviews with the researcher. The poster focuses on one participant, Disha, and how she used hypophora. *Hypophora* are questions that speakers pose and then immediately answer themselves (e.g., "Why would we want to take the derivative? (no pause) So that we can find the critical points for the function."). Disha, who was in her fifth semester teaching, asked an average of 128 questions per class. Most of these (74%) were comprehension checks (e.g., "Is that ok?", "Do you see what I am trying to say?") The next most common question type was hypophora. While it was unusual for students to attempt to answer, in at least one instance a student attempted to answer a hypophoric question. Disha did not acknowledge the student in any visible way and continued talking, answering it herself. The poster will include details about the types and uses of questions noted during instruction.

Influence of Video-case Professional Development. Disha was impressed with the "wait time" of one of the instructors in a video case and seemed to relate this "wait time" to "breaking things into smaller pieces" or scaffolding. Evidence from observation indicated her types and uses of questions changed after this case. Disha rejected the idea that her teaching had changed, though she did state that during her office hours she would "break things into smaller pieces" and wait for an answer when working with students. Kung (2010) observed that TAs learned about student thinking through interacting with students, watching them work problems and listening to them discuss mathematics, as one would during office hours. The influence of the video case may have been indirect: as a moderator of her perception of her own office hour experiences, which were in turn a moderator of her classroom practice. After video case activity, Disha spent more time exploring incorrect answers with students and asked questions of a greater depth. By exploring incorrect answers and asking deeper questions, Disha may have gained further insight into student thinking (Ball, 1997; Fennema et al., 1996; Kung & Speer, 2009).

Discussion Points at the Poster Session. Can hypophoric questions be valuable and in what ways? Is its use related to mathematical discourse? How might language acquisition be connected to and supported by a phase of hypophora use? How might the use of hypophoric questions can be changed to allow students time to think, process, and respond?

Individual and Group Work with Nonstandard Problems in an Ordinary Differential Equations Course for Engineering Students

Svitlana Rogovchenko [a] Yuriy Rogovchenko [a] Stephanie Treffert-Thomas [b]
[a] *University of Agder, Norway* [b] *Loughborough University, UK*

We explore understanding of the Existence and Uniqueness Theorems (EUTs) by a group of engineering students working on nonstandard problems. Students presented three sets of solutions: individual solutions produced in the first tutorial, individual solutions submitted as a homework, and solutions submitted after the discussion with peers in small groups during the second tutorial. The focus of the study is on the role of individual and group work with nonstandard problems. The results show that students gained a deeper understanding of EUTs and appreciated the experience.

Key words: existence and uniqueness theorems, design research, individual work, group work, nonstandard problems.

Description of the Study

The importance of the subject of ordinary differential equations (ODEs) for engineering students is supported by the majority of engineering lecturers (Francis, 1972). It is known that students experience difficulties with ODEs and even with the very concept of a differential equation (Arslan, 2010). It has been emphasized that it is essential to teach engineering students EUTs (Roberts Jr., 1976); an innovative approach in differential equations called the Inquiry Oriented Differential Equations (IO-DE) project has been shown to be effective in developing students' more conceptual understandings of ODEs (Rasmussen and Kwon, 2007). However, for students, understanding and the correct use of the EUTs remain as serious challenges (Raychaudhuri, 2007).

Nowadays EUTs are among very few theoretical results included in standard ODE courses for engineering students. The lecturer in this study devised a set of six nonstandard questions to challenge students' conceptual understanding of the EUTs. The tasks were embedded into the course design and used in two tutorials in the final part of the course when students had acquired sufficient theoretical knowledge and developed good computational skills. Students were requested first to work on the problems individually in the tutorial and at home. One week later the students discussed their solutions in small groups and presented revised solutions to their peers.

Research Questions

1) How can nonstandard questions be used to challenge students, develop analytical skills and further conceptual understanding of important concepts and ideas in an ODE course?
2) To what extent have individual work and group discussions contributed to students' conceptual understanding of the EUTs?

Conclusions

Lecturers should include more nonstandard questions that they know their students will find difficult and may not be able to answer, and do it more often. Our research has shown that students valued the experience, were not distressed by it, and gained a deeper understanding of the EUTs.

A Topological Approach to Formal Limits Supported by Technology: What Concept Images do Students Form?

Tamara Lefcourt Ruby
Bar Ilan University/Efrata College of Education

Shulamit Solomon
Rutgers University/Efrata College of Education

The formal definition of the limit of a function was taught in a first-year calculus course using open intervals and a topological approach. Student understanding was supported with computer-based visualization tools. The concept image framework was used to interpret results of a pilot study in which data was gathered through concept maps and analyzed using categorical content analysis. Results indicate some bridging between students understanding of formal limits presented via open sets and their informal limit conceptions; absolute values inequalities did not appear in the students' concept images.

Key words: formal definition of the limit, calculus

The standard formal definition of the limit of a function includes absolute value inequalities, which are difficult for students to master (*e.g.*, Almog & Ilany, 2012). This hinders student understanding of the concept (Quesada, Einsporn, & Wiggins, 2008). In addition, the standard formal definition is far removed from the initial intuitive approach to limits (Nagle, 2013).

Student understanding of the limit has been studied using the concept image framework (*e.g.*, Tall & Vinner, 1981) to uncover the cognitive structures that students associate with the limit. Results indicate that students have difficulty forming the mental constructs required for full understanding (Cottrill, Dubinsky, & Nichols, 1996; Maharaj, 2010; Tall & Vinner, 1981).

While graphing technologies have been used to support visualization of the formal definition of the limit (Cory & Garofalo, 2009; Verzosa, Guzon, & De Las Peñas, 2014), students nonetheless have difficulty connecting the graphical presentation to the absolute value inequalities in the standard definition (Quesada et al., 2008).

For functions between general topological spaces the formal limit is defined in terms of open sets. When restricted to $\mathbb{R}^1$, open sets correspond to open intervals. A rigorous definition of the limit using open intervals can replace the standard absolute value formulation; absolute value inequalities can be introduced at a later stage as a computational tool.

Open intervals are more easily understood and visualized than their equivalent absolute value counterparts. The potential benefits of an open interval approach, motivated by David Tall (2008), include more effective use of visualization technologies, minimization of the algebraic/visual disconnect, and a bridge between the intuitive notion of "close" and its formal presentation. This prompts the research question: *what concept images of the formal limit are formed by students when it is defined in terms of open intervals and supported by technology-based visualization tools?*

The formal definition of the limit of a function was taught in a first-year calculus course using the outlined approach. Preliminary data was collected from students in the course through structured concept maps (Ritchart & Perkins, 2008) and analyzed using categorical content analysis (Shkedi, 2005; Strauss & Corbin, 1990) to uncover students' concept images. Results indicate some bridging between formal limits presented via open sets and informal limit conceptions; absolute values were not part of students' concept images as revealed by the concept maps. A full study including clinical interviews is in progress. An intriguing question arises: are absolute value inequalities a necessary component of a complete image of the formal definition of the limit?

Leveraging Research to Support Students' Quantitative and Co-variational Reasoning in an Online Environment

Grant Sander, Dr. Marilyn P. Carlson
Arizona State University

Quantitative and Co-variational reasoning have been shown to be important facets of a student's mathematical learning. We are proposing an online workbook as a tool for supporting students in reasoning quantitatively and co-variationally. In this poster, we will briefly present a section on understanding graphs as representing the co-variation of two quantities' values.

Key words: Online learning, Quantitative reasoning, Graphing

Introduction and Theoretical Framework

Thompson (1990) has described *quantitative reasoning* to be the analysis of a situation into quantities and relationships between quantities, and Saldanha & Thompson (1998) and Carlson et. al. (2002) have described *co-variational reasoning* to be attending to how two varying quantities change together. Researchers have found that students' ability to reason quantitatively and co-variationally is crucial for them to write formulas and draw graphs to represent how quantities vary together (Moore & Carlson, 2012). However, there has been little research on how modern technology can be leveraged to support students in: reasoning quantitatively and co-variationally, and making connections between different representations of a situation.

Mathematical Meanings and the Workbook

Thompson & Carlson (2017) have proposed that for students to use *variables* in meaningful ways, they must be able to reason about variables as representing the varying values of quantities. If a student reasons about variables as representing the varying values of quantities, she is in a position to reason about *formulas* as representing the value of one quantity *in terms of* another, i.e. a formula describes how the two quantities are related and vary together. Another form of representing how two quantities are related and vary together is the use of graphs.

As described by Thompson & Carlson (2017), students should reason about a point on a graph as representing the simultaneous values of two quantities at some moment in their co-variation. If one imagines two quantities varying together while tracing the point that represents their simultaneous values, a *graph* emerges that represents their co-variation (Moore & Thompson, 2015, in press).

To support students in reasoning in the aforementioned ways, and making connections between mathematical representations, we have developed online workbook content that contains text, interactive questions, videos, and animated applets. In this poster presentation, we will share select pieces of the online workbook. The image below is a snapshot of one of the animated applets portraying a tub being filled with water, while representing the volume of added water and the total volume of water with variables, and graphically.

Problem Posing and Developmental Mathematics Students

Steven Silber
University of Delaware

Engaging in mathematical problem posing activities can have positive effects on students' mathematical thinking and can advance students' understanding of mathematical concepts. Knowing how underprepared undergraduate students pose problems informs the use of problem-posing activities for helping these students advance their understanding of mathematics as they transition to college-level mathematics courses. Forty-five undergraduate students enrolled in a developmental mathematics course participated in a written problem-posing assessment to describe what underprepared undergraduate students' problem posing looks like. Students' written responses were assessed for whether the response was a mathematical question, whether the responses were solvable, and the connections between each response a student provided. Results of the assessment indicate students at all levels of course performance posed solvable mathematical problems and commonly posed problems by changing the objective for each problem created.

Key words: Problem Posing, Undergraduate Students, Developmental Math, Exploratory Analysis

Posing mathematical problems is an important mathematical activity, playing a foundational role in mathematical problem solving (Polya, 2009), mathematical exploration (Cifarelli & Cai, 2005), and in people's everyday interactions (Kilpatrick, 1987). Engaging in mathematical problem-posing activities can have a positive effect on students' mathematical thinking, such as advancing students' skills at analyzing mathematical problems (English, 1997) and advancing conceptual understanding of operations on fractions (Toluk-Ucar, 2009). As knowledge of mathematics is a mediating factor while posing problems (Silver, Mamonda-Downs, Leung, & Kenney, 1996; Kontorovich, Koichu, Leiken, & Berman, 2012), undergraduate students who are underprepared for college mathematics stand to benefit from participating in problem-posing activities. Engaging these students in problem-posing activities could provide these students an opportunity to advance their mathematical thinking.

Forty-five students enrolled in an undergraduate developmental mathematics course participated in a written problem-posing assessment to investigate what undergraduate developmental mathematics students' problem posing looks like. Participants were given thirty minutes to pose three responses each for four problem-posing tasks, consisting of varying amounts of given information. Participants written responses were analyzed to determine if a response was a mathematical question, if the mathematical question solvable, and the connectedness between responses written for each task. Additionally, participants' final course grades were obtained to examine for differences in problem posing performance based upon level of course performance.

Analysis of students' written responses revealed that undergraduate developmental students at all levels of course performance posed solvable mathematical problems, and students were more likely to pose problems by changing the objective of a previous problem or changing the situational context of another problem than they were to pose problems by varying numerical quantities in each posing situation. These findings suggest that problem-posing activities are an accessible venue for undergraduate developmental mathematics students at all levels of achievement to engage in mathematical thinking.

Students' Ways of Thinking About Transformational Geometry

Natasha Speer
University of Maine

Jennifer Dunham
University of Maine

Eric Pandiscio
University of Maine

Shandy Hauk
WestEd

Eric Hsu
San Francisco State University

As part of a proof-of-concept project, we created multi-media activities and instructor support materials for secondary mathematics teacher preparation. One focal topic was transformational geometry. Data collection included undergraduate and secondary school students responding to tasks in surveys and in interviews. Despite its prominence in the Common Core State Standards for Mathematics, little is known about how students think about ideas in transformational geometry or about how they engage with items used on assessments for this topic. The poster reports findings on student thinking and invites discussion to inform future work.

Keywords: Transformational geometry, Teacher preparation

Using tasks based on sample CCSSM assessment items, we gathered data from undergraduate and secondary school student via written surveys and interviews to inform answers to the question: What productive and unproductive ways of thinking do students exhibit when working on transformational geometry tasks involving translation, reflection, rotation and dilation? Findings are based on data from 137 written surveys and 12 task-based clinical interviews containing multiple-choice and free response questions modeled after sample CCSSM items. During interviews, to gain insights into student thinking, participants were asked to carry out all transformations described in each of the answer options. In addition to coding responses for correctness, constant comparative analysis was used to identify ways students thought productively and unproductively as they completed the tasks.

Students were successful in selecting the correct sequence of transformations in the multiple-choice question. However, further examination revealed that many who correctly performed the transformation sequence given in the correct answer choice struggled with the transformations described in the other answer choices. This suggests that having students work all answers of a multiple-choice item may be valuable to teachers as a part of formative assessment of students.

We documented unproductive ways of thinking that confirm some noted by others (e.g., Portnoy, Grundmeier, & Graham, 2006; Thaqi & Gimenez, 2012; Yanik, 2011) and augment the set. These include thinking: order of transformations does not matter (and they can be done in the "easiest" order), a reflection "over" the x-axis means the image must remain above the x-axis (a horizontal shift), absence of a stated rotation direction implies a clockwise rotation, and dilation refers only to a shrinking in size. Some students also did not draw intermediate steps in a transformation sequence. On the other hand, many students demonstrated productive ways of thinking, such as performing transformations point-by-point (though this was only productive if students applied the rigid motion to each point correctly) and creating rectangles between points and the origin to help when performing rotations about the origin.

We seek advice from RUME poster session attendees to identify implications for practice and formulate future directions for research. We also hope to solicit focal topic ideas for development of additional activities for pre-service secondary teacher development as well as gather input from college instructors, department chairs, and other stakeholders.

Linear Algebra Laboratory: Transitioning Between three Worlds of Mathematical Thinking

Sepideh Stewart — University of Oklahoma
Jonathan Troup — University of Oklahoma
Han Do — University of Oklahoma
Mark Camardo

The aim of this study is to investigate students' transition between the three worlds of mathematical thinking and the challenges that they face in making these transitions. We anticipate that by creating more opportunities to move between the worlds we will encourage students to think in multiple modes of thinking and hence gain richer conceptual understanding.

Key words: three worlds, linear algebra, transition

Linear algebra is a core subject for mathematics students and is required for many STEM majors. Research on linear algebra has revealed that many students struggle to grasp the more theoretical aspects of linear algebra which are unavoidable features of the course. Linear algebra is made out of many languages and representations. Instructors and text books often move between these languages and modes naturally and rapidly, not allowing students time to discuss and interpret their validities. They assume that students will pick up their understandings along the way, but the linguistic and epistemological studies show how these assumptions are rather deceiving. As Dreyfus (1991, p. 32) declares "One needs the possibility to switch from one representation to another one, whenever the other one is more efficient for the next step one wants to take… Teaching and learning this process of switching is not easy because the structure is a very complex one." We hypothesize that most students do not have the cognitive structure to perform the switch that is available to the expert.

In order to examine the nature of the switch between the representations in linear algebra, we employed Tall's (2013) three-world model of conceptual embodiment, operational symbolism, and axiomatic formalism. In Tall's view, the embodied world involves mental images, perceptions, and thought experiments; the symbolic world involves calculation and algebraic manipulations; the formal world involves mathematical definitions, theories and proofs.

The aim of this study is to investigate students' transition between the three worlds of mathematical thinking and the challenges that they face in making these transitions. As part of the design of this study we have created a set of linear algebra tasks that are specifically crafted to move learners between the worlds. In particular we will examine where students get "stuck" and which direction would be more challenging for students (e.g., embodied to symbolic or symbolic to embodied, etc.). The data will be generated from students' laboratory work. Students will also write a reflection on each lab, specifically describing their thought processes using the 3-world model theory. They need to particularly emphasize if the task helped them to move between the worlds and if yes, how. We will integrate Geogebra, into our teaching materials (slides, applets, etc.) to demonstrate a variety of concepts, and into our lab worksheets to create a geometrically rich environment that will have a significant effect on understanding linear algebra concepts that are difficult to access otherwise. Our working hypothesize is that by creating more opportunities to move between the worlds we will encourage students to think in multiple modes of thinking and hence gain richer conceptual understanding.

Schema as a Theoretical Framework in Advanced Mathematical Thinking

Ashley Berger
University of Oklahoma

Sepideh Stewart
University of Oklahoma

In this talk we present a theoretical framework based on Skemp's idea of schema. According to Skemp, concepts are embedded in a hierarchical structure of other concepts, these levels in the structure being classifications of concepts. As the concepts are paired together, relations between them as well as classifications are also possible. The complexity of this hierarchical structure comes from the fact that these classifications of concepts and relations are not unique, giving way to multiple hierarchical structures, which can be interrelated. When components of these conceptual structures come together to make a structure that would not be realized by only looking at the individual components, the resulting structure is called a schema.

Key words: schema, Topology, understanding

Teaching and learning of advanced mathematics topics are often challenging. The aim of this study is to create a theoretical framework based on the notion of *Schema*, in order to investigate undergraduate students' difficulties in Topology.

Skemp (1987) gives a detailed definition of schema in his chapter, "The Idea of a Schema". He describes a system where concepts are embedded in a hierarchical structure of other concepts, these levels in the structure being classifications of concepts. For example, a train can be classified as a mode of transportation and can contribute to one's concept of transportation. There are not only single concepts, but when we pair concepts together, we can have a relation between them, for which a classification is also possible. We can also look at transformations of concepts, which can be combined to make other transformations. What makes this hierarchical structure of concepts, relations, and transformations so deep and complex is the fact that these classifications are not unique, giving way to multiple hierarchical structures, which can be interrelated. When components of these conceptual structures come together to make a structure that would not be realized by only looking at the individual components, we call this resulting structure a schema. Skemp (1987) claims that a schema integrates existing knowledge, serves as a tool for future learning, and makes understanding possible. Without a suitable schema in position, students will have difficulty in understanding or making sense of new concepts. The proposed framework will promote schematic learning and seek to identify whether the presence or absence of a certain schema will have an effect in understanding new knowledge in Topology. Skemp (1987) used Topology for the reason that "the relevant schema can be quickly built up, whereas most mathematical ones take longer." (p. 30)

Piaget and Garcia's (1989) triad framework gives a starting point in developing a suitable schema in Topology:

Intra Stage: Working purely within a definition of a topology; basic examples
Inter Stage: Connecting definition with previously knowledge
Trans Stage: Coherent structure (e.g. Skemp's *understanding*); Viewing a topology as how open sets are defined for a topological space

Beyond the Exam Score: Gauging Conceptual Understanding from Final Exams in Calculus II

Kristen Amman
University of Michigan

Ciera Street
The College of William and Mary

Instructors often want to evaluate their students' degrees of conceptual understanding in their mathematics courses, but are typically limited to course assignments and exams. In this research we ask: To what extent can mathematics instructors recognize conceptual understanding of their students based on final exam responses? During a summer REU program we examined pre-existing exams along with other course materials to address this question. We developed codes for student responses that were guided by Anderson and Krathwohl (2001), Mejia-Ramos et al. (2011), Thurston (1994), and the APOS framework. Student responses more clearly and often demonstrated lower level understanding than deeper, conceptual knowledge because few problems called for explanations or justifications. The goal of this research was to improve the effectiveness of assessments in evaluating conceptual understanding. In future exams, we suggest that prompting students to display behaviors typical of varying levels of understanding with justification would make evaluations more accurate.

Keywords: Conceptual understanding, Calculus, Exams

Instructors want their students to have a "conceptual understanding" of the topics in their mathematics courses, but do not always know how to find evidence for this. Undergraduate Math Education Researchers have found evidence in in-depth interviews with students, classroom observations, and student responses on tasks created specifically for an educational study. However, an instructor is typically limited to information that can be conveyed through written work such as homework and exams. Thus, we asked: 1. How can we use information about the problem-solving behaviors that students demonstrate when solving final exam problems to make inferences about their degrees of conceptual understanding? 2. How can we create new instructional tools that would provide more evidence for conceptual understanding? We coded responses from 40 final exams randomly selected from four Calculus II sections taught in Fall 2015 at a large, land-grant university. The construction of our codes was guided by the frameworks of Krathwohl (2002), Mejia-Ramos et al. (2012), Thurston (1998), and Dubinsky & McDonald (2001), and an in-depth analysis of first-year calculus. After two rounds of revision, the final codes ordered from lower to higher conceptual understanding were: Execute Computations, Recognize Definitions, Represent Visually, Recognize and Apply Procedure, Recognize Details, Generate Examples, and Analyze Relationships. Success on the exam was largely determined by performance on low-level tasks. Students most often struggled with higher-level behaviors based on error proportions and frequency. Compared to students with lower levels of understanding, the lack of justification in student work made differentiating between medium and higher levels more difficult. Finally, we often coded only one or two behaviors per question, which emphasized the exam's lack of opportunity to demonstrate higher-level understanding. In future exams, designing problems that require varying types of justification, or prompt students to display specific behaviors would make coding more accurate. We would like to expand upon this research to create assignments designed to build conceptual understanding of specific calculus concepts through tasks increasing in conceptual complexity.

Categorizing Teachers' Beliefs About Statistics Through Cluster Analysis

Gabriel Tarr
Arizona State University

The CCSSM emphasize statistical concepts for grades 6-12. The paper will attempt to answer the following question: How do middle school mathematics teachers in a professional development program differ from each other with regard to how they view statistics?

Key words: Statistics Education, Statistics

The emphasis on teaching statistics standards in The Common Core State Standards for Mathematics (National Governors Association, 2010) is much greater than in previous standards (Tran, Teuscher, Dingman, & Reys, 2014). Since beliefs and conceptions influence how teachers teach (Thompson, 1992), it is important to attend to the beliefs that teachers possess about statistics to study how these teachers would teach statistics. In this paper, the researcher will answer the following question: How do middle school mathematics teachers in a professional development program differ from each other with regard to how they view statistics*?* This paper will include analysis on teachers' responses for seven open-ended survey items about their beliefs on statistics.

Methodology

Instruments for assessing statistical beliefs and attitudes tend to be Likert-scaled items with no room for the respondents to elaborate on their answer choices (Gal & Ginsburg, 1994; Gal, 2003). The researcher designed this survey to be open-ended, so that teachers would have the freedom to answer the items as they wished.

The following is the list of the survey items that were given to a population of 50 in-service middle school teachers in the beginning of their second year in a two-year professional development project: a) Briefly give a definition for statistics. What do you take this to mean? What comes to mind when you see or hear the word statistics? b) How would you describe your personal background in statistics? c) To you, what are the differences, if any, between statistics and mathematics? What are the similarities, if any, between statistics and mathematics? d) I am looking forward to statistics content in year two because: e) I am not looking forward to statistics content in year two because. f) I see statistics being useful to my students because. g) I see statistics as not being useful to my students because.

The teacher response data were not ordinal or interval scale in nature, so the researcher used partitioning around the medoid clustering which does not depend on Euclidean distance (Kaufman & Rousseeuw, 1987). The researcher determined the number of clusters by choosing the value for the number of clusters, $k(\leq 6)$, that would maximize the silhouette distance (Charrad, Ghazzali, Boiteau, & Niknafs, 2014).

Student Understanding of Elements of Multivariable Calculus

John R. Thompson — University of Maine
Benjamin P. Schermerhorn — University of Maine
J. Caleb Speirs — University of Maine

We present preliminary findings from written, post-instruction surveys to gauge student understanding of various elements of multivariable calculus. The content addressed includes contour plots, partial derivatives, representations of gradients and slopes, construction of volume difference integrals.

Key words: Multivariable Calculus, Difficulties

While student understanding of single-variable calculus has received a great deal of attention in the literature, overall few studies have been done on multivariable calculus topics. This area has rich research potential, including characterization of the student understanding landscape as well as how students generalize various concepts such as domain and range (Dorko & Weber, 2014) and integrals (Jones & Dorko, 2015) from single- to multivariable calculus. We present preliminary findings from written, post-instruction surveys to gauge student understanding of various elements of multivariable calculus.

Methods

The written questions discussed here were administered in a survey administered at the end of multivariable calculus classes, typically as part of the final exam. Results come from multiple institutions, with variations in class size and instructional approach. Our findings have not sorted among these variables, and thus are described qualitatively.

The content addressed includes partial derivatives; representations of gradients, slopes, and contours; and volume integrals. The surveys were developed as part of the *Raising Calculus to the Surface* project (Wangberg & Johnson, 2013), which seeks to build a stronger geometric understanding of multivariable calculus using a pedagogically modern approach. Results on student concept images of one-dimensional integration pre-instruction have been reported previously (Fisher *et al.,* 2016).

Results

Here we summarize the most significant findings. Basic computational tasks (partial derivatives, gradients, directional derivatives) yield low success rates, primarily due to what appear to be executive or arbitrary errors (Orton, 1983). A question asking for an estimate of a function value along the direction of the gradient vector demonstrates significant misinterpretation of the graphical representation: students interpret the magnitude of the gradient vector according to the grid spacing. Students are successful interpreting the general meaning of a partial derivative, consistent with prior findings in physics (Thompson *et al.,* 2006). However, results from a subsequent question asking for the meaning of an equation for the numerical value of a partial derivative at a particular point suggest that application of the general meaning is not straightforward. Finally, very few students in this sample are able to set up an integral for the volume enclosed between two surfaces; despite many different approaches to the integral, the most common error is the determination of the correct limits.

Designing a Richer Flipped Classroom Calculus Experience

Mathew Voigt
San Diego State University

Helge Fredriksen
University of Agder

The study presented here is an illustrative example of an action based research project, which was focused on broadening student partition in the flipped classroom experience in order to address issues of equity and social justice in the calculus curriculum. While flipped classrooms have gained recent notoriety within the literature, they rarely incorporate or addresses other critical perspectives. Our study highlights how using design principles such as realistic mathematics education (RME) and culturally responsive pedagogy can effectively target the hidden curriculum and shape the norms and classroom discourse features (Sfard, 2008).

Keywords: Flipped, Realistic Mathematics Education, Culturally Responsive, Calculus

In this action based research, we designed and implemented a two-week classroom teaching experiment for calculus students covering topics in trigonometry and vectors. Based on the current best practices in flipped classroom (Bagley, 2015) we created three different types of instructional videos (*expository, inquisitive and illustrative*) and used the design principles of RME to create the paired classroom activities (Gravemeijer & Doorman, 1999). The *expository* videos introduced the mathematical topic, provided an overview of the content, and made connections to prior mathematical topics. The *inquisitive* videos provided a single mathematical problem that was discussed in length, giving probing questions and possible solution paths, but did not present a final solution to the problem. The problem presented in the *inquisitive* videos was then the focus for the classroom discussion. The *illustrative* videos were designed to show procedural techniques and operations to solve particular problems.

The study took place with 27 students enrolled in a first years course in Mathematics at a Northern Norwegian University. This unique setting provided the opportunity to include design elements to support students with varying degrees of fluency in English, a challenge that is faced by many educators in the United States (Mosqueda & Maldonado, 2013). We draw on several curriculum constructs (formal, observed and hidden) to frame the complete life cycle of this classroom teaching experiment (Stein, M.K., Remillard, J.T., & Smith, 2007). We highlight how our unique role as both the designer of the materials and the teacher of the content allowed for us to use a critical lens to address and shape the underlying norms and beliefs in the classroom through the hidden curriculum (Yackel & Rasmussen, 2003).

For example, we were compelled by culturally responsive pedagogy and RME such that our goal was to have students critically analyze the world they live in, and attend to how mathematics is used within that realm (Aguirre, 2009). We designed the curriculum in this way such that example problems were based in the local context of the town (e.g. using vectors to describe the movement from the local airport to the university) and at a national level (e.g. modeling wolf population zones in Norway). We also wanted students to use mathematics to engage with 21st century issues so we designed a curriculum unit around modeling historical temperature data in Norway to make arguments for climate change. We analyzed features of the mathematical discourse that were made salient within the curriculum (Sfard, 2008) as well as using interview data, to showcase the impact the inquisitive videos may have had on fostering commognitive conflict related to the mathematical topic. Finally, we provide some recommendations, insights and further areas of research based on the outcomes measured in this study.

Putting on the Uniform: Coordination within the Calculus Curriculum

[1]Matthew Voigt, [1]Shawn Firouzian & the Progress through Calculus team*
[1]San Diego State University

The study presented here examines the types and relative frequency of uniform course components (exams, textbooks, etc.) currently in place in the Precalculus through single variable calculus sequence at graduate universities and how those components are effected by the presence of department factors such as regular course meetings, instructor type, and the presence of a course coordinator. Our results indicate that while the total number of uniform course components decline throughout the Precalculus through single variable calculus sequence, its effect is mitigated by the presence of a course coordinator and regular course meetings. In addition, student success is significantly related to the presence of both a course coordinator and regular course meetings.

In this current study, we provide a comprehensive report regarding the coordinated course structures in place to support university students in introductory mathematics sequences across the country – both in terms of uniform course elements and departmental factors. Bressoud, Mesa and Rasmussen (2015), during their initial study examining the characteristics of successful programs in college calculus identified that a "system of coordination" such as having a course coordinator or uniform exams in a calculus programs resulted in a powerful net effect promoting student success. While that study's design did not allow for documenting the frequency of such options across the country, the Progress through Calculus (PtC) project does, including precalculus and the entire single-variable calculus sequence.

During phase 1 of the PtC project, a national census survey was distributed to all 330 American mathematics departments that offer a graduate degree in mathematics and closed with a 68% response rate. The survey asked for details (including enrollment data, delivery format, etc.) of all courses in the mainstream Precalculus to Calculus 2 (P2C2) sequence. Mainstream refers to any course in this sequence that is part of student preparation for higher-level mathematics courses. Using the survey data collected from 265 institutions, we identified factors that quantified uniformity and coordination within and across the P2C2 sequences. In this presentation, we focus on coordination within a courses.

Our descriptive results showcase that the only uniform course elements held by a majority of courses in the P2C2 sequence are textbooks and course topics. While still relatively common we observed less uniformity with regards to graded elements (Final Exam, Midterms, and Grading) and even less with regards to course materials (handouts, videos, and graphing calculators). We note that besides the exception of gateway exams, the prevalence of uniform elements decreases between preparation for calculus and calculus 1, and again between calculus 1 and calculus 2. However, this decline in the total number of uniform elements is not significant when controlling for the frequency of course meetings and the presence of a course coordinator.

In addition to presenting the relative frequency of the uniform course components, we also note that regular meetings and instructor type (tenured faculty) were significant predictors for student success, as measured through DFW rates. These finding suggests that having an

** The Project through Calculus PI team consists of Linda Braddy, David Bressoud, Jessica Ellis, Sean Larsen, Estrella Johnson, and Chris Rasmussen. Graduate students include Naneh Apkarian, Dana Kirin, Kristen Vroom, and Jessica Gehrtz.*

organized structural system in place increases the overall uniform experience for students regardless of the prescribed uniform components.

Who is teaching the Precalculus Through Single-Variable Calculus Sequence and How are they Teaching it?

[1]Kristen Vroom, [1]Dana Kirin, & the Progress through Calculus team*
[1]Portland State University

It is well documented that the precalculus through single-variable calculus sequence (P2C2) acts as a barrier for many STEM intending students. Students often cite poor instruction as a primary reason for switching out of STEM programs (PCAST, 2012; Seymour & Hewitt, 1997), which leads to questions about what instructors and instruction look like across the country. This poster presents findings from national census survey data collected as part of a larger study, Progress through Calculus (PtC). In particular, we answer: (1) What types of instructors are currently teaching courses in the P2C2 sequence and how prevalent are they nationally? (2) What relationship exists (if any) between instructor type and primary instructional format?

Key words: Instructors, Instructional Practices, Precalculus, Calculus

Sample Results

To address the first question, we consider the types of instructors participants identified as *frequently* teaching courses within the P2C2 sequence. 205 institutions provided detailed course information on instructors of 894 mainstream courses. At these institutions, full-time faculty frequently taught 67.3% of the courses within the P2C2 sequence; tenured and tenured-track faculty frequently taught 60.4% of the courses; part-time teaching faculty, visiting faculty, or postdoctoral researchers frequently taught 42.5% of the courses; and graduate teaching assistants/associates (GTAs) frequently taught 29.1% of the courses. Note that these percentages do not add up to 100%, because more than one type of instructor might frequently teach any given course.

Our second question considers the relationship between instructor type and primary instructional format. Participants identified the primary instructional format for the regular class meetings of each course. The following results are based on the four categories of instructors identified above and four categories of instructional format: lecture, lecture incorporating some active learning, minimal lecture with mainly active learning techniques, or lecture plus computer based instruction. 200 institutions provided information about the instructional format for 881 courses. Of these, 66% were identified as being taught using mostly lecture, 16% used some active learning in tandem with lecture, 2.5% of courses were taught using mostly active learning, and 3.6% of these courses used computer-based instruction alongside lecture. This trend is consistent across instructor type. While all instructor types utilized lecture most often for their courses, when conditioning on instructor type, proportionally GTAs employ lecture less often in their courses than other instructor types. For example, 57.5% of the courses GTAs frequently taught were lecture based while part-time teaching faculty, visiting faculty, or postdoctoral researchers utilized lecture in 71.1% of their courses.

Along with the results reported here, we will present a more detailed description of instructor type and instructional formats for all courses, including findings using similar analysis separated by course type (e.g., Precalculus, Calculus 1) and highest mathematics degree awarded.

The Effects of Graphing Calculator on Learning Introductory Statistics

Wei Wei — Metropolitan State University
Katherine Johnson — Metropolitan State University

Abstract: Graphing calculators have been used for teaching introductory statistics for decades. They helped students to obtain accurate statistical analysis results. However, heavily relying on graphing calculators may hinder students' understanding of certain statistical concepts such as the normal distribution and p-value. In this study, we focused on the effects of using a graphing calculator on students' conceptual understanding of normal distribution and p-value, and their performance of calculating normal probabilities and conducting a hypothesis test.

Methods

This study included four sections of an introductory statistics course from two instructors. Each instructor taught one section with the use of graphing calculator and another section without graphing calculator. The goal was to test if the average grade was significantly higher from the graphing calculator section (referred to as TI section) than that from the section without using graphing calculator (referred to as non-TI section).

Two quizzes and three final exam questions were included in this study. Quiz one contained one multiple choice question of the conceptual understanding of standard normal transformation, and one calculation question covering the normal probabilities. Quiz two contained one multiple choice question of the conceptual understanding of p-value, and a short answer question covering a hypothesis test of difference in proportions. The three final exam questions were used to test on retention, including two multiple choice questions of the concepts of standard normal transformation and p-value, and a calculation question of hypothesis testing of a single mean. Each quiz was given to both the TI section and non-TI section at the same time.

Mantel-Haenszel analyses were used to analyze the multiple choice questions and 2 by 2 ANOVAs with two independent factors, instructor (instructor one and instructor two) and the use of calculator (TI and non-TI), were used to analyze short answer questions.

Results

The Mantel-Haenszel analysis for quiz one multiple choice question showed that the proportion of correctness was significantly higher for the TI section than that for the non-TI section when testing on the conceptual understanding of standard normal transformation. The Mantel-Haenszel analysis for quiz two multiple choice question showed that there was no significant difference in proportions of correctness between the TI and non-TI sections when testing on the conceptual understanding of p-value. The 2 by 2 ANOVA of quiz one calculation question showed that the average score was significantly higher for the TI section than that for the non-TI section when students did the calculation of normal probabilities. The 2 by 2 ANOVA of quiz two short answer question showed that the average score was also significantly higher for the TI section than that for the non-TI section on performing hypothesis testing. All of the Mantel-Haenszel analyses and 2 by 2 ANOVAs of the final exam questions did not show significant differences between the TI and non-TI sections for retaining the knowledge of standard normal transformation, normal probability calculations, p-value and hypothesis testing.

Exploring Conceptions of Mathematics: A Comparison of Drawings and Attitudinal Scales

Ben Wescoatt
Valdosta State University

This study explores beliefs about doing math held by pre-service teachers. Pre-service teachers in a mathematics content course drew pictures of a person doing math. Additionally, modified Fennema-Sherman Mathematics Attitude Scales (FSMAS) (Ren, Green, & Smith, 2016) were administered to the students. The drawings were analyzed using a framework developed from the Farland-Smith (2012) rubric. In addition to exploring beliefs about doing math held by the students as evidenced by the drawings, the study considers the validity of the drawing methodology through a comparison to the FSMAS results.

Key words: Mathematical beliefs, Pre-service teachers, Drawing methodology

Teachers play a key role in helping students form perceptions about mathematics and what it means to do math. A teacher's beliefs can influence the mathematical experiences they have with their students and so can influence the conceptions about math that the students form (Mewborn & Cross, 2007). As teachers can have such impact on the impressions about mathematics held by future generations, and as these impressions may dissuade students away from mathematical disciplines, understanding teachers' conceptions of mathematics is an important area of study. The focus of this current study is to better understand pre-service elementary and middle school teachers' conceptions of doing mathematics. That is, when someone thinks about "doing mathematics," what comes to mind? It could be that very specific applications are imagined or that feelings or emotions are evoked.

To better understand this question, two types of data were collected from 49 students in a capstone mathematics content course for pre-service teachers at a regional university in the southeastern United States. In one data collection phase, participants responded to the prompt, "In the box below, draw a picture of a person doing math. Place as much detail into the drawing as you can." Participants then used several sentences to explain their drawing. In the other data collection phase, students completed a version of the Fennema-Sherman Mathematics Attitude Scales (FSMAS) as modified and validated, for use with lower primary teachers, by Ren, Green, and Smith (2016). The scales used by Ren, Green, and Smith were *Confidence*, *Effectance Motivation*, and *Anxiety*. The collection phases were spaced one week apart.

A framework developed by Wescoatt (2016) will be used to explore the drawings. The framework is a refinement of a rubric developed by Farland-Smith (2012) and modified by Bachman, Berezay, and Tripp (2016). To explore the "doing" of math, each drawing will be analyzed for elements of Action (what is being done), Mathematics (mathematical elements such as symbols), Appearance (the person's physical appearance), Location (a description of surrounding elements), and Affect. Each image will be assigned a score from 1 to 7 for the Affect category, with 1 representing an extremely negative image and 7 representing an extremely positive image. The written explanations will be used to verify interpretations.

One of the drawbacks of the framework is that it has not been completely validated. As a participant draws his or her image, the possibility exists that he or she is merely drawing an image of stereotypical elements that are not reflective of his or her actual beliefs. In an attempt to begin rectifying this shortcoming, a comparison between the participants' FSMAS results and the Affect scores from the drawings will be explored.

Developing, Implementing, and Researching the Use of Projects Incorporating Primary Historical Sources in Undergraduate Mathematics

Janet Barnett

Diana White
University of Colorado Denver

Mathematics faculty and education researchers increasingly recognize the value of the history of mathematics as a support to student learning. There is an expanding body of literature in this area which includes direct calls for the use of primary historical sources in teaching mathematics. The current lack of classroom-ready materials poses an obstacle to the incorporation of history into the mathematics classroom. Transforming Instruction in Undergraduate Mathematics via Primary History Sources (TRIUMPHS) is a seven-institution collaboration that will design, implement, test, and publish curricular materials based on primary historical sources, train approximately 70 faculty and graduate students on their development or implementation, and conduct and evaluation-with-research study. We present an overview of the project, including activities and research to date.

Key words: Primary Sources, History of Mathematics, Meta-discursive Rules, Case Study

Introduction

In addition to the general benefits of inquiry-based learning, particular advantages incorporating primary sources include providing context and direction to the subject matter, honing students' verbal and deductive skills through reading the work of some of the greatest minds in history, and the invigoration of undergraduate mathematics courses by identifying the problems and pioneering solutions that have since been subsumed into standard curricular topics. By working collaboratively to develop Primary Source Projects (PSPs) while training faculty across the country in their use, TRIUMPHS will ensure these materials are robustly adaptable to a wide variety of institutional settings, while simultaneously developing an ongoing professional community of mathematics faculty. Additionally, our evaluation-with-research study will directly contribute to a greater understanding of (a) how student perceptions of the nature of mathematics evolve, (b) the potential of particular PSPs to promote student learning of meta-discursive rules in mathematics, and (c) how to support faculty in developing and implementing this research-based, active learning approach in undergraduate STEM education.

Online STEM and Mathematics Course-Taking: Retention and Access

Claire Wladis
Borough of Manhattan Community College and the Graduate Center, City University of New York
Alyse C. Hachey and Katherine Conway
Borough of Manhattan Community College at the City University of New York

Using survey data and interviews from a large urban university system, this study explores factors that impact student decisions to take math classes online. The results suggest that access to online math courses likely impacts student course taking patterns, with significantly more students taking a different course if their desired math course is not offered online, compared to non-math courses.

Keywords: Online learning, student characteristics, access.

In 2013, over 40 million college students took online classes worldwide; by 2017, that number is expected to triple (Atkins, 2013). Online courses are often thought to provide access to education, particularly for student parents, and students who work, but little research has been conducted to explore how the availability of online courses impact student course-taking patterns (Jaggars, 2011).

Research question: When online sections of a particular course are not offered, do students take the same course face-to-face, and does this differ for math classes?

Methodology: This research used a sample of students who enrolled in online or comparable face-to-face courses at one of the two- or four-year colleges at the City University of New York (CUNY) from 2004 to 2017. These results focus on survey results for those students enrolled in spring 2016, for a total sample size of 14,689. In addition, 49 interviews were conducted. Student responses to survey and interview questions were coded using grounded theory (Glaser & Strauss, 1967). For student responses to survey questions related to their enrollment, z-scores were calculated.

Results: What factors impact student decisions to enroll in online math classes? In interviews, students expressed different perceptions explaining whether and why they preferred to take math classes online or face-to-face. Many students specifically felt that it was better to take math classes face-to-face: *"Some courses can be done online... The complicated courses, you have to be there—like math—to ask questions directly. Like math—you can't miss a day, and you really need a face-to-face course for something like that… something where you have to read and remember and take a test, you know that's okay for [an] online course."*

But other students had the opposite opinion, feeling that math was particularly well-suited to online learning: *"[I took] math [online] as opposed to English, where I can truly benefit from class discussion. Math is what it is. So I figured that would be a good course to take [online]."*

Even more striking, almost half of all students in an online math course would have taken a different course if that course had not been offered online; this is significantly higher compared to students who took other subjects online (see Table 1).

	all	math	
different course	37%	46%	***
* $p<0.05$, ** $p<0.01$, *** $p<0.001$; Significance calculated using two-tailed z-test for proportions			

Table 1: Student reports of alternative course selection if the course had not been offered online

Students who took math classes online often needed them to complete a specific degree, so if the class had not been offered online, this could have been a barrier to degree completion.

"[If the computer math class had not been offered online that semester], I don't know—[I would have taken] any other math—calculus or algebra—online. [If I had not been able to take an online math class that semester,] I wouldn't be able to finish my college during the fall."

Limitations: CUNY's highly diverse, urban population of low-income, foreign-born, and first-generation students may not be generalizable to other less-diverse college populations.

Conclusion: These results suggest that students take different courses if the math class that they are interested in is not offered online. Delaying developmental math and progressing more slowly through course sequences are both associated with college dropout (Attewell, Heil, & Reisel, 2012; Fike & Fike, 2012). Because of these patterns, colleges should be cautious about restricting access to online math courses or offering insufficient math course sections online to meet student demand.

Service-Learning and a Shift in Beliefs about Mathematical Problem Solving

Ekaterina Yurasovskaya
Seattle University

During academic service-learning experiment, students in an experimental Precalculus class regularly tutored basic algebra to middle-schoolers. At the end of the quarter, student-tutors demonstrated academic improvement and a shift in beliefs about importance of conceptual understanding in problem solving. These manifested benefits can motivate mathematics departments to implement service-learning as part of academic curriculum.

Key words: Precalculus, service-learning, beliefs, social justice in mathematics education

Academic service-learning combines coursework and community service: students gain or enhance subject knowledge by participating in structured outreach (Hadlock, 2013). Prior studies on math and service-learning showed gains in tutors' subject knowledge, decrease in mistakes (Yurasovskaya, 2016), and reduction of math anxiety (Henrich & Lee, 2011).

Beliefs about mathematics influence student learning (Leder, Pehkonen & Torner, 2002). Our research explores impact of academic service-learning on student beliefs about mathematical problem solving. This work is motivated by the need to improve Calculus preparation and retention (Bressoud, Mesa & Rasmussen, 2015), and the necessity for more research on the effect of service-learning on mathematics education.

Our study explores two research questions: Will students who engage in tutoring algebra pre-requisites to middle-school students demonstrate a significant shift in beliefs about mathematical problem solving? Will students-tutors demonstrate significant improvement in course performance? Following a pseudo-experimental setup of McKnight, Magid, Murphy, and McKnight (2000), control and experimental sections are randomly chosen for the experiment. For theoretical background, we refer to the work of McLeod (1989) on the impact of beliefs on student performance in mathematics.

Methodology

Our study takes place in a Precalculus class at an urban Catholic university: twenty university students tutor algebra to middle-school kids 2-3 hours per week for the duration of the quarter. Control section receives traditional course instruction. At the start and the end of the quarter, students in both sections take a diagnostic test to establish a baseline, and fill out a survey composed of Indiana Mathematics Belief Scales (Kloosterman & Stage, 1992). Exam performance and the shift in attitudes and beliefs are analyzed at the end of the quarter.

Results

Experimental class showed a shift in the average score for the question group "Understanding concepts is important in mathematics", from 22.23 to 24 with t-value 1.78 and p=0.1, along with a change in standard deviation: from 4.07 to 1.8 in pre vs post scores. Control section did not show any statistically significant shift in any of the belief groups. Experimental section made a significant shift on individual items measuring importance of computational skills and of conceptual understanding why a given numerical answer is correct. Initially, experimental section showed lower averages on the diagnostic and exam one: 59% vs 76% in the control section. By exam two and the final, the difference in averages was no longer statistically significant (74% experimental to 76% control).

Positive results of our research can serve to provide departments of mathematics with incentives to implement outreach and service learning as part of academic curriculum.

Interpretive Reading of Mathematical Propositions for Proving: A Case Study of a Mathematician Modeling Reading to Students During Joint Proof Production.

Anna Zarkh
University of California Berkeley

Successful proof production in advanced mathematics relies on meaningful apprehension of the to-be-proved proposition, yet we know that this is a challenge for many students. This study examines the ways in which a mathematician-instructor, addressing this issue, models the practice of interpretive reading of mathematical propositions to a pair of students in the context of joint proof-production in a Real Analysis course. Taking a social practice perspective on reading and adopting Sfard's commognitive framework as a theoretical lens, I identify three aspects of the discursive work the expert engages with to demonstrate processes of active meaning-making to students: (1) re-reading of text with grammatical shifts, (2) posing comprehension monitoring questions, and (3) narrative enactment of text.

Keywords: Reading; Proof Production; Expert-Novice Interaction; Real Analysis.

Many students have difficulties understanding to-be-proved propositions (Selden & Selden, 1995). A key challenge is that relevant information is not readily available in the text, and thus interpretive work is required to make propositions sensible for proving (Weber, Brophy, & Lin, 2008). Not enough is known about the processes by which successful proof writers read propositions with understanding, or how such practices can be taught.

Theoretical Framework. This study relies on two central assumptions. First, I posit that reading of advanced mathematical text is a social practice (Rasmussen, Zandieh, King, & Teppo, 2005). Second, following Sfard (2008), I consider mathematical meaning to be constituted by the discursive work within which text is embedded.

A Study of a Mathematician Modeling Reading; Methods, Results and Implications.

Methods. Data for the present study are taken from a larger video corpus collected to investigate the teaching practices of a highly experienced mathematician-instructor of a Real Analysis course. This paper focuses on a single classroom event in which the instructor performs interpretive-reading while assisting a pair of undergraduate students in constructing a proof to a statement about uniform convergence during a review session. The focal episode was analyzed using micro-ethnographic techniques (Erickson, 1992). A stimulated-recall interview with the instructor served as an additional data source to inform analysis.

Results. Three aspects of the instructor's demonstrative reading emerged as important meaning-making devices: (1) repetitive re-reading of text with shifts in the grammatical structure of the natural language within which signifiers are embedded (e.g. "*it*'s a sequence that is bounded" "*they*'re all bounded"); (2) posing of rhetorical, comprehension-monitoring questions (e.g. "And what do we know about it?"); and (3) narrative enactment of text using multi-modal symbolic devices (e.g. "Here are the f_ns ((draws overlapping curves on the board)) ... and they converge to something down here"). In a stimulated recall interview the mathematician-instructor described his performance as "forcing them to read slowly in order to learn to breakdown the sentences. So they begin to understand what's in the question".

Implications. This case study sheds light on the complexity involved in enacting mathematical meaning from text, and can thus contribute to our understanding of the difficulties students experience. The analysis can also help position the practice of interpretive reading, tacitly assumed in current models of proof production (Weber & Alcock, 2004), as an explicit goal of instruction in advanced mathematics courses.

Mathitude: Precalculus Concept Knowledge and Mathematical Attitudes in Precalculus and Calculus I

Oyuki Aispuro, Jerica Bañares, Grant Dolmat, Todd CadwalladerOlsker, Sissi Li
California State University, Fullerton

The concept knowledge and attitudes and perceptions about mathematics of students in precalculus and calculus were measured using the Precalculus Concept Assessment (PCA) and Mathematical Attitudes and Perception Survey (MAPS). We found significant differences in these measures among several subgroups, and found correlations between these measures and student success.

Key words: Concept Knowledge, Perceptions, Attitudes, Calculus

There is a pattern of students citing calculus as a major factor in their decision to leave STEM majors (Rasmussen and Ellis, 2013). Industry and government leaders are calling for colleges and universities to understand and address this problem as it has implications in the hindrance of our nation's economy and intellectual power. In this study we have explored students' conceptual knowledge and mathematical attitudes in precalculus and calculus, using two instruments. First, the Precalculus Concept Assessment (PCA) instrument can assess student learning, effectiveness of curricular treatment, and determine student readiness (Carlson, Oehrtman & Engelke., 2010). Second, Mathematics Attitudes and Perceptions Survey (MAPS) instrument can provide information about how well student beliefs of mathematics align with expert beliefs (Code, Merchant, Maciejewski, Thomas & Lo, 2016). Concept knowledge and expert-like attitudes and perceptions about mathematics are both critical components of mathematical expertise. By studying these components, we can help students to reach higher levels of expertise.

Students enrolled in Precalculus and Calculus I during Spring 2015, Fall 2015, and Spring 2016 were invited to participate in the two surveys described above at the beginning of the semester prior to any instruction or opportunity to attend SI. Both surveys were administered online. After the 15 week semester was nearly over, students were asked to complete the same two surveys again. The matched data set used in this study included N = 181 participants which are all students who provided complete data for both pre and post surveys.

We found several interesting results from our study. First, when we examined concept knowledge as measured by the PCA, we found that although Calculus students began the semester with a higher score on the PCA than precalculus students (as expected), at the end of the semester, the precalculus students had caught up to the calculus students, whereas the calculus students PCA scores improved only slightly. Second, we examined the MAPS scores of different subgroups of students. We found that male students were significantly more likely than female students to agree with expert beliefs on mathematics' relation to the real world; and that students who attended a peer-led supplemental instruction (SI) program were more likely to improve their confidence throughout the semester. We also found a weak but statistically significant relationship between PCA scores and agreement with expert opinions on the MAPS instrument, especially with the MAPS subscores of Confidence and Exploration in Problem Solving. Finally, both the post-semester PCA and MAPS scores are positively correlated with higher grades.
