In synthesizing the preceding theories, abstraction has a dual nature: it can be seen both as a cognitive activity and as the concept resulting from that activity. When viewed as a cognitive activity, *abstraction* is a process that transforms a concept via given means. The resulting concept is said to be an abstraction (or "abstracted"). In what follows, we use the term "level of abstraction" to refer to the means by which the student carries out the abstracting activity. Thus, in *reducing abstraction*, an individual is acting cognitively via specific means in order to reduce for herself the level of perceived abstraction. Reduction is tied to the specific context in which the student is working. The Expanded Reducing Abstraction framework in Table 1 presents the levels of abstraction and operationalizes the means by which the activity is carried out.

# Reducing Abstraction: An Expanded Framework

We leverage the prior discussion of abstraction theories to introduce an expanded classification of reducing abstraction. As in Hazzan's (1999) work, we do not claim that these ways of reducing abstraction are mutually exclusive or exhaustive. Rather, we introduce the framework as a tool for making sense of the many ways students engage with tasks containing abstract concepts. We illustrate categorization with data from several of our studies (Melhuish 2015; Melhuish & Fagan, 2017), Hazzan's original paper, and outside literature.

*Table 1. Expanded Reducing Abstraction Framework*

| Abstraction Level as: | Operationalization of Reducing Abstraction |
|---|---|
| Relationship between the object of thought and the thinking person | • Moving from an unfamiliar concept/context to a familiar one[1]<br>• Using familiar concept to bridge between unfamiliar concepts<br>• Moving from decontextualized to familiar context |
| Reflection on the process-object duality | • Moving from an object to a algorithm<br>• Moving from an object to a process[1] |
| Complexity of concept of thought | • Moving from a set to an element[1]<br>• Moving from cohesive concept to disjoint parts<br>• Moving from connected concepts to isolated concepts |
| Precision/formality of concept of thought | • Moving from formal definition to informal definition<br>• Moving from definition to metaphor<br>• Moving from formal definition to generic model |

[1] Aligned with Hazzan's (1999) operationalization.

**Relationship between the object of thought and the thinking person**

Hazzan (1999) operationalized reducing abstraction in this sense via moving from an unfamiliar to familiar situation. She introduced an example where students engaged in tasks related to modular arithmetic groups and instead used properties and knowledge of familiar groups like the real numbers. This type of reducing abstraction occurs not when a particular concept is more general, but rather when it is new and unfamiliar. In many ways, a specific modular arithmetic group is just as concrete as a group like the reals. In our work, we similarly found students reverting to properties of familiar groups such as desiring identities to be either "0" or "1" regardless of binary operation.

We argue that Hazzan's (1999) second example, misapplying Lagrange's theorem to determine that $\mathbf{Z}_3$ is a subgroup of $\mathbf{Z}_6$ constitutes a parallel, but different way of reducing abstraction. In this application, a student does not replace an unfamiliar concept with a familiar concept, but rather uses a familiar concept (divisibility) as a bridge between the unfamiliar setting and an unfamiliar concept (Lagrange's Theorem). We found many students engaging in this type of abstraction reduction. For example, when students identified the size of cosets- rather than attend to the order of the subgroup used to build the coset- they provided the index as their answer. This illustrates a lack of familiarity with cosets bridged via a familiar concept divisibility to an unfamiliar concept, index.

In our third category, a student moves from unfamiliar (general) to familiar (specific) contexts. We saw students do this in a number of places in our data. For example, when students were asked to determine if the equation $(ab)^2=a^2b^2$ holds in groups generally, students returned to a number of familiar contexts including integers under multiplication (a misleading reduction of abstraction) or permutation groups (a productive reduction of abstraction). We see this activity as related to Gravemeijer and Doorman's (1999) referential activity in Realistic Mathematics Education designed tasks. During the process of reinvention of mathematical ideas, students often reduce abstraction and return to a specific context to productively explore ideas. (For an example, see Larsen and Lockwood's (2013) teacher-student exchange about left and right coset equivalence (p. 14).)

## Process-Object Duality

As in the previous category, we subdivide Hazzan's (1999) process-object duality category. Process-object theories often distinguish between holistic processes and step-by-step actions (Tall et al., 1999). The use of "I" statements as highlighted by Hazzan (1999) may reflect algorithmic approaches where procedures are carried out step-by-step. Hazzan presented such an example where a student makes sense of the definition of a quotient group by explaining the canonical procedure for creating a coset using such language as "each one [element] by itself" (p. 81) as she walks through the relevant product creation.

We see this individual algorithm or action as one way to reduce abstraction. However, students may also go from an object and de-encapsulate (productively) to a process or inappropriate replace an object with a process (unproductive). For example, when a student was asked to find the kernel of a specific mapping, they responded, "The kernel of the homomorphism is what is inputted in $\boldsymbol{Z}$ [domain] to output the identity in $\boldsymbol{H}$ [codomain]." The student continued to treat the homomorphism holistically and identify the correct kernel set. This was a productive reduction in abstraction as de-encapsulating the kernel allowed the student to leverage the holistic process to correctly identify the kernel. In contrast, many students reduced abstraction to an action and provided incomplete kernel sets often identifying only one specific element that mapped to the identity of the codomain. In general, this type of abstraction reduction captures object-process duality with varying degrees of sophistication.

## Complexity of the concept of thought

Hazzan (1999) provided one conception of abstraction within this category: using elements rather than a general set. We found Hazzan's (1999) classification useful and observed students engaging in similar reductions of abstraction. For example, consistent with Asiala et al. (1997), many students conflated the equivalence of left and right cosets with the commutativity of their individual elements. However, we also identified other ways students reduced abstraction by reducing complexity. We expand this category to include: *Moving from cohesive concept to disjoint parts* and *Moving from connected concepts to isolated concepts*. An example of the former category can be found in Melhuish and Fagan (2017). Students' engaging with tasks around binary operations reduced abstraction via attending to only one property. When asked if a given function (such as $x^3$) is a binary operation, majority of students focused on one property: closure. Reducing abstraction to this property is productive in traditional tasks where there are two inputs, however unproductive in a setting where not all functions are binary. This example illustrates that a student may reduce abstraction by attending to one aspect or property of a concept rather than the totality. The consequences of the reduction may be unintentional, especially if the students' concept image does not contain all relevant properties.

Alternately, a reduction of abstraction can occur when students lose relationships between other concepts that connect to the meaning of a concept at-hand. For example, when students were asked to find the inverse of $c$ in the Cayley table below (table 2), many students identified $c$, treating $a$ as the implicit identity element. Note that the identity element is not in the first row and column. When asked to explain their thinking on this task, such students did not attend to the role identity played in the concept of inverses. Rather, students explained inverse as, "[i]t's the opposite element of an element." In this way, their abstraction level is lowered via loss of an important connection to another concept: identity. We see these additional complexity theories as related to abstraction theories of properties and theories of connectedness. Students may reduce abstraction via attending to only a subset of properties or alternately losing important connections to additional concepts.

*Table 2. Cayley Table defined on set {a,b,c}*

| | a | b | c |
|---|---|---|---|
| a | c | a | b |
| b | a | b | c |
| c | b | c | a |

**Degree of precision/formality**

This category was not from Hazzan's (1999) framework; rather this additional category emerged to reflect theories of abstraction such as Davydov (1990) where abstraction level reflects the transition of mathematical object from informal/imprecise and to delineated and concrete. This process is sometimes equated to formalization in advanced mathematics. We identified three literature-based ways abstraction can be reduced from this theoretical lens.

Students may replace a formal definition with an informal definition. Lajoie and Mura (2000) identified this type of abstraction reduction when students engaged in tasks related to cyclic groups. We similarly found students leveraged an informal definition of cyclic when tasked with determining if particular groups were cyclic. Their definitions often relied on a generating action: "Start with the unit element and keep piling that onto itself" until a group is created. Reducing abstraction to this informal definition will be successful for finite group, but become problematic for the infinite cyclic group. See Melhuish (2018) for a discussion of how such an informal definition may be supportive for understanding the convention of powers in group theory.

Students may also use metaphors as a way to reduce abreaction. Rather than deal with a concept mathematically, they may leverage a metaphor such as an input-output machine for function (e.g. Zandieh, Ellis, & Rasmussen 2017). When identifying a specific homomorphism's kernel, a student used such a metaphor: "All the elements in the integers that would fit through the function and go to the identity on the codomain. Then start plugging things into that function." The function is treated as something that elements are fitted through. This particular reduction in abstraction was productive when attempting to identify the kernel of a given map.

A third variant is through creation of visual representations. As noted by Sfard (1991), abstraction can be reduced through returning to a visual image which is "more tangible, and encourag[ing] treating them almost as if they were material entities" (p. 6). In our work, we found this type of reduction of abstraction to be infrequent, but often productive when it occurred. One example can be seen in Figure 1. This student was asked to determine if cosets can always be formed from a given subgroup *H* and if so, what their size would be. The student drew a generic group partitioned into cosets to reason that this can always occur and the size would be the same as *H*. The group *G* was represented as a visual that can be reasoned from. This type of abstraction reduction aligns with Pinto and Tall's (2002) generic abstraction.

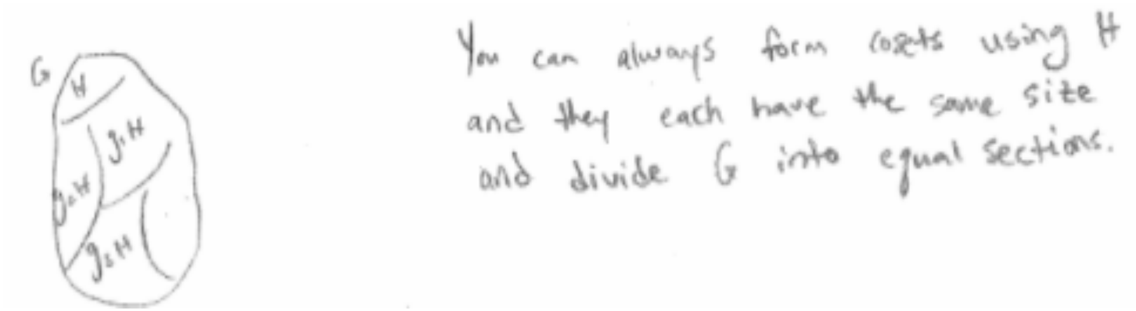

*Figure 1. A student's visual representation of group G with cosets built using subgroup H*

## Discussion

In this paper, we sought to expand Hazzan's (1999) reducing abstraction framework by leveraging a number of abstraction theories. As Hazzan acknowledged, this type of framework cannot be exhaustive, nor mutually exclusive. In fact, the theories of abstraction which inform such an analysis often have overlap themselves. In this sense, we see this framework as a productive lens for analyzing student activity, but not a lens meant to categorize students. As Hazzan did originally, we made our theoretical expansions based on data from abstract algebra tasks. This subject area is populated with concepts that are abstract across many characterizations of abstraction (decontextualized, objects, complex, and stipulated.)

In addition to expanding the framework, we also wished to further highlight that reducing abstraction can be productive. Hazzan (1999) cautioned, "The term 'reducing abstraction' should *not* be conceived as a mental process which necessarily results in misconceptions or mathematical errors" (p. 75). However, Hazzan illustrated student activity that was either erroneous or neutral in problem-solving situations. While this if often the case, we also shared a number of examples of students working productively via reducing abstraction. In fact, we argue the ability to *appropriately* lower abstraction reflects a high level understanding. For example, to move from a formal representation to an accurate generic model reflects an advanced re-construction of a formal idea (von Glasersfeld, 1991). Similarly, Dubinsky and McDonald (2001) identified the ability to de-encapsulate from object to process as an essential feature of object-level conceptions. In this sense, we see parsing reduction of abstraction as more than just a tool for analyzing the cause of inaccurate student responses.

Such a framework can also provide insight into how we meet students where they are at in order to promote *productive* reduction of abstraction. There is power in being able to reduce abstraction in problem-solving (or proving) situations. Weber and Alcock (2004) presented contrasting cases where students (and graduate students) may produce proofs via working in an entirely formal system or through semantic explorations. In some sense, moving out of the formal system reduces abstraction level. It is this reduction that allowed successful provers in their study to gain insight into proofs. In Larsen and Lockwood (2013), students moved between decontextualized and contextualized situations to productively explore conjectures and ultimately reinvent mathematics. The question is not, how do we prevent students from reducing abstraction, but rather how do we promote students in reducing abstraction in productive ways? Through better understanding of reducing abstraction, we may ultimately aid in supporting students as they navigate abstract concepts in advanced mathematics.

# The Potential Virtues of Wicked Problems for Education

Jeffrey Craig
University of Arizona

Lynette DeAun Guzmán
University of Arizona

Andrew Krause
Michigan State University

*We offer a contribution to a theory of transdisciplinary curriculum based in empirical research of an undergraduate mathematics course in quantitative literacy. By organizing around contexts and developing open, semester-long projects, this course blurred disciplinary boundaries. Fortunately, ignoring debates about where mathematics ends and these contexts begin is well-suited for the goals of general undergraduate courses. We found that the language of* transdisciplinary *and* wicked problems *fitted our experiences designing, teaching, and studying the course. We share selected empirical findings, then develop a transdisciplinary curriculum theory for wicked problems.*

*Keywords*: wicked problems, transdisciplinary education, curriculum, quantitative literacy

> This is the first human generation in which the majority will live in crowded cities, whose actions will flood low-lying islands and whose rate of resource use exceeds 2.5 times the production capacity of the planet (Melkert and Vox, 2008). Well-founded projections suggest that future supplies of the air we need to breathe, the water to drink and the food to eat are in doubt. (Schneider et al., 2007 as cited in Brown, Deane, Harris, & Russell, 2010, p. 3).

> It seems as though some problems are tame, such as factoring a quadratic equation, traversing a maze, and solving the tower of Hanoi puzzle. But problems of importance… are invariably 'wicked.' (Coyne, 2005, pp. 5-6)

The first excerpt above is the opening paragraph of a book, *Tackling Wicked Problems* (Brown et al., 2010), which focuses on uniting people across and outside of disciplines to confront the global problems that affect us all. In the book, scholars argued that this particular class of problems requires *transdisciplinary inquiry*--fusion of knowledges across and outside of disciplinary boundaries. Transdisciplinary approaches create knowledge that "is more than the sum of its disciplinary components" (Lawrence, 2010, p. 19).

The *wicked problems* at the center of this transdisciplinary inquiry require imaginative approaches because they cannot be (or at least, have not been) fully resolved through disciplinary techniques. In the second quotation above, Coyne (2005) illustrated wicked problems by contrasting them with tame problems. Coyne used these three examples--factoring, navigating a maze, and the tower of Hanoi puzzle--which inadvertently criticized the prevalence of tame problems in mathematics education. The tame problem examples he chose subtly posed a challenge to mathematics education to consider different problems, called "wicked."

*How might we, mathematics educators, react?* In this paper, we produce a theoretical report grounded in an empirical study of a quantitative literacy (QL) course which involved a focus on wicked problems. The theoretical perspective is a transdisciplinary curricular theory focused on education about wicked problems. We found that such an approach can involve at least four things: a context-based curricular organization, a blurring or erasure of disciplinary boundaries to classroom activity, opportunities to engage in open problematizing of the world, and a repositioning of the teacher relative to students.

## Transdisciplinary Education for Wicked Problems

Rittel and Webber (1973) first conceptualized wicked problems in design and planning. They argued that there are ten distinguishing characteristics of wicked problems:

1. There is no definitive formulation of a wicked problem.
2. Wicked problems have no stopping rules.
3. Solutions to wicked problems are not true or false, but good or bad.
4. There is no immediate and no ultimate test of a solution to a wicked problem.
5. Every solution to a wicked problem is a 'one-shot operation'; because there is no opportunity to learn by trial-and-error, every attempt counts significantly.
6. Wicked problems do not have an enumerable (or an exhaustively describable) set of possible solutions, nor is there a well-described set of permissible operations that may be incorporated into the plan.
7. Every wicked problem is essentially unique.
8. Every wicked problem can be considered to be a symptom of another problem.
9. The existence of a discrepancy representing a wicked problem can be explained in numerous ways. The choice of explanation determines the nature of the problem's resolution.
10. The planner has no right to be wrong.

Wicked problems have been conceptualized within many fields, including: environmental studies (e.g., Kreuter, De Rosa, Howze, & Baldwin, 2004), political science and public policy (e.g., Head, 2008), public health (e.g., Blackman et al., 2006), public risk and defense (e.g., Ritchey, 2001), and economics (e.g., Batie, 2008). The move to consider work in their fields as wicked problems generally emerged alongside recognition of limitations of attempts to quantify complexity. Ritchey (2001) claimed, "if you work with long-term social, commercial, or organizational planning – or any type of policy planning that impacts *people* – then you've got *wicked problems* (p. 1). The presence of wicked problems can be signified by a sense of reactivity, where after attempting resolution, the problem transforms and "fight[s] back when you try to do something" (Ritchey, 2001, p. 1).

Studying complex wicked problems, therefore, poses a challenge to disciplinary approaches to knowledge; in response, transdisciplinary approaches "step outside the limiting frames and methods of phenomenon-specific disciplines" (Davis, 2008, p. 55). The transdisciplinary approach mirrors the collective nature of wicked problems and values not only the multiplicity of knowledges from different disciplines, but also their tapestry (Lawrence, 2008). Transdisciplinary approaches involve redrawing the boundaries of inquiry (to the extent possible) *around the problems themselves*, to ask what disciplines and their unifications can contribute to addressing and resolving a problem, rather than whether a problem belongs inside a discipline.

### Transdisciplinary Wicked Problems and Quantitative Literacy (QL)

In mathematics education, Vacher (2011; 2017) has begun to argue that QL is transdisciplinary. His claim ultimately hinges on the fact that people from different disciplines have used QL or numeracy as terminology to connect the quantitative to their fields. Our approach to transdisciplinary is different in that we are decentering the disciplines, and instead focusing on wicked problems. As a result, the early empirical underpinnings of this transdisciplinary curriculum theory emerge from an undergraduate QL course not centered solely on learning mathematics and statistics; instead, the course is centered on exploring what mathematics and statistics might offer us while we learn about *contexts and wicked problems within them*. Of course, the course certainly did involve students learning significant mathematics and statistics, but that was not the primary organizational element.

This QL classroom was located at a large Midwestern university--a predominantly white institution located in what is often described as a “college-town.” The studied course emerged from institutional efforts to provide multiple routes to fulfilling the university’s general mathematics degree requirement. This course was organized around three different context-based modules: *The World and Its Peoples*, organized around the choices and power involved in counting people and quantifying the world; *Numbers and Media*, designed around the flexibility of numbers as socially constructed, rhetorical, subjected, and powerful; and *Health and Risk*, centered on considering the quantification in health and risk and its implications on fear and safety narratives. In the next section, we used examples from students’ work to further illuminate characteristics of wicked problems. We pulled the examples from a larger study of students’ course projects (Craig, 2017). All names are pseudonyms.

## Examples of Wicked Problems Characteristics

The students chose a wide variety of issues to study, but formulating the particular problem or set of problems was challenging. Many students asked about the suitability of a particular topic for this project. Upon first impression, many students’ topic choices had developed ideas around problems of massive scope (e.g., racism, climate change). Despite students completing the same project phases, their work was unique content because they focused on different problems and formulated similar problems differently.

### (Characteristic #7) Every wicked problem is essentially unique.

We begin our exploration of wicked problem characteristics with Characteristic #7 to share some students’ project topics, found in Table 1. The range project topics illustrates how wicked problems are not confined to any disciplinary boundary, including mathematics. Further, the list also suggests how all disciplines, including mathematics, are relevant to considering wicked problems.

*Table 1. Selected Student Projects Titles and Descriptions*

| Title | Description |
|---|---|
| Censorship | Internet censorship policies and histories across countries |
| Climate Change | Looking at the impacts of polar ice shifts on climate from a religious perspective |
| Do Schools Kill Creativity? | Budget cuts to arts and humanities programs in K-12 public schools in the United States |
| Domestic Violence | The perpetual cycle of domestic violence across generations |
| Drug Abuses and Overdoses | The prevalence of heroin abuse in specific cities across the United States |
| Gun Violence | Advocating ways to avoid gun violence, specifically preventative learning about guns |

| | |
|---|---|
| Impact of Big Money on Politics | The results of the Citizens United court decision on money entering politics |
| Overpopulation | The effects of a one-child policy on China and the persistence of problems of resource use |
| People of Color in Media | The erasure of entertainment and media achievements of actors of color |
| Recycling Practices | Cross-country analysis of recycling practices and constraints on recycling |
| Representation of Women in Media | The disparities in gender representation in political news reporting |
| Stigmas around Mental Illness | How different cultures respond to depression and stigmatize the illness |

**(Characteristic #1) There is No Definitive Formulation of a Wicked Problem**

> Another issue that internet censorship is tied to is that sometimes internet censorship can be a good thing. For example, I don't think it is okay for people to be posting pro-terrorist webpages, or terrorist recruitment forms online. If it really is a threat to national security, then I believe that the government has a right to restrict that. (Matt, Phase 2, Media Synthesis)

Matt confronted the challenge of formulating what the problem of censorship entirely involved. Rittel and Weber (1973) stated that "the formulation of a wicked problem *is* the problem!" (p. 137). To formulate a wicked problem involves establishing a discrepancy between what *is* and what *should be*. But there are plural perspectives on both what is and what should be, and therefore multiple formulations of the problems we face.

**(Characteristic #2) Wicked Problems Have No Stopping Rules**

> The one child policy was published to limit people to have only one child. This stopped the growth of population. And people's life changed a lot from this. Then, population aging became another issue for China. Population aging hurts the economy and the government decides to end the one child policy. The new policy is "One Couple, Two Children. (Leilei, Phase 2, Media Synthesis)

Because wicked problems have no stopping rules, that implies they have a history. Students engaged with the histories of these complex wicked problems through media analyses and syntheses, which usually included their own formulation of the problem and explanation for the cause. The reintroduction of the initial problems underscored the complexity and fluidity of these projects. The challenges involved in testing solutions to wicked problems are underscored by the idea that those solutions cannot be evaluated in the same way that tame problems can.

**(Characteristic #3) Solutions to Wicked Problems are Not True or False, but Good or Bad**

> I think we can measure improvement with the issue of the lack of diversity by continuing to take data on how diverse film characters are in general. But, by how many women are directing mainstream? People of color? Who are running these networks? Who are writing these shows? Orange is the New Black has one of the most diverse casts on

> television right now. The writing room is mostly women, but no people of color. Do we chalk this up to a win anyway? (Aisha, Phase 4, Written Reflection)

Aisha's reflection further complexified the relationship between mathematics and statistics as disciplines and the resolution of wicked problems. She recognized the limitations of mathematics in determining the quality of a solution. The transdisciplinary reasoning emerged from how open problematizing, as Smith (1997) predicted, burst the boundaries of mathematics curriculum.

**(Characteristic #4) There is No Immediate and No Ultimate Test of a Solution to a Wicked Problem**

> I think it's interesting that the world measures depression by suicide count. I don't know how accurate I feel that is but it's interesting and I wish that we could change it. *But how do you measure depression? Through chronic, manic, and other forms of breakdown or do we not measure it by severity and simply mush it all together? It's difficult to measure something that can't be seen*. (Beth, Phase 4, Written Reflection, emphasis added)

Beth summarized how wicked problems change what it means to do problem solving. The choices of what to measure, how, and when, are political and aligned with particular formulations and particular explanations of a wicked problem discrepancy (Best, 2008). Quantitative methods and information cannot provide evidence of improvement on a wicked problem, unless situated within a particular formulation of the problem. Within the boundaries of mathematical problem solving, this deeper consideration of how to engage quantitative methods involves traversing disciplinary boundaries for other information.

**(Characteristic #5) Every Solution to a Wicked Problem is a 'One-Shot Operation'; Because There is no Opportunity to Learn by Trial-and-Error, Every Attempt Counts Significantly**

> He brings up the fact that there are so many murders in Central America and Mexico and other parts of the world, prisons packed, the global black market is estimated at 3 hundred billion a year, *all due to the war on drugs. Yet more people are using drugs than there ever was before*. (Diana, Phase 2, Media Analysis, emphasis added)

Diana's analysis of a piece of media reflects something critical about the urgency of these wicked problems. Despite this course being labeled mathematics, many forms of reasoning were salient. Specifically, quantitative methodologists would have very particular and technical strategies for determining the effects of the war on drugs (not the least of which would be formulating what that means). At the same time, there is very serious moral, social, historical, psychological, and intuitive reasoning involved in my students' projects.

**(Characteristic #6) Wicked Problems Do Not Have an Enumerable (Or an Exhaustively Describable) Set of Possible Solutions, Nor is There a Well-Described Set of Permissible Operations that May Be Incorporated into the Plan**

> I'm not entirely sure what the plot of the story that I am hoping to tell is but I know *that I want to talk about the collective solution to the problem from multiple sources…* community awareness, education on certain matters revolving around mental health, and acceptance are the ideal ways to combat more easily preventable mental health problems

> or at least to lessen the effects of the problem. (Beth, Phase 3, Infographic Check-in, emphasis added)

This aspect of wicked problems came out the most in a class check-in where I asked students to report the plot of the infographic they were creating for the third phase of the project. There are no limits on what can be included in resolving a wicked problem, and the acceptance of multiple forms of data and engagement of multiple forms of reasoning across and outside of disciplinary boundaries is central.

**(Characteristic #8) Every Wicked Problem Can Be Considered to Be a Symptom of Another Problem**

> After doing the research, I found the issue is not only too many people, but also pollution, land, resources and other issues. (Leilei, Phase 4, Written Reflection)

Leilei produced a project on China's One-Child Policy and concluded that overpopulation itself is an amalgam of other interlocking problems. Although the first phase of the project was the explicit time when students formulated their topic, the challenges to problematizing wicked problems persisted through complexity. I had five students make significant changes to their topics during the second phase of the project, as they clarified their own interests, but all students reformulated their problems at some point during the course.

**(Characteristic #9) The Existence of a Discrepancy Representing a Wicked Problem Can Be Explained in Numerous Ways. The Choice of Explanation Determines the Nature of the Problem's Resolution**

> There are a few different issues revolving around the stigma that exists around mental illness; the first being that people sometimes avoid or bully those suffering from mental illness just due to their differences, the next is that mental illness is often misrepresented in the media, those suffering from mental illness in television shows or movies are almost always depicted as some sort of antagonist, murderer, or criminal. (Beth, Phase 2, Media Synthesis)

Beth's project on mental illness evolved into an investigation of cultural differences in identifying and treating mental illness. She focused on a discrepancy between perceptions of mental illness taking the form of stigma and the realities of people suffering from mental illness. She had different explanations for that discrepancy which she explored during her project.

**(Characteristic #10) The Planner Has No Right To Be Wrong**

> …In 2014 it is estimated that at least 6,800 overdose deaths occurred in the European Union. In Oceania, which includes Australia and New Zealand, there were 1,700 and 2,100 drug related deaths in 2013. In Scotland there were 613 drug related deaths in 2014. In South America, the Caribbean and Central America reported between 4,900 and 10,900 drug related deaths in 2013. In the United States, overdose deaths from opioids, including prescription opioids and heroin, have nearly quadrupled since 1999. Overdoses involving opioids killed more than 28,000 people in 2014. During 2014, a total of 47,055 drug overdose deaths occurred in the United States. *These statistics make it known that*

> *the use of drugs is a very serious issue that needs to be fixed somehow.* (Diana, Phase 2, Media Synthesis, emphasis added)

Diana's project on the opioid epidemic developed out of her hometown struggling with drug addiction. Although Diana herself formulated the problem in a particular way with a particular resolution – "our drug policies care more about criminalization over health and this has to be changed" (Diana, Phase 2, Media Analysis) – she explicitly noted the seriousness, urgency, and responsibility for policy planners to act.

## Discussion

Our purpose for sharing these examples of how wicked problem characteristics manifested in students' course projects was to give life to the characteristics, rather than leave them as strictly theoretical. Craig (2017) explored three themes that emerged from a deeper analysis of the course projects, transdisciplinary, complexity, and democratic openness. Here, we focused on transdisciplinary to begin developing a curriculum theory. A *transdisciplinary curriculum theory for wicked problems* both connects with and diverges from disciplinary education in mathematics or statistics. On one hand, the openness of transdisciplinary inquiry is fully inclusive to all disciplines, therefore, mathematics and statistics play indispensable roles. On the other hand, exploring wicked problems within disciplinary boundaries necessarily excludes important considerations and leaves resolutions more fragile, incomplete, and possibly counterproductive.

For wicked problems where boundaries are elusive (or impossible) to draw, the inquiry process should be inclusive. All knowledges are relevant and applicable to resolving wicked problems, and transdisciplinarity "is created by including the personal, the local and the strategic, as well as specialized contributions to knowledge" (Brown et al., 2010, p. 4). This lack of boundaries is conducive to a *transdisciplinary imagination* (Brown et al., 2010). In the transdisciplinary imagination are attempts "to generate fundamentally new conceptual frameworks, hypotheses, theories, models, and methodological applications that *transcend* their disciplinary origins" (Hall et al., 2012, p. 416, emphasis in original).

Wicked problems facing the world regarding sustainability are staggering in scope, and elusive. Further, evidence increasingly suggests that addressing sustainability questions necessarily involves addressing myriad social injustices and complex economic relationships (Peterson, 2016). Nearly two decades ago, education for wicked problems was "taken seriously by no one, even if they are included with some regularity in official curriculum documents" (Parker, Ninomiya, & Cogan, 1999, p. 119). Serious consideration of these wicked problems as justifiable school curriculum remains uncommon. Although some argue we prepare students to be wicked problem resolvers by becoming expert tame problem solvers, we still generally avoid these problems during schooling in favor of self-contained and sanitized word problems, particularly in mathematics education.

That wicked problems theory emerged from design theory is fitting for considering curriculum theory. Designing curriculum involves reactive, complex, and transdisciplinary students, situated among reactive, complex, and transdisciplinary social institutions and wicked problems. Perhaps curriculum design is a wicked problem, without final resolution. But, what right do we have to be wrong about education? We share responsibility for the social problems caused by and embedded in how schools, curricula, assessments, and teaching are designed and planned (Butin, 2002).

# Generating Equations for Proportional Relationships Using Magnitude and Substance Conceptions

Sybilla Beckmann and Andrew Izsák
The University of Georgia

*We discuss a magnitude conception and a substance conception of fractions and variables that future middle-grades and secondary teachers used when developing and explaining equations for proportional relationships by reasoning about quantities. We conjecture that both conceptions are important for developing equations. The substance conception is useful when a fraction or variable functions as a multiplicand, but not when it functions as a multiplier. The magnitude conception is useful when a fraction or variable functions as a multiplier, but may not be essential when it functions as a multiplicand. Expertise may involve recognizing that the conceptions are distinct and developing a sense of when each conception is useful.*

*Keywords:* Equations, proportional relationships, variables, fractions

The domain of ratio and proportional relationships is a gateway to algebra, other topics in K-12 and undergraduate mathematics, and science (National Center on Education and the Economy, 2013). Yet this crucial domain is also one of the most challenging to learn (e.g., Lamon, 2007). Our research group has been studying how future middle grades and secondary teachers reason about ratios and proportional relationships as they take our mathematics content courses, which focus on multiplicative ideas. In this paper, we are interested in reasoning that takes a *variable-parts* perspective on proportional relationships (Beckmann & Izsák, 2015), a perspective that had been largely overlooked in the research literature, but provides a pathway to developing equations and solving proportions. In these reasoning situations, we are interested in what ideas are useful and generative, and what ideas are especially hard. We discuss a conjecture about two conceptions of fractions and variables—a magnitude conception and a substance conception. Based on preliminary analysis of data, we conjecture that both conceptions play an important role in generating and explaining equations for quantities in a proportional relationship, and that knowing when to use which conception is an aspect of expertise.

## Background and Theoretical Perspectives

We view ratios and proportional relationships as part of the multiplicative conceptual field (Vergnaud, 1988)—a web of interrelated ideas that also includes multiplication, division, fractions, and linear relationships. According to Beckmann and Izsák (2015), a quantitative definition of multiplication can organize and connect multiplication, division, and proportional and inversely proportional relationships. We therefore use quantitative definitions of multiplication and fractions as central organizing ideas in our mathematics content courses for future middle grades and secondary teachers.

### Quantities and Magnitudes

Measurement includes describing the size of entities (objects or stuff) as some number of a chosen measurement unit, which can be a standard unit, such as a liter, or a non-standard unit, such as a strip drawn on a piece of paper. Although quantities are often described as numbers with units (e.g., CCSS; Common Core State Standards Initiative, 2010), we agree with Thompson (1994) that one need not have selected a specific measurement unit to conceive of an entity as a quantity. In this paper, we define “quantity” to mean an entity that either serves as a measurement unit or could be expressed as some number of another measurement unit, where “some number” means any positive whole, rational, or irrational real number. For example, if a student views one strip drawn on a piece of paper as 2/5 of another drawn strip, then we consider the student to be treating both strips as quantities.

The language of linear algebra may be helpful for thinking about quantities. For each measureable attribute, such as length, weight, or volume, we can associate with that attribute a one-dimensional vector space over the real numbers. Given such a vector space, there is no automatic choice for a basis, and we can work with the vector space without having chosen a basis. Therefore, when we view an entity as a quantity, we essentially consider it as an element of one of these one-dimensional vector spaces, but we need not think of the quantity in terms of a basis for the vector space. When we choose a measurement unit for a given attribute, this measurement unit forms a basis for the one-dimensional vector space, and a quantity can be expressed as a scalar multiple of the basis vector, i.e., the quantity can be expressed as so and so many of the chosen measurement unit. We call this scalar (real number) the magnitude of the quantity with respect to the chosen measurement unit (see also Thompson, Carlson, Byerly, & Hatfield, 2014).

**A Quantitative Definition of Multiplication**

Although people can use intuitive models to recognize some multiplication situations (e.g., Fischbein, Deri, Nello, & Marino, 1985), if we want students and teachers to be able to make principled arguments for why multiplication applies in a situation, then we need a definition of multiplication. If multiplication is to be understood as a single coherent operation that applies across many different types of situations and across whole numbers, fractions, and decimals, then we need a definition of multiplication that applies to all these cases. One version of a definition we use in our courses for future teachers is as follows. In a situation involving quantities, we say that $M \bullet N = P$ if $M$ is the number of groups in the product amount, $N$ is the number of base units in 1 group, and $P$ is the number of base units in $M$ groups for a suitable base unit, group, and product amount in the situation. We call $M$ the multiplier, $N$ the multiplicand, and $P$ the product; $M$, $N$, and $P$ can be non-negative whole numbers, fractions, or decimals. This definition is similar to the one given by Beckmann and Izsák (2015). In some of our courses we have reversed the order of multiplier and multiplicand and written the multiplicand first and the multiplier second. Within a course, we use a consistent order to facilitate clear communication.

This definition of multiplication connects multiplication with measurement (e.g., Davydov, 1992). In the definition, $N$, $M$, and $P$ are magnitudes of the quantities “the group” and “the product amount” with respect to the measurement units “the base unit” and “the group.” In particular, the multiplier and the product are the results of measuring the product amount in two ways. In some versions of our definition, we clarify the measurement language by defining the multiplicand as the number of base units it takes to make 1 group exactly, the multiplier as the number of groups it takes to make the product amount exactly, and the product as the number of base units it takes to make the product amount exactly.

Reasoning with the definition of multiplication requires organizing and structuring quantities by unitizing, iterating, and partitioning—ideas that have been identified as foundational to multiplicative reasoning in the literature (e.g., Hackenberg & Tillema, 2009). It requires unitizing because $N$ base units form 1 group, so those $N$ base units function as a unit; it requires iterating because if $M$ is 5, one must consider 5 copies or iterates of that group; it requires partitioning because if $M$ is 1/5, one must consider 1/5 of that group, so one must partition the group into 5 equal-sized parts.

### A Quantitative Definition of Fraction and Fraction Subconstructs

In our courses for future teachers, we use essentially the same definition of fraction as in the *Common Core State Standards for Mathematics* (CCSS, 2010). We define a unit fraction $1/B$ to be the amount formed by 1 part when a unit amount (or whole) is partitioned into $B$ equal-sized parts. A fraction $A/B$ is defined to be the amount in $A$ parts, each of size $1/B$ of the unit amount (or whole). Therefore, this definition relies on partitioning to form unit fractions and on iterating unit fractions to form both proper and improper fractions. Viewing fractions as obtained by iterating unit fractions can be valuable for students (e.g., Behr, Lesh, Post, & Silver, 1983), and we have found that our future middle grades and secondary teachers reason effectively with this definition.

Various fraction subconstructs or interpretations have been identified in the literature, including the measurement and operator subconstructs (e.g., Behr, Lesh, Post, & Silver, 1983; Kieren, 1976). With the measurement interpretation, fractions can be viewed as plotted on number lines via measurement. To plot the fraction A/B we measure A parts, each of size 1/B of the unit (the interval from 0 to 1). With the operator interpretation, the fraction A/B is seen as a transformation that takes one quantity to another, for example by stretching or shrinking.

Later in this paper we identify substance and magnitude *conceptions* of fractions, which are different from the fraction *subconstructs* in the literature. The magnitude and substance conceptions are essentially orthogonal to the measurement subconstruct, whereas the magnitude conception may be a prerequisite for some instances of the operator subconstruct.

### Equations for Proportional Relationships

Proportional relationships in which two unknown quantities are in a fixed ratio can be modeled by equations in two variables, including equations of the form $y = m \cdot x$ or $y = x \cdot m$, where $m$ is a constant of proportionality. By "variable" we mean a letter or symbol that stands for any number from some set (which might not be explicitly specified). Multiplication is numerically commutative, but the multiplier and multiplicand play different roles in quantitative situations. Depending on how the quantities in a situation are structured and organized, one of $y = m \cdot x$ or $y = x \cdot m$ might be better for modeling the situation.

In this paper, we are interested in cases where the constant $m$ is a fraction $a/b$ (so $a$ and $b$ are positive integers). Thus, our quantitative definitions for multiplication and fractions are potentially useful for explaining and generating equations for quantities in a proportional relationship. We are interested in ideas needed to generate and explain equations that relate quantities, especially when the quantities are viewed from the variable-parts perspective (Beckmann & Izsák, 2015), as in the paint task in Figure 1. The 2 parts of blue paint and the 5 parts of yellow paint in that task are all the same size as each other, but that size is unspecified and could vary. The equations $Y = 5/2 \cdot X$ and $X = 2/5 \cdot Y$ (among many others) model the situation in the paint task and fit with the definition of multiplication by taking 1 base unit to be 1 gallon and 1 group to be either all the blue paint or all the yellow paint.

**Paint Task**: The figure below shows volumes of blue paint and yellow paint. The diagram does not show specific numbers of gallons of paint, but each small part of both strips represents the same number of gallons.

Let's say there are X gallons of blue paint (in all) and Y gallons of yellow paint (in all). How are X and Y related?

*Figure 1. A proportional relationship task about paint, from a variable-parts perspective.*

Generating algebraic equations is known to be difficult in part because understanding how algebraic notation symbolizes quantitative situations is difficult (see Kieran, 2007). Even advanced students produce equations with a "reversal error," such as $6S = P$ for a situation in which there are 6 students for every professor (e.g., Clement, 1982). Hackenberg and Lee (2015) explained students' difficulties with generating equations in terms of students' multiplicative concepts, which involve capacities to coordinate multiple levels of nested units and to anticipate, hold in mind, and reorganize such structures. Other authors have pointed to students' conceptions of variables as a source of difficulty, such as treating a variable as a shorthand label for an object or unit (e.g., Küchemann, 1981; Lucariello, Tine, & Ganley, 2014, McNeil et al., 2010). These authors described such a conception of variables as low level or as a misconception. According to Küchemann, using a letter as an object amounts to reducing the letter's meaning from something abstract to something more concrete. He noted that such a reduction often occurs when it is not appropriate, especially in cases where one must distinguish between objects themselves and the number of objects. Yet Beckmann & Kulow (2018) found that future middle grades teachers often used variables as labels when they generated valid equations and produced viable arguments using fractions and multiplication.

### A Knowledge-in-Pieces Stance Toward Cognition

We take Knowledge-in-Pieces as our theoretical frame for studying cognition (e.g., diSessa, 1993). In particular, we assume students' knowledge in a mathematical domain is an ecology consisting of many elements, some of which are primitive and intuitive, and simply taken as given, and some of which are more scientific in nature. Some knowledge elements may be closely coordinated, whereas others may be seen as unrelated. Knowledge elements are highly sensitive to context. A knowledge element might be cued in one context but not in another where an expert might view it as relevant. We view learning as a process that involves refinement and coordination of knowledge elements, not a process of repealing and replacing ideas (e.g., Smith, diSessa, & Roschelle, 1993). In particular, this refinement and coordination consists of separating ideas as well as connecting them, and it consists of discerning features of new contexts that make an idea applicable or not applicable, or that make using one idea preferable over another idea (Wagner, 2006). Thus, becoming proficient in generating and explaining equations could involve distinguishing different ways of thinking about a variable or a fraction and a sense of when each way of thinking is more useful or less useful.

## Methods, Data Sources, and Research Question

As part of a larger ongoing investigation into future middle grades and secondary teachers' reasoning in the multiplicative conceptual field, we are interested in generating and testing conjectures about ways of thinking about fractions and variables that may be important when developing, explaining, or interpreting equations and expressions involving multiplication. This paper is primarily theoretical because it discusses conjectures we have generated based on initial passes through our data. Our research question for this paper is therefore: Based on our project's data, what ways of thinking about fractions and variables, beyond those already identified in the literature, can we conjecture to be important for generating and explaining equations to relate two unknown quantities that are in a proportional relationship, viewed from a variable-parts perspective?

Data come from 104 semi-structured 75-minute interviews conducted individually with 22 participants, 10 from 2 cohorts of future middle grades mathematics teachers (5 interviews each) and 12 from 2 cohorts of future secondary mathematics teachers (6 with 5 interviews each and 6 with 4 interviews each). All participants were taking mathematics content courses focusing on ideas in the multiplicative conceptual field between the fall of 2014 and the spring of 2017. Interview questions were related to course topics, although some interview questions preceded instruction in a relevant topic. The participants were selected to be mathematically diverse based on their performance on a fractions survey (Bradshaw, Izsák, Templin, & Jacobson, 2014). The data included transcribed video-recording of each interview and scanned copies of the written work each participant generated. To analyze the data, members of the research team watched interviews multiple times, attending to words, gestures, and inscriptions, and wrote cognitive memos discussing and summarizing participants' reasoning.

## Conjectures about Conceptions of Fractions and Variables

Based on our initial analysis, we identify two conceptions about fractions and variables—a substance conception and a magnitude conception—that we conjecture play important roles in developing and explaining equations for proportional relationships. To illustrate these conceptions, we use examples that are glosses of reasoning we found across multiple participants, interviews, and interview tasks.

### A Substance Conception of Fractions and Variables

A person uses a *substance conception* of a fraction or variable if the person explicitly views the fraction or variable as a label, name, or descriptor of an entity, or as the entity itself. In the case of variables, the substance conception is essentially the same as the label or object conception of variables that has been described in the literature (e.g., McNeil et al., 2010). For example, if a student describes the second strip in Figure 1 as $Y$ and means it as a label or name for the strip, then at that moment, the student is using a label conception of the variable $Y$. We do not use the term "label conception" because in the case of numbers, we do not want the conception to be confused with cases where a number serves as a non-quantitative label or name, such as a house number or telephone number.

In the case of fractions, if a student describes one of the 5 parts in the second strip in Figure 1 as "a one-fifth-part," or says that the part "is one-fifth," and means that 1/5 is a descriptor or name for the part, or stands for the part itself, then at that moment, the student is using a substance conception of fraction.

We note that the substance conception can also apply to phrases. For example, a student might describe the 5-part yellow paint strip and 2-part blue paint strip in Figure 1 as "the yellow paint" and "the blue paint" respectively, write the equation "the blue paint = 2/5 of the yellow paint," and then write the equation $X = 2/5Y$. In this case, the student uses a substance conception of the phrases "the blue paint" and "the yellow paint," and they might continue to use this substance conception with the variables $X$ and $Y$. In any case, the student treats the blue paint and the yellow paint as quantities, but they might not be thinking of those quantities as some number of a specified measurement unit, and therefore might not be thinking of $X$ and $Y$ as magnitudes. In essence, the student's equations would be like saying that one vector is equal to a scalar multiple of another vector. In fact, if we interpret $X$ and $Y$ as elements of a vector space, then the equation $X = 2/5Y$ makes perfect sense even if no basis has been chosen for the vector space. So even though we expect the equation $X = 2/5Y$ to be about numbers and to fit with the definition of multiplication, this might not fit readily with a student's interpretation.

**A Substance Conception of a Multiplicand may Be Productive.** In the example just presented, which led to the equation $X = 2/5Y$, the variable $Y$ functions as a *multiplicand*: it represents 1 group, and 2/5 of that group is the amount of blue paint, $X$. We conjecture that more generally, when a fraction or variable functions as a multiplicand, a substance conception of a fraction, variable, or related phrase may help the student (1) view the situation in terms of quantities and (2) formulate a correct equation by reasoning about quantities in the situation.

This conjecture is consistent with productive reasoning we have seen with improper fractions. In fact, our definition of fraction almost invites a substance conception. For example, the fraction 5/2 is defined as the amount formed by 5 parts, each of size ½ of the unit amount. According to this definition, 5/2 is essentially the product 5•1/2, where ½ is the multiplicand. Working with the strips in Figure 1, a student might view ½ as a label for each of the 2 parts in the first strip, and also for each of the 5 parts in the second strip. The student might then describe the second strip as 5 parts, each ½, and therefore as 5/2. Even though the student views ½ as a label, the ½ also functions as a quantity for the student because the student considers 5 of the halves. This seems to be a productive way to make sense of improper fractions. What could still be missing, however, is the idea that ½ and 5/2 are magnitudes—the numerical outcome of measurement by the 2-part strip.

**A Substance Conception of a Multiplier may Be Unproductive.** In contrast, when a fraction or variable functions as a *multiplier*, we conjecture that a substance conception can lead to unproductive interpretations of multiplication. For example, if a student is asked to make a drawing to help explain the meaning of 1/6•X according to our definition of multiplication, the student might draw a 6-part strip, call each part a 1/6-group, and write X in each part, explaining that each 1/6-group has X in it. The student sees each part as 1 group, and sees 1/6 as describing the type of the part, thereby taking a substance conception of 1/6. The substance conception doesn't help the student view 1/6 as *how many* groups are being considered.

This conjecture is consistent with Küchemann's (1981) finding that students were especially challenged to formulate correct algebraic expressions in situations where variables stood for (whole) numbers of objects. The students may have interpreted the variables as the names or types of the objects rather than as their number.

## A Magnitude Conception of Fractions and Variables

A person uses a *magnitude conception* of a fraction or variable if the person explicitly views the fraction or variable as a magnitude, i.e., as the result of measuring one quantity by another quantity (which need not be separate from the first quantity). For example, if a student understands that it takes 2/5 of the second strip in Figure 1 to make the first strip, then at that moment, the student is using a magnitude conception of 2/5. Similarly, if a student views $Y$ as the number of gallons of yellow paint in the situation of Figure 1, then at that moment, the student is using a magnitude conception of $Y$.

**A Magnitude Conception of a Multiplicand may not Be Necessary.** To use the definition of multiplication as intended does require understanding the multiplicand as a magnitude. However, some students might be able to formulate and explain valid multiplication equations by reasoning about quantities while using only a substance conception of the multiplicand. They might even be able to use the equations by substituting numbers for variables even though they don't think of the variables as magnitudes.

**A Magnitude Conception of a Multiplier may Be Necessary.** In contrast, when a fraction or variable functions as a *multiplier*, we conjecture that a measurement conception is necessary for a productive interpretation of multiplication. We also conjecture that a measurement conception can be cued by asking a measurement question such as "How many of the second strip in Figure 1 does it take to make the first strip exactly?" A student who answers this question as 2/5 may then see that it takes 2/5 of $Y$ to make $X$ and may therefore formulate the equation $2/5 \cdot Y = X$ even if they have a substance conception of $Y$ and $X$ at the moment.

### The Two Conceptions and Moment-by-Moment Reasoning

Finally, we conjecture that the substance and magnitude conceptions are not mutually exclusive. In particular, we conjecture that (1) students can hold the two conceptions simultaneously or that they may switch between the two from one moment to the next, (2) students may not recognize that are using two distinct conceptions when they are reasoning about fractions or variables, and (3) developing expertise with equations involves developing a sense of the difference in the two conceptions and knowing when to use which one.

## Conclusion and Future Directions

The future teachers in our mathematics content courses on multiplicative reasoning come to us with various ideas about developing equations, including intuitive or rote approaches, such as setting up an equation of the form $a/b = c/d$ from "$a$ is to $b$ as $c$ is to $d$." We teach our students to refine their ideas and develop mathematically sound explanations for equations and solution methods by reasoning about how to structure, organize, and relate quantities. To structure, organize, and relate quantities, students must engage with ideas about unitizing, iterating, and partitioning. In addition to these ideas, we conjecture that students also need to refine how they think about quantities, the measurement of quantities, and the mathematical notation we use to describe quantities and their size.

The conjectures we have formulated for this paper come from an initial analysis of a large amount of data. The next step is to find a principled way to select a circumscribed portion of the data for closer examination, so that the conjectures can be put to a rigorous test. We are especially interested in discussions with the audience about this next phase of analysis.

# Networking Theories to Design Dynamic Covariation Techtivities for College Algebra Students

Heather Lynn Johnson Evan D. McClintock Jeremiah Kalir Gary Olson
University of Colorado Denver

*Covariational reasoning is a challenging form of reasoning for undergraduate students to develop and employ. Yet, students' lack of opportunities to use covariational reasoning may account, in part, for some of their difficulties. Building from the work of mathematics education researchers (e.g., Kaput, Thompson, Moore), we developed a suite of Techtivities—free, accessible, digital media activities linking dynamic animations and graphs. Using a Cannon Man Techtivity to illustrate, we provide four key design components and three theoretically based design principles underlying the Techtivities. To inform design both within and across the Techtivities, we network theories of different grain sizes: Thompson's theory of quantitative reasoning and Marton's variation theory. Developing Techtivities for students in the gatekeeping course, College Algebra, we intend to expand students' opportunities to employ covariational reasoning. We discuss implications stemming from students' opportunities to use free, accessible digital media activites, such as Techtivities, to promote their covariational reasoning.*

*Keywords:* Covariational reasoning, Task Design, Quantitative Reasoning, Variation Theory

Covariational reasoning is a critical form of mathematical reasoning imperative for students' understanding of key concepts of introductory college level mathematics such as functions, rates, and graphs (Thompson & Carlson, 2017). At its core, covariational reasoning entails a twofold conception: conceiving of attributes as capable of varying and possible to measure, then conceiving of a relationship between those attributes (Carlson, Jacobs, Coe, Larson, & Hsu, 2002; Thompson & Carlson, 2017). By investigating situations involving multiple changing attributes, students can have opportunities to employ covariational reasoning (e.g., Moore, Stevens, Paoletti, & Hobson, 2016; Johnson, McClintock, & Hornbein, 2017; Thompson & Carlson, 2017). For example, students might investigate a Cannon Man situation, in which a person is ejected into the air, then falls down to the ground with the help of a parachute. In this situation, students employing covariational reasoning could conceive of two possible attributes as capable of varying and possible to measure: Cannon Man's height from the ground and Cannon Man's total distance traveled while in the air. Students could then conceive of a relationship between Cannon Man's height from the ground and total distance traveled.

Building from the work of mathematics education researchers (e.g., Kaput, Thompson, Moore), we developed a suite of Techtivities—free, accessible, digital media activities linking dynamic animations and graphs. We designed the Techtivities for students in College Algebra, an introductory course that can serve as a gatekeeper for many students (e.g., Gordon, 2008; Herriot & Dunbar, 2009). Using a Cannon Man Techtivity to illustrate, we provide four key design components and three theoretically based design principles underlying the Techtivities. Networking theories of different grain sizes—Thompson's theory of quantitative reasoning (1993, 1994, 2002, 2011) and Marton's variation theory (2015)—we designed both within and across the Techtivities. By designing the Techtivities in Desmos (www.desmos.com), we increase accessibility, and thereby expand students' opportunities to employ covariational reasoning. We conclude with implications for students' use of Techtivities to promote their covariational reasoning and for the networking of theories to design digital media activities.

## Background

Despite the importance of covariational reasoning, researchers have documented challenges that undergraduate university students enrolled in calculus and trigonometry courses face when encountering situations calling for covariational reasoning (e.g., Carlson et al., 2002; Oehrtman, Carlson, & Thompson, 2008; Moore, 2014; Moore & Carlson, 2012; Moore, Paoletti, & Musgrave, 2013). Broadly, undergraduate students have difficulty using covariational reasoning to make sense of situations involving variation in change that occurs in a single direction, such as a temperature increasing at a decreasing rate (e.g., Carlson et al., 2002; Oehrtman et al., 2008). In addition, students' impoverished conceptions of the "things" that are changing may decrease their likelihood for covariational reasoning (Moore, 2014; Moore & Carlson, 2012). Furthermore, students' lack of covariational reasoning can impact their ability to view graphs as representing relationships between quantities (Moore & Thompson, 2015; Moore, Stevens, Paoletti, & Hobson, 2016).

Through their programs of research, Thompson and Carlson, together with colleagues, have developed and implemented innovative learning materials to provide opportunities for university students in Calculus and Precalculus to employ covariational reasoning (e.g., Carlson et al., 2002; Carlson, Oehrtman, & Engelke, 2010; Carlson, Oehrtman, & Moore, 2010; Thompson & Ashbrook, 2016a; Thompson & Carlson, 2017). In a PreCalculus course designed to foster university students' covariational reasoning, students encountered instructional tasks designed to provide students opportunities to conceive of change in attributes prior to determining numerical amounts of change (Thompson & Carlson, 2017). In their online Conceptual Calculus textbook, Thompson & Ashbrook (2016a) included a task situation involving a droplet of water landing into a bowl of water and creating circular ripples that increase in size (Thompson & Ashbrook, 2016b). We view this situation as having potential to serve as background for a task requiring students to conceive of and represent change in the area and radius of the ripples. Overall, the research programs of Thompson and Carlson have resulted in opportunities for university students to use innovative learning materials designed to promote covariational reasoning. Yet, we argue that there is room for the development of more accessible and multimodal learning materials, so as to provide digital media that broadens access and learning opportunities to an even wider range of students.

## An Approach to Technology Development and Use for Greater Access and Participation

By developing a suite of Techtivities in Desmos, we increase accessibility and opportunities for participation in multiple ways: across operating system platforms (Apple OS, Microsoft Windows), across various browsers (i.e., Google Chrome, Mozilla Firefox, Microsoft Edge), via mobile devices (Desmos is compatible with iOS and Android), and as an app extension via Google's Chrome browser (Desmos has 2.8 million app installations within Chrome). Furthermore, Desmos has low barriers to entry and initial use, which afford more expansive opportunities for student participation. Specifically, learner use of Desmos begins in just a few clicks via a web browser or mobile platform; supports learning in over two dozen languages; complies with WCAG 2.0 accessibility standards for learners who may be blind or visually impaired, with screen reader capability on both web-based and mobile platforms; includes authenticated sign in with Google credentials; and incorporates a robust set of web tutorials on Youtube (over a quarter million views). We have intentionally partnered with Desmos because the development and use of each Techtivity will maintain these technical features for greater access and participation, and also align all Techtivities with the broader "ecosystem" of Desmos users, social media networks, technical supports, and complementary resources.

## Networking Theories to Design Techtivities

Rasmussen and Wawro (2017) called for researchers investigating research problems in undergraduate mathematics education to network theories, thereby providing new lenses and tools to study the complexities of learning and teaching mathematics. By networking theories of different grain sizes to design the Techtivities, we respond to the call put forth by Rasmussen and Wawro (2017). Watson (2016) articulated three different grain sizes of theories: grand theories (e.g., Piaget's constructivist theory), intermediate theories (e.g., Marton's variation theory), and domain specific/local theories (e.g., Thompson's theory of quantitative reasoning). Following Johnson and colleagues (Johnson, McClintock, Hornbein, Gardner, and Grieser, 2017; Johnson & McClintock, in press), we networked Thompson's theory of quantitative reasoning and Marton's variation theory to design both within and across the Techtivities.

### Thompson's Theory of Quantitative Reasoning

In explicating a theory of quantitative reasoning (e.g., Thompson 1993; 1994; 2002; 2011), Thompson employed a constructivist perspective. Thompson's theory of quantitative reasoning focuses on students' mental operations, which individuals can enact in thought as well as action (e.g., Piaget, 1970, 1985). Drawing on Thompson's theory of quantitative reasoning, by quantity we mean how students conceive of the possibility of measuring some attribute. For example, a student might conceive of using a fixed distance between her thumb and forefinger to measure Cannon Man's height from the ground. Thompson's theory of quantitative reasoning undergirds our perspective on covariational reasoning.

Following Thompson and Carlson (2017), we argue that covariational reasoning entails at least four different kinds of mental operations: students' conceptions of attributes as being possible to measure (quantitative reasoning), students' conceptions of attributes as being capable of varying, students' conceptions of a relationship between attributes capable of varying and possible to measure, and students' images of change. Thompson, Hatfield, Yoon, Joshua, and Byerly (2017) built on Saldanha & Thompson's (1998) term, *multiplicative object*, to specify a conception of a relationship between attributes capable of varying and possible to measure. A student conceiving of a relationship between attributes as a multiplicative object can conceptualize a new attribute, which coordinates the constituent attributes (Saldanha & Thompson, 1998; Thompson et al., 2017). For example, a student could conceive of a new attribute, coordinating Cannon Man's height from the ground and total distance traveled at every value of height and distance. By images of change, we mean more than a mental picture, we mean students' mental operations (see also Thompson, 1996). Castillo-Garsow, Johnson, & Moore (2013) posited two contrasting images of change: chunky and smooth. A smooth image of change refers to a conception of change as occurring in progress. A chunky image of change refers to a conception of change as having occurred in particular increments. For example, a student might conceive of Cannon Man's height as changing continually (smooth image of change) or as having changed to reach a certain amount (chunky image of change). Students' use of smooth images of change correlates to more advanced levels of covariational reasoning (Thompson & Carlson, 2017). Researchers have argued for the utility of students' smooth images of change (e.g., Castillo-Garsow et al., 2013), reporting case studies to demonstrate that utility for both undergraduate and high school students (e.g., Johnson, 2012; Moore, 2014).

### Marton's Variation Theory

We used Marton's (2015) variation theory to guide design across the Techtivities. Broadly, Marton (2015) argued that instructional designers should develop task sequences that provide students opportunities to discern critical aspects (Marton, 2015). When interacting with the Techtivities, we view covariation to be a critical aspect for students to discern. Furthermore, covariation is a critical aspect comprised of interrelated aspects. For critical aspects comprised of interrelated aspects, Marton (2015) recommended that task sequences first include variation and invariance in each interrelated aspect, then variation in both aspects. To discern covariation, students need to conceive of two constituent attributes as capable of varying and possible to measure, as well as a relationship between those attributes. Consequently, in designing the Techtivities, we first included variation and invariance in each constituent attribute, then variation in both attributes.

**Networking Theories to Move Beyond Existing Theoretical Perspectives**

Networking theories can take different forms. We network Thompson's theory of quantitative reasoning and Marton's variation theory to design both within and across the Techtivities. To design within each Techtivity, we drew on Thompson's theory of quantitative reasoning to inform our selection of different attributes to use and to inform our design to promote students' use of smooth images of change. To design across the Techtivities, we drew on Marton's variation theory to include variation and invariance in the type and representation of constituent attributes, then variation in both attributes.

For the purposes of designing the Techtivities, we view Thompson's theory of quantitative reasoning and Marton's variation theory to complement, rather than to compete, with each other. From a constructivist perspective, we do not assume that covariation is something that is "out there" for students to notice (see also Johnson, McClintock, Hornbein, et al., 2017). From a variation theory perspective, Marton (2015) asserted that researchers should not assume that students already attend to the critical aspect prior to encountering a task sequence. We concur with Marton (2015), as we do not assume that students already attend to covariation prior to encountering the task sequence. Furthermore, in the design of the Techtivities, the critical aspect for students to discern—covariation—is a conception (see also Johnson, McClintock, Hornbein, et al., 2017). By discernment, we mean students' engagement in mental operations entailed in covariational reasoning. In the next section, we articulate four key design components, encompassing design decisions both within and across the Techtivities.

## Four Key Design Components of Each Techtivity

Building from the work of mathematics education researchers (e.g., Kaput & Roschelle, 1999; Moore et al., 2013; Moore et al., 2016; Saldanha & Thompson, 1998; Thompson, 2002; Thompson, Byerly, & Hatfield, 2013) we provide four key design components of each Techtivity. In explicating these components, we expand on Johnson's previous task design research (2013, 2015). Furthermore, we find our design components to be complementary to the task sequence reported by Moore et al. (2016). In their task sequence, Moore et al. (2016) began first by providing students with a video or animation depicting changing attributes; second, they prompted students to sketch a graph showing a relationship, and third, they prompted students to sketch a second graph, containing either the same or similar attributes. Furthermore, Moore et al. (2016) recommended that tasks not include numerical amounts, concurrent with Johnson's (2013, 2015) recommendations. In our design components, we adapt and expand on the task sequence reported by Moore et al. (2016). We include opportunities for students to vary individual attributes, and we constrain the attributes in the second graph, such that those attributes are the same as the attributes in the first graph.

## Dynamic Animations of Situations Involving Changing Attributes

Johnson, McClintock, and Hornbein (2017) articulated a need for task designers to take into account the types of attributes included in tasks. In the suite of Techtivities, we intended to select attributes that we thought students may more readily conceive of as measurable. Furthermore, alongside the animation, we identify attributes which will serve as the focus of the Techtivity (Figure 1). We use an animation in part to provide students opportunities to conceive of attributes in the process of changing, or put another way, to use smooth images of change.

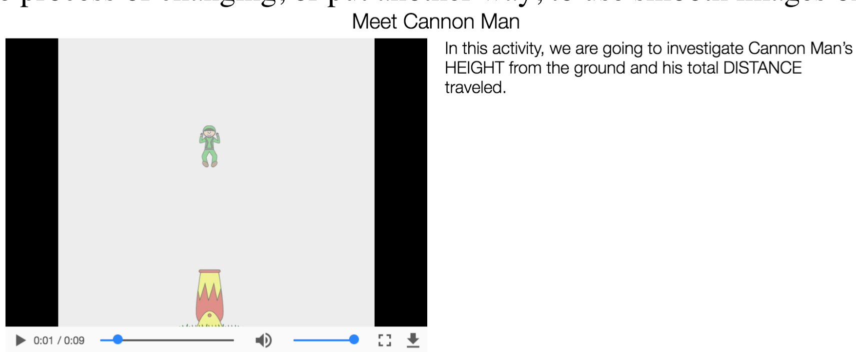

*Figure 1. Cannon man animation*

## Cartesian Graphs Containing Dynamic Segments on the Axes

It is useful for students to use their fingers as tools to represent variation in individual attributes (Thompson, 2002). Through the dynamic segments on each axis (Figure 2, left), we provide students opportunities to use digital media to represent variation in individual attributes. We include freely stretching segments and avoid using numerical amounts to foster students' use of smooth images of change.

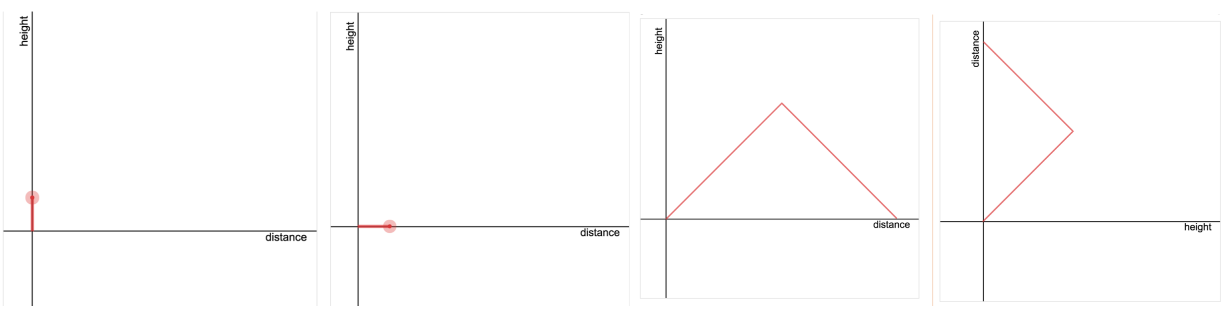

*Figure 2. Dynamic segments (left). Graphs varying representation of the same attributes (right).*

## Opportunities to Sketch a Cartesian Graph after Varying Individual Attributes

Johnson (2015) showed that students' opportunities to conceive of variation in individual attributes impacted their conceptions of covariation. In each Techtivity, after varying individual attributes, students have the opportunity to sketch a Cartesian graph. When working to sketch the graph, students may replay the animation. To sketch a graph, students may select between two digital tools: a free-form pencil or a line segment.

## Variation in Representation of Attributes

Students may find it challenging to conceive of graphs as representing relationships between attributes (Moore & Thompson, 2015; Moore et al., 2016). We incorporated Cartesian graphs that represented the same attributes in different ways (Figure 2, right). In so doing, we intended to provide students opportunities to conceive of graphs as representing relationships, rather than forming a particular type of shape (See also Moore & Thompson, 2015).

## A Blueprint for a Techtivity

Each Techtivity consists of a series of screens, which students move through in a particular order. Table 1 provides a blueprint for a Techtivity. First, students watch an animation of a situation involving changing attributes (Table 1, Item 1). Second, students move dynamic segments to represent change in each attribute. After moving segments, students view the dynamic segments changing together, appearing in conjunction with the animation (Table 1, Items 2-4). Third, students sketch a Cartesian graph representing how both attributes are changing together. After sketching a graph, students view a computer generated graph, appearing in conjunction with an animation (Table 1, Items 5-6). Fourth, students answer a reflection question (Table 1, Item 7). Fifth, students repeat the process for a new Cartesian graph representing the same situation, with attributes on different axes (Table 1, Item 8).

*Table 1. A Blueprint for a Techtivity*

| A Blueprint for a Techtivity |
|---|
| 1. View animation of a situation involving changing attributes. Identify the changing attributes on which to focus in this situation.<br>2. Move a dynamic segment to show how one attribute is changing.<br>3. Move a second dynamic segment to show how the other attribute is changing.<br>4. View both dynamic segments changing together, appearing in conjunction with an animation. (In 2-4, dynamic segments are located on horizontal or vertical axes on a Cartesian Plane.)<br>5. Sketch a Cartesian graph representing how both attributes are changing together.<br>6. View a computer-generated Cartesian graph, appearing in conjunction with an animation.<br>7. Reflect on an aspect of the Cartesian graph. For example, is the graph what you expected? Is there anything about the graph that surprises you? Why might it make sense for a graph to look that way? Is it possible for two different looking graphs to represent the same situation?<br>8. Repeat 2-7 for a new Cartesian graph representing the same situation, with attributes on different axes. |

## Design Principles Emerging from the Development of the Techtivities

### Increase Accessibility to Expand Students' Opportunities to Employ Covariational Reasoning

Kaput (1994) argued that technology could provide students opportunities to investigate areas of mathematics once reserved only for students at more advanced levels. Covariational reasoning is a critical form of reasoning that cannot be reserved only for students at the upper levels of undergraduate mathematics. At CU Denver, the student population is becoming increasingly diverse. In 2016, 57% of new freshman, and overall 43% of undergraduate students identified as students of color (Williams, 2016). Across Spring and Fall 2016, 70% of students enrolled in College Algebra at CU Denver self-identified as students of color. By designing our Techtivities in Desmos, we increase access for undergraduate students, as well as their instructors. We designed the Techtivities so that students could work in ways that are self-paced, or with direction from their instructors. Furthermore, students and educators have free online access to the suite of Techtivities, to use as a just-in-time curricular resource or as an embedded component of a course, allowing for entire cohorts of students to have opportunities to employ covariational reasoning.

### Leverage Domain Specific Theories in Mathematics Education to Design Task Components

By drawing on Thompson's theory of quantitative reasoning, we augment the design of the Techtivities by infusing what we have learned from researchers focusing on students' conceptions. Specific to our focus on covariational reasoning, we leveraged Thompson's theory of quantitative reasoning in three ways. First, provide opportunities for students to conceive of attributes as capable of varying and possible to measure (Table 1, Items 1-3). Second, provide opportunities for students to discern a relationship between attributes, or put another way, to discern covariation (Table 1, Items 4-7). Third, by representing attributes on different axes, provide opportunities for students to conceive of a graph as representing a relationship between attributes capable of varying and possible to measure (Table 1, Item 8).

### Network Theories of Different Grain Sizes to Design Both Within and Across Tasks

Networking theories of different grain sizes, we were able to design both within and across the Techtivities (see also Johnson, McClintock, Hornbein, et al., 2017; Johnson & McClintock, in press). Thompson's theory of quantitative reasoning informed our selection of attributes within each Techtivity and across the suite of techtivities. In the Cannon Man Techtivity, total distance traveled is monotonically increasing. In another Techtivity, we include attributes such that neither is monotonically increasing or decreasing (see also Moore et al., 2016). Marton's variation theory informed the sequencing of design across sections of individual Techtivities as well as across the suite of Techtivities. Individual Techtivities include variation in each attribute, then variation in both attributes. The suite of Techtivities provide different backgrounds.

## Discussion

Despite the existence of some innovative learning materials for Calculus and Precalculus students (e.g., Carlson, Oehrtman, & Moore, 2010; Thompson & Ashbrook, 2016a), we argue that a broader range of university students need access to such materials. We contend there is an *opportunity* gap for university students to develop and employ covariational reasoning. We view this opportunity gap to be particularly problematic for students enrolled in College Algebra. Furthermore, increasing numbers of College algebra students identify as students of color, and university College Algebra courses have had low success rates (e.g., Gordon, 2008; Herriot & Dunbar, 2009). By developing a suite of Techtivities designed to promote College Algebra students' covariational reasoning, we intend to address this opportunity gap.

Broadly, a dual commitment has motivated our design decisions when developing the Techtivities. We intend to increase students' access to opportunities to employ covariational reasoning, and expand learning opportunities through the development of free, accessible, digital media activities that link dynamic animations with graphs. By attending simultaneously to disciplinary and technical barriers, while foregrounding the expansion of learning opportunities for nondominant students at CU Denver, we make explicit our "researcher positionality" (Aguirre et al., 2017), acknowledging that mathematics education research is both a political and equity-oriented endeavor.

*Acknowledgment.* This research was supported by a Grant from the National Science Foundation (DUE-1709903). Opinions, findings, and conclusions are those of the authors. We are grateful to Dan Meyer for his efforts to support the development of the Techtivities in Desmos.

# Mathematics Cognition Reconsidered: On Ascribing Meaning

Thorsten Scheiner
The University of Auckland, New Zealand

*In contrast to the common assumption that mathematics cognition involves the attempt to recognize a previously unnoticed meaning of a concept, here mathematics cognition is reconsidered as a process of ascribing meaning to the objects of one's thinking. In this paper, the attention is focused on three processes that are convoluted in the complex dynamics involved when individuals ascribe meaning to higher mathematical objects: contextualizing, complementizing, and complexifying. The aim is to discuss emerging perspectives of these three processes in more detail that speak to the complex dynamics in mathematics cognition.*

*Keywords:* complexifying, complementizing, contextualizing, mathematics cognition, sense-making

## Introduction

Mathematics cognition is a complex phenomenon that has been addressed and discussed in the literature in different ways and with various emphases. The work presented here arose from a primary cognitive tradition, focusing on critical processes in mathematical concept formation and their complex dynamics. In search for more dialogical possibilities in thinking about mathematics cognition, a new understanding of mathematics cognition emerged (see Scheiner & Pinto, 2017): mathematics cognition does not merely involve the attempt to recognize a previously unnoticed meaning of a concept but the attempt to ascribe meaning to the objects of one's thinking. The purpose of this paper is to provide deeper meaning to the complex processes involved when individuals ascribe meaning. In this paper, three processes are foregrounded: contextualizing, complementizing, and complexifying. Over the past few years, theoretical perspectives and insights emerged (in reanalyzing students' knowing and learning of the limit concept of a sequence) that advance our understanding of these processes. These new perspectives and insights inform research on mathematics cognition and enable one to see not only new phenomena in mathematical concept formation but to think about them differently. In this presentation, emerging interpretative possibilities in thinking about contextualizing, complementizing, and complexifying are discussed that speak to the complex dynamics in mathematics cognition.

## Theoretical Orientations

The work presented here relies on and projects theoretical assertions made by Frege (1892a, 1892b). First, the meaning of a mathematical concept is not directly accessible through the concept itself but only through objects that fall under the concept (Frege, 1892a). Second, mathematical objects (different to objects of natural sciences) cannot be apprehended by human senses (we cannot, for instance, 'see' the objects), but only via some 'mode of presentation.' That we only have access to mathematical objects in using signs and representations, however, leads to what Duval (2006) called a 'cognitive paradox':

"how can they [individuals] distinguish the represented object from the semiotic representation used if they cannot get access to the mathematical object apart from the semiotic representation?" (Duval, 2006, p. 107)

It seems to be an epistemological requirement to distinguish the 'mode of presentation' (or 'way of presentation') of an object from the object that is represented. Frege (1892b) revealed this critical insight, by proposing that an expression has a *sense$_F$* ('Sinn') in addition to its *reference$_F$* ('Bedeutung') (the subscript F indicates that these terms refer to Frege, 1892b). The reference$_F$ of an expression is the object it refers to, whereas the sense$_F$ describes a particular state of affairs in the world, the way that some object is presented. Thus, it seems to follow that we may understand Frege's notion of an idea$_F$ the manner in which we make sense of the world. Ideas$_F$ can interact with each other and form more compressed knowledge structures, called conceptions. A general outline of this view is provided in Figure 1.

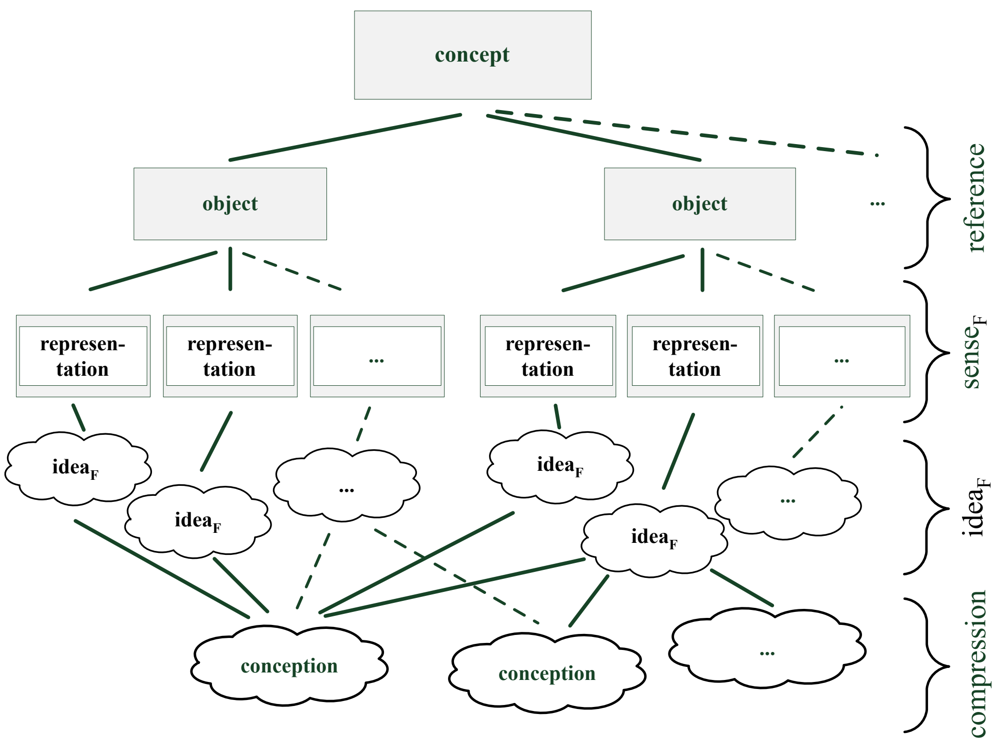

*Figure 1: On reference$_F$, sense$_F$, idea$_F$, and compression (reproduced from Scheiner, 2016, p. 179)*

Duval (2006) argued that via systematic variation of representation registers that is, "investigating representation variations in the source register and representation variations in a target register" (p. 125), one can detach a sense$_F$ from the represented object. This resonates a critical function of reflective abstraction that is, reflecting on the coordination of actions on mental objects (see Piaget, 1977/2001). The special function of reflective abstraction is extracting meaning of an individual's action coordination. Underlying these approaches is the assumption that meaning is inherent in objects and is to be extracted via manipulating objects (or representations of those objects).

Over the past few years, a new understanding of mathematics cognition emerged from reanalyzing students' knowing and learning the limit concept of a sequence (see Scheiner &

Pinto, 2014, 2017; Pinto & Scheiner, 2016): mathematics cognition does not so much involve the attempt to recognize a previously unnoticed meaning of a concept (or the structure common to various objects), but rather a process of ascribing meaning to the objects of an individual's thinking. That is, meaning is not so much an inherent quality of objects that is to be extracted, but something that is given to objects of one's thinking. Three processes are considered as critical in the complex dynamics involved when individuals ascribe meaning to higher mathematical objects: contextualizing, complementizing, and complexifying (see Scheiner & Pinto, 2017).

### Contextualizing: Particularizing Senses$_F$

In Frege's view, a sense$_F$ can be construed as a certain state of affairs in the world and an idea$_F$ in which we make sense$_F$ of the world. In the work presented here, we started from an understanding of sense$_F$ as not primarily dependent on a mathematical object, but as emerging from the interaction of an individual with an object in the immediate context. That is, a sense$_F$ of an object at one moment in time can only be established in a more or less definite way when the process of sense$_F$-making is supported by what van Oers (1998) called *contextualizing*. Van Oers (1998) argued for a dynamic approach to context that provides for the "particularization of meaning" (p. 475), or more precisely, the particularization of a sense$_F$ that comes into being in a context in which an object actualizes.

Recent research suggests that individuals seem to reason and make sense from a specific perspective (see Scheiner & Pinto, 2017). It might be suggested that individuals take a specific perspective that orients their sense$_F$-making, or more accurately: in taking a certain perspective, individuals direct their attention to particular senses$_F$. Contextualizing, in this view, means taking a certain perspective that calls attention to particular senses$_F$. Attention in such cases, however, may not involve an attempt to 'sense' or 'see' anything, but it seems to be attentive thinking: attention as the direction of thinking (see Mole, 2011). As such, calling attention to particular senses$_F$, then, means directing mind to sense$_F$. In this respect, contextualizing is intentional: it directs one's thinking to particular senses$_F$.

### Complementizing: Creating Conceptual Unity

Frege (1892b) underlined that a particular sense$_F$ "illuminates the reference$_F$ […] in a very one-sided fashion. A complete knowledge of the reference$_F$ would require that we could say immediately whether any given sense$_F$ belongs to the reference$_F$. To such knowledge we never attain" (p. 27). (Translated from Frege (1892b): "[mit dem Sinn] ist die Bedeutung aber […] immer nur einseitig beleuchtet. Zu einer allseitigen Erkenntniss der Bedeutung würde gehören, dass wir von jedem gegebenen Sinne sogleich angeben könnten, ob er zu ihr gehöre. Dahin gelangen wir nie"). This is to say, that just from sense$_F$-making of one representation that refers to an object, we are typically not in a position to know what the object is (see Duval, 2006). As contextualizing serves to particularize only single senses$_F$ of a represented object, the same object can be 're-contextualized' (see van Oers, 1998) in other ways that support the particularization of different senses$_F$ of the same object. Notice that senses$_F$ can differ despite sameness of reference$_F$, and it is this difference of senses$_F$ that accounts for the 'epistemological value' of different representations. It is the diversity of senses$_F$ that has 'epistemological significance' and forms conceptual unity (see structuralist approach, Scheiner, 2016), not the similarity (or sameness) of senses$_F$ (as might be advocated in an empiricist approach). This means, what matters is to coordinate diverse senses$_F$ to form a unity, a process called complementizing. However, the notion of 'complementizing' might be misunderstood as accumulating various senses$_F$ (until an individual has all of them); this is not the case. Complementizing means to coordinate different senses$_F$ to create conceptual unity.

As each idea$_F$ is partial in the sense of being restricted (in space and time) and biased (from a particular perspective), it needs to be put in dialogue with other ideas$_F$ that offers an epistemological extension. The function of complementizing, then, is extending the epistemological space of possible ideas$_F$. Complementizing as extending the epistemological space of possible ideas$_F$ brings a positive stance, indicating that seemingly conflicting ideas$_F$ can be productively coordinated in a way such that these ideas$_F$ are cooperative rather than conflicting. Hence complementizing is the ongoing expansion of one's epistemological space, the ever-unfolding process of becoming capable of new, perhaps as-yet unimaginable possibilities.

### Complexifying: Creating a Complex Knowledge System

It is not only creating a unity of diverse senses$_F$, but creating an entity in its own right that forms a 'whole' from which emerges new qualities of the entity. That is, rather than treating the unity as a collection of different senses$_F$ that can be assigned to objects that actualize in the immediate context, it is the forming of the unity that emerges new senses$_F$ that might be assigned to potential objects. In forming a unity, senses$_F$ are not merely considered as the parts of the unity, but "they are viewed as forming a whole with distinct properties and relations" (Dörfler, 2002, p. 342). It is, therefore, not an unachievable totality of senses$_F$ (or ideas$_F$) that matters, but how senses$_F$ (or ideas$_F$) are coordinated that develop emergent structure. This brings to foreground a critical function of complexifying that has not been attested yet: blending previously unrelated ideas$_F$ that emerge new dynamics and structure (for a detailed account of conceptual blending, see Fauconnier & Turner, 2002). The essence of conceptual blending is to construct a partial match, called a cross-space mapping, between frames from established domains (known as inputs), in order to project selectively from those inputs into a novel hybrid frame (a blend), comprised of a structure from each of its inputs, as well as a unique structure of its own (emergent structure). This strengthens Tall's (2013) assertion that the "whole development of mathematical thinking is presented as a combination of compression and blending of knowledge structures to produce crystalline concepts that can lead to imaginative new ways of thinking mathematically in new contexts" (p. 28).

### Discussion

Mathematics cognition, as asserted here, evolves in the dialogue of contextualizing, complementizing, and complexifying. As such, mathematics cognition is ongoing and cannot be pre-stated. That is, mathematics cognition does not follow a determinable developmental trajectory, but the evolution of mathematics cognition is directional: it seems to move toward higher levels of internal diversity, interactions, and decentralization of ideas$_F$.

Scheiner and Pinto (2017) suggested that individuals take a specific perspective in ascribing meaning to the limit concept of a sequence. For instance, individuals, who take the perspective of a limit sequence as approaching, may activate dynamic ideas$_F$ (such as the idea$_F$ of a sequence of points 'getting closer' to a limit point). Consider Figure 2: one might activate the idea$_F$ of a limit that can be approached monotonically (see idea$_F$ A) or the idea$_F$ of a limit that can be approached from above and below (see idea$_F$ B) in making sense$_F$ of the respective representation (see Cornu, 1991; Davis & Vinner, 1986; Tall & Vinner, 1981). On the other hand, individuals, who take the perspective of closeness in thinking about the limit concept of a sequence, might activate rather static ideas$_F$ (such as the idea$_F$ of points of a sequence 'gathering around' the limit point). One might activate the idea$_F$ that infinite many points of a sequence can lie within a given epsilon strip (see idea$_F$ U or V) in making sense$_F$ of the representations (see Przenioslo, 2004; Roh, 2008; Williams, 1991).

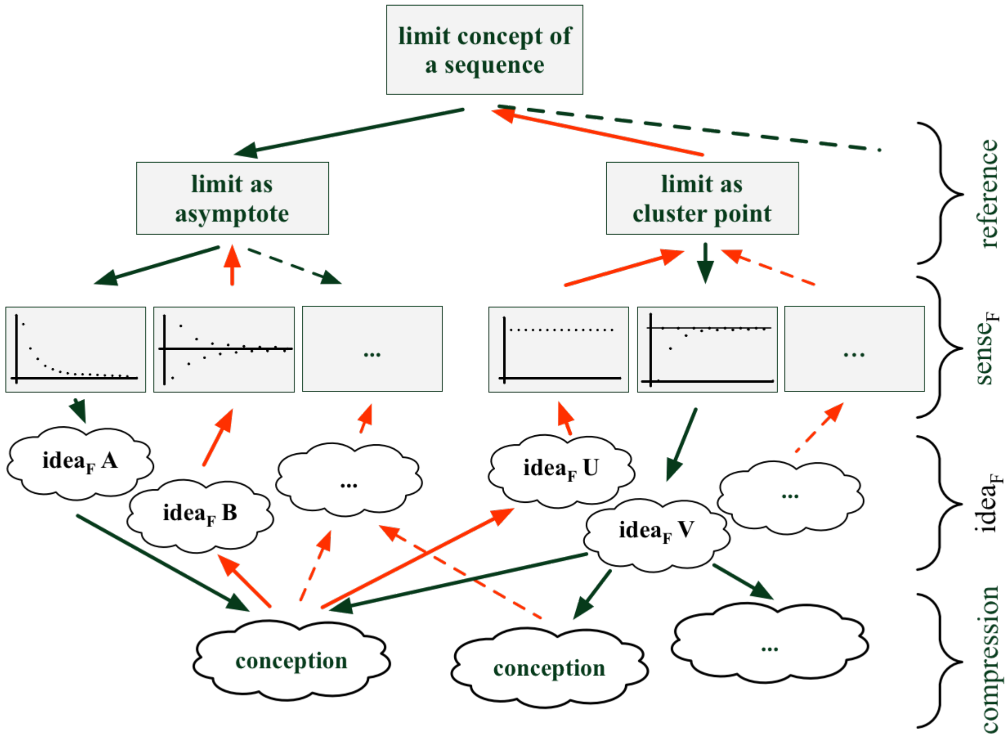

*Figure 2: On the complex dynamics in mathematics cognition*

The critical point here is that it is not one single idea$_F$ around one's thinking is to be organized (such as the idea$_F$ that only finite many points lie outside a given epsilon strip), but a variety of diverse ideas$_F$ that provides a resource of activating productive ideas$_F$ and of making sense$_F$ in the immediate context. Decentralization and internal diversity of ideas$_F$, however, are not only critical for making sense$_F$ in the immediate context, but also for creating novel ideas$_F$. Whereas analogy theory typically focuses on compatibilities between ideas$_F$ simultaneously connected, blending is equally driven by incompatibilities (see Fauconnier & Turner, 2002).

Creating novel ideas$_F$, however, only occurs if there is a certain level of interaction between existing ideas$_F$. That is, only if ideas$_F$ can compensate for each other's restrictions and limitations, one is able to extend the space of possibilities in thinking about a mathematical concept. In this view, novel ideas$_F$ can ascribe *new* meaning to the objects of one's thinking (see Figure 2). This substantiates the assertion that mathematics cognition is as much concerned with creating a meaning of a concept as it is with comprehending it (see Scheiner, 2017).

# A Model of Task-Based Learning for Research on Instructor Professional Development

| Billy Jackson | Jenq-Jong Tsay | Shandy Hauk |
| --- | --- | --- |
| SUNY Geneseo | University of Texas Rio Grande Valley | WestEd |

*We present a theoretical framework that synthesizes and increases the descriptive power of existing models of task-based learning. Grounded in social constructivism and activity theory, the framework supports collegiate mathematics education researchers in identifying, investigating, and reporting on task-based learning in instructor professional development contexts. Relevant definitions and connections to the larger realm of inquiry-based, problem-based, and other general inquiry-oriented instruction are addressed. We conclude with a discussion and illustration of how the framework may be used in design, materials development, and evaluation research related to instructor professional learning.*

*Key Words:* Activity, Task-based learning, Professional development, Teaching for robust understanding

Experts in the social and behavioral sciences, such as mathematics education, often deal with the challenge of specialized language. Technical terms can have shades of meaning that differ significantly from everyday language-in-use counterparts. For example, Cook, Murphy, and Fukawa-Connelly (2016) point out that the absence of a concise and consistently applied definition of *inquiry-based learning* (IBL) in science, technology, engineering, and mathematics education has meant researchers use the term to mean fundamentally different things. This divergence has created confusion. Kirschner, Sweller and Clark (2006) claimed that inquiry-based learning does not work, while Hmelo-Silver, Duncan and Chinn (2007) responded that the claim was based on a fundamental flaw: the authors had oversimplified and treated IBL as if it were unguided discovery (which, for Hmelo-Silver and colleagues was a very different thing).

The importance of concise and shared definitions is amplified in research on instructor professional development. Hayward, Kogan and Laursen (2016) note that presenting IBL as a broad and inclusive set of pedagogical practices appeared to be critical in the willingness of college mathematics faculty to adopt it. Instructors viewed questions (inquiry) and learning as existing aspects of their own practice. Faculty saw this new "inquiry-based learning" as an extension of something they already knew, as professionally relevant and useful. As faculty learned more, read more, spoke more about IBL, they practiced using a specialized language, an IBL lexicon, for describing and re-defining their goals, resources, and orientations about teaching, about what learning was, and about what constituted evidence of it.

Here we operationalize a theory of *task-based learning* (TBL). Our focus is in the context of faculty professional development. The goal is to create a sufficiently detailed framework that has descriptive power and is useful for evaluating professional learning and for doing design-based research. In particular, there is a need for a model of TBL for research and development work on professional growth among mathematics faculty new to teaching future school teachers (Masingila, Olanoff, & Kwaka, 2012).

Some might argue with the feasibility of singular definitions in mathematics education. At the same time, the attempt to negotiate a definition, to create a useful model of meaning, can have valuable descriptive power (Schoenfeld, 2000). It is this aspect of research and design in professional development, and the knowledge that there are linguistic and cultural norms related to particular views of teaching and learning, that influences our framework effort. Consider the case of college mathematics faculty in the U.S., most of whom are fluent in one or more natural languages (e.g., English and Chinese) and one or more dialects of research mathematics. These are people who also know the Western academic cultural norms of the transmission and product models for college instruction (Davis, Hauk, & Latiolais, 2009). Place a person with these multiple fluencies and areas of expertise in a room with 20 undergraduates whose life goal is to become a primary school teacher and tell the instructor: Teach them math. Three words: Teach. Them. Math. Each word has a cacophony of meaning. The layers of meaning are large in number and the likelihood of shared definitions for "teach," "them," and "math" are small. What does it mean to teach? What distinguishes "them" from "me" or "us" (if anything)? And *which* math does "math" mean? Indeed, many American teachers perceive mathematics as a static body of knowledge where knowing mathematics is equivalent to efficiently manipulating symbols without necessarily understanding what they represent (Thompson, 1992).

## Mathematical Knowledge for Teaching (MKT) for Grades K-8

Several decades of research rooted in Shulman's (1986) work have indicated that there are particular understandings and skills associated with effective instruction, a sociological synergy of mathematics and mathematics education called *mathematical knowledge for teaching* (MKT; Ball, Thames, & Phelps, 2008). MKT for elementary grades as modeled by Ball and colleagues is made up of six kinds of knowledge. Three are types of subject matter knowledge: *horizon content knowledge,* about how topics are related across the span of curriculum; *specialized content knowledge* which is specialized in the sense that it is specific to the task of *teaching*, and is complementary to *common content knowledge*. In particular, specialized content knowledge includes ways to represent mathematical ideas, provide mathematical explanations for rules and procedures, and examine and understand innovative solution strategies from the student's perspective. This specialized knowledge for teaching K-8 is sparse or absent for many with advanced mathematics expertise but little teaching experience (e.g., mathematics professors; Bass, 2005). As an example, consider fraction division. Most novice instructors can readily use the invert-and-multiply algorithm to divide fractions. Thus, this piece of knowledge is *common content*. Yet, few can explain to someone *why* the algorithm is justified in some problem situations and not in others, thereby making knowing the "whys" *specialized*.

The other three categories in MKT are types of *pedagogical content knowledge* (PCK) and are neither purely pedagogical nor exclusively mathematical. *Knowledge of curriculum* includes awareness of the content and connections across standards and texts (i.e., of the intended curriculum; Herbel-Eisenmann, 2007). *Knowledge of content and students* (KCS) is "content knowledge intertwined with knowledge of how students think about, know, or learn this particular content" (Hill, Ball, & Schilling, 2008, p. 375). *Knowledge of content and teaching* (KCT) is about teaching actions or moves (i.e., productive ways to respond in-the-moment to students to support learning). So, in our fraction example, teachers who are aware that students often invert the dividend instead of the divisor are demonstrating KCS and might use fraction diagrams to scaffold understanding if they have the appropriate KCT. Both KCS and KCT are associated with improved student learning (Hill et al., 2008; Hill, Rowan, & Ball, 2005).

A related idea at the college level is *mathematical knowledge for teaching future teachers* (MKT-FT) held by college instructors who teach pre-service teachers (Hauk, Jackson, & Tsay, 2017). A rich and textured MKT-FT is especially vital in the inquiry-oriented or activity-based approaches to teaching shown to improve student learning, increase persistence, and reduce inequities (Bressoud, Mesa & Rasmussen, 2015; Freeman et al., 2014; Holdren & Lander, 2012; Laursen, Hassi, Kogan, & Weston, 2014). College instructors acquire MKT-FT in many ways: grading, examining their own learning, observing and interacting with students or colleagues, reflecting on and discussing practice (Kung, 2010; Speer & Hald, 2009; Speer & Wagner, 2009).

## Defining and Illustrating Tasks

With a focus on MKT and MKT-FT in mind, we examined *task-based learning* (TBL) and the task and activity framework of Christiansen and Walther (1986). Growing from social constructivist roots, their view of TBL is as adaptation, human behavior in response to the conditions between the individual and the social, physical, and cognitive environments perceived by the individual. In other words, human behavior is a result of goal-directed seeking for a regulation of mutual relationships between the individual and environment(s). Within this framework, the terms *task, activity, action,* and *plan* each play distinctive roles. Christiansen and Walther explicitly characterize *task* as *interplay* among teacher, students, curriculum and objectified mathematics (see Figure 2). They implicitly express activity as inherent in the relations among the various components indicated by the unlabeled arrows in Figure 2.

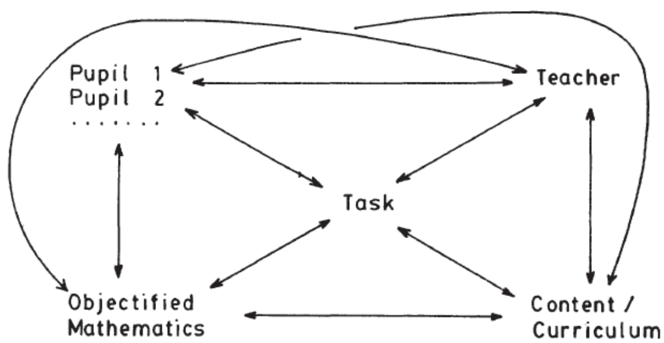

*Figure 2. The relational character of task and activity (Christiansen & Walther, 1986)*

A *task* is the "goal of an action, with the goal being framed by distinct conditions" (p. 256). Specifically, a task is the assignment set by the teacher, which is the object for students' activity. A mathematical task generally includes one or more problems whose solving is expected (by the task designer) to involve mathematics. The task also includes a set of instructions, directives, and/or extensions to which learners are expected to respond. Two caveats here: (1) how explicitly the goals and conditions of the task are communicated varies widely, and (2) replacing "mathematics" with "MKT" or "MKT-FT" in the paragraph above provides parallel definitions for tasks in the context of college instructor professional development for teaching.

*Activity* is a process that includes reactions and adaptations by the student that are in response to the changes in task conditions that arise during the students' work on the task (these are theorized to be based upon student-specific needs and motives). Activity is realized through a collection of *actions*, goal-directed processes arising from the students' motives:

> Activity exists only in actions, but *activity* and *actions* are different entities. Thus, a specific action may serve to realize different activities, and the same activity may give rise to different goals and accordingly initiate different actions. (p. 255).

Each action in activity serves to attain a goal of the task: the collection of actions is goal directed and together forms a *plan*. For Christiansen and Walther, the teacher is the central agent of authority. We argue that in contexts where students are adults, the locus of control may well lie with the learner (e.g., future elementary teachers, faculty who are learning about teaching). And, social, mathematical, and socio-mathematical mediation occur among students and between students and instructor. That is, how an activity induces action depends on the agents and their relationships. Moreover, moving between actions and from actions to related plan (and back again) involves many decisions. Figure 3a summarizes our interpretation of the framework, overall, and Figure 3b illustrates one possible decision process across actions and planning.

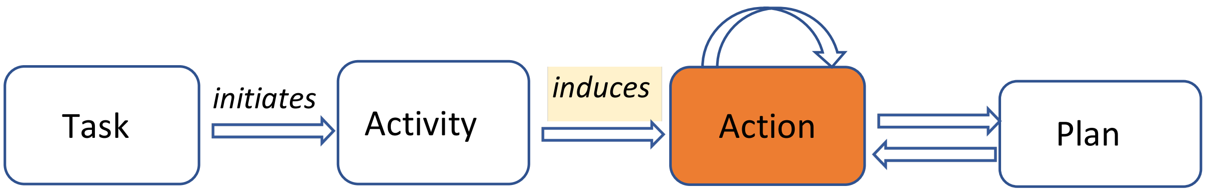

*Figure 3a. Detailed task and activity framework.*

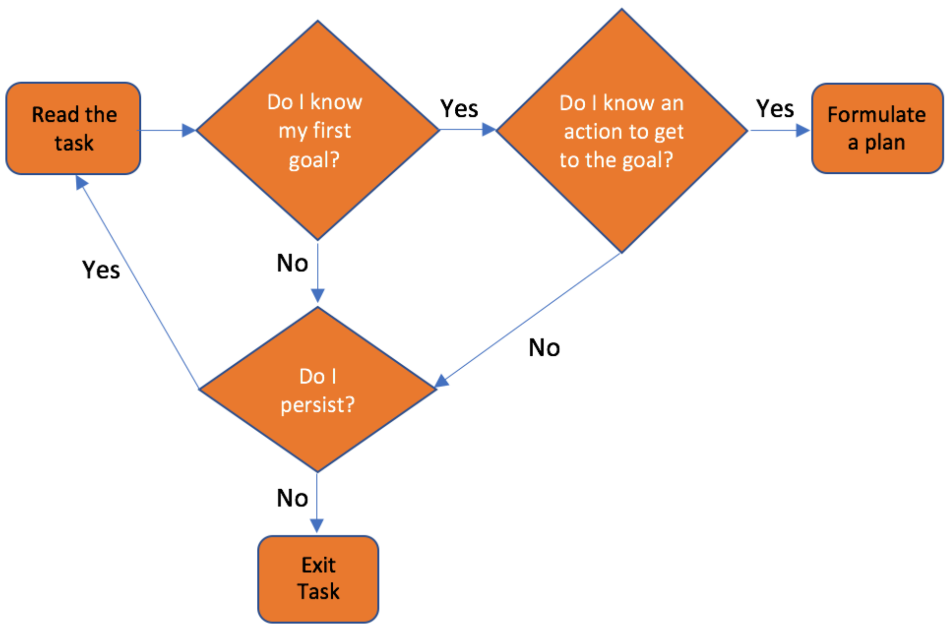

*Figure 3b. Example Action – Plan feedback tree.*

Christiansen and Walther (1986) offer different non-exhaustive types for each element in the framework. For instance, they distinguish different tasks by the type of mathematical activity in which students will engage: exploratory, constructive, or problem-solving. Smith and Stein (2011) offer a further delineation of problem-solving tasks as those that (a) call on memorization, (b) use procedural knowledge but require limited connections to other knowledge, (c) require procedural and connected knowledge, and (d) engage students in actually doing novel (to the learner) mathematics by calling for conjecturing, reasoning, and justification.

For Christiansen and Walther, *educational activity* is what leads to work in response to a task-driven behavioral goal (e.g., produce a graph), while *learning activity* is activity that results in someone achieving the intended learning outcomes. When engaged in an activity, learner actions may be *preparatory, observational/reflective, control-focused, safeguarding,* or *corrective*. Preparatory actions are those that establish conditions for success or which facilitate another action (e.g., *formulating a plan* is a preparatory action). Observational and reflective actions develop or identify information needed to complete or plan other actions. Safeguarding actions ensure that information and results obtained along the way in the task are readily available to the learner later in the task. Control actions are calibrations: learners compare the intended goals/actions with those that were actually achieved/performed. Corrective actions refer to acts by learners to anticipate or remove possible errors.

As an illustrative example of the framework, suppose an instructor of pre-service elementary teachers gives students a collection of questions similar to the one in Figure 4.

| | | |
|---|---|---|
|  | Suppose a whole serving is 1/2 of a cookie. How many servings (whole or fractional) can I make from 3/4 of a cookie? |  |
|  | Suppose a whole serving is 1/2 of a cookie. How many servings (whole or fractional) can I make from 1/4 of a cookie? |  |

*Figure 4. Fraction word problems (adapted from Gregg and Gregg, 2007).*

Notice that based upon definitions given here, a collection of a dozen such word problems, in and of itself, does **not** constitute a task because there are no instructions or extensions asking for response/resolution. However, the collection might be transformed into a task with an MKT development goal by inducing two different activities:

1. Suppose you are a 6th grader who is completing this activity for the first time. You have never been exposed to an algorithm for fraction division, and so you do not have that knowledge going into the activity. Do the activity accordingly.
2. What algorithm for fraction division does the activity suggest would be appropriate? HINT: To answer this, think about HOW you got your answers to each of the questions.

Now students are being asked to do more than to solve problems. They are required to engage in several activities. One activity introduces planning and actions for imagining (and then thinking like) a 6th grader, and as an extension, deducing the common denominator algorithm from the task by thinking about another (imaginary) person's solution process. In the course of completing the task, common learner actions tend to include reflection on how what they have done in solving each of a parallel set of problems about serving size as it relates to an algorithm, safeguarding as they search for patterns to determine the algorithm, and control actions as they begin to think about what a typical 6th grader might know.

## Characteristics of Task-based Learning (TBL)

Having now established definitions and a framework relating task and activity, we are in a position to elucidate the defining characteristics of task-based learning:

- Learners work on a task collaboratively (usually in groups of 2 to 4 members). Often tasks will include activity with manipulatives, video, and/or other technology.
- As learners work to complete the task, they consistently engage in activity that is mathematical and/or pedagogical in nature. The task is designed to elicit actions such as sense-making, conjecturing, reasoning, justifying, problem posing, questioning, challenging, role playing, reflecting, and anticipating.
- The task makes explicit queries about the nature of learners' thinking, reasons for steps they take, and what they produce as they work to complete the task. Teacher utterances include challenges to student productions, questions that extend activity or call for re-planning, and brokering guidance for struggling students.

Note that the first element is collaboration – working together towards a group goal or outcome. This is different from cooperation – working together for mutual benefit towards individual goals/outcomes. Both can be powerful supports for building community (Banilower et al., 2013).

**Juxtaposition with Other *-Based Learning**

Task-based learning certainly shares characteristics with most uses of "inquiry-based learning" we have encountered. It requires inquiry-oriented instruction (Rasmussen and Kwon, 2007) in that teacher and student play important roles in the process. Within the science education community, inquiry-based learning is often categorized as *structured*, *guided*, or *open* (Biggers and Forbes, 2012; Chinn and Malhorta, 2002; Kuhn, Black, Kesselman, & Kaplan, 2000). In structured inquiry, the instructor provides the materials and procedures necessary to complete the task, with the expectation that students will discover the intended learning outcomes in the process. In guided inquiry, the instructor poses a problem and provides necessary materials, leaving students to devise their own solution methods. In open inquiry, students pose their own problems and seek their own solutions. By design, TBL is either guided or structured, depending on how the task is presented to the learner. This is in contrast to *problem-based learning* which is an open model starting with something problematic for the learner rather than *problems,* which are the starting point for TBL. Likewise, TBL is different from *project-based learning* because tasks as defined here are not generally projects that require synthesizing significant amounts of information over time.

Every task starts with a novel (to the learner) problem (i.e., not an exercise involving a single stream of well-rehearsed actions). The activity and actions of students required in TBL ensure that they are doing mathematics. Actions that occur during task activity form the basis for self-regulation, a critical component of metacognition which is crucial for effective and efficient problem solving. Self-regulation is a behavior that can be acquired over time as learners engage in authentic problem solving regularly (Schoenfeld, 1992). That is, repeated exposure to tasks that scaffold agency and self-regulation can support the taking up of agency and self-regulation. The teacher's role in TBL mirrors that in teaching problem solving: as a cultural broker of mathematically rigorous meaning and facilitator of self-aware use of mathematical language.

Enacting or assigning tasks does **not** guarantee learning. In much the same vein, presenting students with problems to solve does not constitute teaching of problem solving. Other criteria must be met by instructor and students. For example, having future teachers use base ten blocks to demonstrate operations does not mean they can explain common algorithms for the operations. Concretism does not always ensure that intended learning activity will follow. To achieve the desired activity and, ultimately the goal learning outcome, it takes focused effort by the expert (teacher, instructor, facilitator of professional development) during activity in the task to direct attention as needed. Thus, task-based learning for faculty, where the goal is to build MKT-FT must do more than tell participants to watch some mathematics classroom video and reflect on it (Seago, 2004). Specific prompts before video viewing might direct people to prepare themselves to notice and identify evidence of student thinking about the meaning of slope. Twice. That is, the task includes purposeful repetition of activity. The prompt for two viewings makes explicit the goal and sets expectations that participants will do a particular kind of intellectual work (notice, identify) about particular aspects of the video (student utterances and actions that can be considered evidence, slope). These prompts are intentional in preparing the participant for possible extensions like: Create at least two potential responses to the noticed thinking.

**Why Promote TBL Among Mathematics Instructors and in Professional Learning?**

First, TBL is a form of active learning and active learning has been shown to significantly improve undergraduates' performance in science, technology, engineering, and mathematics courses by half a letter grade (Freeman et al., 2014). Second, the recent *Standards for Preparing*

*Teachers of Mathematics* by the Association of Mathematics Teacher Educators (2017) calls for the use of task-based learning in courses for future teachers:

> In such settings, learners are typically provided challenging tasks that promote mathematical problem solving and … discuss their thinking in small and full-group discourse, thus promoting important mathematical practices (Webb, 2016) (p. 31).

As does the *Mathematical Education of Teachers II* (MET II, 2012):

> Courses should also use the flexible, interactive styles of teaching that will enable teachers to develop [mathematical] habits of mind in their students (p. 19).

Indeed, a task-based approach empowers the skilled teacher to meet many (if not all) of the criteria in the Teaching for Robust Understanding (TRU) framework for high quality instruction (Schoenfeld, 2014, 2017). Moreover, Connolly and Millar (2006) noted that faculty in teaching workshops wanted professional development that used the TBL methods being advocated in the workshop. In a current project by the authors, we are offering faculty a task-based approach to professional learning about task design and task use in their own classrooms.

## Conclusion and Avenues for Further Investigation and Research

We end by giving some examples of tasks for faculty professional learning. Our focus is ways to teach mathematics courses for future K-8 teachers. Note that the main goal of these professional learning tasks is not to build mathematical knowledge, but to foster development of MKT-FT. A task requires a problem. Rich problems of instructional practice might center on pedagogical content or specialized content knowledge for teaching future teachers or building understanding of the MKT that future teachers need.

In this spirit, consider the cookies task discussed earlier. In a task for faculty, participants are asked to "put on your student hat" and do the task. Then the nature of the task and activity are discussed. Then comes a meta-aware extension to the task, "Imagine you are a pre-service teacher and have been given this task, what is challenging? Why?" Faculty work involves *knowledge of content and (pre-service teacher) students,* a component of MKT-FT parallel to knowledge of content and students in MKT. Faculty then read a transcript of pre-service teachers completing the original task. They identify things that the pre-service teachers struggled with and compare that with their anticipations. The task has two intended learning outcomes: (1) faculty build knowledge of (pre-service teacher) student thinking and (2) faculty unpack the demands and consequences of designing/revising tasks for achieving particular learning goals.

Areas for use of the TBL framework in research and development include addressing questions such as: How do designers and facilitators know that they are effectively implementing task-based learning in faculty professional development? What constitutes evidence of this? Also, what are indicators of success of a task-based professional learning experience? The productive use of tasks by participants in their own practice is one important factor, but are there others? Finally, the scant research literature on professional development for teaching in higher education has yet to delineate the conditions that promote (or hinder) faculty success. For example, what experiences and supports may be needed for faculty to use, as an instructor, a TBL model they have experienced as learners in professional development?

Theorizing Silence

Matthew Petersen
Portland State University

*Different norms govern the use of silence in mathematical collaboration and in every-day Anglo-conversation. Research is therefore needed into the ways students are enculturated into the distinctive uses of silences employed in mathematics collaboration. This project will require a new theoretical perspective that facilitates the study of silence. Drawing off studies of silence and embodiment from multiple disciplines, this paper advances a view of silence and the body, and so lays the groundwork for a rigorous study of silence in mathematics education.*

*Keywords:* Silence, Embodiment, Sociomathematical Norms, Interaction

Two recent conference papers (Petersen, in press; Lim, 2017) have raised the prospect that the mathematics education community may benefit by attending to silence. First, Petersen argued that while engaged in intense collaborative mathematical activity, mathematicians remain silent for lengthy periods of time; a practice at odds with the every-day Anglo conversational norm that exactly one person speak at a time (Erickson, 2004; Liddicoat, 2011). This disconnect between the norms of every-day Anglo conversation and mathematical practice makes mathematicians' collaborative silences pedagogically interesting. Second, Lim, argued that though the reform movement has done a good job giving students voice in the classroom, introverted students who value silence and careful thought, may have a difficult time in reform classrooms.

As I have thought about these issues over the last year, two anecdotes have helped convince me that silence is in fact an important, though understudied aspect of mathematical activity and of learning to be a mathematician. First, while discussing silence with a mathematician, he told me that he had the distinct impression of being apprenticed into silence while working on both his Master's degree and Ph.D. The second episode occurred while tutoring students in a 300-level proof class. On one occasion, as I attempted to answer student questions, I realized that the solution I had worked out in advance was incorrect and, with the mathematics I then knew, I was unable to address the students' questions—though I could tell that my error was small, and relatively easy to fix. My natural strategy was not to speak, but to perform mathematical activity by attending to the problem closely and carefully, in silence. The students, however, responded to my silence as a lapse in conversation, and repeatedly attempted to engage me in further conversation. To my surprise, I quickly realized that though, on my own, I would be able to fix the bug in my proof quickly and easily, the interactional requirements of the tutoring situation, and the norms governing the conversation, made me incapable of performing the mathematical activity necessary to adequately address my students' questions.

Though these are just anecdotes, both stories provide corroborating evidence that in learning to collaborate as mathematicians, students need to learn to employ silence in ways that violate the norms of every-day Anglo-conversation. The second, in particular, points to potential difficulties students may face as they attempt to collaborate on mathematics. If research is to be conducted into silence, strong new theoretical and methodological papers are needed. This paper attempts to make a beginning in providing a theoretical foundation for the study of students and mathematicians uses of silence.

## Communities of Practice

Several important strands of research in mathematics education attend to the way students learn mathematical ideas and concepts in communities of practice. Several are particularly relevant to research on silence.

First, research in the emergent perspective (Cobb and Yackel, 1996; Yackel and Cobb, 1996; Voigt, 1985, 1989, 1995) attends to sociomathematical norms, that is, ways students and teachers negotiate what sorts of answers are normatively treated as expressing mathematical concepts and practices (such as justification) (Cobb and Yackel, 1996; Yackel and Cobb, 1996; Voigt, 1985, 1989, 1995). If, as previous research suggests (Petersen, in press), there are distinct norms governing silence in face-to-face mathematics collaboration that differ from the norms governing silence in every-day conversation, there are peculiar sociomathematical norms governing silence, and, as students become mathematicians, they are enculturated to those norms. On the other hand, Yackel and Cobb attempt to "account for how students develop specific mathematical *beliefs and values*" (p. 458, emphasis mine), whereas though silence may be used peculiarly in mathematical collaboration, it does not itself signify any mathematical reality.

This focus on overtly mathematical aspects of the classroom, however, does not preclude attention to what Voigt (1985) calls "patterns of interaction", e.g. questions of who is authorized to speak when, or how much wait-time teachers give their students, behavioral patterns that are not overtly mathematical in nature, but which give the classroom a particular order in which explicitly mathematical practices can be learned. These patterns of interaction which undergird mathematical activity, however, are not strictly mathematical, and so the norms governing them are not sociomathematical norms; whereas, if the norms governing silence are discipline specific, because they are an aspect of mathematical activity, they are as sociomathematical norms.

On the other hand, a very different line of research in mathematics education attends not to mathematical concepts and beliefs, but to mathematical *activity* (Rasmussen, Zandieh, King, & Teppo, 2005). In learning mathematics, students and teachers engage in activities endemic to the mathematics profession, like justification, algorighmatization, and defining.

Like that from Cobb and Yackel's emergent perspective, research from this perspective focuses on overtly mathematical aspects of learning. This line of research, however, opens up the possibility that actions that are not overtly mathematical nevertheless play an important role in allowing people to perform mathematical actions, and so are an important aspect of mathematical activity and an important line of research in mathematics education. Though not from the same perspective, Savic (2015), can be read as an existence proof for this sort activity. He found that when mathematicians reach a proving impasse, they will sometimes resolve the difficulty by stepping away from the problem and doing something else, e.g. taking a walk, going to lunch with their family. Savic's research does not address the potential for aspects of mathematical activity that are *socially* interesting, and that require students to learn new sociomathematical norms, but together with Cobb and Yackel's research into sociomathematical norms, it raises the prospect that, as part of their collaborative mathematical activity, mathematicians follow norms contrary to the norms used in every-day interaction. If the results in Petersen (in press) hold up, silence falls into this category. This claim, however, needs unpacking unpacking.

Philips' (1792; 1983) ethnography of education on the Warm Springs Indian Reservation in Oregon provides helpful information regarding the ways different norms for silence can structure classroom interaction. According to Philips, the Native community she studied placed a high value on the difficult skill of effective, brief, speech; and therefore, lengthy pauses often preceded responses. On the other hand, in Anglo-conversation, pauses longer than a second carry meaning, often indicating a dispreferred response (Liddicoat, 2011). This disconnect between the norms governing silence for Anglo teachers and their native children meant that student silences, directed at both teacher and peer as signs of respect, were read by the teacher as signs of incompetence. Furthermore, the Anglo teachers would often cut native student's silences short, thus depriving them of the chance to speak. It goes without saying that, in the university mathematics classroom, the power relations are very different than in the elementary classrooms Philips studied, however, this example illustrates the possibility for deep miscommunication caused by different norms for silence. Furthermore, if those norms are specific to mathematical activity, they are sociomathematical norms.

## Silence

Silence seems difficult to study scientifically for two reasons: First, silence seems to be the lack of speech or of sound and not a phenomenon in its own right. This issue has theoretical and methodological aspects: What is silence, and how can we attend to it? Second, silence does not regularly signify anything mathematical, and if it does, it only does so accidentally. It seems therefore, silence should be addressed when it happens to come up, but should not be a topic of research in its own right. This section will address the theoretical aspects of the first question, whereas the subsequent section will address the second question. A separate paper will be required to address the methodological aspect of the first question, though the final section of this paper provides a sketch of a methodology.

Silence is not a mere absence or a lack (Acheson, 2008; Ephratt, 2011), but a phenomenon, actively heard with our ears, that both frames sounds and words, and is in turn framed by sounds and words (Acheson, 2008; Chrétien, 2004). So, for instance, as Dauenhauer (1980) notes, a performance of music is only heard as a unity because of the silences that bracket it. On the other hand, Handel often underscores dramatic moments in his music with lengthy silences (Harris, 2005), which are only heard as dramatic parts of the music because they are surrounded by sound (cf. Kim, 2013). Nor is silence not one-dimensional: The sorts of sounds that bracket a particular silence, and the posture and gestures employed during a silence, give a particular color and meaning to silences (Margulis, 2007a, 2007b; Acheson, 2008). Finally, silence is not a default state, but is actively produced. Thus, for instance, silence can be a design feature of buildings (Kanngieser, 2011; Ergin, 2015; Meyer, 2015; Bonde & Maines, 2015); and we are all familiar with how difficult holding our tongue can be.

Because silences are actively produced and heard, they can bear particular meaning (Acheson, 2008; Ephratt, 2011). They are therefore perhaps best understood as a particular sort of gesture; a gesture which we can perform in concert with others, or alone while others are speaking (Acheson, 2008). For instance, Quaker worship is structured by lengthy collaborative silences (Lippard, 1988), and the bond of a nursing mother with her infant can be strengthened through mutual eye-contact and silence (Maitland, 2008); while, on the other hand, the children Philips (1983) studied on the Warm Springs Indian Reservation communicated that they were actively listening, not through eye-contact or back-channeling (e.g. "mhm"), but through silence.

## Embodiment

Two recent papers (Abrahamson & Sánchez-García, 2016; Abrahamson, Sánchez-García, & Trninic, 2016) have called for attention to the ways students develop their bodily capacities and so, open up new avenues for action in the world. In this call, they have opened up a new avenue for research into the body in mathematics education, the ways skilled uses of the body are a prerequisite for mathematical learning, and how, by training our bodies to be capable of new actions, new affordances for action are opened. Following their lead, mathematics education research can attend to the various ways we train our bodies to perform otherwise difficult actions which can subsequently give rise to mathematical meaning. Since acting according to new norms is difficult, this perspective is a helpful starting point for theorizing silence.

There are, however, two aspects of their theoretical perspective that make it inadequate for theorizing research on silence. First, they do not attend to the ways bodies are used in social interaction. But silence is an interactional accomplishment and challenge. It is relatively easy, however, to modify their perspective to incorporate social interaction. As McDermott (1978) notes, in interaction, we are the environment in which our peers act. Thus, developing new ways of acting in the world means developing new ways of acting on our peers, and of being acted on by our peers. Abrahamson Sánchez-García's (2016) perspective can be modified to say that as we acquire new skilled uses of the body, new affordances are opened up not only for learning mathematics, but for orienting ourselves and our peers collaboratively toward mathematics.

Second, their focus is still on actions that signify mathematical realities—the actions just do not yet have mathematical significance when learned. But there is another way actions, in our bodies both natural and social, can be connected to doing mathematics: They can order the parts of the body in a way that gives the capacity to do mathematics. Morgan and Abrahamson (2016) take something like this tack in their preliminary investigation of the ways meditative practices like tai chi and yoga could be utilized to enable students to engage with difficult mathematics, and Savic (2015) showed that not doing mathematics is an aspect of doing high-level mathematics. But otherwise, I have not encountered research that examines ways the body is used to give agents the capacity to do mathematics; and none that examine interaction. However, ordering the parts of our bodies, natural and social, in a way that facilitates the doing of mathematics is a necessary condition for doing mathematics, and so is a valid topic for mathematics education research. Furthermore, as noted above, if in doing mathematics, the body social is ordered in a novel way that relies on social norms different from those used in every-day interaction, this order, and the way it is learned, is educationally *relevant*.

While little mathematics education research that attends to the ways bodies are utilized to give an agent, or a group of agents, the capacity to perform mathematics, this perspective on the body is akin to some perspectives employed in anthropology. In particular, Marcel Mauss' (1935/1968) concept of a *habitus*, a pre-reflective, bodily know-how, that gives a subject the capacity to engage in an activity, has proven fruitful in examining a number of different phenomena, e.g. the transmission of oral literature (Saussy, 2016), and to the mosque movement (Asad, 2003; Mahmood, 2005). Mauss's concept also has a deep resonance with the theorization of the body Targoff (2001) employed in her investigation of poetry and prayer in early modern England (Mahmood, 2005). Finally, though not related to Mauss, Esaki (2016) argues that Japanese-American gardeners employ silence to give them the capacity to tell what sorts of cuts they should perform on their trees.

## Interaction

The issues surrounding silence, however, are not individual, but arise in interaction. Petersen (in press) argues that, while engaged in intense mathematics, mathematicians collaboratively engage in lengthy silences, in violation every-day conversational norms. How do students learn these norms? And how does conflicting interpretation of silences, and conflicting norms governing its use, influence students capacities to engage in mathematical activities? In order to address these questions, we need to theorize not only the body, but interaction. In this section I will argue that the claim that interacting participants form a complex dynamic system, or what some researchers call a synergy (e.g. Chemero, 2016), is a plausible hypothesis.

A pair of recurring question in behavioral sciences concern the mechanisms involved in the bodily coordination presupposed by the pursuit of a behavioral goal, either by an individual or by a group of individuals (Takei, Confais, Tomatsu, Oha, & Seki, 2017; Ashraf et al., August 24, 2017). Though the addition of multiple agents makes the second question more complex, there are reasons to believe that similar dynamics underlie both. As Marsh (2015) claims "in both cases, some kind of information…leads to entrainment; each involves the creation of a coordinative structure or synergy" (p. 321).

Researchers studying the material aspects of interaction have found that participants mutually entrain multiple aspects of each other's movements, including posture, limb-movement, speaking rate, vocal intensity, and, critically, length of silences (Marsh, Richardson, & Schmidt, 2008; Shockley, Santana, & Fowler, 2003; Sebanz, Bekkering, & Knoblich, 2006; Shockley, Richardson, & Dale, 2009; Noy, Dekel, & Alon, 2011; Fowler, Richardson, Marsh, & Shockley, 2008; Schmidt & Richardson, 2008; Capella & Planlap, 1981). What functional goal has this entrainment evolved to serve? The answer seems to be that it allows people to join together in a common activity, in pursuit of a common good (Richardson, Dale, & Marsh, 2014). This hypothesis is, partially, confirmed, by a recent paper on professional string quartet performance (Chang, Livingstone, Bosnyak, & Trainor, 2017). They demonstrated the body-sway of the musicians is auditorily and visually coupled, is a tool musicians employ to shape performance, and more coupling is correlated to the musicians' perception of successful performance.

These results in mutual entrainment allows the tentative conclusion that the body functions, in part, to knit people together into a body social with a common end, either through the mediation of shared representations, or immediately by allowing them to engage in joint activity (Marsh, Richardson, & Schmidt, 2008). Because research in silence is not attending to mental constructions, the second option seems to better fit for research on silence: In interaction, we utilize our bodies not only to signify the world, but to order each other and ourselves toward a common good, e.g. discovering and proving a new theorem, symbolizing and defining a mathematical object, etc. (cf. Rasmussen, Zandieh, King, & Teppo, 2005), and so to give a body social, and its individual members, the capacity to pursue that good.

This theoretical perspective on interaction requires that the activity of the body social—the linked dynamic system (Richardson, Dale, & Marsh, 2014), synergy (Chemero, 2016), or teleodynamic system (Walton, Richardson, & Chemero, 2014)—be the unit of analysis, not the isolated actions of the particular persons in the interaction. However, because the individual mathematicians are material parts of the body social, the analysis cannot be carried out in abstraction from the bodily actions of the individual mathematicians. Rather, the unit of analysis is the body social precisely because the actions of the individual mathematicians are treated as constraining, and constrained by, the activity of their peers. As certain activities—say, in piano playing—are not difficult for each hand individually, but in the coordination between hands; so some activities that are not difficult for individuals, when working alone, may be difficult to achieve *in common* (Marsh, Richardson, & Schmidt, 2009). On the other hand, because of the mutual entrainment, social order belongs to the body social—that is, to the dynamic system—and cannot be understood merely as the work of the individual participants, considered in isolation. Two points are key here: First, if peers engaged in joint interaction act according to different interactional norms, joint action may be particularly difficult. Second, when participants in face-to-face collaborations engage in high-level activity, and act according to the same norms, the fact that each member of the body social perceives the others are engaged in the same activity should serve to strengthen their own engagement (Walton, et al. 2014).

This theoretical position is heavily influenced by, and very similar to, the position McDermott (1978; McDermott, Gospodinoff, & Aron, 1978) employed in his ethnographic descriptions of a classroom, and to Erickson's (1996, 2004) microethnography. McDermott (1978), attended ways two teacher and student reading groups established an order through the postural positions of each member of the groups and the way the orders facilitated, or did not facilitate, learning to read. Similarly, employing the concept of the *habitus* mentioned above, Erickson (2004) argues that when there is a disconnect between the *habitus* actors attempt to employ in joint activity, "seemingly automatic workings of the players' *habitus* are no longer effective for engagement in the collective activity…If the player is to be able to stay in the new game, that player's *habitus* must change" (p. 12).

On the other hand, it shares similarities with several influential perspectives in mathematics education, while differing from them in key respects, namely Cobb and Yackel's (Cobb & Yackel, 1996; Yackel & Cobb, 1996) emergent perspective on classroom activity, and a Realistic Mathematics Education (RME) (Rasmussen et al., 2005) discussion of mathematical activity.

My research shares with Cobb and Yackel an emphasis on the ways participants in concerted activity co-create the activity, mutually conditioning the activity of all the others, and so forming the group into a single "dynamic system" (Yackel and Cobb, 1996, p. 460), and with a concern with the sociomathematical norms that govern this activity. It differs from them in two key, interconnected, respects. First, though Cobb and Yackel are concerned with one aspect of the way students and teachers mutually position each other around mathematics; the bodily aspects of that activity are not relevant to their investigations. But research into silence attends to one aspect of the way individual students and mathematicians engaged in mathematical activity hold themselves, physically, and so mutually orient themselves and peers toward doing mathematics. Second, their fundamental goal is to determine how mathematical *beliefs* are learned in learned in concert; whereas my focus is more like Rasmussen's research, in that it is focused on joint mathematical *activity*. This second difference shapes a methodological divergence: Whereas they envisage zooming in to a psychological investigation of student beliefs and understandings; I envisage zooming in from an investigation of the materiality, including the silences, of interaction, to an investigation of the bodily activity and gestures, including silence, of each individual mathematician or student.

Second, this perspective is closely related to a RME understanding of mathematics not merely as individual belief, but as particular sociocultural activity (Rasmussen et al., 2005). The key difference is that their work is focused on a different aspect of mathematical activity than research into silence is. Though they sometimes attend to gestures (e.g. Rasmussen, Stephan, & Allen, 2004), these gestures are relevant because of their ability to symbolize and communicate mathematical realities, whereas whether a student working to mathematize is, at that instant, seated or standing, motionless or pacing, etc. is irrelevant. Cooperative student mathematizing is, however, supported by shared bodily orientations that order group participants toward the mathematics at hand, norms regarding what bodily actions are appropriate, etc. It is to these norms that facilitate mathematical activity that research into silence should attend.

## Sketch of a Methodology

The first methodological challenge a study of silence faces is that traditional transcripts make silences invisible, rather than highlighting them (Ochs, 1979). A new form of transcription is therefore required that highlights silences, both collective and individual, and the postural nuances that give silences distinct characteristics. Figure 1 contains a sample transcript from three calculus students' attempt to identify which of three functions represent the position, velocity, and acceleration of a car. Not all the transcription conventions are relevant, but the following are most salient: Individual students' verbal utterances are placed in columns on the left, and non-verbal gestures, on the right. Footnotes show when, relative to the speaking and silences, individual gestures occurred. Mutual silences are highlighted in dark grey, and their length notated in the center column. Silences that do not include all students are highlighted in light grey, and their duration indicated to the left of the column. In the gesture columns, "eg" abbreviates "eye-gaze". These conventions highlight silence and allow its investigation.

In this episode, how do the three students respond to the lengthy mutual silences at the beginning? Andy, responds to the silence by speaking, approaching the board and seeking eye-contact with his peers (bottom row; 2, 3, 5, 7, 8, 10). Jason and Katherine, however, remain mostly still, do not move in response to Andy, and avoid eye-contact with him. A much longer analysis of this episode is possible, but these facts suggest Andy responds to the silence as an awkward pause, and attempts to resume the lapsed conversation; whereas Jason and Katherine, treat the silence as a part of their mathematical activity, and seek to continue it. This leads to the tentative conclusion that Jason and Katherine hear Andy's talk as an interruption of their silent mathematical activity; whereas Andy hears Jason and Katherine's silence as silencing him.

## Conclusions

Silence, though a peculiar aspect of mathematicians collaboration, does not fit well with existing theoretical perspectives in mathematics education research. Novel theorizations are therefore required for the study of silence. This paper provides the beginnings of a new theorization of silence, and the body, and provides a brief analysis of silence.

| Verbal | | | | Non-Verbal | | |
|---|---|---|---|---|---|---|
| Andy | Jason | Katherine | | Andy | Jason | Katherine |
| [1] | of [1]**b** //but] **c** is still °just the derivative of **a** [a]ri:ght°[z] | \\of **b**] | | [1]steps toward graph | [a]turns head slightly to right (still at board) then motionless | [z]starts slowly rocking back with rigid body |
| 35 Seconds | | 2 Sec | 2s | | | |

# Didactical Disciplinary Literacy

Aaron Weinberg, Ellie Fitts Fulmer, Emilie Wiesner, John Barr
Ithaca College

*Undergraduate mathematics students are routinely asked to learn from various "texts" such as textbooks, videos, and lectures. In order to understand how students read and learn from discipline-specific texts, literacy researchers in recent years (e.g. Shanahan & Shanahan, 2012) have begun to direct their attention to disciplinary literacy: the ways that disciplinary experts themselves interpret, create, and critique materials. In this vein, we set out to investigate the disciplinary literacy practices of calculus students and non-mathematics STEM faculty, but found that focusing on this form of literacy alone was insufficient to explain the differences between the students' and faculty members' practices. To address this, we propose a new construct of didactical literacy, provide examples, and discuss its details and ramifications.*

*Keywords:* Disciplinary Literacy, Textbooks, Expert-Novice Studies

## Background

Over the past several decades, numerous groups have advocated for learning mathematics by participating in mathematical practices, which includes mathematical communication (e.g., National Council of Teachers of Mathematics, 2000; National Governors Association, 2010; Schumacher, Siegel, & Zorn, 2015). Students have long been asked to use and learn from a variety of mathematical texts, such as textbooks, lectures, and videos; and the proliferation of new didactical formats such as "flipped" classrooms have led to increased interest in using these formats in mathematics classrooms (e.g., Maxson & Szaniszlo, 2015a, 2015b).

There has been relatively little research that has focused on literacy in the context of teaching, learning, and doing mathematics. Although there is a body of research focused on undergraduates' reading and comprehension of mathematical proof (e.g., Inglis & Alcock, 2012; Mejia-Ramos & Weber, 2014; Weber, 2015), there is scarce other research that describes how students interpret and learn from printed texts (e.g., Borasi, Siegel, Fonzi, & Smith, 1998; Draper & Siebert, 2004; Shepherd, Selden, & Selden, 2012; Shepherd & van de Sande, 2014) or lectures (e.g., Lew, Fukawa-Connelly, Mejía-Ramos, & Weber, 2016; Weinberg, Wiesner, & Fukawa-Connelly, 2014). As Doerr and Temple (2016) noted, the paucity of research combined with the increased need for students to interact productively with mathematical texts underscores the "need for greater attention to reading in mathematics instruction" (p. 6).

As Moje (2008) noted, as educators have come to view participation in discipline-specific discourses as an essential aspect of disciplinary learning, educators and researchers have begun to focus on literacy as an aspect of disciplinary practice. In this paper, we begin by discussing the concept of disciplinary literacy. Then, we describe selected results from a study we undertook to investigate the literacy practices of students and non-mathematics STEM faculty members. Based on these data, we propose a new form of literacy called *didactical disciplinary literacy*, which, we hypothesize, may play an important role in learning from didactical mathematics texts.

## Literacy in Teaching and Learning Mathematics

The term "literacy" is used in a variety of contexts. In the mathematics education community, it appears most often as part of "quantitative literacy" (e.g., Steen, 2001), which focuses on the capacity of an individual to identify and work within quantitative situations and to use mathematical skills for citizenship. In contrast, the types of literacy that we focus on in this paper involve creating and learning from texts. We use the term “text” broadly, as defined by Draper and Siebert (2010): “a *text* is any representational resource or object that people intentionally imbue with meaning, in the way they either create or attend to the object, to achieve a particular purpose” (p. 28).

Literacy experts have emphasized the pervasive and complicated role that texts play in teaching and learning, and students’ roles as active learners—and their interactions with new forms of media—have led researchers to propose a broad definition of literacy, such as: “the ability to negotiate (e.g., read, view, listen, taste, smell, critique) and create (e.g., write, produce, sing, act, speak) texts in discipline-appropriate ways or in ways that other members of the discipline (e.g., mathematicians, historians, artists) would recognize as ‘correct’ or ‘viable’” (Draper & Siebert, 2010, p. 30).

Each discipline produces its own types of texts (Bass, 2011) and uses distinct, grammatical resources and agency (e.g., Coffin, 1997; Martin, 1993; Veel, 1997, Wingnell, 1994). For example, a history text might take the form of a historical argument (advocating for a particular interpretation of events) while a science text might take the form of a science explanation (describing how and why phenomena occur).

In addition to the disciplinary-specific aspects of texts, recent research has shown that experts in different disciplines engage in reading processes in different ways. In one of the few studies to examine aspects of mathematics disciplinary literacy, Shanahan, Shanahan and Misischia (2011) compared the reading practices of historians, chemists, and mathematicians and identified distinctive features of the ways they interacted with research texts from their respective discipline. For example:

- Historians used the time period in which a text was written and other contextual factors as interpretive tools; chemists attended to time period to determine the value of the text in the context of rapidly-evolving scientific theories; and mathematicians did not contextualize the text.
- Historians used intertextual connections to identify the effects of the author’s perspective; chemists corroborated connections to explain the outcomes of various experiments; and mathematicians used corroboration to limit interpretive differences.

This focus on the “particular norms for everyday practice, conventions for communicating and representing knowledge and ideas, and ways of interacting, defending ideas, and challenging the deeply held ideas of others in the discipline” (Moje, 2008, p. 100) has led some literacy researchers to move towards the construct of disciplinary literacy as a way to identify discipline-specific practices and to structure students’ engagement with these practices. We define *disciplinary literacy* as the capacity to create, interpret, and critique texts using the practices, skills, tools, and ways of constructing, representing, using, and communicating knowledge that are specific to a particular discipline.

## Investigating Literacy Practices for Mathematics Textbooks

The initial goal of our research study was to describe the literacy practices that are important for learning from reading mathematics textbooks. We expected that asking mathematicians to read a mathematics textbook wouldn’t reveal such practices because they would likely already know most of the ideas presented in the textbook. Thus, we interviewed two groups of people. The first group consisted of five student volunteers from the third author’s second-semester calculus class. The students regularly read their textbook outside of class and engaged in various online and in-class discussions of the reading.

Our goal for the second group was to find readers who might have similar disciplinary literacy practices as mathematicians but wouldn't have the same extensive background knowledge. Thus, we recruited five faculty members from our institution, one each from the physics, chemistry, biology, computer science, and economics departments. Although each of these faculty members had taken calculus courses as part of their coursework, none had actively engaged with ideas from introductory calculus for (at least) the past ten years.

For our text, we used two excerpts from a section entitled "Applications [of the integral] to Geometry" in the students' textbook (Hughes-Hallett et al., 2012): the section introduction and an excerpt on arc length. The students had already read about other applications of integration in their textbook, so we posited that they were likely to have constructed the necessary background knowledge for understanding the concepts in the chapter.

To collect data, each person participated in an hour-long interview, which was video-recorded to capture the interviewee's speech, gestures and writing. We asked each participant to read the excerpts for the purpose of learning the content and to stop at any places where they had questions or were confused to engage in discussion. After completing the reading, the participants were asked to describe the main ideas of the sections, and to explain the meaning of each graph and/or formula, how the terms in the graphs and formulas had been derived, and why the text's explanation of the connections and derivations made sense.

## Results

Both the students and the faculty interviewees engaged in numerous interactions with the textbook that mirrored aspects of disciplinary literacy in mathematics—for example, they all engaged in close reading and rereading, understanding terminology and defining variables, interpreting graphics as part of the text, and not attempting to contextualize the text. The faculty members were not familiar with the mathematical concepts that were used in the sections—namely, Riemann Sums and limits—but the students were. However, the faculty members all were able to make sense of and construct mathematically-accurate descriptions of the concepts and, in many cases, to do so more successfully than the students.

In the process of identifying aspects of the students' and faculty members literacy skills, we noticed that the faculty members appeared to be identifying and using what we called "didactical aspects" of the textbook in order to make sense of the reading. We identified patterns in the faculty members' interactions and present them here with several examples from the faculty members' interviews. The italicized portions of the interview excerpts highlight particular language we identified as indicating a didactical focus. Although we also describe aspects of the students' work, space limitations prevent us from including excerpts from the students' interviews.

### Framing the Text in Terms of the Authors' Intentions

All of the faculty members routinely framed their interpretation of the text in terms of the authors' intentions. For example, Professor E, when asked to describe "what's going on" at the beginning of the section on arclength, described the authors' motivation for using the hypotenuses of right triangles to approximate a curve:

> What's going on here is *they want to show you one of these really small lengths* and so along the horizontal axis, the distance is this amount right here, the change in x, but as x

goes from this point to this point, we want to know how long that length is right there, and it's going to be longer because it's not a straight line.

Similarly, Professor K, when asked to describe why the textbook used a Riemann Sum before presenting the corresponding integral, described the authors' didactical intentions:

> I think *they're trying to provide steps for the reader* so there's no great leap in logic. That it makes sense that I have these small lengths. And then what am I gonna do with these small lengths? I'm going to add them up. So *I'm reminded at this step* that I'm doing a summation. That's essentially what an integral is.

Although most of the students also sometimes framed the text in terms of the authors' intentions and choices, their statements tended to focus more on mathematical rather than didactical aspects and ramifications of these choices.

**Thinking about Didactical Motivation**

The faculty members identified didactical motivation as the basis for the ways the authors presented the concepts. For example, when Professor K was asked to explain why the book's method for developing arclength made sense, she stated a didactical motivation and sequence, rather than a mathematical/logical description of the concepts:

> *They're starting with things that are easier to understand*. So delta x and delta y are easy to understand. We can really see those. They're physical lengths in my picture. So I can see them, and I can see how if I [gestures with fingers as if squishing lengths] made these lengths smaller and smaller, I could approximate a curve. *So they've shown me how to get* delta x and delta y, and then *using tools I've learned before*, we can rewrite these in terms of these [indicating a small quantity with her thumb and forefinger] very small steps, these derivatives. And then turning that into an integral, so *they're taking me through their process and explaining why they're doing it. Which is really important*. *So I'm not just facing an equation with no understanding of where it came from*. But with the understanding, I can apply this now with greater confidence.

When other faculty members were asked why the book first used a Riemann Sum before introducing the integral, they framed their description in terms of a didactical motivation that the Riemann Sum would be easier to understand than the integral. For example, Professor D noted that the Riemann Sum was based on intuition:

> I think *they're just reestablishing that intuition* that like, really an integral is just a sum of just an infinitely small pieces. And it's just a natural—and they're saying also the arc length is approximately equal to—that's what the squiggly lines are saying—but in the limit, it's actually equal to.

The students were less likely than the faculty members to frame aspects of the text in terms of didactical motivation. When they did so, they often framed their explanations partly in terms of mathematical necessity rather than solely in terms of pedagogy.

**Thinking about Didactical Structure**

In addition to identifying didactical motivation for various aspects of the text, several of the instructors also identified the didactical *structure* of the text and used this to inform their learning and to wrestle with uncertainty. Professor E summarized an example of such a structure:

> I've taken a lot of math courses and I think that this is the standard pedagogy that I see in math textbooks. So they kind of try to say in words what they're doing, those words get translated into notation and then there's examples.

Another didactical structure is to outline a general procedure and then use that procedure to develop specific applications. In our study, several faculty members described the structure of the chapter introduction, identified how this structure was mirrored in the presentation of the arclength derivation, and used this knowledge to develop a conception of arc length. For example, when asked to describe the book's method for arc length, Professor K framed the entire derivation in terms of the outline in the chapter introduction:

> I'm not quite sure how to describe it, except that *they're following the same steps that they suggested in their box* [in the chapter outline]. So the first step that they have here is that they show how you can find the length by breaking this up into small pieces. So in delta x it's a two-dimensional function, and so delta x and delta y. So they show how you could approximate it. And then they take that into a summation over very small pieces. So you go from these delta y's to derivatives. So that gives me very small pieces. And then they take that sum, and they turn it into an integral. *So they're following their own steps and laying out their procedure.*

There were several faculty members who, at the start of the interview, couldn't describe what Riemann Sums, limits, or integrals were, but identified and used this didactical structure to assist them in constructing a new understanding of what each of these terms meant. In contrast, only one student identified the structure of the chapter introduction and related it to the arc length derivation, but she didn't appear to actively draw parallels between the two structures

**Didactical Authority**

The faculty members also engaged with the text from a position of didactical authority by offering suggestions to change the presentation of ideas to make concepts clearer. For example, Professor M. suggested adding several diagrams to the arclength derivation to illustrate the steps of the derivation:

> The order in which things are presented, I think they could've, you know—it would have taken more paper, but I think they could've done a little bit better job of starting with this curve [points to diagram], just to illustrate what they're talking about, you know. 'Cause like I go straight from here [points to arc length introduction] and I look at this [points to diagram], and I'm like, "What are these?" [points to algebraic expressions in diagram] You know? And they start introducing stuff I haven't read about yet [points to "Length" calculation]. So you know, if I were presenting this in a class, I would sort of say these words [arc length introduction], show this picture [diagram] without these things [blocks off the text in the diagram with his hands]. And then I'd say these words [text following diagram], and I'd start to pop in the new things.

**Recognizing Didactical Conventions/Necessity**

The faculty members also recognized didactical convention of assuming that the readers possess all of the background knowledge that has been previously addressed. For example, when asked whether there were any parts of the textbook that might be difficult for students, Professor I said:

> Hopefully by the time you've got to this point in your calculus book, you know what the relationship is between delta-x and dx, even though that's a little bit fuzzy to me. Or

was—still is a little fuzzy. *So you can't explain what a derivative is every time in the book uses a derivative. You have to remember that's the slope, blah blah blah blah*.

In contrast, several students commented that they wanted the book to re-explain concepts as they were (re-)used.

### Didactical Literacy

As Shepherd and van de Sande (2014) noted, students—particularly at the undergraduate level—are asked to use their mathematics textbooks as a learning tool. Thus, it is important to understand how students read and learn from textbooks. At the same time, we argue that textbooks are a special type of mathematical text. We propose that the literacy most relevant to engaging with mathematics textbooks may also be specialized and merits focused attention.

Richards (2002) noted that "school mathematics" is a different domain of discourse than the domains used by research mathematicians, mathematically literate adults, and academic journals. Love and Pimm (1996) argued that the mathematical writing in textbooks is not just "a special version of mathematics written for a learner" (p. 375), but rather its own type of mathematical text, written specifically for mathematics students; it "provide[s] an authoritative pedagogic version" of mathematics (Stray, 1994, p. 2), is written from the position of a teacher (Kang & Kilpatrick, 1992), employs its own type of rhetorical forms (Fauvel, 1998), and attempts to provoke the development of specific cognitive structures in the reader (Van Dormolen, 1986). Moreover, textbooks employ structural literary devices, including exposition, explanation, questioning, exercises, examples, and formatting, and each of these structures typically has a specific didactical function (Love & Pimm, 1996).

Members of a discipline interact with disciplinary texts in ways that are guided both by disciplinary practices and discipline-specific features of the texts. Moreover, among disciplinary texts, there are *didactical texts*, created for the purpose of teaching. Didactical texts are usually created using particular norms of teaching within the discipline, and these norms are instantiated as conventions in the structure and discourse of the textbook, such as "introduce big ideas to frame later examples" or "connect theory to [what is viewed as] ideas that will be intuitive to students."

To capture the specialized nature of students' and teachers' interactions with didactical texts, we introduce the notion of *didactical literacy*: the capacity to create, interpret, and critique didactical texts using the practices, skills, tools, and ways of constructing, representing, using, and communicating knowledge that are specific to the didactical practices of a particular discipline. Didactical literacy encompasses the knowledge and skills to recognize, interpret, and use these conventions to effectively read the didactical texts—that is, to use, and critique, them as learning tools.

We hypothesize that, like disciplinary literacy, didactical literacy might be specific to particular disciplines. For example, didactical conventions in the teaching of history might be quite different than the conventions in mathematics. In the same way that disciplinary literacy in other STEM fields is similar to mathematics disciplinary literacy, the didactical conventions in other STEM fields might be close enough to those in mathematics to have enabled the faculty participants in our study to recognize and use the didactical structures in the mathematics textbook. However, this is an open question that could be empirically answered in future studies.

Neither disciplinary nor didactical literacy is subordinate to the other. For example, both students and faculty members in this study engaged in various disciplinary literacy practices associated with reading mathematics. However, simply having the capacity to engage in mathematics disciplinary literacy practices was not enough for the students to engage in the didactical literacy practices in the same ways as the faculty members.

Although a certain amount of disciplinary content knowledge is likely necessary to be didactically literate within a discipline, one may engage in didactically literate practices when missing background knowledge relevant to the text. For example, several faculty participants in this study lacked (what we viewed as) essential knowledge for understanding the concepts presented in the textbook, but were able to use the didactical structure in the textbook to construct mathematically accurate meanings for the related terms.

We hypothesize that didactical literacy is distinct from didactical knowledge (i.e., general knowledge about how students learn) and from specialized knowledge about how students learn within the discipline (e.g., mathematical knowledge for teaching (Hill, Ball, & Schilling, 2008)). Didactical literacy is identified with the didactical conventions within a discipline, which may or may not be based on knowledge of how students learn.

## Connections

We believe that the construct of didactical literacy has connections to other research areas in undergraduate mathematics education. It could be used as a way to understand the types of decisions teachers make when preparing materials for their classes. For example, Lai, Mejia-Ramos and Weber (2012) found that mathematicians have various conventions for creating and modifying proofs for the purpose of teaching students; specifically, they advocated for adding introductory and concluding sentences, using formatting to emphasize main ideas, and eliminating redundant information. Although such conventions for constructing or modifying proofs may be accepted by the mathematics didactical community, students may not be in a position to utilize this structure to interpret, construct, and critique mathematical proofs. That is, the ability to engage with these conventions productively may be part of mathematics didactical literacy that students do not generally possess. Didactical (and disciplinary) literacy also has the potential to be used as a theoretical lens to enable researchers to construct alternative explanations for phenomena. For example, Lew, Fukawa-Connelly, Mejia-Ramos and Weber (2016) analyzed students' interpretation of a lecture-based proof and identified both content- and communication-based barriers for the students in comprehending the lecturer's intended main points. Recasting the results in terms of literacy could enable researchers to understand other dimensions of both the structure of the lecture and the students' interpretation, and enable educators to find alternative methods for creating and helping students interpret these texts.

The idea of didactical literacy likely also has implications for teaching. As Fang and Coatoam (2013) noted, teaching disciplinary literacy involves engaging students in the content, literate practices, discourse patterns, and ways of reasoning within the discipline. Enacting disciplinary and didactical literacy practices involves both intellectual and social engagement with the discourse community in the discipline. Thus, helping students use didactical texts effectively may involve making didactical practices explicit and helping students develop the related literacy practices by supporting their participation in the practices of teaching mathematics.

Drawing on Three Fields of Education Research to Frame the Development of Digital Games for Inquiry-Oriented Linear Algebra

*Abstract: Demands in undergraduate education are shifting to reach larger student populations - especially learners beyond the brick-and-mortar classroom - which has led to more pressing demands to incorporate technologies that afford such learners access to high-quality, research-based, digital instructional materials. In this article, we explore three theoretical perspectives that inform the development of such instructional materials. In our team's efforts to develop a game-based learning applet for an existing inquiry-oriented curriculum, we have sought to theoretically frame our approach so that we can draw on the corpus of researcher knowledge from multiple disciplines. Accordingly, we will discuss three bodies of literature – realistic mathematics education's [RME's] approach to curriculum development, inquiry-oriented instruction and inquiry-based learning [IO/IBL], and game-based learning [GBL] - and draw on parallels across the three in order to form a coherent approach to developing digital games that draw on expertise in each field.*

*Keywords:* Realistic Mathematics Education, Inquiry-Oriented Teaching, Inquiry-Based Learning, Game Based Learning, Linear Algebra

## Introduction

A number of researchers in undergraduate mathematics education have developed curricula that draw on the curriculum design principles of Realistic Mathematics Education (RME) and are intended to be implemented using an inquiry-oriented (IO) approach (e.g., Larson, Johnson, & Bartlo, 2013 (abstract algebra); Rasmussen et al., 2006 (differential equations); Wawro et al., 2012 (linear algebra)). IO curricula fall within the broader spectrum of Inquiry-Based Learning (IBL) approaches that focus on student centered learning through exploration and engagement (Ernst, Hodge, & Yoshinobu, 2017) facilitated by an instructor's interest in and use of student thinking (Rasmussen, Marrongelle, Kwon, & Hodge, in press). For the purpose of this paper we will give examples from an IO curriculum, but also use quotes and references from the more general IBL literature.

In our current project we are exploring the extent to which technology can help mathematics educators extend inquiry-oriented (IO) curricula into learning contexts that are less conducive to inquiry-oriented approaches. Game Based Learning (GBL) provides a reasonable approach to addressing the constraints that large class sizes or non-co-located learning place on instructors' implementation of IO curricula. GBL studies show a clear relation between games and learning as games provide a meaningful platform for large numbers of students to engage, participate, and guide their learning with proper and timely feedback (Barab, Gresalfi, & Ingram-Goble, 2010; Gee, 2003; Hamari et al., 2016; Rosenheck, Gordon-Messer, Clarke-Midura, & Klopfer, 2016). However, despite advances in technology and policy initiatives that support development of active learning and the incorporation of technology in classrooms, few digital games exist at the undergraduate level that explicitly incorporate a research-based curriculum. In this paper, we explore the three theoretical perspectives of RME, IO/IBL instruction, and GBL in order to identify the ways in which the three perspectives align and might contribute to the development of digital media that incorporate knowledge and practices gained from each perspective.

We begin with a discussion of each of the three theoretical framings illustrated with specific examples. For the first two framings we describe a task sequence and strategies for implementing that task sequence that come out of the Inquiry Oriented Linear Algebra (IOLA) curriculum. For the third framing, we provide a brief outline of a mathematics game, *Rolly's Adventure*, developed by the third author, who drew on GBL principles in her game design. We then draw on each of these examples to demonstrate how aspects of RME, IO/IBL instruction and GBL align with each other and to point out a few ways that RME and IO/IBL might be used to inform design of future games, especially as we, the authors, move towards the development of a new digital game rooted in the existing IOLA curricular materials.

## Realistic Mathematics Education and Inquiry-Oriented Linear Algebra (IOLA)

Realistic Mathematics Education is a curriculum design theory rooted in the perspective that mathematics is a human activity. Accordingly, RME-based curricula focus on engaging students in activities that lend themselves to the development of more formal mathematics. Researchers rely on several design heuristics to guide the development of RME-based curricula (Gravemeijer, 1999; Rasmussen & Blumenfeld, 2007; Zandieh & Rasmussen, 2010). For instance, researchers often focus on the historical development of the concept intended to be taught so that the curriculum supports students' guided reinvention of the mathematics. In this paper, we focus on Gravemeijer's (1999) four levels of activity to show how curricula might reflect the design theory. **Situational activity** involves students' work on mathematical goals in experientially real settings. **Referential activity** involves models-of that refer to physical and mental activity in the original setting. **General activity** involves models-for that facilitate a focus on interpretations and solutions independent of the original task setting. Finally, **formal activity** involves students reasoning in ways that reflect the emergence of a new mathematical reality and no longer require prior models-for activity.

The IOLA curriculum (http://iola.math.vt.edu) draws on RME instructional design heuristics to guide students through various levels of activity and reflection on that activity to leverage their informal, intuitive knowledge into more general and formal mathematics (Wawro, Rasmussen, Zandieh, & Larson, 2013). The first unit of the curriculum, referred to as the Magic Carpet Ride (MCR) sequence, serves as our example of RME instructional design (Wawro, Rasmussen, Zandieh, Sweeney, & Larson, 2012). As stated, **situational activity** involves students working toward mathematical goals in an experientially real setting. The first task of the MCR sequence serves to engage students in **situational activity** by asking them to investigate whether it is possible to reach a specific location with two modes of transportation: a magic carpet that, when ridden forward for a single hour, results in a displacement of 1 mile East and 2 miles North of its starting location (along the vector $<1, 2>$) and a hoverboard, defined similarly along the vector $<3, 1>$. As students work through this task and share solutions with classmates, they develop notation for linear combinations of vectors and connections between vector equations and systems of equations, providing support for representing the notion of linear combinations geometrically and algebraically.

The second task in the MCR sequence supports students' **referential activity** – activity in which students refer to and draw generalizations about physical and mental activity, often from the **situational activity** in the original task setting. In the second task, students are asked to determine whether there is any location where Old Man Gauss can hide from them if they were to use the same two modes of transportation from the previous problem. As students work on this task, they begin to develop the ability to conceptualize movement in the plane using combinations of vectors and also reason about the consequences of travel without actually calculating the results of linear combinations. This allows students to form conceptions of how vectors interact in linear combination without having to know the specific values comprising the vectors. The goal of the problem is to help students develop the notion of span in a two-dimensional setting before formalizing the concept with a definition. As with the first task, students are able to build arguments about the span of the given vectors and rely on both algebraic and geometric representations to support their arguments.

As students transition from the second task of MCR to the third, they have experience reasoning about linear combinations of vectors and systems of equations in terms of modes of transportation in two dimensions. In the third problem, students are asked to determine if, using three given vectors that represent modes of transportation in a three-dimensional world, they can take a journey that starts and ends at home (i.e., the origin). They are also given the restriction that the modes of transportation could only be used once for a fixed amount of time (represented by the scalars $c_1$, $c_2$, and $c_3$). The purpose of the problem is to provide an opportunity for students to develop geometric imagery for linear dependence and linear independence that can be leveraged through students' continued **referential activity** toward the development of the formal definitions of these concepts.

In the fourth task, students have the opportunity to engage in **general activity**, which involves students reasoning in ways that are independent of the original setting. In this task, students are asked to create their own sets of vectors for ten different conditions – two sets (one linearly independent and one linearly dependent) meeting each of the five criteria: two vectors in $\mathbb{R}^2$, three vectors in $\mathbb{R}^2$, two vectors in $\mathbb{R}^3$, three vectors in $\mathbb{R}^3$, and four vectors in $\mathbb{R}^3$. From their example generation, students create conjectures about properties of sets of vectors with respect to linear independence and linear dependence. This is **general activity** because students work with vectors without referring back explicitly to the MCR scenario as they explore properties of the linear in/dependence of sets of vectors in $\mathbb{R}^2$ and $\mathbb{R}^3$; furthermore, students often extend their conjectures to $\mathbb{R}^n$. Finally, students engage in **formal activity** as they use the definitions of span and linear independence in service of other arguments without having to re-unpack the definitions' meanings. This does not tend to occur during the MCR sequence but rather during the remainder of the semester as students work on tasks unrelated to the MCR sequence.

## Effectiveness and Challenges of Inquiry-Oriented Instruction

Effectively implemented inquiry-oriented instructional approaches have been related to improved levels of conceptual understanding and equivalent levels of computational performance in areas ranging from K-12 mathematics, to undergraduate mathematics, physics, and chemistry (e.g., Cai, Wang N., Moyer, Wang, C., & Nie 2011; Deslauriers, Schelew, & Wieman, 2011; Kwon, Rasmussen, & Allen, 2005; Lewis & Lewis, 2005). To enact an RME curriculum, a classroom must engage students in inquiry into the mathematics of the problems posed. These classrooms are problem-based and student-centered, characteristics that overlap with other Inquiry Based Learning (IBL) and active learning classrooms (Laursen, Hassi, Kogan, & Weston, 2014). Consistent with others in the field (e.g., Kuster et al, 2017), in this work, we consider inquiry-oriented instruction to fall under the broader category of inquiry-based instruction. Research has shown that students who engage in cognitively demanding mathematical tasks have shown greater learning gains than those who do not (Stein & Lane, 1996). Furthermore, Stein and Lane (1996) found that those gains were greater in classrooms where students were encouraged to use multiple representations, multiple solution paths, and where multiple explanations were considered; in contrast, gains were lower in classrooms where the teacher demonstrated a process students could use to solve the task.

Implementation of the MCR task sequence described above is dependent on an inquiry-oriented classroom environment. Rasmussen and Kwon (2007) describe inquiry both as student inquiry into the mathematics through engagement in novel and challenging problems and instructor inquiry into students' mathematics to provide feedback to advance the mathematical agenda of the classroom. The MCR sequence is comprised of tasks that allow for multiple strategies and representations. Since the tasks are non-trivial, students are challenged with debating their answers and explaining their arguments. In addition, Tasks 2 and 3 each allow students to engage in mathematical activity that can be leveraged by the instructor to introduce formal definitions (span in Task 2, linear independence in Task 3). In both cases the instructor serves the role of broker between the classroom community and the mathematical community (Rasmussen, Zandieh & Wawro, 2009; Wenger, 1998) by taking student ideas and connecting them with the formal mathematical definitions. This brokering move of "interpreting between communities facilitates the students' sense of ownership of ideas and belief that mathematics is something that can be reinvented and figured out" (Zandieh, Wawro, & Rasmussen, 2017).

## Game-Based Learning

Game Based Learning (GBL) is the use of digital games with educational objectives to significantly improve learning outcomes. Games are designed to be enjoyable and fun where students overcome challenges and goals (including educational goals) by gaining mastery of the rules within a constrained environment or setting (Dickey, 2005). Research in game-based learning has emphasized the importance of incorporating thoughtful learning theories into the design of games (Williams-Pierce, 2016; Gee, 2005; Gresalfi, 2015; Gresalfi & Barnes, 2016). Recently, there have been several GBL approaches that have been implemented in secondary and post-secondary classrooms (Sung & Gwo-Jen Hwang, 2013; Lester et al., 2014), most successfully when projects have used GBL in conjunction with an existing pedagogical approach (Salen, 2011; Shute, & Torres, 2012). Several learning and pedagogical approaches have been identified that align well with GBL (e.g., Barab, et al., 2012; Hamari, et al., 2016), and many projects approach learning from a constructivist perspective (e.g., Wilson, 1996; Kiili, 2005; Wu, et al., 2012). Curricula developed from constructivist perspectives typically engage students in activities in a problem-solving scenario so that students have opportunities to build on their understanding through reflective abstraction on their prior activity towards more advanced ways of thinking. We illustrate GBL with examples from *Rolly's Adventure* (RA), a videogame developed by the third author to support student learning about fractions.

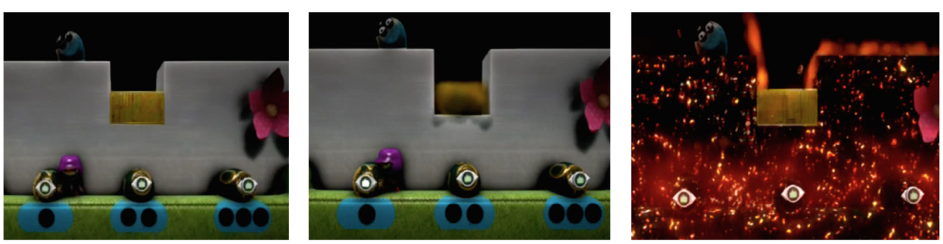

*Figure 1: (a) The player (shown here in a purple helmet) enters the puzzle; (b) the player activates the first button; (c) the puzzle catches on fire.*

RA begins with Rolly in the top left of the screen (see Figure 1). Rolly needs to roll past the obstacle (the gap) in the middle of the screen. The player's avatar is below Rolly in the purple hat. The player can choose from three options to press at the bottom of the screen. If the player chooses incorrectly the area explodes in fire and the golden bricks in the center show the result of the choice (see Figure 1c.)

In Figure 1, the player chose the single black circle and this did not change the size or shape of the golden brick. They then received feedback that their answer was incorrect (the fire that sends their avatar back to start over), and what the direct result of their action was (one black circle results in a single golden brick). Such instantaneous feedback and failure are considered crucial aspects of supporting learning during gameplay (e.g., Gee, 2005; Juul, 2009). If the player chooses the two black circles, the size of the bricks doubles to fill the space and Rolly (and thus the player) is able to move past the obstacle (see Figure 2), thus receiving positive feedback as to the accuracy of their choice.

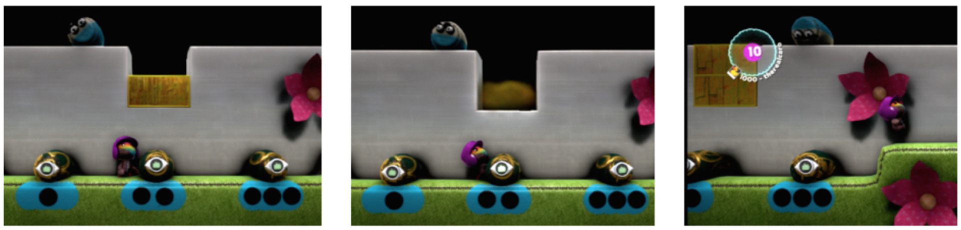

*Figure 2: The player (a) activates the second button, (b) the bricks appear from a haze, and (c) successfully travels over the space now filled with bricks*

As the player progresses through the challenges the brick or bricks in the obstacle will change in relationship to the space, and the way that the choices are indicated will also change. For example, the golden brick in Figures 1 and 2 represent one-half of the hole (the obstacle), and the next puzzle (not shown) has a block that represents one-fourth of the hole, following recommendations that halving a half is a natural next step in the learning of fractions (e.g., Empsen, 2002; Kieren, 1995; Smith, 2002).

*Figure 3: (a) is the fourth puzzle, where the brick is two-thirds of the hole; (b) is the fourteenth and final puzzle in RA, where the brick is one and two-fifths of the hole.*

RA was designed specifically to begin with simpler puzzles and become more complex as players move through the trajectory, such that as players develop generalizations about the game, new puzzles emerge that continue to challenge and nuance these generalizations, so the player has a "pleasantly frustrating" experience (Gee, 2003). Accordingly, mathematical notation becomes introduced that supports the player in being more precise and accurate just as they begin to struggle, as a way of developing a sense of "intellectual need" (Harel, 2013) so that players find the notation immediately useful (following Gee, 2005). Figure 3 shows some examples of how the game becomes more complex. Note that the fourth puzzle (Figure 3a) has bricks that are not an integer multiple of the size of the hole. Correspondingly the player's options include whole and half circles. In the fourteenth puzzle (Figure 3b) the initial bricks are larger than the size of the hole and fraction notation is used to both label the relationship of the brick to the hole (one and two-fifths) and the different choices.

RA was designed specifically with GBL principles to support players in mathematizing their own gaming experience, and engaging in mathematical play (Williams-Pierce, 2017). In this fashion, RA served as a proxy for the role of the instructor in the brokering process (Rasmussen, Zandieh & Wawro, 2009; Wenger, 1998), in that the game required players to act as producers (Gee, 2003) in reinventing the mathematics underlying RA. In other words, an intentionally designed mathematics game can serve as a responsive digital context that mediates interactions between the player, the game, and the mathematical community. Ideally, a well-designed mathematics game uses the principles of failure and feedback to support players in experiencing a pleasantly frustrating and authentically mathematized world. In the following section, we focus more explicitly on how GBL, RME, and IO Instruction can be carefully blended in designs that evoke the best of each world.

## Connecting GBL, RME, and IO Instruction - Blending Theoretical Worlds

The game design principles outlined above and illustrated with Rolly's Adventure align well with the nature of inquiry-oriented instruction using an RME-based curriculum. In Figure 4, we draw heavily on Gee's (2003) notion that good game design is good learning design to show parallels between principles of game design, RME curriculum design, and inquiry instruction and learning. Statements in the boxes of Figure 4 are all quotes or close paraphrases of various authors as indicated.

Looking across the rows in Figure 4 we see that both digital games and RME curricula place importance on the **structure of the task sequence**. The sequence should start with an activity in which students can immediately engage, but that has the potential to be generalized to a more sophisticated understanding that will help in solving more complex problems. We see this both in the increasing complexity of the tasks in Rolly's Adventure (RA) and in the magic carpet ride (MCR) tasks. In particular, student experiences graphically and imaginatively exploring the MCR scenario can be generalized to more formal notions of span and linear independence. As our project progresses, we can envision students being immersed in the MCR scenario through a digital game environment that allows for numerous episodes of growing complexity, from which student generalizations could emerge.

In considering the **nature of the tasks** we see that GBL, RME and IO/IBL all place emphasis on tasks that are novel and ill-structured allowing for a challenging but do-able problem-solving experience. The RA game (Williams-Pierce, in press) and the MCR tasks (Wawro et al., 2012) have both been empirically shown to be challenging, but manageable for students. A digital game based on the MCR sequence would share this novel approach. Through an iterative design process, tasks in the digital game can be created to be challenging but approachable for linear algebra students.

The **teacher's role** in inquiry classrooms is particularly important (Rasmussen & Kwon, 2007; Rasmussen et al., in press). Games can take on some of these roles. A well-designed game can intervene at desired junctures and provide real-time guidance or feedback based on the situation that the player is facing. A game can take on the role of the broker between the player (student) and the larger mathematics community. This brokering occurs both (1) through game play being consistent with the mathematical principles that the students are learning and (2) through students being gradually introduced to accepted mathematical notation and terminology.

| | Theoretical Framing | | |
|---|---|---|---|
| | **GBL** | **RME** | **IO/IBL** |
| Structure of task sequence | Good games confront players in the initial game levels with problems that are specifically designed to allow players to form good generalizations about what will work well later when they face more complex problems. [1] | Lessons should have experientially real starting points and engage in situational, referential, and general activity. [4] | ---- |
| Nature of the tasks | Good games operate at the outer and growing edge of a player's competence, remaining challenging, but do-able **...** **[**therefore**]** they are often also pleasantly frustrating, which is a very motivating state for human beings [1] | Challenging tasks, often situated in realistic situations, serve as the starting point for students' mathematical inquiry. [3] | IBL methods invite students to work out ill-structured but meaningful problems. [2] Students should solve novel problems [3] |
| Teachers' role | Good games give information "on demand" and "just in time," not out of the contexts of actual use or apart from people's purposes and goals… [1] | Teachers to build on students' thinking by posing new questions and tasks. [3] | Students present and discuss solutions; instructors guide and monitor this process. [2] Empower learners to see mathematics as a human activity. [3] |
| Students' role | Games allow players to be producers and not just consumers. [1] | Empower learners to see themselves as capable of reinventing mathematics [3] | Students construct, analyze, and critique mathematical arguments. Their ideas and explanations define and drive progress through the curriculum. [2] |

*Figure 4: Aligning three areas of our team's expertise that inform game design.*
*[1]Gee, 2003; [2]Laursen et al, 2014; [3]Rasmussen & Kwon, 2007; [4]Gravemeijer, 1999*

Ultimately the first three categories are aimed at creating an optimal environment for student learning. The **students' roles** include producing ideas and explanations that allow for their guided reinvention of the mathematics. In RA players create increasingly nuanced generalizations as more complex situations are presented. Student creation of generalizations also occurs in the MCR sequence (Rasmussen, Wawro, & Zandieh, 2015). Our goals as we work toward creating a digital game based on the MCR sequence will be for players of this game to construct, analyze and critique mathematical arguments in the game scenario. For this to happen students need to both (1) experience the mathematical principles/structures through the feedback from gameplay and (2) reflect on their experiences and codify them in some way. In addition to having aspects of the game serve in the teacher role, the game may also need to have aspects that serve in the role of other students in the classroom with whom a student would collaborate in an IO or IBL setting (Ernst et al., 2017).

In conclusion, we believe that these overlapping aspects of GBL, RME and IO/IBL provide a solid starting point for creating a digital game based on the existing IOLA curriculum. As development progresses we will be able to explore affordances and constraints of the digital environment in comparison with the in-person IO classroom.

Modeling the Spread of Ideas in an Inquiry-Oriented Classroom

Rachel Rupnow
Virginia Tech

Sarah Kerrigan
Virginia Tech

*In this study, we model the spread of student understanding of linear combinations in an Inquiry-Oriented Linear Algebra (IOLA) class based on video analysis. Methods adapted from modeling biological systems were used to estimate the rate of spread of Process-level understanding of linear combinations, measured according to Action-Process-Object-Schema (APOS) theory. The amount of time required for all students to achieve Process-level understanding was also estimated.*

*Keywords:* Inquiry-Oriented, Mathematical Modeling, APOS, Linear Algebra

## Introduction

Over the past thirty years, there has been a movement to use active learning in mathematics instruction or "instructional activities involving students in doing [mathematics] and thinking about what they are doing" (Bonwell & Eison, 1991, p. iii). One instructional design theory is Realistic Mathematics Education (Freudenthal, 1991), which focuses on having students discover mathematical concepts through guided reinvention (Gravemeijer, 2004). Here we examine the spread of ideas in an Inquiry-Oriented Linear Algebra (IOLA) classroom. The tasks used in this study were developed from a larger instructional design project (Wawro, Rasmussen, Zandieh, Sweeney, & Larson, 2012). We chose to focus on the spread of the idea of linear combination during the first two class periods of the course, roughly 120 minutes of instructional time.

We used Action-Project-Object-Schema (APOS) theory as a framework to determine whether or not a student "understood" the idea of linear combination (Arnon, et al., 2014). At an Action conception, students are concerned with an external transformation of objects. At the Process level, this activity is interiorized so the student can run through it mentally. At the Object level, that Process is encapsulated into a static entity. At the Schema level, a student is able to coordinate Processes and Objects and thereby act on them. We used Arnon et al.'s (2014) genetic decomposition for spanning set, which included a partial decomposition of linear combination, to determine if a student "understood" linear combinations. In particular, students demonstrating at least a Process-level conception of linear combination were classified as "understanding", specifically:

> Interiorization of [vector addition and scalar multiplication] yields a Process for constructing a new vector which is an element of the vector space, that is, the Process of constructing a linear combination. The reversal of this Process allows the student to verify if a given vector can be written as a linear combination of a given set of vectors. Students who show they have constructed these processes are considered to have a Process conception of a linear combination (p. 36-37).

We operationalized "understanding" linear combinations as verbally articulating a solution method indicating a Process-level conception of linear combination. This includes the ability to add two vectors multiplied by scalar weights and being able to interpret the procedure in at least two contexts (e.g., system of equations, vector equations, graphically).

To follow the spread of the idea of linear combination through an IOLA classroom, we generated two research questions modeled on the language of mathematical biology: (1) what is the infectivity rate for students discussing linear combinations in an IOLA classroom and (2) how long should one expect it to take for all students in the course to reach a Process-level conception of linear combinations?

## Methods

### Data Collection

We watched videos of the first two days of class that recorded three tables of students and captured whole class discussion. We defined a contact as a verbal communication of mathematically relevant content related to linear combinations. We did not consider written work on paper without any verbal explanation to be a contact. Each of the tables' discussions were analyzed for contact rates between members of the table as well as for contacts coming from outside the table. Outside contacts were considered to come from the teacher or the "infected" (understanding) members of the classroom who addressed the whole class. We recorded both contacts from "infected" to "non-infected" (not yet understanding) persons and when we had evidence that a student understood according to our definition.

The coding of the videos for contacts and indications of student understanding was done iteratively. Two researchers independently watched each video and then compared conclusions to check for consistency. After the contacts were counted, we calculated the mean for each student across each researcher's numbers. We only considered contacts for the fifteen individuals at the three tables that we closely observed and assumed their interactions were representative of those in the 35 person class. Due to the variation in duration and types of interactions (e.g. teacher-to-table, student-to-whole class, group member-to-group member), contacts were weighted differently. Contacts between group members at tables were given weight 1 and contacts from the teacher or students from other groups in the class were given weight 0.5 because the group setting allowed for more opportunities for students to engage in each other's reasoning, leading to higher quality interactions. The weighted contact values and times when students understood linear combinations are found in Table 1. Students' names have been replaced with pseudonyms.

### Model Development

We developed an Ordinary Differential Equation (ODE) model and a Continuous Time Markov Chain (CTMC) model for following the spread of understanding. The CTMC was chosen because it better models systems with lower population size than ODE models.

**ODE model.** We used the Susceptible-Infected (S-I) ODE model because we considered all students entering the classroom as being "susceptible" to understanding the concept of linear combination, and we assumed that students who understood the concept did not forget it. Thus there is no "recovery" from understanding, and individuals do not become susceptible again. We assumed that the teacher was the initial infected person, such that $I(0) = 1$ and $S(0) = N - 1$. This yields the following system of equations:

$$\frac{dS}{dt} = -\frac{\beta SI}{N}, \qquad \frac{dI}{dt} = \frac{\beta SI}{N}, \qquad N = S + I$$

The susceptible individuals are the students in the classroom that do not understand yet, and the infected individuals are the individuals that do. The total population, $N = 35$, is the number of individuals participating in the classroom (including the teacher). We used the average number of people from both days as the total population and assumed the size of the population was constant. The parameter $\beta > 0$ is the transmission rate, calculated from the product of the average number of contacts between susceptible and

*Table 1. Students' contacts with understanding persons by researcher and the number of minutes until students displayed Process level conceptions of linear combinations.*

| Table | Student | Weighted R1 | Weighted R2 | Ave Weighted | Minutes to "Infection" |
|---|---|---|---|---|---|
| 1 | Philip | 10 | 9.5 | 9.75 | |
| 1 | Sue | 10 | 9.5 | 9.75 | |
| 1 | Houston | 10 | 9.5 | 9.75 | |
| 1 | Shane | 2.5 | 2 | 2.25 | |
| 1 | Alice | 2.5 | 2 | 2.25 | |
| 2 | Gavin | 1.5 | 0.5 | 1 | 12 |
| 2 | Karl | 4.5 | 8.5 | 6.5 | 23 |
| 2 | Carly | 13 | 21 | 17 | 69 |
| 2 | Mark | 13 | 32 | 22.5 | 76 |
| 2 | Colin | 37 | 67.5 | 52.25 | |
| 3 | Devin | 2 | 2 | 2 | 19 |
| 3 | Ahsan | 4.5 | 12 | 8.25 | 70 |
| 3 | Ernesto | 27 | 23 | 25 | |
| 3 | Kurt | 27 | 23 | 25 | |
| 3 | George | 27 | 23 | 25 | |

infected individuals per time and the probability of infection per contact. Larger $\beta$ values indicate a higher probability of "catching" understanding than smaller $\beta$ values. We assumed that everyone in the classroom had the capacity to understand linear combinations but students did not enter with that understanding, so everyone except the teacher started in the susceptible class.

**CTMC Model.** We also considered a stochastic model using CTMC (Allen, 2008). We define our CTMC on $t \in [0, \infty)$ where $t = 0$ is the time when the class started working with mathematical content on the first day. The states $S(t)$ and $I(t)$ are discrete random variables; that is $S(t), I(t) \in \{0, 1, 2, ..., N\}$ where $N = 35$. Here we are largely concerned with the dynamics for $t \in [0, 120]$, the classroom time in which the students engaged in the tasks. Each random variable depends on the probability functions $p_i(t) = \text{Prob}\{I(t) = i\}$. We assume the Markov property holds: for any sequence of real numbers $t_i$ for $i = 0, 1, ..., n+1$, where $0 \leq t_0 < ... < t_{n+1}$, $\text{Prob}\{I(t_{n+1}) : I(t_0), I(t_1), ..., I(t_n)\} = \text{Prob}\{I(t_{n+1}) : I(t_n)\}$. Thus the transition probability at time $t_{n+1}$ only depends on the most recent time step, $t_n$.

We consider the transition probabilities to be defined for time intervals of length $\Delta t = 1$ minute. We assume this is sufficiently small so at most one person is infected in a single time step. Under this assumption, the transition probabilities are as follows:

$$p_{ji}(\Delta t) = \begin{cases} \frac{\beta i(N-i)}{N}\Delta t + o(\Delta t) & j = 1 \\ 1 - \frac{\beta i(N-i)}{N}\Delta t + o(\Delta t) & j = 0 \\ o(\Delta t) & j \neq 0, 1 \end{cases}$$

Case $j = 1$ gives the probability that one individual transitioned from not understanding to understanding in a time step, $j = 0$ is the probability of no change, and $o(\Delta t)$ is the probability that more than one individual is infected at one time (assumed to be 0). To simplify the probability expression, let $\beta i(N - i) = b(i)$. Then $b(i)$ represents the infection rate of individuals at time $\Delta t$. The simplified version of the model is as follows:

$$p_{ji}(\Delta t) = \begin{cases} b(i)\Delta t + o(\Delta t) & j = 1 \\ 1 - b(i)\Delta t + o(\Delta t) & j = 0 \\ o(\Delta t) & j \neq 0, 1 \end{cases}$$

**Simulation Model**

We used the values in Table 1 to determine the average number of contacts for each of the students at the three tables. We then divided this by 118, the total number of minutes of instruction across the two days. This produced $\beta = 0.1233$. We also found the "best fit" $\beta$ value according to the deterministic ODE model, which was $\beta = 0.0426$ according to nlinfit in Matlab. The code used to generate figures was adapted from a Mathematical Modeling course (L. Childs, personal communication, March 23, 2017) and Allen (2008).

## Results

### Analytical Results

There are two steady states for the ODE system: "disease-free" $(N, 0)$ and "endemic" $(0, N)$. We want understanding to be endemic; that is, we want the entire population to understand. To study the steady states, we used the Jacobian method which yielded eigenvalues of $J(0, N)$ of $\lambda_1 = 0$ and $\lambda_2 = -\beta$. We note that $\beta > 0$; thus $(0, N)$ is always stable, provided there is one infected person initially. Using the same method it is easy to see $(N, 0)$ is always unstable when there is an initial infected person.

For the stochastic model, we consider the inter-event time, $T_i$, which is the expected time until everyone is infected. $T_i = -\frac{\ln(1-U)}{b(i)}$ is an exponentially distributed random variable with parameter $b(i)$ (defined above) and uniform random variable $U$ on $[0, 1]$. We use this to calculate the expected time until everyone understands, which is equivalent to reaching the endemic steady state. Recall that $I(0) = 1$. Thus the first state is one infected person. We know the expected time to reach the next state (two infected people) is $T_1$. Let $W$ be the time it takes to get from state 1 to state 35. Then $W = \sum_{i=1}^{34} T_i$. Because $T_i$ is exponentially distributed with parameter $b(i)$, the expected value is given by $\mathbb{E}(T_i) = \frac{1}{b(i)}$. Furthermore, because $\mathbb{E}$ is a linear operator, $\mathbb{E}(W) = \sum_{i=1}^{34} \frac{1}{b(i)}$.

### Simulation Results

In Figure 1, we see a comparison of the scaled data points extrapolated from the observed fifteen students to the whole class, the deterministic solution to the ODE, and 20 stochastic paths. In Figure 1A the first three data points are close to the deterministic solution and in the midst of the stochastic paths. However the three later data points are far below the deterministic and stochastic paths. Although $\beta = 0.1233$ is based in our classroom observations, it does not appear to model when students obtain Process conceptions of linear combination, though it did perform better than the non-weighted version. The non-weighted version, based on counting contacts from the teacher, students from other tables, and students from the same table equally (Figure 1B) used $\beta = 0.1870$, which fit even worse.

Unlike the curves in Figure 1, which matched the early data points well but missed later points badly, the curve in Figure 2, which is based on the "best fit" $\beta = 0.0426$, misses most of the early data points but fits the later points well. Additionally, at 120 minutes, not all students are "infected". This fits the data better because a number of our students did not appear to obtain a Process conception of linear combination by the end of the 118 minutes of class time we observed.

Furthermore, using $\beta = 0.1233$ produced an expected wait time for all students to obtain a Process conception of linear combination of 67 minutes, roughly half the time we observed the class. When using $\beta = 0.0426$, which represents a reduced probability of infection, the expected time for all students to understand was 193 minutes. This amount of time seems more plausible because only six of the fifteen students we observed in detail appeared to have obtained Process level conceptions by the end of the second class period.

*Figure 1. These graphs use $N = 35$, $I(0) = 1$, and a time step of 1 minute. The black dashed lines represent the deterministic solution to the ODE. The 20 red lines on each graph are stochastic simulations. The blue stars represent the data points obtained by scaling the fifteen students' data to the full class of 35 people. The left simulations (A) ran with $\beta = 0.1233$ and the right simulations (B) used $\beta = 0.1870$.*

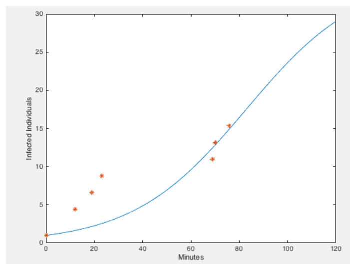

*Figure 2. This graph uses $N = 35$, $I(0) = 1$, initial guess $\beta = 0.1$, and a time step of 1 minute. The blue line represents the number of infected individuals at a given time. The orange stars represent the data points obtained by scaling the fifteen students' data to the full class. The resulting curve results when $\beta = 0.0426$.*

## Discussion

Our goals were to determine the infectivity rate for students discussing linear combinations in an IOLA classroom and to determine the expected time for all students in the course to reach a Process-level conception of linear combinations. We determined that the infectivity rate $\beta = 0.1233$, based on creating weighted contact values, estimated more effectively than the non-weighted contact values, but still did not estimate very well. However, when we used maximum least squares to estimate the infectivity rate from the infection data, we obtained $\beta = 0.0426$, which produced more reasonable long term results, including requiring slightly more than another full period for full class understanding.

We acknowledge that this study and model have a number of limitations, including incomplete classroom data, discontinuous data collection, and a non-constant population of students. Specifically, while we have direct information about 15 students and the teacher, we have limited information about the other 19 students. Even in the data on the 15 students, we were, if anything, a bit conservative on saying a student understood the concept of linear combination. It is possible that students who did not speak as often in the groups also understood; we simply did not have enough evidence to be sure that they did.

Future work could include further refining $\beta$ through more extensive data collection. This could involve observing subsequent class periods to see if 193 minutes was sufficient time for everyone to understand linear combinations. Alternatively, future data collection could involve setting up cameras at more students' desks. We could also refine the weighting of contacts. Perhaps group contacts should be weighted even more heavily or perhaps specific "infected" individuals, like the teacher, have a greater impact than other individuals. Finally, we could consider implementing an age structure or risk structure model instead of basing the model on Markov Chains.

Curricular Presentation of Static and Process-Oriented Views of Proof to Pre-service Elementary Teachers

Taren Going
Michigan State University

*Engaging students in proof-related reasoning is an important but often challenging task for pre-service elementary teachers. Given that limited mathematics content courses and their associated textbooks offer some of the only opportunities for preservice elementary teachers to engage with proof, it is vital to understand what opportunities they offer to understand proof. I conducted an analysis of two textbooks used for elementary mathematics content courses to investigate the view(s) of proof promoted within and the opportunities to learn about proof-related reasoning. My findings suggest a mixed emphasis on static and dynamic views of proof and proving, but also many opportunities for instructors of mathematics content courses to promote an explanatory, process-oriented view of proof.*

## Introduction

Increasingly, calls for mathematical reform in the U.S. specify that mathematics instruction should enable students to "recognize reasoning and proof as fundamental aspects of mathematics, make and investigate mathematical conjectures, develop and evaluate mathematical arguments and proof, and select and use various types of reasoning and methods of proof" (NCTM, 2000, p. 56). These calls reflect a larger effort to align classroom work in mathematics more closely with the discipline of mathematics, especially at elementary levels where proof has not historically been emphasized (Ball, Hoyles, Jahnke, & Movshovitz-Hadar, 2002). However, existing research indicates that those preparing to teach elementary mathematics have difficulty recognizing an argument as proof (Martin & Harel, 1989) and interpreting and evaluating students' proofs and arguments (Morris, 2007). Likely due to the historical disconnect between proof and other aspects of K-12 mathematics curriculum (Herbst, 2002), pre-service elementary teachers (EPSTs) may not have had meaningful experiences with proving in their own education. Further, the curriculum materials from which they are to teach do not offer adequate support in the area of reasoning and proving (Stylianides, 2007). For these reasons, it is vital that we understand how EPSTs' mathematics content courses provide to develop understandings of proof and proof-related reasoning. These content courses represent some of the first, and potentially only, opportunities for pre-service teachers to engage with proof-related reasoning prior to being expected to teach it to their students, so these courses have a potentially powerful influence on how EPSTs will eventually teach.

One way to understand the opportunities EPSTs have to learn about proof and proving in their preparation coursework is to unpack such opportunities as written in the textbooks used for elementary mathematics content courses. Though the written opportunities may not align with the opportunities as enacted in a course, textbooks influence an instructors' course design and shape EPSTs' independent learning opportunities (McCrory & Stylianides, 2014). This study, broadly, aimed to understand the view(s) of proof promoted in these texts and the opportunities provided for EPSTs to learn about the nature of proof, proving and proof-related reasoning.

## A Vision of Proof Communicated to Pre-Service Elementary Teachers

Numerous scholars have drawn attention to how our conceptions of what proof and argument are, as well as what occurs when we engage in proving and argumentation, shape not only the conclusions researchers make about students' thinking and instructional practice related to proof and argumentation (Balacheff, 1988; Stylianides, Morselli & Bieda, 2016) but also how teachers shape how students think about proof and proof-related activities (Conner et al., 2014). Thus, what kind of conceptions should EPSTs have about proof and argument to support the development of student thinking and mathematical practice as proposed in calls for reform?

Schoenfeld (1991) states, "In real mathematical thinking, formal and informal reasoning are deeply intertwined" (p. 311). Proof can serve several important functions: verification, explanation (that is, offering insight into why a statement is true), systematization of axioms, discovery of new results, communication of mathematical knowledge, construction of an empirical theory, exploration of mathematical statements' meaning or consequences, and incorporation of mathematical truths into alternative frameworks (Hanna, 2000). Thus, if classroom practice should align with disciplinary practice, teachers must be familiar with many of these aspects and be able to link informal, exploratory activities with reading or writing formal proofs in order to help students learn mathematics as they prove. Especially in the early grades, explanation, communication, and exploration will have great importance (Hanna, 2000) and engaging with proof in this way can contribute to a process-oriented view of proof (Schoenfeld, 1991). For EPSTs to support their students to engage in proving in this way, it is important that they experience and understand proof as a process.

Existing literature suggests that it is more common for EPSTs to hold more ritualistic and empirical understandings about proving and argumentation that may stem from experiences with a more static view of proof (Harel & Sowder, 1998; Morris, 2002). Classroom practices in content and methods courses for EPSTs should be structured to promote a dynamic view of proof. In a dynamic view of proof, the process of constructing a proof *is* the vehicle for mathematical learning (Schoenfeld, 1991). In this way, a dynamic view of proof relates integrally with the purpose of explanation promoted by Hanna (2000).

From these assumptions about the aspects of proof that EPSTs must have experience with and promote in their teaching practice, this study investigated the nature of opportunities provided in textbooks for mathematics content courses, guided by the questions: *Within the mathematics content textbooks considered here, which functions of proof are promoted, and by extension, which functions of proof will pre-service elementary teachers become familiar with?*

## Methods

The textbooks analyzed were *Mathematics for Elementary Teachers* by Beckmann (2003) and the series *Elementary Mathematics for Teachers* and *Elementary Geometry for Teachers* by Parker and Baldridge (2004, 2008). Both texts are written for use in a year-long mathematics content courses for pre-service elementary teachers, who are assumed to receive no other specialized mathematical training. Both texts were identified by McCrory and Stylianides (2014)'s analysis of tables of contents for elementary mathematics content course texts to provide explicit treatment of proving and argumentation.

Focusing solely on student materials, rather than teacher's guides, I analyzed each textbook page-by-page to identify instances of proof and proof-related reasoning. Analyzing student materials can provide insight into the opportunities to learn about proof regardless of what occurs in class, which is important because textbooks can be utilized in a variety of circumstances

(McCrory & Stylianides, 2014). An analysis of student materials also informs instructor planning around material that might need to be supplemented or particularly emphasized outside of the textbook. I generated categories of proof-related reasoning present grounded from the textbooks themselves, and narrowed to a list of three categories that could be used to code each of the instances I analyzed:

1. Complete general proofs presented somewhat in isolation;
2. Exploration of a topic which the textbook author links explicitly to proof, for example by stating that the mathematical statement can be proved or by assigning a proof to the student as homework; and
3. Exploration of a topic which leads to a complete deductive proof within the text.

For each instance of proof related reasoning, I recorded the forms of reasoning present in exploration and/or final proof as either: written reasoning, symbolic/algebraic reasoning, diagrams/graphs, specific worked examples, and imagined motion (e.g. sliding, turning). I also noted the mode of argumentation (e.g. direct logic, construction of counterexamples, proof by contradiction), to gain insight into how proof is presented overall in these texts. Finally, for any instances of proof-related reasoning that included exploration I noted whether this led to the emergence of a key idea.

To demonstrate this coding process, consider the proof that the base angles of an isosceles triangle are congruent from Parker and Baldridge (2008). Initial exploration for this is presented in discussions of symmetry, where the text invites readers to fold a paper isosceles triangle along its line of symmetry to discover matching parts (Parker & Baldridge, 2008, p. 44). Since at this point this is not a general argument, but pertains to one particular paper triangle, this represents exploration. The forms of reasoning present in this exploration are a diagram (to describe the construction of paper isosceles triangle), a specific example of one isosceles triangle, and a description of imagined motion (folding the triangle). Further along in the text, a general proof that the base angles of an isosceles triangle are congruent is presented to the reader in the form of a "teacher's solution", which closely mirrors a two-column proof (Parker & Baldridge, 2008, p. 92). The forms of representation in the proof were coded as minimal text, a symbolic representation to describe congruent parts of the triangle, and a supporting diagram. The mode of argument was coded as direct because the argument begins with given information and follows a direct chain of logic to the conclusion.

In addition to looking for instances of proof-related reasoning, I noted any statements by the author that included reference to proof or mathematical reasoning, but were not connected to specific instances of proof-related reasoning. These include definitions and descriptions of proof, descriptions of unfamiliar modes of argumentation, advice on how to write proofs, and statements about the nature of mathematical knowledge more generally. I examined these statements and the instances of proof-related reasoning identified in order to learn how a dynamic view of proof is (or is not) promoted in the textbooks.

## Findings

### Conceptions of What Proof Is and Who Does Proof

My analysis revealed that both textbooks included written descriptions, or definitions, of proof. In Parker and Baldridge (2004), proof is defined as "a detailed explanation of why that fact follows logically from statements that are already accepted as true" (p. 110). This definition highlights the purposes of verification, communication, and construction of an empirical theory. Even though the word "explanation" is included in this definition, the authors do not seem to indicate that this refers to explanation of the underlying mathematics in order to provide insight into the statement's truth. By this definition then, it is enough simply that the statement *is* true. Moreover, this definition highlights proof as a finished object, inconsistent with the process-oriented view of proof that pre-service elementary teachers will need to effectively engage their students in learning through proof.

Similarly, Beckmann (2003) chooses to use the term "explanation" in defining proof: , "Proofs are one of the important aspects of this book too, even if we don't usually call our explanations proofs. A proof is a thorough, precise, logical explanation for why something is true, based on assumptions or facts that are already known or assumed to be true. So a proof is what establishes that a theorem is true" (p. 213). Like Parker and Baldridge (2004), Beckmann's definition highlights the purposes of verification, communication, and construction of an empirical theory. Additionally, though, Beckmann (2003) links proof to other types of mathematical explanation, suggesting proof is useful for gaining insight into the mathematics and connecting between informal and formal reasoning. While this definition of proof discusses its value as a product of verification, it hints at the process involved in its creation.

Beyond exact definitions, these texts include written descriptions of the nature of proof. Beckmann (2003) describes a process-oriented view of proof, stating "…mathematics is about starting with some assumptions and some definitions of objects and concepts, discovering additional properties that these objects or concepts must have, and then reasoning logically to deduce that the objects or concepts do indeed have those properties" (p. 65 of volume 2). However several times throughout the text, pre-service teachers are asked to do exercises that warrant a proof but the text indicates that they are not expected to generate such a proof.

Parker and Baldridge (2004) also indicate that there are many forms of mathematical reasoning involved in and related to proof: "In the classroom the reasoning occurs in explanations and guided investigations, while in mathematics textbooks the reasoning often occurs in formal and informal 'proofs'" (p. 109). In this statement the authors do not specifically present proof as a process, but they do present proof as the domain of mathematics textbooks and the mathematicians who write them, and not an area where teachers are expected to be involved. This suggests that pre-service elementary teachers are expected to read and understand proofs, but not write proofs themselves. However, in the context of geometry, Parker and Baldridge (2008) occasionally present "hints" for how pre-service elementary teachers, and eventually their students, might approach specific proving tasks.

**Instances of Proof-Related Reasoning**

Within Parker and Baldridge (2004, 2008) I identified 68 total instances of proof-related reasoning and within Beckmann (2003) I identified 25 total instances of proof-related reasoning. This amounts to one instance of proof-related reasoning approximately every seven pages in Parker and Baldridge, and approximately every 32 pages in Beckmann. The number of instances of proof-related reasoning in each category (proof only, exploration only, and exploration and proof) for each text is listed in Table 1.

*Table 1. Categorization of instances of proof-related reasoning within each text*

| | Parker and Baldridge (2004, 2008) | Beckmann (2003) |
|---|---|---|
| Proof Only | 25 | 6 |
| Exploration Only | 8 | 7 |

| | | |
|---|---|---|
| Exploration and Proof | 35 | 12 |
| Total | 68 | 25 |

The mode of argumentation for almost all instances of proof and proof-related reasoning from Table 1 is direct, where an initial assumption begins a chain of deductive logic (i.e. modus ponens). The only exceptions to this mode of argumentation are two instances in Parker and Baldridge (2004), where proof by contradiction is utilized. The prevalence of direct proofs within both texts indicates a high value on the transparency and understandability of mathematics. Indeed, Beckmann (2003) describes that a good mathematical explanation, which she uses in lieu of the term proof, is clear and logical, without "[requiring] the reader to make a leap of faith" (p. 11). In addition, Beckmann specifies that these should be convincing and usable for teaching, which highlights the possibility that proofs might give insight into the mathematics, and further, might be useful for learning mathematics.

Within Parker and Baldridge (2004, 2008), 27 of the instances of proof take the form of a "Teacher's Solution" or "Elementary Proof" that are similar to two-column proofs from standard geometry textbooks. These instances provide only the minimum number of highly-abbreviated steps. Further directions on the formatting of these proofs specified, "Do not label the two columns 'statement' and 'reason' (everyone already knows this!)" (Parker & Baldridge, 2008, p. 79). Given the similarity of this form to two-column proofs that highlight verification of facts (Herbst, 2002), these elementary proofs do not readily serve the function of explanation. In addition, their emphasis on abbreviation and standard form may distance the final proof from the process that was conducted to create it.

## Conclusion

Through my analysis of both texts, including written statements regarding the nature of proof, the form and modes of argumentation within opportunities to prove, and the emergence of key ideas, I found evidence of both dynamic and static conceptions of proof. The strong presence of direct proving methods that aid in mathematical understanding, as well as inclusion of exploratory processes that lead to general proofs, often with consistent key ideas linking these stages, offer pre-service teachers opportunities to develop a dynamic view of proof. Many written statements and the prevalence of rote modes of argumentation and purely symbolic proving methods, however, offer pre-service teachers opportunities to develop a static view of proof. Given that the two texts analyzed represent strong inclusion of proof-related reasoning compared to other elementary mathematics content texts (McCrory & Stylianides, 2014), it is likely that other texts present potentially a more static emphasis on proof.

These findings suggest the possible value of supplementing these texts with additional opportunities from instructor materials or other sources to emphasize a dynamic view of proof. Classroom enactment, also, should be structured by instructors to build on existing opportunities to see proof as dynamic and directly confront messages that promote a static view of proof. Considering that roughly half of the instances of proof-related reasoning include an entire reasoning process that consists informal exploration and a complete general proof, there is much within these texts that offers opportunities to engage in the process of proof-related reasoning. It is on this that instructors for content courses for pre-service elementary teachers must build.

Mathematical Competencies and E-Learning: A Case Study of Engineering Students' Use of Digital Resources

Shaista Kanwal
University of Agder

*This paper explores how an e-learning environment affords the execution of mathematical competencies in an undergraduate engineering context. Considering the students' mathematical practice as action mediated by the digital resources in a sociocultural sense, we employ the competence framework by (Niss & Højgaard, 2011) to make sense of students' learning. Case-study research design has been implemented to thoroughly observe the mathematical practices of a small group of participants. Observing students' group work and following their mathematical discussions elucidated the way this environment afforded the execution of competencies. Closer analysis revealed that the availability of online tools in this environment has the twofold effects on mathematical thinking, mathematical reasoning and problem-tackling competencies.*

*Keywords*: Calculus, Engineering mathematics, E-learning, Mathematical competencies.

## Introduction

The use of digital resources in mathematics education has started since the development of such tools and is still being researched to study its impact on mathematical learning. Increased dependence on digital tools for practicing mathematics is transforming the mathematics education, and to learn mathematics is not the same as it was before the introduction of digital technology. The use of digital resources is of particular relevance in engineering mathematics in the sense that modern-day engineers during their professional activities rely on technology for mathematical tasks (van der Wal, Bakker, & Drijvers, 2017). The framework for mathematics curricula in engineering (Alpers et al., 2013) also recommends how technology should contribute towards fostering the engineering students' mathematical competencies (Alpers et al., 2013). The notion of mathematical competence from the Danish KOM project (Niss, 2003; Niss & Højgaard, 2011) has been adopted to make sense of the engineering students' mathematical learning.

Previous research studies have also employed this competence framework, either to make sense of students' learning in mathematics or to analyse how these competencies are developed in particular situations or through certain activities. For instance, Jaworski (2012) used Niss's idea of mathematical competencies to design and analyse the tasks and to recognise the engineering students' mathematical learning. Jaworski pointed out that a potential use of the competence framework may be to create opportunities for students to achieve certain competencies (Jaworski, 2013). Furthermore, Albano and Pierri (2014) used a role play activity and identified the first-year engineering students' mathematical competencies through the questions students asked. Albano and Pierri concluded that students seemed to possess all the competencies by Niss (2003) which were evident through the words they used in their questions. García, García, Del Rey, Rodríguez, and De La Villa (2014) presented a model for the integrated use of CAS which they implemented and analysed in engineering classrooms. They suggested that the use of CAS in all learning and assessment activities has the potential to positively influence the development of mathematical competencies. Recently, Queiruga-Dios et al. (2016) analysed the development of mathematical competencies among industrial engineering students through their teamwork which included the use of CAS for solving mathematical problems as an integral part. While their main aim was to integrate these mathematical competencies with the required engineering competencies in Spain, they claimed that the students acquired all the mathematical competencies during this task.

Our study focuses particularly on nature of mathematical competence afforded by an e-learning environment. Realising the contemporary and the future state of mathematics education, we attempt to add to the research literature within the context of engineering mathematics education. In this paper, we analyse engineering students' engagement within a calculus course to report on how their mathematical competencies are supported within an e-learning situation. We attempt to answer the following research questions: What traces of mathematical competencies are observed in students' work when they practice mathematics digitally? How does this environment afford the execution of these mathematical competencies?

## Theoretical perspective

We consider students' mathematical practice in the present situation as mediated action in sociocultural terms (Vygotsky, 1978). The provided resources which support the learning of mathematics serve as mediating artefacts between students and the mathematical concepts. The mediating artefacts used in the present situation are MyMathLab, tutorial videos, textbook, Maxima for programming, and other internet-based resources. The students' homework and eventually the students' assessments are done digitally. There were no regular face-to face lectures thus the situation is considered as e-learning in which students remotely work with the resources. A brief introduction of these resources follows.

MyMathLab is an online interactive learning environment for practicing mathematics digitally. While the main aim of this resource is to provide a platform for digital homework and assessments, it also facilitates in solving the tasks by providing illustrated worked examples and personalised feedback. The tutorial videos replace traditional university lectures and are linked topic-wise with the textbook sections. The videos are recorded by the mathematics teacher using a document camera, and they consist introduction to each mathematical topic along with worked examples. The tutorial videos and the homework in MyMathLab were clearly linked with the chapters in the textbook.

We employ the competence framework by Niss and Højgaard (2011) to make sense of engineering students' mathematical learning (Jaworski, 2012, 2013). The framework is complemented by sociocultural notion of resource mediation. The Danish KOM project (Niss & Højgaard, 2011) enlisted eight mathematical competencies, divided into two groups as follows (Figure 1):

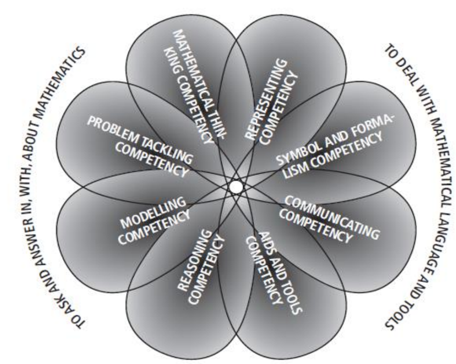

*Figure 1: A visual representation of eight mathematical competencies (Niss & Højgaard, 2011, p. 51).*

### The Ability to Ask and Answer Questions in and with Mathematics

The first group comprises the competencies of mathematical thinking, mathematical reasoning, problem tackling, and mathematical modelling. Mathematical thinking competency involves "awareness of the types of questions which characterise mathematics" (Niss & Højgaard, 2011, p. 52) and "being able to recognise, understand and deal with scope of given mathematical concepts" (Niss & Højgaard, 2011, p. 53). Mathematical reasoning includes following and assessing chains of arguments, comprehending a mathematical proof, and devising formal and informal mathematical arguments (Niss, 2003). In the present study, the proofs were not a part of the mathematics curriculum. Thus, the reasoning competency is only observed within the context of problem solving. Mathematical modelling is neither a part of the curriculum in the present situation.

### The Ability to Deal with Mathematical Language and Tools

The second group includes the competencies of representing mathematical entities, handling mathematical symbols and formalism, communicating in, with and about mathematics, and making use of aids and tools.

## Research Design and Methods

This study is carried out following a case study design (Yin, 2013) and the data has been collected in a Norwegian public university. A small group of three male students, enrolled in the first year of an electronics engineering program, has been observed over the whole semester. The methods used to generate data include group observations, group interviews, individual weekly journals and field notes by the researcher.

For the participant observations, video recordings of their group work, and screen recordings to follow the activity on computer screens have been collected. Additionally, participants provided screen recordings of their individual work, and weekly journals containing self-reports about the use of resources for practicing mathematics. In this paper, we analyse three episodes of the students' group work in order to look for how these competencies are supported in an e-learning environment.

## Analysis

The two sets of competencies are not mutually disjoint, in general, and are intertwined which is evident from the so-called competency flower. Although each competency has a well-defined identity in theory, execution of each competency in practical will draw on some other competencies. This makes it empirically challenging to disentangle one competency from the others (Niss, Bruder, Planas, Turner, & Villa-Ochoa, 2016). We adhere to these considerations and our purpose here is to rather we look for possibilities in which e-learning influences each sets of competencies.

In the quest for finding correct answers to the given tasks in present situation, participants needed to go through certain procedures where they could demonstrate these competencies. Geogebra (https://www.geogebra.org/) and WolframAlpha (https://www.wolframalpha.com/) were main tools used by the students to make sense of various mathematical functions, checking for the functions' behaviour and to look at the solutions of the tasks. Textbook served as a main written help material in terms of consulting for mathematical formulas, explanations or illustrations, and for checking whether their solutions were correct by comparing these with the answers to tasks provided in the end of textbook. At several occasions, the textbook served as an aid to get acquainted with the mathematical topics, as the students read the textbook to understand the mathematics. The introduction of Maxima was done in a project in this course, and the purpose was to make engineering students capable of using this programming language to solve mathematical problems thus it also served as a resource.

The exposure to Google and different online calculators, in this case, for finding solutions of the given tasks, has shared the role for computing and calculating the solutions. We noticed that in participants' arguments, the element of tool dependence was evident.

In this regard, WolframAlpha and GeoGebra have a central role, since it in the present situation supported students in making sense of the functions, expressions and mathematical concepts in different ways. For example, when the students were not able to solve an integral $\int_0^1 \frac{\sin(x)}{x} dx$ by programming with Maxima, they started wondering whether it was solvable at all, and they used WolframAlpha to make sense of the scope of the task or to know the answer:

Per: (…) Maybe it… (we) can't solve it? Have you tried Wolfram? [Per is addressing Jan and visits WolframAlpha website himself. Per has looked up $\int_0^1 \frac{\sin(x)}{x} dx$ on WolframAlpha (Figure 2)]

Per: No, you're supposed to get an answer.

In this example, when asked by Jan, Per was trying to handle the scope of this integral. He used WolframAlpha to see what this integral is all about, and based on the output, he decided that it could be solved. This example illuminates how the mathematical thinking and problem-tackling competencies are being executed along with the obviously observed aids and tools competency.

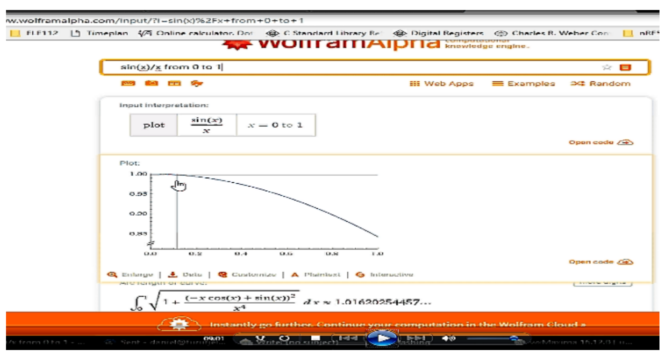

*Figure 2: Screenshot of a participant's work on WolframAlpha.*

The online tools mediated in the students' abilities to think and reason mathematically either by providing the complete calculations or the opportunities to explore the tasks at hand. By using paper and pencil techniques, both of these functions require a different kind of knowledge and skills as it says in the competence framework.

The following excerpt indicates how this environment is supporting the competencies of dealing with mathematical language and tools. While trying to solve a definite integral $\int_{-1}^{1} e^{-\sqrt{-1}wt}\, dt$ using Maxima, they got apparently a different outcome than what it said in the book.

Per: It is the same? It is the same thing, just written in a different way.
Jan: Yeah
Per: Simplify [Per tries to use the "simplify" command on the expression in Maxima]
Jan: Yeah, it just looks that much nicer when you do it in…
Per: In Wolfram.
Jan: Yeah. Yeah, or at that. Did you get…You got the same in Wolfram?

Per: Nnn… I haven't checked it. I assume I get what it says in the book.

[Per looks up $\int_{-1}^{1} e^{-\sqrt{-1}wt}\, dt$ in WolframAlpha.]

Per: Then I get sine w to…2 sine w divided by w, and that's exactly the same as it says in the book.

Jan: There, it… If you go back. Wolfram has moved -1 outside.

[Jan is trying to make Per aware how WolframAlpha has changed the representation.]

Per: Where?

Jan: Put the square root outside the parentheses.

Per: Yeah, but that's just if… I don't think it matters if...

[Meanwhile Per writes the original expression slightly differently in Maxima and gets the same output]

Per: It is exactly the same. I think it is correct.

Here, Per and Jan were trying to make sense of the different representations of the expression when both resources offered the result in a slightly different manner. The second set of competencies concerning representing mathematical entities, handling mathematical symbols and formalism, communicating in, with and about mathematics, and making use of aids and tools are *in action*.

An interplay of different resources had also been helping to approach a given task from different perspectives and to gain more information about the task in hand. Also, the use of Maxima apparently seemed as a short cut for getting ready-made answers. However, it has been observed that it required some effort from the students to decode the mathematical language into programming language.

## Discussion

We intended to look for the execution of mathematical competencies in an e-learning environment in our case, and the findings of this study differ from the previous findings by (García et al., 2014). We found that while this environment supports some competencies, it does not ensure enhancing all of these in all learning environments. The way in which this online learning environment provides possibilities for practicing mathematics makes it different from the traditional way of doing mathematics in a paper and pencil environment.

For instance, from the first set, when the competencies of thinking and reasoning mathematically have to be executed in an online environment. We conjecture that the effects are twofold. On one hand, the resources are facilitating in computing, calculating and providing answers requiring less effort from the students thus limiting the possibilities for exploration. However, on the other hand, when used for comprehension of the tasks at hand they have potential to enhance the possibilities of exploration. We further observed that e-learning is certainly not on the same lines as it means to think and reason mathematically in a traditional way. In a traditional paper and pencil environment, students use their own knowledge and skills for performing the tasks at the hand.

The second set of competencies has more scope in the present context owing to the use of different tools and aids for practicing mathematics. When students used different tools for practicing mathematics, and each one of those tools uses different symbolism which provides some opportunities for the students to experience and handle varied mathematical formalism in a way.

Question for discussion: How to devise a better systematic scheme for analysing mathematical competencies in this environment?

## Shape Thinking: Covariational Reasoning in Chemical Kinetics

Jon-Marc G. Rodriguez, Purdue University
Kinsey Bain, Purdue University
Felix Ho, Uppsala University
Marcy H. Towns, Purdue University

*This work addresses the following research question: In what ways do students use mathematics in combination with their knowledge of chemistry and chemical kinetics to interpret concentration versus time graphs? The study was designed and implemented using a resource-based model of cognition as the theoretical framework. Data was collected through the use of an assessment involving short-answer test items administered to 109 students in a first-year, non-majors chemistry course at a Swedish university. The student responses were translated from Swedish to English and subsequently coded. Data analysis involved using the shape thinking perspective of graphical reasoning as a methodological framework, which was adapted to analyze the covariational reasoning used by students in the context of chemical kinetics. Open-coding and considerations of shape reasoning have provided insight into student understanding of mathematical models of chemical processes.*

*Keywords*: Graphing, Covariational Reasoning, Shape Thinking, Rates, Chemistry

### Introduction and Rationale

Chemical kinetics is concerned with the rate of change of concentration of compounds in a chemical reaction, which readily lends itself to be described using differential calculus. Mathematical operations and graphical reasoning centered around the derivative provide useful tools for modeling systems that are changing over time. However, a review of the literature indicates students lack a clear understanding of rate and rate-related ideas, with ample evidence supporting the claim that students struggle with a conceptual understanding of functions, covariational reasoning, and assigning meaning to variables (Aydin, 2014; Bain & Towns, 2016; Castillo-Garsow, Johnson, & Moore, 2013; Moore, 2014; Moore, Paoletti, & Musgrave, 2013; Rasmussen, Marrongelle, & Borba, 2014; White & Mitchelmore, 1996).

Given this backdrop, it is not surprising students have difficulty using and applying calculus in other contexts, such as modeling physical systems (Becker & Towns, 2012). The act of modeling, in which processes are translated into mathematical formalism, is a common practice in the sciences, and it has been identified as a foundational scientific practice that students should engage in at all levels of education (Bruce, 2013; National Research Council, 2012; Edwards & Head, 2016; Posthuma-Adams, 2014). However, problem-solving, reasoning, and modeling in the physical sciences is particularly challenging because it introduces an additional domain of (scientific) knowledge that must be integrated with a student's mathematical knowledge, a problem that is further compounded when considering that chemistry requires students to think abstractly at the particulate-level, which is not readily observable or accessible (Becker & Towns, 2012). Nevertheless, researchers agree that making connections across different domains of knowledge through modeling is necessary to promote a deeper understanding of chemistry (Becker, Rupp, & Brandriet, 2017; Sjostrom & Talanquer, 2014; Taber, 2013; Talanquer, 2011).

Based on this rationale, research studies have investigated student understanding of mathematical expressions and their relationship to chemical phenomena, and published literature reviews indicate there have also been a number of other studies that focus specifically on chemical kinetics (Bain & Towns, 2016; Becker et al., 2017; Becker & Towns, 2012; Greenbowe & Meltzer, 2003; Hadfield & Wieman, 2010; Jasien & Oberem, 2002; Justi, 2002). In their review paper, Bain and Towns (2016) echo the call of the National Research Council for more discipline-based education research (DBER) that focuses on studies at the undergraduate level and emphasizes interdisciplinary work, such as collaborations between chemistry and mathematics communities. They also comment specifically on the need for more studies that incorporate prompts aimed at investigating graphical reasoning in a chemical context such as kinetics (Bain & Towns, 2016).

Among the reviewed literature, few studies focus on the overlap of chemical and graphical reasoning, and among the chemical kinetics studies reviewed, none focus exclusively on reasoning related to graphical representations. However, student difficulties with graphs are discussed briefly as part of larger studies and the general consensus among the literature is that students are often unable to make conclusions about the chemical mechanism that is implied in graphical representations of chemical processes (Cakmakci, 2010; Cakmakci & Aydogdu, 2011; Cakmakci, Leach, & Donnelly, 2006; Kolomuç & Tekin, 2011; Tastan, Yalçinkaya, & Boz, 2010). This study seeks to fill the gap in the literature and contribute to the body of knowledge related to graphical reasoning in the physical sciences. To this end, our guiding research question is the following: In what ways do students use mathematics in combination with their knowledge of chemistry and chemical kinetics to interpret concentration versus time graphs?

## Theoretical Underpinnings

This study was developed using the resource-based model of cognition as a theoretical framework (Hammer & Elby, 2002, 2003). The resources perspective describes student knowledge as being defined by resources that are activated in specific contexts. These resources are broadly defined as pieces of knowledge or ideas about the nature of knowledge. Hammer and Elby (2002) emphasize that resources may be productive or unproductive, and instruction should focus on understanding what resources students have and how to encourage students to use resources that are useful for a given context. As mentioned by Becker and colleagues (2017), using the resources perspective to frame data analysis and dissemination of results provides the opportunity for researchers and practitioners to consider what instructional support would be useful to help students productively use their knowledge. By considering the nature of the student responses and the reasoning elicited from the prompt, appropriate scaffolding can be developed to encourage scientific reasoning and promote scientific practices such as modeling.

To aid in the analysis of our data, we used the shape thinking perspective as a methodological framework (Moore & Thompson, 2015). Within the shape thinking framework, reasoning related to graphical understanding and problem-solving is characterized as static or emergent: static thinking is reasoning that describes graphs as objects ("a wire") that have associated properties; emergent thinking is reasoning about graphs as a mapping of all of the possible inputs and outputs, a trace in progress (process) involving covarying quantities.

## Methods

### Data Collection

The primary source of data was an assessment administered to 109 students following the chemical kinetics unit in a first-year non-majors chemistry course at a Swedish university. The prompt given to the students provided a concentration vs. time graph along with three short-answer questions related to the graph (see Figure 1). One of the learning objectives for the kinetics unit involved getting students to extract information about what is happening at the molecular level from a graphical representation of a reaction. This is reflected in the design of the prompt, which focuses on conceptual understanding and requires students to integrate chemical and mathematical knowledge.

**Kim got the results of an experiment that a friend performed, where a particular substance X was involved in a reaction. The graph shows how the concentration of X changed with time during the experiment. Given this graph:**

**(a) Is X better described as a reactant or product in the reaction? Explain your answer.**

**(b) At which of the time points t = 1 min, 5 min, 10 min was the rate of reaction the highest? At which time point was it the lowest? Explain carefully how you arrived at your answer.**

**(c) Kim is trying now to figure out what could have led to the concentration of X behaving the way it did and is asking you for some help and ideas. Suggest to Kim possible things that could have happened in the reaction that could explain the difference in reaction rates at t = 1 min and t = 10 min. Be sure to justify your response with explanations at the molecular level for why your suggestions can reasonably explain the difference.**

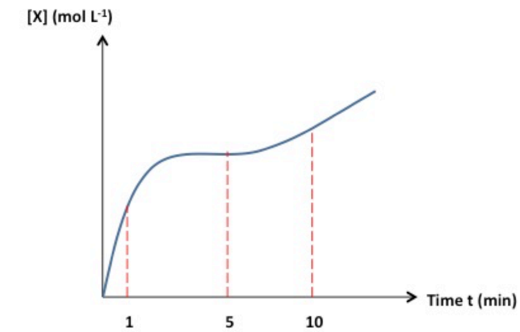

*Figure 1. Prompt used for assessment.*

This emphasis on conceptual understanding led the researchers to consider ideas of transfer. Transfer involves applying knowledge to unfamiliar situations, and the ability to transfer knowledge has been identified as a key component of conceptual understanding (Holme, Luxford, & Brandriet, 2015). Within the resources framework, transfer is conceptualized as the *activation of resources*, and in order for students to be able to use knowledge in novel situations, resources related to the task need to be coherently organized in such a way that they are not dependent on a single context (Hammer, Elby, Scherr, & Redish, 2005).

The prompt was designed, in part, to evaluate the extent in which students are able to use the appropriate knowledge in a different context. The graph in the prompt did not reflect the concentration vs. time graphs normally depicted in textbooks, and although chemically possible, it exhibited deviations from empirical results one would observe in typical laboratory work done in a general chemistry course (see Figure 2). In addition to representing a somewhat unfamiliar problem-solving scenario, item (c) in the prompt reflects what is described as an “ill-defined” problem, in which the question is more open-ended and there is not just one correct answer (Singer, Nielson, & Schweingruber, 2012). For this problem students are prompted to suggest a plausible explanation for the observed graph shape, which could encompass a myriad of possible justifications. Content validity of the assessment items was achieved by discussing and co-developing this prompt among a group of four researchers, and the wording in the prompt was refined after initially being piloted (in both English and Swedish) with a group of participants that included three professors, a postdoctoral researcher, and two Ph.D. students.

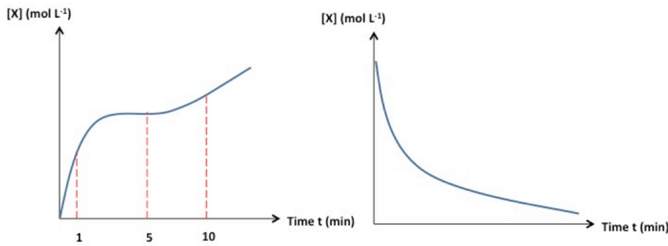

*Figure 2. Graph used in the prompt (left) and a graph used in a typical chemistry textbook (right).*

After translating the student responses from Swedish to English, they were analyzed using open coding and the shape reasoning framework. Through the process of constant-comparison a list of codes was created and refined, with a graduate student and a postdoctoral researcher coding in tandem and requiring 100% agreement for assignment of codes (Patton, 2002). The coding scheme developed into a multi-tier categorization system that was used to characterize student reasoning. The scheme characterizes the student responses, first based on whether the student answered the question correctly, then on the discipline-specific (chemistry vs. mathematics) resources, such as the content and reasoning the students used. This was developed through a combination of inductive and deductive analysis, in which the chemistry categories developed as a result of the observed student responses and the mathematical reasoning categories were modeled after the previously mentioned delineation of emergent vs. static reasoning in the shape thinking framework (Moore & Thompson, 2015). For the chemistry categories, a "Less Productive" sub-category was created to encompasses responses that involve ideas that are not useful for problem-solving in this context and/or reflect incorrect reasoning about relevant ideas, and a "Kinetics Concepts" sub-category was created to encompasses ideas and reasoning that more appropriately address the prompt. It is also important to note that chemical and mathematical reasoning categories are not mutually exclusive (e.g. a student response can employ both chemical and mathematical reasoning), and here the authors describe the development of a new construct called *process thinking*, which encompasses chemically plausible explanations and emergent reasoning, illustrating higher-level modeling that involves the productive use of cognitive resources (example to follow).

## Preliminary Results

Analysis of the data reveals that students employ multiple different types and combinations of chemical and mathematical reasoning when interpreting concentration vs. time graphs.

When considering student responses to the first item on the assessment, (a), which asks the students to decide if the graph depicts changes in the amount of product or reactant, it can be seen that there was little variation in student reasoning; most students responded with the same chemically plausible idea that since reactants are consumed (decrease) and products are formed (increase) over the course of the reaction, the graph represents products increasing over time. In responding to this prompt, students also tended to consider how both variables change over time, displaying emergent reasoning. For the second assessment item, (b), which tests students' abilities in making connections between a graphical understanding of the derivative and ideas related to rate, the students tended to respond in purely mathematical terms without bringing in chemical knowledge, with most students reasoning statically, only thinking about the general shape and the steepness of slopes, rather than considering more formal definitions of the derivative. In the case of the final prompt, (c), which asks students to essentially trace the function and discuss the chemical phenomena that could explain the observed graph, most students responded in general terms, providing lists of factors that affect rate, rather than specifically considering the chemistry occurring at each point. However, a few students expressed a deeper level of understanding. Consider Eleanor's response to (c):

> We can see from the graph that from t = 0 to about t = 3, the rate of reaction increases, it means the concentration of reactants is greater than the concentration of products. Such a difference in concentration leads to the increase in the products' concentration. But when the reaction reaches t = 5 we can see that the product's concentration has stopped increasing, this means that the reaction has reached an equilibrium. That is why we do not get an increase in the concentration of X. But we see how at t = 7 the reaction will keep forming products. This is because we no longer have an equilibrium. And one way to change the equilibrium can for example be through changing the temperature in the reaction or through adding more reactants to the reaction so that they can continue to form products.

In her response, Eleanor considers multiple points on the graph and provides chemically plausible explanations that could justify the observed shape of the graph. Responding to item (c) requires mechanistic thinking about the process the graph models, and as instructors, we would like to move students toward a more sophisticated understanding that encompasses practices such as modeling, a level of reasoning (exemplified by Eleanor) that defines the construct we call *process thinking*. Process thinking combines chemically plausible explanations with emergent reasoning (mathematical reasoning related to functions and covariation), and preliminary results indicate process thinking was not common among the student responses. This does not necessarily imply students are unable to engage in this level of reasoning, because this prompt may not have been effective in activating or eliciting this type of reasoning.

Preliminary analysis also yielded some interesting considerations regarding language and culture. In Swedish, the standard mathematical term for the gradient of a line in two-dimensional space is *lutning*, which is the noun form of the verb *luta*, "to lean". Both words are of general, everyday usage, but are nevertheless used in Swedish to describe the characteristics of a line in the more specialized, mathematical context. Furthermore, this description of the derivative is dynamic in the way that it connotes action. For instance, from its grammatical construction, the word *lutning* is literally "leaning-ness" or the act of leaning. Also, a line can *luta skarpt*, "lean strongly", as opposed the more static description of a line *having* a steep gradient/slope, as is the norm in English. This suggests some level of cultural and colloquial familiarity or association for the students.

## Conclusion and Questions

When viewing the student responses as variations in reasoning that reflect cognitive resources available to the students, it is worth evaluating which resources are more productive for the context, and investigating the extent in which each item in the assessment elicited the desired reasoning. This will provide a better understanding of how to scaffold student reasoning, promote modeling, and develop exams that can assess deeper levels of understanding. Further analysis is warranted and the following questions reflect potential future avenues for inquiry:

(1) How are the types of chemical and mathematical reasoning related for each response?
(2) How do we promote modeling and activate productive resources in unfamiliar situations?
(3) What role do cultural influences such as language have on student mathematical reasoning and our coding scheme?

Building Lasting Relationships: Inquiry-Oriented Instructional Measure Practices

Rachel Rupnow Virginia Tech
Tiffany LaCroix Virginia Tech
Brooke Mullins Virginia Tech

*This study examines the relationships between instructional practices in the Inquiry-Oriented Instructional Measure (IOIM). The IOIM consists of seven practices developed from four guiding principles of Inquiry-Oriented (IO) instruction: generating student ways of reasoning, building on student contributions, developing a shared understanding, and connecting to standard mathematical language and notation. A 2-tailed correlation test was applied to IOIM scores from 36 instructors and found six of the practices had strong positive correlations to each other and the seventh had a moderate positive correlation. Cronbach alpha was calculated indicating the IOIM is an internally consistent measure.*

*Keywords:* Inquiry-Oriented, Instructional Measure, Quantitative

Inquiry based learning (IBL) encompasses a broad range of teaching approaches focused on engaging students in mathematical argumentation while performing a sequence of tasks (Yoshinobu & Jones, 2013; Laursen, Hassi, Kogan, & Weston, 2014). Studies have shown better student outcomes from self-reported IBL instructors than from non-IBL instructors (Laursen, et al., 2014; Kogan & Laursen, 2013). However, IBL is a "big tent" with different meanings to different researchers (Kuster, Johnson, Keene, & Andrews-Larson, 2017). Here we focus on the more narrow Inquiry-Oriented (IO) instruction, which generally adheres to the tenets of IBL.

Measures have been developed in other branches of math education, with purposes such as teacher noticing (Jacobs, 2017) or determining the mathematical quality of instruction (Learning Mathematics for Teaching Project, 2011). These measures can help clarify the degree to which a standard is met and can clarify how researchers are conceptualizing phenomena (Jacobs, 2017). For IO instruction, this conceptualization is particularly important because IO curricular materials have presented a number of challenges for implementation. These challenges include developing mathematical knowledge for teaching, anticipating how to build on students' ideas, and facilitating whole-class discussions (Johnson & Larsen, 2011; Rasmussen & Marrongelle, 2006; Speer & Wagner, 2009; Wagner, Speer, & Rossa, 2007). Therefore, it is essential to define what IO instruction looks like, to develop a clear measure to better understand the nature of improved outcomes observed in IBL courses, and to see to what extent they were observed in IO intending classes. This measure can also help address implementation challenges by highlighting specific aspects of high-quality IO instruction.

Researchers have created the Inquiry-Oriented Instructional Measure (IOIM), a rubric that quantifies the degree to which a class can be characterized as IO. For more background information on this measure as well as the measure itself, refer to Kuster, Rupnow, & Johnson (2018) in this volume. We used the IOIM to score 36 Abstract Algebra, Linear Algebra, and Differential Equations instructors. Based on those scores, the purpose of this paper is to explore the relationships between different practices in the IOIM to determine the value of using the IOIM to measure IO instruction.

## Theoretical Perspective

The IOIM is based on four guiding principles from Kuster et al. (2017): *generating* student ways of reasoning, *building* on student contributions, developing a *shared understanding*, and *connecting* to standard mathematical language and notation. Generating student ways of reasoning includes engaging students in mathematical tasks so their thinking is shared and explored with the class. Building on student contributions involves taking students' ideas and using them to direct class discussion, potentially in unforeseen ways. Developing a shared understanding describes helping individual students understand one another's thinking, reasoning, and notation so that a common experience can be "taken-as-shared" in the classroom (Stephan & Rasmussen, 2002). Connecting to standard mathematical language and notation involves transitioning students from the idiosyncratic mathematical notation and terms used in class to standard descriptions and notation, such as "groups" or phase planes. These four principles are enacted though seven instructional practice. The four principles and the seven practices supporting them are listed in Figure 1.

| Principles | Practices Supporting Each Principle |
|---|---|
| **Generating** student ways of reasoning | 1. Teachers **facilitate** student engagement in meaningful tasks and mathematical activity related to an important mathematical point. |
| **Generating** student ways of reasoning<br>**Building** on student contributions | 2. Teachers **elicit** student reasoning and contributions. |
| **Generating** student ways of reasoning<br>**Building** on student contributions | 3. Teachers **actively inquire** into student thinking. |
| **Building** on student contributions<br>Developing a **shared understanding** | 4. Teachers are **responsive** to student contributions, using student contributions to inform the lesson. |
| Developing a **shared understanding** | 5. The teacher engages students in **one another's reasoning**. |
| **Building** on student contributions | 6. The teacher guides and manages the development of the **mathematical agenda**. |
| Developing a **shared understanding**<br>**Connecting** to standard mathematical language and notation | 7. Teachers support **formalizing** of student ideas/contributions and introduce language and notation when appropriate. |

*Figure 1: Principles and their supporting practices*

Practice one reflects the extent to which the teacher engages students in "doing mathematics," or the extent to which students engaged in cognitively demanding tasks and used mathematical argumentation to support or refute any claims (Stein, Engle, Smith, & Hughes, 2008). Practice two reveals the degree to which the teacher elicits rich mathematical reasoning from students, as opposed to simple recitation of procedures. Practice three signals the level to which the teacher further probes students' statements and reasoning in order to improve their own understanding of what students meant and in order to help students reflect on their own thinking. Practice four indicates how much the teacher uses students' questions and ideas as a springboard for further discussion in class that enriches the mathematical development for the class as a whole. Practice five examines the extent to which the teacher prompts students to directly compare and contrast each other's reasoning without the teacher needing to act as a filter that interprets statements for the students. Practice six exhibits the level to which the teacher guides and manages the development of a lesson in a coherent way that reaches a mathematical goal while using student reasoning and contributions to reach that mathematical goal. Practice seven displays the degree to which the teacher transitions from students' own language and notation, which have been developed to address tasks, to standard mathematical language and notation and the extent to which the teacher allows students to take ownership of this transition (i.e., at a high level, the teacher provides the standard name but the students translate their notation into standard notation once given a template for the standard form). Based on this perspective, we explore the following question: To what extent are the practices related?

## Methods

This quantitative study uses a relational research design to look at the relationships among the seven IOIM practices by investigating data collected from a project designed to support instructors interested in implementing IO instructional materials. Five volunteers trained for five days to understand how to score videos with the IOIM. Coders then scored videos of professors teaching Abstract Algebra, Linear Algebra, and Differential Equations that had been collected during the IO project. Mean scores for each video were calculated and examined using correlation and linear regression analysis to determine the relationships among the practices.

### Coders

Classroom videos were coded by one expert coder and five graduate students recruited by researchers involved in a large project designed to support instructors as they implemented IO curricular materials. The expert coder was a graduate student involved in the development of the IOIM, who had been trained by an IO project researcher on coding each practice. The other five coders were recruited from three different universities associated with the IO project. These five coders completed a week of training conducted by the expert coder to learn about scoring the IOIM practices from 1 to 5, with 1 being low and 5 being high (Kuster, et al., 2018). The first three days were spent in online meetings watching and discussing different teaching scenarios representing the five levels of IO teaching described in the IOIM. Special emphasis was placed on characterizing low, medium, and high levels of IO teaching to aid interpretation of the IOIM. During this time, the expert coder explained each IOIM practice and the associated score for each of the videos. The expert coder also answered the coders' questions and facilitated debates about scores to ensure all coders gained an understanding of the IOIM practices and scores. The last two days involved coding practice videos. Each coder individually scored a video, discussed their scores with another coder, and then met as a group online with the expert coder. Once the coders and expert coder reached agreement on a score for each IOIM practice, they scored the next video. This repetitive process continued throughout the last two days. Coders had to be within one score from the expert coder for each IOIM practice before coding another video. This benchmark helped ensure coders understood the IOIM practices and scoring.

### Data Collection

The five coders individually watched eight to twenty-one classroom videos from the Abstract Algebra, Linear Algebra, and Differential Equations IO project professors. The videos were from TIMES fellows, who had engaged in professional development while using IO materials. After watching each video, coders used the IOIM to score each practice and wrote a justification of the score. Individual coders met online with the expert coder after every fifth video to discuss scores. If all of the coder's IOIM scores were at most one away from the expert's scores, the coder proceeded to the next set of videos. However, if the coder's IOIM scores were off by more than one score, the coder was asked to re-watch and recode the video. This benchmark ensured consistency in coding. Final IOIM scores were compiled in a spreadsheet for each video. The goal was to have at least two coders score each video.

### Data Analysis

To determine the relationships among the IOIM practices, correlations and linear regression analysis were conducted using the mean scores of each IOIM practice for each video. The goal was to determine the strength of the relationships between practices and if the score of one practice predicted the score of other practices from the IOIM rubric. A total of 36 scored videos were used, each containing one mean score for each of the seven IOIM practices. Simple linear regressions were conducted by defining one practice as the independent variable with all other practices defined as the dependent variables for all 36 videos. To assess this measure's internal consistency, Cronbach's alpha analysis was conducted using all seven practices.

## Results

The preliminary results indicate each practice is positively correlated with every other practice, which provides justification for the cohesion of the measure (Table 1). Cronbach's alpha was calculated to assess internal consistency for the seven practices ($\alpha = .969$). This indicates the IOIM has high internal consistency and is a reliable measure for assessing IO instruction. As a video receives high scores for one practice, it receives high scores for the other practices, and likewise if the scores are low. We found practices one through six had very strong correlations to each other, and practice seven had a moderate correlation with the other practices (Table 1). This means video scores for practices one though six strongly depended on each other, whereas video scores for practice seven were only moderately dependent on the scores from practices one though six.

*Table 1. Correlations between IOIM Practices*

| Correlations | | | | | | | |
|---|---|---|---|---|---|---|---|
| Practices | Practice 1 | Practice 2 | Practice 3 | Practice 4 | Practice 5 | Practice 6 | Practice 7 |
| Practice 1 | 1 | .892** | .932** | .883** | .817** | .932** | .716** |
| Practice 2 | .892** | 1 | .910** | .893** | .889** | .917** | .726** |
| Practice 3 | .932** | .910** | 1 | .834** | .798** | .911** | .659** |
| Practice 4 | .883** | .893** | .834** | 1 | .883** | .871** | .695** |
| Practice 5 | .817** | .889** | .798** | .883** | 1 | .846** | .642** |
| Practice 6 | .932** | .917** | .911** | .871** | .846** | 1 | .660** |
| Practice 7 | .716** | .726** | .659** | .695** | .642** | .660** | 1 |

## Discussion

The preliminary results indicate practices one through six have strong, positive correlations between each other, but practice seven is only moderately correlated with the other practices. According to our theoretical perspective, the first six practices map to the generating student ways of reasoning, building on student contributions, and developing a shared understanding IO principles. This explains the strong correlation between them since they rely primarily on student thinking and how the instructor responds to such thinking. However, practice seven is the only practice mapped to the connecting to standard mathematical language and notation principle. Practice seven focuses on formalizing student contributions to standard mathematical language and notation, which does not appear to strongly depend on student thinking stemming from an IO task. Due to the difference in mapping, this could explain the difference in correlations between practices one through six with practice seven. For practices 1-6, the high correlations suggest, for example, that a teacher who can probe student thinking also has students engaged in mathematics and vice versa.

Because only TIMES fellows who were trained in doing IO instruction were scored with this rubric, a future area of research would be to use the measure with professors who lecture, who use other forms of IBL, or who use a mixture of IO and lecture to see if the measure can distinguish among teaching styles. Professors who are excellent lecturers could also be a potential subject pool to investigate whether the correlations would be similar with professors who excel with a different instructional method. It is also worth studying whether there are differences between practice scores when the data is broken down by course or coder. Additional research could investigate the interaction between practice, course, and coder.

**Questions for Audience**

1. We analyzed the data with correlations. What other data analysis methods would be appropriate and for what purposes?
2. What might we learn by using this rubric on other data sets (e.g., IBL or lecture based)?
3. Do you think the rubric would be applicable for K-12 instruction? If so, how?
4. Do you think the rubric would be applicable for mathematics preservice teacher evaluation? If so, how?

Productive Failures: From Class Requirement to Fostering a Support Group

| Milos Savic | Devon Gunter | Emily Curtis | Ariana Paz Pirela |
| --- | --- | --- | --- |
| U. of Oklahoma | U. of Oklahoma | U. of Oklahoma | U. of Oklahoma |

*Mistakes occur frequently in mathematics. In two classes (Abstract Algebra and Calculus II), mistakes were brought to the forefront in the form of a "productive failure." Through five interviews with students, we initially looked for affectual responses to the pedagogical allowance and student-led demonstration. Many of the responses, both benefits and drawbacks of the productive failure, were interpreted by the research group to resemble peer-led support groups such as Alcoholics Anonymous. Descriptions of both productive failure and support groups, as well as quotes from the students, aim to shed light on psychological benefits of valuing mistakes.*

*Keywords:* productive failure, affect, inquiry-based learning

## Introduction

At one point in their life every student will reach a mathematical impasse when attempting to solve a problem. What students do after such an impasse might define how they view mathematics as a process. Additionally, what instructors do to cultivate such a process may further (and perhaps ultimately) influence students' thoughts about mathematics. The present investigation focused on the pedagogical action of allowing students to demonstrate their problem-solving impasses and explain their struggle positively. We call this struggle a "productive failure." At first, we investigated affect in students' interview responses to productive failures. However, we conjecture that many of the affectual responses may also be found as benefits and drawbacks in peer-led support groups such as Alcoholics Anonymous. While the two do not equate on a societal level, the characteristics and effects seemed to align. This proposal describes what a productive failure is, gives background on affect and support groups, and argues the resemblance of a support group to the demonstrations of a productive failure.

## Background Literature

### Productive Failures

The notion of using mistakes, difficulties and impasses as productive has been discussed in many capacities, often with success. However, both what constitutes "productive" and what kind of difficulty arises, varies in the literature. For example, Granberg (2016) defined productive failure as a "result in the restructuring of mental connections in more powerful, useful ways through which the problem at hand would make sense and new information, ideas and facts would become assimilated" (p. 34). Granberg, again, stated that errors play a large part: "It appears that making, discovering and correcting errors may generate effort that can engage students in productive struggle" (p. 34). However, productive to Granberg meant to obtain a correct solution, whereas the authors mean productivity in how students learned about their own problem-solving methods. What must occur for a student to be productive in their failure is a recognition of the failure or mistake (the "checking" phase of Carlson and Bloom's (2005) problem-solving process), subsequent recovery or additional approach (the cycle back to "planning" and "executing" phase of Carlson and Bloom (2005)), and the metacognitive awareness of modifying their approach for future problem solving. Research has suggested that during productive struggle, students activate prior knowledge and intuitive ideas (Kapur & Bielaczyc, 2012; Kapur, 2014). Furthermore, the more problem-solving methods that students construct during their struggles, the more prior knowledge is to be activated (Kapur, 2014).

As a pedagogical tool, there is an indication in previous literature that an environment structured for utilizing failures or mistakes can be successful in refining students' problem-solving skills. For example, an explicit incentive to correct their mistakes can be an effective formative assessment tool (Black & Wiliam, 2009). This incentive could be points or other credit in the course: "Offering grade incentives to diagnose and correct mistakes can go a long way to close the performance gap between struggling and high-performing students" (Brown, Singh, Mason, 2015, p. 4). A by-product of this pedagogical action is that it can create "failure tolerance" (e.g., Clifford, 1984; 1988), turning potentially negative occurrences into positive outcomes. Tulis (2013) stated that research into pedagogical actions on failure and mistakes is scarce: "little is known about adaptive classroom practices for dealing with errors and the reciprocal effects of students' and teachers' attitudes towards learning from mistakes" (p. 56). These effects on attitude led us to search for affect in our project, which will be described next.

**Affect**

McLeod (1992) stated that the definition of affect "refers to a wide range of beliefs, feelings, and moods that are generally regarded as going beyond the domain of cognition" (p. 576). He goes on to state that there are three general categories to the affective domain: beliefs, attitudes, and emotions. While others have added categories to the domain (namely, values, motivation and engagement (Attard, 2014)), for the purposes of this project, the focus will be on these three categories, and on affect as a whole. Beliefs are "psychologically held understandings, premises, or propositions about the world that are thought to be true" (Philipp, 2007, p. 259). For example, an instrumentalist view of mathematics may state that mathematics is all about rules and procedures. Attitudes are "develop[ed] from several similar and repeated emotive responses to an event or object" (Grootenboer & Marshman, 2016, p. 19). Emotions are more visceral and momentous. Positive emotions include AHA! moments (Liljedahl, 2013), while negative emotions involve frustration. Negative emotions can largely contribute to how students approach problem solving tasks: "Furner (2000) suggested that two-thirds of Americans either hate or loathe mathematics" (Grootenboer & Marshman, 2016, p. 21).

The difficult part about affect is that it can be influenced by a variety of factors, some that can be controlled by pedagogical actions. For instance, Grootenboer and Marshman (2016), citing Pajares (1992), stated that "because central beliefs have been developed through experience, new activities giving rise to positive experiences and reflection upon those experiences is critical to belief change" (p. 17). Therefore, while affect is personal, and can influence cognition and learning, it is difficult and lengthy to foster or change in students. Nevertheless, a demonstration on the productivity of failure may be an influence students' affect.

## Research Question

What are the effects of demonstrations of a productive failure on a student and the classroom? In particular, what changes in affect occurred during and after a productive failure demonstration?

## Methods

This investigation focused on two classes: an undergraduate/graduate abstract algebra course using TAAFU (Teaching Abstract Algebra For Understanding) materials (Larsen, Johnson, and

Bartlo, 2013); and calculus II, covering from the definition of definite integral to integration techniques. The algebra class was in Fall 2015 with 32 students, and the calculus class was in Fall 2016 with 137 students. Demonstrating a productive failure in front of the class accounted for 5% of the final grade, with 2% extra credit in the calculus course if the student demonstrated in front of the large lecture instead of the discussion sections.

Productive failures generally occurred in the same manner. The instructor asked if any students had a productive failure, and if one did, the instructor would ask them to come to the document camera and demonstrate it. Students would describe their mistakes and were encouraged to reflect on them. Unless already mentioned, they were typically asked why it was productive for them. Often the problem or theorem in question was an entry point to discuss the topic for that day. These demonstrations lasted for an average of five minutes. After questions from other students and the instructor, the presenting student would walk back to their seat while their peers applauded.

The first author was the instructor for both courses and taught using inquiry-based learning (IBL) (Cook, Murphy, & Fukawa-Connelly, 2016). The second author researched the calculus course, taking observation notes of daily classes, interviewing four students (including the fourth author), and conducting an online survey (different than the end-of-course evaluations). All interviews were conducted and transcribed by the second author. One question in the interview focused specifically on productive failures and their presentations. Due to space, both the full interview questions and survey questions are omitted.

The third author was a student in the abstract algebra course and presented a productive failure after the second test, which occurred on week 10. The fourth author was a student in the calculus course, and presented her productive failure to the large class before the first test. Both were asked to participate in a reflection session with the first author about 7 months after their demonstrations, where they discussed the demonstration of the failure, the reactions that they had during the time, and future effects. The first and third authors watched the video of the third author's productive failure presentation (collected for another project), and discussed instances together in an unstructured group reflection. The third author then transcribed that discussion. The first and second author analyzed and coded utterances using affect, and then discussed the importance and significance of those codes. While coding for affect, the authors then found resemblances between the responses given and characteristics of support groups.

## Results

These math classrooms, when incorporating the presentation of productive failure, can be viewed as analogous to a support group. It is prudent to reiterate that this is an analogous relation only and that it is not the intent of the authors to imply that the support that these students are receiving is of the same magnitude to other formal support groups. By the theory of Schopler and Galinsky (1995), support groups have certain characteristics that include:

- "organizational sponsorship or be the creation of an innovative practitioner" (p. 4)
- being member-centric, with members providing experiences, information, advice, and occasionally leadership within the group.
- leaders sharing authority with the members, having their legitimacy often being based on training
- providing a supportive environment and a means for developing coping abilities

The instructor implemented the productive failure requirement in his courses beginning Spring 2016, but was influenced by the IBL community (e.g., Yoshinobu, 2014) and previous literature about impasses (e.g., Savic, 2015). This wasn't necessarily the "creation of an innovative practitioner," but a practitioner that created the productive failure requirement influenced by an innovative community. All productive failures were done by the students, and frequently ended with a round of applause from the majority of the students, hence were "member-centric." The third author stated in the follow-up interview, "We have to clap! This person did such a good job! I was so excited for anyone to get up there and do it that even if it was horrible." The instructor shared the class time (and the power) with the students, and was trained to teach IBL, therefore satisfying the third requirement. As for "providing a supporting environment and a means for developing coping abilities," both may be apparent when discussing the positive and negative effects of the productive failure.

**Positive Effects**

Positive effects of social groups can include "greater social resources, increased knowledge about the focal concern, a sense of relief and reassurance, and enhanced skills for coping" (Schopler & Galinsky, 2014, pp. 6-7). In the interviews, each benefit seemed to align with multiple affectual quotes from the students, which are portrayed in Table 1. The affect code in the quotes is interspersed as normal font.

*Table 1: Benefits with Student Responses*

| Benefit | Student Response |
| --- | --- |
| Greater social resources | "I just remember a lot of people having the same questions that I did and following down the same path that I did [Belief], so I didn't feel all that bad about having a failure and a lot of people [Emotion], I feel, benefited from me going up, because a lot of people were making the same mistake as I was. And we all got to work together to figure out the right way to do it as a class, which felt awesome. It made the class a lot more interactive and I felt that I learned a lot from my first presentation. [Belief]" – Calculus Student 4, Follow-up Interview |
| Increased knowledge about focal concern | "For example, in BC Calc, I really struggled with integration by parts; it never really made sense, I didn't know where it came from, but this year, integration by parts, now that I actually understand all of the background to it, makes so much more sense and it comes so much easier now. And it's because I had that opportunity to try and then fail and then see where it came from [Belief]." – Calculus Student 4, Initial Interview |
| Sense of relief and reassurance | "So, I went to the board and presented my productive failure and, I didn't feel bad [Emotion], which was odd because, you know, most classes when you make a mistake, people just look at you like 'wow, she's so dumb' and not in this class. They value when you make a mistake and then you realize why you made the mistake [Attitude] and you can fix it because then you're not gonna forget it, you're not gonna make the mistake again [Belief]." – Fourth Author, Initial Interview |
| Enhanced skills for coping | "[W]hat I learned from that was I try, really try not to fail [Attitude], but I'm not afraid of it anymore [Emotion]. So, now whenever I'm doing homework or whatever, I'm not thinking about 'I'm not going to get this right.' I think about, 'What can I do to not fail and get it right?' [Attitude] … Like, if I fail, well I fail. I just restart again [Attitude]." – Fourth Author, Follow-up |

**Negative Effects**

There were students that stated negative effects of productive failures. This is also reflective of the support group research literature; Schopler and Galinsky (1994) found that participants felt "pressure to conform, stress related to group obligations, feeling overwhelmed and less adequate, learning ineffective and inappropriate responses, embarrassment, and overconfidence" (Schopler & Galinsky, 2014, p. 7). Calculus Student 2, in her initial interview, stated that productive failures are "terrifying," and preferred a large class because she could "hide with all those people," both are affectual responses that can be categorized as *pressure to conform* and *feeling overwhelmed*. Calculus Student 4, in his follow-up interview, stated that he enjoyed productive failures but did not find that it would transfer to his major in medicine, where he hoped to specialize in cardiovascular surgery. A student evaluation of the course stated that "I don't feel like the productive failures are effective cause it's a hit or miss whether they'll explain it well," which can be categorized as *learning ineffective and inappropriate responses*.

## Discussion

The pedagogical action of a productive failure demonstration seemed to create a support-group environment. Therefore, we expect similar benefits to support groups. Although we have not found any evidence of this yet, Brown, Tang, and Hollman (2014), citing Brown (2009), stated that "Part of [support groups'] strength lies in their empowering nature, where participants help each other as equals rather than taking on dependency roles where they rely on the advice of professionals" (p. 84). Therefore, in addition to inquiry-based learning, demonstrations of productive failures may help shift power to create a more equitable classroom (Tang et al., in press).

The socio-mathematical norm (Yackel & Cobb, 1996) of learning from mistakes has effects on students' approaches to future problems. For example, the fourth author stated in her interview that she is "not afraid of failing," thus her self-efficacy may have increased for subsequent courses. Finally, this study was first conducted in order to figure out affective as well as cognitive and metacognitive shifts due to productive failures. Thus, there may be many metacognitive gains for students when demonstrating a productive failure. The third author stated in her demonstration interview that "I really do think [the productive failure] impacted me. I don't know if it impacted other people but I think that specific instance has changed how I perceive problems when I see them. I had a lot more success in Abstract Algebra 2 I think because of it."

## Conclusion

Productive failure demonstrations allow mistakes to be open and psychologically constructive instead of damaging, give a platform and power that otherwise may not be available, and may influence both the presenter and their peers affectively. The intention is to investigate and collect further data, especially for the gains in problem solving. A conjecture is that as failures tend to be recast, more students will persist in their problem solving. Time and effort may improve their mathematical skills, and allow them to grow to be more content with their abilities. Encouraging productive failures in a classroom can give students the affectual support to grow as practicing mathematicians.

Questions for the readers:

1. What other pedagogical actions can create environments where mistakes are valued?
2. What other pedagogical actions can create support groups?

## Surveying Professors' Perceptions of Incorporating History into Calculus I Instruction

*The goal of this study is to document undergraduate mathematics professors' perceptions of incorporating the history of mathematics into their Calculus I instruction. Although research has been documented on benefits of incorporating history into mathematics teaching and learning, little has been documented on undergraduate professors' beliefs and how they may incorporate history into Calculus I. To address this question, we created a survey based on Schoenfeld's (1999) theoretical framework of knowledge, goals, and orientations to capture perceptions about instructional decisions related to history incorporation. Calculus I professors in a southeastern state were surveyed to gain an understanding of perceptions on the importance of history and how they incorporate history. The majority of professors (80%) view history as important for Calculus I learning for a variety of reasons and incorporate it in different ways. Implications for supporting undergraduate Calculus I teaching and learning are shared along with questions for further research.*

*Keywords:* Calculus, History, Surveying, Instruction

Numerous educational theorists agree that learning the history of a discipline is essential to learning the content of that discipline (e.g. Frederick & Katz, 1997; Munakata, 2005). Regarding mathematics, Berlinghoff and Gouvea (2002) explain, "Learning about math is like getting to know another person. The more you know of someone's past, the better able you are to understand and interact with him or her now and in the future" (p. 1). While a number of researchers have investigated the usefulness of incorporating history into mathematics instruction, we found little research on undergraduate mathematics professors' views on this topic. Understanding professors' perceptions is important to the field of undergraduate mathematics education. Smestad (2011) points out that teachers' views on incorporating history into mathematics instruction must be taken into account before attempting to influence their teaching.

To better understand the views of Calculus I professors, the study documents aspects of professors' perceptions on usefulness of mathematics history and how they may employ history. The research begins to fill the particular gap in the literature regarding the perceptions of Calculus I professors. The results of this work may better inform the field of undergraduate mathematics education on how to best support professors seeking to enhance Calculus I teaching and learning through incorporating history.

### Background and Literature

The National Science Foundation (NSF) has supported a number of scholars in their attempts to disseminate research and resources on the benefits of incorporating history into undergraduate mathematics. Frederick and Katz (1997) established the NSF supported endeavor, Institute in the History of Mathematics and its Use in Teaching. The institute was associated with the Mathematical Association of America, and one of its many aspirations was "to increase the presence of history in the undergraduate mathematics curriculum" (p. 1). Another NSF supported project, TRansforming Instruction in Undergraduate Mathematics via Primary Historical Sources (TRIUMPHS), narrows the focus employing history in undergraduate mathematics through developing curricular materials based on primary historical sources. Barnett, Clark, Klyve, Lodder, Otero, Scoville, and White (2017) explain:

> That faculty with an interest in primary sources can use them in their teaching is well and good, but we are convinced that there are so many benefits derived from their use that we would like to see them available to all instructors of university mathematics (p. 1).

A relevant question emerges of what type of historical resources professors use, primary or otherwise, and how they perceive them as useful.

Ferreira and Rich (2001) reviewed literature on incorporating history to conclude that using history improves perceptions of mathematics and increases enthusiasm for learning. While these benefits have been established, Calculus I professors' perceptions of incorporating history and how they use history in their instruction are largely unknown. Furthermore, while most undergraduate mathematics textbooks include historical anecdotes throughout the text (e.g. Stewart, 2015), it is also unknown to what degree such anecdotes influence instruction. Research on undergraduate mathematics education must account for Calculus I professors' perceptions in order to adequately guide curricular resource development and instructional practice.

**Theoretical Framework**

While there is general consensus that the history of mathematics is important to mathematics teaching and learning (e.g. Frederick & Katz, 1997; Fauvel & van Maanen, 2000), we found little research on undergraduate faculty perceptions of incorporating history into their Calculus I curriculum. A gap exists in the field of undergraduate mathematics regarding the beliefs, knowledge, and goals professors exhibit on the inclusion of history to teach Calculus I. Research questions were formed and analyzed with the lens of Schoenfeld's (1999) framework of knowledge, goals, and orientations as these three dimensions capture professors' perceptions about both short and long term instructional decisions. The following research questions were addressed: 1) How important do Calculus I professors view the incorporation of history into their instruction and why? 2) What kinds of pedagogical practices do professors use to incorporate history into Calculus I and why?

**Methods and Data Analysis**

Surveying methodology provided an overall picture of professors' perceptions of using the history of mathematics in their Calculus I instruction. Rea and Parker explain, "[t]he ultimate goal of survey research is to allow researchers to generalize about a large population by studying only a small portion of that population" (1997, p. 2). After identifying all undergraduate mathematics professors in the state of North Carolina that reported Calculus I in their professional teaching portfolio, we sent each a mailed letter and emailed invitation to participate in an online survey. Of the 599 survey invitations, we received 96 completed surveys. This provided us a 16 percent response rate.

Survey questions were designed to gain an understanding of the demographic of the responding professors (survey items 1-3), their beliefs about incorporating history (survey items 4-6), how and why they use mathematics history in teaching Calculus I (survey items 7 & 8), and interest in learning more about history incorporation (survey item 9). Survey items six and eight were open ended, and the others were multiple choice. Figure one below summarizes survey data for these categories.

| Survey Item | Responses with Percentage |
|---|---|
| 1) Years teaching at a four year | 0-2 years: 6% 3-6 years: 11% |

| | |
|---|---|
| undergraduate institution | 7-10 years: 16% 11-15 years: 10%<br>15+ years: 57% |
| 2) Number of undergraduate Calculus I courses taught | 0-5 courses: 33% 6-10 courses: 15%<br>11-15 courses: 12% 16-24 courses: 14%<br>25+ courses: 26% |
| 3) Ever incorporated history into Calculus I instruction | Yes: 71%<br>No: 29% |
| 4) Believe incorporating history into Calculus I instruction may benefit students | Yes: 80%<br>No: 20% |
| 5) Importance of incorporating history into Calculus I instruction for teaching and learning (Scale from 0 to 5 with 5 being highest) | 0: 6% 1: 18%<br>2: 20% 3: 24%<br>4: 19% 5: 13% |
| 6) If believe history is beneficial, how will incorporating history into Calculus I instruction benefit students? | See math as *human endeavor*: 28%<br>Make *connections* to history/other disciplines/real world: 27%<br>Increase *motivation*: 27%<br>Increase *understanding*: 14%<br>Broadens *perspective*: 4% |
| 7) If you use history, how often do you incorporate history into Calculus I instruction during a one semester course? | Never: 12% Rarely: 19%<br>Once: 11% 2-4 times: 35%<br>5-9 times: 14% 10+ times: 9% |
| 8) If you include history, describe way(s) you use history and why? | Mentioned during *lecture*: 36%<br>Assigned outside historical *readings*: 30%<br>*Projects* with historical component: 11%<br>*Discussion* on mathematics history: 10%<br>*Videos* about mathematics history: 8%<br>*Papers* with historical component: 5% |
| 9) Interest in learning more about incorporating history into Calculus I instruction (Scale from 0 to 5 with 5 being highest) | 0: 6% 1: 11%<br>2: 14% 3: 36%<br>4: 20% 5: 13% |

*Figure 1. Summary Survey Responses*

To analyze the data, summary statistics were calculated for all numeric data along with thematic analysis of open response data. The thematic analysis work was guided by Creswell's (2012) recommendations for analyzing qualitative data to document emergent themes in responses. We applied thematic analysis to items six and eight with the key word of the theme italicized for clarity in Figure 1 above. A subset of survey participants responded to items six and eight with 75 responding to six and 67 responding to item eight. To address the first research question, we examined summary statistics on professors' beliefs as related to their reporting of how often they incorporate history and the degree to which they are interested in learning more about incorporation. To address the second research question, we examined summary statistics on how history was used and why they reported incorporating it into their instruction. While claims will be generalized to professors in North Carolina, study findings can reasonably be used to inform knowledge of professors' perceptions outside of this state.

## Results

**Beliefs on Incorporating History**

Recall the first research question. How important do Calculus I professors view the incorporation of history into their instruction and why? The majority of professors (80%) indicated that history is useful for students learning in Calculus I however only 71% reported using history in their teaching. On the importance scale from zero to five (see item five), the majority of respondents were clumped towards the middle with 63% providing ranks from 2 to 4. Professors reported multiple reasons for viewing history as beneficial to the Calculus I learner. The top three reasons were the following: 1) See math as *human endeavor* (28%); 2) Make *connections* to history/other disciplines/real world (27%); and 3) Increase *motivation* (27%).

Figure 2 below provides a small sample of the explanations professors offered for viewing the incorporation of history into Calculus I instruction as beneficial to the student.

| **Categories of Benefits of Incorporating History** | **Sample Response in Each Category** |
|---|---|
| See math as human endeavor (28%) | Students benefit greatly from being helped to see that mathematics is, like any other human invention, the product of human activity, often social activity. |
| Make connections to history/other disciplines/real world (27%) | At face value, this can be a dry subject for students who do not see the bigger picture. Incorporating history gives students another connection to the material, and helps to position mathematics. |
| Increase Motivation (27%) | I have found that by placing results within context students tend to be more engaged in the topic. |
| Increase Understanding (14%) | Giving the context of the discovery of l'Hospital's rule, I believe, helped students retain information.<br><br>Gives an understanding of why there are multiple notations for the same things. |
| Broadens Perspective (4%) | It broadens student perspectives, and gives students a break from the "normal" routine. |

*Figure 2. Sample Responses on Beliefs*

In summary, the majority of professors saw incorporating history into Calculus I instruction as beneficial for reasons that were categorized into five groups. The reasons given largely align with research on incorporating history. For instance, increased motivation has been documented as a result of incorporating history (e.g. Ferreira & Rich, 2001). One interesting finding is that the reason, increase understanding, did not make it into the top three reasons. Finally, the majority of professors indicated a substantial interest in learning more about using history in Calculus I instruction.

**How and Why History is Used**

Professors reported teaching Calculus I with history in a variety of ways with varying frequencies. Regarding frequency of use in a one semester course, the bottom three categories (never, rarely, and once) account for 42% of respondents. About a third (35%) reported using history two to four times during the semester, and the remaining 23% use history five or more times. Some professors reported using history in multiple ways while others reported only one. The most common ways reported were in lecture and reading representing 66% of responses. See Figure 3 for a sample of reasons professors gave for incorporating history corresponding to a particular instructional method.

| How History is Used | Description/Why |
|---|---|
| Mentioned during *lecture*: 36% | To compare the methods of either Fermat or Barrow to modern methods of finding tangent lines |
| Assigned outside historical *readings*: 30% | To compare the past with the present |
| *Projects* with historical component: 11% | [T]he biggest project, which I include EVERY time I teach Calc[ulus] I, is a re-enactment of the Newton-Leibniz controversy, in the form of a civil trial that the students plan for about a month and then stage in class.The project, often initially received skeptically, is almost always UNIVERSALLY acclaimed by students by the end. |
| *Discussion* on mathematics history: 10% | In discussions I give short explanations on the history and showcase where/why/how the math in their textbook was developed. |
| *Videos* about mathematics history: 8% | So students can see the evolution of concepts |
| *Papers* with historical component: 5% | To show students the history lets them know that mathematics is a dynamic subject and reinforces the idea that the concepts are most essential so they can apply Calculus to the applications that will arise in the future |

*Figure 3. Sample Responses on How History is Used*

Professors reported augmenting their instruction with history in multiple ways. One dominant theme was that of professors finding that their students were more engaged in the class and found historical ideas interesting. Similar to responses on benefits of incorporating history (item six), few professors mentioned increased understanding in response to item eight (see Figure 3). In categorizing reasons why professors use a particular method of incorporating history, we found no mention of primary historical source use.

## Findings and Implications for Future Research

Two findings stood out. First, while the majority of professors have used history in their Calculus I teaching, even more professors believe that their students would benefit from its use. This study identifies a need to assist the segment of professors who feel that incorporating history into Calculus I is important, even though they reported incorporating such history no more than once per semester. Furthermore, the majority of professors indicated a substantial interest in learning more about incorporating history. Study findings on how history is currently incorporated may assist those concerned with developing curricular supports that enhance Calculus I curriculum with history.

The second primary finding is that only 14% of professors reported increased understanding as a perceived benefit of incorporating history. It is possible that many professors viewed increased understanding as a secondary benefit of an initial benefit they reported. For instance, those that listed increased motivation (28%) may believe this increase leads to increased understanding. Another possible explanation for the low percentage of professors listing increased understanding is their lack of reporting using primary sources to teach Calculus I content. More refined studies are needed to parse out perceptions in these regards.

As further understanding of professors' perceptions on incorporating history into Calculus I instruction is established, the field of undergraduate mathematics education will be better prepared to assist those seeking to harness the potential of using history to teach mathematics. We see at least three relevant research questions for the RUME audience. How can RUME researchers develop adequate resources to assist Calculus I professors to incorporate history in meaningful ways? What are professors' perceptions of using primary historical sources to teach Calculus I? How might RUME researchers add to our knowledge of using primary sources?

Prerequisite Knowledge of Mathematics and Success in Calculus I

Lori Ogden
West Virginia University

Jennifer Kearns
West Virginia University

Nicholas Bowman
West Virginia University

*This preliminary report describes how prerequisite content knowledge is related to success in a first semester calculus course. Data collected included adaptive assessments administered in both Pre-Calculus and Calculus I, standardized test scores, prior enrollment in Pre-Calculus, prior enrollment in Calculus I, and final grades in Calculus I. Analysis revealed that (1) standardized metrics such as ACT, SAT, and placement test scores did not reliably predict students' success in Calculus I, (2) passing Pre-Calculus directly impacted students' prerequisite content knowledge which in turn led to a stronger performance in Calculus I, and (3) students lost a significant amount of knowledge between the end of Pre-Calculus and the beginning of Calculus I. Lastly, in an effort to identify how deficits in specific knowledge domains impact student performance in Calculus I, additional analysis revealed that students' ability to graph trigonometric functions was most predictive of their performance in Calculus I.*

*Keywords:* Prerequisite Content Knowledge, Pre-Calculus, Calculus I

Despite national reports calling for additional Science, Technology, Engineering, and Mathematics (STEM) degrees over the next decade, students are choosing to leave STEM programs of study, in part because of their inability to pass Calculus I (Bressoud, Camp, & Teague, 2012). Although research teams have explored reasons why students struggle with college level mathematics and some have even pinpointed specific topics for which students lack sufficient prerequisite knowledge (e.g., concept of function, composition of functions, quantitative reasoning) failure rates in Calculus I remain problematic nationally (Breidenback, Dubinsky, Hawks, & Nichols, 1992; Carlson, Madison, &West, 2015).

Mathematics instructors in higher education have been regularly contending with students who are unprepared to take college level courses. Porter & Polickof (2011) have found that as many as 20% of students at PhD granting institutions and 60% of community college students are required to take remedial courses before they are permitted to take college level courses. Although, many students have high school credit for precaclulus and calculus courses, Bressoud et al. (2012) added that students who pass high school calculus courses are not necessarily better prepared for success in college level calculus courses (Bressoud et al., 2012).

Most colleges and universities utilize some type of placement procedure with their first year mathematics students. The purpose of a placement procedure is to assess students' prerequisite knowledge and subsequently place them in a course that is commensurate with that knowledge. A land-grant university in the Mid-Atlantic Region of the United States implemented the following placement procedure for all mathematics students taking Calculus 1 during the Spring 2017 Semester. New students were placed in Calculus 1 via their ACT Math score, SAT Math score, scores on a math placement exam, or successful completion of a pre-calculus course. Regardless of this placement process, failure rates (students earning a D, F or withdrawing from the class) in Calculus 1 have remained high. The failure rates from Fall 2015, Spring 2016, Fall 2016, and Spring 2017 were 44%, 55%, 34%, and 50% respectively.

In an effort to better understand the relationship between students' prerequisite knowledge and their performance in Calculus I, this preliminary report will specifically address the following research questions:

1) How does students' prerequisite knowledge influence their success (earning an A, B, or C) in Calculus I?
2) Are students who take Pre-Calculus more likely to be successful (earning a grade of A, B, or C) in Calculus I than those who does not?
3) How do deficits in specific knowledge domains impact students' success (earning an A, B, or C) in Calculus I?

## Method

### Data Collection

Data were collected from 118 students who were enrolled in Calculus I at a land-grant university in the Mid-Atlantic Region of the United States during the Spring 2017 Semester. Forty-eight of the 118 students successfully completed the institution's Pre-Calculus Course during the Fall 2016 Semester. All 118 students took an Initial Assessment during the first week of their Calculus I course. The Initial Assessment was part of a commercial software package that uses artificial intelligence to assess the student's current course knowledge by asking him 20-30 questions open-ended questions. Students who took Pre-Calculus prior to taking Calculus I took a Final Assessment similar to the Initial Assessment in Calculus I at the conclusion of their Pre-Calculus course. Both of these assessments measured the students' level of mastery with respect to 21 knowledge domains including: Equations and Inequalities, Quadratic Equations, Rational Equations, Radical Equations, Lines, Polynomial and Rational Functions, Graphs and Transformations, Logarithmic and Exponential Functions, Trigonometric Functions and Equations. For the 48 students who completed both Pre-Calculus and Calculus I, a change score was determined. This change score was calculated by subtracting the Initial Assessment Score in Calculus I from the Final Assessment Score in Pre-Calculus. This was used to help identify which topics students did not retain between the end of the fall semester and the beginning of the spring semester. In addition to the scores from these assessments and the change score between the two assessments, the following data were also considered: standardized test scores (ACT Math, SAT Math, and Math Placement Exam) used for placement into Calculus I, prior enrollment in Pre-Calculus, prior enrollment in Calculus I (number of students repeating the course), and final grades in Calculus I.

### Data Analysis

A hierarchal regression analysis was used to explore predictors of students final scores in Calculus I, which included a final sample of $n = 83$ (removing students who withdrew from the course, or who did not have standardized test scores to report). Step 1 of the analysis included students' standardized test scores (converted to ACT units, $M = 25.92$, $SD = 2.73$), prior enrollment in Pre-Calculus (about 49% of the sample), and past enrollment in the Calculus I course (about 25% of the sample). Step 2 included students' overall performance on the Initial Assessment in Calculus I ($M = 51.49$, $SD = 20.62$). The only significant predictor of Calculus I performance from these variables was students' Initial Assessment scores, which explained about

20% of the unique variance in their Calculus I scores (see Table 1). No other predictors contributed any significant or meaningful direct impact at any step in the regression model.

*Table 1. Hierarchal regression analysis examining predictors of students' performance in Calculus I.*

| | $B$ | $SE\ B$ | β | $t$ | $p$-value | unique $R^2$ |
|---|---|---|---|---|---|---|
| **STEP 1** | | | | | | |
| Standardized Test Scores | 1.10 | .943 | .140 | 1.17 | .246 | .02 |
| Pre-Calculus enrollment | 2.32 | 5.99 | .054 | .356 | .700 | ~.00 |
| Repeating Calculus I | 1.15 | 6.58 | .023 | .175 | .892 | ~.00 |
| $F(3,79) = .461$, $p = .710$, $R^2 = .02$ | | | | | | |
| **STEP 2** | | | | | | |
| Standardized Test Scores | .720 | .580 | .092 | .846 | .400 | ~.00 |
| Pre-Calculus enrollment | -2.19 | 5.47 | -.051 | .401 | .690 | ~.00 |
| Repeating Calculus I | 1.59 | 5.90 | .032 | .270 | .788 | ~.00 |
| **Initial Assessment Scores** | **48.06** | **10.70** | **.462** | **4.49** | **< .001** | **.20** |

*Note.* Significant predictors bolded for ease of interpretation.

A follow-up analysis considered the potential for prior enrollment in Pre-Calculus to indirectly impact Calculus I performance through a direct impact on Initial Assessment scores. This analysis showed that prior Pre-Calculus enrollment was a significant direct positive predictor of Initial Assessment scores (β = .25, $p < .001$, explaining about 6% of the variance in those scores), which in turn had a significant positive impact on Calculus I Final Grades (β = .48, $p < .001$explaining about 24% of the variance); there was no direct impact of Pre-Calculus enrollment on Calculus I. As a robustness check (and to provide mean group comparisons), students who had previously enrolled in the Pre-Calculus course scored significantly higher, nearly 10% more ($n = 36$, $M = 56.34$, $SD = 20.18$) than those who had not ($n = 47$, $M = 47.76$, $SD = 20.37$), $F(1,80) = 4.42$, partial η2 = .05(and controlling for standardized placement scores, which has no impact, $p < .334$, partial η2 = .01).

Additionally, to determine a cut-off score on the Initial Assessment score for determining the odds of students passing Calculus I, a receiver operating characteristic (ROC) curve was used to determine the test's predictive utility, with area under curve $C = .751$ ($SE = .53$, 95% CI from .647 to .855, $p < .001$). A minimum score of 40% on the initial exam (sensitivity = .825, specificity = .539) was the lowest score predictive of passing Calculus I. Notably, standardized tests scores (such as ACT scores) had no predictive value in a student's odds of passing Calculus I, area under curve $C = .557$ ($SE = .072$, 95% CI from .416 to .697, $p = .389$).

Finally, as more discrete performance data was available on the Pre-Calculus students who eventually enrolled in Calculus I ($n$ = 48), we did additional analysis on their performance on specific dimensions of the Initial Assessment, as well as their Calculus I performance. First, given that these students would have taken the initial assessment twice (once at the conclusion of Pre-Calculus in December (as the final assessment in that class) and once at the start of Calculus I the following January), we compared the change scores on these two tests between students who passed Calculus I and those who did not—higher changes scores are indicative of a decline in performance on the Assessment. Overall, students who eventually passed Calculus I forgot less information on the Initial Assessment after taking Pre-Calculus ($n$ = 26, $M$ = 21.86, $SD$ = 24.18) than students who failed Calculus I ($n$ = 22, $M$ = 44.43, $SD$ = 22.45), $t$(46) = 3.33, $p$ = .002, $R^2$ = .19—students failing Calculus I had a nearly 20% higher discrepancy score between the first and second iteration of the initial assessment that those who passed the course.

For the 21 specific knowledge domains, three tests were conducted. First, we compared tests scores on each domain directly. There was a universal and significant drop in knowledge retention on all domains. The lowest drop was observed with Equations and Inequalities at 10% ($p$ = .003, $R^2$10= .05); all other domains experienced significant ($p$'s < .001) and substantial ($R^2$ ranging from .09 to .75) drops of at least 20% (Slopes) to as much as 67% (Polynomial Functions). Second, we compared change scores for students who passed Calculus I to those who failed the course. In nearly every case, students who passed Calculus I retained more information—the smallest significant discrepancy being Unit Circle Trigonometry with a 20% discrepancy, $t$(46) = 2.02, $p$ = .049, $R^2$ = .07) and the largest being Right Triangle Trigonometry with a nearly 36% discrepancy, $t$(46) = 4.14, $p$ < .001, $R^2$ = 26. Domains that did not observe significant differences in knowledge retention were Composite, Polynomial, and Rational Functions (three separate domains), and the domains of Graphing Trigonometric Functions, Inverse Trigonometric Functions, Trigonometric Identities, and Trigonometric Equations (four different domains)—the average knowledge loss for these domains was $M$ = 50.37, $SD$ = 24.38).

Finally, we used a hierarchal regression to determine which knowledge domains seemed to be most predictive of performance in Calculus I, controlling for standardized test scores. As with the earlier analysis, standardized scores had no impact on Pre-Calculus students' performance in Calculus ($R^2$ ~ .00). The collective addition of the 21 knowledge domains increased $R^2$ by about 16%—of which, nearly half was explained by Graphing Trigonometric Functions ($R^2$ = .08). Notably, significance levels were not interpreted due to the small sample size for this post-hoc analysis.

## Discussion

The analysis showed that although the institution utilized standardized metrics such as ACT, SAT, and placement test scores, these metrics did not reliably predict if a student will pass his or her first calculus course. Interestingly, the Initial Assessment that was given to all students as they entered Calculus I was a better predictor of course performance than any other predictive variable utilized. The score on the Initial Assessment explained 20% of the overall variance in the final course grade in Calculus I. In other words, students who demonstrated weak prerequisite skills began the class two letter grades behind those who exhibited a strong prerequisite knowledge base.

Since the Initial Assessment was a strong predictor of student success in Calculus I, additional analysis was used to determine a cut-score capable of predicting the odds of students passing Calculus I. The analysis revealed that students who obtained a score of at least 40% on the Initial Assessment had an 80% chance of passing Calculus I. Although 40% appears to be a low score, the overall average on the Initial Assessment was only 51.49%. The Initial Assessment has the potential to be quite valuable when assessing students' prerequisite knowledge along with students' ability to be successful in Calculus I.

Students who completed Pre-Calculus successfully were not more likely than their counterparts to be successful in Calculus I. While the analysis revealed that no connection between the two courses existed directly, it did reveal a connection indirectly. Students who passed Pre-Calculus scored higher on the Initial Assessment in Calculus I than their counterparts and subsequently students who did well on the Initial Assessment were more likely to pass Calculus I. This was a significant finding as the Initial Assessment was the only predictive variable for students' final grade in Calculus I. Thus, passing Pre-Calculus directly impacted students' prerequisite content knowledge which in in turn led to a stronger performance in Calculus I.

Furthermore, it was found that students who enrolled in Pre-Calculus had a significant decrease in content knowledge in all 21 knowledge domains between the Final Assessment in December of 2016 in Pre-Calculus and the Initial Assessment in January of 2017. Despite this loss, Pre-Calculus students still outperformed their counterparts by 10 percentage points. Furthermore, students who lost the least amount of knowledge between semesters performed significantly better in Calculus I. On average, students who failed Calculus I had a nearly 20% higher discrepancy between the two assessments than those who passed Calculus I.

Finally, in an effort to identify which prerequisite topics had the most significant impact on students' performance in Calculus I, change scores between the Final Assessment in Pre-Calculus and Initial Assessment in Calculus I were analyzed. Although, the analysis revealed that students' ability to graph trigonometric functions was most predictive of students' success in Calculus I, other interesting findings emerged. First, students retained the most prerequisite knowledge in the domain:  Equations and Inequalities (10% drop). In fact, it was the only knowledge domain with no significant knowledge drop. Second, students lost on average 67% of the content knowledge related to polynomial functions. Last, students who failed Calculus I, had a significant knowledge drop in seven out of 21 knowledge domains.

## Conclusion

It is troubling that some of the predictive metrics utilized in the institution's placement process did not accurately predict who would be successful in Calculus I. Many institutions solely use standardized tests to place students into mathematics courses. If these metrics are not providing an accurate snapshot of students' prerequisite knowledge, then perhaps colleges and universities should consider adjusting their placement procedure to include adaptive assessments such as the Initial Assessment discussed in this report.

Another concern raised in this report is the significant decrease in content knowledge between the end of Pre-Calculus and the beginning of Calculus I, only one month later. Researchers and instructors alike must find ways to mitigate this knowledge loss. These results should inform teaching decisions in pre-calculus courses especially, as students are clearly not retaining topics critical to their understanding of calculus. Lastly, it is important to acknowledge the small sample size used in this preliminary research project. Further research should be conducted to see if these outcomes are replicated in future semesters.

# Validating Proofs in Parallel Mathematical and Pedagogical Tasks

Erin E. Baldinger
University of Minnesota

Yvonne Lai
University of Nebraska-Lincoln

*Educators often use tasks that situate teachers in pedagogical contexts, under the assumptions that such tasks activate knowledge authentic to teaching; and, furthermore, purely mathematical contexts may not activate such knowledge. These assumptions are based on analyses that contrast actual engagement with pedagogical context to hypothetical engagement without pedagogical context. We propose that it is important to conduct a direct comparison of responses, and we report on such a study using a set of tasks with and without pedagogical contexts – featuring the same underlying mathematics. The results revealed differences in how secondary teachers validated proof based on context. Context also influenced the importance participants placed on algebraic notation in validating a proof. This study has implications for how and when secondary teachers attend to validity and the role of algebraic notation, and the messages they may convey to their students about validity and notation.*

*Keywords:* Mathematical Knowledge for Teaching, Proof Validation, Secondary Teachers

Many secondary mathematics teachers find their undergraduate mathematical preparation irrelevant to or disconnected from their teaching (Goulding, Hatch, & Rodd, 2003; Ticknor, 2012; Wasserman, Villanueva, Mejía-Ramos, & Weber, 2015; Zazkis & Leikin, 2010). One possible response to this problem is to embed mathematics into pedagogical contexts (e.g., Stylianides & Stylianides, 2010; Wasserman, Fukawa-Connelly, Villanueva, Mejía-Ramos, & Weber, 2016). The strategy behind this design is that situating teachers in *pedagogical tasks*, as opposed to pure *mathematics tasks*, helps activate "the mathematical knowledge needed to carry out the work of teaching mathematics" (Ball, Thames, & Phelps, 2008, p. 395). Because the work on the task resembles work done in teaching, teachers can experience ways in which mathematics applies to teaching, and thus find these experiences useful for their future teaching.

One implicit assumption underlying development efforts is that pedagogical context activates knowledge that is authentic to teaching. Furthermore, this knowledge may not be activated or perceived as relevant in pure mathematics contexts. For instance, all examples of items in Hill, Ball, and Schilling (2008) contain names of students or teachers, and the authors discussed debates of "how much to contextualize [items]" (p. 379) – not whether to contextualize items. Following a description of a task with pedagogical context, Stylianides and Stylianides (2010) concluded, "Presumably, it would be hard for a teacher educator to engage prospective elementary teachers in a discussion of such a subtle but important mathematical issue in the absence of a 'motivating' pedagogical space" (p. 168). Arguments in support of this assumption rely on analyses of teachers engaged in tasks with pedagogical context, contrasted with hypothetical cases where the pedagogical context is absent. Although the arguments are compelling and have advanced the field, there is no empirical evidence for this assumption based on direct comparisons between responses to tasks with and without pedagogical context.

We propose that it is productive to conduct such a comparison. Suppose that tasks set in pedagogical contexts do in fact activate mathematical knowledge differently than mathematical contexts. For example, if different criteria are used to determine whether or not a proof is valid depending on the context, then that may have implications for how mathematical knowledge is used in teaching. Similarly, the explanation of a mathematical idea might have different features when presented with a pedagogical context, which has implications for how that idea would be understood. Differences based on context might reveal unaddressed incoherence in teachers' mathematical knowledge. Differences might also suggest places where connecting undergraduate mathematical content to the work of teaching is particularly difficult.

We hypothesize that if there are differences in responses to tasks set in pedagogical contexts and mathematical contexts, then these differences might be explained by the norms and values teachers hold about mathematics. We base this hypothesis on the observation that different contexts, including orientations toward problem solving, can influence the norms and values brought to bear in solving tasks (Aaron & Herbst, 2012); and that different contexts can prime different knowledge on identical tasks (e.g., Gick & Holyoak, 1980; Ortner & Sieverding, 2008; Yeager & Walton, 2011). In this paper, we report on a study in which we compared 17 high school teachers' responses to parallel mathematics tasks, one situated in a pedagogical context and the other in a university mathematics context. The tasks were exactly the same except for context; see Table 1. We asked: Do teachers validate proofs based on similar norms and values when situated in teaching mathematics compared to when situated in learning mathematics? Our results are highly suggestive that contexts do elicit different orientations to mathematics, in the form of norms and values.

Throughout this paper, we use *pedagogical context* refer to contextual elements of elementary school, middle school, or secondary teaching practice contained in the task text such as student talk or curriculum materials (Phelps & Howell, 2016). In contrast we use *university context* to refer to tasks that are set in the context of an undergraduate mathematics course, and do not have contextual elements related to teaching. Distinguishing these two contexts explicitly highlights the potential differences in teachers' undergraduate mathematical preparation and the mathematical work of their teaching.

## Theoretical Perspective and Frameworks Used

Teaching decisions are shaped by orientations (Schoenfeld, 2010), which encompass norms and values. Norms refer to expectations and understandings; values refer to what is perceived as important or beneficial; both have forms specific to the discipline of mathematics (Kitcher, 1984) as well as its learning and teaching (Yackel & Cobb, 1996). The norms and values for mathematics inform those of teaching mathematics, but they are not the same (Ball et al., 2008), and priming with different contexts can potentially activate different resources (e.g., Gick & Holyoak, 1980). Consequently, mathematics teaching entails negotiating mathematical and pedagogical norms and values (Ball & Bass, 2003a, 2003b).

Since formal proof is part of secondary mathematics (NGACBP & CCSSO, 2010), a practice of mathematics learning that arises in teaching is validating mathematical arguments, including proof. The validity and communication of a proof can be contextual (Weber, 2014, 2016). Additionally, Lai and Weber (2014) found that mathematicians would improve proposed proofs differently depending on whether the proof had come from a student or a mathematician.

## Data & Method

### Rationale

To determine whether the contexts of teaching and learning would elicit different mathematical norms and values, we used parallel tasks. One task featured pedagogical context to situate the participant in teaching secondary mathematics; the other situated the participant as a student in a university mathematics course. We chose to contrast the pedagogical secondary context with a university context because the most recent and intensive context in which teachers experience proofs as learners is university. We determined that these two contexts served as productive contrasts to inform future work in teacher education.

Table 1 shows the set of tasks used to address the first research question. The university context could be considered a pedagogical tertiary context, however, we note that the task situates the participant as a student, not a professor. Moreover, responses from our participants indicate that they were reasoning from the stance of student, not university instructor.

</table>

## Data source

**Participants.** We interviewed 17 practicing secondary mathematics teachers who had 1 to 14 years of experience teaching, and who had worked with a variety of grade levels and courses.

**Tasks.** To ensure that the pedagogical context was realistic, we used existing tasks that had been extensively reviewed as representing mathematical knowledge for teaching. For the research question reported, we used tasks, shown in Table 1, based on the TEDS-M released item #MFC709 (TEDS-M, 2010), which represents pedagogical content knowledge (Tatto et al., 2008). The full study considers a second set of parallel tasks, focused on explanation.

**Protocol.** All participants answered in teaching context first and learning context second, with a distractor between contexts to prime their identity as university students. We asked participants in each context whether they agreed or disagreed with the statement, “Kate’s proof/Proof 1 is less valid because it does not use algebraic notation". This question targeted teachers' potential belief in the importance of algebraic notation in proof (e.g., Knuth, 2002).

**Analysis**. We first coded the reasons why each proof was judged valid or invalid. In the second coding, we looked for differences across context in the determinations about the proofs, their reasoning, and agreement or disagreement about the role of algebraic notation.

## Results

Clear differences emerged based on context. Table 2 shows how participants validated each of the proofs, in each context. Table 3 illustrates how participants judged the role of symbolic notation in each context. We now highlight two themes of the teachers' reasoning, and will present the remainder of our results in the full paper.

*Table 2. Number of participants determining whether proofs are valid, by context*

| | Pedagogical context | | University context | |
|---|---|---|---|---|
| | Valid | Not valid | Valid | Not valid |
| Kate / 1 | 16 | 1 | 5 | 12 |
| Leon / 2 | 2 | 15 | 0 | 17 |
| Maria / 3 | 2 | 15 | 3 | 14 |

*Table 3. Number of participants who disagree or agree: "Kate's proof is less valid because it does not use algebraic notation"/"Proof 1 is less valid because it does not use algebraic notation"*

| Pedagogical context (Kate's proof) | | | University context (Proof 1) | | |
|---|---|---|---|---|---|
| Disagree | Agree | Other* | Disagree | Agree | Other* |
| 14 | 1 | 2 | 3 | 10 | 3 |

*"Other" denotes equivocation, e.g., "If the teacher wants algebraic proof, then yes, less valid. If that's not the learning target, then it's not more or less valid." In the university context, one participant was unintentionally not asked this question, so $n = 16$ instead of 17.

### Privileged norms of communication

In the university context, teachers valued precision and clarity and privileged algebraic notation: "the algebraic notation is clearer, precise, or better than just words, and it is a skill you should have in university." One teacher's explanation of why Proof 1 was not valid, while Kate's proof was valid, captured the privileging of algebraic notation in a particularly remarkable way: "In university, you have to use mathematical reasoning not logical reasoning."

In the pedagogical context, teachers privileged words and focused on explanation: "If you can get down your idea, that's all that matters" or "Using words is important". Some teachers expressed discomfort, wondering whether it was "okay" to hold differences across context. Several teachers insisted that algebraic notation is absolutely needed at the university level, while at the same time not expecting high school students to use algebraic notation.

### (Not) Attending to the logical structure of proof

In the pedagogical context, some participants praised Maria's "good start" and stated she needed to explain her work more in order to have a valid proof; these same participants in the university context stated that the reason Proof 3 was not valid was because there was an algebraic error. In both contexts, participants implied that the proof approach would work, for instance saying, "This proof is almost correct, however it is not adequate to simply 'cancel the $n$'s'." One common theme in evaluations of this proof was ascribing validity to the *approach*, even when disagreeing with the details to the extent of calling Maria's proof/Proof 3 not valid. (In fact, the approach would only work with a much more complicated structure that considers cases by divisibility.) There was a sense among some participants that the algebraic approach would eventually lead to a valid proof, especially in the university context.

## Significance

Using a novel study design with highly parallel task sets, we contribute a striking example of how the contexts of learning and teaching may activate teachers' norms and values differently. We found that different norms of communication were privileged between the two versions of the tasks. Precision and clarity arose almost entirely only in the university context, and explanation arose almost entirely only in the pedagogical context. The teachers paid explicit attention to algebraic notation, for merits of precision and clarity and because "that's what university professors expect"; teachers at times turned a blind eye to algebraic notation in the pedagogical context, professing that they would be impressed with Kate's work. This contrast raises the issue of how and when secondary students learn to attend to algebraic notation, and what messages teachers send about algebraic notation. Using tasks in varying contexts, especially featuring the same underlying mathematics, can elicit tensions between norms and values about mathematics so that they can be problematized to benefit teachers' use of mathematics in teaching as well as their identities as doers of mathematics.

## Questions for the Audience

This preliminary work has helped us shape several questions that we intend to discuss during our RUME presentation. In the presentation, we plan to share a sample of participant work, and discuss how it might change our thinking about approaches to teacher education. We then ask:

1. How compelling is the framing of the problem?
2. We used references from cognitive science to substantiate our hypothesis (that differences in responses to tasks can be explained by differences in norms and values held by teachers in pedagogical and university contexts). Are there results in mathematics education that make an equivalent point or a related point?
3. What are productive strategies for engaging with these data that attend to differences in reasoning across parallel tasks?

Self-Regulation in Calculus I

Carolyn Johns
The Ohio State University

*Improving STEM retention is a major focus of universities and studies have shown calculus to be a barrier for STEM intending students. Prior to this study, local data indicated students did not pursue STEM fields because they were not passing calculus. In this work, I report on the results of a study on factors that seemingly impacted student success in Calculus I. In particular, I examined the relationship between final grades and self-reported self-regulatory aptitudes after accounting for incoming math aptitude. Results indicate self-regulatory aptitudes predict final grades above and beyond math aptitude. In addition, measures of self-regulation differed amongst high and under achievers as well as low and over achievers. This indicates self-regulation plays a role in student success. Furthermore, gender differences were present in measures of self-regulation which may be of importance for improving retention of women in STEM.*

*Keywords:* Calculus, Motivation, Self-Regulation

Calculus I is known to be a barrier to success for students desiring a career in science, technology, engineering, and mathematics (STEM) fields (National Academies of Sciences, Engineering, and Medicine, 2016). Recent national data shows that little more than half of students in calculus I receive a grade of an A or B and DFW rates are around 22-38% depending on the type of institution in which the course is taken (Bressoud, 2015). Of particular concern is the number of women who do not persist into calculus II with 20.1% of females switching their calculus II intention at the end of calculus I (Ellis, Kelton, & Rasmussen, 2014).

Research has correlated student self-regulation with final grades (Pintrich, Smith, Garcia, & McKeachie, 1991). In particular, recent studies have shown self-regulation measures can predict exam scores in Calculus I (Worthley, 2013) and a calculus based engineering analysis course (Hieb, Lyle, Ralston, & Chariker, 2015). This suggests that addressing self-regulation factors may be important aspects of the curriculum that could potentially improve success for some types of students. However, there is a gap in the literature regarding achievement group differences in self-regulatory aptitudes. Prior regression models indicate self-regulation predicts grades above and beyond incoming math aptitude when considering the sample as one group (Hieb, et al., 2015; Worthley, 2013). However, when classified into four achievement groups based on performance relative to the median incoming math aptitude and median final grade (see Figure 1), it is not known if achievement groups report the same type of self-regulation.

Furthermore, it remains unclear what role gender may play in the relationship between self-regulatory aptitudes and final grades in Calculus I. Prior studies have shown gender differences among self-regulatory aptitude measures (Pintrich & DeGroot, 1990; Zimmerman & Martinez Pons, 1990). In addition, although prior studies have shown aspects of self-regulation impacts success after taking into account incoming math ability, there is a gap in the literature regarding if a model of success for males would differ from a model for females. Better understanding of differences in performance according to gender and achievement groups can aid in designing interventions that cater to specific student populations. To address these gaps in the literature, three main research questions guided data analysis for the current study:

1) Are gender differences present in self-reports of self-regulation among students enrolled in Calculus 1?
2) Is there a relationship between final grades and self-regulation according to gender?
3) How do achievement groups differ in their self-reports of self-regulation?

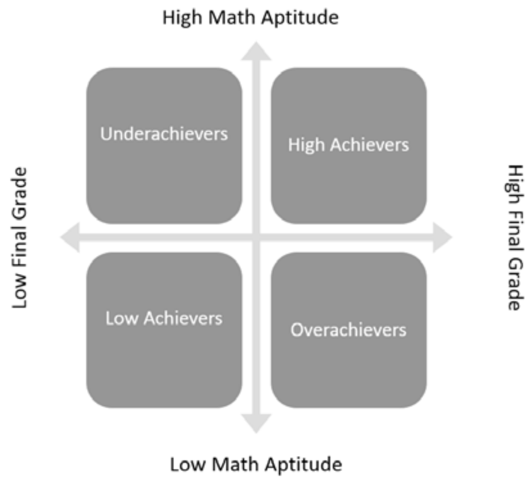

*Figure 1. Achievement groups*

**Theoretical Framework and Literature Review**

Broadly, self-regulation involves setting a standard or goal, monitoring progress toward the goal, controlling oneself to make adjustments if needed, and reflecting on one's performance (Pintrich, 2004). Self-regulation is rooted in social cognitive theory, examining reciprocal interactions between the individual, their behavior, and their environment (Zimmerman, 1989). For example, Pintrich and Zusho (2007) argue classroom contexts such as academic tasks and instructor behavior impact students' self-regulatory processes which in turn impacts student outcomes.

This study draws upon Pintrich and Zusho's (2007) and Pintrich's (2004) frameworks for self-regulation. Pintrich and Zusho's model places self-regulation within the context of the classroom. They argue students' personal characteristics and the classroom context impact students' motivational and self-regulatory processes. While some self-regulation models consider motivation to fall under self-regulation, Pintrich and Zusho distinguish motivational processes apart from self-regulatory processes. They argue motivation only becomes self-regulatory when there are active attempts to monitor and control motivation. In Pintrich and Zusho's model, motivational and self-regulatory processes then affect student outcomes. The outcomes then feed back into the model to impact future classroom context, motivation, and self-regulatory processes. According to Pintrich and Zusho's model, interventions to alter the classroom context could lead to changes in motivational and self-regulatory processes. However, it must first be understood which motivational and self-regulatory processes are impacting outcomes.

Pintrich's (2004) framework provides a means of examining motivational and self-regulatory processes within categories. In his framework, Pintrich (2004) places motivational processes under the umbrella of self-regulation. Pintrich classifies self-regulation as occurring in four areas: cognition, motivation, behavior, and environment. In addition, he considers self-regulation to occur over four phases: forethought and planning, monitoring, control, and reflection. While Pintrich acknowledges that self-regulation does not necessarily occur linearly through the phases and some aspects of self-regulation don't neatly fit into one area, thinking of self-regulation in terms of phases and areas does allow for distinction among self-regulation processes.

Pintrich's (2004) framework stems from his work developing the Motivated Strategies for Learning Questionnaire (MSLQ). The MSLQ is a questionnaire designed to measure students' course specific self-regulatory aptitudes (Duncan & McKeachie, 2005). The MSLQ has 15 subscales which Pintrich (2004) later mapped onto his classification framework.

In recent years researchers have used the MSLQ to consider the role of self-regulation in success among calculus students. In particular, some studies have attempted to utilize models that predict student success in calculus considering variables such as self-regulatory factors. For instance, Worthley (2013) and Hieb, et al. (2015) used subscales of the MSLQ in their models. Worthley found MSLQ subscales of test anxiety and self-efficacy for learning and performance were good predictors of first midterm grades when combined with math placement test results. Hieb, et al. found that of the select MSLQ subscales administered to their subjects, time and study environment management, internal goal orientation, and test anxiety were good predictors of exam scores. These studies indicate self-regulatory factors play a role in student success and should be examined in more detail.

Furthermore, studies have shown males and females differ in their mathematics interest and self-efficacy beliefs as early as middle school (Pajares, 2005) and the trend continues into college (Pajares & Miller, 1994). In addition, females maintain higher test anxiety than males (Hong, O'Neil, & Feldon, 2005; Pajares & Miller, 1994). Considering these results, it seems plausible that different gender groups may need attention on different areas of self-regulation. Thus it is necessary to examine whether the impact of self-regulation aptitudes on grades vary by gender.

## Method

### Participants

All autumn 2016 Calculus I students at a large Midwestern university were invited to participate in the study. Of the 2539 students enrolled in the course on the 15$^{th}$ day of class, 603 consented to have their data be used in research. Among these 603 students, 29 withdrew from the course. Of the 573 remaining students, 36% (*n* = 149) of students had missing data leaving a complete data set for 424 students.

### Measures and Procedure

The Calculus Concept Readiness (CCR) assessment (Carlson, Madison, & West, 2015) was administered to students during the first week of the academic semester. The CCR was used as measure of students' conceptual preparedness for calculus. In addition, the CCR provided an incoming math aptitude measure taken at the same time-point for all students. Students' ACT and SAT Math scores were collected from the university's database system. For students with no ACT Math score their SAT Math scores were converted to ACT Math equivalent scores (Dorans, 1999). In order to create a single composite incoming math aptitude score, ACT/SAT math and CCR scores were combined. The composite math aptitude score was computed by transforming scores on the CCR and ACT/SAT math test into z-scores and then summing the scores.

Students completed 12 of the 15 Motivated Strategies for Learning Questionnaire (MSLQ) (Pintrich, Smith, Garcia, & McKeachie, 1991) subscales during the fifth week of the semester. The motivation subscales that were used were intrinsic motivation, task value, control of learning beliefs, self-efficacy, and test anxiety. The learning strategy and resources management subscales used were elaboration, organization, critical thinking, metacognitive self-regulation, time and study environment, effort regulation, and peer learning.

Final grades as a decimal percentage were collected from the university's learning management system gradebook after the semester was complete and final grades for courses had been submitted.

## Results

### Gender Differences

A multivariate analysis of variance (MANOVA) was performed to determine gender differences in MSLQ subscale scores. Using a Wilks's Lambda, there was a significant effect of gender on MSLQ subscales, $\Lambda = .800$, $F(12,411) = 8.548$, $p < .001$. The MANOVA was followed up with one-way ANOVAs. Adjusting for Bonferroni's correction, significant differences in gender were found on intrinsic motivation, self-efficacy, test anxiety, critical thinking, organization, intrinsic motivation, and time and study environment (*ps* < .004). Females reported significantly lower intrinsic motivation, self-efficacy, and critical thinking than males. Females reported significantly higher test anxiety, organization, and time and study environment structuring than males.

A hierarchical regression was performed in order to determine predictability of final course grade. Math aptitude was entered in the first step. Then all ten MSLQ subscale scores were entered in the second step via forced entry. Finally, gender was entered as the third step. In the first step, math aptitude was a significant predictor of final grades, $R^2 = .352$, $F(1,422) = 228.82$, $p < .001$. In the second step, the MSLQ subscales were added to the model and contributed a significant change in $\Delta R^2 = .136$, $F(12,410) = 9.076$, $p < .001$, for a total model $R^2 = .488$. The third step, entering gender, did not result in a significant change in $R^2$ ($\Delta R^2 = .002$, $F(1,409) = 1.534$, $p = .216$). This final step indicates that after accounting for math ability and MSLQ scores, gender does not significantly predict final grade.

In addition, a secondary hierarchical linear model was applied to determine if the same hierarchical linear model of math aptitude and MSLQ subscales to predict final grades could be used for both men and women. Comparing the fit of the models using Fisher's Z-test ($z = 1.45$, $p = .147$) and the structure of the models using Steiger's Z, ($Z_H = -2.11$, $p = .034$) the same hierarchical linear model can be used for both men and women ($R^2 = .488$, $p < .001$).

### Achievement Level Differences

In order to determine how self-regulation may differ amongst achievement groups, students were categorized into four clusters. Students were ranked according to both their math aptitude and final grade scores. Students below the median in math aptitude and final grade were categorized as low achievers. Overachievers were those students below the median in math aptitude but above the median in final grade. Students above the median in math aptitude but below the median in final grade were categorized as underachievers. Finally, students above the median in math aptitude and above the median in final grade were categorized as high achievers (Figure 1). There were 167 low achievers, 73 overachievers, 67 underachievers, and 176 high achievers in the sample.

## Results

A multivariate analysis of variance (MANOVA) was performed to determine achievement group differences on MSLQ subscale scores. Using a Wilks's Lambda, there was a significant effect of achievement group on MSLQ subscales ($\Lambda = .699$, $F(36,1209) = 4.336$, $p < .001$). The MANOVA was followed up by post hoc Hochberg's GT2 tests and confirmed with Games-Howell tests. Group differences at a $p < .05$ level are indicated in Figure 2. When comparing to low achievers the post hoc tests indicate both high achievers and overachievers have greater intrinsic motivation, task value, and self-efficacy but lower test anxiety. Only high achievers have greater metacognitive self-regulation and control of learning beliefs than low achievers. When comparing underachievers, both high achievers and over achievers have greater task value, self-efficacy, time and study management, and effort regulation. Only high achievers have greater intrinsic motivation and metacognitive regulation but lower test anxiety than underachievers. At a $p < .05$ level, no statistically significant differences were found between high achievers and over achievers or under achievers and low.

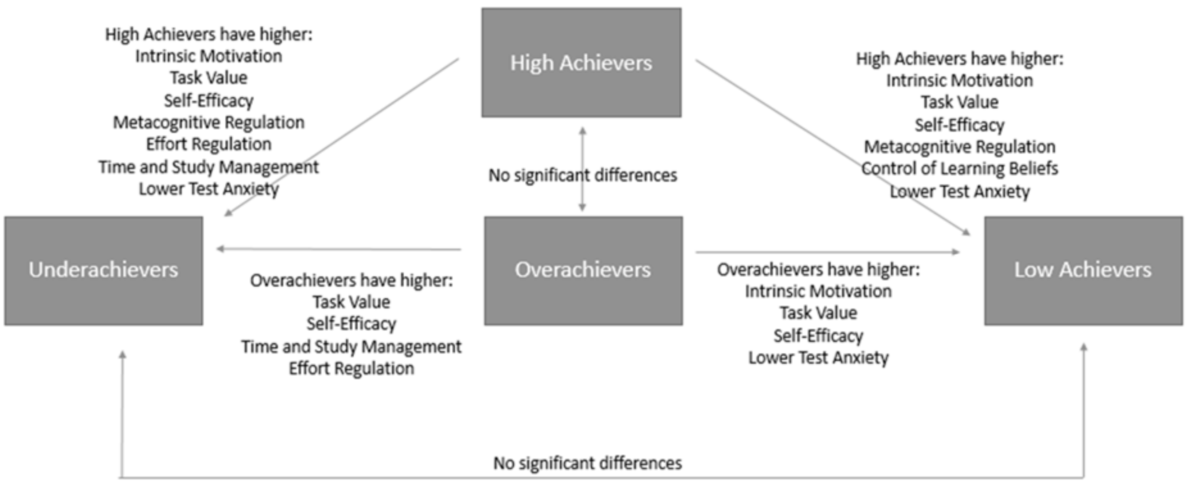

*Figure 2. Differences in MSLQ subscales by achievement group*

## Discussion

Results indicate that the CCR adds significant predictive power when used in combination with ACT/SAT math scores. Combined, these scores can account for 32% of variance in final grades. In addition, adding MSLQ measures of self-regulation, the model accounts for 48% of variance in final grades. This indicates that self-regulation attributes are important for success in calculus I. Incoming math aptitude and pre-requisite knowledge is not enough to ensure success.

Results show self-regulation predicts final grades the same in males and females. However, females reported lower intrinsic motivation, self-efficacy, and time and study environment management, as well as higher test anxiety than males. This indicates addressing motivation and self-regulation for females may be important to retaining females in STEM.

In addition, differences in MSLQ scores amongst achievement groups indicate different populations have different self-regulatory needs. While both high achievers and underachievers came in with above median math aptitude, underachievers ended the course with a grade below the median. Differences in self-regulation may account for the underperformance of underachievers as these students differed significantly on several MSLQ subscales compared to high achievers. Furthermore, low incoming math aptitude does not necessarily doom a student to failure. Self-regulation may again play a role as overachievers and low achievers scored significantly differently on several MSLQ subscales. Data indicates addressing self-regulation in low and under-achievers may promote success in calculus.

Cognitive Resources in Student Reasoning about Mean Tendency

Kelly Findley
Florida State University

Jennifer Kaplan
University of Georgia

*The ability to conceptualize the sample mean as having a distribution is essential to the development of statistical reasoning. Considerable research on student thinking exists on this topic, but this literature largely assumes a misconception model. This study takes a grounded theory approach to investigate the cognitive resources incoming students possess to reason about sampling distributions and mean tendency. This preliminary report includes data from a pilot study with one student enrolled in an introductory statistics course. She completed both a pre- and post-instruction interview that involved prompts about the distribution of the ages of pennies in circulation and related questions about average ages of groups of pennies. We identify several cognitive resources elicited by the pre- and post-interviews, consider the influence of instruction on the activation of these resources, and briefly discuss implications to statistics teaching. Finally, we outline next steps for data collection with 8-10 students.*

*Keywords:* Statistics, Sampling Distributions, Resources, Constructivism

The heart of statistical reasoning in the introductory statistics course is linking the core concepts of sampling, variability, and distribution to a unified conceptualization of sampling distributions and inference (Garfield, 2002). Unfortunately, superficial knowledge of this and other central ideas results in students resorting to procedural, cookbook approaches to tasks involving statistical inference (Garfield & Ben-Zvi, 2008; Garfield & Zieffler, 2012). Sampling distributions and mean tendency have been identified as extremely difficult concepts (Chance, delMas, & Garfield, 2004; Lunsford, Rowell, & Goodson-Epsy, 2006). Through their research on student thinking involving sampling distributions, Chance and colleagues offered specifics regarding what students should understand about sampling distributions, what they should do with that knowledge, and common misconceptions they may hold. Many pieces in the literature on this topic have aligned with a misconception framing (e.g., Posner, Strike, Hewson, & Gerzog, 1982) and view learning as adoption of expert thinking and replacement of novice thinking (e.g., delMas, Garfield, & Chance, 1999; Garfield, Le, Zieffler, and Ben-Zvi, 2015; Sotos, Vanhoof, Van den Noortgate, and Onghena, 2007).

This study takes a different perspective by seeking to identify cognitive resources students apply to reason about mean tendency. Smith, diSessa, and Roschelle (1993) define *resources* as designating "any feature of the learner's present cognitive state that can serve as significant input to the process of conceptual growth" (p. 124). Resources may be visualized as "knowledge-in-pieces," representing fine-grained intuitions drawn from experiences and activated in multiple contexts where the learner identifies potential connection (diSessa, 1988). We seek to identify resources students use to reason about mean tendency before formal instruction and how resource activation is influenced by formal instruction. Our research questions are as follows:

1) What cognitive resources do students activate when reasoning about mean tendency?
2) How does formal statistics instruction influence student activation of resources on these topics?

## Conceptual Framework

The statistics education literature has traditionally framed novice reasoning about probability and sampling distribution in terms of misconceptions (e.g., ASA, 2016; Cohen, Smith, Chechile, Burns, & Tsai, 1996; Garfield & Ahlgren, 1988; Kahneman, Slovic, & Tversky, 1982; Sotos et al., 2007). *Misconceptions*, as defined by Sotos and colleagues, may represent "any sort of fallacies, misunderstandings, misuses, or misinterpretations of concepts, provided that they result in a documented systematic pattern of error" (p. 99). Misconceptions may be defined to represent any number of ideas, but, a misconception framing has implications on how we view learning, and thus how we define effective teaching. This framing suggests that students have incorrect, stable conceptions of statistical ideas under what Hammer (2004) would term a "unitary" model. In contrast to a unitary model, Hammer suggests we view learners as possessing a "manifold" model that is more fine-grained. Within a manifold model, we will see students applying various resources to arrive at conceptions and conclusions. We view these two alternative perspectives not necessarily as looking at different mountains, but often as looking at the same mountain from different sides. A unitary model tends to look at the outcomes and conclusions the learner makes by synthesizing cognitive resources, while the manifold model searches for starting places and seeks to isolate the learner's cognitive resources.

Some research on student misconceptions suggests that effective instruction involves "confronting" or "eradicating" these misconceptions (e.g., delMas et al., 1999; Eaton, Anderson, & Smith, 1984). For example, delMas and colleagues found it was beneficial to present students with an anomaly to help them understand the Central Limit Theorem (CLT). The researchers modified their simulation program to encourage students to compare predictions with the actual shape of the sampling distribution. While such strategies may have resulted in students accepting the CLT as a fact, it is difficult to ascertain whether students in the study restructured their knowledge cognitively to develop deep and lasting understanding of the CLT.

In his study on student reasoning about probability with dice, Pratt (2000) took a resource perspective. He noted that resources may be contextually appropriate (e.g., the more data we collect, the more stable the results will be) or inappropriate (e.g., the next observation will be 'random' because I cannot steer or control the result). He noted the contextually inappropriate resources were based on short-term, "local" observations that emphasized randomness and unpredictability. The appropriate resources were founded in long-term "global" observations and recognition of probabilistic patterns. Pratt's work contributed to research on children's understanding of probability, but has remained relatively undeveloped in understanding college students' reasoning regarding statistical inference. We intend to work towards that goal.

## Methods

### Setting

This study is ongoing and taking place at a large public university in the southeastern United States. The target population is students enrolled in introductory applied statistics courses for non-majors. This preliminary report discusses findings from a pilot study with a sophomore Biology major at the university. Karen (pseudonym) was enrolled in a small introductory statistics course for Biology majors and reported having limited high school exposure to statistics content. The instructor of her college course was a Chinese teaching assistant enrolled in the Ph.D. program in statistics, in his third semester of teaching this course.

**Data Collection**

Data include a 20-minute pre-instruction and 30-minute post-instruction interview with Karen, field notes from the first author's observations of the class periods, and two interviews with the instructor. All interviews were video recorded and transcribed, and hand-written work from Karen's interviews were also kept as data.

In each of the interviews, Karen was provided with an x and y axis template and asked:

> Think about the age of pennies in circulation, like pennies in cash registers or people's money wallets and purses. What is the range of penny years that we would see in circulation? Draw a line to represent how many pennies you would expect there to be across the range of penny years.

Karen was also asked:

> Now think about if we were to take 5 pennies randomly from circulation and find their average age. If we repeatedly did this and collected a list of 5-penny averages, then what would be the range of averages we would see? Draw a line to represent how many of each average would we see.

The third prompt was a variation of the second prompt with 25 pennies instead of 5. The interviewer (first author) asked clarification questions and probed Karen's reasoning during the interviews. Karen answered the same prompts in both interviews.

The instructional period of interest spanned from the introduction to distributions through the end of instruction on the Central Limit Theorem. Field notes from observations focused on the kinds of tasks students completed and the knowledge that was privileged. Interviews were completed with the instructor to capture both reflections about his instruction and his perceived goals for students. These interviews served to triangulate observations and limit bias in the first author's account of the events taking place in class.

**Methods of Analysis**

We take a grounded-theory approach to identify resources and search for links between formal instruction and student reasoning after instruction. To answer our first research question, we examined the pre-instruction interview for resources by identifying specific statements Karen made and relating them to more general kinds of reasoning (e.g., "I think a larger sample will buffer out the line" was interpreted as "more data means more accuracy"). We tagged spots that were ambiguous, often representing points when Karen's conceptual structure of distributions and mean tendency was potentially underdeveloped or self-contradicting. Using NVivo software, we applied general codes to interview statements and identified three resources.

To answer the second research question, we open-coded Karen's pre-instruction interview, focusing first on the elements of distribution to which Karen attended and the order to which she attended to those things (e.g., the range, the center/middle, the height, the extremes, etc.). We consulted the characteristics from Arnold and Pfannkuch (2015) to guide our organization of these elements. The post-instruction interview was coded in a similar fashion. We compared and contrasted Karen's reasoning before and after instruction to understand how the instruction influenced her reasoning. We also attempted to link elements of the instruction to reasoning approaches and explanations Karen provided in the second interview. We created a causal network diagram to relate Karen's reasoning before and after instruction through elements of the instruction and to synthesize these connections.

Throughout the process, we consulted tactics for generating meaning from Miles, Huberman, and Saldaña (2014). For example, we began the analysis by coding to look for patterns and themes, we clustered and partitioned codes, made comparisons and contrasts across Karen's pre and post interview, subsumed particular statements from the interviews into potential resources, and worked to make conceptual coherence of Karen's reasoning.

## Findings

Figure 1 shows Karen's drawings for the population distribution (on the left) and the sampling distribution for n=5 (on the right).

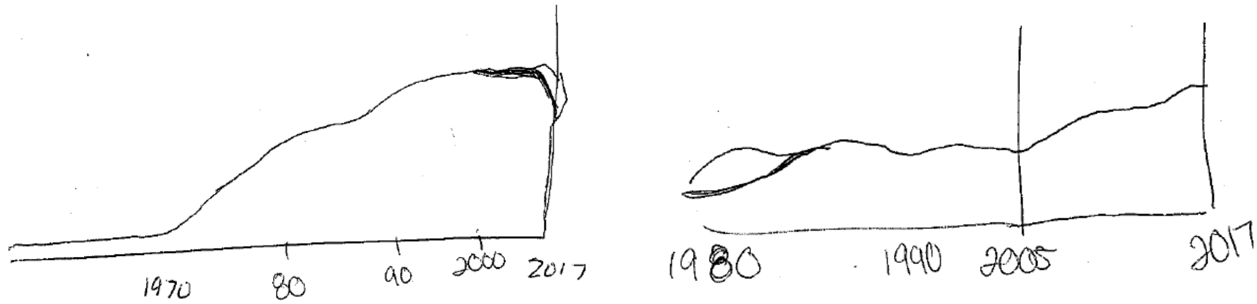

Figure 1. Karen's pre-interview drawings for the population and for sampling distribution with n=5.

### Resources

**Average is middle.** This was the first resource Karen used as she reasoned about the second prompt. She fabricated a likely sample she could imagine pulling from her change purse and thought about the average of that sample: "Let's say you get 5 that are like 1980, 1987, 1992, 1997, and then 2005, then it would be like, the average between that, so, like somewhere around 1993." This resource served as a starting point for reasoning about individual sample means, but was no longer activated when reasoning about the shape of the sampling distribution.

**The sample will resemble the population.** Karen said the following while drawing the sampling distribution for n=5: "Shapewise, [the population and sampling distribution are] not too different, like I have the lower down here and then it increases over time, and then it's kind of like a dip." In this description, Karen recognizes a relationship between these two distributions. What she is noting is a similarity in shape, with the sampling distribution (in her view) being a smoother, slightly flatter version of the population.

**Larger sample will produce more consistency.** This resource was activated as she continued to reason about the second prompt, and again as she reasoned about the third prompt with n=25. "I feel like this [the population distribution] would be less…like consistent than this [sampling distribution for n=5] would be, I feel like this [sampling distribution for n=5] would be not straight but straighter of a line." When reasoning about the distribution of sample means from even larger samples, she said, "if you take 1000 pennies, if there's not that many outliers, or if it's like evenly, dispersed number of years I guess, it would kind of make it a flatter line." She also mentioned penny averages being "more likely to change" when coming from small samples, thus viewing sample size as a sort of weighting component to variability in the mean.

### Two Resource Perspectives

In trying to make sense of the path of reasoning that Karen took, we identified two perspectives of reasoning. The first perspective focuses on the individual pennies and the influence of the population on the samples. This perspective was used frequently in early statements as Karen reasoned about individual pennies that could plausibly be in a sample she took from her change purse. The resources associated with this perspective were "the sample will resemble the population" and "average is middle."

The second perspective focuses more on abstract patterns. When Karen was asked to reason about larger samples, she shifted to thinking about "larger sample means more consistency." As a result, Karen believed there was a correct answer that the sampling distribution shape was approaching. Because she could no longer reason about specific plausible samples, she resorted to this more abstract resource.

**Instructional Influence on Karen's Activation of Resources**

Consistent with a constructivist perspective on learning, we view Karen's pre-instruction reasoning as representing an existing conceptualization of the relevant statistics content. Even though this knowledge structure was inconsistent and flexible, we do not believe Karen's conceptualization was a "blank slate" ready to receive and adopt correct knowledge structures. We view the formal instruction as a filter on Karen's reasoning and resource activation. Such a framing is neutral: the filter can be beneficial by refining, challenging, or introducing new resources, but this filter can also be detrimental by discouraging resource activation and promoting rote memorization with no deeper conceptual connection.

As she began to reason about the sampling distribution in the post-instruction interview, Karen frequently activated the resource that "average is middle." She pulled heavily on the Central Limit Theorem as evidence for why averages cluster in the middle, but as a definition absent of cognitive conviction. When probed to compare her initial interview drawings to her current ones, Karen recalled the previous resource of "larger samples produce more consistency" and her belief that larger samples will "buffer out" the sampling distribution to a flat line. At this point, Karen struggled to reconcile these seemingly contradicting resources. At the close of the interview, she questioned whether there might be a distinction between a frequency distribution and a probability distribution. Overall, Karen had not radically changed her thinking; she instead appeared to be suppressing a key resource, "larger samples produce more consistency," because it did not align with what she learned in class. "Average is middle," however, could still be aligned with the instruction.

## Implications and Future Work

On the surface, it is easy to miss that Karen did not cognitively adopt the Central Limit Theorem. Instead, it was a fact that she could articulate. While she attempted to justify it with one resource she had, she suppressed other resources with the potential to do so. If this pattern can be generalized, it is possible Karen might no longer attempt to reconcile future statistical content with her other resources when such a conflict exists and, instead, resort to a "cookbook" approach to statistical inference. Therefore, arming instructors with a list of relevant resources rather than a list of common misconceptions might lead to more cognitively robust reasoning and avoid leading students to a "cookbook" approach to statistical inference.

In the fall, we will conduct interviews with 8-10 students as we attempt to test and refine the resources we identified, search for others, look for negative cases, and make if-then tests about student reasoning in the instruction. Students will be pooled from a large-lecture introductory course, and students will again be interviewed before and after relevant instruction.

## Audience Questions

- Are there papers we are not aware of in the statistics education literature that take a resource framing of learning?
- In looking at our evidence, do you agree with the resources that we have identified?
- Are there benefits to still identifying misconceptions in student thinking on this topic?

# Exploring the Pedagogical Empathy of Mathematics Graduate Teaching Assistants

Karina Uhing
University of Nebraska - Lincoln

*Mathematics graduate teaching assistants (GTAs) are an important part of the mathematics education community. Recently, there has been a concentrated effort to better understand GTAs' pedagogical beliefs and teaching practices. The purpose of this study is to explore how GTAs would respond to student feelings and if their feedback to student questions can be characterized as attending to emotion. Data was collected through interviews of current GTAs in which participants were shown samples of student work and asked to respond to questions about that work. Preliminary analysis has revealed varying abilities of GTAs to express student feelings.*

*Keywords:* Graduate teaching assistants, students, empathy, emotion

Learning mathematics is an emotional experience for students (Hannula, 2002). Many studies have focused on the role of student affect in learning mathematics. However, little attention has been given to the relationship between teachers and student affect (Philipp, 2007). At the collegiate level, both emotional reactions and interpersonal relationships between teachers and students have been shown to influence what is learned in the classroom (Lowman, 1994).

Often, graduate teaching assistants (GTAs) play a large role in the instruction of lower level undergraduate mathematics courses (Speer, Gutmann, & Murphy, 2005). As a result, GTAs have opportunities to interact with a variety of students on a day-to-day basis and develop interpersonal relationships with them. These interactions likely influence GTAs' identities as teachers and shape their teaching philosophies (Kung, 2010). However, little is known about GTAs' teaching experiences and only recently has the mathematics education community begun to study their development as teachers and potential future faculty members (Kung, 2010; Speer et al., 2005).

This study seeks to add to the growing body of information about mathematics GTAs' pedagogical beliefs and teaching practices by investigating the awareness of GTAs to student feelings using a qualitative research design. The purpose of this study is to explore how GTAs would respond to student feelings and if their responses to questions can be characterized as attending to student emotions. With this in mind, our central research question is: *What are the characteristics of the responses that GTAs have to student questions on a typical pre-calculus problem?* To help refine our focus, we also pose the following two sub-questions:

1. Given sample written work on a typical pre-calculus problem, what feelings might GTAs attribute to students?
2. How might GTAs take student feelings into account when answering student questions?

After providing a brief summary of relevant literature, we give a detailed description of the methods that were used for this study and the data that was collected. Findings from preliminary analysis are also included, followed by some discussion and areas of future work.

## Literature

The basis for this study is found in three key areas of literature: the role of emotions in learning, the relationship between teacher affect and student affect in mathematics education, and the importance of empathy and caring in undergraduate mathematics education.

The process of learning is complex and involves both cognitive and affective factors. In particular, emotions have an effect on student learning and "the teacher has a significant role to play in shaping those emotions" (Mortiboys, 2012, p. 2). Many educational studies have discussed the role of two different types of knowledge needed for teaching: content knowledge and pedagogical knowledge (Grossman, Wilson, & Shulman, 1989; Ball, Thames, & Phelps, 2008; Shulman, 1987). However, Mortiboys (2012) contends that teachers should develop and employ a third type of knowledge, which he terms "emotional intelligence," in order to enhance teaching and address the needs of their learners. Thinking of learning as only a cognitive process deemphasizes the central role of emotions in decision making and learning. Teachers must be able to use emotional intelligence to acknowledge and address the emotions that their students feel while learning (Mortiboys, 2012).

In recent years, neuroscience researchers have found that interconnected neural processes support both emotion and cognition. In fact, it is "impossible to build memories, engage complex thoughts, or make meaningful decisions without emotion" (Immordino-Yang, 2015, p. 18). To better understand the relationship between emotions and learning, Hannula (2002) developed a framework to analyze a student's attitude towards mathematics using the psychology of emotions as a foundation. This framework separates attitudes into four evaluative processes:

> 1) the emotions the student experiences during mathematics related activities;
> 2) the emotions that the student automatically associates with the concept 'mathematics';
> 3) evaluations of situations that the student expects to follow as a consequence of doing mathematics; and 4) the value of mathematics-related goals in the student's global goal structure (Hannula, 2002, p. 26).

With respect to this study, we will focus on the first part of this framework, which attends to the emotions that students experience while working on math problems. Whereas the framework was analyzed from the perspective of a student, we aim to explore how the framework might be viewed from a GTA's perspective and how the responses of a GTA might take into account the initial process of the framework when interacting with students. In addition, we also explicate the relationship between feelings and emotion. Hansen (2005) defines feelings as conscious perceptions used to describe emotions. Because feelings are perceivable and can be articulated by the individuals who experience them, we use this term for discussing student displays of emotion. We also define pedagogical empathy as "the ability to express concern and take the perspective of a student" in accordance with the definition of teacher empathy given by Tettegah and Anderson (2007, p. 50).

In the math education literature, few studies have specifically addressed the intersection between teachers and affect (Philipp, 2007). However, it has been noted that, "all research in mathematics education can be strengthened if researchers will integrate affective issues into studies of cognition and instruction" (McLeod, 1992, p. 575). With respect to math education, the affective domain has been described as encompassing the beliefs, attitudes, and emotions of both students and teachers (McLeod, 1992; Philipps, 2007). In a summary of studies focusing on teacher affect and student affect in mathematics education, Philipp (2007) acknowledges that he knows of no research linking teachers' affect to their instructional decisions. Furthermore, he does not mention any research that connects teachers' responses to student affect.

Although there is limited research connecting teachers' responses to student emotions, previous studies have been conducted which highlight the importance of caring and empathy in higher mathematics education. Weston and McAlpine (1998) present a study where six math professors' characterized as outstanding teachers were interviewed to explore their views on teaching and learning. The most prominent teaching theme that emerged from the interviews was the importance that the professors placed on caring and concern for students. In their paper, the authors include suggestions of how to help teachers become more aware of having an "intentional caring perspective" which in turn, relates to developing pedagogical empathy. One recommendation they provide is to have professors engage in reflection upon their own experiences as learners in order to "recognize the importance of caring as part of the learning process" (Weston & McAlpine, 1998, p. 154).

In another study, Duffin and Simpson (2005) examine the link between cognitive styles and higher levels of cognitive empathy in graduate teaching assistants. As part of their study, the authors interviewed thirteen mathematics PhD students to explore their cognitive style of responding to learning new mathematics. During the interviews, many of the participants unexpectedly brought up experiences with teaching undergraduate students, which prompted the authors to consider the relationship between cognitive style and cognitive empathy. From the data, three levels of cognitive empathy emerged showing increasing levels of understanding how students might struggle with mathematics. These levels of cognitive empathy were then compared with the cognitive styles of the graduate students (Duffin & Simpson, 2005).

While it is apparent from the literature that there is a natural connection between student and teacher affect and that addressing emotions and feelings in the classroom is essential to student learning, this area has been understudied. Our study aims to help fill this gap and provide a qualitative way to capture pedagogical empathy.

## Data and Methods

The participants in this study were 14 mathematics GTAs at a large Midwestern university. Each GTA had at least one semester of experience as an instructor of record for a pre-calculus class. Data was collected during the 2016-2017 school year through structured interviews with the GTAs. Participants selected their own pseudonyms and are used below. During the interview, participants were asked to solve a typical pre-calculus problem in order to familiarize them with the problem. They were then shown five different samples of student work for the problem and asked to respond to questions about the work. The samples of student work were fictitious examples of actual student work based on the author's experiences as a pre-calculus instructor. Student questions about the work were presented through audio recordings intended to simulate an actual student asking the question. At the end of the interview the participants were asked to reflect on how they thought each student might have felt when working on the problem. Participants were also provided with a list of feeling words to use a reference during this part of the interview. After data was collected, select interviews were transcribed and analyzed using open coding.

## Preliminary Findings

By conducting this study, we aimed to find overarching themes related to the nature of responses that GTAs have while helping students in a pre-calculus class. Many of the responses to interview questions focused on helping students develop either procedural or conceptual math knowledge. However, several comments about student feelings surfaced during the interviews, even before being prompted by the interviewer to think about what feelings students might be experiencing in certain situations. In a few notable cases, GTAs were unable to articulate possible student feelings using descriptive feeling words. These responses were categorized under the code "Non-feeling" and were common among only a few participants. Table 1 shows the primary codes that have emerged from the interviews along with representative excerpts from the interviews. These codes help to categorize the characteristics of GTA responses.

*Table 1. Characteristics of GTA Responses*

| Code | Description | Interview Excerpt |
|---|---|---|
| Procedural Math Knowledge | Responses involving procedures, algorithms, rules, or formulas that do not directly attend to conceptual ideas | "If I plug in 25,000 students, do I get out the 13,000?" |
| Conceptual Math Knowledge | Responses connected to underlying concepts of math content including discussion of abstract ideas or relationships | "What sort of function are we trying to come up with here?...Think of the function as a machine." |
| Student-centered Reflection | Evidence of reflection centered around student thinking or past experiences with students, but not directly related to student feelings or emotions | "I think it's important to teach them how to identify their own mistakes." |
| Instructor-centered Reflection | Evidence of self-reflection that is centered around the participant, rather than students, including personal beliefs | "I would look through all of it…so that I'm prepared when something goes wrong." |
| Student feelings or emotions | Anything about what a student might be feeling or anything related to emotions that students might experience | "It's less that they don't know the math and more sort of fear or being uncomfortable with story problems." |
| Non-feelings | Use of words that are unrelated to emotions to describe what a student might be feeling when specifically prompted | "They probably feel medium." |

## Discussion and Future Work

The characteristics listed above help answer the central research question by classifying the types of responses that were common among GTAs. Both procedural and conceptual knowledge was a central focus for most GTAs. However, it is also important to note that GTAs also used both student-centered and instructor-centered reflection during their interviews when responding to student questions. In addition, the presence of potential student feelings or emotions was also brought up by many of the GTAs, although only some of them were able to express those feelings clearly.

Further analysis is ongoing to identify common feelings that GTAs might attribute to students. A few of the feelings that were mentioned in interviews included fear, confusion, uncertainty, and confidence. From the preliminary analysis, it is evident that the GTAs who participated in this study were aware of the potential for student feelings to arise when working on a math problem, but varied in their ability to express those feelings. For example, one GTA, James, found it difficult to attribute emotions to students:

*James*: I guess I have a hard time ascribing emotion to people as they're working on math problems. That's not something I really consider too much.

However, there were other GTAs who were able to articulate student feelings. In addition, a couple of these GTAs mentioned how taking account of student feelings was something that they already did when answering student questions:

*Nicole*: I think that's something that I do think about when a student asks me a question, like where they are not only mathematically but also emotionally.

*Aubrey*: I try to think on the spot about how they're feeling and look at people's faces…I try to pay attention to how they're feeling.

This preliminary analysis of the data has revealed differences between the abilities of the GTAs to describe and account for possible student feelings. These differences provide a rich area for further analysis of the data that has already been gathered, the results of which we hope to present at the conference. In addition to presenting further analysis of the data, we also look to ask the audience a few central questions to help us better answer the research questions.

**Questions for the Audience:**

Within the field of GTA professional development (PD) there is a great deal of anecdotal experience. We wish to check our data to see if it is representative of the experience of others who provide GTA PD. To this end, we intend to ask the audience:

- In your experience, working with both instructors and students, are there characteristics of responses to student questions that are missing?

These interviews provide a rich set of data on GTA responses to students. However, the data did not provide an answer to our second research sub-question: How might GTAs take student feelings into account when answering student questions? To help direct future avenues of research, we also intend to ask the audience:

- What data, or analysis, would you recommend we collect in order to better answer research sub-question 2?

Finally, neither the research questions nor the data collected directly address the content of professional development programs for GTAs. Nevertheless, we are interested in how PD activities can better incorporate aspects of pedagogical empathy. To this end, we intend to ask the audience:

- How can the findings from this research study be incorporated into professional development activities for GTAs?

Existing literature shows the value of empathy in the classroom. However, the existing literature does not address how that empathy is developed or expressed in the collegiate mathematics classroom. This study has begun to outline some characteristics of empathetic interactions that might exist in the classroom. Further research should expand upon these characteristics and help connect experiencing pedagogical empathy with communicating that empathy to students.

# Physics students' construction of differential length vectors for a spiral path

Benjamin P. Schermerhorn
University of Maine

John R. Thompson
University of Maine

*As part of an effort to examine student understanding of non-Cartesian coordinate systems and differential elements related to vector calculus, we interviewed students using tasks similar to typical electricity and magnetism problems. In one task, students were asked to calculate the change in electric potential along a spiral path, involving a common line integral. Analysis focused on conceptual understanding and symbolic expression of differential length vectors. Students were heavily drawn to the angular motion of the path through the radial electric field, often only expressing the angular component of the length vector. This contrasts with earlier work, suggesting context may distract from correct mathematical expression.*

*Key words:* Physics, Differential Elements, Vector Calculus, Multivariable

## Introduction and Relevant Literature

Students' use of vector calculus in upper-division physics is fundamental to developing an understanding of various principles in electricity and magnetism (E&M). However, the choice of differential elements in vector calculus, specifically line integration, depends on physical symmetries of electric and magnetic fields created by charged objects and current-carrying wires, respectively. As these radial and curling fields are often most simply expressed using non-Cartesian coordinates, the appropriate differential lengths differ from the Cartesian $dx\hat{x} + dy\hat{y} + dz\hat{z}$. The curved paths resulting from angular movement lead to differential length components that are arc lengths and that include scaling factors in cylindrical and spherical coordinates (*i.e.*, $dl_\theta = rd\theta\hat{\theta}$ for spherical coordinates in physics).

Additionally, line integration in physics takes on a different form than in typical mathematics courses. Line integrals having physical application are rarely solved using parametric curves (Dray & Manogue, 2003), and vector calculus in physics is typically non-Cartesian (Dray & Manogue, 1999). The high incidence of symmetry in physical situations allows students to choose a particular component of a differential length vector in a given coordinate system, rather than compute the specific dot product explicitly.

Given the different expressions of differential length elements across coordinate systems and the importance of vector calculus in E&M, we seek to investigate the following questions:

- To what extent do students understand the symbolic expressions and conceptual aspects of differential length vector elements [in non-Cartesian coordinates]?
- How do students use their understanding to construct differential length elements?

Earlier work explored students' understanding of the differential length vector absent of physics context by asking students to construct a length vector in an unconventional spherical coordinate system that we named schmerical coordinates (Schermerhorn & Thompson, 2016a; Schermerhorn & Thompson, 2016b). Current work seeks to build on this by investigating students' solving of line integrals closely related to E&M tasks. This allows insight into how aspects of E&M tasks do or do not influence students' determinations of differential elements, which informs the instruction of differential elements and coordinate systems in physics courses.

Previous work related to mathematics in E&M has sought to address students understanding of integration and differentials where the differential is a scalar element of charge or resistance

(Doughty *et al*., 2014; Hu & Rebello, 2013; Nguyen & Rebello, 2011). Research attending to student understanding of vector calculus in E&M has primarily addressed student application and understanding of symmetries associated with Gauss's and Ampère's Laws, two common aspects of an E&M course that involve a surface integral and line integral, respectively (Guisasola *et al*., 2008; Manogue *et al*., 2006; Pepper *et al*., 2012). Researchers turning to vector differential operators have explored student understanding and calculation of gradient, divergence, and curl in both mathematics and physics settings, finding student difficulty in interpreting vector fields despite excelling at calculation (Astolfi & Baily, 2014; Bollen *et al*., 2015; Bollen *et al*., 2016). Little of this work has specifically explored student understanding of the differential vector element as it appears in the non-Cartesian systems used commonly in physics.

## Theoretical Perspective

To explore students' construction of differential length vectors in more typical E&M contexts, we extend theoretical perspectives from previous work on differential length construction in the unconventional coordinate system to allow comparison between tasks. The *symbolic forms* framework (Sherin, 2001) provides insight into students' development of the structure of differential vector elements and determination of how each component is represented in the final equation, while a *concept image* analysis (Tall & Vinner, 1981) gives insight into the particular ideas and aspects to which students attend during construction.

Based on the knowledge-in-pieces model (diSessa, 1993), symbolic forms was developed to explain students construction of expressions when modeling physical situations common to introductory physics (Sherin, 2001). A symbolic form represents the combination of a symbol template and a conceptual schema. The symbol template, an externalized structure such as $\square + \square + \square$, represents the skeleton of an expression containing variables and/or numbers. A student's conceptual schema is the requisite internalized (mathematical) understanding of the role of the template. For example, if students recognized the need to sum multiple quantities that added to a larger whole, they would invoke the $\square + \square + \square$ template. The resulting template-schema pair used here is known as *parts-of-a-whole* (Sherin, 2001).

Meredith and Marrongelle (2008) adapted the conceptual aspects of symbolic forms to describe students being cued to integrate by recognizing reliance on a particular variable (*dependence* symbolic form), or the need to sum up pieces (*parts-of-a-whole)*. The ideas of symbolic forms were expanded to address calculus students' understanding of integrals, often mediated by graphical representations (Jones, 2015). Work exploring physical chemistry students' use of partial derivatives in thermodynamics found that recall mediated students' use of symbolic forms (Becker & Towns, 2012).

A constraint of a strict symbolic forms analysis is that it only yields procedurally based mathematical justifications for the symbolic arrangements and expression structure, neglecting how content understanding plays a role in why the structures or terms are needed. Importing the concept image framework (Tall & Vinner, 1981) from mathematics education rounds out the investigation of conceptual schemata. A student's concept image is a multifaceted understanding including any properties, processes, etc., a student may have about a given topic. A concept image for integration may contain area under the curve or Riemann sums (Doughty *et al*., 2014). It may also contain a specific rule such as that the indefinite integral of $nx^{n-1}dx$ is $x^n + C$, with or without a specific understanding of why that is the result. By incorporating the concept image framework, the symbolic forms analysis gains a contextual meaning associated with students elicited content understanding, which is not explicitly addressed by the conceptual schemata.

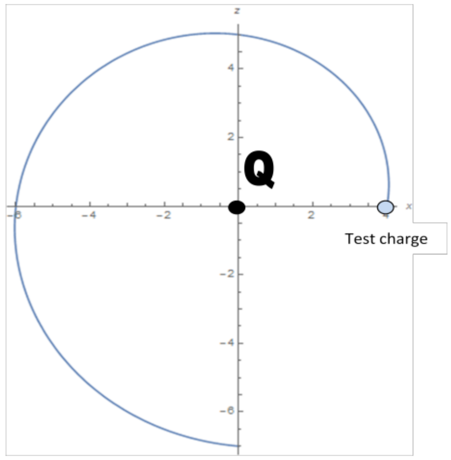

Figure 1: Image given to students, depicting the charges and spiral path of the test charge.

## Methodology

In order to investigate students' performance on typical E&M problems students were given a point charge, Q, centered at the origin (Fig. 1). Students were asked to find the differential length vector for a spiral path given by $r = 2\theta/\pi$ in the *xz*-plane and to find the change in potential experienced by a test charge as it moved along the path from the point (4,0,0) to (0,0,-7). The spiral path complicates the task since it requires two differential length components to describe it completely: $d\vec{l} = dr\hat{r} + rd\theta\hat{\theta}$. The electric field due to a point charge is a highly symmetric case where electric potential depends only on changes in the radial direction. For a typical task students only need $dr\hat{r}$ when computing this line integral. This report focuses mainly on students' construction of $d\vec{l}$ to make comparison to generic $d\vec{l}$ construction.

The task was administered in a clinical think-aloud setting with two pairs of students (B&H, D&V) and six individual students (J, K, L, M, N, O) at one university and one individual (T) at a second university. All students were enrolled in the second semester of a two-semester, junior-level E&M sequence. Pseudonyms are provided for students corresponding to their identifying letter (*i.e.,* Jake for J). This particular question took students about 10-20 minutes in interviews.

Video interview data were transcribed and analyzed using a modified grounded theory approach, with the goal of identifying student attention to *symbolic forms* and the associated aspects of students' *concept images* in line with previous findings, while additionally looking for new aspects now appearing because of the applied context. Previously identified symbolic forms include those consistent with Sherin (2001): *parts-of-a-whole*, *coefficient*, and *no dependence*; and new forms to account for the increased mathematical sophistication: *differential* and *magnitude-direction* (Schermerhorn & Thompson, 2016b). The concept images often spurring the need for these templates or necessary terms included *component and direction*, *dimensionality, differential*, and *projection*, as well as specific associated actions, such as *recall, grouping*, and *transliteration* to other coordinate systems (Schermerhorn & Thompson, 2016a).

## Results

Data analysis showed attention to many of the relevant symbolic forms and concept images identified in the schmerical differential length task, but among fewer students.

In particular, *parts-of-a-whole* (PW) and *magnitude-direction* (MD), both prominent in the acontextual task, were generally absent for students' construction in the spiral task. Five students invoked PW, described earlier as students' recognition of parts summing up to a whole with the template $\square+\square+\square$. However, only one applied a polar coordinate system and initially included MD. MD accounts for the magnitude and unit vector parts of a quantity and is associated with the template $\square\hat{\square}$. Both these symbolic forms are associated with the *component and direction* concept image, where students would recognize that differential length vectors need multiple components, and that each component corresponds to motion in a specific direction. The following transcript illustrates a correct response and highlights the *component and direction* aspect needed for differential length vector construction:

> Molly: Yeah, and then you go a little bit…I'm picturing you go from this point to this point …So first I travel in the $r$ direction so I go dr in the $\hat{r}$, and then I travel in the $\hat{\theta}$ direction and the arc length of a circle is the radius times the angle that you move so that is $rd\theta$, here in the $\hat{\theta}$. (Fig. 2a)

Molly appropriately separates each component as two distinct motions ("I travel"), then encodes each length as the magnitude and the corresponding direction as the unit vector, resulting in a correct $d\vec{l}$.

Two other students invoked PW without encoding components with a MD template. Neither student specifically attended to the directions each component traced out, resulting in differential length components absent of unit vectors (Figure 2b, 2c). Kyle's transcript demonstrates this:

> Kyle: We stay in the one plane… so we're only changing by $\theta$ and $r$, so it we have some $d\theta$ or let's say $\Delta\theta$, then $\Delta r$ is going to be $2\Delta\theta/\pi$, so the actual length is the change in the radius and the change in the angle times the radius so that we stay in units of length.

Upon recognizing a need to account for a dot product during the later integration, both students added unit vectors to each of their terms.

Both of the above transcripts also highlight students' multiple concept images of the *differential,* accounting for "a little bit" of or "changes" in variables, consistent with students' ideas of differentials identified in the literature (Artigue *et al*., 1990; Hu & Rebello, 2013; Roundy *et al*., 2015; Von Korff & Rebello, 2012). These ideas cue students' invocation of the differential symbolic form: representing a differential quantity with template d$\square$.

The last two students to invoke the PW template used Cartesian coordinates. They both mentioned needing small changes in $x$ and $y$, rather than starting in a more appropriate polar coordinate system. Oliver attempted to differentiate coordinate transformations for $x$ and $y$ with respect to $\theta$ in order to express $dx$ and $dy$. Tyler began similarly but then suggested that a spherical transformation would produce $dl = r^2 \sin\theta \, dr d\theta$. He reduces his $dl$ down to one component without addressing a need to maintain a sum of two components, or directionality.

The remaining interview subjects only attend to one component, neglecting both the PW and MD symbolic forms. Dan and Victor addressed just the change in the $r$ direction, ignoring the change in $\theta$ as irrelevant to calculation (Fig. 3a). While this does lead to the correct solution for the potential difference, the length element for the path is incomplete without the $\theta$ component.

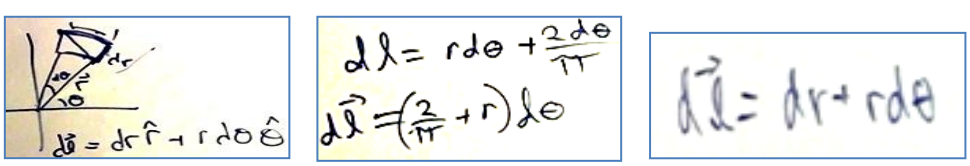

Figure 2. Left to right: (a) Molly's correct differential length elements. (b) Kyle's and (c) Jake's differential length elements absent of unit vectors.

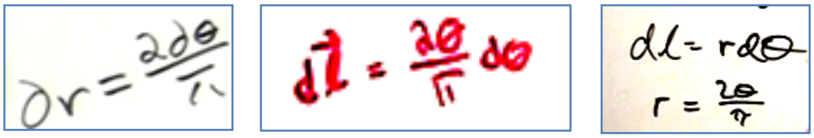

Figure 3. Left to right: (a) Dan and Victor's accounting for only change in $r$-direction and converting to terms of $\theta$. (b) Nate's $dl$, with function replacing $r$ in $rd\theta$. (c) Bart and Harold's $dl$, where the function for $r$ is written with the term to account for changes in $r$ along the path.

The three remaining students only account for the $\theta$ component (Figs. 3b, 3c), correctly including the $r$ in the arc length and including the functional relationship to write the length component in terms of $\theta$:

> Nate: I think I'm going to move just a tiny bit. This point changes, and so $r$ is going to change and $[\theta]$ is going to change… $r$ is going to be obvious because I think it's going to be $[2\theta/\pi]$ and then $[\theta]$ would just change some $d[\theta]$… To me it makes sense, because you're moving some infinitesimal amount in $\theta$ and then you have that $r$ change.

This reasoning appeared across multiple interviews. Students still recognize the need for change in particular variables, an evoked concept image that results in the differential symbolic form. Here students use the functionality of $r$ on $\theta$ and the inclusion of $r$ in arc length to account for $r$ changing. This appears to supersede their need to include change in $r$ as a separate component of the differential length. The need to include a $dr$ is entirely absent from their constructions.

## Conclusions

Analysis of student interviews on differential length construction on a more typical E&M task reveal that students are not as attentive to the vector nature of differential elements compared to similar construction in the unconventional spherical coordinates. This may be due to familiarity with the high symmetry of many tasks in E&M that allow students to select one component of a length or area vector and disregard others. Typically for a task involving a spherically symmetric electric field, students would usually select the $\hat{r}$ component. However, students interviewed on the spiral task are largely only selecting the $\theta$ component. For these students the change in $r$ is activated, but where in schmerical coordinates this would result in an expression of $dr$, it appears the salience of $\theta$ changing and a functionally dependent $r$ being a variable in the arc length, allows students a justification for their choice of one component.

Student use of $\theta$ was prominent. Almost all students, even those expressing multiple components, worked to express their final differential length vector in terms of $\theta$, despite the simplicity of integrating a radially dependent field in terms of $r$. This focus on $\theta$ is most likely due to the salience of the circular nature of the path and/or the functional form of $r$ given to students. It is additionally possible the recent familiarity with circular symmetry in E&M II and Ampère's Law, played a role in students' emphasis on the $\theta$ component.

Whereas students easily recognize the need for multiple components for the general expression of the differential length vector, in this more typical task embedded in a physics context, students have difficulty recognizing the need to separate out directions. We seek to investigate students' work on these tasks without a function for the path, to see if this leads to inclusion of the $\hat{r}$ term. Current instructional implications speak to more emphasis on connecting whole differential length vector construction to the determination of terms based on symmetry arguments However, more work is needed to make specific claims regarding students' choices.

## Abstract

*This study examined the impact of a deliberate attempt to present creativity as a mathematical endeavor on students' conceptions about mathematics, attitudes toward learning mathematics, and approaches to mathematics. Course modules were developed as part of a grant-funded project on creativity in STEM education and implemented in a course for non-mathematics majors. Throughout the course, students engaged in hands-on, active learning of mathematics through discovery. The mathematical topics for the course were chosen based on their relevance to students' everyday lives and their suitability for encouraging creativity. Data were collected through surveys, focus group interviews, and written artifacts. In this paper, we describe the preliminary results of our study and offer implications for both research and teaching.*

*Keywords:* Creativity, General Education Mathematics Courses, Instruction

## Introduction

Creativity is often associated solely with the arts. An online search gives the following definition: "The use of the imagination or original ideas, especially in the production of an *artistic* work." (Oxford Dictionary Online, 2017; italics added). Although creativity is valued among mathematicians (Sriraman, 2004), undergraduate mathematics students do not consider creativity to be important to mathematics (Munakata & Vaidya, 2015). Our Creativity in Mathematics and Science Project, funded by the National Science Foundation, challenges these traditional notions of both creativity and mathematics. Through our project, we developed and implemented course modules that embraced creativity in mathematics for a general education mathematics course and assessed the impact of some innovative teaching methods on students' conceptions of STEM (science, technology engineering, and mathematics), their approaches to mathematics, and their understanding of what it means to "do math".

## Problem statement

Our research explored the impact of a course that deliberately drew upon theories related to creativity in its development and implementation. Namely, we sought to uncover whether this course influenced students' conceptions about mathematics and their approaches to mathematics. The following were our research questions:

1.) Does a deliberate attempt to infuse the undergraduate curriculum with a focus on the creative process lead to changes to students' perceptions of mathematics and attitudes toward mathematics learning?

2.) What is the impact of this instructional strategy on students' creativity, especially as it concerns approaches to mathematics?

## Relation of this work to the research literature

Recent discussions in undergraduate education have proposed active (Wieman, 2014), inquiry-based (Singer, Hilton, & Schweingruber, 2006), and problem-based learning (Freeman et al., 2014). In the STEM fields, especially, there has been a call to make instruction more relevant to students' needs (DeHaan, 2009), and to have it exemplify the work of scientists and mathematicians (NRC, 2000). All too often, undergraduate STEM education is relegated to learning through traditional, lecture-style instruction, with problems and laboratory experiences dictated by questions and exercises posed without regard to context (DeHaan, 2009). There is a need to shift learning away from the acquisition of facts and procedural knowledge and to environments that encourage innovation (Southwick, 2012). This runs parallel to the need to cultivate adaptive expertise in our students whereby they are exposed to opportunities to be flexible and adaptable in problem-solving situations (Cropley, 2015).

The discussion about effective mathematics instruction is particularly important when considering students in general education courses. The fact that these courses for non-majors are often students' terminal courses in mathematics--and that they are composed of students representing various disciplines and interests--adds to the complexity of the issue. Many universities offer courses in the application of mathematics, especially related to societal issues (such as voting) or everyday interests (such as sports and arts), while others focus on practical uses such as finite mathematics for finances. We decided to put aside the list of mathematical topics usually covered, and have the topics emerge naturally from the processes we sought to encourage in our students. That is, we first identified creative processes and learning objectives for the course, then developed content-based modules we believed encouraged these processes.

Our work set out to consider the impact of such a course on students and to use the results to inform further revisions to the course.

## Conceptual framework

Our project draws from different works in creativity--from both psychology and education. As creativity is notoriously difficult to define, we chose to focus on the various traits of creativity identified by researchers (e.g., Amabile, 1996; Hadamard, 1954; Sternberg and Lubart, 1996). These traits include the ability to connect ideas, see similarities and differences, be flexible, have aesthetic taste, be unorthodox, be motivated, be inquisitive, and question norms. We also considered what others have noted as being essential to the work of mathematicians: divergent thinking, and the ability to identify new problems and contribute new knowledge (Nadjafikhah, Yaftian, & Shahrnaz, 2012). In the mathematics classroom, some have suggested problem posing as a way to encourage creativity (e.g, Silver, 1994). With the understanding that the difference between the nature of creativity of mathematicians and of students is chiefly that of degree and level (Hadamard, 1954), we sought to develop a mathematics course that centered around creativity.

Our course introduced students to topics in mathematics of relevance to their daily lives. The course aimed to expose students to the wonders of mathematics and covered various topics in discrete and continuous data modeling, fundamental aspects of Euclidean and non-Euclidean geometry, fractal geometry and probability theory. We took a hands-on approach to learning since we felt that mathematics is best understood by active learning methods such as doing problems, discussions and debates and even performing experiments rather than passively listening to a lecture. No formal textbook was prescribed; all necessarily materials were handed out to the students in class or through our online system, as needed. The only prerequisite was a very elementary knowledge of mathematics which may be required for any college course.

## Research methodology

This study was conducted at a state university in the Northeast US. The institution was recently designated as a Research III doctoral institution and enrolls a little over 20,000 students, including undergraduate, master's, and doctoral students. The university has historically enrolled large numbers of students who are first-time college attendees in their families, and prides itself on its diverse population of students, having the distinction of being a Hispanic Serving Institution.

The course, Contemporary Applied Mathematics, is one of three courses for students who are not STEM or education majors: it fulfills their mathematics general education requirement. The course was taught in Spring 2017 and enrolled 36 students. Three of the four authors developed the course and co-taught the course during the semester: one instructor was the lead, and the other two led certain classes and otherwise assisted or took notes on the course discussions. We met weekly to debrief about the most recent class meeting and to plan for future meetings.

Since this was a general education course for non-science and math majors, the class represented diverse majors from outside science and mathematics including the arts and humanities. Few of these students, if any, had experience with the kinds of mathematical topics that were being discussed and few had seen mathematics presented quite in the hands-on and open-ended form that we adopted.

We employed both quantitative and qualitative research methodologies. Data were collected from the 35 students (21 female, 14 male) who consented to participating in the study. We collected data through semi-structured focus group interviews, surveys, journals, class assignments and two well-known measures of creativity (Guilford, 1958; Torrance, 1965). For the quantitative measures, we compared pre- and post-test gains against a those of a comparison group. This paper will focus on the results of the qualitative data—namely, the focus group interviews, reflective journals, and classroom artifacts. We have completed analysis of the interviews (of 12 students) and are expecting to complete analysis of the journals and written artifacts (from all 35 consenting students) in the next month.

Seven semi-structured group interviews were conducted with 12 students during the last two weeks of the course. The interviews were audio taped and transcribed. The purpose of the interviews was to collect information on the students' attitudes, beliefs, and opinions about the creativity course. The interviews were coded into seven initial categories and later broken down into subcategories. (Please see Table 1.)

During the interviews, students most often discussed the instructional and teaching strategies ($n$=106 times) employed by the instructors of the course. Overwhelmingly, these excerpts distinguished differences between traditional instruction of mathematics and science and the instruction in the creativity course. Students often described specific instructional activities they completed during the course ($n$=72) and discussed how the course influenced their thinking and learning of mathematics ($n$=67).

*Table 1. Subcategories of the Main Themes*

| Theme | Subcategories |
|---|---|
| Mentions Specific Activities | Alignment Among Curricular Materials |

The following offers descriptions with exemplar excerpts for some of the subcategories:

**Teaching How to Think**

Students pointed out that the instructors encouraged students to think mathematically. Therefore, they created a culture where students were not taught what to think, but were active participants in their learning. An excerpt from Mia highlights the contrast between the creativity course and her experiences in the past:

> I think it's really different from like a lot of the courses I've taken um, just because they don't teach in like a conventional way. You know, like, in every other math course I've ever taken it's been like you learn the theory and then like you learn um, they give you like examples, and then you do the homework, and then you take a test. And like it's just like one week doing that whole thing, and this is kind of teaching you the theories but not like I don't, it's hard to explain, with the numbers and stuff in it. So, it's teaching you the way of thinking, I guess, without making it seem as difficult. If that makes sense.

**Discussing Creativity**
There were two subcategories for students discussing creativity: surprise that math can be creative and value of the creative approach. For example, Ann stated, "I think it's different because it's the first class I've taken that tells you that math can be creative instead of just logical. You needed it for practical things, not creativity." Many students had initial thoughts of creativity as art, photography, film, or other endeavors not generally associated with science or mathematics. In general, students believed mathematics to be rule-based, logical, and formula-driven, so they were surprised when they were encouraged to be creative.
Students found that an emphasis on creative approaches stimulated new ideas, allowing them to look at things differently and be less afraid to try something different. They claimed that the creative activities helped them remember what they had learned. Many remarked that younger learners tend to get more creative opportunities in math, but that diminishes in middle and high school. Corey further explained:

> They are more pushing creativity than like getting a solid right answer using the right formula...I've taken Calc so always have to memorize things always have to get the right answer in order for me to get credit. So it is definitely different. Because as long as you are being creative, like supporting how are you getting an answer, it is acceptable...But once you get going and like you said, be creative and thought out of the box helps me become more creative. Because I am very like, I have been learned to go straight forward, use these problems, get the right answer and you're done. Whereas now it's pushing me to like think outside the box and that's not something I am used to.

## Implications for Teaching Practice and Further Research

This study was based on a first attempt at implementing our newly developed course modules. Our plan is to revise our modules based on our results and implement them once more in several sections of the general education course. The results of our pilot study thus far, however, have indicated changes to students' conceptions about mathematics. The study has potential to inform the curriculum of other mathematics courses for non-majors. Namely, the preliminary results indicate that a deliberate attempt to encourage creative thinking among students can influence their confidence, broaden their thinking about mathematics, and even guide their career choices. These traits are especially relevant for non-mathematics majors, who will most likely not take additional mathematics courses.

We are currently implementing the course modules in a similar course (for non-mathematics majors) at our local community college and also in a first-year seminar course for mathematics majors at our institution. The aim of the implementation in the latter course is to expose students to a new way of thinking about mathematics as they begin undertaking the mathematics course sequence. Our continuing research is expected to further elucidate the impact of our instructional strategy on various populations of undergraduate students.

## Discussion Questions

1. What is the place of mathematics content in a course that promotes creative approaches to mathematics (and other disciplines)?
2. How can mathematics courses for majors embrace creativity?
3. How do you assess creative approaches to mathematics?
4. What research would help practitioners consider this teaching innovation?

# Student Understanding of Linear Combinations of Eigenvectors

| Megan Wawro | Kevin Watson | Michelle Zandieh |
|---|---|---|
| Virginia Tech | Virginia Tech | Arizona State University |

*Student understanding of eigenspace seems to be a particularly understudied aspect of research on eigentheory. To further detail student understanding of eigenspace relationships, we present preliminary results regarding students' reasoning on problems involving linear combinations of eigenvectors in which the resultant vector is or is not an eigenvector of the matrix. We detail three preliminary themes gleaned from our analysis: (a) using the phrase "is a linear combination of" to support both correct and incorrect answers; (b) conflating scalars in a linear combination with eigenvalues, and (c) reasoning about the dimension of eigenspaces versus a number of eigenvectors.*

*Keywords:* Linear Algebra, Student Reasoning, Eigenspace, Linear Combination

## Purpose and Background

Linear algebra is particularly useful to science, technology, engineering and mathematics (STEM) fields and has received increased attention by undergraduate mathematics education researchers in the past few decades (Dorier, 2000; Artigue, Batanero, & Kent, 2007; Rasmussen & Wawro, in press). A useful group of concepts in linear algebra is eigentheory, or the study of eigenvectors, eigenvalues, eigenspaces, and other related concepts. Eigentheory is important for many applications in STEM, such as studying Markov chains and modeling quantum mechanical systems. Despite this importance, research specifically focused on the teaching and learning of eigentheory is a fairly recent endeavor and is far from exhausted.

One aspect of eigentheory that seems to be particularly understudied is eigenspace, including how students understand linear combinations of eigenvectors. Some research on eigentheory has included eigenspaces but not as the main focus. For instance, Salgado and Trigueros (2015) found that students struggled to construct the concept of eigenspace as well as to coordinate the number of eigenvectors corresponding to a given eigenvalue with the dimension of the space spanned by the eigenvectors of that eigenvalue. Gol Tabaghi and Sinclair (2013), on the other hand, found that exploration of a two-dimensional "eigen-sketch" in Geometer's Sketchpad helped students understand the existence of multiple eigenvectors for a single eigenvalue as they dragged the vector $\boldsymbol{x}$ along the line of the eigenspace. Lastly, Beltrán-Meneu, Murillo-Arcila, and Albarracín (2016) gave students a test question asking if various linear combinations of eigenvectors in $\mathbb{R}^2$ would also be eigenvectors; they found students either reasoned symbolically by explicitly verifying the eigen-equations for the numerically given matrix and vectors, or formally by reasoning about the resultant vectors belonging or not belonging to an eigenspace.

In order to more explicitly explore students' understanding of eigenspaces and extend research beyond 2×2 matrices, the research question for this study is: How do students make sense of and reason about linear combinations of eigenvectors?

## Theory and Literature Review

This report is part of our ongoing effort to analyze students' understanding of eigentheory. In doing so, we ground our work in the Emergent Perspective (Cobb & Yackel, 1996), which is based on the assumption that mathematical development is a process of active individual construction and mathematical enculturation. In this report we focus on the mathematical conceptions that individual students bring to bear in their mathematical work (Rasmussen, Wawro, & Zandieh, 2015). The literature on the teaching and learning of eigenvectors and eigenvalues points to several aspects of eigentheory that are important as students build their understanding. Here we summarize that literature by highlighting what we have found to be the most important aspects for building a theoretical framework for eigentheory.

Thomas and Stewart (2011) found that students struggle to coordinate the two different mathematical processes (*matrix* multiplication versus *scalar* multiplication) captured in the equation $A\boldsymbol{x} = \lambda\boldsymbol{x}$ to make sense of equality as "yielding the same result" between mathematical entities (i.e., two equivalent vectors), an interpretation that is nontrivial or even novel to students (Henderson, Rasmussen, Sweeney, Wawro, & Zandieh, 2010). Furthermore, students have to keep track of multiple mathematical entities (matrices, vectors, and scalars) when working on eigentheory problems, all of which can be symbolized similarly. For instance, the zero in $(A - \lambda I)\boldsymbol{x} = \boldsymbol{0}$ refers to the zero vector, whereas the zero in $\det(A - \lambda I) = 0$ is the number zero. This complexity of coordinating mathematical entities and their symbolization is something students have to grapple with when studying eigentheory.

Thomas and Stewart (2011) also posit that this complexity may prevent students from making the symbolic progression from $A\boldsymbol{x} = \lambda\boldsymbol{x}$ to $(A - \lambda I)\boldsymbol{x} = \boldsymbol{0}$ through the introduction of the identity matrix, which is often an important step in solving for the eigenvalues and eigenvectors of a matrix $A$. In their genetic decomposition of eigentheory concepts, Salgado and Trigueros (2015) also point out the importance of understanding the equivalence of the two equations through a coordination of $A\boldsymbol{x} = \lambda\boldsymbol{x}$ and solutions to homogeneous systems of equations. Harel (2000) posits that the interpretation of "solution" in this setting, the set of all vectors $\boldsymbol{x}$ that make the equation true, entails a new level of complexity beyond solving equations such as $cx = d$, where $c, x,$ and $d$ are real numbers. Our own work indicates student reasoning when solving eigentheory problems may be influenced by their reliance on or preference for one of the two eigen-equations (Watson, Wawro, Zandieh, & Kerrigan, 2017).

Hillel (2000) found that instructors often move between geometric, algebraic, and abstract modes of description without explicitly alerting students; although the various ways to think about and symbolize linear algebra ideas are second nature to experts, they often are not within the cognitive reach of students. In fact, Thomas and Stewart (2011) mentioned that students in their study primarily thought of eigenvectors and eigenvalues symbolically and were confident in matrix-oriented algebraic procedures, but "the vast majority had no geometric, embodied world view of eigenvectors or eigenvalues … losing out on the geometric notion of invariance of direction" (p. 294). In contrast, other researchers have shown how exploration of eigentheory through dynamic geometry software (Çağlayan, 2015; Gol Tabaghi & Sinclair, 2013; Nyman, Lapp, St John, & Berry, 2010), stretching geometric figures by a linear transformation (Zandieh, Wawro, & Rasmussen, 2017), gesture, time, and space (Sinclair & Gol Tabaghi, 2010), or real-world contexts (Beltrán-Meneu et al., 2016; Salgado & Trigueros, 2015) can be beneficial to developing conceptual understanding of eigentheory. We similarly agree on the importance of understanding eigentheory concepts in multiple ways and successfully navigating between these various modes of description.

## Methods

The data for this study come from student written responses to the 6-question Eigentheory Multiple-Choice Extended (MCE) Assessment Instrument (Watson et al., 2017). This MCE aims to capture nuances of students' conceptual understanding of eigentheory and to inform our working framework of what it might mean to have a deep understanding of eigentheory. This work is part of a larger study of student understanding of eigentheory in mathematics and physics. However, this paper focuses on data from one sophomore-level introductory linear algebra class, at a university in the eastern United States. For this paper we focus on student responses to Questions 3 and 5 (Q3 and Q5), which are about linear combinations of eigenvectors (Figure 1). Of the 28 students in this class, 27 answered Q3 and 23 answered Q5. For each, students selected an answer to the multiple-choice stem and then were to respond to the open-ended prompt: "Because…(Please write a thorough justification for your choice)."

3. Suppose $A$ is a $n{\times}n$ matrix, and $\boldsymbol{y}$ and $\boldsymbol{z}$ are linearly independent eigenvectors of $A$ with corresponding eigenvalue 2. Let $\boldsymbol{v} = 5\boldsymbol{y} + 5\boldsymbol{z}$. Is $\boldsymbol{v}$ an eigenvector of $A$?
   (a) Yes, $\boldsymbol{v}$ is an eigenvector of $A$ with eigenvalue 2.
   (b) Yes, $\boldsymbol{v}$ is an eigenvector of $A$ with eigenvalue 5.
   (c) No, $\boldsymbol{v}$ is not an eigenvector of $A$.

5. Suppose a 3x3 matrix $B$ has two real eigenvalues: for eigenvalue 2 its eigenspace $E_2$ is one-dimensional, and for eigenvalue 4 its eigenspace $E_4$ is two-dimensional. Also suppose that vector $\boldsymbol{x} \in \mathbb{R}^3$ lies on the plane created by the eigenspace $E_4$ and $\boldsymbol{y} \in \mathbb{R}^3$ lies on the line created by the eigenspace $E_2$, as illustrated in the graph below. If $\boldsymbol{z} = \boldsymbol{y} + 0.5\boldsymbol{x}$, which of the following is true?
   (a) The vector $\boldsymbol{z}$ is an eigenvector of $B$ with an eigenvalue of _____ [fill in the blank]
   (b) The vector $\boldsymbol{z}$ is not an eigenvector of $B$.

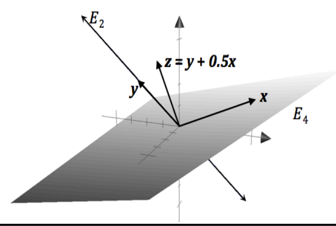

*Figure 1.* Questions 3 and 5 of the Eigentheory MCE Assessment Instrument.

Using Grounded Theory (Glaser & Strauss, 1967), each author of this paper open coded the students' open-ended responses to Q3 independently and discussed our results as a team to find interesting emerging themes. We repeated this process for Q5. In addition, we began comparing a student's open-ended response to Q3 with their response to Q5 to see if the pair of responses provided further insight into each student's understanding. Some of the themes that have emerged from our initial analysis are reported in the following section.

## Results

We detail three preliminary themes from our analysis of justifications that students provided to support their conclusions on Q3 and Q5: (a) using the phrase "is a linear combination of" to support *both* correct and incorrect answers; (b) conflating scalars in a linear combination with eigenvalues, and (c) reasoning about *dimension* of eigenspaces versus *number* of eigenvectors.

### Reasoning about linear combinations

In Q3, we noticed that 13 students wrote "$\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$" in their open-ended justification; however, 3 used it to support (a), 3 used it to support (b), and 7 used it to support (c). We note that the phrase "$\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$" was not written anywhere in the Q3 prompt; rather, the symbolic expression "$\boldsymbol{v} = 5\boldsymbol{y} + 5\boldsymbol{z}$" was given. We find it notable that so many students expressed this algebraic relationship in words and that this correct phrase was used to support all three solution options. Below we provide a few examples of responses supporting each solution option. Students are identified using labels of the form B#.

Examples of justifications given to support the correct solution (a), that $\boldsymbol{v}$ is an eigenvector with eigenvalue 2, are: "$\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$ which have the same eigenvalue"

[B72], and "$\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$. Since the value 2 already causes $\boldsymbol{y}$ and $\boldsymbol{z}$ to equal zero, adding a multiple to it will not change that" [B66]. We note that B72's response includes the critical information that $\boldsymbol{y}$ and $\boldsymbol{z}$ have the same eigenvalue – if this were not true, $\boldsymbol{v}$ would not be an eigenvector of $A$. It is not clear to us what B66 meant by his/her response, but we conjecture that it involved reasoning about solutions to the equations $(A - 2I)\boldsymbol{y} = \boldsymbol{0}$ and $(A - 2I)\boldsymbol{z} = \boldsymbol{0}$. In fact, in Watson et al. (2017) we highlighted B66, using data from work on other Eigentheory MCE questions, as an example of a student who showed some reliance on or preference for the homogeneous equation $(A - \lambda I)\boldsymbol{x} = \boldsymbol{0}$ rather than $A\boldsymbol{x} = \lambda\boldsymbol{x}$.

Examples of justifications given to support (b), that $\boldsymbol{v}$ is an eigenvector with eigenvalue 5, are: "$\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$. Both $5\boldsymbol{y}$ and $5\boldsymbol{z}$ are scalar multiples of their previous form so the resultant vector will be an eigenvector as well" [B71], and "Since it is a linear combination of the other eigenvectors, it would also be an eigenvector" [B69]. Note that 5 is the scalar associated with both $\boldsymbol{y}$ and $\boldsymbol{z}$ in the linear combination $\boldsymbol{v} = 5\boldsymbol{y} + 5\boldsymbol{z}$ given in the problem. However, 2 is the eigenvalue for both $\boldsymbol{y}$ and $\boldsymbol{z}$, and thus also for $5\boldsymbol{y}$, $5\boldsymbol{z}$ and $5\boldsymbol{y} + 5\boldsymbol{z}$. The explanations given by each of these two students would be correct if they had circled the correct eigenvalue in the multiple-choice portion of the question. It may be that both B71 and B69 made a simple error in choosing 5 as the eigenvalue for $v$ rather than the correct eigenvalue of 2; however, as we detail in the next subsection, it may be that these students conflated the scalar in the linear combination with the eigenvalue in a way more rooted in their thinking about what it means to be a linear combination of eigenvectors.

Examples of justifications given to support (c), that $v$ is not an eigenvector, are: "Eigenvectors must be linearly independent from each other so if $\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$ then it cannot be an eigenvector" [B58], and "Because they all correspond to the same eigenvalue they all must have unique eigenvectors and $\boldsymbol{v}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{z}$ and therefore not unique and not an eigenvector of $A$." [B79]. One can understand how aspects of B58's reasoning were sensible to him/her, given that eigenvectors from *distinct* eigenvalues of a matrix are linearly independent. In addition it is common in textbooks to list a basis for the eigenspace as the solution to an eigenvector problem; this might lead students to believe that these linearly independent basis vectors are the only eigenvectors.

The phrase "is a linear combination of" was not as common in student responses to Q5. One notable exception is Student B69. This student answered Q3 correctly but gave the vague justification of "since it is a linear combination of the other eigenvectors, it would also be an eigenvector." On Q5, however, B69 explained that the vector would only be an eigenvector if the two vectors in the linear combination had the same eigenvalue (which is true). When considering B69's Q3 response in light of his/her Q5 response, we hypothesize that B69's vague response to Q3 was most likely based in a correct understanding of linear combinations of eigenvectors.

**Conflating scalars in the linear combination with eigenvalues**

We noticed that some student struggles with Q3 could possibly be explained by a conflation of the scalar 5 in the linear combination $\boldsymbol{v} = 5\boldsymbol{y} + 5\boldsymbol{z}$ with the scalar 2, which is stated as the eigenvalue for both $\boldsymbol{y}$ and $\boldsymbol{z}$. In addition to B71's justification that $\boldsymbol{v}$ is an eigenvector with eigenvalue 5 (seen in the previous subsection), consider B81's justification given to support (c):

> "No, because an eigenvector is defined as some linear combination defined by the eigenvalue so that $A\boldsymbol{x} = \lambda\boldsymbol{x}$, where $\boldsymbol{x}$ is the eigenvector and $\lambda$ is the eigenvalue. The vectors $\boldsymbol{y}$ and $\boldsymbol{z}$ are being scaled by a factor of 5 and $\lambda = 2$ so they cannot be corresponding eigenvectors."

This student seems to conflate the scaling by 5 of the vectors $\boldsymbol{y}$ and $\boldsymbol{z}$ in the linear combination with the scaling by 2 of the vectors $\boldsymbol{y}$ and $\boldsymbol{z}$ when acted upon by the matrix $A$. In the former, $\boldsymbol{y}$ and $\boldsymbol{z}$ have not been acted upon by a transformation – the 5 is used to define the amount of each vector that is needed to create the vector $\boldsymbol{v}$. In the latter, the 2 is used to define that the result of multiplying each vector by $A$ is twice the input vector. B81's reasoning seems to explain the role of the 5 in ways that would be more compatible with the role of the 2 and, because the scalars are different, concluded that "they" could not be eigenvectors. It is unclear what vectors are implied in the student's use of "they" – it could be some combination of $\boldsymbol{v}$, $5\boldsymbol{y}$ and/or $5\boldsymbol{z}$.

This preliminary result reminded us of another data set from our research group. In written data from final exams from an introductory linear algebra courses at a large public university in the southwestern United States, the instructor asked a question specifically targeting this potential conflation. The question first gave students a 3x3 matrix $A$ and the eigenspace $k\begin{bmatrix}-1\\2\\2\end{bmatrix}$ and asked them to find the associated eigenvalue (the correct answer was $-1$). The question then asked students to complete the following and fill in the blank if appropriate: "The vector $\begin{bmatrix}-2\\4\\4\end{bmatrix}$ is … [an eigenvector of $A$ with eigenvalue = ___ ] or [not an eigenvalue of $A$]." 13 of the 32 students correctly found that $-1$ was the eigenvalue for both vectors; however, 11 put that 2 was the eigenvalue for the second vector. Because it is two times the vector representative of the eigenspace, we hypothesize that these students conflated the scalar in the scalar multiple with the eigenvalue. These data need further investigation.

**Reasoning about the dimension of eigenspaces versus the number of eigenvectors**

Our third preliminary theme concerns students' reasoning about the possible number of eigenvectors in contrast to the dimension of the eigenspaces. On both Q3 and Q5, some student justifications referred to a finite number of eigenvectors; this is a potentially problematic view because each eigenspace has an infinite number of eigenvectors. For instance, on Q3, B78 reasoned that the linear combination of eigenvectors could not be another eigenvector because "Technically, you could multiply the eigenvectors by any number and if you did so and another eigenvector was achieved there would be a possibility for infinite eigenvectors which doesn't make sense." On Q5, reasons given by some students to support the correct choice (b) similarly focused on finite numbers of eigenvectors: "Matrix $B$ already has 3 eigenvectors so there's no room for a 4$^{\text{th}}$" [B59], and "$\boldsymbol{z}$ is a linear combination of $\boldsymbol{y}$ and $\boldsymbol{x}$, and there are already 3 eigenvectors for 3 dimensions, so $\boldsymbol{z}$ cannot be an eigenvector of $B$" [B66]. We conjecture these students may have been conflating the total number of possible eigenvectors (infinite) for a 3x3 matrix with the number of linearly independent vectors (three) needed to create the bases for the one- and two-dimensional eigenspaces. Alternatively, B58's justification for Q5 focuses on dimension: "In a 3x3 matrix there can only be 3 dimensions to the eigenspace. $E_2$ and $E_4$ together span the entire space of $\mathbb{R}^3$ so there cannot be another eigenvector of $B$ besides $E_2$ and $E_4$" [B58]. We conjecture grasping the difference between finiteness of dimensions and infiniteness of eigenvectors may be particularly important for understanding eigenspaces.

## Discussion Questions

During our presentation we would like to discuss: how can we further investigate our three preliminary research themes, and what additional analyses might help us uncover students' creative and productive ways of reasoning about eigenspaces?

## First-generation Low-income College Student Perceptions about First Year Calculus

Gaye DiGregorio and Jess Ellis, Colorado State University

### Abstract

*The purpose of this study was to explore first-generation low-income students' experiences with first-year calculus, including their self-belief in being successful in math. As part of the Progress though Calculus project, one STEM-focused institution was studied with survey results from students enrolled in first year calculus, and interviews and a focus group of three first-generation low-income students who completed first year calculus. Qualitative findings emphasized the value of creating connections with other students and faculty, and faculty's impact on students' sense of belief in being successful in calculus. Quantitative results illustrated statistically significant higher rates of faculty interaction outside of class and increased confidence in math while taking first year calculus for first-generation low-income students, in comparison to their continued generation, higher income peers. Promoting non-cognitive factors such as student support and self-belief in math success may influence math completion of first-generation low-income students.*

**Key Words**: First-generation low-income students, self-belief, first year calculus

Along with innovative pedagogies and curriculum enhancements to improve math education, it is also important to consider as part of the formula for student success in mathematics, the increasingly diverse student population, gaps of math completion with marginalized students, and non-cognitive factors such as self belief and support networks. The population of diverse students for this study was first-generation students as the first in their immediate family to be working towards a bachelor's degree, and low-income students.

In this study I explore the experiences of first-generation low-income students in first year mathematics from an asset approach, meaning I focus on what these students bring from their identities to support their success, as well as attending to barriers these students face. For decades college administrators and researchers have viewed the first-generation and low-income identities as "at risk", which is reinforced by the well documented national graduation gaps of these students. For instance, among 4.5 million college students from 1995-2002, six-year graduation rates for first-generation low-income students were 44% lower than continuing-generation higher-income students (Engle & Tinto, 2008).

To address these graduation gaps and move beyond the focus on the disparities of underserved students as a disadvantage to being successful in college, a paradigm shift is needed to to support students that attend college rather than require students to adapt to college. One way to provide support is focusing on first-year mathematics completion since it is highly correlated to graduation rates. By understanding what assets students bring to first-year mathematics success, we can better understand how to support a higher graduation rate among this population.

### First-generation Low-income Students

Most prominent research on first-generation low-income students has focused on deficits as a disadvantage to being successful in college. Academic deficiencies of these students include: higher need for remedial courses (Chen & Carroll, 2005), undeveloped student success skill sets (Collier & Morgan, 2008), less academic and co-curricular engagement (Pascarella, Pierson, Wolniak, & Terenzini, 2004; Warpole, 2003), and lower educational aspirations (Pike & Kuh, 2005). Non-cognitive disparities include a lack of parental support (Ward, 2012), not as much social capital (Lin, 2011), lower levels of a sense of belonging (Aires & Seider, 2005; Ward, 2012), and a cultural mismatch with the university (Roberts & Rosenwald, 2001; Stephens, Fryberg, Markus, Johnson, & Covarrubias, 2012).

A different approach to defining deficits and expecting students to compensate for deficits is research done within the perspective of promoting the strengths and assets of students as an advantage for collegiate success. Although not as prevalent, research within an asset framework focused on self-authorship (Pizzolato, 2003), high motivation to attend college (Martin, 2012) , and a desire to contribute to society (Olive, 2009). Along with research on the strengths of these students, is the importance of meaningful individual connections to support students. For instance, a strong network of faculty who care and have high expectations, and peers who offer encouragement has been found to help first-generation college students transition to college (Coffman, 2011), and obtain a college degree (Lourdes, 2015).

## Math Completion of First-generation and Low-income Students

In considering the success in math of first-generation low-income students, lower levels of math completion have been documented. An analysis of first-generation student college transcripts from 1992 to 2000 shared that 55% of first-generation students took at least one math course in college compared to 81% of students whose parents had a bachelor's degree (Chen & Carroll, 2005). Additionally, at Colorado State University (2016) after controlling for prior academic preparation, first-generation, students of color, and Pell eligible students were significantly less likely to place into college algebra and to complete three credits of math in the first year compared to their peers.

## Self-belief Theoretical Framework

To begin to reflect on ways to enhance math completion with first-generation low-income students, one non-cognitive factor to consider is self-belief based on the power of positive psychology, which is the study of conditions that influence the optimal functioning of people (Gable & Haidt, 2005). Theories to inform this perspective of developing student assets are stereotype threat (Steele, 1997), which challenges college success, and self-belief (Bandura, 1977; Dweck, 2006), which can potentially mediate challenges and promote academic success. Stereotype threat theory asserts that negative stereotypes of one's performance based on his or her social group can put individuals at risk of lower performance (Steele, 1997).

In response to the negative influences of stereotype threat, positive psychology theories of self-belief are used with Bandara's theory of self-efficacy and Dweck's theory of a growth mindset. Bandara's theory of self-efficacy is a social cognitive theory based on the belief that one can achieve his or her goals (Bandura, 1977). Expanding upon self-efficacy is growth mindset, is the belief that one may improve through engagement with the learning process (Dweck, 2006).

## Self-belief and Math Achievement

Research on the relationship of self-efficacy and math achievement is evident both with students who have not performed well in math along with engineering students with high levels of math performance. Investigating students who were repeating a developmental math course, they identified high self-efficacy as the essence of their persistence despite a low self-concept in mathematics (Canfield, 2013). For engineering students who usually excel in math, self-efficacy was correlated with mathematics achievement scores and cumulative grade point averages (Loo & Choy, 2013).

Reinforcing a growth mindset, research has demonstrated greater course completion rates in challenging math courses (Yeager & Dweck, 2012). Many studies have also focused on the growth mindset as a mediating factor to stereotype type threat of marginalized populations in math performance. Dar-Nimrod and Heine (2006) studied math achievement and gender, and illustrated that females with a growth mindset performed better than females with a fixed mindset on math assessments similar to the Graduate Record Examination.

Lower math completion rates of first-generation low-income students, along with the positive impact of self-belief and math achievement, warrant further investigation into ways that self-belief can enhance success in mathematics. The purpose of this study is to explore first-generation low-income students' experiences with first-year calculus, with particular focus on their self-belief in being successful in math. Specifically, the following research questions guide this work: (1) How do first-generation low-income college students experience first year calculus at a STEM focused institution? (2) How does first year calculus influence the self-belief of first-generation low-income college students to be successful in math?

## Methodology

To provide context of this research, a broad overview of the Project through Calculus research that studied ways to enhance student calculus completion rates is summarized. A part of this research project was a pilot study at one STEM institution, which is the focus of this paper.

### Progress through Calculus Research

The Progress through Calculus study is sponsored by the Mathematical Association of America and funded by the National Science Foundation (NSF) to research student success in calculus. Twelve higher education institutions were identified by the research project team as institutions using structural, procedural, curricular, and pedagogical approaches to the pre-calculus and calculus program that has been successful in higher math completion rates, especially with underrepresented students. Prior to researching the twelve institutions, three pilot studies were held at institutions based on geography, convenience, and access; to refine data collection content and procedures.

### Research Design, Participants, and Data Collection

One of the pilot studies for the Progress through Calculus research was done at a private institution that is focused on STEM degrees. This study was implemented with five researchers including a two-day site visit with interviews, class observations, focus groups, and surveys.

The qualitative subset of the pilot study included three first-generation low-income students who were interviewed mid-semester and participated in focus group at the end of the semester. The students that participated were a first year white female, a junior African American female, and a third year Asian male. The student survey was developed by the Progress through Calculus Research team, and was distributed by the instructors in one of the first year calculus course sessions during the middle of the spring semester.

The mixed methods design was a convergent parallel design with both the interviews/focus group and the survey gathered and analyzed independently, and then the results interpreted together (Creswell & Plano Clark, 2011). For the interviews and focus group holistic data analysis was accomplished with an inductive process to identify relevant emerging themes (Yin, 2003), making sense out of the data collection (Miles, Huberman, & Saldana, 1994). To begin, the interviews and focus groups were transcribed and then coded with MaxQDA, a qualitative coding software program. The researcher began with a first-cycle coding process and then reviewed each code and coded segment to illuminate connections between the categories in the second-cycle coding process, and used a second coder to refine the codes (Miles et al., 1994). Survey questions on student self-belief and interactions with faculty and peers as support resources were studied with chi-square analysis.

## Results

Studying this institution may offer insights to math success since they have decreased the first year calculus DFW rates from 22% in fall 2006 to 10% in spring 2015. The qualitative results from interviews and a focus group illustrated that a common theme of their math experiences was the major significance of working with faculty and other students outside of class.

In exploring faculty connections, key factors that emerged were the importance of how faculty responded to questions, and the value of small individual interactions. An example of how faculty reacted positively to questions is illustrated by the following statement by one student, “When you ask a question and a faculty member is really supportive and they don’t look down on what you ask, they just answer this is what it is.” A less supportive response is illustrated by the statement by another student, “if we ask a question that is dumb he looks down on us, so it’s really intimidating.”

In addition to responding to questions, short interactions with faculty had a big impact on the student’s experiences in math courses. One student illustrated the impact of a faculty connection as being the most positive experience in calculus.

> “My math teacher was sitting outside on one of the picnic tables and I didn’t want to sit with him and talk about math….so I sat on a bench …. He was going back into his office and he stopped by and was talking to me….How are your classes going? Then he said he didn’t care about the other classes just mine, it kinda made me laugh… It was kinda of like your cool and we joke around now. I feel like I know him a lot better. Listening to him lecture I have that connection: you know what you’re talking about I will believe what you are saying. I mean I guess it showed because I did a lot better on my last test. That was the best positive experience that I have had in calculus. It was getting that connection.”

Along with faculty interactions, the importance of peer support was highlighted, describing how students worked with other students in math courses. Two students shared that they looked for students that were doing better than them, and then would ask them to be in a study group. Another example was a network of students beginning with two students working together, each branching out to other friends, and then coming back together to complete the homework. The value of peer support was further highlighted when a student shared that she would rather work with other students than a faculty member, even if it took longer to get the correct answer.

The other prominent research finding was the tremendous impact that faculty had on student’s self-belief in being successful illustrated by the quote below.

> “I went in [to her office] and said I can’t do Calc II, I’m a fraud, and she said yes you can. She said we are going to sit down and go through this exam and she went question by question and she said what did you do wrong? It’s not like you don’t understand what’s going on sometimes you are reading the question incorrectly. You know the material you just need to interpret the question and answer it correctly. Okay that clicks. She didn’t give up she didn’t brush me aside as one of twenty students. She remembered my name which was important.”

These results illustrate the power of faculty and student connections integral to first-generation low-income student experiences in math, and especially the impact of faculty believing in student success. Another student experience was how they were able to improve their low grades with new strategies and continued effort which relates to having a growth mindset.

Concerning the survey results, there was 322 respondents, with a 67% response rate. The questions analyzed in this study focused on faculty and student interactions, and self-belief in mathematics. Focusing on faculty interaction, survey frequencies found a higher percentage of first-generation students (21%) compared to continuing generation students (16.5%) saw their instructor outside of class. Chi-square results indicated a statistically significant association between first-generation status and faculty interaction, $\chi 2$ (5) = 11.879, $p < .05$. The effect size was small (Cohen, 1988), Cramer's V = .172. Focusing on interactions with peers for all students, there were higher percentages of working with peers than instructors, and higher percentages with first-generation and low-income students compared to their continuing generation and higher income peers. Aspects of self-belief studied were confidence, ability to do math, and growth mindset. The survey results indicated that most first- generation (66%) and continuing generation (53%) significantly or moderately increased their confidence in math by taking calculus. More importantly, chi-square results indicated a statistically significant association between first-generation students and increased confidence, $\chi 2$ (5) = 14.477, $p < .01$. The effect size was small (Cohen, 1988), Cramer's V = .19.

Along with confidence, findings about a student's ability to learn mathematics revealed that most first-generation students (68%) and low-income students (76%) said that their math ability "moderately or significantly increased" with taking calculus. Additionally, 73% first- generation students and 80% low-income students shared that their growth mindset "significantly or while taking first year calculus. There were no statistically significant differences of the ability to do math and growth mindset between first-generation and low-income students compared to their peers.

## Discussion

A major highlight of this research was the importance of faculty and staff connections and the positive impact that calculus had on students' increased confidence in math which was higher for first-generation and low-income in comparison to their continuing generation and higher income peers. Although strong faculty and student connections reinforce well established high quality teaching practices, it is an important reminder to keep these qualities at the forefront especially in college courses. Additionally, in light of the research findings that first-generation low-income students are working with peers outside of class at higher rates than instructors, perhaps more intentional integration of student study groups would be impactful.

Although the survey findings are based on small sample sizes, results may suggest a possibility that historically marginalized first-generation and low-income students are gaining self-belief as part of their experience in calculus courses at this institution. This is an important finding considering the stereotype threat that is well documented with students having marginalized identities. Learning even more about how faculty can provide an environment for enhancing student self-belief is recommended. Additionally repeating this same study at other institutions as part of the Progress through Calculus research project, will provide cross institutional results and additional insights. These findings will hopefully suggest ways to create an environment that promotes self-belief in developing the talent of first-generation low-income students, thereby increasing success in math.

# Gauging College Mathematics Instructors' Knowledge of Student Thinking About Limits

Jessica Gehrtz
Colorado State University

Natasha Speer
University of Maine

Jess Ellis Hagman
Colorado State Unversity

*A theme in the literature surrounding instructional practices and knowledge for teaching is that knowledge of how students think about mathematical ideas plays important roles in supporting effective instruction. However, the undergraduate mathematics education community lacks tools for assessing this kind of knowledge. As an initial step toward the development of such assessments, we documented instructors as they examined students' work on calculus tasks during individual interviews. Transcripts were coded as exhibiting robust, limited, or no evidence of knowledge of student thinking using Jacobs, Lamb, and Philipp's (2010) framework. The coding process highlighted the varying depth and breadth of instructors' knowledge. Once refined, this coding process can be used to develop instruments for gauging knowledge of student thinking through means other than interviews. Such instruments will be of use to researchers, to those who design professional development for experienced and novice instructors, and for evaluation of professional development efforts.*

*Keywords:* mathematical knowledge for teaching, limits, instructor professional development

## Introduction

There have been many calls for increased attention to the teaching of undergraduate mathematics and professional development for those who do such teaching as part of efforts to improve enrollment and retention rates in STEM disciplines (Bok, 2013; Holdren & Lander, 2012). From extensive research at K-12 levels, we know multiple factors shape teachers' instructional practices (see, e.g., Borko & Putnam, 1996) and developing practices consistent with findings from research on teaching and learning can be challenging (see, e.g., Fennema & Scott Nelson, 1997). In this body of literature, a recurring theme is that knowledge of how students think about particular mathematical ideas plays important roles in supporting effective instruction (Carpenter, Fennema, Peterson, Chiang, & Loef, 1989; Hill, Rowan, & Ball, 2005). Moreover, recent findings encourage increased active learning approaches in undergraduate instruction (Freeman, et al., 2014; Laursen, Hassi, Kogan, & Weston, 2014), and a necessary ingredient in enacting such instruction is a rich understanding of and ability to interpret student meanings. In particular, to respond effectively and support further student learning, instructors need to infer what thinking (correct or incorrect) might underlay what students write and say.

There are many ways in which teachers can and do develop such knowledge, including from experiences with their own students. Researchers of teacher professional development (PD) have touted the value of designing opportunities for teachers to examine and analyze students' written work (see, e.g., Little, Gearhart, Curry, & Kafka, 2003). College mathematics instructors frequently engage in this practice while grading homework or tests and/or while interacting with students who are working on problems as part of classroom activities. However, often the goal is to assess students' understanding rather than to unpack and make sense of that understanding.

Although knowledge of student thinking supports effective instruction and examining student work appears to be a context in which teachers learn how students think, the undergraduate mathematics education community lacks tools for assessing this kind of knowledge. Being able to gauge the depth and breadth of this knowledge for particular topics will aid both researchers (seeking to evaluate and/or study the development of such knowledge) and those who provide PD (who wish to determine the need for attention to particular topics). For example, such an assessment could inform PD activities so that they are accessible to the instructors based on their current knowledge of student thinking. This, in turn, could enhance the PD we provide to graduate students and other novice instructors of college mathematics.

The value of these kinds of assessment instruments is readily apparent from the body of work that was made possible at K-12 levels because of the existence of such tools (e.g., Hill et al., 2005). Such studies have been extremely powerful in establishing the importance of this form of knowledge in the K-12 mathematics community. Because of the content-specific nature of this knowledge, it is not possible to merely adopt existing instruments for use at the undergraduate level. As an initial step in this development process for topics in the undergraduate curriculum, we documented instructors as they examined students' written work on calculus tasks with the aim of developing a rubric for gauging the extent of their knowledge of student thinking. Our analysis was focused on answering two questions: (1) What meanings and/or ways of thinking do instructors attribute to the student work? (2) How extensive (or not) is each instructor's catalog of such meanings? Answers to these questions are needed to inform future development of short answer, multiple choice and/or case-based assessment items.

## Research on Knowledge for Teaching

Findings from decades of research point to the important roles components of mathematical knowledge for teaching (MKT) play in teachers' practices and the learning opportunities they create for students. Of particular relevance to this study are the Pedagogical Content Knowledge (PCK) components of MKT that represent knowledge teachers use when hypothesizing what a student meant when they show their thinking when speaking, writing, and interacting with others. Studies have illuminated links between this kind of teaching-specific knowledge and both teachers' instructional practices and their students' learning (Carpenter et al., 1989; Hill et al., 2005). As part of these efforts, instruments have been developed to assess teachers' MKT. These instruments were based on findings from the substantial body of research on student thinking in the K-12 literature and on a robust set of classroom- and interview-based studies of teachers (Hill, Schilling, & Ball, 2004; Krauss, Neubrand, Blum, & Baumert, 2008).

As part of an effort to weave these findings from the K-12 MKT body of literature with findings from research on undergraduate student thinking, we are focused on categorizing college mathematics instructors' knowledge of student thinking. Our approach shares features with that of Jacobs, Lamb and Philipp (2010), who investigated the extent to which teachers paid "…attention to children's strategies but also interpretation of the mathematical understandings reflected in those strategies" (p. 184). By examining responses to assessments from teachers with varying levels of experience, these researchers were able to shed light on and characterize expertise in knowledge of student thinking, and document that this expertise can be developed.

## Research Design and Methodology

We conducted our work from a cognitive theoretical perspective because of the prevalence of this perspective in the research on knowledge and knowledge development as well as the primarily individual nature of the out-of-classroom teaching work that is the focus of our investigation. This perspective, with the premise that human cognitive activity is accessible via written and spoken communication, has been used productively to examine teachers' knowledge and its roles in teaching practices (Borko & Putnam, 1996; Escudero & Sanchez, 2007;

Schoenfeld, 2007; Sherin, 2002). One specific way to access what teachers know about their students' thinking is by attending to what they notice when looking at student work (Jacobs, Lamb & Philipp, 2010). In this paper, we leverage Jacob, Lamb, and Phillip's noticing framework as a way to unpack what mathematicians know about their undergraduate students' mathematical thinking related to limit.

Interview data came from task-based individual interviews with seven research mathematicians at three institutions who had been recognized for their excellence in teaching, through being nominated for or winning a teaching award. The interviews were audio-recorded and transcribed to aid in the coding and data analysis. Tasks were taken from or modeled after tasks used in research on student thinking about limit, function (as it appears in calculus), and derivative. Interview design was adapted from one used previously to examine college instructor MKT (Speer & Frank, 2013). This consists of three parts per task for each interviewee: (1) Solve the task and describe the solution, (2) describe how students would solve the task, including difficulties they may encounter and/or mistakes they might make, and (3) examine and discuss student work, noting productive and unproductive ways of thinking demonstrated in each response. Here our focus is on the participants' insight and understanding of student thinking based on their examination of sample written work from the limit tasks.

Data analysis was guided by grounded theory (Corbin & Strauss, 2008) but also made use of findings from research on student thinking about limit, particularly those that provide insights into common productive and unproductive ways of thinking demonstrated by calculus students (e.g., Oehrtman, 2008, 2009). Following the approach of Jacobs, Lamb and Philipp (2010), chunks of interview data were labeled as demonstrating robust evidence, limited evidence, or absent of evidence of insight and understanding of student thinking. Descriptions of these levels were then developed considering similarities and differences among coded interview excerpts and among various levels of evidence. Our unit of analysis was each participant's discussion of the set of student responses to an individual task.

## Findings

We found that Jacobs, Lamb, and Philipp's (2010) framework for classification of knowledge of student thinking was easily adapted to our data set. We demonstrate the applicability of this approach for use with instructors at the post-secondary level with interview excerpts and descriptions of how we operationalized the robust-limited-absent evidence rubric for use with our data. Although mathematicians examined several samples of student work, we illustrate our findings with data from their discussions of one student response to the prompt: "Describe what it means when we say 'the limit of $f(x)$ as $x$ approaches 3 is 12' ($\lim_{x\to 3} f(x)=12$)." The sample written student response said, "It looks like *f(x)* is 12 although *x* never actually reaches 3." Descriptions and transcript excerpts are shown in Table 1.

In interview excerpts coded as being *absent* in demonstrating insight into student thinking, the instructor does not explain what the student might be thinking and only notes that the response is not correct, remarking that she would assign it partial credit on a test. In the interview excerpt coded as *limited*, the instructor recognizes that this is a typical student response, suggesting one possible reason why a student might come up with this answer. However, this response is somewhat vague and does not demonstrate extensive or rich knowledge of student thinking. Responses coded as *robust* demonstrate an understanding of and validity in the student work, despite the not completely correct response. To demonstrate robust interpretation of student work and knowledge on this scale, one must provide examples of why students might answer in such a way, recognizing common productive/unproductive ways of thinking and describe possible origins for such ways of thinking.

*Table 1. Examples demonstrating three levels of knowledge of student thinking*

| Level | Description | Example from Interview |
|---|---|---|
| **Absent** | Does not articulate understanding about student thinking when interpreting the student work. Further, does not consider the student perspective and see validity in the portions of students' incorrect responses. | **Interviewer:** If that was an answer you saw on a test, or someone said to you in office hours, how do you feel about that one?<br>**Instructor 1:** (pause) I don't know.<br>**Interviewer:** It has that approaches 3 thing that you mentioned before.<br>**Instructor 1:** Yeah, there are some parts that I would give some partial credit, but I certainly would not get full credit because you know it is like "it *looks* like f(x) is 12", that is not quite correct, and "although *x* never reaches 3", so I would probably give something like partial credit, but no full credit. |
| **Limited** | Some articulation of student thinking; able to explain thinking demonstrated in common student responses, but either some pieces are left unexplained, or the interpretation of student work is vague. | **Instructor 2:** I mean this is – the very apt response, arcitypical [archetypal].<br>**Interviewer:** arcitypical?<br>**Instructor 2:** No I think it is fine; … I think this is a reasonably good approach. A good answer, if imprecise. It looks like f(x) is 12, so that's – I mean, it is just lacking the language to say that f(x) is within epsilon-delta of 12, right?<br>**Interviewer:** There is a tolerance –<br>**Instructor 2:** One way to imagine is that this is accompanied by a graph. And maybe they are thinking of the graph picture. |
| **Robust** | Able to take on the student's perspective in all responses, including less common errors, finding validity in aspects and recognizing where the student is still lacking in complete understanding. | **Instructor 3:** That's fine, this is exactly Newton's way of approaching limits.<br>**Interviewer:** What is the student thinking?<br>**Instructor 3:** So that's exactly this picture of as x *approaches* 3, but never touches…the limit they learned that you don't necessarily hit, and Newton had exactly this issue of what happened when you were trying to calculate the derivative…<br>**Interviewer:** Alright, and what do you make of the "it looks like f(x) is 12"?<br>**Instructor 3:** That's a response to this stuff, limit of f(x)=12, that's a reinterpretation of what they would think there. |

## Discussion and Implications

The goal of this work was to categorize what instructors do when interpreting student meanings/thinking in order to gain a better understanding of what it means to have knowledge of student thinking of undergraduate mathematics topics. This is the first step to developing an assessment grounded in practice adapting Jacobs, Lamb, and Philipp's (2010) framework of classifying the professional noticing of teachers.

The coding process revealed that mathematicians demonstrated multiple levels in their interpretation of student work across various tasks. This suggests that even experienced instructors may have had different opportunities to hear students' reasons for answers or may engage differently with student work on different tasks or topics. Although the central goal of the analysis was to inform assessment development, we offer preliminary thoughts on this apparent variation. Differences could be related to their dispositions towards student thinking and willingness to engage with the student work (although we note that all participants appeared to engage with the tasks). Alternatively, they may have had different opportunities to engage with student thinking due to differences in their instructional approach (i.e., there may be fewer opportunities to hear student thinking in a lecture-based class than one utilizing collaborative groupwork). Further analysis is needed to test and refine this tool to gauge instructor knowledge. This will entail examining data from additional instructors (including more novice instructors) as they examined written student work on limit tasks and also an expansion to data we have from the same instructors as they examined student work from function, derivative and integral tasks.

By operationalizing the Jacobs, Lamb, and Philipp's (2010) framework for our limit tasks we begin the work of identifying characteristics of varying depths and breadths of knowledge of student thinking. We see two features as varying across the levels. One relates to the richness of the participants' descriptions of the student thinking. These range from non-existent to including multiple diagnoses for what a student might have been thinking. Participants also varied in the extent to which they articulate hypotheses for *why* responses might have seemed reasonable to students. We view this empathetic disposition as aligned with Smith III, diSessa, & Roschelle's (1994) perspective on student misconceptions and as an important avenue for further study.

Once refined, these characteristics can then be used to develop instruments for gauging this knowledge through means other than interviews. Such instruments with items in open response, multiple-choice or case-based formats would make other approaches to this work feasible, including assessment in larger instructor populations and/or coupled with observations of teaching. Such a tool could also be used to track growth in instructors' abilities to interpret student thinking and depth of knowledge over time and/or after participating in PD.

Instances of robust understanding provide us with evidence that mathematicians can develop such knowledge. We note that development of this knowledge most likely occurred from their on-the-job experiences of examining student work and interacting with students given the scarcity of teaching-specific professional development opportunities typically available for college instructors (Holdren & Lander, 2012). The varied levels demonstrated by participants suggest that examining student work could be productively used in college instructor PD to further enhance their practice-based learning opportunities. In addition, such an approach could provide an opportunity for exposure to not only student work/student thinking, but also help develop instructors' understanding that knowledge of student thinking is indeed a set of knowledge that is (1) desirable for instructors to possess to support effective instruction, and (2) something that can be attended to and enriched over time. Moreover, this leads to the possibility for more targeted PD when armed with insight into types of responses one might expect from experienced and novice instructors. It also has the potential to illuminate and document growth in knowledge of student thinking over time, pointing to the influence of PD or experience in this development. Utilizing such approaches in the professional development of undergraduate instructors can help our community improve the learning opportunities we create for students.

# A Student's Use of Definitions in the Derivation of the Taxicab Circle Equation

Aubrey Kemp
Georgia State University

Draga Vidakovic
Georgia State University

*Research shows that by observing properties and making conjectures in other geometries, students can better develop their understanding of concepts in Euclidean geometry. It is also known that definitions in mathematics are an integral part of understanding concepts, and are often not used correctly in proof or logic courses by students. APOS Theory is used as the framework in this preliminary data analysis to determine one students' understanding of certain definitions in Euclidean and Taxicab geometry, and her use of these definitions in deriving an equation for a circle in Taxicab geometry.*

*Key Words:* Definitions, Geometry, Taxicab, Geometrical Reasoning

## Introduction

It has been found that commonalities exist in higher-level math courses regarding students' inability to properly complete tasks involving definitions (Edwards & Ward, 2004), despite the expectations held for students enrolled in such courses. Edwards and Ward (2004) state that there were misconceptions in students' understanding of "the very nature of mathematical definitions, not just from the content of the definitions," (p. 411). In the context of geometry, since the properties of geometric figures are derived from definitions within an axiomatic system, it is important to note that a figure is "controlled by its definition," (Fischbein, 1993, p. 141).

In college geometry courses, Euclidean geometry and its axiomatic system is deeply studied, but other axiomatic systems receive little consideration (Byrkit, 1971; Hollebrands, Conner, & Smith, 2010), although research shows that by exploring concepts in non-Euclidean geometry, students can better understand Euclidean geometry (Dreiling, 2012; Hollebrands, Conner, & Smith, 2010; Jenkins, 1968). For example, Dreiling (2012) found that "through the exploration of these 'constructions' in taxicab geometry…[students] gained a deeper understanding of constructions in Euclidean Geometry." (Dreiling, 2012, p. 478).

For this preliminary report from the larger research study, we present results and discussion on the following research question: What is the learning trajectory one student followed to accommodate her understanding of *distance* and *circle* in Taxicab geometry?

## Theoretical Framework

As a constructivist framework, APOS Theory is based on Jean Piaget's theory of reflective abstraction, or the process of constructing mental notions of mathematical knowledge and objects by an individual during cognitive development (Dubinksy, 2002). In APOS Theory, there are four different levels of cognitive development: Action, Process, Object, and Schema. In addition, there are mechanisms to move between these levels of cognitive development, such as interiorization and encapsulation. An Action in APOS Theory is when a student is able to transform objects by external stimuli, performing steps to complete this transformation. As a student reflects on an Action and has the ability to perform the Action in his or her head without external stimuli, we refer to that as an interiorized Action and call it a Process. Once a student is able to think of this Process as a whole, viewing it as a totality to which Actions or other

Processes could be applied, we say that an Object is constructed through the encapsulation of the Process. Finally, the entire collection of Actions, Processes, Objects, and other Schemas that are relevant to the original concept that form a coherent understanding is called a Schema (Dubinsky, 2002).

## Methodology

This research study was conducted in a College Geometry course during Fall 2016, which has an introduction to proof course as a prerequisite. Since it is a cross listed course, there were seven undergraduate and 11 graduate students enrolled in the course, many of whom were pre-service teachers. The study is defined as a teaching experiment, as described by Cobb and Steffe (2010) and Steffe & Thompson (2000), which consisted of sessions of instruction, followed by individual interviews. The textbook used in the course was College Geometry Using the Geometer's Sketchpad (Reynolds & Fenton, 2011), which is written on the basis of APOS Theory. The material of the course covered concepts and theorems often seen in a College Geometry course, with Taxicab geometry included at the end of the semester. Videos from in-class group work and discussion, as well as written work from the semester were collected. After the semester, semi-structured interviews were conducted with the 15 of the 18 students enrolled in the course who volunteered. We focus our attention in this paper to one student and some of her answers to the interview questions, as they provided good insight as to how students transfer definitions to a new context. The following questions are relevant to this paper, and are a subset of the questions asked during the interview:

1. Define and draw an image (or images) that represents each of the following terms, however you see fit: Circle, Distance.
2. For any two points $P(x_1, y_1)$ and $Q(x_2, y_2)$
   (i) Euclidean distance is given by $d_E(P,Q) = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$
   (ii) Taxi distance is given by $d_T(P,Q) = |x_2 - x_1| + |y_2 - y_1|$
   Using the grids below, illustrate each of these two distances. Be as detailed as possible in labeling them.
3. Using the grids below, sketch the following circle in both geometries: Circle with center at $C(3,3)$ and radius $r = 2$.

These questions were used in the analysis for this preliminary report, since they help to identify student understanding of *distance* and *circle*, and the possible pathway a student takes to transfer and possibly modify her definitions to new situations. Specifically, for this paper, we focus on how a student used her definition of *distance* and *circle* in her attempt to derive the algebraic representation of a Taxicab circle.

A genetic decomposition is defined as a "description of how the concept may be constructed in an individual's mind," (Arnon et al., 2014, p. 17). A preliminary genetic decomposition was developed for this study to identify the development pathway students may follow to derive (or understand the derivation of) this equation (see Figure 1). To specify, *geometric representation* includes any sketch or drawing in addition to the students' verbal description of the definition, unless they specifically state the definition is an equation.

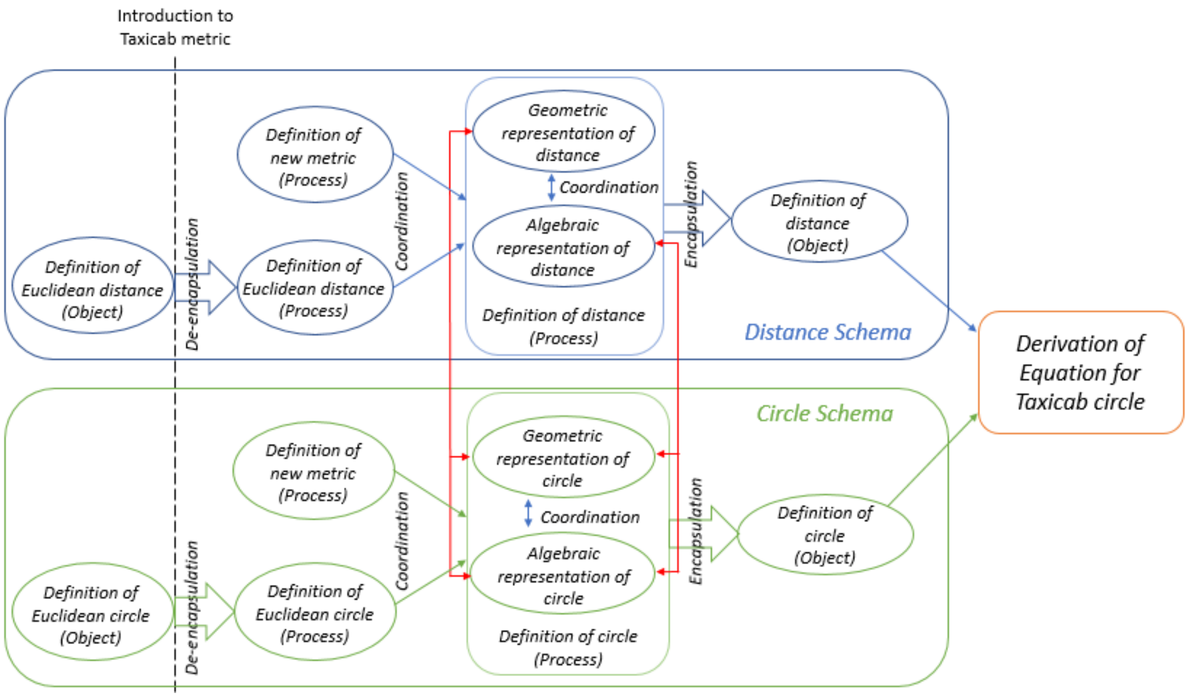

Figure 1: Preliminary genetic decomposition.

Based on our own understanding of historical development of these concepts, along with existent research results, we partitioned the concepts of *distance* and *circle* in terms of their schemas, and illustrated how students develop this equation in Taxicab geometry. As illustrated in Figure 1, we propose that in dealing with concepts of *distance* and *circle* in these two geometries for this task, students exhibit an interplay between two schemas. For the sake of length, we omit a full explanation of Figure 1.

## Preliminary Results

We provide the APOS Theory based analysis of one student's answers, Nicole, as it corresponds to this preliminary genetic decomposition.

### Geometric Representation of Distance

Nicole stated, "I know with Taxicab I can't just look at the distance as this from A to B, I have to go…up and around I mean up, like I'm using the road and not going through," and "there are certain steps I have to take or a certain route…" Illustrations of her conception of these metrics can be found in Figure 2. Later, in responding to a question about her Taxicab circle, Nicole was able to use a definition of Taxicab distance to justify that every point on her diamond shaped Taxicab circle was equidistant from the center. Therefore, she clearly exhibited an object conception of *geometric representation of distance* in Taxicab geometry since she was able to think of it as a totality and apply an action (comparison) to it.

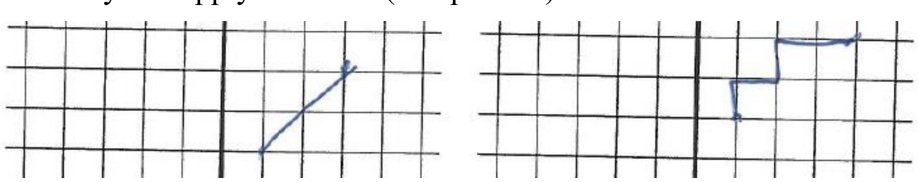

Figure 2: Nicole's illustrations of Euclidean and Taxicab distance, respectively.

## Algebraic Representation of Distance

Nicole defined *distance* as "the measurement in between…two or more points that someone would ask me." Further, Nicole clearly explained that with the two geometries, "the definition [of distance] would be the same, but how to find it with the equation won't be the same," indicating that she distinguishes between these metrics. This is evidence of a process conception of *algebraic representation of distance* since she seemed to have a general definition for distance and would be able to find the distance between any two points in either geometry.

## Geometric Representation of Circle

Nicole demonstrated and stated, that she is able to construct a Euclidean circle easily without plotting specific points on the circle (see Figure 3 - red ink indicates her drawing during the interview discussion). Developmentally, with the addition of Taxicab distance, Nicole reorganized her Euclidean Circle Schema to accommodate this new metric in order to describe and draw the Taxicab circle. When describing this circle in comparison to a Euclidean circle, she says "when I think of in Taxicab geometry …visually it won't be the same, but I do think the definition [of it] would be the same, because it has to be equidistant to be a circle." She explained that when she drew her Taxicab circle, she had to "follow strict routes, making my radius." She attempted to apply her written definition of circle by using the property of equidistance, and constructed her Taxicab circle incorrectly (see blue square in Figure 3, sketched during her individual work). This may be due to her inability to coordinate her *geometric representation of distance* in Taxicab geometry and her definition of circle as a set of equidistant points from a fixed point. More specifically, she was not able to imagine traveling a given distance in all directions from the center following 'strict routes.'

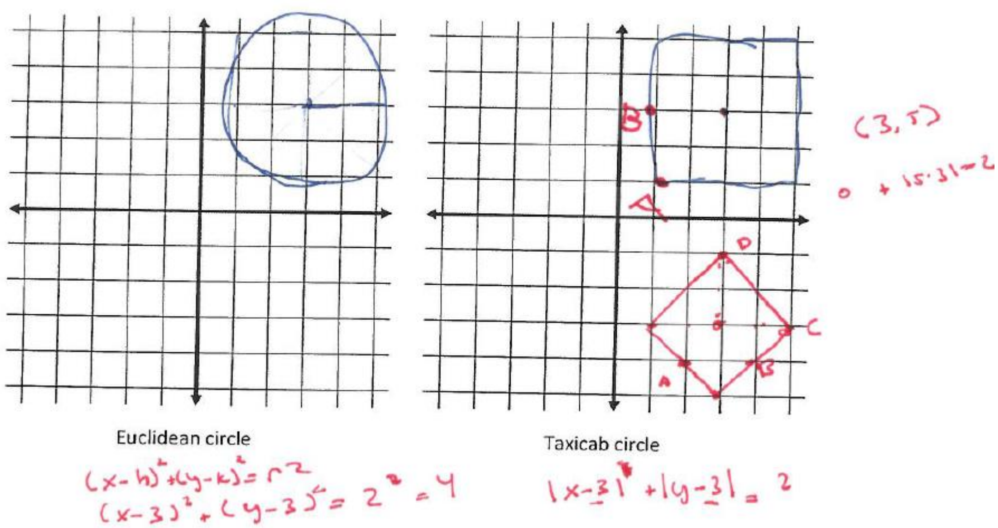

Figure 3: Nicole's illustrations of Euclidean and Taxicab circles, respectively.

During the interview, with prompting, Nicole recalled the shape of a circle in Taxicab geometry is a "diamond." She constructed this by finding four points (vertices) on the diamond and connected them (see red diamond in Figure 3), saying "oh, but it was like this". Thus, Nicole exhibited an action conception of *geometric representation of circle* in Taxicab geometry, since she relied on her memory for the shape of a Taxicab circle and needed external cues to draw it.

### Deriving the Algebraic Representation of Circle

Nicole, with prompting, could recall the equation for the Euclidean circle, and arrived at the correct equation (see Figure 3). She seemed to be completing a sequence of steps, each provoked by the previous, since she first needed to write the general equation for a Euclidean circle, then identified the variables that would be replaced by the given center and radius, and finally plugged them in. By working off memory, Nicole exhibited an action conception of *algebraic representation of circle* in Euclidean geometry. Later, Nicole recognized some relationship between the formula for distance and the equation for a circle when prompted to derive the equation for a circle in Taxicab geometry. She stated, "I'm wanting to use…absolute values simply because we use absolute values for the distance? But that could be wrong." These statements imply Nicole saw the Euclidean distance formula is used in the Euclidean circle equation, and thus inferred the same must be true in Taxicab geometry. It appears she relied on this pattern to create her equation for the Taxicab circle. Thus, we believe that Nicole has an action conception of *algebraic representation of circle*.

## Discussion and Concluding Remarks

Fischbein (1993) explains that in geometrical reasoning, a major obstacle is the tendency to "neglect the definition under the pressure of figural constraints," (p. 155). The results presented in this paper support this notion, with Nicole exhibiting a slightly different path to derive her Taxicab circle equation other than what our preliminary genetic decomposition illustrated. Our data indicates that Nicole had an action conception of *geometric representation of circle* and an object conception of *geometric representation of distance*, which allowed her to eventually draw the given Taxicab circle.

We expected that to derive the equation for a Taxicab circle, Nicole would need to have an object conception of *algebraic representation of distance.* Although she eventually arrived at the correct equation for her Taxicab circle with a process conception of *algebraic representation of distance*, her success was reliant on reproducing patterns instead of logic. Further, we claimed that she must have an object conception of a definition in Euclidean geometry to consider applying it in a new geometry. Nicole demonstrated that out of the concepts considered, she had an object conception of *geometric representation of distance* only, which could be why she struggled to derive the Taxicab circle equation from logic. Vinner (1991) and many others support this, since knowing a definition does not imply a real understanding of the concept.

As evidenced in this study, Nicole knew the definitions of *circle* and *distance*, but was unable to apply them effectively to derive an equation, and instead relied on patterns. We still believe an object conception of definitions is necessary prior to operating in another geometry to logically derive this equation. We plan, for future analysis, to identify the cognitive paths for each student and further investigate misconceptions these students illustrate in their discussion about deriving the equation for a Taxicab circle.

## Questions for the Audience

1. What obstacles have your students faced when transferring their knowledge of definitions to a new context?
2. What are some good activities that can assist students in encapsulating their definitions?

# Assessing Group Learning Opportunities in a First Semester Calculus Course

Jennifer M. Kearns
West Virginia University

Johnna Bolyard
West Virginia University

*The purpose of this study was to examine how undergraduate calculus students positioned themselves within group work and how that positionality influenced their own and others' learning opportunities. Using qualitative methods, this study examines the specific group social interactions and positionalities that led to productive and unproductive group problem solving. The study used a sociocultural lens to identify productive group work and learning. The findings of this paper suggest the roles students assume are very fluid throughout the problem solving process. In addition, the roles that the students assume influenced the learning opportunities. Furthermore, groups that utilized individualistic group practices were not able to build opportunities for conceptual understanding nor have productive group learning.*

*Keywords:* Calculus I, Collaborative Learning, Positionality

This study adds to the body of research on group work and collaborative learning in the mathematics classroom. Prior research suggests that collaborative learning aids in positive learning outcomes. For example, research suggests that in the mathematics classroom small group learning can increase academic achievement and promote positive attitudes to learning mathematics (Draskovic, Holdrinet, Bulte, Bolhuis, &Van Leeuwe, 2004; Smith, McKenna, & Hines, 2014; Springer, Stanne, & Donovan, 1999). Forbes, Duke and Prosser (2001) found that students perceive group-based instruction as effective as traditional lecture based learning models. A related body of literature examines group compositions and how to promote productive group learning (Cohen, 1994; Dolmans, Wolfhagen, Scherpbier, & Vleuten, 2001; Engle & Conant, 2002; Esmonde, 2009; Haller, Gallgher, Weldon, & Felder, 2000; Johnson & Johnson, 1999; Webb, 1991). Cohen (1994) recommends moving away from the standard academic achievement measures and examining group interactions and group engagement as a means of defining successful group work. Additionally, this body of research suggests that status within groups can cause inequitable interactions and learning discrepancies (Haller et al., 2000). This research is mainly situated in primary and secondary mathematics classrooms with very little research at the undergraduate level and more specifically within the context of a first semester Calculus course. The purpose of this study is to add to this collection of literature a meaningful analysis of how group interactions and positionality impact the learning opportunities and problem solving process.

## Theoretical Framework

Two bodies of literature are utilized to build the theoretical framework for this study. The first, sociocultural theory, provides a means for understanding and defining conditions in which learning occurs. The second body of literature is the work on positionality and roles within groups as defined by Cohen (1994), Draskovic et al. (2004), and Esmonde (2009).

### Sociocultural Theory and Defining Learning Opportunities

Sociocultural frameworks are rooted in the Vygotskian school of thought where all learning is socially constructed (Goos, 2004). Within this framework all knowledge is constructed through the lens of social interaction institutions (Nasir et al., 2008). Saxe (1999) identifies cultural activities as integral to understanding cultural changes but also cognitive change. It is in the cognitive change where knowledge is developed through a communicative process engaging and reacting to others. Lastly, learning is facilitated through the use of tools and language available to the student. It is the social interactions in which the individual participates that generates the Zone of Proximal Development (ZPD) (Steele, 2001). Within the ZPD there is an intersection of individual meaning making and social constructs that allows for active engagement in the learning process. ZPD is the space between the individual's current understanding and potential for new understanding. Within this space is where learning and growth occur within the sociocultural framework (Lerman, 2001).

**Defining Roles and Positionality**

Another body of literature that informs this study examines how group interactions develop, nurture, or impede upon the learning and growth of the individual. How individuals choose to participate and are positioned influences learning (Draskovic et al. 2009; Esmonde, 2009; Webb, 1991). Results have shown some roles aid in productive group work and others hinder the process. One significant role within groups that has been studied is the role of *facilitator* (Cohen, 1994, Esmonde, 2009, Draskovic et al. 2004). Facilitators or tutors direct the path of knowledge and problem solving by providing explanations and rationales to the group. This role is significant for two reasons. First, this role provides a valuable resource to the other group members, aiding in the extension of knowledge and potential for learning of others within the group. Secondly, the individual assuming this role is able to build conceptual understanding through articulating his or her ideas. Esmonde (2009) identified the complementary roles of expert and novice. Experts have significant influence over the direction of the group and provide a source of information and resources. However, contrary to the facilitator role, experts go unquestioned with their authority. This role can cause a problem in instances when experts provide incorrect knowledge to the group. The counterpart to this role is the novice. The novice is the receiver of the knowledge from the expert. This role is counterproductive to aiding in building conceptual knowledge or the problem solving abilities of either role. In Vyogotskian thought, learning is developed through conversation that supports understanding and meaning making. In the roles of expert and novice, the unidirectional communication is directive rather than conversational. Thus, meaning making and conceptual learning is severely restricted when students assume these two roles.

Although many studies have found positive gains through collaborative learning, there are positionalities that impede upon learning in a group context. Dolmans, Wolfhagen, Scherpbier, and van der Vleuten (2001) recognize the impact of *sponging* on the learning of the individual and overall group. Sponging occurs when an individual sits idle with little to no input yet expects to profit from the work of others in the group. Additionally, a dominant personally as described by De Grave, Dolmans, and van der Vleuten (2001) can also impede the overall group interactions and learning. Draskovic et al. (2004) hypothesize that collaborative group problem solving aids in positive knowledge gains when the occurrences of undesired positionalities are mitigated.

The goal of this study is to examine students' positionality as a means of understanding productive group problem solving and learning opportunities. With a dual perspective that learning is constructed through social interactions and developed through internalization of the individual's new constructs with existing constructs, the primary research questions are (1) How does an individuals' positionality in the group influence the group problem solving process? (2) How do the roles that students take influence their learning opportunities?

## Methods

The participants of this study were enrolled in a first semester calculus course (Calculus I) at land-grant institution in the Mid-Atlantic region of the United States. Participants in this study were placed in groups based upon student major. This particular grouping method was significant in order to control for the individuals that may be automatically placed in the role of expert by the group due to field-specific knowledge relevant to solving the problem. Group A consisted of four female biology majors. Group B consisted of three males and one female bio-chemistry majors. There was no preference given to gender or prior academic performance in the course in the group construction.

## Data Collection and Analyses

This study examined the group interactions in a clinical setting where students were presented the group work within the context of their normal recitation portion of the course. Students were first presented with standard pedagogical methods for introducing optimization problems to first semester calculus students as part of their standard lecture-based instruction. These instructional methods are out of the scope of this study. However, as noted by Crooks and Alibali (2013), the way students encode prior knowledge significantly influences how students perceive and ultimately solve problems. The findings of Llinares and Roig (2008) suggest that students use particular cases in the development of the modeling process. Given a particular case, students will base mathematical decisions from the model constructed. This encoding was addressed by presenting each group with a novel optimization problem related to their intended field of study. Both groups were required to minimize the resistance of blood flow in veins. Minimizing of resistance problems required the participants to have some understanding of the biological concepts to aid in the orientation phase in the problem.

The group problem solving cognitive process was documented through video recording. This structure builds upon the work of De Grave, Boshuizen, and Schmidt (1996) as a way to investigate cognitive and metacognitive processes in a group problem solving setting. Recording the problem solving process without interfering provides an authentic representation of students' conceptualization and problem solving. The recordings were transcribed for analysis.

To understand the group interactions and positionalities the transcripts were coded using the work of Esmonde (2009). The first round of coding identified the group work as collaborative, individualistic, or helping. Collaborative group work was identified as interactions where the group members asked questions, debated ideas, and worked together toward a common goal. Individualistic group work was identified as situations in which the individual group members worked separately and then used each other as a resource for checking and verifying purposes only. Lastly, helping group work involved one or more individuals who instructed other group members. In this case there was no back and forth conversation or questioning of ideas. Rather, helping was clearly a unidirectional flow of information from one individual to another.

The second tier of coding examined the roles each group member held. First, phases of the problem solving process were identified for each group, including the orienting, planning, executing, and checking phases as described by Carlson and Bloom (2005). Within each phase the work of Esmonde (2009) was used to develop provisional categories of facilitator, expert, and novice to describe the positionality of each individual. Through reiterative coding, additional categories were defined of associate and by-stander. These two positionalities were not identified in the work of Esmonde (2009). Associates were fully engaged in the group discussion, however were not considered facilitators as they were not the gatekeepers of information. Associates were individuals that were perceived as equals in knowledge acquisition. By-standers were still engaged in absorbing information, however these individuals did not provide feedback, questions, or suggestions. Unlike a novice, by-standers were not directly engaged with an expert and appeared when other group members were engaged as associates. By-standers did not provide any meaningful direction to the problem solving.

## Preliminary Results and Discussion

The analyses revealed there were two key findings. The first finding suggests that the roles that students hold significantly impact the individual's and the group's learning opportunities. These roles were very fluid throughout the problem solving process. Secondly, the group's work practices influenced the learning opportunities. For example, the group that utilized individualistic group practices did not have the same learning opportunities as the group that utilized more collaborative group practices nor successful completion of the problem.
Phases of the problem solving process become more fluid in a collaborative setting. This allowed the individuals the opportunity to take on various roles throughout the entire process. Figures 1 and 2 show the fluidity of the roles individual group members held. Several of Group B member's phases were individualistic and therefore positionality could not be determined. Thus, a sixth category, individualist, was introduced to describe the positionality of the group.

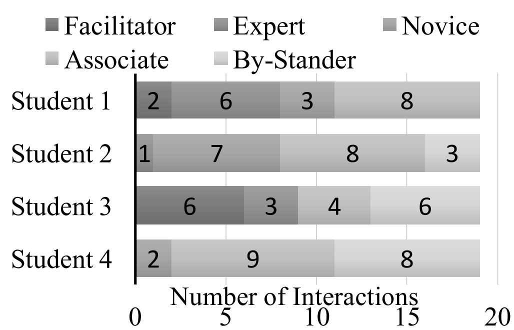

*Figure 1. Group A Positionality*

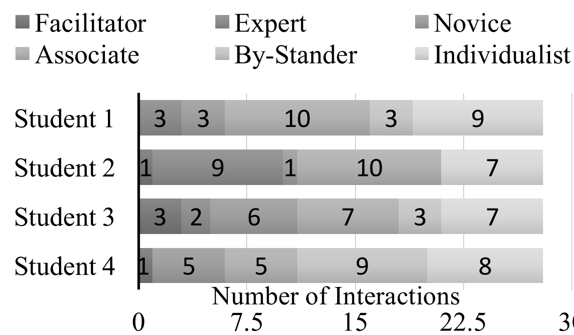

*Figure 2. Group B Positionality*

By examining the positionality of each group member, the expectation is to understand how the positionality of the individual influenced learning opportunities. Results of this analysis indicate that, although the roles of facilitator and expert are critical in successful problem solving, students in those roles do not necessarily benefit from the collaborative work. However, students benefit from the role associate as a means of building conceptual knowledge and mathematical skills. The roles of facilitator and expert can be interpreted as knowledge disseminators. These key roles are distinctive in a way that these students are the knowledge holders. In Vygotskian thought, students in the expert role are not in a position to learn. The only case in which learning would occur would be if there was a contradiction between the meaning held of the student and the interpretation of the other group members. This was not observed due to unquestioned authority of experts. Therefore, only a facilitator who is engaged in conversation with others would have the opportunity for learning. Interestingly, in both groups, even if the content knowledge from the expert was incorrect or the explanation by the facilitator was inappropriate, the other group members failed to recognize the inconsistencies. This may be due to the fact that students in both of these roles where viewed as having stronger mathematical knowledge, leading to these students not being questioned thoroughly or at all. It was only in the role of associate that group members questioned each other and expected full explanations. In these instances, students used the approaches cautiously until either the approach was validated by the instructor or a consensus among the group. Within the sociocultural framework, students engaged in the associate role found themselves in the ZPD by positioning themselves with the highest potential for learning and growth to occur. Thus, in terms of productive group work, it is suggested that students be encouraged to engage in this equal playing field of questioning ideas and approaches.

The role distribution played a significant function in whether a group could successfully complete the problem. Thirty-eight percent of Group A's interactions were identified as associate role. Contrary to this, only 29 percent of Group B's interactions were identified as associate roles. Furthermore, the problem given restricted the students' ability to model a previous example to solve the problem. There was evidence that both groups used the diagram provided in order to relate to a previous example. However, Group A was able to dismiss the incorrect approach through a continuous back and forth discussion. Group B continuously reverted back to individualistic roles once a strategy was introduced. This led the group to continue down paths that led to incorrect solutions. Group B struggled significantly at orienting themselves to the problem and determining a clear and defined approach to solve the problem. This group relied heavily on the instructor for direction and clarity.

The group work practices also contributed to the groups' ability to complete the problem. Group A never worked in an individualistic manner. All the interactions were either collaborative or helping. This led to more group discussion thereby creating ZPD. In the Vygotskian thought, these dialectic conversations created more learning opportunities for this group. In contrast, Group B spent over a third of the interactions working individually rather than collaboratively. This may be attributed to the group composition. Group A was entirely female whereas the majority of members in Group B were male (three out of four). The findings here support those of Haller et al. (2000) who found women prefer collaborative interactions to competitive interactions. The all female group solely utilized collaborative group practices. The primarily male group not only utilized collaborative work practices less, but the group applied individualistic practices which are more indicative of competitive interactions. Furthermore, this may have significant impacts for the one female in Group B (Student 4). She spent 60 percent of her interactions as either a by-stander or working individually compared to Group A where only 22 percent of interactions were described as by-standers (no individualistic interactions were recorded). This significantly reduced Student 4's group discussion and therefore significantly reducing her learning opportunities.

## Conclusion

This study confirms the findings of Draskovic et al. (2004) and Esmonde (2009) where positive group interactions lead to successful learning opportunities in a group context. However, it was found that within the role of associate, where the students provided meaningful back and forth dialog and questioning, that one can find evidence of increased ZPD and learning opportunities. Moreover, individualistic group work can lead to unproductive group work and this may be more prevalent in male dominated groups opposed to female groups. These results of this study suggest that educators should be fostering a strong back and forth dialog amongst students and help initiate those types of interactions. Furthermore, additional research should focus on the gender gap that was observed in the positionality and group practices of the group along with the potential impact on women in male-dominated groups. Lastly, future research may include the student perception of roles and the impact on positionality.

# Leveraging the Perceptual Ambiguity of Proof Scripts to Witness Students' Identities

Stacy Brown
California State Polytechnic University, Pomona

*Recognizing identity not only as an important educational outcome but also being inter-related to students' knowledge and practice, this paper explores an affordance of proof scripts; the witnessing of students' identities. Drawing on proof scripts from teaching experiments and the construct of perceptual ambiguity, this paper argues that proof scripts afford access not only to students' understandings, problematics, and ways of reasoning but also students' identities.*

*Key words*: Identity, perceptual ambiguity, proof scripts

There exists a host of reasons for why researchers have grown increasingly interested in identity. Yet, this interest has not been accompanied by a growth in methodologies that afford the study of identities. The aim of this paper, therefore, is to demonstrate how the perceptual ambiguity of proof scripts can be leveraged to explore students' identities. To accomplish this goal, three steps are taken. First, I explore why interest in identity has grown in recent decades. Second, I describe the proof script methodology. Third, I present a characterization of perceptual ambiguity and then draw on proof script data to illustrate and discuss how proof scripts afford access not only to students' understandings, problematics, and ways of reasoning but also their identities, if we work to leverage their perceptual ambiguity.

## Identity

Students' identities have become increasingly of interest to researchers. As researchers have grown in their capacity to document student affect and its impact on learning (cf. Bishop, 2012), organizations (e.g., NCTM, 2000) have increasingly called for teachers and researchers to work to better understand the emergence of productive dispositions. Also, researchers interested in equity oriented instruction have increasingly recognized not only that knowledge and practice are interactively constituted but also that students' identities impact students' knowledge and practice. Boaler (2002), for instance, has argued that classroom learning is constituted through interactions between students' knowledge, identities, and practices (see Figure 1); arguing, like Wenger (1998), that learning "is an experience of identity" (p. 215). Last, Bishop (2012), has argued that due to their impact on dispositions, affect, persistence, and achievement, identities are recognized as an important educational outcome.

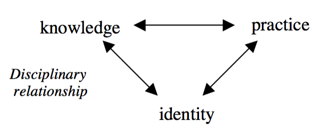

Figure 1. Boaler (2002) Learning Model

Despite agreement on its importance, definitions of identity vary widely. Due to length limitations, the discussion will focus on the definition of identity proposed by Bishop (2012). Bishop (2012) defines *identity* as: "a dynamic view of self, negotiated in a specific social context and informed by past history, events, personal narratives, experiences, routines, and ways of participating…. (it) is both individually and collectively defined" (p. 38). This definition highlights that identities are interactively constituted within environments and, in part, by others.

One of the primary means for interactive constitution is *discourse* – a point emphasized by Gee (2001, 2005) who argued that identities are created through discourses, by Sfard and Prusak (2005) who define one's identity in terms of internalized communications and narratives, and by Bishop (2012) who argues "discourse plays a critical role in enacting identities." Indeed, identities become visible through discourse as interlocutors position themselves and others in relation to their current social context, institutional setting, and history – a point poignantly illustrated by Setati (2005), who studied how class and power are enacted through mathematics classroom discourses. Like, Bishop (2012) and Setati (2005), the position taken in this paper is that discourses can serve as a primary means for exploring identity.

## The Proof Script Methodology

Interest in students' reading strategies, difficulties with, and comprehension of mathematical proofs, has led to a host of studies. These studies have either employed proof comprehension assessments (*cf*. Mejia-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012), clinical studies (*e.g*., Weber, 2015), or novel methodologies, such as *proof scripts* (Koichu & R. Zazkis, 2013; D. Zazkis, 2014; R. Zazkis & D. Zazkis, 2016). The latter entails having students produce a written dialog where the interlocutors discuss a given proof, highlighting *problematics* (i.e., difficulties identified by students) and elaborating on key points to promote understanding. The dialogs are then analyzed by researchers to create models of students' understandings of the content and practices attended to, their perceptions of key points and ways of reasoning about *problematics*. This methodology emerged for a variety of reasons. First, as noted by Koichu and Zazkis (2013), past research examined students' difficulties from the researchers point of view. Methods were needed that enabled the identification of problematics, a point also emphasized by Brown (2017). Second, the methodology aligns with theoretical perspectives that see discourse as integral to thinking. Specifically, the methodology builds on Sfard's (2007) commognitive theory, in which Sfard argues thinking can be viewed as individualization of "the activity of communicating" (p. 571) that is derived from the collective patterned activities one experiences.

## Perceptual ambiguity as a means to witness students' identities

At its core the proof script methodology calls on students to produce a written dialog in which the participants discuss a proof, paying special attention to the key ideas and problematics observed. Taking the perspective that the dialogical interactions generated are reflective of students' thinking, recent studies have shed light on students' understandings of important mathematical topics and practices (Koichu & R. Zazkis, 2013; D. Zazkis, 2014; R. Zazkis & D. Zazkis, 2016; D. Zazkis & Cook, *in press*). However, is this all that we can learn? The position taken in this paper is that the methodology affords not only a means to explore students' understandings but also to witness students' identities, if we attend to their perceptual ambiguity.

Figure 2. W. E. Hill's Cartoon

In 1915, W.E. Hill published the drawing shown in Figure 2. Staring at the drawing one of two images will appear, either a young lady with her head turned or an elderly woman looking down pensively. Both images are present. Yet, there is just one drawing. Both reside in the same set of lines. Yet, *we can only see one image at a time*. This is why the drawing has what psychologists call *perceptual ambiguity*. Perceptual ambiguity refers to instances in which one's grouping of certain contours, images, or ideas supports one's perception of a figure, object, or meaning while the grouping of other contours within the same image promotes a different singular perception. Such drawings were of interest to psychologists for they demonstrated that vision is an active rather than passive process; what is seen is constructed by the viewer actively. In this paper, perceptual ambiguity is of interest for it aptly describes an affordance of proof scripts: they afford observation of students' ways of attending to proofs while at the same time enabling us to witness students' identities, if we engage actively in the process of *seeing* students' positioning of themselves in relation to others, to the discipline, its practices and knowledge.

## The Study

To examine students' ways of attending to contradictions, 43 proof scripts were collected from 2nd and 3rd year university students enrolled in an IBL - Introduction to Proof course who were given the proof task shown in Figure 3 during the last week of the term. Data collection occurred at a designated Hispanic-serving institution, where the majority of students are first generation college students, who qualify for need-based financial assistance. The original research question was "Which problematics and key ideas are salient to and noticed by students, when producing scripts for proofs involving contradictions?" However, when analyzing the data it became increasingly apparent that the discursive interactions did more than provide a window into students' reasoning about contradictions, for they also afforded an opportunity to witness students' enacted identities. In other words, the proof scripts embodied a form of perceptual ambiguity. Taking the position that students' identities are an important learning outcome of *all* mathematics courses, this affordance became the focus of the research. The purpose of this preliminary report is to provide an existence proof of proof scripts' perceptual ambiguity and in so doing establish a methodological approach to the study of students' identities that is distinct from but in harmony with the discursive approaches taken by Bishop (2012) and Setati (2005).

***Assignment:***
***Part 1***. Start by reading the proof and identifying what you believe are the "*problematic points*" for a learner when attempting to understand the theorem and its proof. A *problematic point* is anything you think is incorrect, is confusing, or is correct but warrants further discussion. List these "*problematic points*" in a bulleted list.

***Part 2.*** Write a dialogue between you and Gamma in which you and Gamma discuss the theorem and its proof. The dialog should address the *problematic points* you identified (and listed in your bulleted list) through questions posed either by you or Gamma.

***Theorem*:** For any real numbers $x$ and $y$, if $x \leq y$ and $y \leq x$ then $x = y$.
***Proof*:**
1) Assume $x$ and $y$ are real numbers such that $x \leq y$ and $y \leq x$.
2) Then ($x < y$ or $x = y$) and ($y < x$ or $y = x$).
3) We will consider four cases
Case 1. $x < y$ and $y < x$.
Case 2. $x < y$ and $y = x$.
Case 3. $x = y$ and $y < x$.
Case 4. $x = y$ and $y = x$.
4) In Cases 1 through 3 our assumptions contradict the Law of Trichotomy.
5) We are left with Case 4.
6) Case 4. $x = y$ and $y = x$.
7) Therefore, $x = y$.
8) The result follows. ♦

Figure 3. The Proof Script Task

The remainder of the paper, which will constitute the findings of the study, will proceed in two parts. In the first part, we examine excerpts from proof scripts to demonstrate how they afford the opportunity to examine students' understandings of the attended to problematics and content.

In the second, the same excerpts are analyzed to witness students' identities. Here it is important to note that the term *witness* is used intentionally and in reference to the belief that, at best, researchers can only hope for *disciplined subjectivity* (LeCompte et al., 1999) when seeking to understand others' identities and histories.

**Findings, Part I: Proof scripts as a means to examine student understandings**

While it may seem that there is not much to say in relation to the proof, the IBL-Introduction to Proof students had little difficulty elaborating on the given, arguably brief, argument. The majority of students produced discourses in which either Gamma or the student elaborated on why four cases were called for. Furthermore, many explained not only the generalized Law of Trichotomy but also the role of axioms and/or definitions in mathematics. To see this we consider Excerpt A, in which Student A explains the Law of Trichotomy to Gamma.

*Excerpt A*

| | |
|---|---|
| *Gamma:* | *Why can't the first three cases be true?* |
| *Student A:* | *Because of the law of trichotomy.* |
| *Gamma:* | *What's the law of trichotomy?* |
| *Student A:* | *The Law of Trichotomy is an axiom we use. An axiom is a statement that is regarded as being the truth or accepted as true. So this axiom states that only one of the three following cases may happen: either $x < y$, $y < x$, or $x = y$. Applying this knowledge we can see why the first three cases don't work.* |

This brief excerpt demonstrates several key understandings: (1) the status of the Law of Trichotomy within the theory of the real numbers; (2) the status of axioms within the discipline of mathematics; and, (3) a perhaps tentative understanding of contradictions – namely that they indicate an inconsistency has occurred within a mathematical theory, which must be resolved by deference to that which is taken to be true (i.e., given a choice between a result and an axiom we choose the axiom and label the result "*false*" or "*impossible*"). Beyond students' understanding of the components of mathematical theories, the proof scripts also often indicated students' understandings of a generalized proof structure. In particular, several scripts included the proofs for Cases 1 and 2, often citing basic axioms and definitions, and an explanation as to why Case 3 was not needed, if a proof of Case 2 was given.

*Excerpt B*

| | |
|---|---|
| *Student B:* | *What's the word Mockingbird?* |
| *Gamma:* | *No much ese, just working on this pinche proof!* |
| *Student B:* | *Chale, that stuff ain't easy homes.* |
| *Gamma:* | *Que no, check it out and see if I got this mierda right?* |
| *Student B:* | *It looks good Homes except in linea 2 and 3 you got no detail ese. You need to explain cases 1 – 3!* |
| *Gamma:* | *Don't yell at me ese!* |
| *Student B:* | *Stop acting like a chavala!* |
| *Gamma:* | *Whatever homes!* |
| *Student B:* | *Anyways, lleva, with Line 2 you didn't state Axiom 6 which lets you split the inequalities foo.* |
| *Gamma:* | *Chingada madre! I forgot Axiom 10 in Line 3 for the cases 1, 2, 3.* |
| *Student B:* | *And for Line 4 you forgot Definition 6. Another thing for Case 2, if you prove it by contradiction using Axiom 10, because $x \neq y$, Case 3 is found without loss of generality because of Case 2.* |

As is the case with Excerpt A, Excerpt B sheds light on several key understandings that are employed by the student. First, the remarks clearly indicate an understanding of the symbol $\leq$ and the fact that it has a mathematical definition which takes the form of a disjunctive statement; i.e., a form that justifies the partitioning of the proof into cases. Second, the script indicates the student has an observable understanding of a practice that is important to proofs at this level; namely, that sub-proofs which are identical in structure are not replicated within in a proof.

**Findings, Part II: Proof scripts as a means to witness students' identities**

When producing a dialog, a student must decide on how to position the interlocutors, their knowledge and status, goals and relationships. Moreover, the students must share or question specific actions taken within the proof and respond to questions about those actions by either drawing on interlocutors' knowledge and ways of reasoning or their interpretations of the expectations of participants of a discipline. Hence, by attending to students' positioning, use of language, characterizations of practice or articulation of expectations within a dialog, proof scripts afford the opportunity to perceive the inter-relationships between identity, knowledge, and practice experienced by students. It is for these reasons they afford opportunities to witness students' identities. Consider for example, Excerpt A. In the dialog, Student A is not positioned as an unknowledgeable or uncertain peer (a stance taken by authors in several proof scripts) but rather is positioned as a knowledgeable other, who can decidedly determine the status of statements ("*The Law of Trichotomy is an axiom")* while also acknowledging the relative status of "truth" in mathematics ("*regarded as being the truth or accepted as true"*). Likewise consider, Excerpt B, where the student skillfully pinpoints key gaps in the proof and the axioms and definitions necessary to elaborate on those gaps, while at the same time maintaining the dialect common to students in the area – essentially translating sophisticated mathematical ideas into an urban dialect. Here we see not only evidence of a student's content knowledge but also evidence of the *blending of identities*: identities common to the discipline of mathematics, where attention to detail and structure reigns supreme, and identities common to our urban youth, which are expressed through specific temporal and situated dialects that employ terms outside of formal English and Spanish (e.g., *ese* means "that" in Spanish but is slang for "man" or "dude" in parts of Mexico and the southwestern United States). Viewed in this way, the dialect presents an instance of true ownership, for the mathematics has bridged the great divide between the institutional home of the discipline, where the practices of mathematics are both recognized and valorized, and a community that is often structurally excluded from the discipline. Hence, the bridging represents an expression of identity, where the individual has taken ownership of the mathematics through its acculturation (as opposed to the student's).

## Discussion & Concluding Remarks

Recognizing that, as argued by others (Bishop, 2012) identities are not only an important educational outcome but also critical to learning (Boaler, 2002), I have sought to demonstrate how proof scripts' perceptual ambiguity affords an opportunity to witness students' identities. Perceptual ambiguity in this context refers to an affordance of a static artifact, when that artifact can convey particular meanings through one's intentional focus on particular attributes, yet convey a distinct set of meanings should one's intentional focus shift to other, present but not yet attended to, attributes. The artifact – the student's proof script – being static does not change but rather our goal oriented activities do when actively "seeing" the artifact. As such, this work proposes that proof scripts can serve as a productive means for examining students' identities.

**Questions**

1. Is *perceptual ambiguity* the appropriate construct for describing the dualities of proof scripts?
2. What issues are there with describing researchers' inferences of identity as *witnessing*?

# Emerging Instructional Leadership in a New Course Coordination System

Naneh Apkarian
San Diego State University

*This paper reports on the instantiation of a coordination system in a university mathematics department, and in particular the transition of three faculty members into their new roles as course coordinators. Course coordination, characterized by uniform course elements and instructor meetings, is a programmatic feature that supports student success in introductory mathematics courses. When courses are coordinated, the person or people responsible for the coordination play a critical and complex role in ensuring that all students experience comparable, well-designed classes – but building such a system is complex and has not been studied in situ. In this report, I explore one coordinator's transition from a peripheral participant in discussions of teaching to a highly central figure with significant influence on instructors and colleagues in the department. Surveys and interviews with involved parties reveal nuance of this shift in leadership and shed some light on the process.*

*Keywords:* Precalculus/Calculus, Institutional Change, Course Coordination, Leadership

This report is about the implementation of a course coordination system in an undergraduate mathematics department, situated in a broad change initiative, considering in particular how one coordinator in particular rose from relative obscurity to a strong position of instructional leadership – a result which has the potential to support student success in introductory mathematics courses. In recent years, numerous reports and recommendations have been published at the national scale calling for improvements in undergraduate STEM education, and mathematics education in particular (e.g., CBMS, 2016; National Research Council, 2013; PCAST, 2012; Saxe & Braddy, 2015). Critical to STEM majors, and so to improvement efforts, is the Precalculus to Calculus 2 (P2C2) sequence which is required for most upper division STEM courses. In particular, these documents have called for the implementation of evidence-based instructional practices (notably active learning) and resources to support students in social as well as academic aspects of their lives. In the same time period, research has identified particular programs and features that support student success in the calculus courses that are critical for STEM majors (e.g., Bressoud, Mesa, & Rasmussen, 2015; Bressoud & Rasmussen, 2015). However, these practices and programs are not widespread – lecture still dominates the classroom, and even those departments which have such programs do not feel they are as successful with their implementation as they would like (Apkarian & Kirin, 2017; Rasmussen et al., in review). Furthermore, change is difficult and little is known about best practices for initiating and sustaining change in undergraduate departments. The role of social and cultural factors is viewed as an important part of the puzzle, and this has been demonstrated at the K-12 level repeatedly (Borrego & Henderson, 2014; Daly, 2010; Henderson & Dancy, 2007; Penuel, Frank, & Krause, 2010). By investigating the process by which one department implemented a major change initiative, and in particular how one member of that department grew into a new and critical role, this project contributes to our understanding of the social factors that affect the instantiation of evidence-based change in undergraduate mathematics department.

Apkarian and Rasmussen (2017) report on a sample of successful programs with coordination, where the coordinators held both formal power, by way of their titled role, and informal power, by way of social influence and leadership. In light of their findings, this paper considers three faculty members who were assigned the role of course coordinator, their social standing prior to this assignment, and how this shifted during the first two years of the new program. The analysis includes interviews with the coordinators and their colleagues in the mathematics department and social network surveys which capture informal power through interaction patterns and the nomination of expertise.

## Theory and Literature Review

The choice to focus on course coordinators, in this report, is due to their potential to impact multiple elements of the P2C2 course experience. The Characteristics of Successful Programs in College Calculus (CSPCC) study identified course coordination as one of the features of successful Calculus 1 programs (Rasmussen & Ellis, 2015). Through management of uniform course elements (e.g., common textbook, common exams) coordinators affect the basic elements of course curriculum, and through regular meetings with instructors they can affect the culture surrounding teaching. Their position can be leveraged to nudge instructors toward specific practices, particularly powerful during a systematic change effort, and their actions have the potential to engender communities of practice. Apkarian and Rasmussen's (2017) further investigation of successful departments in the CSPCC study revealed that, at those institutions, the course coordinators were primary sources for advice and information about teaching, meaning that they have informal social influence as well as formal, official power from their position. Their work suggests that alignment of informal and formal leadership with regards to teaching is a feature of more successful course coordination programs. The departments in that study, however, have had coordination systems intact for many years. This study investigates the development of such a system, and in particular the shift in coordinators' informal roles as they adopt their new, formal roles.

Wenger (1998) defines the practice of a community of practices as "doing in a historical and social context that gives structure and meaning to what we do. In this sense, practice is always social practice" (p. 47). This report considers both the practice of the coordinators and the social context in which they practice – the interactions and attitudes they carry and those of their colleagues. To do so, I draw on social capital theory and social network analysis (SNA). Social capital refers to the "resources embedded in social relations and social structure, which can be mobilized when an actor wishes to increase the likelihood of success in purposive actions" (Lin, 2002, p. 24), and these resources are considered to be "the potential and actual set of cognitive, social, and material resources made available through direct and indirect relationships" (Bridwell-Mitchell & Cooc, 2016, p. 7). SNA is one productive way to investigate social capital and its distribution among members of a community, because "an actor's network of social ties create opportunities for social capital transactions" (Adler & Kwon, 2002, p. 24). Thus, I leverage the tools of SNA to investigate interaction patterns identify central and peripheral participants, based on their potential access to social capital. Interviews and observations are used to characterize the social capital resources that are accessible through that network.

## Methodology

### Data Collection and Participants

The data for this study comes from a three-year longitudinal mixed methods study of a single mathematics department at a large state university. The P2C2 courses in particular were considered a problem at the university due to low pass rates, low persistence, lack of preparation in future courses, and student dissatisfaction. A newly elected chair set out to improve the situation using evidence-based practices, specifically considering the seven features of successful Calculus 1 programs laid out by the CSPCC project (Bressoud et al., 2015; Bressoud & Rasmussen, 2015). He determined that the P2C2 program had none of these characteristics and so, along with a task force, set out to implement them all. This report focuses on one of these characteristics: coordination systems for P2C2 courses that consist of regular instructor meetings and uniform course elements, organized by course coordinators. This department appointed three coordinators, one for each P2C2 course: Precalculus, Calculus 1, and Calculus 2. Data for this report comes from three major sources: (1) a survey to all people involved in the P2C2 sequences and changes therein; (2) interviews with instructors, coordinators, and the P2C2 committee; and (3) observations of P2C2 committee meetings. Data collection for this project has been completed.

A survey was distributed to all those involved with P2C2 courses at the university at three time points: before any changes occurred and at the end of the first and second academic year of the change initiative. It was distributed to all instructors (regardless of rank) all members of the mathematics and mathematics education divisions of the mathematics department, directors of faculty and student support programs, and selected administrators. Part of the survey consisted of Likert-style questions about the culture and climate of the department and P2C2 program, adapted from similar work in both K-12 and higher education contexts (Antonakis, Avolio, & Sivasubramaniam, 2003; Daly, Der-Martirosian, Moolenaar, & Liou, 2014; Moolenaar, 2012). These were aimed at measuring changes in attitudes over time. Another major part of the survey was a set of social network questions aimed at uncovering interaction patterns surrounding instruction of lower-division mathematics courses. Instructors were asked who they go to for advice, for instructional materials, and who they consider influential on their instructional practice. Everyone was asked with whom they discuss lower-division courses, they discuss their own research, discuss the ongoing changes in the department, and who they consider to be friends. This set of questions allows for an understanding of who opinion leaders are with regards to instruction, who is involved in conversations about what is going on and how things are changing, and to what extent this is or is not the same as who are friends. This selection is in line with standard approaches to social network data collection (Daly, 2010; Kadushin, 2011).

In order to understand the goals, implementation, and evolution of the change initiative in general, and the coordination system in particular, semi-structured interviews were conducted with a subset of the large pool that was surveyed. Particularly relevant to the coordination system are the interviews with instructors of coordinated courses and the P2C2 committee, which included all the new coordinators and the department chair. This group has been involved in the decision-making surrounding the change initiative, and so are primary resources for understanding the how and why of changes being made. Two rounds of interviews were conducted, toward the end of the first and second year of the change initiative. These interviews asked about the main goals of the change initiative, how it came into being, who the key players are, their role in the process, how progress toward goals will be assessed, and how well things seemed to be working in their view. Many of those interviewed in the first year were interviewed again in the second year, in which case the follow-up interview was tailored based on their first interview. The purpose of these interviews was to collect (potentially changing) information about and to assess participants' perceptions of P2C2 program, and the ongoing changes. All interviews were audio-recorded and the interviewer took field notes.

The final source of data comes from observations of P2C2 committee meetings. The committee consisted of the department chair, the Precalculus coordinator who is also director of the new learning center, the Calculus 1 and 2 coordinators, a senior mathematics education faculty member, and the GTA professional development leader who is also a mathematics education researcher. This group met on a regular basis to discuss plans, concerns, and strategies for constant improvement. The intention of attending these meetings was to obtain real-time information about the evolution of the change initiative and any concerns that presented themselves, as well as how each member of the committee spoke about the program and the changes. In some instances, the observer was able to ask clarifying questions of the committee. These meetings were audio-recorded, any artifacts (e.g., agenda, official notes) were collected, and field notes were taken. While data collection is complete, following the end of the second year of the change initiative, the department is not finished with their changes. Therefore, committee meetings are continuing to be observed to monitor and document any further significant changes.

**Data Analysis**

The data for this project is being analyzed in a coordinated fashion, with each piece reflexively informing iterative rounds of analysis. Social network data is first being analyzed using basic graph theory ideas of degree and centrality. These measures allow for the identification of key figures (those with higher degree or in-degree) and distribution of ties: high centrality corresponds to a concentration of ties in a few key players, lower centrality corresponds to more even distribution. These results can then be used to identify important characters, and the interviews and observation notes can be used to better understand their influence or position. Likert data from the survey is analyzed to give each person a score for each scale (e.g., perceptions of students and teaching, individual innovative climate), and the department as a whole. This data is compared across time points to identify shifts in attitudes and/or departmental climate and individual perceptions.

Interview data is being transcribed in full, checked, and coded. A first coding pass identified all interview segments pertaining to the seven features from the CSPCC study, which the department hoped to implement. A separate round of coding identifies segments where participants talk about goals and evaluations of any aspect of the change initiative. In addition to this coding using *a priori* schemes, the data is being open coded for emerging themes in line with the principles of grounded theory (Strauss & Corbin, 1994). These codes will be used to ascertain attitudes, priorities, and goals of individuals and how those shift over time. Of particular importance to this report are the segments which touch on the coordination system and coordinators. Meeting observations are being selectively transcribed, omitting discussions of budget and minutiae. Again, the most relevant segments for this report are those which include discussion of the coordination system and the roles of the coordinators, particularly when the coordinators are commenting.

Analyses of the network, Likert-scale, and interview data will be combined to look for characteristics and attitudes that coincide with network connections (e.g., do conversation partners share attitudes about teaching; do those who discuss the change initiative have similar ideas about goals; what interview language coincides with Likert scale scores).

## Preliminary Results and Discussion

Interview analysis and coordination has not been completed, but the social network analysis is well underway. This has revealed that two of the three new coordinators were quite involved in conversations about teaching, and their advice was sought after, before they were selected as coordinators. They retained and/or increased their prominence throughout the initiative, though increased network activity (more involvement in discussions; higher maximum numbers of ties) altered the relative position of many members of the community. The third coordinator, however, was more peripheral, and nearly absent in those conversations. By the end of the second year of changes, he became highly involved and is now one of the most central members of teaching-related networks. This shift results in an alignment of formal position and informal influence, seen in Apkarian and Rasmussen's (2017) study of successful departments. This university's networks are somewhat more distributed than those in Apkarian and Rasmussen's study, but the shift is a sign that this coordinator has taken up the mantle of coordinator and others respect him as such. Further analysis of the interviews and observations, especially his views of the position and other's perception of him, will shed light on how this transition occurred. An understanding of this transition and coordinator may be able to inform future change agents who choose to implement coordination systems and select coordinators.

# Using Machine Learning Algorithms to Categorize Free Responses to Calculus Questions[1]

Matthew Thomas, Ithaca College
Spencer Bagley, University of Northern Colorado
Mark Urban-Lurain, Michigan State University

*Researchers in various science disciplines have begun exploring use of machine learning algorithms to categorize students' answers to constructed-response tasks, achieving inter-rater reliability on par with that between expert raters. We report on a proof-of-concept experiment in which we categorized student responses to conceptually-focused tasks on a calculus final exam. Our results were only modestly successful, but promising. We identify ways in which responses to mathematics tasks are uniquely challenging for these algorithms, and ways in which the algorithms' performance on mathematics tasks can be improved.*

*Keywords:* assessment, calculus, machine learning, constructed response

Advances in machine learning algorithms have introduced the possibility of using computers to categorize written responses to questions based on linguistic patterns. When provided a corpus of hand-scored responses, these programs are able to identify patterns in the responses, and are able to automatically evaluate future responses based on similarities to responses already scored. This has been demonstrated to be successful in several science disciplines and statistics, but these techniques have not yet been applied to mathematics courses more broadly.

Application of these algorithms to education research and to the classroom has many potential benefits. In the classroom, these tools may allow for automated categorization of responses to open questions, so that students in large classes (e.g., large lectures or MOOCs) can receive immediate feedback, as they might in a system such as WeBWorK, but on open-ended, conceptually-focused questions. For research, these algorithms have the potential to identify both students' ways of thinking and how they are connected.

Prior efforts at measuring conceptual understanding have mainly relied on multiple-choice-based concept inventories (see, e.g., Libarkin, 2008); specifically, Epstein (2013) developed a concept inventory for calculus. However, the multiple choice format of a concept inventory is inherently restrictive, and prior research has identified problems with the CCI (Gleason, White, Thomas, Bagley, & Rice, 2015). Machine learning algorithms may allow for the creation of new instructional and assessment tools which capture nuances that concept inventories cannot.

In this study, we consider a proof-of-concept experiment in which we gathered student answers to free-response questions on a calculus final exam and attempted to use these algorithms to analyze the data. In doing so, we identify unique challenges to using these methods in mathematics, and provide ideas for how these challenges can be overcome.

## Background

Our motivation for conducting this study is to improve assessment of conceptual understanding in calculus. Our understanding of assessment is informed by the National Research Council's (NRC, 2001) model: cognition, or models of student understanding;

[1] Acknowledgements: This material is based upon work supported by the National Science Foundation (DUE grants: 1438739, 1323162, 1347740, 0736952 and 1022653). Any opinions, findings and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the NSF.

observations, or the tasks by which students' understanding is elicited in an observable form; and interpretation, in which the assessor uses their cognitive models to make sense of students' observed behavior. In particular, in order to make valid inferences, the tasks must be appropriate to elicit the desired types of cognition, especially when measuring conceptual understanding.

Most tasks targeting conceptual understanding are either forced-response tasks (e.g., multiple-choice or true-false questions, where students must select the correct answer from a prescribed list of possibilities) or constructed-response tasks (where students must explain concepts in their own words). While both item types can serve to elicit students' conceptual understanding, students' own writing on open-ended questions reveals more about their conceptions and misconceptions than does their performance on a multiple-choice exam (Birenbaum & Tatsuoka, 1987), as constrained-response questions obscure nuances and partial conceptions in student thinking (Hubbard, Potts, & Couch, 2017).

Our work is informed by the Automated Analysis of Constructed Response (AACR) project (https://msu.edu/~aacr/), an ongoing NSF-funded project which seeks to use machine learning to rapidly and efficiently categorize students' responses to open-ended conceptual questions. First, researchers develop and administer constructed response questions to students, and experts categorize the student responses. Then, the coded data are given to a machine-learning algorithm, which builds a model of expert rating using a subset of the coded data. The model's performance is assessed through randomized crossvalidation, calculating a measure of inter-rater reliability (usually Cohen's kappa). Further, several different models built with different machine learning techniques can be combined into an ensemble model, weighting each model by its confidence level; the version of the algorithm we used is an ensemble of 8 separate algorithms.

AACR has achieved impressive performance in several disciplines, including biology (Beggrow, Ha, Nehm, Pearl, & Boone, 2014; Prevost, Smith, & Knight, 2016), chemistry (Haudek, Prevost, Moscarella, Merrill, & Urban-Lurain, 2012), interdisciplinary understandings of energy (Park, Haudek, & Urban-Lurain, 2015), and even statistics (Kaplan, Haudek, Ha, Rogness, & Fisher, 2014). This evidence suggests the AACR approach may be successful in other mathematics classes, though there may be unique obstacles not faced in other disciplines.

## Methods

A total of 67 students in two sections of a coordinated introductory calculus course at a mid-sized university in the Rocky Mountain region of the United States were given the following questions on a common final exam:

1. The limit definition of the derivative of a generic function f(x) is: $\lim_{h \to 0} \frac{f(x+h)-f(x)}{h}$ .
   a. What does the numerator mean?
   b. What does the denominator mean?
   c. Why are we taking the limit as h approaches 0?
   d. Explain why the limit definition given above aligns with the overall <u>meaning</u> of the derivative.
2. Suppose the derivative of a function f(x) is negative everywhere on the interval x = 2 to x = 3. Where on this interval (i.e. for what x-value) does the function f have its maximum value? Carefully explain how you know your answer is correct.

We chose to examine student responses to these two questions for several reasons. First, these are conceptually-focused questions, and our ultimate aims are to move toward the development of a library of computer-gradeable items assessing students' conceptual understanding of calculus. Second, student responses to these two questions tended to contain more words than symbols or calculations, which makes the data they produce more amenable to analysis using these machine learning techniques. Third, these questions were designed to elicit a wide variety of ways of interpreting and thinking about the derivative concept.

The two instructors, who are not authors on this report, provided us with anonymized data in the form of digital scans of students' responses to these two questions. Not every student answered every part of both questions; see Table 1 for specific values of N for each question.

We transcribed students' handwritten responses into machine-readable text. In particular, we rendered mathematical symbols into words (for example, we rendered " $\rightarrow$ " as "to") and corrected spelling errors (for example, we corrected various misspellings of "infinitely").

The first two authors independently coded student responses using an emergent open coding process. We independently examined all the student responses to each part of the two questions to identify recurring themes and regularities in student responses, and used these themes and regularities to produce coding schemes. We then met to compare categories, resolve discrepancies, and produce a consensus coding scheme. In the final consensus coding scheme, each part of the two questions had four to six non-exclusive categories (or bins) of student responses, and we coded each student response as either belonging or not belonging to each.

After this coding process was complete, the third author used the coded data as input for the AACR algorithms. The first two authors then performed an error analysis by reviewing the output of the algorithms, looking for bins that performed particularly well or particularly poorly, then seeking to discover possible reasons for the performance of each bin.

## Results

The emergent open coding process resulted in the creation of categories for each question. While space constraints preclude us from giving a full description of every bin of student responses, categories included features of responses such as whether the student identified a "delta" or change in particular values, used common arguments such as "the derivative is negative, so the function is decreasing," or highlighted a geometric or graphical interpretation of a piece of the difference quotient.

Overall, our efforts were only modestly successful, but promising. Our main measure of how well the algorithm performed is inter-rater reliability, as measured by Cohen's kappa. Our kappas ranged from 0.759 to -0.09 (see Table 1). According to Landis and Koch (1977), kappa values between 0.61 and 0.8 represent "substantial" agreement; values between 0.41 and 0.6 represent "moderate" agreement; between 0.21 and 0.4, "fair" agreement; between 0 and 0.2, "slight" agreement; and below 0, "poor" agreement.

| Question | N | Kappas for each category (largest to smallest) | | | | | |
|---|---|---|---|---|---|---|---|
| Question 1a | 67 | 0.616 | 0.576 | 0.290 | 0.000 | | |
| Question 1b | 67 | 0.546 | 0.546 | 0.533 | 0.000 | | |
| Question 1c | 66 | 0.746 | 0.579 | 0.488 | 0.417 | 0.159 | 0.000 |
| Question 1d | 65 | 0.690 | 0.278 | 0.177 | 0.000 | 0.000 | -0.090 |
| Question 2 | 67 | 0.759 | 0.000 | 0.000 | 0.000 | 0.000 | 0.000 |

Table 1: Summary of inter-rater reliability between expert coding and algorithm coding

To gain more insight into the practical performance of the algorithm, we conducted an error analysis, carefully examining all the false positives and false negatives. We looked in particular for commonalities in misclassified responses, as they might reveal the specific difficulties the algorithm faced when attempting to classify responses to math tasks, and thus suggest ways to improve the performance of the algorithm. We illustrate our analysis with a few examples.

**Homogeneity in Responses**

While conducting this investigation, we discovered some elements of these algorithms that worked well in this setting and others which did not. When responses that we coded into a single category all contained the same key phrase (or only small variations), the algorithm tended to be particularly successful in matching our coding. For example, in question 2, one bin included noticing that the derivative was negative. There were very few phrasings students used to capture this idea (for example, "since the derivative of f(x) is negative that means that f(x) is decreasing"), and these phrases showed up repeatedly. In this category, the algorithm achieved a kappa value of 0.759, indicating substantial agreement with our coding. Question 1c included a category about estimating the slope, which performed well for similar reasons; most responses in this bin used the phrase "slope of the tangent line" or the word "secant." Here, the kappa value was 0.579. In categories like these, the algorithm could more easily pick out a pattern that characterizes all the responses in the bin, and thus was able to perform better.

On the other hand, we noted that the algorithm performed poorly on several categories in which the responses were not homogeneous enough. For example, one bin in question 1c was the "cancels out" bin; responses in this category expressed the idea that the *h* in the definition of the derivative should not appear in the correct end result. This idea was expressed in many different ways, such as "cancel out," "get rid of," "plug 0 into *h*," "be removed," "equal zero," "eliminate," and "substitute 0 for *h*." Due to the inability of the computer to recognize these phrases as describing the same ideas, this bin had a kappa value of 0.

**Sample Size**

One clear limitation of our data set was the sample size. Machine learning algorithms require a large enough sample size (often a few hundred) so that patterns in the responses can be identified. In order for the algorithm to differentiate responses, it must detect patterns that exist within the categorized responses *and* do not exist among the remaining responses. Because there will be variation in the phrasing of ideas, enough responses need to exist in order to identify the various ways the same concept may be expressed. This was particularly clear in question 1c's category of "cancels out," as discussed above. Increasing the sample size would increase the likelihood of the algorithm learning that the many variations express the same idea.

**Bag-of-Words Model**

We also consider particular issues which may occur using these techniques in mathematics which may not occur in other subject areas. The ensemble of algorithms used by the AACR project used a bag-of-words (BOW) approach. The raw data is broken into 1-3-word n-grams (that is, words, pairs of words, and three-word phrases). When only 1-word n-grams are used, there is no sense of order or proximity, only the collection of words in a response. When 3-word n-grams are used, there is some sense of proximity, but only within a distance of 3 words.

For many responses to our tasks, the only substantive difference between examples and non-examples of a category was the order of the words they used. One category for question 2 was discussing the derivative being negative. One of the false positives in this category was this response: “If the function is negative on the interval $x = 2$ to $x = 3$ because of the derivative, then the function's maximum value is at $x = 2$. If the function is negative then it means that the slope is decreasing causing the maximum value between 2 and 3 to be at $x = 2$.” Compare this response to a true positive: “The maximum is located on $x = 2$. Since the derivative is negative at every point on the interval, the function's slope is known to be negative for the entirety of the interval. Since $f(x)$ is always decreasing on the interval, the leftmost point is the maximum.” The false positive response contains many of the same words as the true positive response (e.g., “derivative,” “negative,” “slope,” “maximum,” “decreasing”), but uses them in a different order. A strictly-BOW model cannot easily detect the difference between these two responses.

We suspect that the order of words matters more in mathematical writing than it does in writing in other STEM disciplines. Writing a correct description of a mathematical procedure, or rendering mathematical notation into text, likely requires comparatively more precise attention to word order; in contrast, a correct description of the principles underlying evolution likely depends more on the word choice than the word order.

## Future Directions

While we haven’t achieved inter-rater reliability on par with that between human experts, these results provide promise that these machine learning algorithms may be applied to mathematics, while also indicating some ways in which these methods may need to be modified. We aim to begin with a larger sample size to determine whether some of the challenges are solely due to the sample size or are connected with the language of mathematics. We also aim to iteratively refine our coding scheme to allow for a more even split of the responses to aid in the pattern recognition. Additionally, we may need to consider details of how the input is parsed by the software, in particular by considering how to best represent mathematical notation not easily translated into words, such as arrows or functional notation. For instance, our initial exploration with another text classification tool called LightSIDE suggests that we may achieve better performance by replacing the character Δ with the word “delta.”

We also aim to develop more, and better, questions with which to gather data. We initially thought question 1 would be a good choice, because it elicits student understanding of the limit definition of the derivative and tends to produce “wordy” responses. However, our analysis suggests that the question is problematic, since it asks students to make meaning of mathematical notation, leading to responses containing notation or direct translations of notation into words. We hope to create questions whose answers would be more descriptive than notational.

## Audience Questions

- What questions might elicit more descriptive language in student responses?
- The more data we have, the better the algorithms will perform. Are there existing repositories of large numbers of text-based student responses to conceptual questions?
- We want to make our models useful for instructors and researchers. What common understandings exist about the concepts that are most important for students?

Investigating Student Success in Team-Based Learning Calculus I and in Subsequent Courses

Alexis Knaub — Western Mich. Univ.
Stefanie Wang — Trinity College

*With recommendations for active-learning strategies and challenging courses, we applied mixed methods to examine students' success in Calculus I and subsequent courses following instruction using Team-Based Learning (TBL). Overall, TBL students performed better on midterm and final calculus exams, gave more explanations, and completed Calculus I at a higher rate than their peers. These results remained true when students' incoming competencies for calculus were considered. TBL students performed comparably to their peers in Calculus II and Physics.*

*Keywords:* Calculus, Team-Based Learning, Flipped, Active, Large

Research in mathematics education calls for active learning in post-secondary mathematics courses. Freeman et al. (2014) published the findings of a meta-analysis of 225 studies reporting data on exam scores or failure rates for undergraduate STEM students in active learning classrooms versus traditional lecture classrooms. Students in active learning classes consistently performed better. In their nationwide study, Bressoud, Mesa, and Rasmussen (2015), encouraged challenging and engaging courses along with student-centered pedagogies and active-learning strategies as two of seven recommendations leading to successful calculus programs. Active learning also promotes the transfer of knowledge (Billing, 2007). When learning occurs through active engagement while embedding understanding and reflecting upon practices, Billing (2007) says justifications, principles and explanations are socially fostered, generated and contrasted. To identify which active learning strategies benefit learning, Wieman (2014) and Freeman et al. (2014) call for examination of the strategies implemented in classrooms.

Team-Based Learning (TBL) is a specific form of active learning designed to engage students in problem-solving discussions and hold students accountable for their preparation, no matter the size of the class (Sibley & Ostafichuk, 2014). TBL utilizes the flipped classroom model. Many instructors in recent years have investigated the impact of the flipped classroom in Calculus I in both large and small class settings, with the primary benefit to students in flipped sections being higher final exam scores when compared to students in non-flipped sections (Schroeder, McGivney-Burelle, & Xue, 2015, Anderson & Brennan, 2015, Jungic, Kaur, Mulholland, & Xin, 2015, and Maciejewski, 2015). Studies reported mixed performance in students' subsequent performance in Calculus II after having flipped Calculus I, with only one study reporting flipped students performing significantly better (Schroeder, et al., 2015 and Anderson & Brennan, 2015). The study presented here explores the benefits of TBL Calculus I taught to students in large and small class settings both during the semester of engagement and in subsequent courses.

Developed by Michaelsen, Knight, & Fink (2004) to help students learn how to apply concepts, TBL maintains that groups must be formed heterogeneously and remain permanent, students must be made accountable for their individual and group work, group tasks must promote critical thinking and team development, and students must have frequent and timely performance feedback. Aligning to Michaelsen's methods, at the start of the semester instructors assign groups of 5-7 students to teams. A module in TBL covers 2-3 weeks' worth of content and consists of the Readiness Assurance Process (RAP) and application exercises. The RAP holds students accountable for their work completed outside class time and encourages better team functioning. The RAP includes reading and/or viewing videos to gain initial understanding of course information, taking an individual Readiness Assessment Test (iRAT), completing a team Readiness Assessment Test (tRAT), an appeals process, and an instructor mini-lecture. The RATs consist of multiple choice or short answer questions. Students do not receive feedback on the iRATs prior to completing the identical tRATs with their teams. Following the tRATs, instructors give the answers and highlight the main concepts and procedures addressed by the RAP. The RAP positions students to work on the team-based application exercises occurring during subsequent class session(s). The application exercises are rich problem-solving activities designed so each team solves the same significant task, makes a specific choice for an answer, and simultaneously reports an answer. During the tRATs and application exercises, the instructors circulate the classroom to answer questions and nudge students in ways to consider the concepts and solution paths. As done by Nanes (2014) and Prudente (2017) for small linear algebra courses, we modify the TBL process by limiting the length of a module to 2-3 class sessions instead of 8-12 class sessions, and administer the iRATs online outside of class time. At various points throughout the course, students evaluate their team members, further enhancing the team's function and assuring student accountability to the team.

With the emphasis on team communication, interaction, and development of shared understanding, the theoretical framework of social constructivism underlies the foundation and implementation of TBL. Vygotsky highlighted the role of language and social interactions to develop meaning and understanding of a concept (Bigge & Shermis, 1999). The TBL process provides scaffolding for students and situates students in their zones of proximal development. When encountering a new topic, students first engage with material by reading and/or watching instructor-made videos. During the tRATs and application exercises, students engage with other students in interesting, meaningful collaborative problem-solving activities (scaffolding), as they record language and equations and create graphics to communicate their shared understanding (Bigge & Shermis, 1999). The tRATs and application exercises also position students in their zones of proximal development (ZPD) as the designed tasks target skills beyond what students can do independently but can achieve with assistance from both instructors and more knowledgeable peers (Bigge & Shermis, 1999). By design, the heterogeneous teams in TBL offer students different opportunities to serve as the more knowledgeable others to lend assistance in the ZPD (Sibley & Ostafichuk, 2014). Once students in teams complete the application exercises, the students likely will be able to complete future similar tasks individually, thereby raising the ZPD (Shabani, Khatib, & Ebadi, 2010).

## Research Questions

Do students in TBL calculus perform better on departmental midterm and final exams when compared with Non-TBL calculus students? How do TBL students perform on both conceptual and procedural problems on the comprehensive final exam? How well do TBL students transfer their calculus knowledge to subsequent courses, for example, to calculus-related questions on their first physics exam? How do TBL students fare in calculus I and subsequently in calculus II and physics when compared to their peers?

## Methodology

The population at a large (36,000) Midwestern Research I institution includes 43% women, 11% US minority, and 12.6% international students. In Fall 2016, 1845 students enrolled in Calculus I for science and engineering majors. Students registered for a section of Calculus I not knowing the course-delivery system. Three of the authors taught 366 students using TBL (N = 301 students across two large classes and N = 65 students across two small classes). All Calculus I students completed uniformly graded departmental midterm and final exams. TBL students completed pre- and post-tests of the Calculus Concept Inventory (CCI) and an eight-item semantics differential assessing students' confidence in mathematics. The 1507 Non-TBL Calculus students received primarily traditional instruction. For one subset (N=136) of the Non-TBL students, researchers gathered pre- and post-CCI, pre- and post-confidence surveys, midterm exam scores, final exam scores and students' answers to three of the final exam problems. For a second subset (N=108) of Non-TBL students, researchers collected pre- and post-confidence surveys and midterm and final exam scores. During Spring 2017, 232 students consented to the release of information regarding their first exam in calculus-based physics. For 771 students, the Registrar's office provided demographic information and Calculus I, II, and Physics course grades for consenting TBL and Non-TBL Calculus I students and Physics students.

For TBL students, a subset of Non-TBL Calculus students, and students who consented after the drop date to provide physics exam information (i.e., survivors in physics), researchers calculated "incoming competency scores" by averaging students' ALEKs placement score (of 100), students' pretest CCI score (of 22), and the number of high school calculus units (of 6). If students did not take the CCI, the incoming competency score was the average of the number of high school calculus units and the ALEKs placement score. Table 1 displays the averages of the scores for the three groups.

*Table 1. This table shows the incoming calculus competency averages.*

| TBL Calc | | | Non-TBL Calc | | | Non-Calc I Physics | | |
|---|---|---|---|---|---|---|---|---|
| Mean | SD | N | Mean | SD | N | Mean | SD | N |
| .477 | .113 | 298 | .478 | .116 | 354 | .583* | .141 | 116 |

Note. *p < 0.001. The Non-Calc I Physics completed Physics in Spring 2017 but not Calculus I in Fall 2016.

Researchers determined the quintiles of the incoming competency scores for 744 students. For each quintile, researchers analyzed students' performance in Calculus I, II, and Physics. Additionally, for both TBL and Non-TBL Calculus I students for whom researchers possessed pre- and post CCI scores, final exam scores, including scores on three problems of the final exam, researchers partitioned the final exam scores into quintiles. Based on the final exam, researchers selected exams from a subset of each quintile and of each instruction type. For quintiles one through five, researchers randomly selected 14, 24, 24, 24, and 14 exams[1], respectively and performed qualitative analysis on three of the eight final exam questions. Applying a detailed scoring rubric, two of the authors blindly evaluated students' solutions from the 200 final exams. Of the three questions selected, a conceptual question provided the graph of a derivative ($f'$) and asked students to graph the second derivative ($f''$), identify where $f$

[1] Researchers sought to oversample the middle quintiles but the Non-TBL group had exactly 24 exams in quintile 3.

increases, decreases, is concave up and concave down, and where *f* has critical points and inflection points. A procedural question asked students to evaluate a definite integral whose integrand involved the sum of three parts: a simple polynomial, a function for which substitution was required, and a third requiring interpretation of an integral as an area. The third question required optimizing an area given a function containing a parameter. This problem required students to consider multiple techniques including integrating, calculating derivatives, and verifying an optimal value. Each of these three problems was worth 15 points.

Two graders applied the rubric for the conceptual, procedural, and complex procedural problems having inter-rater reliability calculated using percent agreement of 93.79, 86.75, and 96.18, respectively. The two raters and another researcher discussed and resolved all differences.

## Results

When considering the final exam scores for all students in Calculus I, Table 2 shows TBL students outperformed Non-TBL students on the uniformly graded departmental exam. Additionally, Table 3 displays the rate at which students earned D, F, or withdrew (DFW) from the course, demonstrating a significantly lower DWF rate for TBL students when compared to Non-TBL students.

*Table 2. This table gives Fall 2016 departmental final exam scores.*

| TBL | | | Non-TBL | | |
|---|---|---|---|---|---|
| Mean | SD | N | Mean | SD | N |
| 55.52* | 21.88 | 325 | 50.05 | 21.89 | 851 |

Note. *p < 0.001.

*Table 3. This table gives DFW Rates for Calculus I.*

| Fall 2016 | TBL | Non-TBL |
|---|---|---|
| Overall | **19.1** (70/366)* | 32.0 (473/1479) |
| Female only | **24.7** (18/73) | 30.1 (85/282) |
| Ethnic Underrepresented only | **34.8** (8/23) | 45.5 (61/134) |
| International Only | 50.0 (5/10) | **37.1** (65/175) |

Note. *p < 0.01. Boldface type indicates lower DFW rate.

For students categorized based on incoming competency scores, researchers analyzed student success on the departmental midterm and final calculus exams, on the first physics exam, and the DFW or DF rates for Calculus II and calculus-based physics course. As shown in Table 4, for students with comparable incoming competency, for all but the first quintile, students in TBL Calculus outperformed their Non-TBL peers on the midterm exam. For the final exam, TBL students performed better than Non-TBL students significantly so for quintiles 4 and 5.

For students who took Calculus II or Physics during Spring 2017, very few differences occurred in performance on the first Physics exam or when considering the rates at which students completed Calculus II. TBL students in the top four quintiles completed Physics at a higher rate than Non-TBL students, but never significantly different.

Qualitative analysis performed on three of eight of the final exam problems for 100 TBL and 100 Non-TBL students partitioned by quintiles showed TBL students outperformed Non-TBL students on the conceptual problem, with significance for quintiles two and four. Differences in the numbers of explanations and correct explanations arose as shown in Table 5. TBL students sometimes gave three times as many correct explanations as their peers. For the procedural and complex procedural questions, TBL students and Non-TBL students performed comparatively.

Note. Numbers are based on 100 TBL exams and 100 Non-TBL exams. *p < 0.05. **p < 0.01.

## Discussion

Similar to the studies examining flipped calculus, (Schroeder, et al., 2015, Anderson & Brennan, 2015, Jungic, et al., 2015, and Maciejewski, 2015), this study demonstrates that when compared to their peers, TBL students performed higher on calculus midterm and final exams, gave more explanations and correct explanations on a conceptual question, and performed comparatively in downstream courses relying on calculus knowledge. This study adds to the literature in that we explored students' performance based on their competencies brought to calculus. The few distinctions in performance of TBL students with Non-TBL students in downstream courses could be due to a mismatch of assessments. TBL students were frequently assessed in their conceptual understanding during Calculus I while assessments in downstream courses likely targeted more procedural understanding.

Noteworthy in this study are the smaller DFW rates in Calculus I for TBL students compared to Non-TBL students. The higher DFW rates for female and ethnic underrepresented students show significant work yet remains by mathematics departments to better serve all students. In addition, the emphasis on communication in TBL likely challenges international students beyond what occurs in Non-TBL courses.

## Questions

What additional aspects of the data should be investigated? Does the incoming competency calculation fairly assess a student's position at the start of Calculus I? What are effective ways to measure students' performance in downstream courses and to capture students' transfer of calculus knowledge?

# Investigating Students' Meta-Level Object-Reflections and Discourse-Reflections: The Provocative Power of Primary Historical Sources

| Cihan Can | Janet Heine Barnett | Kathleen M. Clark |
|---|---|---|
| Florida State University | Colorado State University – Pueblo | Florida State University |

*We discuss research based on Sfard's theory of mathematics as a discourse, which we used to investigate the potential of engagement with primary historical sources for motivating undergraduate students to participate in and accept new mathematical discourses. This preliminary report focuses on characterizing the nature of students' participation in mathematical discourse in their written work on primary source projects (PSPs), as well as the question of what constitutes evidence of students' noticing of meta-level rules in that work. We present our analysis of a brief excerpt from one PSP, and provide an analysis of two student work samples to exhibit students' object- and discourse-reflections at the meta-level.*

*Keywords:* Primary Historical Sources, Analysis, Rigor, Metadiscursive Rules

## Introduction

Recently we initiated a study based on Anna Sfard's theory of mathematics as a discourse to investigate the potential of engagement with primary historical sources for motivating students at the undergraduate level to participate in and accept new mathematical discourses. Part of a larger project focused on the use of primary sources in the teaching and learning of undergraduate mathematics, the investigation we report on here seeks in particular to contribute to the growing body of research on the "metadiscursive rules" that govern participation in a mathematical discourse community (Sfard, 2008).

Prior research suggests, for instance, that engagement with primary historical sources may help students learn the metarules that govern mathematicians' discourse (Kjeldsen & Blomhøj, 2012). Given these and related findings, we believe it is important to look more closely at students' interactions with unfamiliar mathematical discourses and investigate their progress in "figuring out" (Sfard, 2014, p. 201) the meta-level rules that govern a new mathematical discourse as a result of those interactions. We are further interested in determining the extent to which students' (verbal/written/other) actions both during and after engagement with the primary source projects provide evidence of their acceptance of a new discourse. In this preliminary report, we focus on the following two questions within the context of an undergraduate analysis course:

- How can we characterize the nature of students' participation in mathematical discourse in their written work related to primary source projects?
- What constitutes evidence of students' noticing of meta-level rules in this written work?

## Theoretical Framing and Literature

In an attempt to resolve certain quandaries related to mathematical thinking and learning, Sfard (2008) operationally defined thinking as a personalized version of communication. Given the collective nature of communication, she introduced the term *commognition* to highlight the communicative nature of activities in our minds, emphasizing that individual cognitive processes (thinking) and interpersonal communication are "but different manifestations of basically the same phenomenon" (Sfard, 2008, p. 83). Using this communicative, or discursive lens, Sfard

(2008) determined that "mathematics begins where the tangible real-life objects end and where reflection on our own discourse about these objects begin" (p. 129). Cobb, Bouf'i, McClain, and Whitenack (1997) also noted the connection between students' mathematical development and *mathematizing* (or *reflective*) *discourse*, which they described as "characterized by repeated shifts such that what the students and teacher do in action subsequently becomes an explicit object of discussion" (p. 258). That is, what identifies the objects of communication in mathematics is their discursive nature: they come to exist as we talk about them. From this viewpoint, mathematics emerges as a highly situated human activity which generates itself. As a result, the learner of mathematics faces a paradoxical situation: How can a person join a discourse for which familiarity with the discourse is a precondition for participation in that discourse?

As a further complication, Sfard (2008) noted that participation in any discourse requires adopting the rules that govern that discourse, in addition to becoming familiar with the objects of the discourse. She referred to the former rules as *meta-level*, or *metadiscursive*, and the latter as *object-level*. For instance, asserting that a particular function is differentiable constitutes an object-level narrative about functions. However, a student's method of justifying this assertion (e.g., sketching a graph versus an ε–δ proof) would be indicative of the metadiscursive rules that govern her discourse about functions. Despite the usual implications of the word *rule* as being invariable and strictly deterministic, metadiscursive rules are subject to change in time and space, and are tacit, contingent, constraining, flexible, and value-laden. Sfard posits that these characteristics render meta-level learning possible only through direct encounters with a new discourse that is governed by meta-level rules different from those governing the learner's current discourse (p. 256). Furthermore, such encounters generally entail a *commognitive conflict* when the discursants unknowingly operate under completely different meta-level rules.

Given their role in governing the actions of the participants in a mathematical discourse, researchers have paid particular attention to factors that affect the learning of metadiscursive rules in mathematics. In a number of these studies, the history of mathematics, and primary source readings in particular, emerged as an instructional approach with strong potential to promote such learning. In their study of university mathematics students, for example, Kjeldsen and Blomhøj (2012) showed that a careful selection of historical sources can help students learn about the metadiscursive rules that govern mathematicians' discourse about functions, and allow them to recognize that these rules changed during the development of that concept. This meta-level learning, they argued, fostered students' learning of mathematics at the object-level as well. In her teaching experiment with pre- and in-service teachers, Güçler (2016) designed an instructional sequence in which the metadiscursive rules implicit in various historical sources were made explicit to students. She showed that by reflecting on their own and mathematicians' definitions of function, students experienced changes in their discourse; within the commognitive framework, it is precisely such changes that constitute evidence of learning.

## Data Sources and Methods of Analysis

For our metadiscursive rules investigation, we collected data in a one-semester *Introduction to Analysis* course for senior mathematics majors. The instructor (the second author) has extensive experience in the development and use of primary source materials for teaching undergraduate mathematics courses. During the semester in question, students completed two Primary Source Projects (PSPs). Analysis PSP #1 (Barnett, 2017a) examines nineteenth century concerns about the foundations of analysis that led to an increase in formal rigor at that time; it was implemented in the second week of class through a combination of individual advance reading/preparation followed by 1.5 days of whole-class discussion. Analysis PSP #2 (Barnett, 2017b) also relates to standards of rigor in analysis, but within the context of counterexamples satisfying certain function properties (e.g., a continuous but nowhere differentiable function). This PSP was implemented over two weeks via a combination of individual advance reading/preparation, whole class discussion, and small group work. A traditional textbook (Abbott, 2015) was also used in the course. Students were guided in their reading and study of the PSPs and the textbook by daily "Reading and Study Guides" (RSGs) prepared by the instructor.

The data collected for this study include video recordings of all class meetings, audio recording of each group during small group work for Analysis PSP #2, students' written work on both PSPs and the related RSGs, instructor class notes, pre-interviews with nine students prior to work on Analysis PSP #2, and post-PSP interviews with two of those nine. We also implemented four student surveys: a pre-course survey, two post-PSP surveys, and a post-course survey.

Since our goal in this report is to share our preliminary findings related to the evidential foundation of this metadiscursive rules investigation, we limit our analysis to just one data source: students' individual written work on Analysis PSP #2 and related RSGs. One reason for this choice is that written work is generally narrower in terms of the variables involved. In particular, students' written work allows us to focus exclusively on the individual's interactions with the material, in contrast to interview or small group work data that also involves students' discourse with each other, the instructor, and/or the interviewer. However, the primary source excerpts and the student tasks contained in Analysis PSP #2 do include considerable breadth and variety of discourse. We thus anticipate that the preliminary analysis and findings we present here will serve as a useful guide to our analysis of the more complex data sources which we will need to complete in order to align our investigation with Sfard's situated-learning framework.

For this preliminary report, we analyzed the PSP itself, the related RSGs, and students' written work on these instructional materials. Given our focus on metadiscursive rules, the main consideration that guided our analysis was whether and how the written narratives of the different discursants did or could provide indications of the implicit rules governing the various discourses. In our analysis of the PSP, for example, our goal was to identify its potential to motivate student noticing of and/or reflection on the various metadiscursive rules, either those of the student or of the discursants in Analysis PSP #2. In that PSP, there are three different discursants: Darboux, Houël, and the project author. Darboux's and Houël's voices are represented through excerpts drawn from letters exchanged during a ten-year correspondence in which they debated issues related to rigor in analysis. The voice of the project's author is present in the background narrative that describes the historical context, in the selection of particular excerpts from the Darboux-Houël correspondence, and in the student tasks based on those excerpts. The instructor-prepared RSGs directed students to read specified portions of the PSP and complete preliminary work on certain PSP tasks for the next class period.

In our analysis of student work on the RSGs, we were interested in aspects of students' written work that could be interpreted as "talking" about the actions of the PSP discursants. We completed this analysis in three stages. First, we examined student responses on specific PSP or RSG items that our document analysis identified as having potential to provoke a meta-level response, and made note of those responses in which students wrote about the actions of the discursants. In the next stage, we examined each of those student responses in detail. As we completed this analysis, we became aware that students' meta-level responses could be further classified as either reflections about specific mathematical objects, or reflections about the discourse itself. Finally, based on this new sub-categorization scheme, we analyzed student written work on all PSP and RSG items to determine if we could document evidence for students' noticing of metadiscursive rules in the form of meta-level reflections of either kind.

## Findings

Based on our analysis, we developed a two-tiered categorization scheme for student discourse in their written work. First, students produced narratives at either the object-level (i.e., they simply "did the math"), or at the meta-level (i.e., they "talked about" – or reflected on – doing mathematics). Second, the focus of students' meta-level reflections was either on the mathematical discourse in the PSP, or on the mathematical objects under discussion in that discourse. We limit our attention in this preliminary report to the second tier of this categorization scheme and consider the focus of students' meta-level reflections, as we believe these findings best characterize the nature of students' noticing of metadiscursive rules. For each subcategory within this tier, we also analyze one student response for evidence of such noticing.

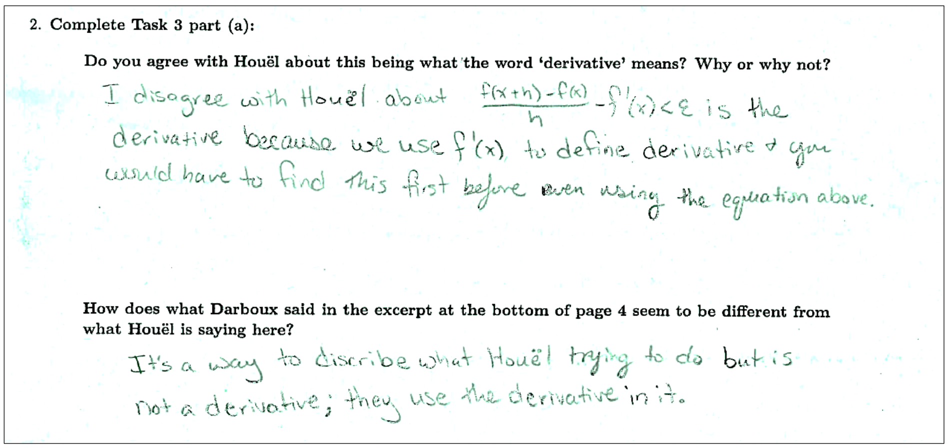
We start with a short sample from the PSP to illustrate how its design could motivate students' noticing of metadiscursive rules. In Figure 1, we read from two of the discursants in the PSP: the author in the narrative before the excerpt, and Darboux in the excerpt itself. As noted by the PSP author, Darboux had been raising his concerns regarding the rigor in Houël's proofs for a fairly long time. We argue that this disagreement results from a difference in the metadiscursive rules that govern their respective discourses regarding rigor. As Darboux noted in his letter, there was a shift occurring in the discourse on rigor among mathematicians of that time, which he felt implied that "no one would find [Houël's reasoning] rigorous." We believe that, through their observations of these shifts in the discourse, students will come to notice the metadiscursive rules that govern the discourse, and begin to experience the commognitive conflict required for a shift in their own metadiscursive rules as a result.

In this same letter, Darboux also returned to a second specific concern that he had about the proofs that Houël's provided for certain theorems involving derivatives. In fact, Darboux raised this other concern as early as January 18, 1875, when he wrote[2]:

> Here is what I reproach in your reasoning which no one would now find rigorous. When we have
>
> $$\frac{f(x+h)-f(x)}{h} - f'(x) = \epsilon,$$
>
> $\epsilon$ is a function of two variables $x$ and $h$ that approaches zero when, $x$ remaining fixed, $h$ approaches zero. But if $x$ and $h$ [both] vary as they do in your proof, or worse yet, if to each new subdivision of the intervals $x_1 - x_0$ there arise new quantities $\epsilon$, then I find it altogether unclear and your proof has nothing but the appearance of rigor. [Darboux, as quoted in (Gispert, 1983, p. 99)]

*Figure 1. Excerpt from Analysis PSP #2 (Barnett, 2017b).*

We now share a representative student response related to this particular excerpt, and a subsequent statement made by Houël about the inequality $\frac{f(x+h)-f(x)}{h} - f'(x) < \varepsilon$ and the meaning of the word "derivative." Figure 2 displays a student response that we characterized as an *object-reflection*: although the RSG prompt invites participation at the meta-level, and the student is engaged with the discourse of the PSP, her response focused on talking about the mathematical object "derivative," rather than about the discourse itself. Analyzing this response for the student's noticing of metadiscursive rules in the discourse, we highlight her response to the second part of the RSG item: "It's a way to discribe *[sic]* what Houël *[sic]* trying to do but is not a derivative; they use the derivative in it." We are aware of a potential objection here, in that the student provided neither an explicit or implicit narrative on the metadiscourse. However, we interpret the commognitive conflict she appears to have experienced regarding definitions in mathematics – that terms should not be explicitly used in the equations/inequalities that define them – to be a result of her noticing of the disagreement between the metadiscursive rules that governed Darboux and Houël's discourses.



2. Complete Task 3 part (a):

**Do you agree with Houël about this being what the word 'derivative' means? Why or why not?**

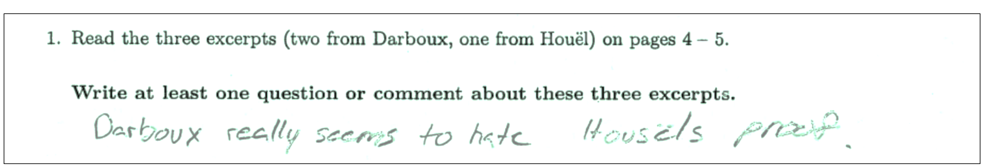
I disagree with Houël about $\frac{f(x+h)-f(x)}{h} - f'(x) < \varepsilon$ is the derivative because we use $f'(x)$ to define derivative & you would have to find this first before even using the equation above.

**How does what Darboux said in the excerpt at the bottom of page 4 seem to be different from what Houël is saying here?**

It's a way to discribe what Houël trying to do but is not a derivative; they use the derivative in it.

*Figure 2. Student object-reflection at the meta-level (Student Response, RSG).*

In the sample of a *discourse-reflection* student response shown in Figure 3, we argue that the student noticed the tension that arose between Darboux and Houël surrounding their lack of communication: by talking about (the nature of) the discourse itself, the student participated in the discourse at the meta-level. We also pay attention here to what the student did not say, as well as what he said. The student did not, for instance, evaluate Darboux's or Houël's letters for mathematical correctness, but provided instead a statement regarding the nature of their communication that has a metadiscursive characteristic. Again, we acknowledge the potential criticism that the student did not explicitly talk about the rules that might be governing Darboux's and Houël's discourse; he did, however, clearly notice the ineffective communication between them, which, in time, created the tension in the letters.



1. Read the three excerpts (two from Darboux, one from Houël) on pages 4 – 5.

**Write at least one question or comment about these three excerpts.**

Darboux really seems to hate Housël's proof.

*Figure 3. Student discourse-reflection at the meta-level (Student Response, RSG).*

Although space considerations allow us to share only very brief examples to suggest the richness of our data set, we anticipate that analysis of further examples will open up discussion of other topics of research interest, including the role of commognitive conflict in promoting metalevel learning and the implications of the discursive framework and our classification scheme for instructional practice.

*The results presented in this paper are part of a larger mixed-methods study examining relative instructional priorities among mathematics graduate teaching assistants (MGTAs). In this paper we share some early results and observations from a limited test-retest analysis of a pilot survey administered to MGTAs in two large public institutions in the Southeast United States. This is not intended to be an exhaustive statistical analysis of the pilot survey results or test-retest analysis. Instead, we focus on specific items to serve as a lens for better understanding the complexity of the choices MGTAs make in instructional settings.*

*Keywords:* Graduate student teacher identity, Instructional choices, Survey validation

### Introduction and Background

The notion of *teacher identity*, the extent to which one identifies as a teacher, informs a large body of literature related to professional preparation and development of secondary mathematics teachers (Ward, Nolen, & Horn, 2011; Beauchamp & Thomas, 2011; Ball & Bass, 2004; Beauchamp & Thomas, 2009; Flores & Day, 2006; Hamman, Gosselin, Romano, & Bunuan, 2010; Heyd-Metzuyanim & Sfard, 2012; Horn, Nolen, Ward, & Campbell, 2008; Lasky, 2005; Sexton, 2008; VanZoest & Bohl, 2005; Hodges & Cady, 2012). Although novice secondary mathematics teachers and new mathematics graduate teaching assistants (MGTAs) share many characteristics such as undergraduate mathematics coursework, stage of life, and assumption of new professional teaching duties, the frameworks developed for understanding secondary teacher identity do not translate easily to work with MGTAs (Gallagher, 2016).

In this paper, we build on previous work that explored the ways in which experienced secondary teachers saw themselves as subject matter, didactical, and/or pedagogical experts, and then assigned those teachers locations within a "personal knowledge triangle" to represent the relative weight given to each of those types of expertise (Beijaard, Verloop, & Vermunt, 2000). A multi-year multiple case study following the development of teacher identity and instructional practice among four MGTAs led the lead author to develop a modified framework to represent the types of expertise and actions valued by MGTAs. For that population, instructional decision-making and value judgments were stratified into three zones: subject-matter concerns, class-level structures, and individual-level needs. For a more complete description of the boundaries of each of those zones, we refer the reader to (Gallagher, 2016).

We refer to the collective framework of these choices as Relative Instructional Priorities (RIP) and visualize each individual MGTA's balance as being situated within a triangle, where the vertices represent the components of the RIP (individual needs, subject-matter knowledge, and class-level considerations). *Individual needs* items are focused on the students as individuals and prompt for instructor prioritization of individualized instruction, supporting diversity, and awareness of campus resources for students. Items in the *subject-matter knowledge* category focus on content and curriculum, including content mastery and preparation for subsequent courses. *Class-level consideration* items include the use of technology in the classroom, physical classroom arrangement, choice of instructional activity, and pacing of a class session.

The relative position of a point along an edge of the triangle represents the weight given to that RIP component. For instance, in Figure 1, the point along the I-S edge is closer to vertex I meaning that this respondent prioritizes the individual needs of students over subject-matter concerns while the point along the C-S edge reveals that the respondent is relatively balanced when choosing between class-level versus subject-matter. Triangulating the three edge points gives the respondent's overall RIP placement, the “star” inside the triangle.

## Survey Development

Our goal with the RIP survey was to have students make choices between pairs of statements that were anchored strongly at one of the three vertices. For example, a descriptor such as “knowing how the course content is used in subsequent courses” would be anchored at S, while “having a range of strategies to encourage group discussion” would be anchored at C and “knowing what resources are available for a student who is upset about a non-academic issue” would be anchored at I. On the other hand, a descriptor such as *‘adapting class activities based on students’ prerequisite knowledge’* contains aspects of subject-matter knowledge (S), individual needs (I), and class-level decision-making (C).

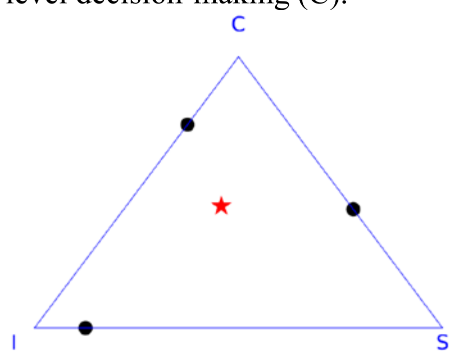

*Figure 1. Visualization of an Example RIP*

For our first implementation, we drew on our prior multiple case study interview and survey data to draft items capturing different aspects of each category, as shown in Table 1. Each item in a category was then paired with every item in the other two categories, generating a total of 48 pairings; all possible cross-category pairings were present and each pairing was prefaced with the prompt, *‘For each item, circle the statement that is more important to you in your teaching.’*

*Table 1. Early Version of RIP Items*

| Individual (I) |
|---|
| **I1** Knowing how to help underrepresented students feel welcome in your class |
| **I2** Knowing how to adapt instruction for individual students |
| **I3** Having a range of strategies for encouraging a struggling student |
| **I4** Being able to support the emotional needs of your students |

Class-level (C)

**C1** Having a range of strategies for evaluating class outcomes
**C2** Knowing how to manage a classroom setting
**C3** Having a range of instructional options for structuring a class session
**C4** Knowing how to plan a class

Subject-matter (S)

**S1** Knowing how to apply the mathematical content in other contexts
**S2** Being able to answer questions about the content
**S3** Being able to identify mathematics mistakes in student work
**S4** Knowing the content of the course

This early paper-based version of the survey was administered to a group of 21 first-year MGTAs in a mathematics professional development course near the beginning of the semester at one large, public, southeastern university. In this version, students circled the item from each pair that was more important to them. Following administration of the paper version, we engaged in a focus group discussion to understand the students' perceptions of the individual prompts. In this discussion, it became apparent that some of these prompts were too broadly phrased, as some students saw an overlap of items. For example, one participant interpreted the item, *'Knowing how to help a struggling student,'* as an S item, as evidenced by her statement, "Knowing your content *is* helping your struggling student, they're the same thing!" Similar statements from other participants allowed us to refine the phrasing of prompts within the C, S, and I categories.

For the second version of the survey, which is the focus of this paper, we used results from the paper-based pilot administration and focus group discussion to generate a bank of 120 items, with each of the four authors generating ten potential items within each category. Each of the potential items was then classified by the other three members of the team as either C, S, or I. Items that did not reach unanimous agreement on classification were discarded or modified until they reached consensus of classification. That winnowing process resulted in 21 C items, 28 I items, and 20 S items. From those, each member of the team selected the eight that he or she felt best captured the range of archetypal prompts for the category. Those votes resulted in the selection of four prompts for each category.

We then created 27 pairings distributed evenly among C-S, C-I, and I-S pairings. Each of the four prompts within a category occurred 2-3 times and was never paired twice against the same prompt from another category. The nine prompts within each pairing were evenly distributed among three groupings to explore whether participants differentiated between preferences, importance, and appeal in choosing between prompts. Each group of nine pairings was prefaced by one of: *'Which is more important to you?' 'Which scenario appeals to you more?'* and *'Select the one you prefer.'* To avoid biasing generation of new archetypal prompts in the discussion portion of the session, we purposefully do not include here a list of all twelve prompts we selected. Some specific prompts are discussed below, and the full set is available from the corresponding author.

## Survey Administration and Retest

We used Qualtrics® to develop, edit, and distribute the survey. At the beginning of the survey, participants were asked to enter a participant ID or code that was generated to protect their anonymity. Additional prompts after the item-selection blocked pairs asked demographic questions about their undergraduate and graduate majors, languages spoken, year of study, teaching background, etc. Participants were given the option of entering into a random drawing for a Visa® gift card incentive, and a separate option to enter their email address to indicate willingness to participate in a follow-up interview.

Thirty-six MGTAs from two large southeastern universities responded to the survey, out of 88 who were invited to participate (40.1% response rate); there was an incentive of two $25 gift card in a random drawing from among respondents. From the responses received, we eliminated those who did not complete the survey and those who completed it in under four minutes, leaving us with 28 responses (31.8% valid response rate). The participants at one university (n=25) could voluntarily enroll in one of several course-specific professional development seminar courses, while participants at the other university (n=3) were required to enroll in a general professional development course. We conducted single-session observations of each semester-long seminar course; each seminar leader indicated that the session we observed was typical of the course. From those observations, the seminars ranged from a focus on instructional planning, to a focus on content mastery, to a focus on planning instruction around common student misconceptions. Participants were a mix of domestic and international, and traditional and non-traditional. All were in their first, second, or third year of graduate school. They held a range of teaching duties including teaching assistant, classroom assistant, and instructor of record.

We sent follow-up emails to all 28 participants six weeks following their original survey completion, inviting each to retake the survey for test-retest comparison. Fifteen participants (53.57%) completed the re-test. It is worth noting that we had 12 retest responses from one institution (48%) and 3 retest responses from the other (100%). Agreement statistics were calculated using Cohen's κ in JMP® Pro 12 (DeVellis, 2016; McHugh, 2012) and we use these results to direct our attention to avenues for improvement of the survey.

## Results and Discussion

We use McHugh's recommendations for Cohen's κ estimates of reliability (McHugh, 2012), and recognize that with only 15 respondents our values of κ are likely underestimates of stability. Under those guidelines, 4 of our 27 items were classified as 'moderate agreement ($0.60 \leq \kappa \leq 0.79$)' and another 9 as 'weak agreement ($0.40 \leq \kappa \leq 0.59$).' Six met the criteria for 'minimal agreement ($0.21 \leq \kappa \leq 0.39$)' and the remaining eight were classified as 'no agreement ($\kappa \leq 0.20$).' We discuss here two specific item pairings: one with weak (nearly moderate) agreement, and one with no agreement. We have selected these items not because they represent the extremes, but because they provide insight into issues with specific phrasings. It is worth noting that although we chose one C-I and one C-S item for this discussion, all three category pairings had pairs that scored well and pairs that scored poorly.

### No Agreement, κ = -0.05. PROMPT: *Which is more important to you? Knowing how to evaluate class activities, OR writing a thorough test that assesses content mastery.*

Here, we have a C item paired against an S item. We suspect that *'evaluate class activities'* may be too broadly worded and could have also elicited elements of subject-matter although it was intended as a class-level item, which includes planning, delivering, and assessing instructional activities. This is because one may perceive the evaluation of class activities as dependent on subject-matter knowledge.

**Weak Agreement, κ = 0.59. PROMPT:** ***Which scenario appeals to you more? You know how and when to adjust class pace and focus, OR you know what resources are available on campus for a student who is upset in class about an issue not related to content.***

This question is a pairing of a C item to an I item. This pairing shows weak agreement likely because each individual phrasing is a strong item in its own category and is not likely to be confused with the other categories. We anticipate that with a larger sample, this item might reach moderate or strong stability.

In general, the items with minimal or no stability are those that have one or both prompts conflated with a second category, rather than being strong anchors to just one category. For example, the prompt, *'Having multiple styles of teaching the same concept,'* was interpreted by some respondents as reflecting full mastery of the content. Although we built this item to exemplify C, it can also be seen as a strong S item. Confounding the stability test, several of the respondents were engaged in teaching and professional development during the six-week period between test and retest. Thus, some lack of stability may reflect an actual shift in instructional priorities. Since we do not have specific professional development enrollment linked to individual survey responses, we cannot clearly account for this effect.

## Questions for the Audience

While most items in this version of the RIP survey failed to meet the criterion for moderate or strong stability, analysis of items that had minimal to no agreement as compared to items that had weak or moderate agreement has provided additional insight into the complexities of the choices MGTAs make as they develop their instructional practice. We continue to struggle with developing prompts that are anchored at the poles of our model in such a way that we can quantitatively capture the nuances that emerged in previous qualitative analysis. We welcome audience input to help guide our next steps. In particular:

- Our attempts to prime for different aspect of decision-making (importance, appeal, preference) do not appear to have produced meaningful differences in response category or test-retest stability. In our next iteration, we plan to prompt for what the MGTA's response has been, or would be, in specific scenarios. Do the additional insights we could potentially gain from pairing an action-based prompt with either an importance- or preference-based prompt outweigh the much higher participation rate we would need in order to analyze the data for differences in responses and stability between those two prompts?
- We have struggled particularly with crafting prompts that isolate aspects associated with the I category: meetings the needs of individual learners. Suggestions from the audience for specific prompts in this category would be most welcome.
- One eventual goal for the RIP survey is to use it to capture change in MGTA's instructional decision-making over time. Do you see an 'ideal' location in the triangle as an outcome for professional development for MGTAs?

# A Course in Mathematical Modeling for Pre-Service Teachers: Designs and Challenges

Joshua Chesler
California State University, Long Beach

Jen-Mei Chang
California State University, Long Beach

*The increased status of mathematical modeling in the K-12 curriculum requires teacher preparation programs to adapt. This design experiment examines a course in mathematical modeling for pre-service secondary mathematics instructors that was co-developed and co-taught by a mathematics educator and an applied mathematician. The students in the course, all mathematics majors, experienced growth as well as challenges, some rooted in quantitative reasoning.*

*Keywords:* mathematical modeling, teacher preparation, quantitative reasoning

Mathematical Modeling is one of just six conceptual categories for high school in the Common Core State Standards for Mathematics (CCSSM) and is one of the eight CCSSM mathematical practices which span all of K-12 mathematics (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). These standards are adopted in 42 of the United States ("Standards in Your State," 2017), however there is reason for concern about teachers' preparation for implementing mathematical modeling tasks. It is rare for teacher preparation programs to even introduce students to mathematical modeling (Doerr, 2007; Lingefjärd, 2007a). Moreover, programs that do currently include or wish to develop instruction in mathematical modeling may be hindered by the lack of a robust research base about best practices, both for teaching mathematical modeling and for preparing teachers to teach modeling.

The elevated status of mathematical modeling in the curriculum, both as a practice and as a conceptual category, requires many secondary teacher preparation programs to adapt. Herein, we report on a design experiment in which the authors, a mathematics educator and an applied mathematician, co-designed and co-taught an undergraduate course in mathematical modeling for mathematics majors intending to be secondary teachers (N=9). In this first iteration of our design experiment, we were guided by a very broad research question about the nature of students' dispositions for engaging in and teaching mathematical modeling both before and after the course.

## Perspective

The Guidelines for Assessment & Instruction in Mathematical Modeling Education (GAIMME) report described mathematical modeling as a process used to answer "big, messy, reality-based questions" (Garfunkel & Montgomery, 2016, p. 7). The process begins with identifying a problem and ends with reporting results. In between, the mathematical modeler makes assumptions; defines variables; refines the original question; develops and implements models; and analyzes the outputs of the model. This all transpires in a non-linear, often cyclic manner. The messiness, openness, and time requirements of authentic mathematical modeling tasks present an array of both pedagogical and conceptual challenges for teachers and for teacher preparation programs.

Some of the challenges for learners of mathematical modeling are documented by Thompson (2011) in his description of mathematical modeling as emerging from quantitative reasoning, which serves as grounding for several nontrivial abilities that are essential to mathematical modeling. Foundationally, the ability for quantitative reasoning allows a student to conceptualize a situation quantitatively. Extending this, covariational reasoning is needed for students to make sense of dynamic situations in which quantities vary in relation to each other. The ability to generalize, in the context of mathematical modeling, allows a student to represent these relationships. Thompson describes a mathematical model as a generalization "of a situation's inner mechanics—of 'how it works'" (p. 51).

Doerr (2007) noted that the pedagogical knowledge for teaching modeling is distinctive and she enumerated some specific pedagogical tasks for teachers of mathematical modeling, among them: choosing and adapting modeling tasks; anticipating and evaluating students' varied strategies; and helping students make rich mathematical connections. This description of a teacher's role in supporting mathematical modeling is largely echoed in the GAIMME report (2016), which also devotes considerable attention to the challenge of assessing mathematical modeling. Unfortunately, there is a dearth of research which investigates the development of the pedagogical knowledge teachers need for teaching modeling. Indeed, Doerr observed that "how teachers acquire this knowledge… remains an open question for researchers" (p. 77).

Doerr (2007) also describes a mathematical modeling course for pre-service teachers (N=8) which she developed and taught. In her course, students read about the modeling cycle and they engaged in and reflected on the modeling processes. She suggested that pre-service teachers engage in a variety of modeling tasks that require explanations, justifications, and reflection. Zbiek (2016) designed and taught a course for a similar audience. She focused on productive beliefs and corresponding unproductive beliefs about teaching and learning mathematical modeling. For example, it is productive to believe that mathematical modeling is a messy process, as opposed to the unproductive belief that problem solving should follow a clearly determined path. Through modeling and pedagogical tasks, students in her course moved toward productive beliefs, though this was accompanied by some persistent confusion about mathematical modeling. She echoed Lingefjärd's (2007b) recommendation that modeling be integrated throughout teacher education programs, not just in a single course.

## The Mathematical Modeling for Teachers Course

We co-designed and co-taught the Mathematical Modeling for Teachers course from the joint perspectives of our disciplines, mathematics education and applied mathematics, and with direction from the GAIMME report. Students in the course engaged in the modeling cycle through in-class team activities, homework/exam questions, and a final team project. From the first day of class, we were explicit about the modeling cycle and, after modeling tasks were completed, students reflected on their work as an expression of the cycle.

We did not organize the course as instruction in a sequence of different modeling techniques. The first half engaged students in a variety of modeling tasks in which they relied primarily on their existing algebraic, geometric, and statistical knowledge. This was followed by three weeks of instruction in linear programming, statistical and mathematical simulations, and some useful features of Microsoft Excel (2013) such as visualizing data, using random numbers to do simulations, making predictions with models, and solving linear programming problems. The next three weeks focused on pedagogical content knowledge such as modifying high school textbook tasks, analyzing curricular materials, and evaluating student work; some of this was foreshadowed by similar tasks in the first half of the course. The rest of the course was devoted to final projects by teams of students in which they identified a question, developed a model, reported on the model, and connected their work to the CCSSM. Throughout, we adjusted instruction according to what we perceived to be difficult parts of the modeling process for students. For instance, students struggled with generalization, as described by Thompson (2011), so we focused on this piece of the modeling process with some matching activities; students linked equations to verbal scenarios and linked the structures of equations to scenarios.

Rather than using a textbook, we developed, adapted, and curated tasks for the students. Students did readings from the GAIMME Report and from teacher-focused articles about mathematical modeling. An often used resource was the set of high school textbooks used by the local school district which claimed to be aligned with the CCSSM. The books labeled questions as “Modeling with Mathematics” within each problem set. However, to borrow phrasing from the GAIMME report (2016), the tasks would more aptly be described as “traditional word problems or textbook applications where all of the necessary information is provided and there is a single, known, correct answer” (p.28). This echoes Meyer’s (2015) analysis of two different supposedly CCSSM-aligned textbooks — tasks labeled as “modeling” rarely required students to model. The local textbooks were valuable both as illustrations of some of the curricular challenges our students would face as teachers and as a source of tasks for students to analyze and modify.

## Methodology

We approached the development and implementation of the Modeling for Teachers course as a design experiment in which course design and theory development are “iterative and interactive” (Schoenfeld, 2006, p. 198). Herein, we report on the first iteration of the course; our research goals were to: 1. identify emergent themes related to the mathematical modeling preparation of teachers, and 2. generate hypotheses to be tested in future iterations. Our data are comprised of student-generated artifacts from the course (e.g., homework, projects, exams), notes from weekly planning meetings between the researchers/instructors, and an end-of-course survey. Seven of the nine students were undergraduate students in a Bachelor of Science (BS) program in Mathematics, Option in Mathematics Education. The remaining two students had already completed the BS program and were taking the course out of interest. All of the students had at least completed Linear Algebra and a first course in proof.

We are in the process of iteratively coding the data to expose patterns in student work (Coffey & Atkinson, 1996). This initial round of coding is guided by the components of the modeling cycle as defined in the GAIMME report, e.g., “make assumptions and define essential variables” (Garfunkle & Montgomery, 2016, p. 13). Within each of these components, subcodes are based largely on the knowledges and dispositions needed for doing and teaching mathematical modeling that Thompson (2011) and Doerr (2007) enumerated. For example, we are identifying challenges and patterns related to generalization and to types of pedagogical content knowledge. Subsequent rounds will lead to a refinement of the codes.

## Preliminary Results

Given the preliminary nature of this report, we will briefly document some emergent themes, some initial results related to the students’ pedagogical and content knowledge of mathematical modeling, and some plans/hypotheses for the next iteration of the course. The end-of-course survey indicated that students found the course to be worthwhile. They reported that their knowledge of mathematical modeling increased and that they were excited to teach mathematical modeling. They also expressed comfort with the openness of the tasks they did in class. They reported that they intend to, as teachers, adapt textbook tasks to engage students in various aspects of the mathematical modeling process though they expressed somewhat less confidence in their ability to do so.

Our initial analysis and reflections have made us rethink our decision to begin the course with a discussion of the modeling cycle. Throughout the course, we asked students to reflect on the modeling process and connect it to their work. These reflections revealed that the process began to make sense only after substantial engagement with mathematical modeling. Moreover, there were instances in which students unproductively looked to the cycle for quasi-procedural guidance in the problem solving process. Even after successful completion of a modeling task students had trouble answering, “What is the model?” As a remedy for this discomfort, many students later communicated that they would have preferred to begin the course by watching the instructors demonstrate the mathematical modeling process. Though we are unlikely to honor that request in the next iteration, it may be a sign that the students have greater comfort with more traditional modes of teaching.

By delaying the explicit naming of the components in the modeling process, we can first begin to address some unproductive problem-solving dispositions of students. In particular, we found that we had to encourage the students to approach modeling tasks by first considering specific examples and exploring a “toy model.” Without intervention, students often became mired in premature attempts to define appropriate variables and develop an abstract model. Furthermore, their work with abstraction often betrayed a lack of comfort connecting verbal and symbolic representations. In an early linear programming task adapted from a local school district’s quarterly Algebra II exam, six of the nine students made errors with units while connecting an inequality to the problem’s context. In general, most students experienced some level of difficulty with quantitative and covariational reasoning; ongoing analysis aims to characterize this with more granularity.

We also observed challenges with more pedagogically focused tasks. For example, students’ attempts to modify textbook problems to create authentic mathematical modeling tasks often resulted in tasks that were not open enough or were imprecisely stated. As instructors, we sympathized with this as we also experienced the challenge of finding or producing appropriate tasks. Other pedagogical tasks posed challenges that were likely not exclusive to the context of modeling. Of note, on an exam we asked students to make sense of and recommunicate a hypothetical student’s linear model for a scenario that our students had already modeled (geometrically) during an in-class activity. In our analysis of their work, we have not yet been able to parse out the sources of difficulty, whether they be related to the nature of their content knowledge or insufficient practice evaluating student work or something else.

We have thus far documented several challenges faced by students. We view these challenges as opportunities to improve the Mathematical Modeling for Teachers course and to frame an examination of students’ experience throughout our teacher preparation program. Certainly, as instructors, we faced several challenges that stemmed from our lack of familiarity with and resources for teaching mathematical modeling to preservice teachers. But that is a subject for another paper.

## Discussion

Though students were satisfied with the course and we generally viewed it as a success, students and instructors encountered significant challenges that extended beyond those reported above. The existence and persistence of these challenges may give credence to the call for greater integration of mathematical modeling throughout teacher preparation programs, not just in a single course. However, if we accept Thompson’s (2011) view that mathematical modeling depends on quantitative and covariational reasoning, our preliminary analyses indicate that increased focus on these foundational abilities is merited and, from a pragmatic perspective, are perhaps more feasible to implement throughout the program. This is not to say that engagement in mathematical modeling cannot be done in service of developing those reasoning abilities (e.g., see Swan, Turner, Yoon, & Muller, 2007), but our experience illuminated that, even with two instructors for nine students, teaching mathematical modeling as envisioned in the GAIMME report and finding (or developing) good modeling tasks requires time and expertise. Furthermore, the challenges students faced related to generalizing (e.g., translating from verbal or specific scenarios to symbolic representations) and quantitative reasoning (e.g., working with units) may not be detected by assessments in more computationally-focused lower-division courses. Building foundational reasoning abilities and mathematical dispositions for mathematical modeling in those courses would yield impactful benefits throughout the students' undergraduate careers and their careers as teachers.

As we continue analysis and interpretation of data from the Mathematical Modeling for Teachers course, we are also planning the content for and research of the next iteration of the course. Input from the RUME community will provide valuable guidance. Audience discussion will be prompted, in part, by the following questions:

1. Given the breadth of our data, we could investigate it with various foci: the teacher educators, the students as mathematics majors, the students as future teachers, the curricular materials, and the teacher preparation program. How can we capture that in our analysis? Or how should we narrow the focus?
2. Widening the scope, what are the broader questions about the nature of mathematics teacher preparation across the curriculum? How can this work contribute to answering those questions?
3. What are particularly salient opportunities for research during the second iteration of the course?
4. What are the broader implications of this study for undergraduates who are not pre-service mathematics teachers or mathematics majors? What attainable goals should we set in designing college-level mathematical modeling courses or experiences at various levels?

# Assessing Visual Literacy Competency in Undergraduate Mathematics

Deniz Kardes Birinci, University of South Florida
Mile Krajcevski, University of South Florida
Greg Mccolm, University of South Florida

*We investigated how linear algebra students acquired mathematical knowledge from visualization objects, and to what extent these students exhibited visual literacy standards in higher education. Seven linear algebra students were the subjects of this research project. The data were collected through questions with high visual content and through semi-structured interviews. We analyzed the data by using descriptive and content analysis techniques. Our study found that linear algebra students were not sufficiently competent in using visualization techniques.*

*Keywords:* visual literacy, visualization, linear algebra, assessment.

## Introduction

Research into the teaching of undergraduate linear algebra confirms the advantages of using the visual approach when introducing mathematical content, and that visual representations of mathematical notions have a positive effect on students' learning (Hannah, Stewart & Thomas, 2013; Dorier & Sierpinska, 2001; Dubinsky, 1997; Harel, 1989). Guided by the Visual Literacy Competency Standards for Higher Education (ACRL, 2011), we have designed a framework for assessing students' visual literacy competency level in undergraduate mathematics and used this framework to indicate students' use of visualization objects in linear algebra.

The earliest attempt to define visual literacy was in Debes (1969, p.27; as cited in Avgerinou & Ericson, 1997, p.281). Following his definition, visual literacy will "…enable a visually literate person to discriminate and interpret the visible actions, objects, symbols … that he encounters in his environment." As Bieman (1984) noted, Debes's definition tells what a visually literate person can do, rather than what visual literacy is. Researchers in distinct fields have offered various definitions of visual literacy (Bristor & Drake, 1994; Braden, 1996; Burns, 2006). For example, Ausburn and Ausburn (1978) defined visual literacy as a group of skills that will enable an individual to understand and use visualization objects to communicate with others. Hortin (1980) defined visual literacy as the ability to understand and use images, and to think and learn in terms of images. We adopt the definition of visual literacy given by Stokes (2002) as the ability to interpret images, and to generate images for communicating ideas and concepts.

In 2011, the Association of College and Research Libraries (ACRL, 2011) published standards providing tools for educators seeking to measure visual literacy competency (VLC) of college and university students in undergraduate education. ACRL emphasized that standards outlining student learning outcomes have not been articulated in the research on visual literacy. They proposed the following standards:

The visually literate student should be able to:

**1.** Determine the nature and extent of the visual materials needed.
**2.** Find and access the needed images and visual media effectively and efficiently.
**3.** Interpret and analyze meanings of images and visual media.
**4.** Evaluate images and their sources.
**5.** Use images and visual media effectively.
**6.** Design and create meaningful images and visual media.
**7.** Understand many of the ethical, legal, social, and economic issues surrounding the creation and use of images and visual media, and access and use visual materials ethically.

In terms of assessing VLC, there are a limited number of instruments in existing literature (Avgerinou, 2007; Arslan & Zeren-Nalinci, 2014). However, we could not find assessment instruments for specific disciplines. We develop a framework based on standards for assessing VLC in undergraduate mathematics, with attention to linear algebra.

**Adjusted Framework for Assessing VLC in Undergraduate Mathematics**

We adjust the Visual Literacy Standards in Higher Education to undergraduate mathematics, to assess students' visual literacy competencies. The adjusted standards are as follows:

The visually literate students in undergraduate mathematics should be able to:

| | |
|---|---|
| – perceive a given visualization object and recall prior knowledge related to a given visualization object. | PERCEPTION |
| – understand a given visualization object and make connections between prior knowledge and the given visualization object. | UNDERSTANDING |
| – analyze the properties of a given visualization object and interpret that given visualization object. | ANALYSIS and INTERPRETATION |
| – use a given visualization object. | USAGE |
| – create a meaningful visualization object. | CREATION |
| – evaluate a given or personally created visualization object. | EVALUATION |

Each standard has sub-categories which can be used to assess students' VLCs. The order in which the standards are given should not indicate their significance. Being focused on the mathematical skills and procedures, we did not attend to ethical and social components addressed in ACRL (2011). For a working definition of a "visualization object" we embraced the definition of a visualization object as a physical object that is viewed and interpreted by a person for the purpose of understanding something other than the object itself. These objects can be drawings, pictures, 3D representations, animations, etc. (Philips, Norris & Macnab, 2010 p.26).

We specifically focused our research on the following adjusted standard: Use a given visualization object (usage standard). To gain insight into the extent linear algebra students' usage of visualization object, our main research questions are as follows:

- How do linear algebra students use a visualization object in the problem-solving process?
- To what extend do linear algebra students exhibit usage standard in the problem solving-process?

## The Method

We adopt the qualitative-interpretative paradigm (Lodico, Spaulding & Voegtle, 2006, p. 264) applied to a holistic single case study (Yin, 2003, p. 39). Seven undergraduate linear algebra students were selected via the purposive sampling technique (Cohen, Manion and Morrison, 2007, p. 114). Collected data consisted of students' responses to three linear algebra questions with high visual content (Table 1). These questions were given to students at different occasions as test questions. Webb's (2009) Depth of Knowledge model was used to identify questions' complexity level; six mathematics professors assisted with classifying questions' complexity level. We also conducted five semi-structured interviews with student volunteers that were recorded and transcribed. Obtained data was analyzed and interpreted using percentage frequency distribution (Shapiro, 2008, p. 292) and content analysis techniques (Cohen, Manion and Morrison, 2007, p. 475).

*Table 1. Questions and their complexity levels*

| Level | Questions | Possible Solutions |
|---|---|---|
| **1- recall and reproduction** |  Determine if the vectors given in the figure below are linearly independent or linearly dependent without computing. Please, use the figure to justify your answer. |  One possible answer is to construct a parallelogram in which $\vec{b}$ is a diagonal and $\vec{a}$ and $\vec{c}$ are on adjacent sides. Then (following the figure) $\overrightarrow{a'} = \alpha\vec{a}$ for some $\alpha > 1$ and $\overrightarrow{c'} = \gamma\vec{c}$ for some $0 < \gamma < 1$. We have $\vec{b} = \alpha\vec{a} + \gamma\vec{c}$. |
| **2- skill and concepts** |  Assume T: $\mathbb{R}^2 \to \mathbb{R}^2$ is a linear transformation that is a composition of two transformations: reflection with respect to the origin ($\boldsymbol{x} \mapsto -\boldsymbol{x}$), followed by scaling by factor 2. Write the standard matrix of the inverse transformation. Please justify! | Note that $T = S \circ R$ where $R(\vec{x}) = -\vec{x}$ and $S(\vec{x}) = 2\vec{x}$. So $R^{-1}(\vec{x}) = -\vec{x} = R(\vec{x})$ and $S^{-1}(\vec{x}) = \frac{1}{2}(\vec{x})$. Therefore $T^{-1}(\vec{x}) = (S \circ R)^{-1}(x) = R^{-1}\left(S^{-1}(\vec{x})\right) = R\left(\frac{1}{2}(\vec{x})\right) = -\frac{1}{2}\vec{x}$ and standard matrix of $T^{-1}$ is $\begin{bmatrix} -\frac{1}{2} & 0 \\ 0 & -\frac{1}{2} \end{bmatrix}$ |
| **3- strategic thinking** |   Assume that the mapping $F: \mathbb{R}^2 \mapsto \mathbb{R}^2$ maps each vector $\boldsymbol{x}$ into the vector $\boldsymbol{x} + \frac{\boldsymbol{x^r} - \boldsymbol{x}}{\boldsymbol{2}}$ where $\boldsymbol{x^r}$ is the reflection of vector $\boldsymbol{x}$ through the line $y = x$. Find the subset $H \subseteq \mathbb{R}^2$ such that $F(\boldsymbol{x}) = \boldsymbol{0}$ for every $\boldsymbol{x}$ in $H$. Sketch the subset *H*. |   Note that if $\vec{x} = \begin{bmatrix} a \\ b \end{bmatrix}$ then $\overrightarrow{x^r} = \begin{bmatrix} b \\ a \end{bmatrix}$ so $F\left(\begin{bmatrix} a \\ b \end{bmatrix}\right) = \begin{bmatrix} a \\ b \end{bmatrix} + \frac{1}{2}\left(\begin{bmatrix} b \\ a \end{bmatrix} - \begin{bmatrix} a \\ b \end{bmatrix}\right) = \begin{bmatrix} \frac{a+b}{2} \\ \frac{a+b}{2} \end{bmatrix}$ so F is a linear transformation. All vectors $\begin{bmatrix} t \\ -t \end{bmatrix}$ ( t a real number) will be mapped into the zero vector or $H = \left\{\begin{bmatrix} t \\ -t \end{bmatrix} \middle\| t \in \mathbb{R}\right\}$ |

The sub-categories for standard 'usage' are auxiliary drawing, algebraic interpretation and justification. The scores based on students' responses ranged from zero (0) to three (3) as shown in Table 2. In each of the three problems presented in Table 1, we expected that the student would use the given visualization object as a tool to advance his introspective visualization (Phillips, Norris and Macnab, 2010, p. 10). We also expected the student to produce an auxiliary drawing. We consider that would indicate higher level of VLC of the students. Students had opportunities in class to see how linear transformations transform particular sets of points in the plane, but we could not measure to what extend they have developed their intuition and benefitted from those opportunities in their solutions to Problem 3. Some of the difficulties students had with problem 2 could be result of inexperience with the notion of the inverse of a composition of bijections, which they have encountered in their previous courses.

*Table 2. Scores and explanations*

| Score | Explanation of expected response in the standard of usage |
|---|---|
| 3- excellent | Adequate and effective auxiliary drawing<br>Accurate and relevant algebraic interpretation<br>Valid and relevant justification |
| 2- satisfactory | Adequate but ineffective auxiliary drawing<br>Accurate but irrelevant algebraic interpretation<br>Inappropriate justification |
| 1- fair | Inadequate or ineffective auxiliary drawing<br>Inaccurate or irrelevant algebraic interpretation<br>Invalid justification |
| 0 | No-response |

## Preliminary Findings

In Figure 1, we present the results of three test questions in the percentage distribution bar chart. (Y-axis represents the percentage of students achieving the measured category)

*Figure 1. Using visualization objects*

The bar chart (Figure 1), gives students' performance on these three questions and the three categories: effectiveness of their auxiliary drawing, the extent of their algebraic interpretation of a problem and appropriateness of their justifications. Notice that auxiliary drawing in all three problems is present, but it varies depending on the complexity of the question. One can also see a very mixed show of algebraic interpretation in all three questions. Students' ability to justify mathematical statements was weak, with good results only for question number one.

We will illustrate some of these conclusions with two examples of students' responses to question 3 and a question that was given as a part of the interview process.

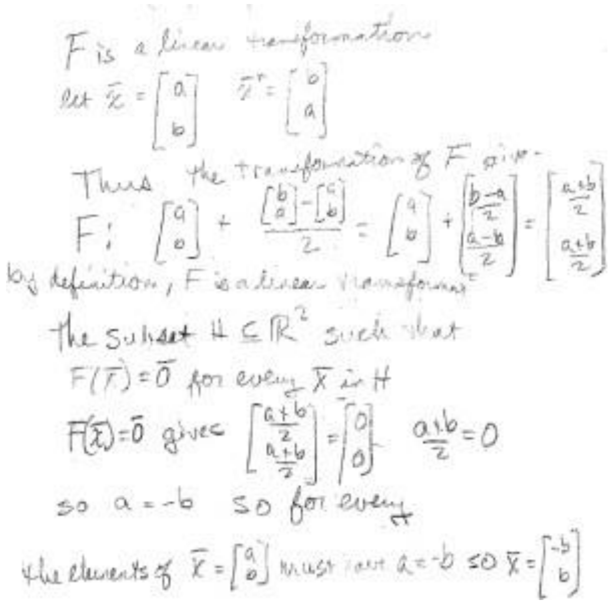

*Figure 2a. An example response to the third visual linear algebra question*

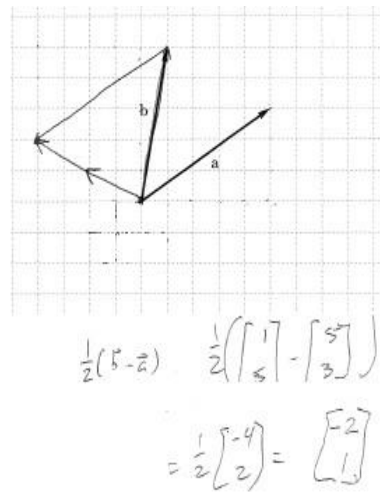

*Figure 2b. An example response to interview question: Sketch (**b-a**)/2*

The above two examples of student responses illustrate their primary learning strategy in solving the problems. Figure 2a illustrates a solution to problem 3 with correct response and conclusion to which student arrives in purely algebraic way, almost ignoring the image showing $F$ as an orthogonal projection on the line $y=x$. The required sketch of $H$ is obtained *after the* analytic solution to the problem was obtained. We observe a similar pattern in Figure 2b, where the student uses the unit grid as a coordinate system and assigns specific coordinates to given vectors. After computing the components of the vector (***a-b***)/2, the student sketched the answer. Again, the analytic reasoning precedes the visual way and illustrates the low 'usage' level of the student.

## Conclusion

In this ongoing research, we proposed to use a new framework for assessing undergraduate mathematics students' visual literacy competency based on ACRL's (2011) standards and presented the findings of this usage standard. We found that students struggle to use given visualization objects in linear algebra. Students did not use auxiliary drawings very much, despite their usefulness, a phenomenon reported in Krajcevski and Keene (2017). We intend to continue developing the framework in our further research.

## Intended Questions for the Audience

1. Are the components of the adjusted framework (perception, understanding, analysis and interpretation, usage, creation, and evaluation) sufficient to characterize visual literacy?
2. What sub-categories might be useful for assessing students' visual literacy?

**Measuring Self-Regulated Learning:**
**A Tool for Understanding Disengagement in Calculus I**

Ben Sencindiver
Colorado State University

Mary E. Pilgrim
Colorado State University

James E. Folkestad
Colorado State University

*Calculus 1 has been and continues to be a key gateway course to STEM majors, which contributes to a loss of students in the STEM pipeline. Student-learning behaviors impact performance and, in turn, the student experience. By analyzing early online homework activity and help seeking, rich descriptions of students can be used for early prediction for at-risk students, but can be misrepresentative for students who have not yet engaged with these resources. This preliminary report presents self-regulated learning (SRL) theory as a way to understand student behaviors. Using this framework, online tools were designed to collect behavioral data which was used to create a SRL score based on in-course student activity. This preliminary report presents findings on the relationship between student behaviors in Calculus I, a behavioral SRL score, and failure rates, particularly with students disengaged with course content.*

*Keywords:* Calculus I, Self-Regulated Learning, Learning Behaviors

Calculus I is commonly identified as a weed-out course for students majoring in STEM disciplines. This is further supported by data gathered from the Mathematical Association of America national calculus study that reports a 25% DFW rate nationally at research institutions. Additionally, they report that Calculus I students experience lowers confidence in, enjoyment of, and the desire to continue pursuing a degree requiring mathematics (Bressoud & Rasmussen, 2015). Research evidence suggests that how students engage with their studies effects success (Vandamme, Meskens, Superby, 2007). By leveraging the high level of data that can be collected from online engagement and digital interactions, we theorize that it may be possible to identify students early in the semester, based on their behaviors with digital content, who are at-risk of being unsuccessful (defined as a grade of D or F here) in Calculus I (Fonti, 2015; Hu, Lo, & Shih, 2014; Macfadyen & Dawson, 2010). In the past, techniques from learning analytics and data mining have been employed with relative success using early performance data to predict course outcomes. In this study we use data from the Canvas LMS (quiz-log data), the online homework system, and sign-in logs from when students visit the calculus help center (CHC).

While fine-grained interactions with digital resources can provide a rich set of data about individual students, those who do not engage with resources can be easily be misrepresented by their digital footprint, as their temporary disengagement can result for many reasons. Self-regulated learning (SRL) theory provides a way to better understand student behaviors.

This preliminary report presents initial findings toward understanding disengaged students' self-regulation, academic performance, and learning behaviors. We draw on student interactions with online tools developed around SRL theory and then organized into a behavioral SRL score. We aim to address the following research questions:

1. *Can we quantify SRL through student interactions with online tools?*
2. *How does SRL relate to academic performance, particularly for those students that are disengaged in the course content early on?*

## Theoretical Framework: Self-Regulated Learning

Mathematics students often cannot identify mistakes in their work, why the mistakes exist, or how to change their study habits to address their mistakes (Zimmerman, Moylan, Hudesman, White, & Flugman, 2011). SRL - "the self-directed process by which learners transform their mental abilities into academic skills" (Zimmerman, 2002, p. 65) - enables students to develop an understanding of their learning processes so that they can implement strategies and modify their study habits and learning behaviors to address difficulties to become more successful learners. Zimmerman's (2000, 2002) three-phase process model provides the SRL framework for this proposal. The phases focus around a learning task and consist of a planning phase (forethought), performance phase, and self-reflection phase – each occurring before, during, and after the learning task, respectively. The model is cyclic, with each phase informing the next. The cyclic nature of SRL allows students to continually review course material and deepen their understanding of concepts, which can promote learning, transferability, and retention (Bannert, Sonnenberg, Mengelkamp, & Pieger, 2015; Sonnenberg & Bannert, 2015).

### Forethought

The forethought phase consists of task analysis and self-motivational beliefs around the learning task. Task analysis involves setting goals and identifying strategies to employ so that those goals can be achieved (Zimmerman, 2000, 2002). Self-motivational beliefs involve "self-efficacy beliefs, outcome expectations, task interest or value, and goal orientation" (Zimmerman, 2008, p. 178). A student's beliefs regarding their self-efficacy about a task impact the value placed on that task and, in turn, the motivation and expectations of how effort for task will be executed. When a strategy cannot be identified, confidence and motivation play a role in determining if the learner intends to seek help. The forethought process connects directly to beliefs about one's learning (Zimmerman, 2002), influencing how the performance phase will be carried out.

### Performance

The performance phase is where strategies identified in the forethought phase are implemented. Elements of regulation of performance require self-control and self-observation, where one can modify or adapt the strategies identified during forethought to optimize the learning process. Self-control competencies such as time management and attention focusing are key during this phase to be able to make such adjustments (Zimmerman, 2000, 2002). By monitoring and having a record (mental or physical) of event details and duration during the performance phase, one can assess current and future adjustments that may need to occur. Upon completing the task (i.e. finishing the performance phase), learners reflect on their processes.

### Self-Reflection

Self-reflection involves learners looking back on their performance to assess what went well and where improvements could be made. This phase involves judging performance and then reacting to that judgment. Self-judgment means evaluating one's own performance to some personal standard, and self-reactions will differ depending on whether or not that standard was met (Zimmerman, 2000, 2002). For example, a student may receive a C on an exam, when, in fact, they had anticipated an A. The student may then react by changing study habits or strategies. Results from the self-reflection phase then impact subsequent forethought and performance phases of future tasks in this cyclical process as students move forward.

## Measuring Self-Regulated Learning

The most commonly used instrument for measuring SRL is the Motivated Strategies for Learning Questionnaire (MSLQ) - an 81-item self-report questionnaire that assesses “college students’ motivational orientations and their use of different learning strategies for a college course” as well as their “goals and value beliefs” (Pintrich, Smith, Garcia, & McKeachie, 1991, p. 3). The MSLQ has primarily been used to study components of SRL and the relationship of the components to academic performance (Pardo, Han, & Ellis, 2016; Pintrich & De Groot, 1990; Pintrich, Smith, Garcia, & McKeachie, 1993; Zimmerman & Kitsantas, 2014). However, due to the nature of self-reports, student responses on the MSLQ tend to reflect “how they [think] they should study, rather than how they [do] study” (Worthley, Gloeckner, and Kennedy, 2015, p. 137). Further, the validity of the MSLQ has been put into question, as it does not always align with observable behaviors such as strategy usage (Winne & Jamieson-Noel, 2002). While the three-phase cyclic model of SRL describes the learning process, methods to find evidence of SRL outside of self-reports are non-trivial (Winne & Baker, 2013). To address this discrepancy, we designed online tools specifically to coax SRL into observable, measurable events that can be recorded, which led to the formulation of a behavioral SRL metric.

## Methods

For this research, online tools were developed and implemented through the university’s learning management system (LMS). They were based on the three SRL phases: forethought, performance, and self-reflection. Since students often struggle with precalculus content (Agustin & Agustin, 2009), we focused on SRL around the task of assessing and remediating one’s knowledge of precalculus topics at the start of the semester. A self-assessment (forethought), content quiz (performance), and post-quiz reflection (self-reflection) were created, all of which were optional for the students.

Focusing on the forethought phase, we designed a Prerequisite Self-Assessment (SA), an 8-item survey asking students to rate their confidence in correctly answering questions on relevant prerequisite material on a Likert Scale from one (No confidence) to five (Very Confident). By assessing their confidence in precalculus topics, the tool determines if students were engaging in the task analysis component of forethought – how well they think they know the material.

Students’ participation in performance phase of SRL was determined by whether or not the student took the Prerequisites Content Quiz (CQ). The CQ is comprised of 12 multiple-choice and multiple-answer questions about prerequisite material essential for Calculus I. Upon finishing the CQ, students received information on what questions they answered right and wrong. When any question was answered incorrectly, immediate feedback was provided, including the relevant topic to review and available resources. Student responses, time spent per question, and order in which questions were answered can provide insight to better understanding the performance phase of SRL, as these data provide information on self-control and strategy implementation.

Students were given a five-item survey called the prerequisite reflection tool (RT) which was intended to be used after the CQ. The RT asked students questions such as ‘What topics from the prerequisite content quiz do you plan to study?’ and ‘How do you plan to study/practice problems from the prerequisite content quiz material?’. Use of the RT provides evidence that a student is reflecting on his or her performance on the CQ. This behavior indicates that a student may be planning to address possible content weaknesses, but does not provide evidence of subsequent follow through (i.e. additional forethought and performance of the intended task) without further investigation, such as tracking access of resource materials.

## Formulating a Behavioral SRL Metric

Of students that used the SA, they were considered to have either high confidence (mean confidence score of three or greater) or low confidence (mean confidence score less than three). Students that completed the CQ were considered to have either high precalculus ability (score of eight or greater) or low ability (score less than eight). Results from the SA and CQ were combined with use of the RT (used or did not) as well as precalculus resource access (accessed or did not) to formulate a behavioral SRL score. Results in each of these categories produced 36 different possible outcomes, and each outcome was then evaluated using Zimmerman's three-phase model as to whether or not they needed to remediate and if they were self-regulating appropriately. Each behavior was then assigned behavioral SRL scores of 0, 20, 40, 60, 80, or 100, from 0 (no self-regulation) to 100 (highly self-regulating).

## Data and Initial Findings

In addition to data gathered to compute the behavioral SRL score for each student, course performance data, online homework access data, and CHC attendance was collected. Online homework for the entire course was due at the end of the semester. Success in Calculus I was identified by a final letter grade of A, B, or C. Grades of D and F were classified as failure.

Table 1 presents the distribution of behavioral SRL scores across the 376 consenting students with the failure rate for each group. The same data is also shown for students that were considered 'disengaged' in the course with regard to both digital interactions with online homework and in person help-seeking in Calculus I as of week four. For example, 64 students had an SRL score of 60, 31.2% of which failed the course. In addition, 23 of these students were identified as being disengaged with the course, and 52.2% of these disengaged students failed.

*Table 1: Statistics for Behavioral SRL Score Within Two Groups: All Students and All Disengaged Students.*

| Behavioral SRL Score | Number of Students | Failure Rate | Number of Disengaged Students | Failure Rate |
|---|---|---|---|---|
| 0 | 32 | 46.9% | 20 | 60% |
| 20 | 50 | 32% | 16 | 56.2% |
| 40 | 18 | 27.8% | 6 | 16.7% |
| 60 | 64 | 31.2% | 23 | 52.2% |
| 80 | 104 | 24% | 29 | 31% |
| 100 | 108 | 17% | 23 | 21.7% |
| Total | 376 | 26.3% | 117 | 41% |

Within both groups, failure rates tend to decrease as students' behavioral SRL score increase, with the exception of the small group of students who have a behavioral SRL score of 40. Additionally, the subset of disengaged students has a particularly high rate of failure.

To begin validating the behavioral SRL score, we compared mean behavioral SRL scores with students' behavior with online homework and help seeking in the CHC. Of these four groups, the disengaged students, those who had neither been to the CHC nor worked on their Calculus I course online homework as of week four, had the lowest mean behavioral SRL score (56.1), while students who both sought help and used the online homework had the highest mean score (72). Those who only worked on online homework had slightly higher mean behavioral SRL score (70.3) than those who only sought help (mean score=63.2). A Kruskal-Wallis nonparametric test verified that these four behavioral groups differ in mean rank behavioral SRL score, $\chi^2(3)=15.0625$, $p=0.013$. Post Hoc Dunn's test with FDR correction revealed that the mean rank of disengaged students are statistically lower than students who only engage in the calculus course online homework before Exam 1, $z=-3.67$, $p=0.0018$, $r=0.21$.

## Discussion

These preliminary findings show promise for being able to use an SRL framework to develop tools that measure students' SRL behaviors and identify which disengaged students are potentially at-risk of failing Calculus I. Using these tools, we developed a method for generating SRL scores for students by analyzing their behaviors, specifically those around prerequisite remediation and readiness for Calculus I. The relationship between SRL scores and academic performance metrics suggests that more self-regulatory behaviors around prerequisite material promote success in course performance, which aligns with what is seen in the literature (Labuhn, Zimmerman, & Hasselhorn , 2010; Zimmerman et al., 2011; Zimmerman & Schunk, 2001). These statistical relationships grow stronger when looking at only those students who are disengaged with Calculus I before their first exam. Students who are disengaged, but have a higher SRL score tend to have higher success rates in the course than those who are disengaged with lower SRL scores. Similarly, when looking across all students (not just those who are disengaged), we see that students who have higher SRL scores generally fail less on average, showing the benefit of measuring SRL for all students.

## Limitations and Future Direction

In this report, presence of the different phases of SRL was determined by whether or not the students used the designed online SRL tools. This method relies on students' understanding the purpose for each tool and makes the assumption that lack of use is a conscious effort to avoid the tool and the associated SRL phase. We recognize that this has limitations as we have yet to further develop ways to measure SRL for students that do not use online tools. In moving forward, while we recognize there are several limitations, we plan to address the following two: (1) student awareness of online tools and their purpose, and (2) student usage of a selection of tools rather than engaging with all tools, which leads to a lack of evidence of students' SRL behaviors (e.g. despite a student reflecting on CQ performance, they fail to use the RT). As part of our efforts in addressing these limitations, we plan to merge multiple tools into one.

Student self-regulatory behaviors around prerequisites leave breadcrumbs about their self-regulation in Calculus I. This may help frame the temporary disengagement of some students as intentional regulated prolonging of engagement. For instance, a student well positioned in Calculus I may temporarily divert their exam study time to a different class in which they are struggling. Preliminary reports show some success with using high and low behavioral SRL scores as predictors for success and failure in Calculus I. Further, when focusing on disengaged students, our methods for identifying those at-risk of failure become more precise. Based on student interactions with online tools and other external resources, we are deepening our understanding of SRL's role in Calculus I with student learning behaviors. While this data combined with the SRL framework is informing modification, enhancements, and addition of online tools, we plan to conduct student interviews as a way of triangulating our data. We plan to use Zimmerman and Pons' (1986) protocol as another way to measure SRL. Student interviews will provide an opportunity to better understand student engagement in the course as well as validate our quantitative findings. SRL scores and qualitative data can then inform intervention support to improve student success in Calculus I and STEM.

**The Emergence of a Video Coding Protocol to Assess the Quality of Community College Algebra Instruction**

AI@CC Research Group*
Anoka-Ramsey Community College, Delta College, Glendale Community College, Scottsdale Community College, University of Michigan, University of Minnesota

*The Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM) is a video coding instrument that provides indicators of the quality of instruction in community college algebra lessons. The instrument is based on two existing instruments that assess the quality of instruction in K-12 settings—the Mathematical Quality of Instruction (MQI) instrument (Hill, 2014) and the Quality of Instructional Practices in Algebra (QIPA) instrument (Litke, 2015). EQIPM addresses three dimensions focused on quality of instruction via 17 codes. In this paper, we describe two codes: Instructors Making Sense of Procedures from the Quality of Instructor-Content Interaction dimension, and the Mathematical Errors and Imprecisions in Content or Language, a code spanning all three dimensions. The purpose of the paper is to illustrate what we have learned from these codes and the new instrument to advance our understanding of post-secondary mathematics instruction.*

*Keywords:* Algebra, Instruction, Video Coding, Community Colleges

Various reports have established an indirect connection between students leaving science, technology, mathematics, and engineering (STEM) majors because of their poor experiences in their STEM classrooms (Herzig, 2004; Rasmussen & Ellis, 2013). Interestingly, however, most of these reports are based on participants' descriptions of their experiences in the classroom, rather than on evidence collected from large scale observations of classroom teaching (Seymour & Hewitt, 1997). When such observations have been made, they usually focus on superficial aspects of the interaction in the classroom (e.g., how many questions instructors ask, how many students participate, or who is called to respond, Mesa, 2010) or their organization (e.g., time devoted to problems on the board, or lecturing, Hora & Ferrare, 2013; Mesa, Celis, & Lande, 2014). Undeniably, these are important aspects of instruction, yet these elements are insufficient to provide a characterization of such complex activity as instruction in classrooms.

A key concern in post-secondary mathematics education is the lack of teacher training that mathematics instructors received in their graduate education (Ellis, 2015; Grubb, 1999). We argue that the lack of a reliable and valid method to fully describe how instruction occurs hinders our understanding of the complexity of instructors' work in post-secondary settings and therefore limits the richness of professional development opportunities focused on the faculty-student-content interactions (Bryk, Gomez, Grunow, & LeMahieu, 2015). As part of a larger project that investigates the connection between the quality of instruction and student learning in community college algebra, we have developed an instrument, EQIPM, that seeks to characterize instruction.

Colleges and authors are listed alphabetically.

In this paper, we present the current form of the instrument and describe two codes that show promising findings from our pilot data.

## Theoretical Perspective

We assume that teaching and learning are phenomena that occur among people enacting different roles—those of instructor or student—aided by resources of different types (e.g., classroom environment, technology, knowledge) and constrained by specific institutional requirements (e.g., covering preset mathematical content, having periods of 50 minutes, see Chazan, Herbst, & Clark, 2016; Cohen, Raudenbush, & Ball, 2003). We focus on instruction, one of many activities that can be encompassed within teaching (Chazan et al., 2016), and define instruction as the interactions that occur between instructors and students in concert with the mathematical content (Cohen et al., 2003). Such interaction is influenced by the environment in which it happens and it changes over time. Empirical evidence from K-5 classrooms indicates that ambitious instruction is positively correlated with student performance on standardized tests (Hill, Rowan, & Ball, 2005). The definition of instruction requires attention to the discipline and is fundamental in understanding mathematics teaching practice. Therefore, we assume, first, that the experiences of instructors and students while interacting with mathematical content have a significant impact on what students are ultimately able to demonstrate in terms of knowledge and understanding, and second, that it is possible to identify different levels of quality of the instruction that is enacted in mathematics classrooms.

## Methods

In the pilot phase of the larger research study, we video-recorded 15 lessons in introductory, intermediate, and college algebra classrooms from three different community colleges in three different states during the Fall 2016 semester. The lessons ranged in duration between 45 and 120 minutes, and were taught by six different instructors (two part-time and four full-time). The lessons covered one of three topics: linear equations/functions, rational equations/functions, or exponential equations/functions. These topics were chosen because they offer us opportunities to observe instruction on key mathematical concepts (e.g., transformations of functions; algebra of functions) and to attend to key ways of thinking about equations and functions (e.g., preservation of solutions after transformations; covariational reasoning), which are foundational algebraic ideas that support more advanced mathematical understanding. The development of EQIPM was similar to the process used by Hill and colleagues (2008) and by Litke (2015). Their instruments describe and qualify instructional practices from video-recorded lessons deemed representative by rating all individual 7.5-minute segments.

EQIPM evolved through various iterations of segment and lesson coding and discussion with a subset of segments. In the final phase of development, all 151 segments in the data corpus were double-coded using an earlier version of EQIPM. Each code received a score ranging from 1 to 5. The team of 10 researchers, all co-authors on this paper, worked in pairs to independently code three lessons; for each of their lessons, each pair held calibration meetings to discuss codes with a discrepancy in ratings greater than one point.

The instrument consists of three dimensions: (1) Quality of Instructor-Student interaction, (2) Quality of Instructor-Content Interaction, and (3) Quality of Student-Content Interaction; two cross-cutting codes (*Mathematical Explanations and Mathematical Errors and Imprecisions in Content or Language*); and three additional codes that help characterize the type of work done on each segment in a lesson (i.e., Mathematics is a focus of the segment, Procedure taught in the segment, and Modes of instruction, see Figure 1). In this paper, we describe one code from the

Quality of Instructor-Content Interaction dimension (*Instructors Making Sense of Procedures*) and one cross-cutting code (*Mathematical Errors and Imprecisions in Content or Language*) to provide the reader with a sense of how these two codes are useful in characterizing key practices in the community college algebra classrooms that we have observed.

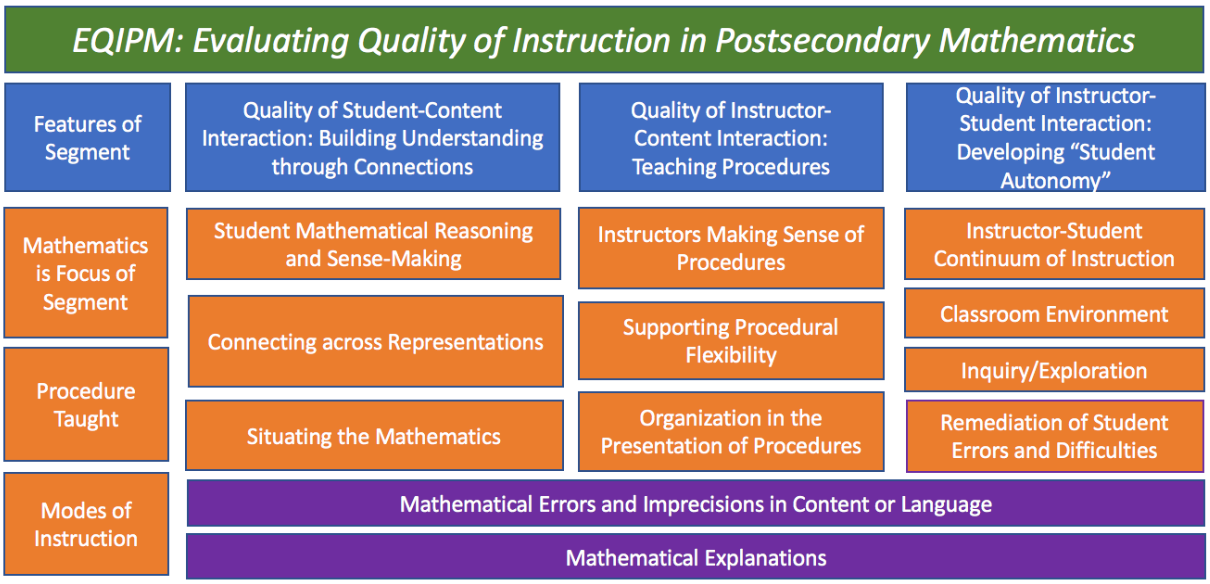

*Figure 1: Dimensions and codes for the EQIPM instrument.*

## Preliminary Findings

*Instructors Making Sense of Procedures* was a code originally from the QIPA instrument, which defined a procedure as "instructions for completing a mathematical algorithm or task" (Litke, 2015, p. 160). With this code, we sought to identify ways in which instructors used mathematical relationships or properties to motivate a particular procedure. Such work includes activities that attend to, for example, the type of solution generated by a procedure and its interpretation or to the conditions of the problem that may suggest what procedure to apply and where in the process to use it. This work also includes activities that attend to the symbols used in mathematical expressions and equations, as well as to the structure of an algebraic expression and how it is transformed by each step in a mathematical procedure. Thus, in general, this code seeks to capture all mathematical work that instructors do to make salient mathematical properties, relationships, and connections embedded in a particular mathematical procedure. Making sense of procedures helps students to understand the underlying logic of the procedure of how to get from one step to the other, not merely reproducing the work from a textbook example. We believe that when the instructors make explicit the sense-making behind procedures, then their students will have an opportunity to make sense of the mathematics as well so that they can engage more substantively with the mathematics.

In order to make an assessment of the evidence found in the videos, each segment was rated on a scale of 1 to 5 depending on whether the instructor did not engage in sense-making while teaching a procedure (a rating of 1) or when the instructor consistently engaged in sense-making throughout the segment (a rating of 5). A rating of 3 is reserved for cases in which sense-making is observed on several occasions in the segment, but they are brief, or for cases in which procedures are not the focus of instruction. Ratings of 2 and 4 were used when the evidence was not sufficient for a 3 or a 5. Out of segments in which a procedure was taught, we only identified one in which no sense-making was present; 59 segments (43%) had a rating of 3, and 55 segments (39%) had a rating of 4 or 5 (30% and 9%, respectively). Thus, in these lessons, we were able to provide evidence for all of the ratings, which suggests that the instrument allows for differentiation of the role of sense-making in the classroom. In most cases, we can say that instructors were making a genuine effort of assisting students in making sense of the procedures taught during the video recorded sessions.

For example, in a lesson on linear functions, instructor 0613 presented a word problem in which students are asked to model the value of a copy machine, $v$, as a function of time, $x$. The instructor asked students to consider how to write a linear function $v$ as a function of $x$. Students contributed three answers: $f(x)$, $f(v)$, and $v(x)$. The instructor reasoned through all three responses using the information in the problem to make sense of the appropriate way to write the function as $v(x)$ (0613_L1, 2016, 26:22). Later in the segment, the instructor asked, "What does the value of $120,000 mean in this problem? What does a slope of negative 12,000 mean in this problem?" (0613_L1, 2016, 29:00). The subsequent conversation detailed the meaning of the values of the $y$-intercept and slope for this specific context. This segment received a rating of 3 because within the segment, the instructor made sense of the procedure more than briefly, but sense-making was not the focus of the instruction on the procedure (how to write an equation to model a situation given in a problem). Instructor 0112 demonstrated sense-making that was rated as a 5, when working with a growth problem modeled by $y = 3(2)^x$. He asked students to think about the meaning of the general equation $y = ab^x$ with a concrete example that used paper folding to demonstrate the meaning of $2^x$, where $x$ was the number of times a piece of paper was folded by half and $y$ the size of the stack of papers generated by the fold: One fold created a stack of 2, two folds created a stack of 4, three folds created a stack of 8, and so on (0112_L1, 2016, 30:00). This segment was rated 5 because, sense-making was the focus of the segment and it saturated the segment.

*Mathematical Errors and Imprecisions in Content or Language* was a code originally from the MQI. The code is intended to capture events in the segment that are mathematically incorrect or that have problematic uses of mathematical ideas, language, or notation. This code applies to the work and utterances of the instructor. Errors made by students are ignored except when the instructor does not correct them. This code also captures cases in which problems are solved incorrectly, when definitions are incorrect, or when the instructors do not use or forget to mention a key condition in a definition. Finally, we apply this code when instructors use imprecise or colloquial mathematical language. Our interest in this code stems from the realization that in some of the lessons we observed, instructors used language that was not mathematically correct to convey ideas, and whereas such uses were appropriate for the lesson—their meaning had been negotiated within the classroom—the continued use of that language could put students at a disadvantage because they would not be gaining proficiency in using correct mathematical language. A rating of 1 indicates that no errors or imprecisions were observed, a desirable situation, whereas a rating of 5 indicates major content, notation, or language errors were made throughout the segment, an undesirable situation. A rating of 3 is reserved for some errors that obscure the mathematical meaning for part of the segment. Out of 138 segments in which a procedure was taught, we only identified one segment with a rating of 5 signaling that major errors were seen, and 45 segments (33%) in which no errors were observed. Fifty-eight segments (42%) had minor imprecisions (rating of 2, e.g., using "bottom" for denominator) and 34 segments (24%) had a rating of 3 or 4 (23% and 1%, respectively). Given that about one fourth of the segments were rated with a 3 or more in this sample, we note that the instrument may suggest areas for professional development that relate to strengthening the rigor in using accurate mathematical language, relationships, and notations. For example, in a lesson on rational equations, instructor 0112 used a graphing calculator to graph $y = \frac{x+1}{x^2-5x+6}$. While identifying the asymptotes using graphical and symbolic representations of the function, the instructor stated that the zeros of the denominator "equal" the vertical asymptotes. We considered this statement as an error in language because that precise statement would require writing a linear equation, as well as an error in content because it does not recognize that there is a removable discontinuity. Later in the segment, the instructor asked the students: "If I let $x$ be equal to 2, with what do I end up at the bottom?" (0112_R1, 2016, 57:12). We considered the replacement of precise mathematical terms (e.g., denominator) with an everyday, colloquial term (e.g., bottom) an imprecision in language. However, the segment was rated as 2 in this code because the imprecise language did not hinder the procedure of identifying the asymptotes.

## Questions for the Audience

The current version of the EQIPM instrument seeks to gather evidence on the quality of the instructor-content, instructor-student, and student-content interactions, thus mirroring the framing on instruction of our work. To advance our work, we have the following questions:

- Are there features of quality instruction that are not being captured in this version of the EQIPM instrument? A preliminary factor analysis with the pilot data points to a three-factor structure (with mathematical errors and imprecision being by itself). During the presentation, we will share the instrument and the current definitions, and we will illustrate how some of the codes fit in this factor analysis.
- The labels for the main categories of codes, mirror our definition of instruction. Are there other possible structures or organizations of the codes? What theoretical framing about quality of instruction could be used for such reorganization?
- Which additional video coding protocols could be leveraged to make the EQIPM instrument more robust?

The Ways Graduate Teaching Assistants Learn to Teach Through Various Professional Development Interactions

Hayley Milbourne & Susan Nickerson
San Diego State University

*Across the nation, there is increased national interest in improving the way mathematics departments prepare their GTAs. However, without an understanding of how GTAs interpret and make sense of various teaching practices, we are working without all of the information. I report preliminary results on the ways in which the understandings of GTAs of various teaching practices changed over a term. With this analysis, we will be able to better understand how to better support GTAs with their teaching in the future. The research presented here represents the start of an increased understanding of how GTAs form their own teaching practices.*

*Keywords:* Graduate Teaching Assistants, professional development, teaching practices

Across the nation, many mathematics departments have begun to change the way they structure the teaching of the Calculus sequence based on the seven recommendations that emerged as a result of the MAA sponsored study of successful Calculus programs (Bressoud, Mesa, & Rasmussen, 2015). One of the recommendations was to improve the professional development (PD) offered to the Graduate Teaching Assistants (GTAs) involved in the teaching of Calculus. GTAs comprise a larger percentage of Calculus I instructors and teach a larger percentage of Calculus I students than tenure-track professors (Ellis, 2014), making their PD all the more important. Though these various mathematics departments have the common goal of improving the teaching practice of GTAs through PD, the structure of the PD programs for GTAs varies greatly among them (Belnap & Allred, 2009). Research on the PD programs across the nation is becoming more common place, as seen by the growth in the number of people in the PD working group at the annual Research in Undergraduate Mathematics Education conference.

Much of the research done on GTA PD programs have focused on the various structures of PD programs, on the outcomes of the programs, or on a small, in-depth case study (e.g., Kung & Speer, 2009). While it is important to know what the outcomes of the program are, it is equally important to understand how those changes occurred so as to improve our PD programs. In a review of the research, Speer, Gutmann, and Murphy (2005) stated the need for studies with longitudinal designs so as to “inform the design of exemplary programs that have a lasting influence on instructional practices” (p. 79).

The mathematics faculty at a large southwestern university made several changes to the calculus program, including to the structure of the PD program for the GTAs. The PD is oriented around supporting GTAs to teach in with a more student centered approach. As part of this program, the GTAs discuss effective teaching practices with each other, their course coordinators, and mathematics education researchers. This paper discusses preliminary results of analysis on the evolving understanding of effective teaching practices as evidenced in their discussions in the various formal meetings attended by the Calculus I and II GTAs. With a better understanding of the ways in which the discourse around various teaching practices evolve over time, we can better support GTAs in their learning to teach in the future.

## Background

In many ways, professional development can feel like a complex game of telephone. The leaders and creators of the professional development have certain ideas of effective teaching practices that they are attempting to convey to the teachers or the facilitators with whom they are working. However, the facilitators and teachers are appropriately going to interpret it in their own way and share and use their transformed version of their ideas of effective practice. Research on the Standards movement reform of the 1980's and 1990's documented only a modest impact of the initiative on teachers' practice and that teachers selectively took up reform ideas and adopted only the surface-level features (Spillane & Zeuli, 1999). Researchers explained the adaptation in terms of teachers' learning processes and suggested that implementation varied because teachers drew on prior knowledge and practices when interpreting the message about the new standards and instructional practices (Coburn, Hill, & Spillane, 2016; Coburn, 2001; Cohen & Ball, 1990).

The similarity with the K-12 context is that when faculty and graduate students undertake reform teaching, all of those involved, including the department chair, course coordinators, faculty who take on the PD of teaching assistants, and the teaching assistants themselves, co-construct the message of the reform. It begins with a small group of faculty with the goal to promote high-quality instruction and its success ultimately, in large part, depends upon the learning of the teaching assistants who interact with the college students most frequently. My particular study focuses on how GTAs make sense of and interpret what they learn about how to lead a student-centered classroom.

There have been only a handful of studies done exclusively on the state of professional development of GTAs across the nation (Belnap & Allred, 2009; Ellis, 2015; Kalish et al., 2011; Palmer, 2011; Robinson, 2011). In addition to national level studies, there are also several case studies of particular programs at specific institutions, with a focus on the structure of or the efficacy of the program (e.g., Griffith, O'Loughlin, Kearns, Braun, & Heacock, 2010; Marbach-Ad, Shields, Kent, Higgins, & Thompson, 2010). So, while there have been studies that describe the various forms of PD or that give an idea of what GTAs have learned from their experiences in PD, little work has been done on the ways in which the GTAs have constructed their understandings of various teaching practices – "what teachers do and think daily, in class and out, as they perform their teaching work" (Speer, Smith, & Horvath, 2010, p. 99). This research contributes to understanding how the GTAs are appropriating and transforming various teaching practices to fit their own needs over time.

## Setting

At the large, public southwestern university in this study, Calculus is taught in large lectures of approximately 160 students. The GTAs lead break-out sessions with approximately 35 students twice a week, with one meeting focused on active learning activities. To support the GTAs in facilitating these active learning activities, the GTAs participate in a three-day teaching seminar the week before classes begin in the Fall. The GTAs continue to meet approximately eight times throughout the term with mathematics education faculty. In addition to the formal PD, the GTAs have weekly meetings with their course coordinator where they talk about the activity for the following week and any additional administrative issues.

The structure of the GTA program has been changed to include a lead TA for each of Calculus I and II. The lead TA is a more experienced GTA who provides support to his or her fellow GTAs with a PD aspect that occurs both before the term begins and throughout the term (Ellis, 2015). Throughout the term, the lead TA visits the activity day sections of his or her fellow GTAs to observe the class and meet with the GTAs afterward to debrief. The lead TA visits all of the other GTAs two or three times a term. A representation of all of these various meetings and observations throughout the term is given below in Figure 1.

## Methods and Analysis

Sixteen GTAs agreed to be part of the study, including both of the lead TAs, seven new GTAs, and seven returning GTAs. I either audio or video-recorded each PD meeting, course coordinator meeting, debrief between the lead TA and a fellow GTA, and any break-out sections observed by the lead TAs. I transcribed each of the video and audio recordings and coded each utterance about teaching practices using descriptive coding (Bakhtin, Emerson, & Holquist, 1986; Miles & Huberman, 1994).

A theoretical perspective that includes both a social and a cognitive aspect is useful in making sense of the evolving nature of discussions around teaching practices. The socio-cultural learning theory put forth by Vygotsky posits learning occurs through a reflexive relationship between the individual and the community in which the individual interacts (John-Steiner & Mahn, 1996). In order to understand the ways in which the discussion evolved over time amongst the GTAs, I am using a modified version of a framework within the socio-cultural learning theory known as the Vygotsky space (Harré, 1983). With this framework, the understanding of a teaching practice can be tracked as it is appropriated and transformed by the GTAs throughout the term. A representation of the Vygotsky space can be seen below in Figure 2.

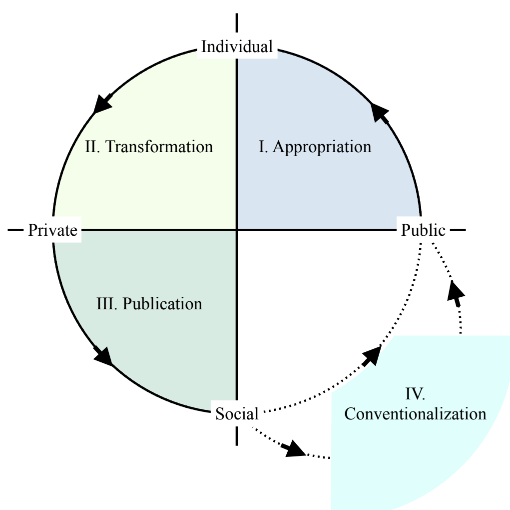

*Figure 2: Modified diagram of the Vygotsky space.*

Within this diagram, there are two axes: Public-Private and Individual-Social. These two axes make up four quadrants, which work to explain the four aspects of the Vygotsky space. For instance, *appropriation* is within the Public-Individual quadrant because it describes how an idea comes to a person from the public. *Transformation* is within the Individual-Private quadrant because it describes the way a person has made the original idea their own. In the third quadrant is *publication*, which is described as how the person makes their own private understanding of the idea known to the social group they are within. At this point, the idea may go through several iterations of these three quadrants before it lands within the fourth quadrant, *conventionalization*, which represents that idea has become normalized within a community (Gallucci, DeVoogt Van Lare, Yoon, & Boatright, 2010).

The modified Vygotsky space framework facilitates our understanding of how changes occur within a community over time. In this study, it sheds light on how GTAs make sense of various teaching practices. Using this framework, a researcher attends to the speaker, the publicized interpretation, and the timing of the utterance, revealing how individuals may affect the community as well as how the community may affect the individual. An example of this sort of analysis is given in the preliminary results below.

**Preliminary Results**

One particular teaching practice that was discussed by the GTAs throughout the term was that of asking students to repeat or rephrase something that had just been said. This may be to repeat or rephrase something another student said, state a given task in their own words, or rephrase something the GTA has just explained. An experienced instructor in mathematics education introduced this teaching practice during the three-day seminar before the semester began:

> "There was something that I wanted to add that I think is really productive [in] engaging your students in a task is to make sure that if someone gives an answer… and they're kind of going in the right direction, you want to make sure the rest of the class understands it as well so you can say 'can somebody revoice what Nick just said or revoice what Joe just said' or basically say what they said but in your own words to make sure that other students do understand…"

After this, several other references to this practice were made public by the professional development leaders, including as a way to reinforce an idea, to get students to interact with one another, to have the students state when they could not hear a response, and to make sure the students understand the task given to them.

Once the term began, a transformation in the way this teaching practice was discussed could be observed in the ways in which various GTAs made public their understanding:

> "One of them is if you see someone who's talking, you say 'hey can you repeat what, repeat what Christian said.' And put them on the spot a little. But if they can't, don't make a big deal. They're already going to make a big deal about it."

Independently of this interaction, the lead TA for Calculus I made a similar suggestion to one of his GTAs:

> "And you had another student re-explain the directions which is always good because that means at least somebody is paying attention. Also, it makes them think oh what if he calls on me."

As the term went on, the understanding of the teaching practice seemed almost become conventionalized around the thought that it was a good way to make sure students are paying attention in class. However, there was one more experienced GTA who continued to push her different version of a more "student-understanding" approach to the teaching practice amongst her peers:

> "I think even asking [inaud] students to like revoice or talk about what just happened is good because it gives different perspectives than you teaching them and you make sure

someone in some group out there understands and maybe when they say it, others will get it better."

When the term began to close, the student-understanding approach became more dominant in the ways GTAs discussed this teaching practice in formal settings, with the lead TA for Calculus I making public this transformed version after watching a fellow GTA's teaching video:

"I think, um, one thing I do, 'cause I do the same thing. I ask them 'do you understand that' and then no one says anything so pick on someone you know, maybe not all the time, but occasionally pick someone you know usually struggles and see if they actually understand. Have them try and explain it. And then at that point they either do and they explain it, or they say 'well, I don't actually get it.' Okay well, take some time, talk about it with your groups and then we'll come back and then tell me what it means."

While there is evidence to suggest the understanding of the teaching practice as useful in determining their students' understandings was becoming conventionalized, the change only took place near the end of the term and so it cannot be said whether or not that understanding continued. What makes this particular example an interesting and important one to consider is the fact that the understanding of this teaching practice as a disciplinary tool may have been inadvertently encouraged by the professor of the professional development course. Approximately one month into the term, the professor was engaging the GTAs in a discussion about what they noticed in a video they had just watched and said the following:

"If you use things like asking them to repeat what somebody else said, asking them to explain what somebody else said, those types of things, those can help get students to listen to each other."

This could be interpreted as the professor suggesting this particular practice as a way to get students to engage with one another but since there was evidence of the GTAs understanding this practice as a disciplinary tool, I believe this could have been interpreted as something that would support such an understanding. So, without a good understanding of how the GTAs are making sense of various teaching practices, we may inadvertently encourage a belief that we ourselves may not believe.

## Conclusion

Analysis for this study is currently on going but the preliminary results are proving to show some interesting conclusions. It is my belief that with the results from this study, we will have a better understanding of the ways in which graduate teaching assistants make sense of various teaching practices and therefore will be able to better support them in the future. Without taking into account the understandings and interpretations of the graduate students we are working to help, we may inadvertently enforce beliefs we do not hold our selves. With this information, the field can begin to understand how GTAs change their practice over time and improve the professional development offered to graduate students who are new to the practice of teaching.

Integrals, Volumes, and Visualizations

Krista Kay Bresock
West Virginia University

Vicki Sealey
West Virginia University

*Many studies have been done on student understanding of integration and this research aims to add to that knowledge base with the study of student understanding of integration when applied to volume problems and how visualizations and sketches are used in the problem-solving process. Participants were recruited from a large, public, research university and interviews consisted of students working through routine and novel volume problems while discussing their thought processes aloud. Preliminary results show that students rely heavily on memorized formulas and have difficulties explaining the concepts behind the formulas. The idea of the integral as a sum of small pieces is present in most students studied, but they have trouble relating this idea to the formulas in their volume integrals. All students drew sketches of the geometric situation for all the problems, but the extent to which they could use their sketch meaningfully varied greatly.*

*Keywords:* Calculus, definite integral, volume, visualization, Riemann sum

## Introduction and Literature Review

After an introduction to the concept of the definite integral, some of the first applications that students encounter are volume problems. Volume problems found in second-semester calculus classes involve a combination of visualization, geometry, and integration skills. Previous studies have found that when solving definite integral application problems, students often rely on formulas, patterns, and previously encountered methods for setting up integrals (Yeatts & Hundhausen, 1992; Grundmeier, Hansen, & Sousa, 2006; Huang, 2010). In one of the first studies on student understanding of integration, Orton (1983) found that students had very little idea of the dissecting, summing, and limiting processes involved in integration when solving area and volume problems. Several authors (Sealey, 2006, 2014; Jones, 2013, 2015a, 2015b; Meredith & Marrongelle, 2008) have found that students are most successful when they are able to conceptualize the definite integral as the limit of a sum of products. Moreover, Sealey's (2006, 2014) work shows that students may have an idea of the underlying structure of the definite integral, but may not fully understand the layers that comprise the whole. In particular, students can easily conceptualize the summation layer but have the most trouble when working in the product layer of the Riemann sum structure.

One key component of a calculus volume problem that students can use as an aid is a visualization of the situation, generally in the form of a sketch made by the student. Stylianou and Silver (2004) found that, even though the construction of a diagram or picture is helpful, it is the quality of the picture that is most important. Bremigan (2005) had similar results, finding that although diagram production was related to correctly solving the problem, the presence of a constructed or modified diagram was not a sufficient condition for problem-solving success. In their study on expert and novice visualization practices, Stylianou and Silver (2004) observed novices' cognitive disconnect between visualizations and the problem-solving process. They state that, "although novices appear to have aspects of the declarative knowledge associated with visual representation use, they lack the necessary procedural knowledge that would allow them to use visual representations functionally and efficiently" (p. 380).

## Research Aim

As volume problems are one of the first applications of the definite integral that students encounter, the aim of this study is to further explore how students view and use the underlying structure of the definite integral when solving these types of problems. We are also interested in how students use their sketches of the geometric situation to aid in solving volume problems.

## Conceptual Framework

Sealey's (2014) Riemann Integral Framework was used to inform both the data collection and analysis of student understanding of the structure of the definite integral. This framework breaks the constituent parts of the Riemann integral down into pieces – product, summation, limit, and function – and it allows us to pinpoint the parts of the underlying structure of the definite integral that students have the most trouble with when solving volume problems. For the visualization aspect, we will be using Zazkis, Dubinsky, and Dautermann's (1996) Visualization/Analysis Framework to analyze student use of pictures and diagrams in the volume problem-solving process. In this model, there is a first visualization, $V_1$ (for example, a sketch of a 2-dimensional region), which is then acted on by an analysis event, $A_1$. In the following act of visualization, $V_2$, the student is still attending to the same picture used in $V_1$, but its nature has changed (due to $A_1$) and could lead to a reinterpretation of the picture or a new image construction. No matter the form the visualization takes in this step, $V_2$ results in a richer understanding of the original situation. The process goes on like this, from visualization to analysis back to visualization, optimally resulting in a more complete understanding of the physical situation.

## Research Methodology

Interviews with students were conducted during summer 2016 (Study 1) and summer 2017 (Study 2). The participants were recruited from summer classes at a large, public, research university. In summer 2016, the participants were four Calculus 2 students (all male) and three Elementary Differential Equations students (one female and two male). In summer 2017, the participants were two Calculus 2 students (one male and one female). The interviews were one-on-one and videotaped, and the students were asked to write their math work on paper or a white board and discuss their thoughts aloud.

During the interviews, the students were asked to complete three second-semester integral volume problems. In Study 1, the problems were three routine solid of revolution problems (e.g., "Find the volume of the solid obtained by rotating the region bounded by the curves $y = x^2$ and $y = 3x$ about the line $x = -1$") and the students drew their sketches and wrote their math work on the same paper. In Study 2, the problems were two routine solid of revolution problems and one geometric solid problem, which we will call the pyramid problem ("Find the volume of the pyramid whose base is a square with side length $L$ and whose height is $h$."). In order to more clearly observe when students were referring to their drawings during the problem-solving process, the method was adjusted in Study 2 as follows. One student in Study 1 drew sketches and performed math work on separate sheets of paper; the second student sketched drawings on a white board and wrote math work on a sheet of paper.

During the interviews for both studies, students were probed about their responses and were asked to explain their work and thought processes. Some typical questions asked during the interview process were: "How do you know this integral gives you a volume?", "How does that particular statement give you the volume of a cylinder/washer/etc?", "What does the *dx* mean?", and "Can you show on your picture the different parts of the volume integral?"

The video data was transcribed and analysis is in the beginning stages. We use thematic analysis (Braun & Clark, 2006) to identify themes and patterns in the data. In particular, we have begun by employing theoretical thematic analysis, which is "driven by the researcher's theoretical or analytic interest in the area, and is thus more explicitly analyst-driven" (p. 84). We feel that this will be an appropriate method for this study, since we have pre-determined codes that we will be looking for in student responses (e.g., working in a specific layer for Sealey's framework or being in one of the visualization/analysis phases of Zazkis' framework).

## Preliminary Results

The students in these studies exhibited a strong attachment to memorized volume integral formulas when solving the routine solid of revolution problems.

*Interviewer*: Do you understand where that [*their volume integral*] came from?
*Student 2*: I treat that just as a formula. Physics is the class where I think about and understand, you know, but, it just could be because they throw a lot of numbers at you fast.
*Student 3*: I know the formula, but sometimes I don't know where to apply them.

Using the formulas is not a detrimental method, but we would prefer that students are also able to unpack the underlying definite integral structure when asked to do so. Few students in this study were able to accurately and consistently discuss the details of their memorized formulas or how they produced a volume measurement.

Another observed occurrence was students linking the line of rotation to the variable of integration without being able to produce meaningful explanations.

*Student 1*: Since the line I'm rotating about is parallel to the $y$-axis, if I use cylindrical shells method, I need to integrate $x$.
*Student 2*: So, if, like it's [*the line of rotation*] parallel to the $y$-axis, I'll integrate $y$.

There were only two students who were given the pyramid problem, but their methods for attacking the problem were very different and highlighted some problems of relying on memorized formulas and mimicking methods seen in class. Student 5 was very successful with the routine solid of revolution problems by relying heavily on the "volume formulas" and was able to produce accurate volume integrals that would receive high marks on an exam, even though her explanation of the details was shaky. When confronted with the pyramid problem, Student 5 continued to try to use a memorized volume formula but with poor results. Student 5 had to be heavily guided in the pyramid problem due to over-reliance on memorized formulas that did not fit with this problem. Even though Student 5 did not succeed in solving the problem completely, there was the presence of "cutting into small pieces and adding them up" in her thought process that seemed to be accessible but not heavily used. Student 5 also had a very hard time visualizing the situation and had to be heavily guided into a 2-dimensional side-view of the pyramid so that she could reduce the cognitive load of the 3-dimensional solid situation.

Student 6 was less successful with the solid of revolution problems; he relied heavily on the memorized formulas but was unsure of how to use them effectively. When probed using the questions stated above, he was very unsure and stated this fact many times. When confronted with the pyramid problem, he had trouble visualizing the situation at first, but then transformed the 3-dimensional solid into a 2-dimensional side view (on his own) and was able to make significant progress. Once the weight of "you must use this formula" was lifted, Student 6 was able to make some strong connections between what he knew of "adding up small pieces" and this novel volume problem. This problem forced Student 6 to give up on his attachment to memorized volume formulas and rely solely on the concept of the definite integral as the sum of smaller pieces.

The students in this study had many misunderstandings but we want to emphasize more what they could do than what they could not do. When faced with volume integral application problems, almost all of the students exhibited some understanding of the dissecting, summing, and limiting structure of the definite integral; they just had trouble applying it to the problem.

> *Student 1*: In that case you're using the, um, areas of [*stacks hands horizontally on top of each other*] … circles. Um, so you're making a series of washers.
>
> *Student 1*: So if you were to take one of those, a slice of the inside of the cylinder, it would be like this sheet with a depth. But when we integrate, we're basically taking that depth to zero. The limit of that depth. Right?
>
> *Student 2*: What I'm looking for then is my radii of my, you know, infinitely concentric circles going on here.
>
> *Student 4*: Basically it's going to be a bunch of different-sized cylinders stacked upon each other.

Students' drawings varied in sophistication and accuracy. All students drew a sketch of the geometric situation for all the problems, but the extent to which they could use their sketch meaningfully varied greatly. The most glaring disconnects came when students produced a correct (or mostly correct) volume integral, but could not relate their integral back to the physical situation of the sketch. One student in particular – Student 2 – was able to produce very detailed sketches of the sum-of-pieces structure (Figure 1), but his description of the underlying mathematics was full of inaccuracies and nonsense. According to Sealey's (2014) framework, this student is appropriately attending to summation layer, but he had great difficulties in the product layer.

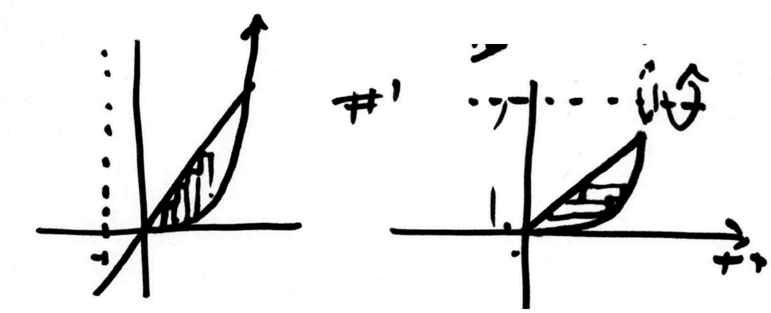

*Figure 1: Drawings produced by Student 2 when describing his volume integrals.*

### Teaching Implications/Future Research

The preliminary results of this study imply that students' heavy reliance on memorized formulas and mimicking of methods observed in class can lead to misunderstandings and brick walls when students are faced with more complicated or non-routine integral application problems. It was also observed that producing an accurate definite integral to a solid-by-revolution problem does not necessarily imply that the student understands integration and how the integral produces a volume. Solid by revolution problems are given a lot of face time in most calculus books, but they can inadvertently tell an incomplete story of how integrals can be used to find volumes in general and how they can be used in other application situations. We believe that more time should be spent on non-revolution and non-routine volume problems, so that students are required to exercise their definite integral muscles and not be tempted to fall into the trap of relying solely on memorized formulas. From this study, it is clear that the idea of “dissecting and summing” is present in many students, and we need to find ways to employ and enrich it.

We plan to continue analyzing our data set, as well as conduct more interviews with the aim of examining student visualization and picture-use when solving volume problems, like the interviews conducted during summer 2017 involving the pyramid problem. In particular, we would like to investigate how they use their sketches to build the pieces of the corresponding volume integral and how they interact with their drawing in the problem-solving process. Furthermore, we would like to develop ways in which students can more meaningfully engage in constructing and understanding the product layer. In the future, we would like to study other aspects of visualization that students use when solving volume problems, like gesture.

## Questions for Audience

1. Aside from eye-tracking software, are there more sophisticated ways to capture when students are going back and forth between picture and math work on camera?
2. How can we determine if separating the drawing space from the math work space bring about any unintended consequences for student problem-solving?
3. Are there any studies on visualization that we have missed that could help us out with this work?

Examining Students' Problem Posing Through a Creativity Framework

Steven Silber
Virginia Tech

*Understanding how students pose problems can inform the development of posing activities to further enhance students' understanding of mathematics. Analyzing students' problem posing through the lens of mathematical creativity provides insight into the creative process of posing problems; namely, the cognitive tools students use to formulate questions. Three undergraduate students, enrolled in a developmental mathematics course, participated in a problem-posing intervention to examine the cognitive resources students used as the foundation for their mathematical problem posing. Session transcripts were analyzed using an analytical framework derived from an investment perspective on creativity, and identified resources were organized into two categories: mathematical knowledge and skills, and social interactions and experiences. Preliminary findings from the fifth session suggest that students associated the mathematical content of a posing task with previously encountered problems, as well as appealed to their familiarity with the situational context of the posing task.*

*Keywords:* Problem posing, Undergraduate Students, Developmental Math, Math Creativity

Problem posing is considered as the creation of mathematical problems, often from a given set of information or from previously presented problems (Christou, Mousoulides, Pittalis, Pitta-Pantazi, & Sriraman, 2005; English, 1997; Silver, 1994). Problem posing is a naturally-occurring activity in which individuals engage during their daily interactions. Kilpatrick (1987) notes that people encounter and recognize problems frequently, proceeding to solve those problems as they arise. Problem posing further occurs as part of the problem-solving process, acting as the foundation for developing a solution strategy (Brown & Walter, 2005) or as a form of reflection on and verification of solution strategies (Carlson & Bloom, 2005). In this capacity, individuals engage in problem posing to gain an improved understanding of the problem scenario in front of them. Understanding how individuals pose mathematical problems can inform the development of problem-posing activities to further enhance students' understanding of mathematics.

One way to examine individuals' problem posing is through the lens of mathematical creativity. Silver (1997) describes mathematical creativity as "closely related to deep flexible knowledge in content domains" (p. 75), viewing the connection between problem posing and problem solving as venue for mathematical creativity. Silver notes, "It is in the interplay of formulating, attempting to solve, reformulating, and eventually solving a problem that one sees creative activity" (p. 76). As students closely examine a mathematical situation, they can begin to generate hypotheses about the situation, develop flexibility in the ways in which they think about the situations, and begin to develop new ideas that expand upon their understanding of mathematics. In other words, students have an opportunity to use and develop the cognitive tools they have cultivated for doing mathematics. Viewing problem posing as an act of mathematical creativity, the descriptors of the creative process can be used to illustrate the creation of mathematical problems.

In this proposal, a framework based on the investment theory of creativity (Sternberg & Lubart, 1996) is used to describe undergraduate developmental mathematics students' problem posing. Under investment theory, individuals use a confluence of cognitive resources, such as content knowledge, thinking styles, and environmental influences, to "invest" in their ideas and develop them over time. These resources are tools individuals use as the foundation of their creative process. The guiding question to this inquiry is, "*How do students use cognitive resources to pose mathematical problems?*" Undergraduate students in developmental mathematics courses are an interesting population to observe; knowledge of mathematics is a mediating factor while posing problems (Kontorovich, Koichu, Leikin, & Berman, 2012; E. A. Silver, Mamona-Downs, Leung, & Kenney, 1996), and these students have been identified as underprepared for the expectations of college mathematics courses. As knowledge is a resource for creativity, one wonders to what extent these students use their knowledge as a resource for posing problems.

## Methods

### Participants & Study Design

Three undergraduate students enrolled in a developmental mathematics course at a mid-Atlantic public university participated in a five-week problem-posing intervention during the spring semester of 2016. The purpose of the intervention was to examine how students' problem posing evolved after learning about two problem-posing strategies described by Polya (2009): accepting the given, and "what-if-not". When accepting the given, students posed problems using only the numerical information and situational context provided in a posing task. When using "what-if-not", students were asked to pose problems by either changing the information they were given or adding new information to the scenario. The intent for the instruction on the two posing strategies was to encourage students to reflect on the given information in each task, using their understanding of the scenario as a resource for creating math problems. This proposal will focus on students' resource use during the final session of the intervention, to illustrate the variety of resources the students' used.

The final session of the intervention consisted of one posing task called "Payment Plan", shown in Figure 1. In this task, students were presented two payment options: one option where the payment increased by $1,000 each day, and a second option where the payment doubled each day. The posing scenario presents an opportunity for students to examine the two rates of growth and make comparisons between the two options. Students worked together to pose ten problems for the task as a group and were not required to use any specific posing strategy when creating their problems. After posing the ten problems, the primary investigator asked the students to describe their thinking behind the problems they posed. Students were not asked to solve the problems they posed. At the end of the session, students were asked to reflect on their experience and discuss their thoughts about posing problems. Recordings of conversations with the students were transcribed, and students written work was collected.

**Payment Plan**

You are given the choice to be paid in one of the following two ways:

1. You will be paid $1,000 the first day, $2,000 the second day, $3,000 the third day, $4,000 the fourth day, and so on for one month.
2. You will be paid $0.01 the first day, $0.02 the second day, $0.04 the third day, $0.08 the fourth day, and so on for one month.

(1) Work with your partner(s) to write ten mathematical word problems.

*Figure 1. Prompt for the Payment Plan task.*

## Data Analysis

The transcript of the session was partitioned into three episodes based on the session activity, and each episode was partitioned into several smaller events based upon what students were doing within the activity. Events were established around the topic of conversation, typically a student's explanation of a response or continued discussion around an idea. As a result, events were varied in length so that a more complete picture of each event could be achieved (Schoenfeld, 1985). Across the three episodes, there was a total of thirty-one events in the transcript. Using the categories of resources outlined by Sternberg and Lubart (1992) as a basis, students' actions, concepts mentioned by the students, and students' experiences were grouped into three types of resource types: task resources; mathematical knowledge and skills; and social interactions and experiences.

This proposal focuses on mathematical knowledge and skills, and social interactions and experiences. *Mathematical knowledge and skills* refers to students' mathematical thinking during the posing activities. This category relates to what students know about mathematics, such as students' understanding of concepts, association with previously encountered problems, use of mathematical terminology, as well as problem posing strategies. The design of the intervention focused on the use of the accepting the given and what-if-not posing strategies; therefore, it was expected that the students would use these strategies. *Social interactions and experiences* refer to students' personal experiences, non-mathematical knowledge, and interactions with other individuals. This resource category primarily relates to students' use of the situational context provided in a posing task, but also includes interactions between the students during the session, such as building from other students' thinking or seeking verification from other students.

# Students' Resources for Posing

Students exhibited use of both their mathematical knowledge and skills, and social interactions and experiences as resources for creating mathematical problems. To illustrate how students used these resources, an example of a resource type under each category will now be discussed. Under the mathematical knowledge and skills category, students associated the posing task with problems they previously encountered. Under social interactions and experiences, students related the situational context of the task to their personal experiences.

## Mathematical Knowledge – Problem Association

To engage with the mathematical content in the posing tasks, the students would relate the posing task to types problems they had previously encountered in the past. Brianna associated the Payment Plan task to comparison problems, posing the problem, "How long will you have to work for the second plan to equal the first plan?" She noted, "We've done problems like this before, where you have two rates of growth, and you compare them. So I was just curious at what point would they intersect?" Brianna recalled that with previous comparison problems, she would often be asked to identify the moment that two mathematical relationships would have the same value.

Students would also recall specific examples of problems they had encountered. Jason posed the problem, "Which would make you more money, a minimum wage job, or the second option?" (Jason later clarified that minimum wage stood for $7.50 an hour with an eight-hour work day.) When asked what motivated him to pose this problem, Jason recalled a previous experience with a teacher he had in high school:

> I looked at the problem, and I remembered that I had seen a similar math problem posed by one of my old teachers, as a…example to show what exponential growth was. Would you rather have a minimum wage job, or the one that starts off paying one cent and then doubles every day? I made it [the second option] because it's pretty obvious that the minimum wage is never going to beat the [first] job in terms of pay.

In recalling this past experience, Jason focused on the exponential relationship presented in the second option, explicitly naming the pattern as an example of exponential growth. It was a combination of his recognition of the exponential relationship and the similarity of the posing task to his prior experience that led him to associate the task with the previously encountered example.

**Social Experience – Familiarity with Context**

Appealing to the situational context of the posing task, the students framed their posing around their familiarity with the context. Brianna interpreted the two options as two jobs offering different pay. Brianna posed the problem, "If there was a 5% tax that was taken every day, how much would you have at the end of the month?", relating the scenario to a recent experience: "I was thinking of real life. Over spring break, I just worked, so that's what I was thinking about. A percentage is taken out every time. It's just a real example." Brianna took her recent employment experience as a resource for the problem she posed, introducing a type of income tax to the payment options.

Students could be familiar with situational context yet not have personal experience with that context. Kelsey had posed the problem, "If you take a sick day on the seventh day, what will your pay be at the end of the month for the first job?" Trying to describe how she created the problem, Kelsey questioned whether her response was realistic:

> *Kelsey:* Well, I just did a real-life problem… I just thought of another problem that could come from this. I don't know if the pattern would just continue and you would just lose that $7,000, or is it going to continue? I don't know. Do you get paid during the sick day?
>
> *Interviewer*: Possibly. I guess it would depend upon the job. What do you think?
>
> *Brianna*: It depends upon the job.
>
> *Jason*: I think that for this problem, just the way it's worded, you're supposed to imply that you aren't paid for it.
>
> *Kelsey*: That's what I thought, but I didn't know if you would get paid or not, because I only volunteer. I don't work. When I was thinking about this [problem], I didn't think of the fact that you might not get paid.

Kelsey began to pose a problem by introducing the idea of sick days and how payment would be impacted by a sick day. Kelsey ultimately revealed that she had not had employment experience, which led her to be uncertain about how her problem would fit within the situational context. Although she did not have employment experience, she was familiar enough with the situational context to pose a problem with a context related to employment.

## Concluding Remarks

The preliminary findings suggest that students can use both their knowledge of mathematics and their social experiences as foundations for engaging in mathematical activity. Students could use this foundation to spring into further discussion around mathematical ideas. This could be especially valuable for students in developmental math courses, as it provides another venue for students to gain access to mathematical activities. A notable limitation of this study is that students were not asked to solve the problems they posed. Because students were only asked to pose problems, it is difficult to determine the extent to which students' resource use shaped their mathematical thinking while posing problems. Due to this limitation, feedback sought from the audience will focus on identifying the depth of students' engagement with the mathematical content while posing problems in the absence of students working towards a solution.

# The Instructor's Role in Promoting Student Argumentation in an Inquiry-Oriented Classroom

Chris Rasmussen, San Diego State University
Karen Marrongelle, Portland State University
Oh Nam Kwon, Seoul National University

Abstract

*Four class sessions in inquiry-oriented differential equations were analyzed to understand the role of the instructor in supporting student argumentation. Three coding schemes were developed to identify arguments, characterize instructor utterances, and connect instructor talk to argumentation goals in inquiry-oriented instruction. Results show that students generated the majority of arguments tendered in the four class sessions. The instructor used questions to generate student arguments more than other types of instructional utterances (e.g., revoicing, telling). Nearly half of the instructor's utterances were aligned with argumentation goals. More detailed examples of student-generated arguments in the class sessions are being constructed to illustrate the flow and function of different goal alignment routines to understand what it is that the instructor did during class to promote student argumentation.*

*Keywords*: Inquiry, Teaching, Active learning, Case study

Mounting research evidence points to the benefits of active learning in improving student outcomes in undergraduate STEM courses compared to more traditionally taught courses (e.g., Freeman et al., 2014; Kogan & Laursen 2014; Larsen, Johnson, & Bartlo, 2013; Rasmussen & Kwon, 2007). Recently, professional societies explicitly recognize the need for faculty to increase their use of active learning to improve student success (Saxe & Braddy, 2015). But to what extent do mathematics departments across the country value active learning and actually use various active learning strategies? In a recently completed census survey of all mathematics departments that offer a graduate degree in mathematics, researchers found that 44% of departments report that active learning is very important in their Precalculus through Calculus 2 courses but only 15% say their program is very successful in implementing active learning (Apkarian & Kirin, 2017). Moreover, recent comprehensive literature reviews (Larsen, Marrongelle, Bressoud, & Graham, 2017; Rasmussen & Wawro, 2017) reveal that very few studies provide detailed analyses of what instructors actually do to create and sustain active learning classrooms. All of this points to the need for in depth case studies of how instructors successfully implement active learning in undergraduate mathematics classes. The research reported here begins to address this pressing, national need.

The analysis presented here focuses on a specific active learning classroom, in particular an inquiry-oriented differential equations class. We define inquiry in terms of three principles: student deep engagement in mathematics, peer to peer interaction, and instructor interest in and use of student thinking (Rasmussen, Marrongelle, Kwon, & Hodge, in press; Rasmussen & Wawro, 2017). This definition of inquiry follows from over a decade of work in creating and investigating active learning classrooms in undergraduate classrooms (Rasmussen & Kwon, 2007; Rasmussen & Marrongelle, 2006) and parallel framing of the inquiry based learning movement (Laursen, Hassi, Kogan, Hunter, & Weston, 2015). At the intersection of deep engagement in mathematics and peer to peer interaction is argumentation, where argumentation refers to classroom discussion featuring significant mathematics, conjectures, reasoning to support conjectures, and students making sense of others' reasoning. In keeping with this focus, we chose for our analysis four days in an inquiry-oriented differential equations class because on these four days students made considerable progress on debating what graphs of solutions to a system of two linear homogeneous differential equations in the phase plane look like and on justifying their conclusions. In other words, argumentation was a distinguishing feature of this class and hence provides an opportunity to unpack the role of the instructor in initiating and supporting student debate. In particular, we address the following research questions:

1. To what extent did the instructor and students contribute to arguments and what was the nature of their respective contributions?
2. What did the instructor do to promote student argumentation?

## Background

The role of student argumentation in mathematics classrooms has a long history in mathematics education reform, both at the K-12 and post-secondary levels. For example, in the late 1980's Cobb and colleagues investigated how classroom argumentation supported student learning and intellectual autonomy in elementary school classrooms. They argued that classroom argumentation provides "opportunities for children to articulate and reflect on their own and others' mathematical activities" (Cobb, Yackel, & Wood, 1989, p. 126). These researchers also examined the role of the teacher in supporting student argumentation, leading in part to the articulation of social and sociomathematical norms (Yackel & Cobb, 1996) and how teachers initiate and sustain productive discursive norms that support argumentation (Wood, Cobb, & Yackel, 1990). This work was later extended to the university setting with further articulation of the role of the instructor (Yackel, Rasmussen, & King, 2000; Rasmussen, Yackel, & King, 2003). Part of this extensive literature has also included the elaboration and extension of particular social norms for argumentation in terms of four broader goals for inquiry-oriented instruction and specific teacher prompts that can function to realize these goals. The four argumentation goals are: (1) getting students to share their thinking, (2) helping students to orient to and engage in others' thinking, (3) helping students deepen their thinking, and (4) building on and extending student ideas (Rasmussen, 2015; Rasmussen, Marrongelle, Kwon, & Hodge, in press).

At the university level, research is just beginning to provide in depth portraits of what inquiry-oriented instruction actually looks like and what instructors do on a daily basis to promote argumentation. For example, one of the studies that examined effective instructional practices in differential equations focused on the instructor-student interaction patterns that facilitated students' reinvention of a bifurcation diagram (Rasmussen, Zandieh, & Wawro, 2009). These researchers identified three instructor "brokering" moves that forged connections between the different small groups, the classroom community as a whole, and conventional terminology and notations of the broader mathematical community. This work resonates with the fourth argumentation goal, building on and extending student ideas. In other work examining instructor-student interactions that contributed to significant student progress in creating, interpreting, and using phase portraits, Kwon et al. (2008) identified and illustrated four functions of instructor revoicing (O'Connor & Michaels, 1993). In this analysis, revoicing was shown to function in multiple ways in support of argumentation - as a binder of ideas among students, as a springboard for new ideas, for ownership of ideas, and as a means for socialization into the discipline of mathematics. These functions resonate with argumentation goals two and three.

In inquiry-oriented classrooms instructors need to decide when and how to insert information, formalize students' informal ideas, and make connections to related mathematics in the midst of students exploring ideas and doing mathematics. Doing so requires a blend of mathematical expertise, pedagogical knowledge, and pedagogical content knowledge. In a case study of two mathematicians implementing an inquiry-oriented differential equations curriculum, Rasmussen and Marrongelle (2006) identified two different ways that inquiry-oriented instructors connected to student thinking while moving the mathematical agenda forward – transformational records and generative alternatives. Transformational records are defined as notations, diagrams, or other graphical representations that are initially used to record student thinking and that are later used by students to solve new problems. Generative alternatives are defined to be alternate symbolic expressions or graphical representations that a teacher uses to foster particular social norms for explanation and that generate student justifications for the validity of these alternatives. Johnson (2013) illustrates other ways that instructors can build on and extend student thinking. In particular, Johnson identified a variety of ways in which two abstract algebra instructors interpreted student ideas, analyzed and evaluated these ideas, and made connections between students' ideas and conventional mathematics.

In more recent work, Kuster, Johnson, Keene, and Andrews-Larson (in press) specify four components of inquiry-oriented instruction: generating student ways of reasoning, building on student contributions, developing a shared understanding, and connecting to standard mathematical language and notation. Each of these components, which connects well with the four goals for argumentation, are further refined by specifying practices that support each component. These components and practices are culled from the K-16 literature and their own work supporting and studying inquiry-oriented teaching in abstract algebra, linear algebra, and differential equations. As this emerging body of research focused on the work of inquiry-oriented instruction suggests, the work of instructors in inquiry-oriented classrooms goes well beyond the typical teaching preparation that mathematicians receive. In depth case studies of such work, as one in this report, can offer useful practical and theoretical accounts of practice.

## Methodology

Data for this analysis comes from four class sessions in an inquiry oriented differential equations class. These sessions were part of an eight-week classroom teaching experiment. Data sources consisted of video recordings of whole class and small group discussions, researcher field notes, and copies of student work. We began the data analysis by making complete transcripts of all whole class discussions from the four classroom sessions.We engaged in three passes of coding. In the first pass, we conducted a Toulmin analysis of all whole class discussion. In the second and third passes, all instructor utterances were coded for the nature of the instructor utterance. The second pass focused on the type of utterance (referred to as talk move) and the third pass focused on the alignment of the utterance with the four argumentation goals. Details on each of these passes follows. We are currently coordinating these three passes to develop a detailed, empirically grounded portrait of how this instructor promoted student argumentation. This preliminary report therefore focuses on results related to the first research question.

**Toulmin coding**: In his seminal work, Toulmin (1969) created a model to describe the structure and function of an argument. The core of an argument consists of three parts: data, claim, and warrant. In any argumentation, the speaker makes a claim and presents evidence or data to support that claim. Typically, the data consist of facts that lead to the conclusion that is made. In order to clarify what the data has to do with the conclusion, a person might also present a warrant that serves as a kind of bridge between the data and the conclusion. Often, warrants remain implied by the speaker and are elaborations that connect or show the implications of the data to the conclusion (Rasmussen & Stephan, 2008). Backings, when offered, provide legitimacy for the core of the argument (that is, the data-claim-warrant).

Videotaped data of the four class sessions and transcripts were reviewed by a group of eight mathematics education researchers and initial arguments identified according to Toulmin's model of argumentation. In particular, elements of claim, data, and warrant needed to be identified and present to be considered an argument. Identification of the arguments was done for a portion of the video data as a whole group. The remainder of the video data was coded in smaller groups. The groups would reconvene as a whole in order to review problematic data or interesting episodes. The collaborative coding process enabled shared interpretations of the codes and decreased instances of interpretations not grounded in the video data. Authorship of an argument was determined by who offered the justification (i.e., data, warrant or backing). Authorship could be attributed to the instructor, a student, or jointly constructed by the instructor and students.

**Talk move coding:** A coding scheme was then developed as we observed video and simultaneously highlighted the teacher's discourse in the transcripts. We broke what the instructor said into identifiable utterances that served a different function. An utterance is not a conventional unit, like the sentence, but a unit nonetheless in the sense that it is marked out in the boundaries of speech (Bakhtin, 1986). We refined and revised our coding scheme of teacher utterances based on review of the literature (e.g., Forman et al, 1998; Krussel, Edwards, & Springer, 2004; Lobato et al, 2005; Mehan, 1979) and multiple passes through our data. The final coding scheme consisted of four main codes: revoicing, questioning/requesting, telling, and managing. Each of these main codes had four subcodes. Full descriptions of the codes can be found in (Rasmussen, Marrongelle, & Kwon, 2009). We used problematic or especially interesting episodes to sharpen and refine the coding scheme and a collaborative, iterative process to share and defend interpretations of the video and corresponding transcripts. In addition, we explained our coding scheme to a mathematics education graduate student who then independently coded all transcripts, resulting in over 80% agreement.

**Goal alignment coding.** Recall that the four argumentation goals for inquiry-oriented instruction are: (1) getting students to share their thinking, (2) helping students to orient to and engage in others' thinking, (3) helping students deepen their thinking, and (4) building on and extending student ideas. In this pass through the data, we aligned the instructor's discourse with these four goals for inquiry-oriented instruction. We did not attempt to make judgements about the thinking or rationale of the instructor; rather, we attempted to align the instructor's speech with how the speech functioned in furthering argumentation in the classroom. Three mathematics education researchers coded the data independently, and discussed differences to reach 100% coding agreement.

## Sample Results

We begin with a top level view of who was responsible for arguments and the nature of the instructor's contributions. As shown in Table 2, the students (Student) gave 35 of the 52 of the arguments (67%), with another 7 of the 52 arguments (13%) being co-constructed between students and the instructor (S&I). Clearly the instructor was not the primary source of justifications for argumentations tendered.

| Day | Student | Instructor | S&I | Total |
|---|---|---|---|---|
| 4/18 | 6 | 3 | 0 | 9 |
| 4/20 | 5 | 3 | 4 | 12 |
| 4/22 | 2 | 2 | 0 | 4 |
| 4/25 | 22 | 2 | 3 | 27 |
| **Total** | **35** | **10** | **7** | **52** |

*Table 2*. Number of arguments given in whole class discussions

To gain insight into what else he was doing we also examined the instructor's utterances for frequency at which he used revoicing (R), telling (T), Questioning/requesting (Q), and Managing (M). As shown in Table 3, the instructor used questioning more than the other types of utterances (approximately 37% of his utterances) over the four days. The other utterances types – revoicing, telling, and managing – were about equally represented (approximately 20% each). The full analysis will look more closely at the role these utterances in the production of arguments, but preliminary analysis points to the key role of questioning/requesting and revoicing (which comprise nearly 60% of the utterances.

| Day | R | T | Q | M | Total |
|---|---|---|---|---|---|
| 4/18 | 16 (25.4) | 12 (19) | 23 (36.5) | 12 (19) | 63 |
| 4/20 | 8 (25) | 8 (25) | 8 (25) | 8 (25) | 32 |
| 4/22 | 6 (20) | 8 (26.7) | 12 (40) | 4 (13.3) | 30 |
| 4/25 | 20 (20) | 20 (20) | 44 (44) | 16 (16) | 100 |
| **Total** | **50 (22.2)** | **48 (21.3)** | **84 (37.3)** | **40 (17.8)** | **225** |

*Table 3*: Total number of instructor utterances per day

Further insight into the function of the instructor utterances is revealed by examining how each utterance relates to the four argumentation goals. Recall that the four argumentation goals are: (1) getting students to share their thinking, (2) helping students to orient to and engage in others' thinking, (3) helping students deepen their thinking, and (4) building on and extending student ideas. Table 4 shows the frequency of utterances that aligned with each of the four goals, as well as the number of utterances that were not aligned with any of the four argumentation goals.

| Day | G1 | G2 | G3 | G4 | No G | Total | G/Tot |
|---|---|---|---|---|---|---|---|
| 4/18 | 13 | 6 | 7 | 7 | 33 | 66 | 50% |
| 4/20 | 1 | 5 | 2 | 4 | 17 | 29 | 41% |
| 4/22 | 4 | 1 | 3 | 1 | 20 | 29 | 31% |
| 4/25 | 21 | 12 | 7 | 8 | 56 | 104 | 46% |
| **Total** | **39** | **24** | **19** | **20** | **126** | **228** | **45%** |

Table 4: Alignment of instructor utterances with argumentation goals

There were a total of 102 total utterances that were argumentation goal-aligned. Approximately 38% of these were aligned with goal 1, getting students to share their thinking. This makes sense because this is the first step for students to explicate their reasoning. The percentage of goals 2-4 were fairly equally distributed, ranging from 19% to 23.5%.

By providing detailed examples of student-generated arguments from initiation to conclusion, we will illustrate the flow and function of different goal alignment routines to understand what it is that the instructor did during class to promote student argumentation, moving beyond simply coding for questions or revoicing. In one such detailed example we will discuss how the teacher, making use of a generative alternative (Rasmussen & Marrongelle, 2008), supports three student arguments about solutions to a system of differential equations. This rich example provides a prototype for how instructors can enact this particular global strategy for promoting student argumentation. We anticipate identifying other prototypes in the full report.

# Teachers' Use of Informal Conceptions of Variability to Make Sense of Representativeness of Samples

Gabriel Tarr
Arizona State University

April Strom
Scottsdale Community College

*A key factor in statistical thinking is reasoning about variability. This paper contains data on how in-service middle school teachers and a community college faculty member reasoned through two statistical tasks. The researcher presents his analysis of the data through the lens of how teachers reasoned about variability as they worked through the two statistical tasks.*

*Keywords*: Statistics, Professional Development, Teacher Education

As data and statistical thinking have become more important in the information age, middle school mathematics teachers have been tasked with placing greater emphasis on statistical concepts than may have been previously required before the introduction of the Common Core State Standards for Mathematics [CCSSM] (National Governors Association, 2010; Tran, Reys, Teuscher, Dingman, & Kasmer, 2016). To reason about and teach statistical concepts in a productive manner, it is critical for teachers to attend to the notion of variability in their personal reasoning and in teaching statistics (Franklin et al., 2015; Garfield & Ben-Zvi, 2005; Moore, 1990; Shaughnessy, Watson, Moritz, & Reading, 1999; Wild & Pfannkuch, 1999). Specifically, Garfield and Ben-Zvi present a framework from which teachers can develop tasks to support and assess strong conceptions of variability in their students. Developing intuitive ideas of variability, using variability to make comparisons, and using variability to predict random samples or outcomes are key ideas in this framework.

In this paper, we compare the following: (1) how middle school math teachers used intuitive notions of variability to make comparisons between sets of outcomes of random processes for two statistical tasks and; (2) how a community college instructor answered the same tasks using more formal notions of variability. We attempt to answer the following question: *How do teachers' informal ways of reasoning using variability compare to an expert's more formal ways of reasoning about variability while working through statistical tasks?*

## Methods

The data collected for this study were gathered in a large-scale professional development and research program, focusing on middle school teachers in a Southwestern state in the United States. Each teacher in the program was asked to participate in professional development activities for two years. The project focused on increasing teachers' mathematical and pedagogical content knowledge.

In the second year of the project, participants were involved in nine full-day workshops focused on both functions and statistics content. Upon the teachers' completion of their second year in the program, the researcher conducted four videotaped, individual, task-based, clinical interviews (Clement, 2000). The subjects for this study were three middle school teachers (Joy[1], Leia, and Nina) and one community college faculty member (Kory) responsible for co-leading the statistics content for the workshops.

[1] All subject names are pseudonyms.

Prior to their second year on the project, the three teachers responded to a free-response survey question that asked them to describe their own personal background in statistics. Joy responded that she was "very limited" in statistics with her background being one college course in educational statistics, the material that she taught to her students, and the statistics-related material learned in her collaborative community of learners[2] (CCOL) facilitated by the other co-leader of the statistics content at the workshop. Leia described her background as limited in the variety of statistics that she used and uncomfortable in justifying her methods for doing statistics, but comfortable in analyzing data and displays. Leia also participated in the same CCOL as Joy. Nina described herself as having "very little background" in statistics other than working with spreadsheets. Kory taught statistics at the secondary and post-secondary levels for over 20 years.

The researcher analyzed each subject's raw and transcribed video data with careful attention to habits or inclinations that the subjects may have shown while reasoning through the tasks. The researcher then created themes based on these habits or inclinations before refining said themes through subsequent passes through the data using open coding principles developed by Strauss and Corbin (1998). Once the researcher felt these themes were sufficiently well-defined, his attention shifted to themes that related to how the subjects utilized concepts pertaining to variability to reason through the statistical tasks. The researcher then analyzed these variability-related themes for each subject individually before coordinating common themes across subjects.

**Task Description**

Participants engaged in two tasks: The Coin Flip Task[3] (Figure 1) and The Orange Bin Task (Figure 2). The Coin Flip Task was chosen to determine how participants would reason about the probabilities of two distinct events when the proportion of outcomes for each event was the same. From prior data collection efforts, the researcher suspected that the teachers would have limited mathematical background, thus making this The Coin Flip Task non-trivial. Thus, the teachers would need to reason about the similarities or differences between the two events in order to provide an answer they deemed to be reasonable.

Event A: A machine flips a fair coin 10 times with the outcome of 7 heads.
Event B: A machine flips a fair coin 1000 times with the outcome of 700 heads.

Which one of the following is true?

1) Event A and Event B are equally probable.
2) Event A is more probable than Event B.
3) Event A is less probable than Event B.
4) Unable to determine given the information.

*Figure 1: The Coin Flip Task*

The Orange Bin Task was chosen to determine if subjects would reason about the role of sample size in the variability of outcomes and use this reasoning to support the grocer's choice of whose method to choose. As an explicit verification of how subjects made a connection between sample sizes and the variability in the two sets of potential mean weights, the following question was asked to any teacher who did not give an example of two mean weight lists[4]: *Suppose that both*

[2] The project's version of a Professional Learning Community (PLC).
[3] Modified task from Schrage (1983) p. 353
[4] Each mean weight was determined by oranges randomly generated from a normal distribution with a mean of 131 grams and a standard deviation of 15 grams.

*of these people had repeated their method only five times. One person yielded the following five mean weights. 133 grams, 124 grams, 129 grams, 129 grams, 140 grams. The other person yielded the following five mean weights. 126 grams, 130 grams, 128 grams, 135 grams, 133 grams. Which set of mean weights belong to which person, and why?*

A grocer wanted to determine the typical weight for oranges in his store. One employee, Jeff, suggested finding the mean weight of 5 randomly-selected oranges, placing the oranges back into the bin, and repeating this process several times. Another employee, Krystal suggested finding the mean weight of 15 randomly-selected oranges, placing the oranges back into the bin, and repeating this process several times.

1) Generate what you believe could be the outcomes for Jeff's process.
2) Generate what you believe could be the outcomes for Krystal's process.
3) The grocer decided to go with Krystal's suggestion of using 15 randomly-selected oranges instead of Jeff's 5 randomly-selected oranges. Give specific reasons for why you believe the grocer decided to go with Krystal's suggestion?

*Figure 2: The Orange Bin Task*

## Preliminary Results and Discussion

### The Coin Flip Task

Kory read the problem and immediately determined that Event A was more probable than Event B due to the difference in the number of trials for each event. To support his reasoning, Kory drew upon his prior statistical knowledge and saw the context of the coin flip problem as a binomial situation. Kory calculated the expected value and standard deviation for each event to determine how far each outcome deviated from the expectation. Kory explained for Event A that "seven is a little bit more than a standard deviation away from the center, it's fairly likely to occur. It's not incredibly likely, but it's still within the realm of possibilities." However, Kory voiced the opposite stance when considering the probability of Event B: "If you think about where 500 and 700 is, that's over 10 standard deviations away, that more like 12 or 13 standard deviations….Yeah not gonna [sic] happen."

$$\mu = 10(.5) = 5$$
$$\sigma = \sqrt{10(.5)(.5)} = 1.58$$
$$\mu = 1000(.5) = 500$$
$$\sigma = \sqrt{1000(.5)(.5)} = \underline{15.8}$$
$$500 \rightarrow 700$$

*Figure 3: Kory's Calculations of Mean and Standard Deviation*

Leia and Nina anticipated that the outcomes of the coin flips should be equally represented. For both teachers, the number of trials in Event A made it seem possible that seven heads could occur in 10 coin flips because this event didn't deviate too much from their initial anticipation. However, when reasoning about Event B, both teachers saw this as a major aberration from what they had anticipated. In fact, when first engaging with Event B, Nina immediately said "Wow! … That seems crazy. Which one of the following is true? The coin is not fair." Nina elaborated on her reasoning about why Event A was more probable than Event B by stating the following:

"It's a fair coin, … the more times I do it (trials), it should be, it (distribution of outcomes) should approach tails and heads should be appearing in an equal frequency, 50% 50%." Leia provided similar explication for her stance on why Event A was more probable than Event B by invoking her image of the law of large numbers "The higher the number of trials is, the less likely it is that these numbers are going to be far away from that theoretical probability….When you only do ten, there's a lot of chance for it to be different." In both instances, the Leia and Nina reasoned that a larger number of trials would decrease the amount of variation that between what they would anticipate for the outcomes of flipping a fair coin, and what the observed outcomes would be.

The only subject to answer The Coin Flip Task incorrectly was Joy. Joy gave the response that Event A and Event B were equally probable because "seven tenths is the same as $\frac{700}{1000}$." When asked by the researcher to create a new event in the same context that would have the same probability of Event A and Event B, Joy created Event C and Event D where the outcomes were 100 coin flips with 70 heads and 50 coin flips with 35 heads, respectively. As Joy reasoned about the differences between Event A and Event B, the only difference that she verbalized was the fact that Event B had 100 times as many trials.

When Joy was presented The Coin Flip Task, she immediately made mention to a prior teaching experience where she presented her students with a probability lesson related to coin flipping. She jokingly lamented about a troublesome student who had challenged her claims to a coin flip outcome because "the coin wasn't fair because one of the sides was heavier." She stated that "he likes to get nitpicky about stuff like that." Initially, the researcher considered this to be a throwaway comment. However, shortly after the Joy recounted her classroom experience, reading the phrase *fair coin* seemed to trigger the response "It's a fair coin, that's what I should have said, one of the sides is not heavier than the other," as if she had just realized a quelling to her troublesome student's refutation. These utterances seem to provide evidence for why Joy had not analyzed the situation in an analogous way to the other subjects. By not considering fairness, it is possible Joy was not anticipating that the outcomes of the coin flips should be equally represented given a large enough size of observations. By not anticipating this equal share of outcomes, she was not perturbed by 70% of the outcomes being heads as deviating far from 50% of the outcomes being heads in either the 10 or 1000 flip case.

The three subjects who were able to correctly respond to The Coin Flip Task shared a common focus that seemed to be paramount in their thinking. Establishing a reference for what they had *anticipated* would happen allowed the subjects to compare the degrees of variability for each event. Kory compared expectations with observations using a measurement tool of standard deviations. Leia and Nina showed more informal reasoning that a small number of trials would result in a greater chance for aberration from expected outcomes than would a greater number of trials. In reasoning through this task, all three successful subjects reasoned using some aspect of variability to fuel their thought processes.

**The Orange Bin Task**

Using some aspect of variability to reason about a statistical situation was present again for participants for The Orange Bin Task. Knowing that there would be variability in the collection of sample means, Kory set off to make the variability explicit. Kory calculated the standard deviation for each sampling mean distribution under the assumption that orange weights would be normally[5] distributed. Comparing the spread of the distribution of sampling means for both Jeff and Krystal's methods allowed Kory to reason about how each sample would be distributed around the true mean weight for the population of oranges (Figure 2). Kory reasoned that: "… she's going to have much less variation…. The grocer will probably go with, he goes with Krystal's suggestion because she's probably closer to the truth than Jeff is. She has got much less variability in her distribution of sample means. Larger samples give better results typically."

Leia, Nina, and Joy also utilized the fact that sample size was the factor in determining why the grocer chose Krystal's method. A common theme in their approach was how extreme values would potentially influence the mean weights for each method. Joy provided two lists of mean weights (Figure 3) where the underlying reasoning was that larger samples would produce more consistent means.

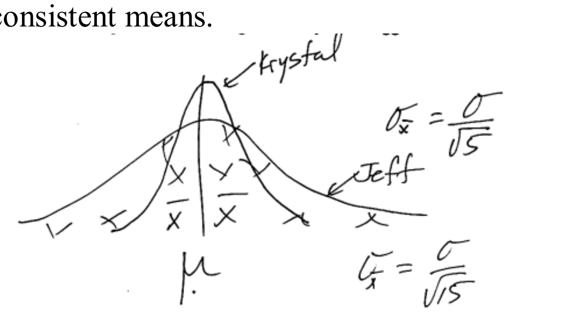

*Figure 4: Kory's Representation of Distributions of Sample Means*

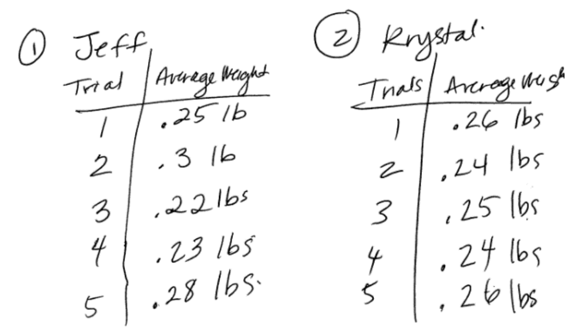

*Figure 5: Joy's Constructed Lists of Mean Orange Weights*

Thus, Joy felt the variation for Jeff's means would be larger than the variation for Krystal's means. While, Leia and Nina did not explicitly produce lists of mean weights, when given the follow-up question, both Leia and Nina reasoned that since the second list of numbers showed less variation, the list had to belong to Krystal.

The teachers were able to use informal ways of reasoning about variability in mean weights to support their arguments about how larger sample sizes would produce more representative sampling results. The teachers were able to reason that a larger sample size would allow for fewer relative aberrations, which in turn would make the collection of means for this larger sample size more consistent with each other. Though not synonymous with Kory's way of reasoning, the three teachers definitely displayed reasoning that can potentially precede thinking about the standard deviation of the sample mean.

## Conclusion

While the ways of statistical thinking presented by the community college faculty member are beyond what most middle school mathematics teachers would teach, these underlying ways can be preceded by the ways of thinking that the teachers displayed. Developing these intuitive ways to use variability to reason about statistical situations can lead teachers to develop more normative, robust ways of reasoning. This in turn may allow middle school teachers to better understand where their students are headed in terms of concepts which will enable them to prepare a better statistical foundation for their students.

Classroom Experiences of Students in a
Community College Intermediate Algebra Course

Anne Cawley
University of Michigan

*There is little understanding of the ways in which students experience developmental mathematics courses at community colleges (Crisp, Reyes, & Doran, 2015). This study investigates the instructional experiences of students in an Intermediate Algebra course using qualitative methods that rely on interviews, surveys, classroom observations and classroom artifacts. I aim to understand (1) what are the experiences of students in a developmental mathematics class at a community college and (2) how students make sense of particular experiences. The findings from this study will support college mathematics departments by providing evidence of the classroom instructional experiences of students.*

*Keywords:* Developmental Mathematics, Student Success, Classroom Experience, Postsecondary Instruction, Community Colleges

Developmental mathematics is an important area of postsecondary mathematics education. Nearly 60% of first-year students at public two-year colleges take developmental mathematics (Radford, Pearson, Ho, Chambers, & Ferlazzo, 2012). Community colleges offer more developmental courses than any other type of postsecondary institution (Nora & Crisp, 2012; Parsad, Lewis & Greene, 2003; Radford et al., 2012). Developmental courses are often viewed as a gatekeeper for students to make progress to degree completion (Attewell, Lavin, Domina, & Levey, 2006; Bettinger & Long, 2005), but are also a pre-requisite for many students aiming to enter technical fields (e.g., science, technology, engineering, and mathematics [STEM], business). Historically, Intermediate Algebra has been the bridge between developmental courses and college courses (Lutzer et al., 2007). To be able to increase persistence, to provide a valuable learning experience and also to keep students in the STEM track, it is essential to know how parts of the "black box" work and student classroom experience is one that is often overlooked.

The most common way to measure student success in higher education is through academic achievement, such as GPA, course completion, the need to repeat courses, student persistence, and degree attainment (Howard, 2010; Valencia, 2015). This scholarship also seeks to predict such "success" using students' previous academic preparation, socio-economic status, mathematics placement test scores, and SAT scores (e.g., Bahr, 2010; Crisp & Delgado, 2014; Crisp & Nora, 2010; Nora & Garcia, 2001). Although such studies attempt to understand what contributes to the low success rates for developmental mathematics students, they, however, do not help us to understand what happens *while* students are enrolled in their math class, undermining the mathematical influence we as instructors can have on student success. The interactions and experiences that students have in a classroom can impact student learning (Cohen & Lotan, 1997) and those experiences in turn, can shape students in ways that can affect the quality of other subsequent educational experiences they may have (Dewey, 1938). Unfortunately, to this date, we know very little about how classroom experiences contribute to the success of developmental mathematics students.

The purpose of this study is to better understand the mathematical experiences of students enrolled in a developmental mathematics. This paper will address two research questions: 1) What are the instructional experiences of students in a developmental mathematics class at a community college? and 2) How do students make sense of these particular experiences? This qualitative case study focuses on how students experience the instruction in a developmental mathematics course, attending to their perception of these experiences, and to the ways in which these experiences influence their mathematical understanding.

## Theoretical Framework

I define instruction as the interactions that occur between instructors and students with the mathematical content (Cohen, Raudenbush, & Ball, 2003). Teaching and learning are essential aspects of instruction that occur within a specific environment, in this case, a developmental mathematics classroom at a community college. The roles of both student and teacher are supported by different resources (e.g., previous educational experiences, classroom environment, technology) and constrained by specific institutional requirements (e.g., classroom assignment/layout, covering preset mathematical content, having periods of 50 minutes) (Chazan, Herbst, & Clark, 2016; Cohen et al., 2003). In order to characterize students' experiences, I choose to focus on instruction. The classroom is an important space within a community college campus because it is the space in which the most interaction occurs for many students and is also where many students draw from when reflecting on their educational experiences (Wood & Harris III, 2015). Given the high attrition rates for STEM fields (69 % of associate's degree students who entered STEM fields between 2003 and 2009 had left these fields by spring 2009; see Chen, 2013), it is particularly important to understand classroom experiences. For example, in a literature review of reasons for dropping out of engineering programs, more than half of studies identified the classroom as a factor for why students leave (Geisinger & Raj Raman, 2013). I believe that the experiences of students, while interacting with their instructor and the mathematical content, significantly impact the success a student has in mathematics.

## Methods

The study takes place at Clear Water Community College[1], a Hispanic serving institution in California, during Fall 2016. Around 90% of the student population at this college enroll in developmental mathematics. I observed one section of Intermediate Algebra taught by a part-time faculty member, following nine focal students throughout the semester. The class met three times a week for 95 minutes. Table 1 describes information about the nine focal students. All students identified as being of Latinx decent. I chose a part-time faculty member because oftentimes developmental mathematics courses are taught mostly by part-time instructors (Blair, Kirkman, & Maxwell, 2013). The instructor was a Black female, who graduated with a Bachelor's degree in Engineering and a Masters in Applied Mathematics. She has 2 and a half years of teaching experience, two of which were while she was a graduate student. During this semester, she is also teaching 3 courses at two other community colleges.

*Table 1. Student Demographics*

| Student | Gender | Age | First Generation | First Year |
|---|---|---|---|---|
| Adriana | F | 19 | Yes | Yes |
| Chris | M | 21 | No | No |
| Guillermo | M | 18 | Yes | Yes |

[1] All institutions and names in this study are pseudonyms

| | | | | |
|---|---|---|---|---|
| Layana | F | 20 | No | No |
| Marisa | F | 18 | No | Yes |
| Nancy | F | 18 | No | Yes |
| Raquel | F | 18 | Yes | No |
| Santiago | M | 18 | Yes | Yes |
| Teresa | F | 18 | Yes | Yes |

The data sources that I used for this paper include interviews, classroom observations, and diary entries (surveys). I interviewed each student three times at the beginning, middle and end of the semester. I also observed the course 12 times, which included video-recording the lesson as well as taking fieldnotes. After each formal observation, the focal students filled out a survey, detailing their experience of that specific class meeting which included reflections on the math content, moments that went well/did not go well, interactions with peers, and ways that they participated in the course.

This study is a case study analysis of one intermediate algebra class. I engaged in open coding of the student interviews and surveys as well as the observation fieldnotes. I captured comments that related to the ways in which the students described the classroom instruction as well as how issues such as race/ethnicity, gender, culture, class, or language affected their classroom experience. To code the video-recordings, I used the *Evaluating the Quality of Instruction in Postsecondary Mathematics* (EQIPM) instrument (Author and colleagues, 2017), which assesses the quality of mathematical instruction at community colleges by providing ratings from 1 to 5 on various codes. In this paper, I will talk about two codes, specifically *Organization in the Presentation of Procedures* and *Mathematical Errors and Imprecisions in Content or Language*. *Organization in the Presentation of Procedures* captures how complete, detailed, and organized the instructor's (or students') presentation (either verbal or written) of content is when outlining or describing procedures, or describing the steps of a procedure used to solve problems. A rating of 1 on this code implies that the instructor's (or students') presentation of the procedure is disorganized, incomplete, illegible, or unclear. A rating of 5 indicates that the teaching is not only clear, but it is also exceptionally organized and/or detailed. *Mathematical Errors and Imprecisions in Content or Language* capture events in the segment that are mathematically incorrect or that have problematic uses of mathematical ideas, language, or notation. A rating of 1 on this code implies that there were no errors or imprecisions in the segment while a rating of 5 implies that content errors and/or imprecisions occur in most or all of the segment or muddle the opportunity for students to make sense of the procedure. I rated the video in 7.5-minute segments using the EQIPM instrument. Given that there are both good and bad moments within our teaching, I averaged the ratings among the segments.

## Preliminary Results

I will describe preliminary findings from Observation 2, which occurred during week 3 of the semester. There was a total of 12 7.5-minute segments in this observation. In particular, I will first describe ratings and evidence given for *Organization in the Presentation of Procedures* and then for *Mathematical Errors and Imprecisions in Content or Language*. I will also describe how students specifically made sense of their experiences in relation to those particular codes.

There were 38 students in the class meeting and all of the focal students were in attendance. The students sat at long table rows, each seating about eight students, with an aisle down the center. Some students sat in chairs at the back of the room as they walked in late. The lesson covered topics such as solving one-variable linear inequalities, absolute values, and solving absolute value equations and inequalities.

**Instruction.** The modes of instruction during this meeting were lecture, individual student work, and student presentations. Out of the 95 minutes of class, the instructor lectured for 60 minutes (63.2% of class time), students worked individually at their desks for 20 minutes (21.1%), three students presented at the board for 13 minutes (13.7%), and two minutes were devoted to classroom business (2.1%). The classroom was considerably quiet with very little interaction, and the instructor sat at the document camera for the entire class session.

***Organization in the Presentation of Procedures.*** The mean rating for *Organization in the Presentation of Procedures* was a 2.5. A rating of 3 indicates that the teaching of the procedure is acceptable, complete, and mostly clear, but not exceptionally organized or detailed. I noted two general areas where organization greatly affected the instruction. First, the instructor used a set of guided notes to lecture from.

The instructor created online note packets for every chapter in the textbook. She lectured from these packets every class meeting. Some say that there are affordances of using such guided note packets in that problems are pre-selected providing scaffolding or that by providing guided notes, students can spend more time focusing on the lesson while also having a set of coherent notes (Montis, 2007). Upon review of the video, it was difficult to follow the notes throughout the lesson: the instructor jumped around from page to page, often left directions or entire problems out of view of the document camera while working on a problem, and also appeared to run out of space when working on a problem. From fieldnotes, I noted that only a handful of the 38 students had the notes printed out. Therefore, the organizational affordances of providing lecture notes were not capitalized during the lesson.

The second area of organization that was evident during instruction is related to the way that the instructor selected the problems in the lesson. Specifically, the instructor did not scaffold the problems so as to set up student success, leaving the students to work individually on very difficult problems. There were three moments when students were asked to work on problems individually at their desks. In each of these instances, the instructor first worked on one to three examples, and then selected a problem within the same section of notes for students to work on.

At one point in the lecture, the instructor assigned the students to work individually on an absolute value problem where the directions said to "Solve the equations". Prior to this moment, the instructor worked through two examples at the document camera, $|y| = 8$ and also $|4x + 1| = 9$. She asked the students to solve the following: $3\left|\frac{3}{2}a + 1\right| + 2 = 14$. The increase in the level of complexity in this problem jumps quite quickly. Students were given three and a half minutes to find and check the solutions to this problem. Later in the class period, the instructor gave students a set of three absolute value equations to solve and indicated that she would ask students to volunteer to present their work at the board. One of the problems in this section was particularly challenging: $\left|\frac{4w-1}{6}\right| = \left|\frac{2w}{3} + \frac{1}{4}\right|$.

Throughout the lesson the instructor selected challenging problems for students to work on, when the problems she selected to use during the note-taking were uncomplicated. In particular, the instructor did not work on any problems in the notes that involved fractions. In the class surveys, five students mentioned these individual practice problems as extremely challenging. Layana said that she felt uncomfortable, "when [the instructor] involved fractions and didn't give examples and kind of let us do it on our own." Teresa said, "when we began to deal with fractions I started to get confused and compared my notes with my partner but turns out we were both confused."

***Mathematical Errors and Imprecisions in Content or Language.*** The mean score for *Mathematical Errors and Imprecisions in Content or Language* was a 3. This implies that there were on average content errors or imprecisions in every segment. This is extremely problematic given the already possible set of misconceptions that students in developmental mathematics classes may already have (Author, 2014). One particular segment scored a rating of 5. In this segment, the instructor says phrases that overly simplify a complex idea. For example, when solving an equation, she tells students to "remember, no matter what, in Algebra the goal is to isolate the term or the variable." This phrase appears to simplify all work done in Algebra down to one notion: solving. By framing mathematics in such a way, students can begin to lose sight of the purpose and utility of mathematics beyond simply solving.

At another point in the segment, the instructor solved an equation and was left with a solution of $x = \frac{-10}{4}$. She asks the students, "What's the LCD between 10 and 4?" A few students say "2". The instructor continues on talking about how she can simplify to $\frac{-5}{2}$, however, catches herself and says, "Sorry, Greatest Common Factor between 10 and 4. The answer is still 2…Remember factors break down, multiples multiply out." It has been documented that developmental math students tend to struggle with the differences between least common multiples and greatest common factors (Stigler, Givvin, & Thompson, 2010). In this exchange, the instructor asks for the least common multiple, which would be 20, but students gave the greatest common factor. This could have been because students assumed what the instructor was asking for. However, later when the instructor catches her mistake, she tells the students that the answer would still be two, not correcting that the LCD between 10 and 4 is in fact 20. Later, when she checks that the solution $x = -\frac{5}{2}$ works for the absolute value equation, $|4x + 1| = 9$, uses inaccurate mathematical language. When simplifying the term $4\left(-\frac{5}{2}\right)$, she indicates to students that they can reduce the fraction by "cross cancel[ing] a little" such that the 4 in the numerator "cross cancels" with the 2 in the denominator to make the mathematics simpler.

Most students did not seem to catch the different mistakes during the lesson, and when they do they usually catch copy mistakes (e.g., missing a negative, not writing the correct number). In student interviews, some focal students indicated that they have overheard others correcting the instructor's mistakes and that they do not mind because it is useful to see your instructor make a mistake. For example, Chris mentions that he sees her making mistakes pretty regularly. Instead of outright correcting her, he tries to ask questions in order to help her catch them with the intention of not embarrassing her. Raquel and Adriana indicate how it really confuses them when she makes mistakes in her teaching. Raquel said,

> Her teaching methods, I'm just not feeling it. I mean, she tries but it's like, she makes too many mistakes. And it's like, you're a professor. You're supposed to know what you're doing. And I, everybody makes mistakes, but not like constantly, when we're trying to really learn and pass this class…I notice 'em, but I don't want to like, say it. Because what if I'm wrong too? So I don't want to look dumb. But I do notice.

Adriana says that that every time the instructor makes a mistake, she feels like they are doing all of the work for nothing, which both confuses and frustrates her.

**Questions.** At the talk, I aim would like to ask participants: 1) What are your thoughts on the mathematical errors that the instructor demonstrates? 2) The participants in my study are all Latinx students. In the larger study, I intend to use Critical Race Theory, specifically Latino Critical Theory to investigate these experiences further. In what ways have audience members used LatCrit theory in their work in undergraduate mathematics education?

# How may Fostering Creativity Impact Student Self-efficacy for Proving?

Paul Regier
University of Oklahoma

Milos Savic
University of Oklahoma

*Mathematical creativity has been emphasized by mathematicians as an essential piece of doing mathematics, yet little research has been done to study the effects of fostering creativity in the undergraduate classroom. In this paper, we seek to understand creativity in the classroom using Sriraman's (2005) five principles for fostering mathematical creativity by studying how these principles impact student self-efficacy for proving. Using online student surveys, interviews, and classroom observation, we demonstrate how Sriraman's five principles and Bandura's four sources of self-efficacy may be used to explore the impact of fostering mathematical creativity on student's self-efficacy for proving. Then from the interviews, we highlight how the use of the free market and scholarly principles may influence student self-efficacy via vicarious role-modeling, and explain why the use of these two principles may be of particular importance in fostering student self-efficacy for proving.*

*Keywords*: mathematical creativity, discrete math, proving, self-efficacy

A large body of research has underscored the importance of *mathematical creativity* (1) in learning and doing mathematics (Mann, 2006), (2) in retaining students in STEM fields (Atkinson & Mayo, 2017), (3) in advancing the field of mathematics (Sriraman, 2005), (4) as a platform for creativity in general (Nadjafikhah et al., 2012), and (5) as one of the aims of mathematics education (Levenson, 2013). But how and to what extent should creativity be incorporated in an introductory proofs course? How does creativity in the classroom impact students' long-term mathematical development? In this paper, we endeavor to better understand these questions by studying the research question: how does instructor use of creative "principles" in the classroom impact students' development of self-efficacy for proving?

## Literature Review

### Importance of self-efficacy in mathematical learning and performance

Perceived self-efficacy (often referred to simply as *self-efficacy*) is one's belief in their own ability to accomplish something, and is highly predictive of general academic performance (Bouffard-Bouchard, Parent, and Larivée, 1991). Self-efficacy for mathematical problem solving is a better predictor of mathematical performance than mathematical ability or prior experience with mathematics (Siegel, Galassi, & Ware, 1985; Pajares & Miller, 1994). Why is this?

Bandura (1997) explains that "academic performances are the products of cognitive capabilities implemented through motivational and other self-regulatory skills." (p. 216). A wide range of studies in cognitive psychology have confirmed that beliefs of self-efficacy mediate the skills that determine how consistently and effectively students apply what they know (Pajares & Kranzler, 1995; Randhawa, Beamer, & Lundberg, 1993). Students with high self-efficacy show increased motivation and use of strategic thinking (Boffard-Bouchard, 1990), are more successful in solving conceptual problems, manage their time better, are more persistent, and are less likely to reject correct solutions (Bouffard-Bouchard et al., 1991). Thus, we suggest that self-efficacy for mathematical problem solving and proving mediates learning in a way that results in long-term benefit of educational principles and practices correlated with increased self-efficacy.

How can self-efficacy be influenced or changed? Social cognitive theory identifies four primary sources of self-efficacy: enactive attainments, vicarious influence, verbal persuasion, and physiological reactions (Bandura, 1997). *Enactive attainments* are experiences of mastery in a given task and are often the most reliable indicators of future capability. *Vicarious influence,* through observation of someone else's competencies in comparison with one's own, provide the next most reliable indicator of ability. *Verbal persuasion*, or direct verbal appraisal of one's ability by someone else, is a somewhat less reliable source of self-efficacy depending on the credibility of the persuader. Lastly, *physiological reactions,* are feelings such as strength, stamina, stress, fatigue, or pain that can provide indicators of ability or inability. Here we note that these sources of information themselves do not influence self-efficacy, but through cognitive processing of this information and reflective thought, they are selected, weighted, and integrated into self-efficacy judgements: "a host of personal, social, and situational factors affect and direct how socially mediated experiences are cognitively interpreted" (Bandura, 1997, p. 79).

### Definition and Principles of Mathematical Creativity

There is considerable variation when seeking definitions of mathematical creativity (Mann, 2006). In this project, while considering mathematical creativity relative to the student, we chose a view influenced by the perspectives of Liljedahl and Sriraman (2006): "a process of offering new solutions of insights that are unexpected for the student, with respect to his/her mathematical background or the problems s/he has seen before" (Savic et al., in press, p, 2). This is based on relative (Beghetto & Kaufman, 2007), process-oriented (Pelczer & Rodriguez, 2011), domain-specific (Baer, 1998) mathematical creativity.

In seeking to study students' experience of creativity in the classroom, we searched for observable characteristics of creativity that instructors and students engaged in the classroom. According to Sriraman's (2005) extensive review of the literature on mathematical creativity, there are five principles that "maximize potential for mathematical creativity" (p. 26):

- the *Gestalt principle* conveys the importance of students engaging in "suitably challenging problems over a protracted time-period, thereby creating the opportunities for discovery and to experience the euphoria of the 'Aha!' moment of illumination" (p. 27);
- the *aesthetic principle* is concerned with appreciating the beauty in discovering and connecting new ideas;
- the *free market principle* encourages risk-taking and atypical thinking;
- the *scholarly principle* encourages students debating and challenging the validity of teachers' and peers' approaches to problems; and
- the *uncertainty principle* embraces ambiguity in mathematics, emphasizing the importance of giving open-ended problems and providing "affective support to students who experience frustration over being unable to solve a difficult problem" (p. 28).

How does instruction seen through the lens of these principles directly or indirectly impact student development of self-efficacy for proving?

## Methods

Pilot data collection was conducted in an 8-week summer session of a discrete mathematics course serving as an introduction to proofs. Five classes were videotaped, one of which was transcribed, then coded by both authors for evidence of the five principles. Differences in codes were discussed until arriving at an agreement for each coded action; otherwise, both would continue for the remainder of the class period. An online survey was given to the students to measure student *experience*[1] of the five principles consisting of ten questions, two per principle. The survey was given twice, once for student experience in *prior* math classes, and once at the end of the semester for experience in *this* class. Then, in both instances, students rated their confidence in their ability to do five tasks related to proving with respect to three specific problems classified as moderately routine, moderately non-routine, and very non-routine (Selden & Selden, 2013). Selection of task questions was based off the EP-spectrum (Hsieh, Horng, & Shy, 2012) deconstruction of the proving process and followed Bandura's guide for constructing self-efficacy (2006, p. 307-337).

At the end of the course, two randomly selected students (Abe and Ben) and the instructor (Dr. One) were interviewed. Each interview was transcribed and coded once by both authors (again compared for inter-rater reliability); once for explicit and implicit examples of instructor use of each of Sriraman's (2005) five principles in the classroom, and again for examples of the student's experience of each of Bandura's (1997) four sources of self-efficacy.

## Results

For the purposes validating the test questions (Bandura, 2006), the surveys were given two weeks apart. The mean scores of the self-efficacy surveys 79 compared to 80 only two weeks later, showing that both surveys were of similar and appropriate difficulty for distinguishing levels of efficacy. Also, the correlation between the two questions for each of the five principles ranged from 0.45 to 0.92, showing convergent validity.

Only nine students participated in both surveys, so with this data we cannot yet say which of the five principles are quantitatively correlated with changes in student self-efficacy. Also, from classroom observation, we were not able to observe enough instances of instructor actions demonstrating the use of the five principles of creativity. Thus, the remainder of this paper focuses on evidence from individual student surveys and interviews.

In the interviews, both students reported teacher actions for the free market and scholarly principles. Abe explained two actions coded as free market and three coded as scholarly. For example, his comment that "quite a few people went up to the board," and that "if we saw, or said what was on our mind," were both coded as an implicit use of the free market principle, since it showed that students were comfortable enough to take risks: going up to the board and saying what was on "our mind." Abe saying "[The instructor] would break questions down to the point where everyone could possibly have an input on why, or on the steps building up to the proof," was coded as scholarly principle, as well as part of the following:

*Interviewer*: Is there any way that the classroom environment did help you learn some of those skills?

*Abe*: It helped me learn a lot faster because if I didn't know the solution right away in most cases someone else did, and once someone else was called up to the board and started writing their proof**, I would follow along and then at a certain point I'd be able to figure out this is where they were going**. I'd finish out the proof and try to continue on. But having people around me that were like-minded and also enjoyed doing these types of proofs... It helped my learning because I wasn't just having to rely on what I gained from the instructor. I could rely on what other people brought to the class as well.

---

[1] In future research, we realize it will be more directly answer our research question to measure to student observation of *instructor use* of the five principles.

Ben described that the instructor would "engage the class like earlier on in the semester and I felt comfortable about like speaking up and answering occasionally." This was coded as implicit use of the free market principle since it showed Ben was able to take the risk of speaking up at that point in the semester. He also stated, "a lot of times [the instructor] would introduce a new problem and tell us to work on it... it'd be like a completely brand-new problem, which I guess is good to try to be able to think of how you'd approach like a brand-new concept." This was coded as uncertainty principle because the instructor did not answer the problem immediately, thus perhaps implicitly allowing the students to tolerate ambiguity.

In coding for sources of self-efficacy, instances of enactive experiences and vicarious role-modeling were identified in both interviews. Abe described seven instances coded as enactive experiences, for which we provide one.

*Abe*: I'm very confident now. I feel like these eight weeks have really given me enough time to work on the formats for everything, to be able to look at a problem rather than just as a solution and more as a problem within a problem and I think I'm pretty confident with solving it now."

However, he did not indicate whether they were due to any actions from the instructor. Ben cited four instances coded as enactive experiences, all on his own, outside of class. He cited *not* having the confidence to engage in class without the "right answer."

Abe describe three instances of vicarious role-modeling. Two were from the instructor: "[the instructor] was very excited when he was talking about proofs and I feel like I feed off the energy of my professors… I think that really helps me learn," and "as he broke it down, he would slowly work it out with us, as we were talking to him." Abe also experienced vicarious role-modeling from other students in the class: "I would follow along and then at a certain point I'd be able to figure out this is where they were going" (quoted above).

Ben described four instances of vicarious role-modeling: two as positive sources of self-efficacy from the instructor: "seeing a teacher like do the proofs repetitively" and "seeing it how you're supposed to approach a proof… seeing like where to start" (in response to the question "what made you confident?"), and two as negative sources from the students:

*Ben:* In this class setting I felt like there were people in this class that already knew, like there's like two people in particular that would always answer all the questions and they seemed… I just kind of like deferred, if it… like the questions to them, so if they didn't… like if the teacher posed a question to the class and they didn't answer it, then I felt it like well, I definitely can't answer it if they can't.

*Ben:* There are other times when he would engage the class like earlier on in the semester and I felt comfortable about like speaking up and answering occasionally, but [later on] I didn't feel comfortable and like around my peers to like answer questions, because I didn't have the confidence.

Lastly, we found that although Ben expressed some confidence in his proving ability in his interview, his self-efficacy score (from one survey) was 8 points lower than average. Abe's self-efficacy score was 6 points (average of two surveys taken) above average.

## Discussion

In Abe's interview, we might infer a potential association between the free market and scholarly principles and increased self-efficacy via vicarious role-modeling. In the same quote, he believed that students were comfortable enough to say, "what was on [their] mind," (free market) then the instructor "would slowly work it out with us, as we were talking to him" (vicarious role-modeling). But, without more data, it is difficult to understand the degree which the free market principle promotes, or may be necessary, for the positive influence of vicarious role-modeling in the classroom. Abe's experience also highlights the importance of the scholarly principle in gaining self-efficacy via vicarious influences. Engaging and considering other's solutions appears to have improved his self-efficacy because he "wasn't just having to rely on what I gained from the instructor." According to Bandura (2007), these kinds of influences (i.e. from peers), provides a stronger source of self-efficacy (than that from the instructor), since the attainments of those who are more like oneself gives better indication of one's own ability.

Although Ben's interview contained evidence of instructor use of scholarly and uncertainty principles, the use of the scholarly principle may not have promoted self-efficacy in this student's case. Firstly, his self-efficacy scores were lower than average. Secondly, when asked, "did you become more confident by the end [of the course]?" he responded, "I still don't think I'd be confident… like if the teacher posed a question to the class and [the two confident students] didn't answer it, then I felt it like well, I definitely can't answer it if they can't." This is an example of vicarious role-modeling giving a negative source of self-efficacy information for the reason described by Bandura: "observing others perceived to be similarly competent fail lowers observers' judgment of their own capabilities and undermines their effort" (1997, p. 87). Interestingly, Ben did not cite any evidence of the free market principle.

After comparing both interviews, we believe that the scholarly with the free market principles *together* may better promote positive student self-efficacy: creating an environment where students can take risks (where mistakes are ok) levels the playing field, helping students see others' experience of both success and failure as part of the proving process. Thus, the way an instructor handles the free market principle may mitigate potential negative effects on self-efficacy associated with the threat of being wrong (inherent with the scholarly principle).

## Conclusion

Although not directly identified thus far in our research, there are some potential connections between Sriraman's principles and self-efficacy suggested by other research. For example, the Gestalt principle may foster self-efficacy via enactive attainment since students' experience of creating proofs though sustained time and effort gives evidence of their future proving ability. The aesthetic principle may serve as verbally influencing student self-efficacy, by convincing students of the joy and beauty inherent in mathematics.

Additionally, as we found above, other principles may have a stronger combined influence on self-efficacy, which may be seen via other mediatory mechanisms such as intrinsic motivation. For example, giving students opportunities to state and defend their solutions (free market) while promoting the understanding of problem design (scholarly) may give students greater ownership, intrinsic motivation, and promote the development of evaluation. As a result, when doing tasks with high intrinsic motivation (i.e. proving), task feedback can have a stronger effect on self-efficacy (Arnold, 1976).

Furthermore, student self-efficacy may influence how students engage or experience these principles. Students with high self-efficacy tend to pursue higher challenges (Pintrick & DeGroot, 1990), suggesting that students with high self-efficacy are more likely to engage the free market principle in and out of class. Also, student experience of the gestalt principle can be influenced by their persistence, which may be supported by self-efficacy beliefs (Selden & Selden, 2010). More research is needed to understand the connections between mathematical creativity and self-efficacy for proving and problem solving. How might this study be modified or applied in a larger context? How might the results inform our use of creative principles in the classroom? What other connections might one find with these theoretical framings?

Teacher Learning About Mathematical Reasoning: An Instructional Model

Robert Sigley
Texas State University

*First, I describe an instructional model for Teacher Learning about Mathematical Reasoning (TLMR), designed for pre-service (PSTs) and in-service teachers (ISTs) to: (a) build knowledge of the various forms of mathematical reasoning that students naturally make use of in their justifying solutions to problems, (b) attend to the development of students' mathematical reasoning from studying videos and student written work, and (c) learn about the conditions and teacher moves that facilitate student justifications of problem solutions. Second, I provide a detailed description of activities from a representative cycle of the TLMR model. Finally, I report briefly on preliminary results indicating teacher growth in identifying and recognizing student reasoning for PSTs and ISTs who underwent the TLMR model compared to a comparison group.*

*Keywords:* mathematical reasoning, pre-service teachers, video-based intervention

As the knowledge required for effective mathematics teaching has become more clearly defined, knowledge needed for PSTs and ISTs to attend to student reasoning in justifying solutions to problems has been recognized as essential (e.g., Francisco & Maher, 2011). In fact, earlier work on student reasoning has been influential in shaping US national policy by developing a set of Standards for Practice in identifying behaviors that are desirable for students as they engage in doing mathematics. (NCTM, 2014). It is essential that PSTs and ISTs become knowledgeable of these practices so that they can attend to and encourage student mathematical reasoning in their classrooms. In addition, while models on how they can do this have been theorized, there is little research testing the effectiveness of these models. In this paper, I will describe an intervention model that is designed to promote teachers' attention to student reasoning through: (a) open-ended problem solving of mathematical tasks, (b) studying videos of children building solutions to the same tasks, and (c) in-class and online discussions about their own and students' problem solving, as well as relevant readings and the results of a quantitative study to test the effectiveness of the model in having PSTs and ISTs attend to student mathematical reasoning.

## Children's Mathematical Reasoning and Justification

Research on the knowledge for teaching mathematics identifies that knowledge of students' mathematical reasoning is essential (Ball, 2003) and that there is a relationship between following how students builds their knowledge and their performance in mathematics (Rowan et. al, 1997). An important early finding in research into mathematical reasoning is that in a natural way, children – even young children – build proof-like justifications, providing convincing arguments that take the form of reasoning by cases, induction, contradiction, and upper and lower bounds (Maher & Martino, 1996). Students' justifications are driven by an effort to make sense of the problem situation, notice patterns, and pose theories (Mueller, Yankelewitz, & Maher, 2012). Three key components surface in promoting the development of mathematical reasoning. These are: (a) reflecting on and revisiting earlier mathematical concepts, (b) collaborating and discussing strategies and modes of solution; and (c) engagement in open-ended tasks that elicit justification (Maher, Powell, & Uptegrove, 2010). Research results across all ages and contexts, formal and informal, indicate that certain tasks tend to elicit particular forms of reasoning (e.g., upper and lower bound arguments, inductive arguments) when students are encouraged to provide a justification for their solutions (Yankelewitz, Mueller, & Maher, 2010).

## Teacher Learning About Mathematical Reasoning: A Model

TLMR was implemented as a design-research study in a graduate mathematics education course over 5 years, with each implementation co-taught by the author. The problems used during class were from the domain of counting and combinatorics. Each iteration was over a 14-week period. Overall, 86 teachers participated. The model has six cycles of interventions with each cycle containing five components. These are: (a) teacher collaborative problem solving (b) teacher study of videos of children working on the same problems, (c) teacher analyses of samples of student written justifications of the same problems, (d) teacher small-group online discussions (with guiding questions) designed for synergistic reflection on their own and students' problem solving, in light of the assigned readings, video study, personal experience, and collaborative problem solving. Throughout the course, teachers engaged in each of the six cycles by first working collaboratively on the related mathematical tasks. I offer an example for each of the five components of a cycle.

## A Sample Cycle

**The Tasks**: The TLMR intervention utilized tasks from earlier research studies that were shown to elicit student reasoning in justifying solutions to problems. All tasks were introduced prior to the mandated school curriculum. During this cycle, teachers worked on two variations of pizza problems: Pizza with Halves, selecting from two toppings; Whole Pizzas, selecting from four toppings. They were asked to discuss the strategies used in solving both problems, attend to similarities or differences, compare their strategies, reflect on strategies for previous problems, and report findings to the entire class.

**The Videos:** Teachers were then assigned to study two video clips online, read and react to two articles, and examine four samples of student work from fifth graders working on the same Pizza with Halves Problem. The first video, http://dx.doi.org/doi:10.7282/T3HM57PQ, followed twelve, fifth-grade students across two class periods as they worked on the Pizza Problem with Halves selecting from two toppings. The clip showed students constructing various representations to justify their solution of the ten pizzas. The second clip, http://dx.doi.org/doi:10.7282/T3VX0FRD, was a task-based interview with fourth grader Brandon. It shows Brandon, explaining his solution to the Pizza Problem selecting from four toppings (without halves). After explaining his solution, Brandon is asked whether this problem reminds him of any other problem he had worked on earlier and he said it reminded him of the Towers Problem, a problem where he had to find the unique number of towers he could build four high selecting from two colors of Unifix cubes. After resolving the Towers problem, he makes a connection between the similarity in structure of the two problems, recognizing that the two choices for a pizza topping (represented by 1 or 0) for being on or off the pizza is similar to the two choices for the color of a particular block of the tower, e.g. red or yellow (PUP Math, 1999).

**The Readings:** The first readings discussed details of the Brandon Video (Maher and Martino, 1998). The second reading dealt with the topic of isomorphisms in mathematics education (Greer and Harel, 1998). The Maher and Martino, paper situated the Brandon video as a part of a longer study and included details that preceded the interview as well as an analysis of Brandon's problem solving. The Greer and Harel paper referred to Brandon as an example of a nine-year old student having an insight in recognizing an isomorphism, similar to the mathematician, Poincare.

**Student Work:** The student work module contained four pieces of student solutions from the Pizza with Halves problem, selecting from two toppings. These were chosen to illustrate the variety of representations and arguments produced by the students. The teachers were asked to review the students' representations and work and specifically address: (1) the correctness of the solution, (2) description of the strategy, (3) the validity of the reasoning, and (4) whether or not they find the solution convincing and, if so, why. If they did not find the solution convincing, they were asked to indicate from studying the student work what pedagogical moves they might take to help the student develop a convincing argument.

**Online Discussion:** For this module, the guiding questions focused on the notation that Brandon used in his problem solving. Teachers were asked to discuss how, if at all, Brandon's choice of notation was helpful to him in recognizing the relationship between the Pizza and Tower problems. They were also asked to discuss the forms of reasoning displayed by Brandon in the video, and the role of isomorphisms in mathematical cognition. Finally, they were asked to compare their own problem solving with that of the students in the Pizza with Halves and in the Brandon video.

## The Study

Limitations in time and space allow only a brief description of preliminary results. A reasoning assessment (RA) was administered as a pre-test before the course and as a post-test after the course. The group that underwent the intervention above was 86 teachers over the five iterations. Additionally, pre and post data was collected from 48 teachers from the same course taught by a different instructor. The comparison group's course had the same emphasis on attending to mathematical reasoning, but did not use the TLMR model. The comparison group is used to check if the students just got more on the post-test because they watched the video twice, if that is true, we would expect to not see a significant difference in the post-test scores between the comparison and experimental group. The RA consisted of a ten-minute video of fourth-graders sharing their arguments for an open-ended problem-solving task. Teachers were asked to: (a) identify the arguments presented by the children, (b) determine the validity of the arguments, (c) provide evidence to support their claims, and (d) explain whether or not the arguments were complete. The clip contained arguments by induction, cases, an alternate cases argument, and contradiction. The responses were scored by a group of three people using an established rubric to determine if the participant noted no features, partial features (the alternate cases and contradiction responses did not contain a partial feature, the other two did), or complete features of the argument. Initially, the group worked with responses from a pilot study for training and to establish reliability. For the analysis, growth was defined as recognizing more features on the post-test than the pre-test. Each argument was analyzed using a Wilcoxon rank-sum test, a nonparametric alternative to the t-test to determine if the growth from pre-to-post was significant. The effect sizes were calculated using an estimator suggested by Grissom and Kim (2012) which takes the U statistic generated by the test and then divides it by the product of the two sample sizes that will estimate that a score randomly draw from one population will be greater than the other. This methodology was chosen over using Cohen's d due to the smaller sample size and non-normality of the data.

## Results

The pre-test results for the comparison and experimental group were not significantly different and the differences in each iteration for the experimental group was not significant, so the experimental group was put together into one group, giving a size of 86 teachers. For the first cases argument, on the pre-test the experimental group had 50% missing the argument, 2.3% had a partial argument, and 47.7% had the complete argument compared to 61.2% missing, 6.1% partial, and 32.7% complete for the comparison group. On the post-test, in the experimental group 21.6% was missing the argument, 1.1% partial, and 77.3% complete compared to 57.1% missing, 8.2% partial, and 34.7% complete. The growth from pre-to-post for the experimental group was significant with a moderate effect size ($p < 0.01$, effect size = 0.351) and for comparing the experimental to comparison post with a moderate effect size ($p < 0.01$, effect size = 0.248). For the alternate cases argument, the experimental group went from 69.3% missing on the pre-test to 33% on the posttest and 30.7% complete on the pre-test to 67% complete on the posttest. This growth was significant ($p < 0.01$, effect size = 0.277) and the post score compared to the comparison group was significant ($p < 0.01$, effect size = 0.32). The inductive argument for the experimental group had 55.7% missing, 37.5% partial, and 6.8% complete on the pre-test and 23.9% missing, 53.4% partial, and 22.7% complete on the post-test for a significant growth ($p < 0.01$, effect size = 0.317), and a significant difference in post compared to the comparison group ($p < 0.01$, effect size = 0.324). Finally, the argument by contradiction was missing from 95.5% of the experimental teachers' pre-test and complete in 4.5% compared to missing in 68.2% of the post-test with 31.8% complete for a significant growth ($p < 0.01$, effect size = 0.364) and significant difference than the comparison post results ($p = 0.011$, effect size = 0.402).

## Discussion and Implications

The design TLMR research study produced an extensive and valuable database about teachers learning to attend to student reasoning. Preliminary analyses suggest significant changes in teacher beliefs in recognizing the potential for student reasoning. In addition, there is evidence that teacher recognition of the forms of arguments used by children in the video as they expressed their justifications of solutions improved over the course of the intervention (Maher et. al, 2014). Analysis of teacher online discussions of one cycle of intervention also indicated some interesting findings. As teachers compared their own problem solving with that of (a) other teachers, (b) students from the videos, and (c) student work samples, they pointed out similarities and differences, especially when the representations differed from their own and were in their view, "more elegant". These comparisons prompted further reflection about what constitutes a convincing argument in posing a solution to a challenging mathematical task and raised expectations about students' creativity in representing their solutions. It is interesting that teachers focused heavily on attending to details in the videos, relating their observations to their own personal experience. Reference to the readings was also made by teachers who tried to situate their learning within a particular theoretical perspective. Implementation of the TLMR holds promise for teacher growth in attending to the development of mathematical reasoning in students. Further studies building off this work can focus on the application of teacher learning through the TLMR model to their practice.

## Questions

(1) I collected some qualitative data as well (online discussions, in-class problem solving) – would those help strengthen the argument that the model is successful in promoting attending to reasoning?

(2) Is it worthwhile to follow PSTs into their practicum and initial classroom experience to see how it affects them or would it be too messy?

Student's Semantic Understanding of Surjective Functions

Kelly M. Bubp
Ohio University

*Reasoning and proof are essential to mathematics, and surjective functions play important roles in every mathematical domain. In this study, students in a transition to proof course completed tasks involving composition and surjective functions. This paper explores students' semantic understandings of surjective functions, both individually and in the context of composition of functions. Most students demonstrated productive semantic understandings of surjective functions that allowed them to produce counterexamples and arguments for the truth of statements. Furthermore, in the struggle of using the syntactic definition of surjective in a proof, some students used their semantic understanding to try to make sense of the definition. This demonstrates the potential of students' ability to reason semantically to build understanding of the syntactic definition and structure of proofs of surjective functions.*

*Keywords:* Proof and Proving, Semantic and Syntactic Reasoning, Surjective Functions

Reasoning and proof are fundamental aspects of mathematics on which mathematical teaching and learning should focus. Weber and Alcock (2004, 2009), describe two distinct reasoning styles and approaches to proof production that they call *semantic* and *syntactic*. Semantic reasoners produce proofs through a focus on general understanding guided by examples, diagrams, or other informal explanations, and syntactic reasoners produce proofs mainly through deductive reasoning based on axioms, definitions, theorems, and standard proof frameworks (Weber & Alcock, 2004). Although a mathematical proof is a syntactic product, understanding the proving process involves both types of reasoning. Thus, "neither of these approaches should be used exclusively by students and both syntactic and referential [semantic] approaches to proving are necessary for proving competence" (Alcock & Weber, 2010, p. 96).

Students typically encounter surjective functions for the first time in precalculus. Although they are not necessarily emphasized at this level, surjective functions are important in upper-division courses as bijections and isomorphisms permeate nearly every mathematical domain. My students consistently struggle with proofs of statements involving surjective functions, so as a step toward understanding why, this paper addresses the following research questions: In what ways do students approach proofs of statements involving surjective functions? What are students' semantic understandings of surjective functions?

## Literature Review

Both semantic and syntactic reasoning present students with opportunities and difficulties in proof production. Semantic reasoning can provide a basis for and support the development of a syntactic proof or counterexample by suggesting a main idea or underlying structure (de Villiers, 2010, Moore, 1994; Raman, 2003; Weber & Alcock, 2004). However, students often do not make these connections due to inaccurate or incomplete semantic understanding (Moore, 1994; Tall & Vinner, 1981) or difficulty relating their semantic understanding to a syntactic definition or proof (Raman, 2003; Weber & Alcock, 2009). Additionally, students may use semantic reasoning as a substitute for syntactic proof (Harel & Sowder, 1998, 2007).

When students have such difficulties with semantic reasoning, syntactic reasoning can help them produce proofs even if they do not fully understand them. Understanding may then develop through students' reflection on how syntactic proofs relate to their semantic understanding of the concepts involved (Weber & Alcock, 2009). On the other hand, students' struggles with syntactic reasoning, such as use of imprecise or incomplete definitions (Harel & Sowder, 2009; Vinner, 1983) or failure to use definitions to structure proofs (Harel & Sowder, 2009; Moore, 1994) may limit their ability to construct and understand mathematical proofs.

Both semantic and syntactic reasoning are important in proving, and the affordances above suggest that students may come to understand proving and proof in one of two ways: by using semantic reasoning to build syntactic proofs, or by making sense of syntactic proofs through reflections on their semantic understanding (Weber & Alcock, 2009).

## Method of Inquiry

The data in this paper come from a larger study that investigates students' proofs of statements involving relations and functions.

### Participants

The participants were ten undergraduate students at a public university in Ohio enrolled in a transition to proof course. Six students were secondary mathematics education majors, and one each was a computer science, meteorology, mathematical statistics, and applied mathematics major. Although the course was intended for sophomore level students who had not taken a proof-based mathematics course, only one participant met these criteria. The other students were juniors and seniors with varied levels of experience with proof-based mathematics.

### Course Structure

The transition to proof course was an inquiry-based learning course taught by the author of this paper. The topics in the course were: problem solving, logic, set theory, proof techniques, counting, induction, relations, orderings, functions, and cardinality. Students read about and completed ungraded pre-work on new topics before class. In class, they discussed the pre-work in small groups, followed by whole class discussions and ungraded student presentations. Students had graded post-work due weekly, which could be discussed with others, but write-ups were to be individual. In addition, there were four quizzes, a midterm, and a final exam in class.

### Data

The data come from the assigned coursework in the transition to proof course. Although the students completed a variety of tasks involving surjective functions, this paper focuses specifically on the three tasks below involving composition and surjective functions. Overall, three weeks of class were spent on functions, with four days including study of surjective functions. Surjective functions were introduced the first day on functions with the following definition from Schumacher (2001):

> A function $f: A \to B$ is said to be onto if for each $b \in B$, there is at least one $a \in A$ for which $b = f(a)$. In other words, $f$ is onto if the codomain and the range of $f$ are the same set.

In this definition, I consider the first sentence the syntactic definition and the second sentence a semantic understanding of the definition. The next three days of class focused on injective and surjective functions, composition of functions, and their interactions. Students constructed examples and explored conjectures on the composition of functions with both finite and infinite domains satisfying varied combinations of injective and surjective. The tasks examined in this paper were explored as pre-work and in class before being assigned as post-work and on in-class assessments, but complete solutions were not provided.

**Task 1.** Task 1 was on a post-work assignment due on the fifth day of study of functions.

True or False? If true, prove it; if false, provide a counterexample.

Let $f: A \to B$ and $g: B \to C$ be functions. If the composite function $g \circ f: A \to C$ is onto, then $g$ is onto $C$.

**Task 2.** Task 2 was on an in-class quiz, four class days after the due date for the post-work containing Task 1.

Let $A, B,$ and $C$ be nonempty sets and $f: A \to B$ and $g: B \to C$ be onto functions. State the domain and codomain of $g \circ f$. Prove that $g \circ f$ is onto its codomain.

**Task 3.** Task 3 was on the final exam, four class days after the quiz containing Task 2.

True or False? If true, prove it; if false, provide a counterexample.

Let $f: A \to B$ and $g: B \to C$ be functions. If the composite function $g \circ f: A \to C$ is onto, then $f$ is onto $B$.

## Results

### Task 1

Every student correctly identified the statement in task 1 as true. Seven of the ten students used an indirect proof, but it was often unclear whether they were using proof by contradiction or contrapositive. Not a single student used the word "contradiction," and each indirect argument concluded $g \circ f$ was not onto, many starting similarly to "if $g$ is not onto, then $g \circ f$ is not onto because…." Most subsequent arguments were based on semantic understandings of surjective functions instead of the syntactic definition. It is unclear what provoked the use of an indirect proof strategy, but it aligned almost naturally with their semantic reasoning in this context.

The students demonstrated five different semantic understandings of surjective functions, some specifically in the context of composition, and some which overlapped. Two students' arguments included diagrams such as those discussed in Task 3 below. Non-surjective functions in the diagrams are represented with an element in the codomain that is not in the range. Additionally, two students' arguments expressed this idea in words, specifically speaking of mapping elements:

> Assume $g$ is not onto. If $f$ is onto $B$, then all the elements in $B$ can be mapped back to $A$. When we map $B$ to $C$, not all of the elements of $C$ can be mapped back to $B$. Since $B$ is not onto $C$, $A$ cannot be onto $C$. Therefore $g$ must be onto $C$.

Another student argued similarly to the students above in the language of codomain and range:

> If $g \circ f$ is onto, is $g$ onto? True. This is true because if $g: B \to C$ had an element show up in its codomain that was not in the range, then the mapping from $A \to C$ would contain that same element in its codomain and not its range.

Two students argued on the consequences of $g$ be the last function applied in the composition:

> Suppose not, that $g$ is not onto $C$. Therefore $g \circ f$ would also <u>not</u> be onto $C$. This is because $g$ is the highest level function that provides the final range of the entire composite, and if $g$ can't reach all of $C$, then the composite $g(f(x))$ certainly won't either.

Finally, three students used the idea that $g$ and $g \circ f$ have the same range when $g \circ f$ is onto:

> True because the range of $g$ will also be the range of $g \circ f$. So, if $g \circ f$ is onto, then that means $f$ has its domain and range, the domain of $g$ that has the same elements as range

of $f$ will have a range also, and that range of $g$ of those elements will be the same range of $g \circ f$.

Only two students used the syntactic definition of surjective on task 1. Each student gave a correct proof, with one being a direct proof and the other a proof by contrapositive.

**Task 2**

Nine of the ten students used a direct proof strategy on Task 2, and six students attempted to use the syntactic definition of surjective function. This approach was in stark contrast to students' approach to Task 1. However, in attempting to follow the forward structure of a prototypical direct proof – start with the assumptions and use definitions to work to the conclusion – students missed the backward structure of the definition of surjective and were unable to use it appropriately to structure their proofs. Each proof attempt started in the domain of $g \circ f$ and moved toward the codomain as in this example:

> Let $a \in A, b \in B,$ and $c \in C$. Note $(g \circ f)(x) = g(f(x))$. Since $f$ is onto, $\forall b \in B$, there is an $a \in A$ such that $f(a) = b$. Furthermore, since $g$ is onto, $\forall c \in C, \exists b \in B$ such that $c = g(b)$. Suppose $(g \circ f)(a)$. $(g \circ f)(a) = g\big(f(a)\big) = g(b) = c$. Hence, $g \circ f$ is onto.

For an analysis of the difficulties that lead to this type of proof, see Epp (2009).

Four of the students who used a version of the syntactic definition also used semantic reasoning in their proof attempt, as illustrated in the following example:

> Let $a \in A$. Since $f$ is onto, $\exists b \in B$ such that $\forall a \in A, f(a) = b$. Every value in $B$ is mapped to. Similarly with $g$, $\forall c \in C, \exists b$ such that $g(b) = c$. And since all values in $B$ are mapped to, and $g$ is also onto, all values in $C$ get mapped to. $g \circ f$ is onto $C$.

Finally, four students used semantic arguments only – three based on all elements in the codomain of surjective functions getting mapped to, and one cardinality argument presumably based incorrectly on surjective functions having the same codomain and range.

**Task 3**

Every student correctly identified the statement in Task 3 as false and attempted to construct a counterexample using a diagram to represent the sets and functions as in Figure 1:

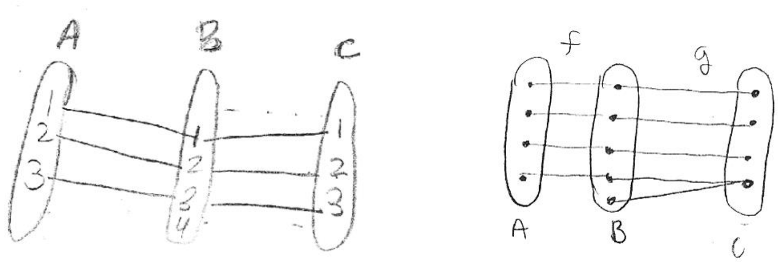

*Figure 1. Sample counterexamples for Task 3*

Three students provided a diagram only, although two of these students circled the element in B that was in the codomain of $f$ but not the range. Four students accompanied their diagram with some version of the statement "$g \circ f$ is onto, but $f$ is not onto." The other three students included explanations with their diagrams. One student used the syntactic definition of surjective and reasoned semantically about mapping elements in their explanation:

Assume $g \circ f$ is onto, this means for each $c \in C$, there is at least one $a \in A$ for which $c = g \circ f(a)$. This means each $c$ must map to a $b \in B$ so $c$ can map to $a$. But there does not need to be an $a \in A$ for which $b = f(a)$ for every $b$ as long as there is a path from $c \in C$ to $a \in A$.

This student's diagram was similar to the diagram on the right in Figure 1. The other two students used only semantic reasoning with their diagrams, with one student arguing that there was an element in $B$ that was "unmapped by any element in $A$" and the other student using an argument based on the cardinality of $B$ being greater than the cardinality of both $A$ and $C$. Although each student's counterexample correctly showed that $g \circ f$ was onto and that $f$ was not onto, $f$ and/or $g$ were not functions in half of the students' counterexamples, as is shown in the example on the right in Figure 1.

## Discussion

The discussion will focus on two promising results: (1) Most students exhibited valid and useful semantic understandings of surjective functions (2) Some students tried to use their semantic understanding to make sense of the syntactic definition of surjective.

### Semantic Understanding of Surjective Functions

Every student in this study demonstrated at least one semantic understanding of surjective functions, notably, some form of the diagram in Figure 1. Eight students exhibited at least one other semantic understanding. For the other two students, one used diagrams on every task, displaying no other semantic or syntactic understandings, and the other used the syntactic definition on Tasks 1 and 2. Overall, the students' semantic reasoning about surjective functions was correct and useful in arguing for the truth of statements and constructing counterexamples.

In addition to the diagram the students exhibited the following semantic understandings of surjective functions: having the same codomain and range, and all elements in the codomain being mapped to. Additionally, students easily negated these concepts for semantic understandings of non-surjective functions: diagrams with unmapped elements, elements in the codomain not being mapped to, and unequal codomains and ranges. Although these are simply different representations of the same concept, only one student demonstrated all three semantic understandings. It would be interesting to see if students could recognize and articulate the connections between these semantic understandings.

Finally, the students reasoned semantically about surjective functions specifically in the context of composition, including: considering the impact of which function was applied last in the composition; using the fact that $g$ and $g \circ f$ have the same codomain; using diagrams representing both surjective functions and composition; and arguing using cardinality as mentioned above in Task 3.

### Connecting Semantic and Syntactic Reasoning

On Tasks 1 and 3, only one student used both semantic and syntactic reasoning about surjective functions, but most students demonstrated useful semantic understandings on which they could build. However, on Task 2, as six students struggled to use the syntactic definition of surjective, four of them included semantic reasoning in their proofs to try to make sense of and connect to the syntactic definition. With more time and practice, these students' semantic understandings have the potential to be valuable in helping them understand the syntactic definition and structure of proofs of surjective functions.

A Framework for Analyzing Written Curriculum from a Shape-Thinking and (Co)variational Reasoning Perspective

Halil I. Tasova
University of Georgia

Irma E. Stevens
University of Georgia

Kevin C. Moore
University of Georgia

*This preliminary study provides a framework to analyze the extent and nature of (co)variational and quantitative reasoning in written curriculum. In order to test and refine our framework, we examined both the narratives and worked examples in calculus textbooks on lessons dealing with the topic of functions. We present examples from those textbooks to illustrate the categories of our framework. We conclude with questions concerning potential areas to improve our framework.*

*Keywords:* Textbook Analysis, Quantitative Reasoning, Covariational Reasoning, Calculus

Over the past couple decades, researchers have studied students' quantitative and covariational reasoning – the cognitive activities in which students conceive of measurable attributes varying in tandem (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002) – and have categorized specific forms of reasoning. They argue its importance to understanding numerous K-12 topics (Carlson et al., 2002), and yet "many popular U.S. textbooks do not emphasize or support students in conceptualizing quantities and viewing function formulas and graphs as representing how two varying quantities change together" (Thompson & Carlson, 2017, p. 457). Paoletti, Rahman, Vishnubhotla, Seventko, and Basu (in press) have started analyzing graphs used in STEM textbooks and journal articles. Thompson and Carlson (2017) and Mesa and Goldstein (2014) reported how secondary level precalculus textbooks addressed the conception of function and inverse trigonometric function, respectively, in their textbook reviews. However, we were unable to find any textbook analysis frameworks that attend to the degree to which textbook narratives and worked examples provide students with the opportunity to conceptualize quantities or reason (co)variationally.

In this report, we describe our attempt to create such a framework. To do so, we adapt two cognitive-focused categorizations – Moore and Thompson's (2015) shape thinking constructs for graphs and Thompson & Carlson's (2017) variational and covariational reasoning framework into categorizations appropriate for analyzing static curricular materials. In order to test and refine our framework, we analyzed calculus textbooks sections readily available to us. We specifically analyzed the introductory material to calculus textbooks (i.e., the pre-calculus topics the authors included) because it provides insights into the conceptions of graphs, functions, etc. the textbook authors believe are foundational for students to have before entering calculus. In this paper, we introduce the framework with specific examples from our analysis.

## Background and Rationale

Two main sources – shape thinking constructs (Moore & Thompson, 2015) and the framework for variational and covariational reasoning (Thompson & Carlson, 2017) – informed our construction of a framework that enables users to analyze the narratives and worked examples when textbook authors explain, define, or use terms, expressions, formulas, and graphs. Firstly, as we describe in more detail when introducing the framework, we adapt the shape thinking construct to analyze the extent to which the narratives and worked examples provide students with opportunities to develop quantitative and covariational reasoning.

Secondly, Thompson and Carlson's (2017) frameworks for variational reasoning and covariational reasoning enabled us to distinguish between various levels of covariation in the narratives and examples provided in the curriculum. We also benefit from other research (i.e., Carlson & Oehrtman, 2005; Cooney & Wilson, 1993; Confrey & Smith, 1994) to construct our framework. The structure in which those researchers provided various levels of understanding functions (i.e., correspondence vs. process/covariation view of functions) was useful in providing a way to analyze algebraically and geometrically defined functions in the narratives to determine how they promote opportunities for students to understand and use functions as values of two variables or quantities covarying.

Researchers have demonstrated that textbooks have significant influence on student learning and teacher practice (Begle, 1973; Schmidt, McKnight, & Raizen, 1997; Kilpatrick, Swafford, & Findell, 2001; Stein et al., 2007; Valverde, Bianchi, & Wolfe, 2002). For example, Kilpatrick et al. (2001) stated that "what is actually taught in classrooms is strongly influenced by the available textbooks" (p. 36). In particular, Carlson, Oehrtman, and Engelke (2010) showed a positive influence of a curriculum (i.e., *Precalculus: Pathways to Calculus*) on students' productive understanding of functions. They reported that students who completed a curriculum focused on quantities and their covariation scored significantly higher on the *Precalculus Concept Assessment* at the end of the course than at the beginning. However, given the important role of textbooks in students' learning and classroom instruction, there is limited investigation regarding how (co)variational reasoning is promoted in textbooks. Hence, we decided to develop a framework to analyze curriculum materials in order to determine the extent and nature of (co)variational reasoning provided students in the narrative and worked examples.

## Framework

We had two main categories in our framework: static and emergent. We illustrate each of these categories along with examples from five calculus textbooks we investigated.

### Static

We use the term *static* to refer to any instances of narratives or worked examples that do not reference quantities and relationships among them in ways that entail those quantities[1] varying. For example, we code things as *static* when they entail instances that provide students images of variables and formulas based on perceptual associations among visual shape, analytic form, and perceptual features. *Static* instances encountered in the narratives and worked examples during our initial work fell into several categories (see Table 1).

**Perceptual Associations**. One category is what we call *perceptual associations*. This category has subcategories (i.e., form-name, form-shape, shape-name, and property-shape associations). *Form-name associations* involve perceptual associations between an analytic form and a function class terminology (e.g., linear, quadratic, or exponential). We adapted this particular category from Moore and Thompson's (2015) shape thinking construct to account for representations that were not graphs but still seemed associated with a particular form of an equation. For example, the following description of linear function was provided based on its analytic form without giving attention to an invariant relationship between the variables $x$ and $f(x)$ that change together: A function of the form $f(x)=ax+b$ is called a linear function (Larson & Edwards, 2010, p. 24; Rogawski, 2012, p. 13). *Form-shape associations* involved perceptual

[1] We use quantities here to refer to both a quantity's magnitude and a quantity's value. We return to this idea in the discussion section.

associations between an analytic form and shape of graph. For example, Johnston & Matthews (2002, p. 20) describe "a nonvertical line in the Cartesian plane, or ($x$, $y$) plane, can be described by an equation of the form $y$=$mx$+b" with little or no attention to the coordinate system or axes' scales and no attention to the invariant relationship between variables $x$ and $y$ as they vary. We also recorded instances as *form-shape associations* when the narratives provide a perceptual association between a change in a parameter in the analytic form and a change in the shape of graph. For example, Edwards and Penney (2014) stated "[the] *size* of the coefficient $a$ in Eq. (9) [$y=ax^2$] determines the 'width' of the parabola; its *sign* determines the direction in which the parabola opens" (p. 18). *Shape-name associations* involve perceptual associations between the shapes of graphs (e.g., "line" or "curve up") and a specific function class terminology or name of a mathematical object. For example, Steward (2008) stated, "When we say that $y$ is a linear function of $x$, we mean that the graph of the function is a line" (p. 24). *Property-shape associations* involve perceptual associations between the shape of graph and a feature of the graph (e.g., slope). For example, Rogawski (2012) provided a pair of parallel lines on a Cartesian coordinate axis that were not scaled and labeled, and stated that "[l]ines of slopes $m_1$ and $m_2$ are parallel if and only if $m_1 = m_2$" (p. 14–15)—with no attention to changes in one variable with respect to changes in another variable by considering the axes' scales or orientations.

*Table 1. Framework for coding the extent and nature (co)variation provided in the narrative of a lesson*

| **Static** | **Emergent** | |
|---|---|---|
| | Variation | Covariation |
| Perceptual associations | Continuous | Continuous |
| • Form-Name Associations | Gross | Gross Coordination of Values |
| • Form-Shape Associations | Discrete | Coordination of Values |
| • Name-Shape Associations | | |
| • Property-Shape Associations | | |
| Variable as unknown | | |
| Correspondence | | |

**Variables as Unknown.** A second category of *static*, named *variables as unknown*, involves presenting a variable as having a fixed unknown value of a quantity or being only a visual symbol that is not varying in the way Thompson and Carlson (2017) categorized as "no variation" and "variable as symbol." One example in Stewart (2008) is to "express the cost [$C$] of materials as a function of the width of the base" of a rectangular storage container (p. 15). In the solution, they note $w$ and $2w$ as "the width and length of the base, respectively, and $h$ be the height" and "the area of the base is $(2w)(w)=2w^2$" without considering $h$ or $w$ as varying. Furthermore, they use these variables to write an equation for $C$, also indicating a treatment of $C$ as an unknown variable whose unique value needs to be computed.

**Correspondence.** We used the code *correspondence,* the third category under static, when the narratives provide instances in which there exists an established static link among numbers in sets, but there is no consideration of either the covariation of variables or the dynamic relationship between number of sets (Cooney & Wilson, 1993; Vinner & Dreyfus, 1989). We also coded instances as correspondence when they simply provide a rule for students to calculate a unique value of a variable or quantity by using any given value of another variable or quantity (Confrey & Smith, 1994). For example, Edwards and Penney (2014) provide the following definition of a function: "A real-valued function [*originally bolded*] $f$ defined on a set $D$ of real numbers is a rule that assigns to each number in $x$ in $D$ exactly one real number, denoted by $f(x)$" (p. 2). This definition is common across all the textbooks we investigated. These definitions do not provide a *process* view of function of how input values covary with output values, emphasizing the change over a continuum of values (Carlson & Oehrtman, 2005).

**Emergent**

The other main category in our framework, named *emergent,* identifies the narratives and worked examples representing various levels of varying and covarying quantities or variables based on Thompson and Carlson's (2017) outline of levels of reasoning variationally and covariationally. We adjusted those levels to fit a textbook analysis and used them as our sub codes under *emergent* to determine the level of opportunities provided in a written curriculum for students to develop quantitative and covariational reasoning. We acknowledge that Thompson and Carlson included smooth and chunky distinction for both variational and covariational reasoning. For the purposes of this framework, however, we chose not distinguish between chunky and smooth continuous (co)variation. We made this decision because of the research (Castillo-Garsow, Johnson, & Moore, 2013) done to indicate that it is the *student* who conceives of a situation as either chunky or smooth, and in our preliminary analysis, we did not find a narrative or example that attempted to distinguish between the two.

**Covariational Reasoning (Thompson & Carlson, 2017).** The other part of our framework under *emergent* outlines the level of opportunities to develop covariational reasoning. *Gross coordination of values* involves representing two variables or quantities whose values increase or decrease together without mentioning the individual values of variables as varying together in the narratives. For example, "As the independent variable $x$ changes, or varies, then so does the dependent variable $y$" (Edwards & Penny, 2014, p. 3). *Coordination of values* involves instances of coordinating the values of one variable or quantity with values of another by providing specific and discrete pairs of values without providing the opportunity for students to conceive two variables or quantities whose value varies together in between those pairs of values. For example, a narrative in Edwards & Penny's (2014) box problem wants students to "[s]tart by expressing the box's volume $V = f(x)$ as a function of its height $x$, and then use the method of repeated tabulation to find the maximum value $V_{max}$" (p. 12). Here, the textbook offers various values for $x$ and asks for students to find their corresponding values in order to determine when the value of $V$ will be maximum. *Continuous covariation* involves instances providing a simultaneous and continuous change in the values of two variables or quantities. We do not have an example of this category; however, the narrative presented as an example for coordination of values would have been an example of continuous covariation if each of the functional representations was linked to a motion in a dynamic geometry software with a slider for students to change the value of $x$ and simultaneously see the corresponding changes in the values of $V$ continuously.

**Variational Reasoning (Thompson & Carlson, 2017)**. One part of our framework under *emergent* outlines the level of opportunities to develop variational reasoning (i.e., discrete, gross, continuous variation). *Discrete variation* involves presenting a variable or quantity in the narratives as taking specific values, but without providing the opportunity for students to conceive the variable or quantity whose value varies in between those specific values. *Gross variation* involves presenting a variable or quantity whose values increase or decrease without mentioning the specific values of the variable or quantity while increasing or decreasing in the narratives. C*ontinuous variation* involves presenting a variable or quantity whose values increase or decrease continuously. We do not provide examples from textbooks for each category of variational reasoning because they can be seen in the examples for covariational reasoning. For example, we can see discrete variation in Edwards and Penny's (2014) box problem when they ask students to change the values of $x$ to find the maximum values of volume. Here, the textbook provides the variable $x$ as having specific values but without considering how its value varies in between those specific values.

## Discussion

The aforementioned research upon which we base our framework describes how students think about quantities. We recognize that the frameworks we chose to adapt were cognitive in nature, and we contend that students conceptualize the written materials differently. For example, as Thompson and Carlson (2017) pointed out, "A variable's variation comes from *a person thinking* [emphasis added], either concretely or abstractly, that the quantity whose value the *letter* [emphasis added] represents has a value that varies" (p. 425). In other words, we cannot know whether a student will interpret a variable provided in a written curriculum as varying, a letter that has a fixed value, or as a symbol. Nevertheless, the curriculum (including textbooks) students receive will influence how students think and learn. Thus, although there will invariably be discrepancies in the intended curriculum, the written curriculum, and what students interpret from the written curriculum, we argue certain narratives promote ways of reasoning that scaffold students in a way that supports reasoning covariationally. Hence, we are constructing a framework to determine which conceptualization students are likely to have based on what we see as evidence from written curricula.

In our framework, we did not include the attention to the distinction between quantities' values and quantities' magnitudes because we have not seen any instances from textbooks representing this distinction. We note that the most sophisticated version of quantitative and covariational reasoning includes explicit attention to such difference (Ellis, 2007; Thompson & Carlson, 2017). Even though textbooks provide opportunities for students to develop productive ways of thinking about quantities that were identified in this study, we found it unfortunate how little evidence we found of curriculum materials intentionally supporting student development of sophisticated quantitative and covariational reasoning schemas. This missing emphasis in written materials may be a partial explanation for why researchers have identified students having difficulties with ideas such as rate of change (Carlson et al., 2002)

To conclude this report, we identify some of the challenges we experienced in developing the framework. For instance, when coding the narratives and worked examples, we determined any instance the textbook seemed to promote (co)variational reasoning or to develop static meanings for quantities and variables. The units of analysis varied from phrases, to sentences, to whole paragraphs, to specific representations of mathematical objects (e.g., graphs, tables, etc.), but we would like to define parameters for our unit of analysis. We will provide examples of how our current unit of analysis influences how we code specific textbook examples and narratives. Lastly, we have been considering various methods of reporting and further analyzing the data (e.g., by textbook vs. by topic, international vs. national) and discussing affordances each offers.

**Impacts of Peer Mentorship in a Calculus Workshop on the Mentors' Identities and Academic Experiences in Undergraduate STEM**

Aditya P. Adiredja
The University of Arizona

Luis Leyva
Vanderbilt University

Jorge Mendoza
The University of Arizona

*Research has shown the positive impact of peer mentorship on the educational experiences of mentored students from underrepresented backgrounds. National survey data of peer leaders indicate that peer mentors also benefit from the mentoring experience. This report unpacks this survey finding related to peer mentors' increase in a sense of belonging in college and academic persistence as a result of participating in the mentorship. Our data draws from interviews with six historically marginalized students of color after their participation as mentors for a group of first-year calculus students during a summer bridge calculus workshop. The mentors' main responsibility was facilitating critical conversations about racial and gender in Science, Technology, Engineering, and Mathematics (STEM). Preliminary analyses found that mentoring contributed to their confidence in succeeding in a STEM field and their ability to make sense of gendered and racialized educational experiences in STEM.*

*Keywords:* equity, identity, peer mentors, STEM

Research has documented the benefits of mentorship in facilitating persistence of students of color in Science, Technology, Engineering, and Mathematics (STEM; Griffin et al., 2010). Some research has shown that, second to faculty mentoring, peer involvement is the strongest predictor of African American and Hispanic students' academic performance and educational satisfaction (Cole, 2008). Some qualitative studies have also documented the desire for many successful students of color in STEM to give back and be role models in their communities (e.g., Ellington & Frederick, 2010; McGee & Martin, 2011). Peer mentors can be defined as, "students who have been selected and trained to offer educational services to their peers [that] are intentionally designed to assist in the adjustment, satisfaction, and persistence of students toward attainment of their educational goals" (Ender & Kay, 2001, p.1 as cited in Shook & Keup, 2012). Benefits of peer mentorship on students being mentored documented in the literature include: the development of communities and relationships with students of similar identities, and the sharing of resources among students (Shook & Keup, 2012). Higher education research has also explored the benefits of peer mentorship on the institution (e.g., cost-effective student support). For this paper, we focus on the benefits of peer mentorship on the mentors themselves.

The National Peer Leadership Survey by the National Resource Center for The First-Year Experience and Students in Transition in 2009 found that, among the nearly two thousand students in peer leadership programs in different institutions, 81 percent of them said that their experience increased feeling of belonging at the institution. Seventy-one percent indicated an increase in their desire to persist academically (Shook & Keup, 2012). This paper aims to unpack those findings from the survey. In particular, we want to explore possible mechanisms behind the increase in sense of belonging and desire to persist in the discipline. Thus, in this report, we focus on the following research question: How does participating in a peer mentorship program about race and gender in STEM impact the mentors' STEM identities and participation?

## Theoretical Frameworks

This paper employs a sociopolitical perspective, which focuses on investigating some of the accepted norms and practices within the field of mathematics that privilege some people while excluding others (Gutiérrez, 2013; Valero, 2004). Gutiérrez (2013) explains that adopting a sociopolitical perspective involves considering the interrelatedness of knowledge, power, identity, and social discourse. This is to say that power and positioning as a result of existing narratives about groups of students impact the way they see themselves as learners and how they learn. Past research in mathematics education has illustrated how students' identity constructions shape participation and vice versa in mathematics learning specifically (Boaler & Greeno, 20002; Esmonde, Brodie, Dookie, & Takeuchi, 2009; Cobb, Gresalfi, & Hodge, 2006; Langer-Osuna, 2011; Martin, 2000; Oppland-Cordell, 2014). We build on these insights to explore the connections between identities and participation in STEM and the more informal learning context of peer mentoring.

Martin (2000) presented a multi-level framework on sociohistorical, community, school, and intrapersonal influences on African American students' racialized opportunities for mathematical participation and co-constructions of mathematics and social identities. Martin (2000) defined *mathematics identity* as individuals' beliefs about "their ability to perform in mathematical contexts, the instrumental importance of mathematical knowledge, constraints and opportunities in mathematical contexts, and the resulting motivations and strategies used to obtain mathematics knowledge" (p. 21). Our analysis is framed by an extension of Martin's (2000) framework and definition to allow for consideration of how other social identities (e.g., gender) intersect with race to shape peer mentors' identities and participation in STEM.

## Methods

### Context

The Calculus summer workshop was originally designed to increase the representation of underrepresented minority students in the mathematics major. The five-day summer calculus workshop prepares students for their first calculus course in college, highlights productive study skills, and builds a peer support network. Students also receive individual academic advising. As part of the workshop, students engaged in five critical conversations about race, gender, and STEM. The curriculum for the conversations was designed in collaboration with the Dean of Students on Diversity and Inclusion. Two conversations were held during the five-day workshop, two in the fall semester, and the final session in the early spring semester. The conversations served two goals. First, they aimed to empower students with language and tools to make sense of and navigate racialized and gendered experiences they might encounter in being a STEM major (McGee & Stovall, 2015). Second, the conversations were opportunities for students to check in about their first semester in college and their calculus course. Topics for the conversations included students' hopes and fears about their first semester, the importance of a STEM network, and stereotype threat and management.

### Data Source

This study is part of a larger study investigating the impact of the summer workshop and critical conversations on participants' personal and academic success. Eight peer mentors received training in facilitating conversations about race and gender in STEM. We recruited these students from different cultural centers on campus. Their training mainly involved engaging students in activities that their mentees would complete. They also received some training on opening and facilitating discussions. Six of the eight peer mentors for the workshop participated in an individual 60-90 minute exit interview at the end of their participation. Their background information is provided in Table 1. In addition, as part of their training for the 2017 workshop, they briefly reflected as a group on their experiences as a peer mentor in the 2016 workshop.

*Table 1. Peer Mentors Personal and Academic Background*

| Student | Racial/Ethnic Background | Academic Major | Grade Level |
|---|---|---|---|
| Fernando | Hispanic/Latinx | Physiology[a] | Sophomore |
| Hamza | African American/ Black | Physiology | Junior |
| Hugo | Hispanic/Latinx | Biochemistry & Molecular and Cell Biology | Senior |
| Lorena | Hispanic/Latinx | Physiology | Sophomore |
| Sarah | Hispanic/Latinx | Biochemistry | Sophomore |
| Sabrina | Hispanic/Latinx & White (Non-Hispanic) | Physiology | Junior |

[a]Most students planning to attend medical school major in Physiology

We were able to observe impacts of their participation as students reflected on their own STEM learning experiences and related them to their social identities. We looked for statements where there was a clear attribution of a change in behavior to participation in the peer mentorship program. We transcribed all of the interviews. The first author of this report is the interviewer in the study.

## Analysis

We specifically focus on the impacts of the peer mentorship on the way students perceived their experiences and participation in the STEM field. Some themes emerged from our analysis. The critical conversations that these students facilitated focused on empowering students with language and tools to make sense of and navigate any racialized and gendered experiences. Most of the themes that emerged related to students' identities and sense-making of their own racialized and gendered STEM experiences.

One of the documented benefits of peer mentorship for mentored students was that it provided them opportunities to connect with mentors who shared similar social identities. We found that the peer mentors experienced similar benefit. Hamza spoke about the impact of the peer mentorship and critical conversations on him as a Somali-American:

> It was impactful because it was the first type of conversation I was able to have on campus here at the University. It was special for me. Myself, I am going through social identities and finding out who I am /…/ I don't get to have conversations with other immigrants because of distinct language barrier. I didn't grow up knowing Somali. Me and like all the other refugees that came, there is that distinct separation. When my parents came in the 1970s and other families came in 2002 and 2001. So I, there is a very big disconnect between that point and I was able to have the discussion, yeah this is what it's like. I really liked having our conversation.

There happened to be two Somali students in the workshop that summer, and it provided Hamza with a particularly powerful experience. Lorena shared a similar experience of resonating with a

Hispanic mentee's feelings of isolation on September 16th, Mexican Independence Day. The mentee shared with Lorena that he noticed that no one in class knew the significance of that day.

Five of the six students mentioned at least one specific racialized and gendered experience that they identified after participating in the program. Sabrina shared her awareness of being the only woman of color in her research lab. In her reflection, she spoke about how the training she received as part of this program helped her make sense of this experience and allowed her to learn from and relate to another peer mentor.

*Sabrina:* Especially in a lab or something and I think I have thought about it more because of this peer mentor stuff because the first time I walked in there I was like oh this is what doctor Adi and everyone was talking about. This is weird [*laughs*]. So I have never had an experience like that. So that was just so weird on the very first day.

*Interviewer:* So we had a conversation like this? Was before the training or was it during the training?

*Sabrina:* Yeah. It was during the training. I don't remember who it is, but someone was saying, it might have been Hamza, how he was saying how he was the only Black person in a sea of White people. I think it was one of his classes. I never actually had to deal with being the only person of some sort in a sea of different people. That was the first instance where I was the only person. So I understood how he felt on the gender spectrum of it. I feel like that's something he has to deal with all the time especially here at [the university]. So, I was thinking about that couple days ago. I hope he doesn't always feel like this and coping with it and dealing with it one way or another because this is a terrible feeling. It's not a good one.

*Interviewer:* It really isn't. How has this experience helped you with your experience? The first time you recognized it but do you do anything about it. Do you do anything different?

*Sabrina:* I almost do it where we're in the lab meetings and almost intently make sure that everyone knows I'm listening like I'm nodding my head like, oh yeah. So it's almost like I want them know that I'm engaged in what they're saying and not just some undergrad who is there to not just get credit or just working in a lab, because I don't want that perception to go back on me.

McGee and Martin (2011) have shared similar accounts from other students of color in managing stereotypes by staying on top of things, sitting in front of the class, and appearing engaged. What is powerful about Sabrina's learning is that her awareness led to this change in behavior, but it also allowed her to empathize with other students' experiences at the university.

Lorena provides another example of a mentor making sense of a racialized STEM experience. Initially in her reflection she could not articulate what bothered her about seeing students who did not put in as much effort into their education continuing to be in her program. The interview was the first time she made sense of it. After recalling a conversation she had while walking to class with some students, she came to this conclusion:

> You know, my parents did not go to college. I'm totally here because of me. It's 100% me because I'm very smart and all these things. It is true and I don't know if it's a bad thing or it is, I'm saying true things. These people, it's not a bad thing that their parents are educated. I hope to be a very educated parent living financially stable and comfortable. But does the way that they [pause]. See, I'm talking about they. You know certain types of groups [pause]. You know like I'm just so thankful and that I can do all of this. To them it's like, "Oh. All I need to get is like a D so that my dad can keep paying

for college." It's like you're paying 12,000 dollars so that you can go to fun parties. And that's kind of my stereotype to that group of people. It's like you're doing all of that and I'm doing all this and we're still on the same track.

In this quote, Lorena not only positioned herself as a smart and resourceful student, but she also challenged the lack of consequence to the more privileged students who did not work as hard as her. This brings us to the next pattern we observed in our data: a change in self-perception and perspective as STEM students.

During their group reflection, Fernando spoke about an increase in confidence in being a STEM student as a result of his ability to give advice on the spot to the students.

*Fernando:* You've been through enough and you've done well enough. You can provide that information to help other students succeed. It gives you confidence.

*Interviewer:* Others feel free to chime in. Do you realize you're successful *after* you give the advice, or before you give the advice? Or the act of giving advice, "Oh I didn't know I could do that!"

*Fernando:* I'd say during.

*Lorena*: Yeah.

*Fernando*: They asked you a question. And it's not like you prepared for these questions. And they asked you. And you're like oh [*everyone laughs*].

*Interviewer:* Lorena is patting herself on the back.

Fernando and Lorena shared this increase in confidence as a STEM student. Hugo provided a different impact on his participation. He shared that, leading up to the peer mentorship, he had felt worn out by his class work. Interacting with students in the mentorship program gave him "more positive energy" to finish his studies.

## Discussion and Implications

The aim of this report is to unpack some of the findings from the National Peer Leadership Survey (2009). In particular, we were interested in understanding the impact of a peer mentorship program on the peer mentors' identities and participation in STEM. We found that the program impacted the peer mentors by: 1) providing them opportunities to connect with other students who shared their social identities; 2) helping them recognize and make sense of their own racialized and gendered experiences as STEM students; 3) giving them a new perspective and confidence as STEM students. We note that Fernando, Hamza, and Hugo were inspired and acquired other leadership positions on campus as a result of their participation in this program.

This report has implications on the learning and teaching of undergraduate mathematics. The aim of these conversations is to provide both the peer mentors and the calculus students a space to process racialized and gendered experiences in their STEM education. The calculus workshop and the critical conversations serve as academic and social forms of support in students' STEM educational experiences. How can we intentionally and systematically link these initiatives with calculus courses across mathematics programs? How might we extend this work to the training of graduate students as future instructors? We hope to discuss these questions during the session.

## Appendix

### Peer Mentor Exit Interview Protocol

1. Tell us about your experiences as a peer mentor?

   a. Describe an impactful experience
   b. Describe a challenging experience
2. How would you describe the STEM atmosphere at [the university]?
3. What successes have you had in your major?
4. What challenges have you had in your major?
5. Is there anything that set you apart from other students or students of color/female students in your program?
6. How do you think your different identities impact your experiences in STEM? Be sure to ask about positives.
7. Re-answer the application questions
   a. Have you ever had an experience in a STEM class where you were made aware of your race and/or gender? If so, how did you respond?
   b. Imagine you come across a 1st year student of color who is interested in becoming a STEM major. What types of advice would you give them to be successful at [the university] and in the major. Feel free to assume that they are interested in your major.
   c. Imagine you come across a 1st year student who is interested in becoming a STEM major. What types of advice would you give them to be successful at [the university] and in the major. Feel free to assume that they are interested in your major.

Validation of an Assessment for Introductory Linear Algebra Courses

Muhammad Qadeer Haider
Florida State University

*Research-based and validated open-ended assessments are useful tools to explore students' reasoning and understanding of a subject. The primary goal of this study is to validate an assessment which can accurately measure students' conceptual understanding of four focal topics, typically covered in an introductory linear algebra course; span and linear independence, systems of linear equations, linear transformations, and eigenvalues and eigenvectors. I used the assessment data of 255 students, from nine linear algebra classes at eight different institutes across the country to validate the assessment. By administering the assessment in their classes, linear algebra instructors can gauge their students' conceptual understanding of linear algebra concepts and can identify the concepts which are generally vexatious for students.*

*Key Words:* Assessment Validation, Linear Algebra, Conceptual Understanding

I draw on the research that has developed and validated assessments of student understanding at the undergraduate level in the areas of physics, calculus, and abstract algebra to inform the process of validation for the linear algebra assessment. A review of the literature on assessment development and validation has revealed that there are few research-based instruments available for the assessment of students' reasoning and conceptual understanding in undergraduate mathematics courses. Additionally, there is no reliable instrument available for large-scale usage which can measure students' conceptual understanding of linear algebra.

Math education literature privileges conceptual understanding of mathematics and identifies a disconnect between students' conceptual understanding and their ability to follow a procedure to produce correct answers. Students should learn mathematics with conceptual understanding and they should actively build new knowledge from their prior experience and knowledge (NCTM Principles and Standards for School Mathematics, 2000). Understanding mathematical concepts are critical in advanced mathematics but not trivial (Melhuish, 2015).

> "Conceptual knowledge is rich in relationships. It can be thought of as a connected web of knowledge, a network in which the linking relationships are as prominent as the discrete pieces of information…Procedural knowledge consists of rules or procedures for solving mathematical problems. It is also a familiarity with the individual symbols system and with the syntactic conventions for acceptable configurations of symbols (Hiebert & Lefevre, 1986, pp. 3,7)."

However, attending to procedures is not only about memorizing the list of steps to solve problems (Star, 2005; Hassenbrank & Hodgson, 2007). Researchers have also provided evidence that both methodologies of teaching concepts and teaching procedures can be integrated. Keene & Fortune (2016) have advocated the importance of the connection between teaching concepts and teaching procedures and proposed a framework for Relational Understanding of Procedures, the framework can help instructors to merge both types of teaching to help students better learn the subject matter.

The goal here is not to discuss the artificial dichotomy between procedural and conceptual knowledge but to support the argument that the connection between both is important for better learning. However, sometimes instructors can neglect the testing of conceptual understanding in regular class assessments and focus only on procedural questions (Tallman & Carlson, 2012). Therefore, assessments must be designed carefully to ensure that students have attended to the concepts in the course along with procedural efficiency.

Validated and reliable assessments are not only to assign grades, but many other important goals can be achieved through the assessment results. Teachers, principals, researchers, and organizations can use validated assessments for different purposes; for example, to provide feedback to students on their learning, to use as a diagnostic tool, to inform a placement criteria, to motivate students, to design and adjust student instructional activities, to distinguish between high and low performing students, to evaluate instructional innovations, and to sense overall performance of students, teachers, and organizations (e.g., Brown & Knight, 1994; Gibbs, 2003; Hestenes, Wells, & Swackhamer, 1992). Sainsbury and Walker (2007) argued that tests can also help students in focusing their attention and drive their learning process in the right direction. Additionally, a validated instrument can also evaluate efforts to improve learning and can help researchers to measure the quality and achievements of instructional innovations (Melhuish, 2015).

Research-based validated instruments are required to measure students' learning accurately. The central goal of this work is to validate an assessment which is sensitive to students’ ways of reasoning and understanding of linear algebra concepts.

## Literature Review

In this section, I organize my summary of the literature into two main categories: studies that focus on describing different phases of assessment development and studies that focus on processes for assessment validation. Most assessment development studies also discuss validation, but the focus of the studies remain to elaborate different phases of assessment development (e.g., Carlson, Oehrtman, & Engelke, 2010; Melhuish, 2015; Sadaghiani, Miller, Pollock, & Rehn, 2013). Similarly, the validation studies also briefly describe the process of their assessment development (Barniol & Zavala, 2014; Wilcox & Pollock, 2014). Since the goal of this study is to validate the linear algebra assessment, consulting the literature on assessment validation is critically important to driving my work.

Concept inventory is another assessment development and validation approach which is gaining popularity in undergraduate STEM areas. While there is no universally accepted definition of a concept inventory, Epstein (2013) defined concept inventory as a test of a student’s most basic conceptual comprehension of a subject’s foundations, not the computational skills involved. Concept inventories measure only conceptual understanding and usually concentrate on specific topics within the course curriculum (e.g., Halloun & Hestenes, 1985a, 1985b; Hestenes & Wells, 1992; Hestenes, Wells, & Swackhammer, 1992). Although all initial work on concept inventory was in the field of physics, recently researchers have developed some concept inventories for Pre-Calculus, Calculus, and Abstract Algebra (Carlson, Oehrtman, & Engelke, 2010; Epstein, 2013; Melhuish, 2015).

It is worthwhile to do the challenging work of assessment development and validation because validated assessments produce more accurate results of students' learning than usual classroom assessments. Typically, classroom assessments are loosely structured and have several limitations including a) the instructor's expertise in the subject, b) amount of time the teacher can invest to administer, grade, and provide feedback to students, and c) performance of students in one section of a course cannot be compared with the performance of students in another section of the same course (Thissen-Roe, Hunt, and Minstrell, 2004).

Assessment validation studies usually focus on validity, reliability, and discriminatory power of the entire test and individual items on the test (Barniol & Zavala, 2014). Validity is the extent to which an instrument can measure what it is supposed to measure. To establish the validity of a test, researchers use a variety of validation techniques. Content validity is a measure of how accurately test items covered the content domain the test planned to cover, and reliability of a test is the likelihood that the test will produce consistent results repeatedly (Crocker & Algina, 2008). Cronbach's alpha is a well-known statistical method to determine how closely related a set of items are as a group. A reliability index of 0.7 and higher indicates that the test is reliable for group measures. Discriminatory power is the characteristic of a test to differentiate among high and low achievers. Some statistical analysis can also determine the quality of individual items on the test. Researchers typically determine item difficulty index and item discrimination power of individual items of assessment to validate the assessment (e.g., Barniol & Zavala, 2014; Gleason, White, Thomas, Bagley, & Rice, 2015; Wilcox & Pollock, 2014). Item discrimination is the ability of an item to differentiate between high achieving and low achieving students by establishing a relationship between how well students performed on the item and their total score on the exam (Crocker & Algina, 2008).

My review of the literature on assessment development and validation revealed that there is no valid instrument available to assess conceptual understanding of undergraduate linear algebra topics. Therefore, the purpose of this work is to validate a linear algebra assessment tool which will focus on specific concepts of linear algebra and instructors can use it in their classes.

## Data Sources

Our research group has collected the assessment data as part of a broader NSF project which aimed to develop and assess a system of support for undergraduate mathematics instructors interested in teaching in inquiry-oriented ways. The project supported three subject areas: abstract algebra, differential equations, and linear algebra. The project provided participating instructors three types of support: a summer workshop, inquiry-oriented linear algebra (Inquiry-Oriented Linear Algebra IOLA; http://iola.math.vt.edu) teaching material, and a weekly online instructors' work groups (Bouhjar, Andrews-Larson, Haider, & Zandieh 2017). Previously, a team of mathematician and math educators has developed the IOLA instructional materials. The IOLA covers four major topics span, linear dependence and independence, transformations, and eigenvalues eigenvectors (Wawro, Rasmussen, Zandieh, & Larson, 2013). Linear algebra instructors usually cover these topics in introductory linear algebra classes, and the linear algebra assessment was developed to cover these four topics.

The goal of the NSF project is to improve students' learning experience in undergraduate mathematics courses; this creates a need to develop a validated assessment to measure the difference of understanding of students who attended inquiry-oriented classes. In a previous work, members of our linear algebra research group and I developed the linear algebra assessment and collected data (Haider et al., 2015). In this study, I have used the assessment data of 255 students, which were collected from linear algebra classes of nine different instructors at eight different institutions across the country to validate the assessment.

## Methods of Analysis

For this study, we first need to score the assessment data. Therefore, our research group worked together to develop a reliable scoring rubric to score the assessment copies. Statistical analysis was branched into the analysis of individual items on the test and the analysis of the entire test. More details on the development of scoring rubric, scoring process, and the analysis of data are provided in the section below.

Naturally, scoring the assessment data is the first step towards the analysis of the assessment data. To maintain the reliability of the assessment, it needs a well-defined scoring rubric so different iterations of the assessment produce comparable results. I worked with three other members of our research group to develop a scoring rubric for the assessment. Initially, a senior math education researcher developed a solution key by using a variety of student approaches from pilot data. The solution key was discussed, adjusted, and explained to other members of the group to make sure that every team member completely understood every question and a potential solution of each item. I randomly selected ten copies of the assessment from the entire data set and four researchers independently identified if the given response is correct, incorrect, or partially correct according to the solution key. If we noticed other correct approaches apart from initial solution key, I added those approaches to the potential solutions.

Later, the researchers discussed and resolved any disagreements that appeared and made four categories of student responses: fully correct (awarded 3 points), partially correct (awarded 2 points), some relevant information provided (awarded 1point), and completely incorrect and irrelevant answers (awarded 0 points). For the pilot testing of the scoring rubric, I again randomly selected six different copies of the assessment from the data, made four copies of the six assessments, and every researcher in our research group scored the first question of the assessments following the scoring scheme independently, and then we compared the scores among the team members. We repeated this processes for all the questions on the assessment, and on average, there was more than 85% agreement among the researchers. We also discussed all the disagreements and came to a consensus and fine-tuned the scoring rubric accordingly.

After finalizing the scoring rubric, the next step was to score the assessment data. I randomly selected one-third of the assessment copies (i.e., 85 copies out of 255) with the help of random number generator tool. To ensure the accuracy of my scoring, I will randomly select 20% of the scores copies, and members of my research group will double code those assessment copies. We will be looking for more than 80% of intercoder reliability. The process will be repeated for the rest of the data.

## Analysis of the Assessment and Validation Results

The linear algebra assessment was designed to align with the four main topics of IOLA material, which were mentioned earlier, and the goal of this study is to validate the assessment. Initial analysis shows that all the items on the test have discriminatory power and item are reasonably correlated with each other. Overall, the assessment is reliable enough to use for large groups. For the initial findings, I have scored and used 51 assessment copies in the statistical analysis. Next analysis with larger data set will support the current findings.

During the development of the test, the content validity was established through expert validation. The content areas of the assessment and selected questions for each area were consulted with three mathematics faculty members at three different institutions. The field experts helped us to identify the items which focused on the four focal topics and had potential to measure students' conceptual understanding of those topics.

I used Cronbach's alpha to measure the overall test reliability and found $\alpha = .74$ for all questions (including multiple-choice and open-ended parts), which shows that the assessment is acceptably reliable. However, when I checked the Cronbach's alpha for multiple-choice and open-ended questions separately, the values of $\alpha$ were dropped to .49 and .66 respectively. Item-total statistics showed that deleting any item from the test will decrease the reliability of the assessment. These statistics show that separating MCQs and open-ended items or deleting an entire item will adversely affect the assessment reliability. Statistical analysis of the assessment also revealed none of the items on the assessment have a negative correlation with other items and the corrected item-total correlation for all items is between 34% and 68%. This shows that items are not completely disconnected, but they also do not measure the same construct redundantly.

At item level analysis, the average score of all items was between 54% and 83%, which indicates that some items on the assessment were easier than others. Overall, the average score of students on multiple-choice items was 69%, and slightly lower, 65% of the open-ended items. A separate analysis of the performance of students in four focal areas showed that students performed better on the questions related to span, linear independence, and system of linear equations where the average score was above 75%. However, students were struggling with transformation and eigenvalues & eigenvectors questions where the average score was less than 65%. These results indicate that the linear algebra assessment can help to differentiate among high and low achievers and to identify the linear algebra concepts which are typically challenging for students.

## Questions for Audience

- What are the methodological issues and disadvantages for having different types of questions (variety of MCQs, true/false, fill in the blanks, and open-ended) in one assessment?
- What are other appropriate validation techniques for an assessment with mixed format items?
- How can I gradually shift this work towards concept inventories? What could be possible methodological difficulties in the shift?

Guiding *Whose* Reinventions?
A Gendered Analysis of Discussions in Inquiry-Oriented Mathematics

Christine Andrews-Larson, Cihan Can, and Alexis Angstadt
Florida State University

*The under-representation of women in STEM fields is well-documented and undisputed. Evidence suggests that students' experiences in undergraduate mathematics courses contributes to this disparity, and that student-centered approaches to instruction may be more equitable than lecture-based approaches. However, the generalizability of this finding has not been established. In this study, we explore how female students are positioned in whole class discussions in two inquiry-oriented mathematics classes selected to reflect differences in how female students reported experiencing whole class discussions.*

*Key words:* inquiry, equity, linear algebra, argumentation

Gender-based disparities in various forms of mathematics participation are well documented. For instance, women make up 50% of the workforce but only 25% of the STEM workforce (Beede, Julian, Langdon, McKittrick, Khan, and Doms, 2011). Two possible explanations for this disparity are that biological differences give rise to different abilities or preferences, or that these differences are socially constructed. In a critical analysis of literature related to gender and mathematics learning, Leyva (2017) argues that studies of both achievement and participation in mathematics suggest these differences are socially constructed. The rates at which women choose to discontinue study in math-intensive fields following first semester college calculus suggest that inequities in the way students experience collegiate mathematical learning environments likely contribute to these gender disparities (Ellis, Fosdick, and Rasmussen, 2016).

Recent research has suggested that student-centered approaches to instruction in undergraduate mathematics are related to improved and more equitable outcomes for students, particularly when considering gender differences (Laursen, Hassi, Kogan, & Weston, 2014). However, the mechanisms by which such instructional approaches relate to more equitable outcomes for women are not well understood. Some have raised questions about whether Laursen and colleagues' (2014) findings in the context of Inquiry Based Learning (IBL) classes apply to their own efforts to teach in student-centered ways (e.g. Hagman, 2017). This begs the question: Are emerging research-based, student-centered approaches to instruction contributing to or disrupting the pattern of underrepresentation of women in mathematics? More broadly, when and under what conditions are student-centered approaches to instruction more equitable? These broader questions are beyond the scope of this preliminary report, but we aim to move toward answering them by taking on the following, more modest set of questions:

- How do instructors distribute opportunities to contribute to whole class discussions in inquiry-oriented mathematics classes, and how does this relate to the gender composition of the class? (Who is invited to / does contribute and how are contributions framed?)
- How do whole class mathematics discussions vary in relation to how male and female students experience them?

## Literature & Theoretical Framing

We broadly adopt a socio-political perspective, taking the view that knowledge is constructed through social discourses, and that power and identity play important roles in the construction of that knowledge (Adiredja & Andrews-Larson, 2017). Inquiry-oriented instructional approaches aim to support students' reinvention of important mathematical ideas through sequences of carefully designed tasks; they are instructionally complex in that instructors inquire into students' thinking as students are inquiring into mathematics (Kwon & Rasmussen, 2007). Such approaches reposition students to take mathematical authority in a way that may reorganize traditional norms of knowledge construction associated with lecture-based classes. We aim to relate this instructional approach to literature on gender equity in mathematics, as well as settings of cooperative learning and decision making.

Some literature suggests that learning environments that require students to develop their own problem-solving strategies may favor male students in that development of invented approaches aligns with traits traditionally valued as masculine (e.g. independence and confidence), whereas use of standard algorithms aligns with traits like compliance, which are traditionally valued as feminine (Fennema, Carpenter, Jacobs, Franke, & Levi's, 1998; Hyde & Jaffe, 1998). Other literature suggests that female students acclimate better than their male peers to learning environments that emphasize collaboration, work on open-ended problems, and conceptual understanding (Boaler 1997; 2002). Laursen et al.'s (2014) work suggests that reform-based approaches that involve collaborative problem solving may 'even the playing field' for male and female students.

Research from other fields on group decision-making suggests female students are likely to experience marginalization in instructional settings that involve collaborative group work. Karpowitz, Mendelberg, and Shaker (2012) found that when a group was charged with arriving at a decision, women spoke significantly less and were interrupted more frequently (undermining their ability to influence the group's decisions) when they were in the minority. When a group was required to come to consensus, women did not experience this. In mathematical classrooms where discussions are facilitated, students from non-dominant groups (including women) are often marginalized (Becker, 1981; Black, 2004; Walshaw & Anthony, 2008). If emergent research-based instructional approaches are to broaden participation in mathematics by constructing more equitable learning environments, it is important that we consider the gendered and racialized experiences of students in these courses. In this preliminary report, we contribute to this goal by examining gender dynamics in two inquiry-oriented classrooms.

## Data Sources, Case Selection, and Methods of Analysis

We draw on data taken from a broader project interested in the teaching and learning of undergraduate mathematics through inquiry-oriented pedagogy. Instructors in this project received three forms of instructional support: access to research-based instructional sequences with implementation notes, a 16 hour summer workshop, and facilitated weekly online workgroups in the semester when they implemented the instructional materials. In this analysis, we use student surveys from seven classrooms at different institutions to select cases in which there was evidence of gender-based differences in how students were experiencing whole class discussions. We then analyzed video recordings of the selected cases to examine the relationship between mathematical discussions and gendered interactions in these classess.

Students' views of their experience in the course were captured using the Student Assessment of their Learning Gains in Mathematics (SALG-M) instrument (Seymour, Wiese, Hunter, & Daffinrud, 2000; accessible at http://salgsite.org/); surveys were conducted at the end of the semester via Qualtrics, an online survey platform. Classroom videos were recorded from two different instructional units, each of which included 2-3 days of classroom instruction. We selected video from the second instructional unit to analyze, as it took place later in the semester when instructors were more likely to be familiar with the instructional approach and classroom norms were more likely to be well-established. The instructional unit is described in Zandieh, Wawro, and Rasmussen (2017).

To select cases, we first eliminated classess with survey response rates lower than 40%. We then disaggregated students' survey responses by their self-reported gender for each class, and identified classes in which female students reported learning more from whole class discussions than male students and vice versa. We selected two classes, one from each of these categories, with similar class size and gender composition (15-20 students, approximately 25% female). On the survey, no students in either of the classes selected for analysis identified as a gender other than male or female. In video analysis we relied on visual and audio cues (e.g. hair length and style, clothing, vocal pitch, names and pronouns used) to make inferences about the gender of participants when analyzing video data. As such, all claims about participants are based on the researchers' interpretation of gender expression.

Following the selection of two cases, we created summaries of the video recordings of the two classrooms, where we first attempted to characterize instruction in each class broadly. We paid particular attention to the framing of student contributions by the instructors, how students and the instructor attributed mathematical authority, and distribution of opportunities for students' participation to the mathematical discourse in the classroom – with an eye toward gender throughout. We then transcribed the whole class discussions to analyze the mathematical argumentation, paying particular attention to how opportunities and expectations for female students to participate were framed. To this end, we selected mathematically similar focal episodes of similar length (~9 minute long whole class discussion) in the two classrooms. Both discussions addressed the image of $\begin{bmatrix} -2 \\ 2 \end{bmatrix}$ under a linear transformation from $R^2 \rightarrow R^2$ that fixed points along the line $y = x$ and stretched points in the direction $y = -3x$ by a factor of 2.

## Initial Findings

The number and nature of contributions made during whole class discussions by students of each gender in each class appear in Table 1. We note that female students contributed 50% of the student ideas in instructor B's class, which is a greater portion than instructor A's class. Table 2 reorganizes student contributions according the ways in which those contributions were solicited (also sorted by the gender of student who made the contribution). Similar portions of female students offered unsolicited contributions in both classes, but instructor A called only on male students by name, and instructor B called on only female students by name. In instructor A's class, female students volunteered to speak at slightly lower rates than in instructor B's class.

Table 1: Number of contributions by nature of student contribution

| | Word or phrase | | Question | | Idea | |
|---|---|---|---|---|---|---|
| Instructor | Female | Male | Female | Male | Female | Male |
| A | 1 | 5 | 0 | 2 | 1 | 7 |
| B | 6 | 17 | 0 | 2 | 3 | 3 |

Taken together, this suggests instructor B made deliberate efforts to include female students in whole class discussion. Based on this information, the reader might think that female students reported getting more out of whole class discussions in instructor B's class than instructor A's class. Interestingly, this is not the case. To better understand the nature of differences in whole class discussions, we describe for each instructor, the task set-up, group formation and composition, and mathematical content of whole class discussion of the focal episode.

Table 2: Number of contributions by nature of instructor solicitation

| | Unsolicited | | Called by name | | Volunteer requested | |
|---|---|---|---|---|---|---|
| Instructor | Female | Male | Female | Male | Female | Male |
| A | 1 | 4 | 0 | 3 | 1 | 7 |
| B | 1 | 4 | 3 | 0 | 4 | 19 |

**Development of Mathematics: Instructor A**

*Task setup and grouping:* Before students began working on the task in groups, the instructor framed the task as difficult to understand, noting that she did the problem incorrectly in her first attempt. The instructor asked students to read the task to themselves, then to explain their understanding of what is happening to make sure they are all interpreting the task the same before the students began working on the task in small groups. Students were in groups before the camera was turned on. In interviews, the instructor had indicated an explicit effort to avoid isolating female students in predominantly male groups.

*Whole class discussion:* After students had worked in the groups for some time, the instructor stops students, telling them she has asked one particular student to share his idea. The instructor noted that this student didn't have it all figured out but that his group's ideas might be helpful for everyone to consider.

MS1: So, basically what we did is we started by sketching $y={}^{-}3x$ and $y=x$. We decided to draw parallel lines next to it so we could get a better visual understanding to see how to sketch. We understand from the above these parts are going to stay and these are going to stretch like this. So, we tried to fix points on corners of the box to see how it goes. What we understood is, the farther it gets from the $y=x$ axis, you could say, the points will stretch farther. So it'll have this sort of diagonal look, if that makes sense.

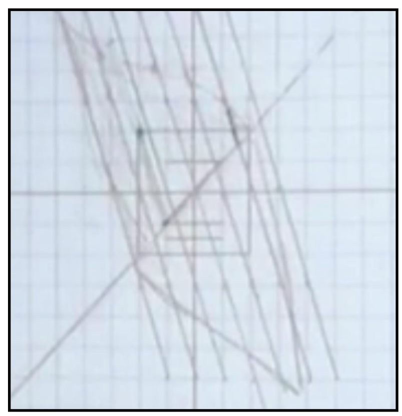

Figure 1. MS1's drawing

After the student had argued that points farther from the "$y=x$ axis" will stretch further than points close to that axis, the instructor asked students where points were stretching "from" – eliciting responses that revealed disgreement on this point. One student (incorrectly) suggested they stretched from the origin, so the instructor drew a line from the origin to the point and noted that wouldn't be in the direction of stretch stated in the problem. The instructor clarified that points stretch from the y=x axis, as the presenter had indicated, before extending this argument to geometrically show how $\begin{bmatrix}-2\\2\end{bmatrix}$ maps to $\begin{bmatrix}-3\\5\end{bmatrix}$ under this transformation by doubling its distance from the $y = x$ line in the direction of the $y = -3x$ line.

**Development of Mathematics: Instructor B**

*Task setup and grouping:* Students were expected to complete the first part of the task before class. Students were asked to "share with everybody in your table what you think this image looks like." Then, students spent about three minutes in their groups to talk about their drawings. Although students were in groups before the camera was turned on, the instructor changed that formation, saying, "I wanna form a did-the-work-[assigned at home] group over here. The rest of you can work for two minutes without the benefit of […] the people who did their work." In contrast with instructor A's class, there were no female majority groups.

*Whole class discussion initiation:* The instructor requested a group to volunteer to share their solutions for the second part of the task following their work in small groups. There were no volunteers, and the instructor called a female student by name to ask if her group would share. The discussion began:

FMS1: We use that matrix to transform the two vectors $\begin{bmatrix}2\\0\end{bmatrix}$ and $\begin{bmatrix}-2\\2\end{bmatrix}$ to see what their transformed values would be. So, we did matrix multiplication with matrix A times $\begin{bmatrix}2\\0\end{bmatrix}$ and then times $\begin{bmatrix}-2\\2\end{bmatrix}$ to find this. Any questions?

I: I got a question. How did you go about finding the matrix with those two you knew?

FMS2: Well, so, we say that T is $x_1$, $x_2$, and then $x_3$, $x_4$, and then you multiply that out again then using the rules of matrix multiplication. You get these four… equations and then you can use equations to solve for the four unknowns and hence you get that. [pointing to the matrix on the board.]

I: Did anybody do it a different way?

MS: I used linear combinations… first of all $\begin{bmatrix}2\\0\end{bmatrix}$… I got the linear combination of 1.5 times $\begin{bmatrix}1\\1\end{bmatrix}$ and 0.5 times $\begin{bmatrix}1\\-3\end{bmatrix}$. So, then when you multiply the $\begin{bmatrix}1\\-3\end{bmatrix}$ times 2 you got $\begin{bmatrix}2.5\\-1.5\end{bmatrix}$, which I was glad to see because that is a, that's what it would look like in my graph. And, then I used the same procedure to get a vector transformation of $\begin{bmatrix}-2\\2\end{bmatrix}$ to equal to $\begin{bmatrix}-3\\5\end{bmatrix}$.

The instructor then agreed that both methods were sensible and correct, referring to the first group's approach using matrix muliplication as "Method 1" and the second group's approach using the linear combinations as "Method 2." The instructor recapped the two methods and offered an explanation for how they related to one another.

## Discussion

Our analysis suggests that identifying female students with correct solutions and asking them to share does not ensure a more equitable learning environment for female students. Taken together with the literature, our findings suggest that female students report getting more out of whole class discussions in the class where we observed explicit discussion of the ambiguity of mathematics and underlying meanings, intuition, and interpretation. It is both plausible and likely that factors beyond what we were able to observe in whole class discussion contributed to different student experiences, and we are eager for feedback to inform our ongoing analysis.

Modus Tollens in Modeling

Jennifer A. Czocher
Texas State University

Jenna K. Tague
Fresno State University

*The purpose of this paper is to present a case study of a mathematics major exhibiting logical reasoning to validate her mathematical model. The case study demonstrates how constructing a mathematical model can be construed as making an argument for its validity.*

*Keywords:* mathematical modeling, mathematical argumentation, mathematics majors

There is a plurality of views and foci on teaching and learning mathematical modeling (Cai et al., 2014). The cognitive view on modeling has focused on how the modeler transforms the nonmathematical problem into a mathematical one (Kaiser & Sriraman, 2006). Several frameworks have been introduced to capture this transformation and allow it to be finely analyzed according to modeling competencies (Blum & Leiß, 2007), prior mathematical knowledge (e.g., Stillman, 2000), prior real-world knowledge (e.g., Czocher, under review), and theories of metacognition arising from problem solving (e.g., Galbraith & Stillman, 2006; Panaoura, Gagatsis, & Demetriou, 2009). While prior analyses have explained a great deal of how productive and unproductive moves within the modeling process may be characterized, they are limited to examining only specific modeler moves *within* the modeling process. With respect to mathematical reasoning, these frameworks are limited to examining only the mathematics the modeler uses to set up, analyze, compute, or solve the resulting model which can usually be explained in terms of the mathematics content intended by the task writer. That is, these frameworks do not allow documentation of validating the model if the means to do so fall outside of the expected mathematics or modeling context. This paper presents a case study of how an individual might use logic to guide her use of mathematical content knowledge. We follow with a discussion of why students' logic might have been overlooked in other frameworks and then discuss why an alternative lens for examining modeling behavior, especially of more advanced students, is promising for shedding light on similarities among modeling, problem solving, and proving.

## Background

From a cognitive perspective, studying mathematical modeling means attending to the mathematical thinking that produces the model (Borromeo Ferri, 2007). Mathematical modeling is viewed as a process that transforms a question about the real world into a mathematical problem to solve (Frejd, 2013). The answer to the mathematical problem is then interpreted as a solution to the real world problem. This process is often represented as a cycle (e.g., Blum & Leiß, 2007), which is summarized in Table 1. Much of the research on modeling from the cognitive perspective focuses on the simplifying/structuring phase (identifying variables, making assumptions) and on the mathematizing phase (introducing conventional representational systems). Comparatively less research has focused on validating, which involves checking that the mathematical model is representative of the situation and that it is correctly analyzed (solved) mathematically. Validating is challenging to study because of how the modeler perceives and resolves cognitive conflict between their expectations of their model (e.g., predictions) and outcomes (e.g., empirical observations) (Czocher, 2014, 2015). Students may respond to cognitive conflicts in less-than-ideal ways (Goos, 2002). They may fail to notice that something is amiss, perceive difficulties that do not exist, provide an inadequate response, or even change the problem to suit their readily-available knowledge (Goos, 1998, 2002; Stillman, 2011). Indeed, some have observed that validating is a "uniform shortcoming" of students' mathematical modeling because they do not *reflect* to improve their models at all (e.g., Blum & Leiß, 2007). However, some small amount of work has revealed that engineering undergraduates do engage in validating their models, typically through techniques like dimensional analysis, checking special and limiting cases, making comparisons to empirical results, and relying on number sense (Czocher, 2013). On the other hand, mathematics majors' conditional reasoning has been documented, particularly as it relates to comprehending an argument (Alcock, Bailey, Inglis, & Docherty, 2014). The following analysis is an effort to begin to document and understand the reasoning mathematics majors use to validate their mathematical modeling work.

*Table 1 Indicators from the observational rubric to identify subprocesses in the MMC* (Czocher, 2016)

| Modeling Subprocess | Definition | Examples of Observed Student Activity |
|---|---|---|
| Understanding | Forming an initial idea about what the problem is asking | Reading the task<br>Clarifying what needs to be accomplished |
| Simplifying & structuring | Identify critical components of the mathematical model (i.e., create an idealized view of the problem) | Listing assumptions or specifying conditions<br>Identifying variables, parameters, or constants<br>Operationalizing quantities or relationships |
| Mathematizing | Represent the idealized model mathematically | Writing or speaking mathematical representations of ideas (e.g., symbols, equations, graphs, tables, .) |
| Working mathematically | Mathematical analysis | Explicit algebraic or arithmetic manipulations<br>Making inferences and deductions without reference to nonmathematical knowledge<br>Changing mathematical reprsentation |
| Interpreting | Recontextualizing the mathematical result | Speaking about the result in context of the problem or referring to units<br>Considering if the result answers the question posed |
| Validating | Verifying results against constraints | Implicit or explicit statements about the reasonableness of the answer/representation<br>Checking extreme or special cases of variables, parameters, relationships, etc.<br>Dimensional analysis of units |

## Methods

Qualitative data were generated via an individual task-based interview (Clement, 2000; Goldin, 2000). The tasks were a variety of modeling and application problems drawn from previous research (e.g., Ärlebäck, 2009; Czocher, 2016; Schoenfeld, 1982; Swetz & Hartzler, 1991). The 10 tasks were sufficiently open to allow participants to select their own variables, assumptions, and solution techniques. The purpose of the interviews was to elicit participants' mathematical thinking as they engaged in mathematical modeling; the interviewer did not guide participants to a solution, but intervened only to request clarification or to extend the task. In this paper, we focus on a single case to illustrate a mathematics major's reasoning on a conventional word problem. The case is illustrative of a mathematics major using clearly outlined logic despite arriving at a wrong answer. The data are presented and analyzed as a narrative, a "spoken or written text giving an account of an event/action or series of events/actions, chronologically connected" (Czarniawska, 2004, p. 17). To do so, we view the interview participant, Safi, as presenting an account her series of decisions during mathematical modeling.

Safi was a senior mathematics major at a large southwestern university. She was enrolled in a vector calculus course and stated that her favorite subjects thus far were "linear algebra, hands down, and differential equations." She was nearing completion of her mathematics requirements and was seeking secondary teacher certification. Safi had completed her first classroom internship in geometry at a local high school, but stated a preference for teaching algebra.  The following semester, before graduation, she was scheduled to do her student teaching in an algebra 2 classroom. Safi did not describe herself as good at mathematics. She said, "since being here [at university] I have struggled with like my math classes and everything but I've worked really hard to get even like the C's I have gotten." Safi valued the hard work she put into her classes, which fueled her drive to be a teacher, despite the fact that the higher level mathematics courses she didn't "really see being useful, like the proof classes." She elaborated that the content of the proof classes would not be something she used in her high school classes but that "maybe the different way of thinking" would be useful.

Below, we present Safi's work on the Turkeys & Goats problem (Czocher & Maldonado, 2015) and analyze it in terms of the correctness of her response, her engagement in mathematical modeling, and the reasoning she used to arrive at her conclusions. The problem was: *A nearby farm raises turkeys and goats. In the morning, the farmer counts 48 heads and 134 legs among the animals on the farm. How many goats and how many turkeys does he have?* The problem is a word problem (see Gerofsky, 1996) that is ubiquitous in secondary school algebra textbooks and on standardized tests. The answer, 19 goats and 29 turkeys, can be obtained in a variety of ways including setting up a system of two equations in two unknowns. Because of Safi's mathematical training and recent experiences in mathematics pedagogy, the task was well within her capabilities. In order to analyze Safi's engagement in modeling, the observational rubric from Table 1 was applied. When Safi was observed, in speech or writing, to be carrying out one of the activities in the right-most column, her activity was coded with the corresponding modeling subprocess from the left-most column.

## Presentation of Safi's Reasoning

Safi began by reading the Turkeys & Goats problem aloud [understanding]. She then emphasized some information, "48 heads and 134 legs" which she repeated aloud and wrote down [simplifying/structuring]. She then explicitly identified what needed to be accomplished, "and then they're asking how many of each animal" [understanding]. She narrated her reasoning, "48 heads means he has 48 animals in total because he wouldn't have more heads than animals because that wouldn't make sense." In this statement, Safi engaged in both simplifying/structuring because she established the condition that 48 heads means 48 animals in total and validating because she was evaluating its sensibility. To carry out her validating, she used counterfactual reasoning (reasoning from a situation that doesn't or can't exist) to set up and evaluate a brief propositional logic argument positing a one-to-one correspondence between heads and animals. She assigned the variable $x$ to the number of turkeys and the variable $y$ to the number of goats [mathematizing]. She then wrote the two equations $x + y = 48$ and $2x + 4y = 134$ [mathematizing], checking that "two legs per turkey will give you the amount of turkey" legs [validating]. Safi used elimination method to solve the system [working mathematically]. She obtained $y = 19$ which she interpreted to mean "there should be 19 goats" [interpreting]. Then to obtain the number of turkeys, she computed $48 - 19 = 27$ using the standard algorithm [working mathematically]. She wrote 27 turkeys [interpreting]. To check her work, she used standard algorithms to compute $2 \times 27 + 4 \times 19 = 134$ [validating]. She obtained 130 for the left hand side. She asked "Am I allowed to ask you the amount of turkey legs?"

Safi had arrived at a contradiction: her solution 19 goats and 27 turkeys did not yield the same number of legs set by the conditions in the problem statement. Her first recourse was not to doubt her computation but to doubt whether turkeys had 2 legs. The interviewer followed up by exploring whether 2 legs per turkey was a logical antecedent or logical consequence of 19 goats.

*Safi*: I solved it with turkeys having two legs, but I am short 4 legs.

*Interviewer*: You're short 4 legs. And you are certain that they are turkey legs?

*Safi*: No. But if turkeys have 2, then I am not sure. Well, 'cause I solved it to where goats have the 19, there were 19 goats.

*Interviewer*: Okay, so given that turkeys have 2 legs, there must be 19 goats. Is that what you're saying?

*Safi*: Yeas. Oh wait, wait wait. But okay wait. The goats here…they have 38 legs, and then [[talks quietly then laughs]]. Yeah, so given that turkeys have 2 legs, there should be 19 goats.

Safi continued this chain of logical reasoning to argue that given that turkeys have 2 legs, there must be 19 goats, so there have to be 27 turkeys. There can't be 27 turkeys because $27 \times 2 = 54$, meaning just turkeys alone would have 54 legs. Given that there are 19 goats and goats have 4 legs, they would have 76 legs. Altogether there would be 130 legs, which is too few legs. Safi "called into question" the assumption that turkeys have 2 legs.

After a brief discussion about why Safi had chosen to use the operations + and × where and how she did to set up her system of equations, the interviewer extended the problem. Instead of Turkeys and Goats, the interviewer posed a problem in which the farm had pigs and goats, with 48 heads and 134 legs. The resulting system of equations was inconsistent. Safi set up the equations, solved them via elimination and obtained the result "0 equals negative." She interpreted it to mean that there could be no goats and therefore there were 48 pigs.

*Safi*: But then if you have 48 pigs, each pig should have 4 legs, which would mean 192 legs. But there is 134. So that's, that's not accurate.

*Interviewer*: Which isn't accurate? The 192 or the 134 or something else?

*Safi*: Well, if you're paying attention to the heads, like it depends on what you're looking for, if you're looking at the heads. Then the legs, the 134 doesn't make sense because you have more, you realistically have 192 legs here with 48 pigs. And it says you only have 134. So that's not enough to complete your farm [[laughs]].

*Interviewer*: So, when you, I noticed you like put in this adjective there, you "realistically" how would you have 192 legs? What did you mean by that?

*Safi*: So, we mean, you could have pigs missing legs. Um, 'cause they don't need four legs to be able to live so if you take out some, we mean we guess you could get to 134. But realistically, if they all have 4 legs then that's how many you would have, you have 192.

In follow-up questioning, Safi revealed that she noticed that both versions of the problem were similar to those she had seen in "algebra and algebra 2 and linear algebra" and so she was readily able to set up the system of equations and "in order to solve for each variable you usually just do any process that you can," though she did not use the vocabulary of linear algebra to seek solutions or explain the lack of solutions to each system.

## Discussion and Conclusions

Safi did not arrive at the correct solution for either the Turkeys & Goats problem, due to the arithmetic error $48 - 19 = 27$. She also did not realize that there was no solution to the system of equations she derived for the extension problem although she recognized a contradiction for the number of legs required. However, in both versions of the task she did engage in the cognitive activities underlying mathematical modeling (as suggested by the observational rubric) and she did reach conclusions that were logically consistent with the information she gleaned from the task statement. On the surface, it seems unreasonable that Safi would doubt a basic fact like *turkeys have two legs*. Closer inspection reveals that it is a logical consequence of an argument she constructed to validate her model (the system of two equations in two unknowns) and its prediction (the number of turkeys and goats on the farm). Table 2 shows her argument's structure mapped to propositional logic:

*Table 2. Safi's logical argument*

| | | | |
|---|---|---|---|
| 1. | There are 134 legs on the farm (premise) | 5. | There are 27 turkeys (3, 4) |
| 2. | Turkeys have two legs (premise) | 6. | There are 130 legs on the farm (3, 4, 5) |
| 3. | The system $x + y = 48$, $2x + 4y = 134$ describes the number of animals on the farm (1, 2) | 7. | Contradiction (1, 6). |
| 4. | There are 19 goats (3) | 8. | Reject (2). |

Safi checked her by-hand computations twice to be sure that (4) and (5) turned out correct (committing the same mental arithmetic error each time). Her only course of action, logically, is to reject one of the two premises upon which (3) stands. Since (1) is given in the problem, she must reject (2). Her spoken argument can be reduced to the form of modus tollens: If turkeys have two legs, then there are 130 legs on the farm. There are not 130 legs on the farm. Therefore, turkeys do not have two legs (she expressed an equivalent summary verbally). She displayed similar reasoning patterns on the extension to the pigs and goats problem.

What is interesting about Safi's response is not that she is a math major who is a preservice teacher who got a routine word problem incorrect (which is the sort of result documented in the past); rather, the novelty of Safi's work is how she used logical reasoning from her advanced mathematics courses to make sense of and support her conclusions about the validity of the mathematical model she constructed. Students' untrained reasoning may be incompatible with mathematical logic and students' application of logical structure largely depends on the semantic context (Dawkins & Cook, 2017). Safi was a student trained in logic and mathematical reasoning with knowledge of the semantic context. Deconstructing Safi's response in terms of a first-order propositional logic revealed how it supported her interpretation and validation of her model, and opens questions about whether students' mathematical thinking during modeling may be productively analyzed according to argumentation models (e.g., Toulmin schemes). Her responses also suggest that such lenses might reveal insights into the interaction between content knowledge and mathematical modeling. Further, Safi's use of logic shows that mathematics majors may not all have the same validating techniques at their disposal as engineering or science majors, implying that caution must be exercised when generalizing conclusions about modeling behavior among any of these populations (Czocher, 2013). In particular, if mathematics majors are using the skills and patterns of reasoning that they learn in advanced proof-based courses in other domains it raises new questions about the natures of mathematical modeling, problem solving, and proving and what characteristics they may share. Scholars in either area must be cautious of overlooking kinds of reasoning not typically linked to the domain of inquiry. For these reasons, further work needs to be done to document what validation processes students are likely to bring from various backgrounds and how they contribute to the students' mathematical modeling processes.

# Identifying Subtleties in Preservice Secondary Mathematics Teachers' Distinctions Between Functions and Equations

James A. Mendoza Álvarez[(1)] Theresa Jorgensen[(1)] Kathryn Rhoads[(1)]
[(1)]The University of Texas at Arlington

*For more than thirty years, the secondary school mathematics curriculum has seen a shift to functions-based approaches to algebra. Advancing comprehension of the equals sign as an equivalence relation is critical for beginning algebra students studying equations, and developing understanding of functions is foundational as a gateway to courses required of science, technology, engineering, and mathematics majors. This study explores the ways in which mathematics majors seeking secondary mathematics teaching certification distinguish between the concepts of function and equation. Participants (n=24) completed a ten-item pre- and post-assessment on functions and equations. Open coding techniques were used to identify emerging categories that describe participants' distinctions between the concepts. After a mathematics course experience with an eight-week unit on functions, the participants' concept image for functions focused primarily on input and output whereas their concept image for equations centered broadly on the equivalence of two quantities.*

*Keywords:* preservice secondary mathematics teacher preparation, function, equation

The topic of *functions* has been well-documented in the research literature as "difficult for students to learn, challenging to teach, and critical for students' success as learners and in their future lives and careers" (Cooney, Beckmann, & Lloyd, 2010, p. v). Students in the United States are commonly introduced to functions in secondary school (National Governors Association Center for Best Practices and Council of Chief State School Officers [CCSSM], 2010). Given the importance and difficulty of functions, it is essential that secondary mathematics teachers have the depth and breadth of understanding necessary to teach this critical topic (e.g., Stacey, 2008), and undergraduate studies offer an opportunity for teachers to build a profound understanding of functions.

Part of a profound understanding of function includes a clear articulation of the differences between functions and equations. Although there are ways to relate the topics of *function* and *equation*, they are sometimes inappropriately conflated by students and teachers alike. In this study, we investigate the following research questions:

1) How do preservice secondary mathematics teachers distinguish between functions and equations?
2) What subtleties exist in preservice teachers' distinctions?

## Theoretical Framework

To frame this study, we draw on Tall and Vinner's (1981) theory of *concept image* and *concept definition*. Throughout their school studies, preservice secondary math teachers develop a concept image of the topic of functions, which includes "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (Tall & Vinner, 1981, p. 152). A teacher's concept image of function (for example) may be well-developed and align with the formal definition of function, or their concept image may be fragmented, incomplete, or misaligned with the formal definition. Teachers may also have a personal concept definition for function—that is, the words the teacher uses to define function. A teacher's personal concept definition may reflect their concept image, or it may be misaligned from their concept image. At the same time, one's personal concept definition may align with (or be a memorized recitation of) the formal concept definition in the mathematical community, or it may be inconsistent with the formal definition.

Alignment between concept image and the formal concept definition is important because conflicts between these two may cause difficulties in students' learning (Tall & Vinner, 1981). In addition, concept images or personal concept definitions that are misaligned with the formal definition may cause students to think that the formal definition is "inoperative and superfluous" (Tall & Vinner, 1981, p. 184). Alignment between concept image and concept definition is especially important for teachers who are guiding students' learning of the concept. In this study, we investigate preservice secondary teachers' concept images and personal concept definitions of function and equation.

## Research Literature

Throughout high school and undergraduate mathematics, students are accustomed to working with functions which can be defined by algebraic formulas, and students often use formulas to identify the functions they discuss (Cooney et al., 2010). Formulas for functions are especially useful in calculus, and undergraduate courses such as calculus can reinforce students' concept image of functions being defined by formula. In fact, students' conceptions of functions can be limited by thinking of them as defined by formulas. For example, Even (1993) surveyed 152 preservice secondary mathematics teachers about functions, and ten additional preservice teachers were interviewed. Many of these preservice teachers thought that functions could always be represented by an algebraic formula. Similarly, using questionnaires with 30 secondary teachers, Hitt (1998) reported that many teachers believed that functions could always be represented by a single algebraic expression, and Carlson (1998) reported the same finding for students who earned A's in College Algebra.

Secondary school curriculum emphasizes that zeros of a function *f* are the solutions to the equation $f(x) = 0$ (CCSSM, 2010). Although this connection is valuable, students sometimes muddy this relationship. For example, in a study with students earning A's in College Algebra, Carlson (1998) found that these top-performing students "do not make a distinction between the zeros of functions and solutions to equations" (p. 141). In a 1999 study, Carlson also reported that second-semester calculus students had similar confusions between solutions to equations and zeros of functions.

To further complicate matters, in high school as well as undergraduate mathematics, a formula such as $f(x) = 3x + 2$ is sometimes referred to as *the equation for the function* $f$ or *the defining equation for the function* $f$. Perhaps perpetuated by this terminology, many preservice teachers have some incorrect conceptions about the relationships between functions and equations. For example, in Even's (1993) study, some preservice teachers provided definitions of function in which they claimed a function *was* an equation or expression. Breidenbach, Dubinsky, Hawks, and Nichols (1992) found that some preservice mathematics teachers described a function as "a mathematical equation with variables" (p. 252). Not surprisingly, Chazan & Yerulshamy (2003) documented that learners also have difficulty in distinguishing between functions and equations.

## Methodology

This study was conducted at a large, urban university in the southwestern United States with an on-campus student enrollment larger than 37,000 students. Due to the large enrollment (greater than 25% of the student body) of Hispanic students, the university carries a US Department of Education Hispanic Serving Institution designation. In addition, the university is described as one of the most diverse national universities in the United States.

The population for this study was preservice secondary mathematics students who were enrolled in a second-year mathematics course in the fall semester of 2016. The course, Functions and Modeling, is a required course for mathematics majors seeking secondary mathematics teaching certification. The intent of the course, which carries a second-semester calculus prerequisite, is to deepen preservice secondary mathematics teachers' experiences with the mathematics that they will teach, immerse them in an inquiry-based learning environment, and develop a profound understanding of important concepts for secondary school mathematics. In the 15-week fall 2016 semester, approximately eight weeks of the course focused on functions and patterns, four weeks on regression and modeling, and three weeks on various topics such as parametric equations, polar coordinates, vectors, and the geometry of the complex numbers.

Thirty students (17 females and 13 males) were enrolled in the course and 24 students participated in the research study. The overall student population enrolled in the university's science and mathematics secondary teacher certification program is 41% Hispanic, 38% White, 14% Asian, and 7% Black.

A written instrument consisting of ten items (and corresponding sub-items) targeting the students' understanding of function and equation was used as a pre- and post-assessment. The items on the assessment required the preservice teachers to explain their reasoning and, where appropriate, provide multiple representations. The assessment took the students approximately one hour to complete. This study examines student responses to two of the assessment questions.

- "Can the terms *function* and *equation* ever be used interchangeably? Why or Why not?"
- "If a student in Algebra I asked you to explain the difference(s) between a function and an equation, what would be your response?"

The pre-assessment was administered during the first week of the course. The post-assessment was completed after the course final exam. Qualitative methods were used to analyze the written responses from the assessments. Participant responses were systematically coded by elements in their explanations and by themes that emerged in the data relevant to their descriptions comparing the concepts of function and equation.

In the analysis of the pre-and post-assessments, we used principles of the grounded theory method (Strauss and Corbin 1990), allowing the data to be coded through the lens of emerging themes. The data were then grouped into similar conceptual themes characterize the preservice teachers' descriptions of contrasting function and equation.

## Results

Participant responses to "Can the terms *function* and *equation* ever be used interchangeably? Why or Why not?" on the pretest were coded as ambiguous (AMB), relationship/both (RLB), non-answer (NAN), some equations are not functions (ENF), some or all equations are functions (SEF), and some or all functions are equations (SFE) (see Table 1).

On the posttest, the new codes relationship vs. equivalence (RVE) and definition (DEF) arose from the posttest data. Responses that rejected interchangeability by mentioning the difference in the way the terms are defined were coded DEF. For example, "no, their definitions are not the same" was coded DEF. Responses that claim equations assert equivalence between two quantities but functions depict an input-output relationship were coded RVE. The codes RLB and ENF did not appear while there were 2 AMB, 6 NAN, 3 SEF, 8 SFE, 3 RVE, and 2 DEF.

*Table 1. Codes arising from the Pretest interchangeability question and their frequency.*

| Code | Description | Selected Response | Freq. (n=24) |
|---|---|---|---|
| AMB | Ambiguous response that does not offer reasons. | "not always interchangeable; depends on how it is written" | 3 |
| RLB | Claim that both express a relationship. | "Yes, because they both describe a relationship between variables…" | 4 |
| NAN | Non-sensical or non-mathematical response. | "No! hmm maybe…wow, you've got me stumped…" | 6 |
| ENF | Asserts that not all equations are functions. | "no, because not every equation is a function" | 5 |
| SEF | Asserts that some or all equations are functions. | "they can be interchanged sometimes there are equation that describes functions, but not always" | 2 |
| SFE | Asserts that some or all functions are equations. | "they can be, for example the function of x (f(x)) can be displayed as y" | 4 |

Three of the six participants who provided an NAN-coded response on the pretest also provided an NAN-coded response on the posttest. Three other participants' response codes remained the same from pretest to posttest—two SFE responses and one SEF response. The five ENF-coded responses on the pretest provided two NAN-coded responses, two SFE, and one SEF-coded response on the posttest.

Participant responses to "If a student in Algebra I asked you to explain the difference(s) between a function and an equation, what would be your response?" on the pretest were coded as NAN, SEF, input-output (IO) with sub codes equation equivalence (EE) or equation number specific (NS), and relationship (RL) with sub codes equation equivalence (EE) and equation number-specific (NS) (see Table 2).

*Table 2. Codes arising from the Pretest Algebra I student question and their frequency.*

| Code | Description | Selected Response(s) | Freq. (n=24) |
|---|---|---|---|
| IO<br><br><br>IOEE<br><br>IONS | Refers to input-output or independent-dependent variables for functions and<br>-equations asserting equivalence of two quantities, or<br>-equations as specific situations when numbers are used. | -IOEE: "Function: independent variable dictates the value of the dependent variable. Equation: something equals something else."<br>-IONS: "…equation may just involve solving for one variables [sic] given a number…" | 6<br><br><br><br><br><br>2 |

| | | | |
|---|---|---|---|
| RL<br><br><br>RLEE<br><br>RLNS | Refers to mapping or relationship between variables and<br>-equations asserting equivalence of two quantities, or<br>-equations as specific situations when numbers are used. | -RLEE: "An [sic] function assigns all the elements in set x to set y simultaneously. While an equation does not assign it simply equates.<br>-RLNS: "…equation takes that relationship and puts numbers in it…" | 2<br><br><br><br><br><br>5 |
| NAN | Non-sensical or non-mathematical response. | "I'm not sure I'd have the best response right now." | 7 |
| SEF | Asserts that some or all equations are functions. | "An equation can be a type of function…" | 2 |

On the posttest, the new code representation vs. equation equivalence (RPEE) was needed to code answers that referred to a representation to distinguish between function and equation; for example, "…a function has to pass the vertical line test." The sub codes IONS and RLNS disappeared while there were 2 RPEE, 7 IOEE, 4 NAN, 7 RLEE, and 4 SEF. The six of the seven participants with NAN responses on the pretest coded for IOEE or RLEE on the posttest with one receiving a SEF code.

## Discussion

Although participants completed several inquiry-based lessons that focused on precise definitions of functions and equations as well as several lessons using functions to model data, only one participant, on the "Algebra I student question," used the terms domain and codomain when attempting to make an equation-function distinction. Somewhat akin to Carlson's (1998) findings, no participants attempted to contrast equations and functions by referring to solution sets or domain and range, respectively. As in Even (1993), the use of the equal sign when defining a function with an algebraic expression may explain why 8 of 48 responses—aggregating the responses to both questions—still assert that some functions are equations.

The prevailing concept image for function entailed input-output or the idea that a function establishes a relationship between inputs and outputs, regardless if their description of an equation also used the idea of a relationship between quantities. Possibly a result of a lesson specifically focusing on the role of the equal sign in defining, equivalence, and computation may have influenced a shift from number-specific responses about equations to 14 of 24 responses that gave a mostly-correct equation concept definition.

The purpose of this study is to further investigate the subtleties in preservice secondary mathematics teachers' conceptual distinctions between function and equations. Further input from researchers is needed regarding developing interview protocols, alternative assessment questions, and ways to interpret the data that inform curriculum development and instruction.

Supporting Prospective Teachers' Understanding of Triangle Congruence Criteria

Steven Boyce
Portland State University

Priya Prasad
University of Texas at San Antonio

*This poster describes an instructional sequence for supporting college geometry students' justifying Euclidean triangle congruence criteria using properties of isometries. We hypothesized that investigating transformations in the taxi-cab metric would perturb students' understandings of the relationships between triangle congruence criteria and isometries, so they would more explicitly identify the properties of transformations as a necessary part of their justifications of triangle congruence criteria. We report on the results of pre-post written assessments of our college geometry students' justifying SAS to a hypothetical 10th grade student.*

*Keywords:* Geometry, Congruence, Mathematical Knowledge for Teaching

Research has demonstrated that supporting college geometry students' understandings of transformational geometry remains a challenge (e.g., Hegg & Fukawa-Connelly, 2017). Because many of our college geometry students are prospective secondary teachers, supporting their mathematical knowledge for teaching secondary geometry is an important course goal. The United States' Common Core State Standards state that high school geometry students should be able to justify triangle congruence criteria (ASA, SAS, SSS) as a consequence of properties of rigid motions (NGACBP/CCSSO, 2010). Hegg and Fukawa-Connelly (2017) found that college geometry students struggle with explicitly using relevant properties of transformations in such justifications, and they suggest that "asking for the kinds of explanations of ideas that [college geometry students] would give [secondary geometry] students has value in both giving researchers insight into their understanding of the content and giving policy-makers a better understanding of what additional supports will be needed going forward" (p. 8).

We designed a written task prompting our college geometry students to justify SAS to a hypothetical 10th grade student, and we administered the task before and after an instructional sequence investigating transformations in taxi-cab geometry in our Spring 2017 courses. With consideration of Harel's (2013) notion of intellectual need, we theorized that after experiencing perturbation that some Euclidean isometries are *not* isometries in a different metric (the taxi-cab metric, $d_t((x_1, y_1),\ (x_2,\ y_2)) = |x_1 - x_2|\ + |y_1 - y_2|$), our students would understand triangle congruence criteria in Euclidean geometry as depending on the *properties* of the isometries and thus be better-prepared to support future secondary students' in constructing that way of thinking about triangle congruence criteria. Using a constant comparative method (Glaser, 1965), we each independently coded students' written justifications of the SAS congruence criteria, considering aspects such as their (a) understanding of the premises and conclusions of SAS, (b) use of other Euclidean axioms or theorems to justify SAS, and (c) use of transformations to justify SAS. We then rated the written justifications on validity, substantiveness, and appropriate use of transformations. Our analysis suggests that students' responses were complicated by their beliefs about (and conceptions of) what it means to justify in secondary school mathematics. In our poster we will present the task, explicate findings, and future directions.

Adjunct Instructor Learning Through Implementing Research Based Curriculum

Zareen Gul Rahman, Eileen Murray, Amir Golnabi
Montclair State University

*Due to high demand, part-time adjunct instructors play an increasingly important role in introductory classes at many higher education institutions. As part of a project to support adjunct instructors teaching Precalculus, we are exploring the impact of course coordination and support on content knowledge and instructional practice of instructors.*

*Keywords:* Teacher learning, adjunct instructors, Precalculus teaching

There is a need for research on retaining students in STEM disciplines (Carnevale, Smith & Melton, 2011; Hurtado, Eagan, & Chang, 2010). Students' classroom experiences influence their decisions to pursue STEM degrees, especially initial experiences in introductory math courses (Hutcheson, Pampaka, & Williams 2011; Pampaka, Williams, Hutcheson, Davis & Wake, 2012). Thus, improving instruction quality may influence their decision to stay in STEM fields (Ellis, Kelton & Rasmussen, 2014). At our institution, Precalculus sections are taught by adjunct instructors. This proposal presents ongoing data analysis from a project focusing on promoting adjunct instructors' learning through course coordination and job supports. Specifically, this analysis aims to answer the following research question: In what ways does implementing a research based Precalculus curriculum impact adjunct instructors' mathematical content knowledge and instructional practice?

To explore the impact on instructor content knowledge, we use Shulman's (1987) conception of content knowledge. According to Shulman, there are three facets of content knowledge: structures of subject matter (rules, procedures, definitions, and axioms), principles of conceptual organization (conceptual web of content), and principles of inquiry (mathematical habits of mind (Cuoco, Goldenberg, & Mark, 1996)). These three facets of content knowledge allow teachers to develop a broad understanding of their field by grasping the main concepts, gaining expertise, and learning modes of analysis that take the field forward (Shulman, 1987). We are analyzing transcripts from pre and post semester interviews with adjunct instructors teaching our newly implemented research-based Precalculus curriculum. Each member of our research group reads the transcripts, identifying segments of talk focused on mathematical content, and categorizing each segment as one of the three facets of content knowledge, while allowing for segments to be placed in the intersection of one or more category. As we continue this work, we are thinking about how to incorporate other measures of instructor content knowledge, including pre and post knowledge assessments as well as interviews from more recent semesters.

To explore the impact on instructional practice, we use Teucher, Moore, and Carlson's (2015) construct of decentering introduced by Piaget (1955) as a way "to characterize the actions of an observer attempting to understand how an individual's perspective differs from her or his own" (Teucher, Moore, & Carlson, 2015, p. 5). We are analyzing transcripts from classroom observations from the first semester of implementation to explore how our instructors may, or may not, be employing decentering practices. As we continue this work, we will explore how the decentering practices of our instructors relate to course coordination and supports.

Students' Engagement with a Function Vending Machine Applet

Patrick Martin
Middle Tennessee State University

Heather Soled
Bucknell University

Jennifer N. Lovett
Middle Tennessee State University

Lara K. Dick
Bucknell University

*The purpose of this study is to examine the ways students engaged with a Vending Machine applet designed to problematize common misconceptions associated with the function concept. Findings indicated a need to redesign the applet to further disrupt students' misconceptions of the concept of function. Design decisions for the redesigned applet and the new version will be shared.*

*Keywords:* Functions, Calculus, Teaching with Technology

Research has revealed common misconceptions that persist among undergraduate students with respect to the definition of function (Vinner & Dreyfus, 1989), use of function notation (e.g., Oehrtman, Carlson, & Thompson, 2008) and connections between function representations (e.g., Dreher & Kuntze, 2015; Stylianou, 2011). Hence, we designed and studied the ways that undergraduate students, all who have completed Calculus I, from six universities engaged with an applet designed to test and improve their understanding of the function concept.

The Vending Machine applet (https://ggbm.at/qxQQQ7GP) is a four-page GeoGebra book. When the user presses a button (input), one or more cans appear in the bottom of the machine (output). Students are asked make conjectures about why the machines are or are not functions. These machines were designed to provoke dilemmas (Merizow, 2009) with the students' common function misconceptions to lead them toward a robust understanding of the function concept such as students' use of the term "unique" when describing outputs of functions, misunderstanding of what represents an element in the range, and misidentifying horizontal lines as non-functions.

## Method & Results Summary

To answer our research question, How do undergraduate students engage with a vending machine applet designed to provoke dilemmas with their understanding of the function concept?, we analyzed screencasts from 123 students that completed the vending machine assignment. Results showed that even after engaging with the applet, many students applied their previous understandings of the function concept to each of the machines and continued to demonstrate two misconceptions that we had intended to disrupt: 1) a horizontal line (each button returning the same can of soda) as not representing a function and 2) what represents elements in the range (a button consistently producing two identical cans).

## Conclusion

Despite our Vending Machine applet's intended design to provoke dilemmas related to students' understanding of function which we hoped would promote reflection and ideally deepen students' understandings related to the function concept, we found that many students continued to apply their common misconceptions when engaging with the machines. Based on these results, we have redesigned the applet and will share how the new design arose from our analysis of the students' engagement with the applet.

Pre-Service Teachers' Mathematical Understanding of the Area of a Rectangle

Betsy McNeal* Sayonita Ghosh Hajra** Ayse Ozturk* Wyatt Ehlke** Michael Battista*
*Ohio State University **Hamline University

*This poster will share contrasting responses of two pre-service teachers (PTs) to problems that were part of an ongoing study of PTs' conceptions of area of a rectangle. They were asked to a) find the area of a rectangle in terms of a non-square rectangular unit and relate that to multiplication, and b) interpret a fictional child's attempt to connect the area formula with counting square units. These cases showed that an ability to explain a systematic covering of a 2D space with an area unit does not imply an ability to respond to a student who might think "the corner square gets counted twice". Further, the ability to describe this structure, L rows with W area units per row, does not imply readiness to understand the area formula for a rectangle.*

*Keywords*: area, rectangle, geometry, pre-service teachers

Numerous studies indicate that when teachers obtain appropriate knowledge of mathematics, their instructional practices change in ways that improve their students' mathematics learning (e.g., Cobb et al., 1991; Fennema et al., 1996). As mathematics educators who design and teach mathematics courses for future teachers, we are constantly reevaluating our course curriculum and goals in light of our current understanding of what mathematics will be needed by our PTs in their careers. In our courses, explanations of all mathematical ideas are emphasized, and our role is to orchestrate sharing of different answers, ideas, questions, and solution methods. In our daily observations of their work in class, we developed theories of the PTs' conceptions of area and its measurement that are explored in our research.

This study took place at a public university in a mid-western state with ten PTs who were enrolled in a geometry course for future elementary teachers. We conducted clinical interviews (Clement, 2000) with these PTs outside of class. These focused on (a) the idea of measuring the area of a rectangle with non-square units and explaining the meaning of the covering process used, and (b) the interpretation of a fictional child's thinking about the connection between the area formula and counting square units. Each interview was videotaped and transcribed. Videos and transcripts were analyzed to capture the progression of PTs' thinking from task to task (Auerbach & Silverstein, 2003). Specifically, each of the researchers read the transcripts multiple times, and documented the changes over the interview sessions. Key excerpts were flagged, reviewed, and examined closely for insights about PTs' reasoning.

The poster will present data from interviews with two of the PTs. These were selected because of contrasts across their own answers as well as contrasts with each other's answers. One PT covered a rectangle with rows of area units and used this to explain why multiplication will yield the total number of units. The same PT then had difficulty assisting a fictional student who, looking at an array of squares, was worried that the corner square was counted twice. The second PT also iterated the unit to cover the rectangle. She got confused when trying to explain this process in terms of "L x W", but then clearly explained to the imaginary student how to use multiplication to count the squares. These PTs' responses prompted questions and ideas that we wish to consider with the other researchers and the RUME audience.

# How Experts Conceptualize Differentials: The Results of Two Studies

Tim McCarty
West Virginia University

Vicki Sealey
West Virginia University

*The mathematical symbol "dx" is a symbol for which there can exist different views about its characteristics, purposes, and roles. We conducted two studies to see how experts viewed the dx in a variety of contexts. For our first study, we interviewed four mathematicians in order to understand their various concept images of the dx, and for our second study, we interviewed two mathematicians and one physicist about both their own concept images and the concept images they would like for their students to have. Overall, we found little agreement among all of the experts' responses, and we believe that that further study of experts' concept images of the differential is warranted.*

Keywords: Calculus, Differentials, Concept Image

The differential is a symbol that is found in various, commonly-used mathematical notations, such as the derivative $\left(\frac{dy}{dx}\right)$ and integrals $\left(\int f(x)dx, \int_a^b g(t)\,dt\right)$. However, while these notations are standard, the meaning behind the differentials in these notations is not necessarily so: do those differentials represent small amounts of a quantity (Hu & Rebello, 2013; Von Korff & Rebello, 2012), do they only exist to indicate important variables (Artigue, 1991; Jones, 2015), are they merely notation with no intrinsic meaning (Artigue, 1991; Hu & Rebello, 2013), or can they possess some combination of all three of these meanings (Tall, 1993)? We wished to interview experts about differentials not only in an attempt to understand their concept images (Tall & Viner, 1981) of differentials, but also to see how much agreement existed among all interview subjects.

Our first study (McCarty & Sealey, 2017), conducted during the summer of 2016, involved interviewing four mathematics professors about how they perceived differentials in various contexts. In no context did all four subjects view the differential similarly, and while every context had agreement between some subjects, no two successive contexts had agreement between the same subjects. Three of the four subjects exhibited strong, personal images throughout all contexts, but these individual images were dissimilar, suggesting that no formal, unifying concept image can be found. Our second study, conducted during the summer of 2017, involved interviewing two mathematicians and one physicist about differentials in various contexts, as well as giving them potential concept images of differentials and asking if they would accept these potential images from their students. Again, there were no contexts in which all subjects agreed. Moreover, the responses from the physicist differed markedly from those of the mathematicians, and we found instances where the subjects might hold a concept image that they would not want their students to possess and vice versa.

In both studies, there were many and varied rich concept images suggested by some interview subjects; nevertheless, we conclude that there is no formal concept definition for the differential. We feel that these studies can be used to stimulate additional research, including, but not limited to, deeper study of differential concept images, further explorations into either how mathematician and physicist concept images might differ, or the differences between expert concept images and acceptable concept images from their students. We wish to present our results to encourage feedback and suggestions, as we move forward with this work.

Transitional Conceptions of the Orientation of the Cross Product in CalcPlot3D

Monica VanDieren
Robert Morris University

Deborah Moore-Russo
University of Oklahoma

Jillian Wilsey
Niagara County Community College

Paul Seeburger
Monroe Community College

*Students struggle with computing the direction of the cross product in relation to the two vectors that form it, but very little research has involved a non-contextual geometric cross product activity, especially in an online context. This study uses grounded theory to analyze student work completed for a dynamic, online visualization activity. Our preliminary research aims to develop categories that could outline a conceptual model of student understanding of the cross product.*

*Keywords:* vectors, cross products, visualization, transitional conceptions

The topic of determining cross products is prevalent in multivariable calculus, engineering, and physics curricula. Yet, research indicates that students struggle with problems involving the cross product (Knight, 1995; Barniol & Zavala, 2014). In particular students have difficulty determining the direction of the cross product and may not comprehend the non-commutative nature of the cross product (Kustusch, 2016; Scaife & Heckler, 2010). Research on understanding of the cross product has focused on symbolic manipulations. When graphical manipulations have been examined, it has been in a static environment on paper (e.g., Van Deventer, 2006; Zavala & Barniol, 2014). Here, we report on how grounded theory methodology was used to analyze student work in a dynamic virtual environment in order to understand how students communicate the direction and non-commutativity of the vector cross product.

The data for this study came from exploratory activities in the CalcPlot3D applet (Seeburger, 2017). The data set included electronic responses from 434 college-level, multivariable calculus students collected over four years to two embedded questions in the online cross product activity: *Considering the right-hand rule, what is true about the angle between the two vectors when the cross product vector points in the a) positive z-direction and b) negative z-direction?*

The responses were examined for emerging themes through a general inductive analysis (Thomas, 2006) using intercoder reliability where a single response to a single question was treated as the unit of analysis. Four main categories were identified and used for coding. Three were relevant properties to cross product: orthogonality, right-hand rule, cross product magnitude, and one was not: location of vectors. Ainsworth notes that one problem learners face in using multiple representations is retrieval of the relevant information and that this is strongly affected by a learners' familiarity with the topic (2008). Furthermore, developing ideas or "transitional conceptions" (Moschkovich, 1999) gleaned from student responses provided support for the categories created.

We report on the methodology, the findings, and limitations of the study as an initial step in developing a conceptual model of student understanding of cross product. This poster will provide visual displays and supporting evidence for the developed categorization system that allowed representation of both completely correct statements and statements that showed some thought in the category but that the idea expressed was neither correct nor precise.

# Dynamic Textbooks and their Use in Teaching Linear and Abstract Algebra

Angeliki Mali and Vilma Mesa
University of Michigan

*In this poster we present two analyses of two dynamic textbooks. One analysis attends to their dynamic features, the mathematical practices embedded, and the scope of contents. The second analysis uses the documentational approach (Gueudet & Trouche, 2009) to investigate the ways in which these textbooks are used by instructors and their students. Data collection involves seven instructors and nearly 150 students across four states (New York, Texas, California, and Michigan; 50% female, 30% non-Caucasian or Asian) and surveys, logs, student tests, classroom observations, and clinical interviews. In both textbooks the interactive features are prominent via links and interactive computational cells (with Sage). They both include deduction, symbolization, and representation as mathematical practices. There are differences in the scope of contents. Regarding use we found that instructors took advantage of the features only when those could be integrated into their usual practices.*

*Keywords:* dynamic textbooks, textbook use, teaching, instruction

Even though the textbook continues to be one of the most important resources for instructors, textbooks enhanced with technologically advanced features are still in their infancy. In Undergraduate Teaching and Learning in Mathematics with Open Software and Textbooks (UTMOST, Beezer et al., 2016), we investigate whether and how instructors and students take advantage of features that are included in dynamic textbooks enhanced with Sage computational cells (Beezer, 2015; Judson, 2017). Data sources include bi-weekly logs, surveys, video recordings of the planning and the enactment of lessons, interviews, and tests of content knowledge with seven volunteer instructors (one female, five Caucasian), four teaching linear algebra and three teaching abstract algebra. The textbook analysis allowed us to discern textbook characteristics in terms of three emerging thematically connected categories: dynamic features, mathematical practices, and scope of contents. Using the documentational approach (Gueudet & Trouche, 2009) we analyzed two processes, instrumentation (how the textbooks "affect" the instructor) and instrumentalization (how the instructor "affects" the textbooks), present when instructors used the textbooks for planning and teaching. While the textbook analysis indicated that the potential for novel use is embedded in the design of the textbook features, we found that novel use was not as extended, in part, because the instructors lacked familiarity with, or experience using, the features embedded in the textbooks. In particular, we found that instructors took advantage of the features only when those can be integrated into their usual practices. All the participant instructors used their textbooks to create their lecture notes attending to the sequencing of topics presented in the textbooks and maintaining the notation, definitions, and theorems. Their lecture notes nevertheless included either different proofs (because the proofs provided were not satisfactory for the instructors) or additional examples (because the ones available in the textbook were not contextualized or had no geometric visualization). We explained those departures with instructors' personal and professional histories and experiences teaching a particular course, their understandings about how resources should be used, and their goals for teaching the course, according to the documentational approach.

Benefits to Students of Team-Based Learning in Large Lecture Calculus

Travis Peters
Iowa State University

Heather Bolles
Iowa State University

Elgin Johnston
Iowa State University

Craig Ogilvie
Iowa State University

Alexis Knaub
Western Michigan University

Thomas Holme
Iowa State University

*Team-Based Learning (TBL) is a specific form of active learning that utilizes the flipped classroom model. We implemented TBL in Calculus I in both large and small classes and investigated the impact of this form of instruction over two semesters. In the second semester, we observed many positive benefits to students, including exceptionally high class attendance, higher midterm and final exam scores, significantly lower DFW rates, and larger gains on the Calculus Concept Inventory when compared to students enrolled in non-TBL sections.*

*Keywords:* Team-Based Learning, flipped classroom, active learning, calculus, large class

Our ongoing study at Iowa State University addresses the following research question: Is Team-Based Learning Calculus I instruction more effective than non-TBL instruction? In Fall 2015 and Fall 2016, three members of our research group taught Calculus I in large (N~150 students) and small (N~35 students) classes using Larry Michaelsen's TBL approach (Michaelsen, Knight, & Fink, 2004). This teaching strategy is based on a constructivist learning theory and involves students first engaging with introductory material individually and then at a higher level in teams (Hrynchak & Batty, 2012). The students do preparatory work outside of class using reading guides and instructional videos before completing a five-question quiz individually and then again with a team. The majority of class time is spent working on application exercises in teams.

We investigated the impact of this form of instruction over two semesters and noticed steady improvement from the first implementation to the second. In our second implementation, we observed exceptionally high class attendance, including an overall attendance rate of 92% in one of our large classes. In analyzing midterm and final exam scores as well as DFW rates (percentage of students who finish the course with a D letter grade, F letter grade, or withdraw from the course), we compared our TBL students (N~370 students) to non-TBL students enrolled in the course (N~1500 students). The mean score on the departmental midterm exam (out of 100) for the TBL group exceeded that of the non-TBL group by 5.0 points, and the mean score on the departmental final exam (out of 100) for the TBL group exceeded that of the non-TBL group by 7.4 points. The DFW rate for the TBL group (19.1%) was significantly lower than the DFW rate for the non-TBL group (32.0%), with sufficient evidence at an alpha level of 0.01 using a two-sample t-test. We noticed lower DFW rates for TBL female students (24.7%) and TBL ethnic underrepresented students (34.8%) than their non-TBL counterparts (30.1% and 45.5%, respectively). By ethnic underrepresented, we mean African American, Hispanic, Native Hawaiian, Native American, or two or more ethnicities. Finally, the average of gains on the Calculus Concept Inventory (Epstein, 2013) for the TBL group (0.20 +/- 0.02) was larger than that of the non-TBL comparison group of 93 students (0.13 +/- 0.03), and this is statistically significant ($t(357)=2.16$, $p<0.05$).

Our findings have important implications for the way in which calculus is taught. The findings provide further evidence that active learning is an effective way to teach calculus, keeping in line with the study of Characteristics of Successful Programs in College Calculus undertaken by the Mathematical Association of America (Bressoud & Rasmussen, 2015).

# Faculty Collaboration and its Impact on Instructional Practice in Undergraduate Mathematics

Nicholas Fortune
North Carolina State University

Karen Keene
North Carolina State University

*To reform instruction by moving towards student-centered approaches, research has shown that faculty need and could benefit from support and collaboration (Henderson, Beach, & Finkelstein, 2011; Speer & Wagner, 2009). In this qualitative instrumental case study I examine the ways in which a mathematician's instruction developed during his participation in a faculty collaboration geared towards reforming instruction and aligning it with inquiry oriented instruction (Kuster, Johnson, Keene, & Andrews-Larson, 2017; Rasmussen & Kwon, 2007). Preliminary results indicate ways in which student thinking was used as a discussion point in the faculty collaboration connected to the ways in which student thinking was used in the classroom to advance the mathematical agenda. Further, results indicate that the mathematical beliefs of the mathematician sometimes took precedence over the use of student work in the classroom.*

*Keywords:* faculty collaboration, instructional practice, differential equations

Research has shown that mathematicians may struggle implementing a new curriculum without support (Speer & Wagner, 2009; Wagner, Speer, & Rossa, 2007). Further, research has shown how summer workshops and online forums aid mathematicians in sustaining instructional change (Hayward, Kogan, & Laursen, 2015). Research is underway that explores diverse ways to engage mathematicians and support them in reaching their goal for instructional change (e.g., online video calls). This study focuses on one participant of an ongoing project to support mathematicians' instructional change, Dr. DM, and seeks to find links between his experiences in the online faculty collaboration and his instructional practice. The poster will address the following research question: How does one mathematician's instructional practice develop while participating in a faculty collaboration for inquiry-oriented differential equations (IODE)?

## Methods and Preliminary Results

Data for this case study comes from observations of the faculty collaboration online meetings, Dr. DM's classroom observations, and audio recordings of three interviews. Analysis of the classroom instruction uses the inquiry oriented instructional framework (Kuster et al., 2017) while analysis of the faculty collaboration and interviews uses a priori coding from our previous work (Keene, Fortune, & Hall, under review) as well as research on the roles of speakers and listeners in mathematics (Krummheuer, 2007, 2011).

Analysis is ongoing but preliminary results seem to indicate that Dr. DM's implementation of the IODE materials was influenced by his participation in the faculty collaboration. During the semester-long faculty collaboration Dr. DM shifts from discussing his students' thinking to evaluating and anticipating it. When that shift occurred, Dr. DM also shifted the way in which he used his students' thinking to advance the mathematical agenda. This use of student thinking, however, was stifled by his own mathematical beliefs when the content of the course aligned with his research agenda. While it is desirable for faculty to be passionate about their research and integrate it into their teaching for authentic learning experiences, in this case, it was sometimes at odds with the students thinking at given moments in the class. Further work will describe the connections and offer ideas to other facilitators of faculty online instructional support groups.

# Student Intuition Behind the Chain Rule and How Function Notation Interferes

Justin Dunmyre
Frostburg State University

Nicholas Fortune
North Carolina State University

*Recently, Speer and Kung (2016) informed the RUME community on what was missing from our research. In an effort to begin to fill these gaps in the literature, we explored students conceptual understanding of the chain rule in Calculus I classrooms taught by the first author. In this teaching experiment (Steffe & Thompson, 2000), our preliminary results indicate that if students are afforded opportunities to engage in experientially real tasks (Freudenthal, 1991; Rasmussen & King, 2000) on the chain rule, they understand the purpose it serves and can extend that understanding to varied contexts. However, the largest interference to this understanding was function notation, particularly nested function notation. Implications indicate that the instruction of chain rule could be enhanced by preempting a chain rule unit with nested function notation, while still maintaining tasks centered around a conceptual understanding of the chain rule.*

*Keywords:* chain rule, function notation, student mathematical thinking

While little is known about student understanding of the chain rule, much is known about student understanding of function and function notation. From this extensive body of research, we know that challenging activities, particularly constructive ones, aid in the development of the function concept (Carlson, 1998). Additionally, research highlights the importance of linking representations of functions and how that connects to learning function concepts (Even, 1998; Ronda, 2015). Research has also shed light on common misconceptions students have about functions. For example, students have been shown to not fully understand the use and meaning of parentheses in function notation (Carlson, 1998). In this study, we aim to answer the following research question: How do Calculus I students interpret various forms of notation when related to their understanding of the chain rule?

## Methods and Preliminary Results

In this teaching experiment, we filmed a full unit of chain rule from two Calculus I sections taught at a public university in the eastern United States. Focus of video data was always on small group work while students were solving tasks designed by the first author. The context for the tasks was as follows: A student, Mary, is taking a hike between two nearby towns. Students were given a graph of Mary's elevation height in terms of time and a table of the temperature of her location given an elevation height. Ultimately students were prompted to develop a need for the chain rule when ascertaining the change in Mary's temperature based on time.

Analysis is ongoing; yet, our preliminary results indicate that students were able to understand the need for the chain rule. That is, if a function $r$ depends on the function $s$, which itself depends on the variable $t$, the rate of change of $r(t)$ is the rate of change of $r$ in terms of $s$ times the rate of change of $s$ in terms of $t$, $\frac{dr}{dt} = \frac{dr}{ds} \cdot \frac{ds}{dt}$. However, when confronted with the parenthetical notation of nested functions, $r(s(t))$, students' ability to generalize the chain rule was impeded. Oftentimes students considered this parenthetical notation to be an indication of multiplication which lead them to misconceptions. Future work will consider ways to redesign instruction to preempt this pitfall in student thinking.

Preservice Secondary Mathematics Teachers' Conceptions of the Nature of Theorems in Geometry

Tuyin An
Georgia Southern University

*Proof plays an important role in school mathematics curriculum across grade levels and content areas. Being able to understand and apply the axiomatic system, such as with theorems, is considered as a high level of proof and reasoning ability in geometry. By adopting a collective case study design, I investigated preservice secondary mathematics teachers' (PSMTs) conceptions of theorems in geometry, in order to develop knowledge about PSMTs' current conceptions and provide mathematics educators and researchers with a possible means to unpack PSMTs' conceptions. This proposal focuses on one dimension of PSMTs' conceptions, the nature of theorems (NoT) in geometry. The Findings include interpretations of PSMTs' conceptions of the NoT, in terms of the ways they claimed the truth of mathematical statements, examined the validity of given proofs, and disproved given statements, as well as the role of task-based interviews in understanding their conceptions.*

*Keywords:* theorems, conceptions, proof and reasoning, geometry, teacher education

Proof and theorems form part of the core content of secondary geometry curriculum, and should be well grasped by secondary math teachers and their students (NCTM, 2000, 2003, 2012). Studies show that both secondary teachers and students have encountered challenges in teaching and learning proofs (Cirillo, 2009; Knuth, 2002; McCrone & Martin, 2004; NCES, 1998; Senk, 1985). In this study, I examined the essential elements of three PSMTs' conceptions of the NoT through research-informed task-based interviews, in order to answer the research questions: What conceptions do PSMTs hold regarding the NoT in geometry? And how do research-informed task-based interviews help unpack PSMTs' conceptions of the NoT in geometry?

I created a set of principles of the NoT that served as the conceptual framework for the development of the task-based interviews, including the elements *theorem has to be proved (NoT 1)*, *theorem is true for all instances (NoT 2)*, and *one counterexample is sufficient to disprove (NoT 3)* (Cirillo, 2014; Dreyfus & Hadas, 1987; Duval, 2007; McCrone & Martin, 2004). Each of the PSMTs participated in an individual task-based interview that addressed the above principles. The data analysis process started by "dividing the overall data set into categories or groups based on predetermined typologies" (Hatch, 2002, p. 152). An analytical framework was developed to identify the typologies of the data, including the definitions of PSMTs' *goals of the task*, *goal-directed activities (GAs)*, *sequence of actions* within the GAs, and *effects* of their GAs (Simon, Tzur, Heinz, & Kinzel, 2004; Tzur, 2007; Tzur & Simon, 2004).

The findings included interpretations about PSMTs' clarity of understanding about NoT 1, confusion about NoT 2 that the validity of the proving result and the validity of the proving process could be evaluated separately, and varied understandings about NoT 3 in terms of the definition of a counterexample and its role in disproving. In addition, the study discussed the role of the task-based interviews, in terms of providing an accessible problem-solving environment, encouraging free problem-solving, encouraging PSMTs' reflection, and letting the researcher be open to unforeseen activities during the interview (Goldin, 2000; Lin, Yang, Lee, Tabach, & Stylianides, 2012). The implications of the use of prompts in the interviews were also discussed.

# Perceptions of Underrepresented Community College STEM Majors

Daniel Lopez
Brookdale Community College, Rutgers University

*Community College STEM majors from underrepresented groups were interviewed about their experiences in math classes and their motivations behind choosing a STEM major. The goal was to uncover events that may occur in math classrooms that serve to marginalize underrepresented students and contribute to the dearth of these demographic groups in these majors. As interview data was gathered, it became clear that these students did not suffer from feelings of marginalization. Results suggest that involvement in co-curricular activities, guidance and encouragement from faculty members, and support from family and peers may serve to mitigate feelings of alienation that can occur in students from these underrepresented groups.*

*Keywords:* Equity, Females, Minorities, STEM

The STEM fields in the United States have traditionally been dominated by white males. Females and minorities continue to be underrepresented in STEM occupations (NSF, 2017). These minority populations will comprise an increasingly larger percentage of the workforce moving forward, with the Hispanic population expected to increase by 115% between 2014 and 2060 (Colby & Ortman, 2015). If the United States hopes to remain competitive in these fields in the future, more candidates from these demographic groups must enter STEM degree programs at colleges and universities, earn degrees, and enter the STEM workforce.

The explanation for the dearth of females and minorities in STEM fields is multifaceted. However, the common denominator (pun intended) for STEM disciplines is their connection to math. Most of these disciplines require at least Calculus I, and many typically require through Calculus III. It is hypothesized that many underrepresented STEM majors may be lost due to racialized (McGee & Martin, 2007) and gendered (Hughes, 2000) encounters in these classes.

A group of underrepresented students in STEM majors at a suburban community college on the East Coast were interviewed about their experiences in math classes and the reasons behind their choosing a STEM major.

Research Questions:

1. Do specific events occur in math classes at the high school and college level that serve to marginalize females and minorities, affecting their retention in STEM fields?
2. What kinds of supports can help encourage the persistence of underrepresented students in STEM?

Interviews were conducted in the Spring and Fall semesters of 2017. Results suggested that these students did not suffer from feelings of marginalization in their math classes. On the contrary, encouragement they received from family, peers, and faculty members were instrumental in their success. Additionally, it is hypothesized that the community college context for this study impacted its results. Similar studies (Chavous et al, 2004; Cole & Espinoza, 2008; Wells, 2008; Espinosa, 2011) found varying student experiences based on the type of institution the student attended and its perceived campus climate. These results suggest that cultural capital (Bourdieu, 1986) may play a role in underrepresented student persistence and that the community college, with its unique positioning among institutes of higher education, may provide a more nurturing environment for underrepresented students to succeed in STEM.

# Mathematical Reasoning and Proving for Prospective Secondary Teachers

Orly Buchbinder
University of New Hampshire

Sharon McCrone
University of New Hampshire

*The design-based research approach was used to develop and study a novel capstone course: Mathematical Reasoning and Proving for Secondary Teachers. The course aimed to enhance prospective secondary teachers' (PSTs) content and pedagogical knowledge by emphasizing reasoning and proving as an overarching approach for teaching mathematics at all levels. The course focused on four proof-themes: quantified statements, conditional statements, direct proof and indirect reasoning. The PSTs strengthened their own knowledge of these themes, and then developed and taught in local schools a lesson incorporating the proof-theme within an ongoing mathematical topic. Analysis of the first-year data shows enhancements of PSTs' content and pedagogical knowledge specific to proving.*

*Keywords:* Reasoning and Proving, Preservice Secondary Teachers, Design-Based Research

Our NSF-funded 3-year project addresses the limited practical and theoretical knowledge base on how to prepare PSTs to teach in ways that emphasize mathematical reasoning and proving (Ko, 2010; Stylianides & Stylianides, 2015). We designed, implemented and studied a novel capstone course: *Mathematical Reasoning and Proving for Secondary Teachers.* The focus of reasoning and proving was motivated by the persistent discrepancy between the value of proof as advocated by researchers (e.g., Hanna & deVillers, 2012) and policy documents (NCTM, 2009; CCSS, 2010) and the marginal place of proof in school mathematics, which is often viewed by students and teachers alike as redundant confirmation of known results, rather than a means for deepening understanding (Knuth, 2002; Kotelawala, 2016).

The course consists of modules corresponding to four proof-themes: quantified statements, conditional statements, direct proof and indirect reasoning, which were identified in the literature as challenging for students and PSTs (Antonini & Mariotti, 2008; Weber, 2010). Each module has activities to enhance PSTs' knowledge of a certain proof theme, followed by developing and teaching lessons at a local school integrating that proof-theme with current mathematical topics.

We used multiple sources of data to evaluate how PSTs' knowledge of content and pedagogy, and their dispositions towards proof evolved throughout the course. These included pre- and post- measures of mathematical knowledge for teaching proof and dispositions towards proving. We collected PSTs' lesson plans and 360° video-recordings of their lessons, which captured simultaneously the PSTs teaching performance and the school students' engagement with proof-oriented lessons. The PSTs also submitted self-reflections after each lesson, and cumulative teaching portfolios at the conclusion of the course.

Preliminary data analysis of the first-year course implementation shows improvement in PSTs' content knowledge of the four proof-themes. The repeated cycles of lesson development, implementation and video-supported reflection contributed to PSTs' pedagogical knowledge for proving. However, analysis reveals that integrating the proof-themes with pedagogical practices can be challenging for PSTs. To better support PSTs in this aspect, we plan to further conceptualize and enhance instructional scaffolding of the course in the subsequent iterations of the study. Through this process we seek to generate an evidence-based instructional model, and four proof-modules that can be adopted by other courses or institutions to improve preparation of secondary mathematics teachers.

# The STEM Service Courses Initiative of Project PROMESAS:[1]

***Pathways with Regional Outreach and Mathematics Excellence for Student Achievement in STEM***

Hortensia Soto
University of Northern Colorado

Cynthia Wyels & Selenne Bañuelos
California State University Channel Islands

Bret Black
Oxnard College

Chris Cole
Moorpark College

Lydia Morales
Ventura College

*In this poster, we present preliminary results of how Project PROMESAS' STEM Service Courses (SSC) initiative assists collegiate instructors (n = 14) in transforming their teaching of Calculus I. These instructors participated in a one-week summer institute focused on integrating student-centered activities via rich tasks and promoting a sense of community in the classroom. During the fall 2017 semester, they adopted and adapted ideas from the summer institute and participated in monthly day-long follow-up meetings. The monthly meetings were an opportunity to continue learning about student-centered activities and to share newly created teaching materials. As part of the evaluation of this project, the instructors journaled during the summer institute and each month during the fall. These journal entries serve as our data: it suggests that although our instructors struggle balancing student-centered activities with teaching the required content, they are committed to transforming their teaching.*

*Key words:* collegiate PD, rich tasks, sense of community, student-centered learning

Nationally, lack of student persistence through the Calculus sequence is a significant contributor for students leaving their intended STEM disciplines (Bressoud, 2013). Research indicates that negative learning experiences "endured" during Calculus courses have the most effect on student retention (Seymore & Hewitt, 1997; Ulricksen, et al., 2010). Project PROMESAS is a regional STEM initiative where mathematics faculty from a 4-year Hispanic-Serving Institution (HSI) and 2-year HSI community colleges collaboratively address systemic change in teaching. The aim of Project PROMESAS' SSC initiative is to transform mathematics pathways into STEM and to strengthen the STEM student success pipeline.

The project emphasizes faculty development on cultural competency, inclusive pedagogy, and renewing the curriculum itself. Thus, we created a 2-year long professional development program for collegiate instructors. The curriculum for the PD focused on integrating student-centered activities via rich tasks while promoting a sense of community in the classroom as emphasized in the MAA *Instructional Practices Guide* (in press). The first cohort has completed a summer institute and follow-up monthly meetings for a semester, for all of which they responded to journal prompts. Preliminary analysis of these journal entries suggests that although our instructors struggle balancing student-centered activities with teaching the required content, they are committed to transforming their teaching. In our poster, we will detail the program, participants, data collection, and preliminary results of how this program is transforming our instructors' teaching of Calculus I. We will also share plans for the second cohort and our plans to assess the impact that this program has on STEM students' attitudes towards mathematics and their success in their STEM discipline.

[1] Project PROMESAS is funded by a $6m US Department of Education, Title III, Hispanic-Serving Institutions STEM Grant (P031C160017).

**Computational Thinking in Mathematics: Undergraduate Student Perspectives**

| Chantal Buteau | Ami Mamolo | Eric Muller | Meghan Monaghan |
|---|---|---|---|
| Brock University | University of Ontario Institute of Technology | Brock University | Brock University |

*Computational thinking (CT) is understood as the thinking, strategies, and approaches for solving complex problems with algorithmic considerations and in ways that can be executed by a computer. This survey study (n=104) reports on the conceptions of undergraduate mathematics majors and future mathematics teachers enrolled in a sequence of programming-based mathematics courses. Results suggest that students' emerging conceptions of CT became relatively well-aligned with expert views and that their characterization of CT included many computational practices (e.g. from modeling and simulation) and related affordances (e.g., creativity, agency) and outcomes (e.g., benefits learning, deeper mathematics understanding).*

*Keywords:* Computational Thinking; Concept Image/Definition; Taxonomy of Practices

Computational thinking (CT) has had a place in mathematics learning and education research since early experiments with Logo (e.g., Papert, 1980), and the push to introduce learners to CT practices has also recently increased in conjunction with the integration of computational applications into professional mathematical endeavors (e.g., Weintrop et al., 2016). Whereas research has been focusing primarily on school learning (e.g., Gadanidis, 2015) and more recently on ways computer programming can be used in undergraduate mathematics (Leron & Dubinsky, 1995), much work still needs to be done to understand how learners are engaging with CT practices, how they come to understand the mathematical content, procedures, and skills associated with computational applications, and what instructional interventions can best support student learning and achievement. With this in mind, we sought to investigate mathematics undergraduate students' conceptions of CT practices as they emerged during one of their three programming-based mathematics courses.

We addressed the following research questions:

1. How do undergraduate mathematics students characterize CT?
2. In what ways do undergraduate mathematics students' emerging understandings of CT align with expert categorizations of CT?

We use the framework of concept-image / concept-definition (Tall & Vinner, 1981) to analyze the evoked conceptions of undergraduates as they reflected on their understanding of CT during various stages of their course. For a concept definition of CT, we draw upon descriptions of CT mainly from the work of Wing (e.g., 2008, 2014) as well as the taxonomy of computational practices in mathematics and science proposed by Weintrop et al. (2016). Participants in our survey (3 times during the term) study were 104 undergraduate students enrolled in one of the three project-based mathematics courses at Brock University at which they learn to design, program, and use interactive computer environments to investigate mathematics conjectures, concepts, or real-world applications (Buteau et al., 2015). The specific items of the questionnaires were designed to elicit participants' personal conceptions of CT as related to their experiences coming into, and working through, the courses. Results suggest that overall by the middle of their CT-based mathematics course, students' emerging conceptions of CT became relatively well-aligned with expert views. Their characterization of CT included many computational practices, mainly from modeling and simulation, and computational problem solving; for example, a participant wrote: "[CT] is the ability to look at a problem and use models and computer simulations to solve and understand problems".

# US and Chinese Prospective Elementary Teachers' Problem-posing Performance: A Comparison Study of Specific Problem-posing Processes

Jinxia Xie and Joanna O. Masingila

Syracuse University

*This study reports on 33 US and 55 Chinese prospective elementary teachers' problem-posing performance while engaged in five specific problem-posing processes. The study found that: (1) both US and Chinese participants were able to pose solvable mathematical problems, and (2) the US participants were more challenged by the Selecting and Comprehending processes, while their Chinese counterparts posed a higher percentage of solvable problems for these two processes than the other three processes. In the future, we might investigate the possible causes that triggered the differences and the impacts of the differences on mathematics learning.*

*Key words:* Problem Posing, Prospective Elementary Teachers, Comparison Study

## Literature Review

Teachers and students' problem-posing performance has been investigated in multiple countries (Chen, Van Dooren, Chen, & Verschaffel, 2011; Kojima & Miwa, 2008; Rosli, Goldsby, & Capraro, 2013; Siswono, 2014). However, only a few cross-national comparison studies have examined problem posing (Cai, 1998; Cai & Hwang, 2002; Yuan & Sriraman, 2011), and few were conducted with prospective teachers. Taking into account the unique contribution provided by international comparison study, which "allows us to see different things, and sometimes to see things differently" (Ma, 1999, p. xx), this study attempted to address the following research question: What are similar and different patterns of US and Chinese prospective elementary teachers' problem-posing performance while engaged in specific problem-posing processes?

## Guiding Framework and Methodology

This study utilized four problem-posing processes, i.e., Translating, Comprehending, Editing, and Selecting, as a guiding framework (Christou, Mousoulides, Pittalis, Pitta-Pantazi, & Sriraman, 2005). Two sets of tasks involving fractions and geometric graphs were carefully designed. We first asked participants to pose problems for the above four processes, then to solve a given mathematical problem, and finally to pose two more mathematical problems. Each posed problem was classified into one of the following categories: (1) a solvable mathematical problem, (2) an unsolvable mathematical problem, and (3) not a mathematical problem.

## Results and Discussions

We found that both US and Chinese prospective elementary teachers were able to pose solvable mathematical problems. However, they showed quite a difference in performance in problem-posing processes. More specifically, the US participants were more challenged by the Selecting and Comprehending processes, while their Chinese counterparts posed a comparatively higher percentage of solvable mathematical problems for these two processes than the other three processes. We also noticed that both US and Chinese participants' best performance in problem posing did not occur during the problem posing that came after the problem-solving process. In the future, it would be important to investigate the causes that triggered such big differences as well as the impacts of such differences on their mathematics learning.

Mathematics Through the Lens of Service-learning

| Sayonita Ghosh Hajra | Jen England | Chloe Mcelmury | Hani Abukar |
| --- | --- | --- | --- |
| Hamline University | Hamline University | Hamline University | Hamline University |

*In this poster, we report on a study conducted at a midwestern private liberal arts university where researchers incorporated service-learning into a non-major mathematics course. Data reveal students felt more confident learning mathematical concepts because of its real-world application in the community. Additionally, students reported an increase in the value of mathematics and its importance in societal reforms.*

*Keywords*: mathematical anxiety, service-learning, undergraduate students, civic engagement

Many undergraduate students experience math anxiety, which often results in their being unprepared (Nagy et al., 2010; Ashcraft, 2002) to pass graduation requirements for a bachelor's degree (Bound, Lovenheim, & Turner, 2010). This leads to students developing negative attitudes toward mathematics. One strategy to combat these issues is engaging students in service learning, which can increase confidence (Soria & Thomas-Card, 2014; Soria, Nobbe, & Fink, 2013; Soria, Troisi, & Stebleton, 2012). As students communicate math skills from college classrooms to community settings, they learn practical and applicable uses of mathematics in daily life. This is particularly beneficial for low-income and first-generation students who gain self-efficacy, persistence, and college retention (Yeh, 2010). Furthermore, Schulteis (2013) argues service learning is an "excellent way to enhance the extent of student learning" by helping students develop "greater mastery of classroom material and an increase in civic values and skills" (p. 582). Indeed, there are calls to train instructors to engage in learning beyond the classroom (National Task Force on Civic Learning and Democratic Engagement, 2012; Kielsmeier, 2010) so service learning can be a requirement of college education.

We wanted to explore these opportunities through a non-major mathematics course at our midwestern private liberal arts university. The course incorporated three service learning activities, worth 10 percent of the course grade, by partnering with a local elementary school. The course was offered for one month, Monday—Friday for 3.5 hours every day. Thirty-three undergraduate students were enrolled in the course and participated in our study. Students created and revised lesson plans from the topics discussed in class and then taught the lessons to about 50 third graders. After each teaching session, university students wrote self-reflections on their experience, which were collected, analyzed, and coded as data using open coding methods (Strauss & Corbin, 1998).

Three key themes emerged from this data. First, students expressed more confidence in mathematics communication and a better understanding of its role in society. Second, students found teaching through hands-on mathematical activities more applicable to the real world, which was different than prior experiences learning in a traditional university classroom setting. Third, students reflected on becoming more aware of future generations of young(er) students; they shared hopeful statements that these elementary children would grow up to make a difference in the world because of educational opportunities like this course/study. Ultimately, our data demonstrates that service learning opportunities can transform mathematics from something scary and disconnected to a more meaningful and civically engaged area of study.

# The Distribution of the Mathematical Work during One-on-one Tutor Problem Solving

Carolyn James
University of Portland

Linda Burks
Santa Clara University

*Undergraduate math tutoring is an important context for student learning, yet little empirical work has been done to understand tutor-student interactions. Using frameworks for problem-solving and socially mediated metacognition (Carlson and Bloom, 2005; Goos, et. al, 2002), this poster examines who guides the development of mathematical ideas throughout the problem solving process within a drop-in one-on-one tutoring context. We found that the majority of the tutoring interactions closely followed the Orienting-Planning-Executing-Checking phases of problem solving. The "Executing" phase had the highest degree of student contribution, while the "Checking" phase was least represented.*

*Keywords:* Undergraduate Tutoring, Problem Solving, Socially Mediated Metacognition

Peer undergraduate mathematics tutoring is widespread (Sonnert & Sadler, 2015) and has been shown to lead to significant learning gains for both tutors and students (Graesser, 2011; Lepper & Woolverton, 2002). However, empirical investigation of tutor-student interactions has been minimal (Roscoe & Chi, 2008), particularly at the undergraduate level. Given the lack of theoretical development in this area, our understanding of tutoring interactions can be framed by modifying lenses developed for other contexts. For example, we draw heavily on best practices for teaching, which strongly emphasize the importance of active learning (Larsen et. al, 2015; Freeman et. al, 2014; Topping 1996). In addition, the majority of math tutor interactions, particularly in a drop-in context, are based on solving homework problems. Thus, frameworks for problem solving, such as Carlson and Bloom's (2005) are useful for understanding the progression of the tutor-student interaction. We are interested in understanding the problem-solving process in a tutor-student interaction. In particular, this poster focuses on who guides the mathematics in the interaction, and how that shifts during the problem-solving process.

Data for this study was drawn from 18 undergraduate math tutors at two different universities in a drop-in tutoring environment. Tutoring sessions were recorded using video or scribe-cast. Data for this analysis was based on 6 episodes. The episodes were selected based on their clarity and focus on a problem-solving context. We coded transcripts according to two frameworks. First, we identified the problem solving phase: (1) Orienting, (2) Planning, (3) Executing, or (4) Checking (Carlson and Bloom, 2005). Next, within each phase we identified how the mathematics was being presented or developed. We modified Goos, Galbraith, and Renshaw's (2002) coding scheme for socially mediated metacognition to include kinds of interaction (Explain, Answer, Question, Correct, or Reflect) and types of mathematics for those interactions (Information, Strategy, Concept, or Computation).

We found that many of the tutor-student interactions closely followed the problem-solving cycle proposed by Carlson and Bloom (2005). The "Checking" phase was least represented in our episodes: commonly a single line or completely absent. Across the episodes, the "Planning" phase had the most variation in the level of student participation; either entirely planned by the tutor or planned cooperatively between the dyad. The "Executing" phase had the most consistent student mathematical contributions. This study indicates a need for tutor training that elicits student mathematical contributions at every stage of the problem solving process.

Features of Tasks and Instructor Actions That Promote
Preservice Secondary Mathematics Teachers' Understanding of Functions

Janessa M. Beach[1] James A. Mendoza Álvarez[1] Theresa Jorgensen[1] Kathryn Rhoads[1]
[1]The University of Texas at Arlington

*The Enhancing Explorations in Functions for Preservice Secondary Mathematics Teachers Project is developing research-based tasks and explorations as well as instructor materials to be used in mathematics courses for preservice secondary mathematics teachers. The project, now in year two, continues to develop and refine these items based on data collected in year one and the advice of an expert panel and advisory board. The goal of this poster presentation is to provide information on lesson development and methods used in determining key characteristics of instructor moves for building student understanding of functions as well as gather feedback and suggestions on further design and development.*

*Keywords:* Mathematical Knowledge for Teaching, Preservice Secondary Mathematics Preparation, Functions

High-quality mathematics teaching requires common, horizon, and specialized content knowledge (Ball et al., 2008; Hill, Ball, & Schilling, 2008). Developing this understanding of the content preservice teachers will teach can be done by engaging in tasks that illuminate mathematical concepts (Loucks-Horsley et al., 2003; Zaslavsky, 2008). This project aims to refine and supplement widely-used secondary teacher preparation materials used in a course on functions as well as develop an instructor's guide to scaffold the lessons and explorations.

## Research Questions

Currently, limited research exists on how to facilitate development of profound understanding of functions and key characteristics of mathematical tasks that can promote this specifically for preservice secondary mathematics teachers. Discussion with RUME attendees will assist us in identifying additional design issues that need to be accounted for in addressing the following research questions: (1) What are key characteristics of mathematical tasks that promote development of profound understanding of functions for secondary mathematics teachers in the first two years of undergraduate study? (2) What are key instructor moves and pedagogical strategies for facilitating development of profound understanding of functions for secondary mathematics teachers engaging in high-yield mathematical tasks?

## Discussion

Over two iterations of this course at a large urban university in the Southwest, this project has collected student artifacts including pre- and post-surveys on functions, classroom videos, pre-class instructor logs, post-class instructor interviews, observation notes, and 18 student interviews. This poster will provide details on lesson development as well as the methods used in determining key characteristics of instructor moves for building understanding of functions.

## Connecting Physics Students' Conceptual Understanding to Symbolic Forms s Using a Conceptual Blending Framework

Benjamin P. Schermerhorn
University of Maine

John R. Thompson
University of Maine

*In an effort to understand physics students' construction of equations in terms of mathematical structures, previous work has employed a symbolic forms framework. To account for students' contextual physics understanding related to these structures for vector differentials, we mapped symbolic forms into the framework of conceptual blending to model students' construction of equations. This allows us to shed further light on recent literature in this area.*

Key words: Physics, Equation, Symbolic Forms, Conceptual Blending

Much of physics involves the construction and understanding of equations. Writing an equation to describe a physical system is a process that entails encoding conceptual meaning of the related physics using specific variables and mathematics symbolism to describe the ways in which the physical variables relate to one another. In many theoretical models used to frame how students use mathematics in physics this process is labeled "modeling" or "mathematization" (Redish & Kuo, 2015; Uhden et al., 2012; Wilcox et al., 2013).

Interpreting the equation as a construct of physical-mathematical language, we present a model for the construction of equations, developed from research on student understanding of non-Cartesian vector differentials (Schermerhorn & Thompson, 2017), that combines a symbolic forms framework addressing the structures through which students understand physics equations (Sherin, 2001) and formal conceptual blending theory from linguistics (Fauconnier & Turner, 2002). In this model the conceptual schema of symbolic forms, which describes the justification for the mathematical structures of an equation, serves as the underlying generic space in a conceptual blending framing of students' construction of equations and thus drives the blend of two input spaces: Sherin's symbol template (the externalized structure of the expression) and content understanding. Symbolic forms were designed as acontextual constructs, independent of content understanding. Therefore, by incorporating conceptual blending theory we can explicitly connect students' content understanding to the expression of terms in an equation.

The proposed model for equation construction allows us to reinterpret recent symbolic forms literature (Jones, 2013; Kuo et al., 2013; Meredith & Marrongelle, 2008) which has interpreted the conceptual schema to be on par with, rather than independent from, content understanding. Conceptual blending literature addressing the interwoven nature of mathematics in physics at both the introductory (Bing & Redish, 2007; Brahmia et al., 2016) and upper levels (Bollen et al., 2016; Hu & Rebello, 2013), has not included the generic space, which serves as an underlying structure for each of the conceptual input spaces and determines which pieces combine to form a new blended concept. Our approach uses features of one framework to fill in the missing analytical aspects of the other framework in these contexts.

## Children's Topological Thinking

Steven Greenstein
Montclair State University

Adam Anderson
Montclair State University

**Abstract:** *This poster presents an ongoing investigation into children's topological thinking. Prior research identified and advanced children's informal ideas about topological equivalence – and equivalence and invariance more broadly. This investigation extends that research into children's thinking about related ideas such as order, separation, and coverings. Newly identified forms of geometric thinking have implications for the teaching and learning of geometry and for research into students' mathematical thinking.*

**Keywords:** Geometric reasoning, Topology, Equivalence, Teaching experiment

Children's experiences in geometry throughout elementary school are entirely Euclidean. However, research finds that they also possess intuitive topological ideas (Greenstein, 2014; Laurendeau & Pinard, 1970; Piaget & Inhelder, 1956). These findings lay the foundation for the claim that there are forms of topological reasoning available to young learners that can be identified as mathematical, are significant, and can be seen to develop in ways that would have implications both for research into students' mathematical reasoning and as a focus for further curriculum development and design.

The poster we are proposing will illustrate our current investigation into children's thinking about topological equivalence, as well as the foundations for this investigation in prior research (Greenstein, 2014). That research found that a microworld for topological equivalence (Greenstein, 2017) supported two children's constructions of ways of thinking about topological equivalence. They used those schemes (von Glasersfeld, 1995) to build equivalence classes of shapes and identify the properties of shapes within equivalence classes. Broadly speaking, it was evident from this investigation that engagement with topology provides learners with powerful forms of mathematical engagement that are not available to them in Euclidean geometry.

Our current investigation seeks to develop a superseding model (Steffe & Thompson, 2000) of children's thinking about topological equivalence, and extend the focus of our prior research into additional aspects of equivalence relations that arise in the context of topology, including notions of order, covering, and separation. For example, through their investigations of topological equivalence and invariance, children are also engaging with the ideas of order through examinations of points along a curve; of coverings through a task that provides the child with a square and calls for a collection of shapes that can adequately cover that square; and of separation through a task that provides a collection of distinct points and calls for shapes that can be used to confirm their separation.

Findings from this study are beneficial to students whose topological ideas have yet to be engaged in schools and also to the community of mathematics educators whose research has only nominally investigated them.

# Development of Students' Mathematical Discourse through Individual and Group Work with Nonstandard Problems on Existence and Uniqueness Theorems

Svitlana Rogovchenko [a] Yuriy Rogovchenko [a] Stephanie Treffert-Thomas [b]
[a] *University of Agder, Norway* [b] *Loughborough University*, *UK*

*Research shows that students' learning is affected by the types of tasks. We explore how the use of nonstandard problems influences understanding of the Existence and Uniqueness Theorems (EUTs) by a group of engineering students. The focus is on the development of students' mathematical discourse during the individual and group work with nonstandard problems. We present the evidence indicating that students developed new mathematical routines gaining a deeper understanding of EUTs and appreciated the experience.*

*Key words:* ordinary differential equations, existence and uniqueness theorems, design research, mathematical discourse, individual work, group work, nonstandard problems.

## Description of the Study

Ordinary differential equations (ODEs) is one of important post-calculus courses in university STEM (Science, Technology, Engineering and Mathematics) education. Nevertheless, the recent review of the literature related to research on ODEs in undergraduate education during the last decade surveys only about twenty papers dealing with the understanding of the concepts of solution of an ODE, a system of ODEs and bifurcation (Rasmussen and Wawro, 2017). EUTs are among very few theoretical results included nowadays in standard ODE courses for engineering students. Understanding and the correct use of the EUTs present serious challenges for students (Raychaudhuri, 2007), as even the concept of a solution of an ODE itself (Arslan, 2010). In our study, students consecutively produced three scripts of solutions to the set of six nonstandard problems designed by the lecturer to challenge students' conceptual understanding of the EUTs: individual solutions obtained in the first tutorial, individual solutions submitted as a homework, and solutions submitted after the discussion with peers in small groups and group presentations of solutions during the second tutorial. We analyzed three scripts, pre- and post-activity surveys, and audio recordings of the peer discussions and of the presentations.

## Research Questions

1) How can nonstandard problems challenge students and help to develop analytical skills and further conceptual understanding of mathematical routines in an ODE course?
2) To what extent have individual work and group discussions contributed to the development of students' mathematical discourse?

## Conclusions

Working on the problems, students made use of theorems and definitions, generalized and designed examples, verified validity of statements and analyzed reasoning. All these practices promoted students' conceptual understanding and contributed to the development of a new mathematical discourse because, using a commognitive lens, "learning mathematics means modifying one's present discourse so that it acquires the properties of the discourse practiced by mathematical community." (Sfard, 2009). We believe that lecturers should ask more nonstandard questions that they know their students will find difficult and may not be able to answer, and do it more often. Our research has shown that students valued the experience and gained a deeper understanding of the EUTs.

# Assessing the Development of Students' Mathematical Modeling Competencies: An Information Entropy Approach

Yannis Liakos [a] Yuriy Rogovchenko [a]
[a] *University of Agder, Norway*

*We suggest a new scaling tool for converting big amounts of qualitative data into quantitative data based on the recent developments in the information theory. We believe that it can be used with reasonable efficiency to monitor the development of students' mathematical competencies, and not only. Discussing advantages and shortcomings of this tool along with the possibilities for further development, we invite to discussion of a new approach.*

Keywords: mathematical modeling, competencies, quantitative data, evaluation tool, information entropy.

## Description of the methodology

We introduced mathematical modeling tasks with biological content to engage biology students more actively into learning mathematics and created mathematical competencies profiles for individual learners to follow their development from session to session. From a wide selection of approaches to the notion of mathematical competencies reported in the literature (Maaß, 2006, Boesen et al, 2014, Weinert, 2001), we chose a competency framework from the Danish KOM project (Niss, 2003). Viewing a competency as an individual's ability to use mathematical concepts in a variety of situations, within and outside of the normal realm of mathematics (Niss, 2003), we retain five basic groups of mathematical competencies out of the eight suggested in KOM: thinking/acting mathematically, modeling mathematically, representing and manipulating symbolic forms, communicating/reasoning mathematically, and making use of aids and tools. Fifteen competencies in five groups are coded separately in a reliable manner. When the data collected in the sessions are coded, the record of each competency frequency and strength (beginning, intermediate, developed, exemplary) is being kept. This creates big data sets which we would like to analyze in order to assess and monitor students' competency development. To this end, we rely on a so-called Shannon entropy (information entropy), one of the central concepts in the information theory. Our approach to the competencies development evaluation combines Shannon's entropy and VIKOR method developed for finding closest to an ideal solution to decision problems with conflicting and noncommensurable criteria. Our research questions in this study are: 1) How can large amounts of qualitative data be converted into quantitative data by using the tools from modern information theory? 2) How reliable and efficient is this new scaling tool?

## Conclusions

We believe that a new entropy-based scaling tool opens new interesting opportunities for researchers who need a consolidated evaluation for big amounts of data; it could be efficiently used both to monitor the development of individual students' competencies and to compare their performance. It allows to assign different weights to competencies providing thus possibilities for monitoring the progress in the development of particular skills. However, using this method of data analysis inevitably leads to the loss of some essential information, the risk we are willing to undertake in order to study the potential of this new progress-tracking tool.

Queer Students in STEM: The Voices of Amber, Charles, Jenny and Juan

Matt Voigt
San Diego State University & University of California San Diego

*Abstract: This report provides a rich narrative documenting the experiences of four queer students in STEM, which showcase both the challenges and power of being queer in STEM. Students viewed the nature of STEM through a paradoxical lens of a discipline that is objective and thus neutral to issues of identity, yet hostile and exclusionary to non-normative identities in STEM spaces. In response, queer students in undergraduate math courses described the difficulties in navigating the amount of personal information they reveal about themselves or be faced with the psychological burden or cognitive stress derived from presenting in non-normative ways.*

Keywords: Queer, STEM, LGBT, oSTEM, Narrative Analysis, Equity

Despite growing attention paid to student identities, when it comes to the topic of sexual orientation, the research literature remains largely in the closet; it neglects to address the impact or representation of queer individual in STEM. However, there is some evidence suggesting that marginalization due to sexuality might be felt more acutely within STEM-related courses (Bilimoria & Stewart, 2009).

We recruited students from two LGBTQ-friendly universities (Pride Index, 2017), that have active oSTEM student organizations. Four students, Amber, Charles, Jenny and Juan agreed to participate in the study. We used a semi-structured interview protocol (Ginsburg, 1997) to target information about their experiences as a queer student in STEM; how they perceive the nature of STEM; their favorite courses and instructors; description of the "coming out" processes; advice for other students; and the completion of two mathematical tasks. A narrative analysis based in grounded theory was utilized to identify emergent themes (Strauss & Corbin, 1994).

The students in this study described multiple ways in which they conceived of the nature of math and science, resulting in paradoxical experiences. The students made mention to STEM as an objective set of processes, focused on facts or rules. Yet, their queer identities are often at odds when viewed through a lens of precision within the STEM discipline. Furthermore, the students felt that the nature of STEM is removed from their personal identities, and described the classroom as a vacuum operating without consideration to the external world. As an example, Jenny characterized her bisexual identity in STEM as "silent," and felt that her math professor did not create space for processing traumatic events (e.g. impact of presidential election).

The students' stories further showcase challenges and the impact of being queer in STEM. Students described "coming out" in STEM spaces as either a form of information control or as a psychological distractor. For instance, Charles uses a form of "vetting." If Charles deems a person "safe enough," he will slowly engage the person in conversation to determine whether he will "come out" to the person. Charles also stated that he had "very few positive experiences coming out or being queer within my major." In contrast, Amber did not feel that they have a choice when conveying their gender fluid identity. Amber described feelings of psychological stress induced by presenting in gender non-conforming ways in math classrooms.

While this study seeks to capture and promote voices of queer students using narrative accounts as a means of centering queer identities in STEM discourses, it calls to attention the many voices often silenced by resistance. As an example of persistence in the face of resistance, Juan stated, "not everyone saw the rationale in creating a space for queer in STEM. So that was so discouraging. I was so angry. But that fortunately lit a fire under me."

Red X's and Green Checks: A Preliminary Study of Student Learning from Online Homework

Allison Dorko
Oklahoma State University

*Homework is thought to play an important role in students' learning of mathematics, but few studies have addressed what, if anything, students learn from doing online homework. This study is a preliminary attempt to answer the question* do students learn what instructors intended they learn from an online homework assignment about sequences?

*Keywords:* homework, sequences, instructional triangle

Homework is thought to play an important role in students' learning of mathematics. University calculus students spend more time doing homework than they do in class (Ellis, Hanson, Nuñez, & Rasmussen, 2015; Krause & Putnam, 2016), meaning that homework accounts for the majority of students' interaction with content. Due to increasingly sophisticated technology, online homework has become more prevalent in mathematics courses. However, few studies have investigated student learning from online homework. Researchers have found that online homework format does not have a statistically significant effect on course or exam grades, or that it has a slight positive effect (Dedic, Rosenfield, & Ivanov, 2006; Halcrow & Dunnigan, 2012; Hauk, Powers, Safer, & Segalla, 2002; Hirsch & Wiebel, 2003; LaRose, 2010). A few studies have investigated qualitative factors related to homework, such as students' preferred format (Hauk & Segalla, 2002; Krause & Putnam, 2016) and the resources they use while doing homework (Krause & Putnam, 2016). However, we do not know much about what, if anything, students learn from doing online homework. This study is a preliminary attempt to answer the question *do students learn what instructors intended they learn from an online homework assignment about sequences?*

The study design reflected a theoretical perspective employed by Ellis et al. (2015), who positioned homework as a *task* in Herbst and Chazan's (2012) instructional triangle. In the triangle, edges represent the interactions between teacher, students who complete tasks, and the knowledge at stake. This study used a series of clinical interviews with professors to determine what they saw as the knowledge at stake within a particular online homework assignment, and observations and interviews with students to investigate whether their interaction with the homework supported their learning that knowledge. Specifically, the researcher conducted clinical interviews (Hunting, 1997) with two calculus II instructors about what they hoped students would learn from each of 14 problems on an online homework assignment about sequences. The researcher then video-recorded three students as they worked individually on the homework. In the third phase, the researcher and student watched the video together while the researcher asked questions about what the students did and why, if the student felt (s)he had learned anything from the problem, and if the student felt (s)he had learned or noticed what the professor intended for that problem.

Preliminary findings indicate that students learned some of what professors intended (e.g., how to generate terms in a recursive sequence, what notations like $a_n$ and $b_n = a_{n+1}$ mean) but not all (e.g., that a sequence is defined on a set of sequential integers, not on the set of real numbers). Analysis is ongoing, and should yield implications for designing homework tasks that engender desired understandings of ways of thinking.

Essential Aspects of Mathematics as a Practice in Research and Undergraduate Instruction

Eryn M. Stehr Tuyin An
Georgia Southern University

*A gap between mathematics as used by mathematicians and mathematics as experienced by undergraduate mathematics students has persistently been identified as problematic; A commonly proposed solution is to provide opportunities for students to* do *mathematics and* be *mathematicians (e.g., Whitehead, 1911; Harel, 2008). Conceptions or beliefs about what this means may vary depending on a mathematician's research and experience. The authors explore mathematicians' expressed conceptions of mathematics in their research and in their teaching.*

*Keywords:* conceptions, beliefs

A gap described between meanings of mathematics as used in mathematical research and mathematics as experienced by students has persistently been identified as problematic, potentially preventing students from knowing mathematics in the expected deep and complex ways (e.g., Whitehead, 1911; Harel, 2008). One solution proposed by mathematicians and mathematics educators for all levels is to provide opportunities to students to *do mathematics* and *be mathematicians* (e.g., Whitehead; Harel; Ball, Lubienski, & Mewborn, 2001; Stein, Grover, & Henningsen, 1996). This solution depends, however, on the conceptions or beliefs held about the nature of mathematics itself (e.g., Skemp, 1978). We asked: How do mathematicians at Georgia Southern University view mathematics as a practice in their own mathematical research? What aspects of mathematics do they try to teach their undergraduate students?

We developed 12 broad statements about aspects of mathematics based on descriptions of the nature of mathematics from mathematicians and mathematics educators (e.g., Ball et al., 2001; Ernest, 1989; Harel, 2008; Stein et al., 1996; Whitehead, 1911). Mathematics is: (a) a mass of details and procedures; (b) strategies and solutions with internal or external validity; (c) ideas that can be theoretically interesting, elegant, and beautiful; (d) ways of thinking systematically and analytically; (e) ways of precisely communicating; (f) a powerful tool for interacting with real world and everyday situations; (g) productive struggle through framing and solving problems; (h) experimentation through making and testing conjectures, examining constraints, and making inferences; (i) the study of patterns; (j) the abstraction of properties and characteristics apart from emotions or sensations; (k) a human endeavor, continually growing through the dynamic process of creating knowledge through purposeful activity; and (l) a crystalline structure existing in complete, static, pure form, discovered through logical reasoning.

We selected 10 mathematics faculty with different research interests and experience. We asked each participant to respond to two open-ended questions and two questions that involved a card-sorting task. We used separate open-ended questions to ask them to describe the nature of mathematics as it appears in their research and that they intend to teach to their undergraduate students. We used the 12 statements in separate think-aloud card-sorting tasks. In each, the participant chose to keep, discard, or edit each card or to add new cards. They selected four aspects of mathematics they felt were most critical in 1) their research and 2) their teaching.

We analyzed faculty participants' selections and reasoning to understand how they view the nature of mathematics and how they hope their students will view the nature of mathematics. In this poster, we present their views to explore more deeply what it would mean for students to *do mathematics* and to *be mathematicians* in different areas within undergraduate mathematics.

# Reflections on a Peer-Led Mentorship Program for Graduate Teaching Assistants

Laura Broley, Sarah Mathieu-Soucy, Nadia Hardy & Ryan Gibara
Concordia University

*This poster will describe a peer-led mentorship program offered to Graduate Teaching Assistants (GTAs) in a Canadian University. We present the creators' rationale for implementing this program, as well as the perspectives of the two graduate student peer mentors who have taken the lead in its development and implementation.*

*Keywords:* Graduate teaching assistants, peer-mentoring, professional development

Research concerning the professional development of mathematics graduate teaching assistants (GTAs) has been driven by two seemingly contradictory observations: (1) GTAs typically arrive at their graduate studies with little to no *formal* training in mathematics education (Kung & Speer, 2009); and yet (2) GTAs play a significant role in shaping the current and future state of undergraduate mathematics education (Speer, Gutmann, & Murphy, 2005). To assist GTAs in successfully assuming teaching-related positions like marking, one-on-one tutoring, leading tutorials, or instructing introductory courses, training programs of various natures have been developed and discussed (e.g. Belnap & Allred, 2009; DeFranco & McGivney-Burelle, 2001). With this poster, we aim to contribute to this discussion by presenting and reflecting on one possible approach to "training", in the form of a peer-led mentorship program. This represents the initial phase of a wider research project aimed at better understanding how to provide GTAs with *educational experience* (in the sense of Dewey, 1938). Our work aligns with the goal mentioned in multiple papers (Speer, Deshler, & Ellis, 2017; Speer, Murphy, & Gutmann, 2009) to use research to inform the design, improvement, and efficacy of professional development programs for GTAs.

For almost a decade, a retired professor volunteered at a mathematics department of a large, urban Canadian university to provide support to new GTAs. Following his retirement from all activities, the department decided to initiate a peer-led mentorship program in the fall of 2016. Although the initial motivation for shifting to peers as opposed to professors was mainly an issue of availability, the department grounded its choice on two main goals. First, to provide students with training and guidance from mentors who can closely relate to their current experience, both within and beyond their teaching roles. And second, to build a safe (i.e., confidential and non-evaluative) community within which graduate students come to see it as normal to receive feedback about their teaching, reflect on their teaching choices, and discuss various pedagogical and didactic issues. Two doctoral students were chosen to run the program, based on their previous experience and interest in teaching, certain characteristics of their personality (e.g., their likelihood to put a lot of effort into the development of the program, as well as to be empathetic, open, and constructive in interactions with their colleagues), and their complementarity (e.g., one researches pure mathematics, while the other researches mathematics education at the university level).

Our poster will provide details about the kinds of interactions that have occurred between the mentors and mentees, sometimes over multiple semesters, and reflect on struggles and successes, as perceived by the mentors. As a result, we hope to incite discussions about the participation of peers, who have studied both mathematics and mathematics education, in improving the experience of GTAs and the teaching and learning of mathematics at the undergraduate level.

Capture of Virtual Environments for Analysis of Immersive Experiences

Camden Bock
University of Maine

*This poster addresses emerging technologies for the capture and reconstruction of participants experiences in immersive virtual environments. These methods might improve communication of participants experiences when solving mathematical problems in three-dimensional contexts.*

*Keywords:* Technology, Virtual-Reality, Mixed-Reality, Geometry

Virtual, mixed and augmented reality technologies provide novel opportunities for undergraduate students to investigate three-dimensional mathematical phenomena. For solid geometry, these immersive dynamic spatial displays support dynamic construction with virtual manipulatives in an immersive space without numeric measurements (Dimmel & Bock, 2017). Recent studies observing students solving mathematical problems use a two-dimensional projection of the first-person perspective in immersive (Lai et al, 2016; Bock & Dimmel, 2017) and augmented environments (Radu et al, 2015). However, these renderings might limit researchers' ability to analyze student's experiences in the virtual environment. This poster discusses the research question: How can participant's experiences solving mathematical problems in immersive three-dimensional mediums be understood through two-dimensional mediums? To address this question, this poster explores mixed-reality video capture, three-dimensional gesture capture, and figure logging provide as partial solutions for the reconstruction of a student's experience.

## Mixed Reality Video Capture

Mixed Reality video capture can be used to record and stream live video of the physical participants inside their virtual environment (Figure 1), using both physical and virtual external cameras (Blueprint Reality, 2017). This provides more context about the participant's environment than a first-person view (Figure 1), while it can still be managed within traditional 2-d mediums.

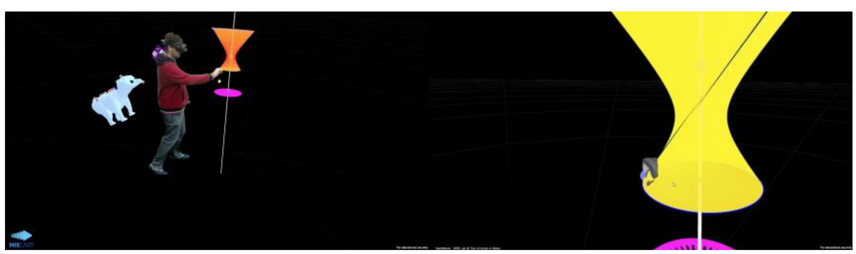

*Figure 1. First Person (left) and Mixed Reality (right) views of the virtual environment.*

## Applications to Future Research

These data capture methods might improve studies using immersive dynamic spatial displays in addition to the first-person screen captures, when researching small groups of participants or sharing research data between multiple researchers. Immersive renderings of dynamic figures might be relevant for future studies of the teaching and learning of college mathematics in contexts where three-dimensional properties are difficult to render in 2D, including solids of revolution, constructions in solid geometry and gradients of three-dimensional surfaces.

Growth Mindset Assessments in Mathematics Classrooms

Hannah Mae Lewis, Kady Schneiter
Utah State University

*Recent scientific evidence shows the incredible potential of the brain to grow and change. Equally important are the observations of the positive impact that having growth mindset has upon students' achievement. Students with a growth mindset view errors and obstacles as opportunities for growth. These students welcome challenges and the opportunity to learn from their mistakes. Although some university instructors are incorporating growth mindset into their lectures and attitudes, unfortunately, the traditional exam method used in undergraduate mathematics classrooms is a fixed mindset model. This poster shows the implementation of a growth mindset structured exam in a multivariable calculus class. The implementation incudes structured opportunities to rework exam problems, give presentations, and papers. All of these focus on assessing the student's achievement of the objectives in the class.*

*Keywords:* Growth Mindset, Assessment, Exam, Attitudes, Multivariable Calculus

A mindset is a self-perception that people hold about themselves. In a fixed mindset, people believe that traits like intelligence and talent are unchanging. They spend time documenting their intelligence instead of trying to learn and grow. In a growth mindset people believe that intelligence and talents can be developed through hard work and dedication. Growth mindset has been shown to have a positive impact on student achievement (Dweck, 2007).

Four techniques that teachers can use to increase the growth mindset of their students are as follows. First, let students know what growth mindset is and teach them that their brains can grow. Second, praise them for their efforts and not for intelligence (Dweck, 2007). Third, tell students stories of people that achieved great things with hard work and a growth mindset (Aronson, Fried, & Good, 2002). Finally, teach students that mistakes are how our brains grow (Moser, 2011) to create an atmosphere in the classroom that leads students to look at mistakes (theirs or others) without any shame, but instead opportunities to improve. Like the other techniques, openness to mistakes can be fostered through changes to classroom instruction. Importantly, it can also usefully be addressed when assessing the students' achievement of the course objectives.

In this poster we describe the implementation of a growth mindset exam structure in a multivariable calculus class at a large public university. Each exam consisted of a traditional in-class portion and a take home portion built on principles of growth mindset. The structure of the assessment had three main elements: students were able to rework, and then orally defend their learning on individual exam problems from the in-class portion of the exam, they gave presentations, including worked out board problems, on a relevant topic, lastly they wrote papers that focused on comprehension, communication and understanding of the objectives for the course.

In this poster, we will describe the course and exam structure; present examples of the exams, paper requirements, presentation descriptions, and corresponding rubrics; exhibit student work; and give feedback from students about the growth mindset exam structure.

An APOS Perspective of Meaning in Mathematics Teaching

Ahsan Habib Chowdhury

Virginia Polytechnic and State University

*The 'meaning of' mathematics can be thought of as mathematical understandings whereas the 'meaning for' mathematics can be understood as understanding the significance of math for non-mathematical purposes. Studies have suggested instructors have difficulty addressing both senses of meaning simultaneously while other studies have indicated factors that affect graduate teaching assistants' (GTA) instruction. Using APOS theory as a theoretical lense, this study examines how these factors affect GTA instruction of the derivative and in turn, how GTAs navigate differing senses of meaning. Through interviews, the researcher found many parallels between GTA instruction and proposed decompositions of the derivative. Regarding meaning, the researcher found when GTAs experience tension between the two senses of meaning, instructional decisions may be taken that anticipate GTA instructional concerns.*

*Keywords:* APOS Theory, Mathematical Meaning, Derivative, Graduate Teaching Assistants

Brownell (1947) defined the "meaning of" mathematics as mathematical understandings and the "meaning for" mathematics as understanding its significance. Studies on instruction in certain contexts, like service learning, have shown tension between these senses of meaning for instructors (Carducci, 2014; Connor, 2008; Donnay, 2014; Hadlock, 2013; Rousseau, 2004; Schulteis, 2013; Zack & Crow, 2013). Whether this occurs in a 'typical' math class needs further study. With respect to graduate teaching assistants' (GTAs') instruction, studies have identified factors such as content knowledge, responsibilities, and control (Addy & Blanchard, 2010; Bond-Robinson & Rodriques, 2006; Hill, Rowan & Ball, 2005). By adapting APOS theory as done Martin, Loch, Cooley, Dexter, and Vidakovic (2010), a decomposition of the derivative was used to categorize instruction while the framework of meaning categorized the 'why' behind those decisions. By doing so, this study aimed to see how affective factors effect instruction.

Participants were mathematics GTAs (Ann and Inigo). Data included interviews and emails which explored instruction of the derivative, beliefs, concerns, and instructional goals. Using a research-based genetic decomposition (Asiala, Cottrill, Dubinsky, & Schwingendorf, 1997; Cottrill, Dubinsky, Nichols, Schwingendorf, Thomas, & Vidakovic, 1996; Hähkiöniemi, 2006), responses on instruction were coded as action, process, or object depending on level of elicited understanding while the reasons for choices were coded as "meaning of" or "meaning for"

Results showed the GTAs covered much of the decomposition, eliciting action up through object level understandings. On derivative rules, Inigo (lacking content control, but content with the set syllabi) would have students go through derivations while Ann (who took issue with the syllabi and mentioned competing responsibilities) only would in some cases to be able to stay on schedule. Cutting engagement with derivations subsequently cuts engaging with the limiting process and perhaps results in a pre-object understanding of derivatives as noted by Zandieh (2000). Interestingly, Ann was concerned students do not connect limits and calculus. If pressure to cover material is a case of focusing on the 'meaning for' and the strictly conceptual aims are cases of 'meaning of', attending to the 'meaning for' seems to have anticipated a teaching concern for Ann. While preliminary, perhaps understanding meaning for instructors may serve as an organizing framework of how affective factors reciprocally influence instruction.

University Teachers' Meanings for Average Rate of Change: Impacts on Student Feedback

Ian Thackray
University of Maine

Natasha Speer
University of Maine

*Previous research that has used Thompson's mathematical "meanings" framework has focused on secondary teachers' meanings for mathematics. We examine the meanings that graduate students and professors hold for average rate of change. Further, we attempt to connect meanings to the facets of student work that graduate students and professors notice. This work lets us start to extend the meanings framework and has implications for graduate student professional development.*

*Keywords:* Meanings, Mathematical Knowledge for Teaching, Average Rate of Change

Using two average rate of change items from the Mathematical Meanings for Teaching Secondary Mathematics (MMTsm) (Thompson, 2016; Yoon et al., 2015), we designed a task-based interview protocol and gathered written and interview data from graduate students and professors to answer these questions 1) what mathematical meanings do graduate students and professors hold for average rate of change (AROC)? 2) Based on these meanings, what do graduate students and professors notice about students' meanings of AROC displayed in written work? Goals for this poster are to present the interview design as well as the results from at least three pilot interviews, and for RUME attendees to discuss how the mathematical meanings framework (Thompson, 2016) connects to Ball and colleagues' framework for mathematical knowledge for teaching (Ball et al., 2008). These discussions will help shape connections we draw between the frameworks after further analysis and data collection.

Average rate of change is a concept commonly included in pre-calculus and calculus curricula in universities across the US. It has been identified as a concept that students *must* grasp to be prepared for calculus (Carlson et al., 2003). Recent work has identified meanings that secondary teachers hold for AROC (Yoon et al., 2015) and for underlying concepts that support AROC such as quotient, measure, covariation, and rate of change (Byerley & Thompson, 2017). In this vein of research, the focus is the teacher-centric personal meaning that each teacher holds for the mathematics they teach. By examining this construct, we can draw conclusions about the ways that student meanings may be supported or limited by teachers' meanings. By utilizing the mathematical meanings framework to examine university professor meanings, we aim to build on existing work by drawing connections between professors' and graduate teaching assistants' meanings and what they notice in student work on AROC tasks.

Results from pilot interviews suggest that graduate students may not have fully coherent meanings for AROC. Interviews were analyzed by coding for meanings identified in Yoon and colleagues' (2015) study. On the MMTsm items, one student conveyed a weak meaning for unit, and another student conveyed a formulaic meaning as the arithmetic mean. Both students were limited by a meaning for rate of change as the slope of a secant line, which made it difficult to convey their meaning in any way besides a graphical representation. Interestingly, in contrast to the professor, both graduate students' noticing of the mathematical meaning in student written work was framed by how similar their meaning was to that of the student. These findings can be used to further refine the meanings framework and inform efforts to design professional development for graduate students.

**MPWR-ing Women in RUME: Continuing Support**

| Stacy Musgrave | Jess Ellis Hagman | Kathleen Melhuish | Eva Thanheiser | Megan Wawro |
|---|---|---|---|---|
| Cal Poly Pomona | Colorado State University | Texas State University | Portland State University | Virginia Tech |

*For the past four years, we have run the MPWR Seminar, a daylong mentoring and networking event for women in RUME. Each year, we have hosted 60 – 90 women at various career stages (graduate students, postdoctoral fellows, faculty and professionals outside of academic positions). The seminar takes place the day before the annual RUME conference, allowing most of the participants to continue engaging with each other throughout the subsequent three days during RUME. In this poster, we address the motivation for the seminar, the structure and topics from the 2017 seminar, modifications in the structure for sustainability purposes, and research related to the efficacy and transferability of MPWR. Our aim in sharing this poster is to disseminate our experiences and gather input from the community on what more could be done.*

**Key Words:** Mentoring, Women, Support

Women in STEM fields are disproportionately underrepresented at all stages of a career in academia (Hill, Corbett, & St. Rose, 2010). Mentoring can serve as a mechanism to draw in and keep women in these positions, but this too is lacking (Beede et al., 2011). Preston (2004) highlighted that mentoring is underutilized, and other researchers suggest that not all types of mentoring are as effective among women (Allen, Day, & Lentz, 2005; Caldwell, Casto & Salazar, 2005). In particular, they point to informal mentoring as most helpful for women, but it may be difficult for women and marginalized groups to seek out and form these informal relationships (Ragins & Cotton, 1999).

Female mathematicians with a research concentration in undergraduate mathematics (RUME) are doubly (and sometimes more) marginalized, firstly for being females in mathematics and secondly for being math education researchers in math departments. The degree of mentoring women historically received varied drastically, primarily due to varied personal or academic networks, creating inequitable access to much needed support for success in this field. The inequity especially stood out for women coming from universities with no other RUME researchers, or for women coming into RUME from mathematics or non-undergraduate mathematics education. As such, we recognized a need for support and mentorship for this subpopulation of the RUME community. We thus began the Mentoring and Partnerships for Women in RUME (MPWR) Seminar in 2014 to establish the first formal mentoring structure for women in RUME, and for RUME participants in general (though there have been recent efforts to change this for the broader RUME community). It is thus the intent of MPWR to establish mechanisms that provide support for all women at all career stages in their academic development.

In this poster, we address the motivation for the seminar, the structure and topics from the 2017 seminar, modifications in the structure for sustainability purposes, and research related to the efficacy and transferability of MPWR. Our aim in sharing this poster is to disseminate our experiences and gather input from the community on what more could be done.

Comparing Students' and Teachers' Descriptions of First Year STEM Instruction

Kristen Vroom & Sean Larsen
Portland State University

*The precalculus through single-variable calculus (P2C2) sequence is often viewed as a barrier for STEM intending students. Additionally, many students point to poor instruction as a primary reason for leaving STEM. This leads to many questions about student experiences in the P2C2 sequence. This study is part of a larger national project and draws on student and instructor survey data from three universities. We aim to lay groundwork for understanding student experiences in the P2C2 sequence by answering: (1) How do P2C2 students and instructors describe their class, (2) Do students and instructors describe them differently?*

*Keywords:* Precalulus, Calculus, Instruction, Student Perceptions, Instructor Perceptions

## Methods

Data for this project pulled from student and instructor surveys administered to all students and instructors in the P2C2 sequence at three universities. To answer our research questions, we replicated Ellis, Kelton, and Rasmussen's (2014) analyses of student and instructor surveys. We consider 430 student surveys and 14 instructor surveys. The student and instructor surveys included 16 parallel items regarding classroom experiences (e.g., 'I listen and take notes as the instructor guides me through major topics' and 'I guide students through major topics as they listen and take notes'). Responses were obtained on a 5-point scale, with five representing most descriptive of their class. We considered descriptive statistics and conducted a paired samples t-test for each of the 16 student-instructor responses.

## Sample Results

Both students and instructors responses indicated that the item related to the instructor knowing the student's name (i.e., 'The instructor knows my name' and 'I know most of my students by name') had the highest mean rating of the 16 items, $M_{students}=4.36$, $SD_{students}=1.08$, $M_{instructor}=4.76$, $SD_{instructor}=0.54$. Alternatively, student responses indicated that 'I explore or discuss my understanding of new concepts before formal instruction' had the lowest mean rating, M=2.75, SD=1.11, while instructor responses indicated that 'I structure class so that students constructively criticize one another's ideas' had the lowest mean rating, M=2.14, SD= 0.81.

Results suggested that the average student rating was significantly different than the average instructor rating for 13 of the 16 items. For instance, instructors indicated that 'students regularly talk with one another about course concepts' was significantly more descriptive of their class, M=3.59, SD=1.24, than students, M=3.20, SD=1.28, $t(421)=6.27$, $p<0.05$, $d=0.31$. Additionally, students indicated that 'I have enough time during class to reflect about the processes I use to solve problems' was significantly more descriptive, M=3.29, SD=1.13, than what instructors indicated for 'I provide time for students to reflect about the processes they use to solve problems', M=2.89, SD=0.91, $t(419)=5.96$, $p<0.05$, $d=0.29$. The Cohen's (1988) standardized effect size suggests that the both of these differences in means were medium.

Along with the results presented here, we will further investigate the differences by separating our data by class. We will compare each class' average student rating to their instructor's rating. Additionally, we will compare our results to Ellis, Kelton, and Rasmussen's (2014) findings.

Support for Active Learning in Introductory Calculus: Exploring the Relationship Between Mathematics Identity and Pedagogical Approaches

Paran Norton
Clemson University

Karen High
Clemson University

*Calculus I is a main gatekeeper course for STEM majors, so increasing student success in this course is imperative to retaining more students in STEM fields. Since students' mathematics identity is a strong predictor of pursing a STEM career, more information is needed about how students are developing these identities in introductory mathematics courses. This study reports a piece of a larger mixed methods approach to gain more insight into how instructional approaches in introductory calculus are related to students' mathematics identity development. Interviews were conducted to explore students' perceptions of the pedagogy used in their introductory calculus class. Students' descriptions of their mathematics identity, which includes the constructs of interest, recognition, and performance/competence beliefs are discussed and compared between an active learning environment and a traditional lecture classroom.*

*Keywords:* Calculus Success, Mathematics Identity, Active Learning

Student success in introductory calculus is imperative to obtaining a degree in any STEM field, with about 75% of students taking Calculus I intending to have a career in STEM (Bressoud 2015). Calculus I has been shown to be gatekeeper course, and research continues to show that Calculus I "lowers students' confidence, enjoyment of mathematics, and desire to continue in a field that requires further mathematics" (Bressoud 2015). One reason for this continued problem is a lack of information about how pedagogical choices influence the culture established in the calculus classroom and how this impacts students' mathematics identity development. Engineering identity has been shown to be significantly related to grade performance in introductory engineering courses, which merits taking a closer look at this relationship for introductory calculus (Schar 2017). Also, Cribbs (2012) found that students' mathematics identity strongly predicts their career choice in STEM fields.

Results from the 2015 MAA national calculus study showed that traditional lecture was the predominant instructional method used in Calculus I throughout the country. However, a meta-analysis of 225 studies comparing traditional lecture to active learning in STEM courses found that failure rates under traditional lecture increase by 55% over the rates observed under active learning (Freeman 2014). A smaller study at a large research university of student grade trends in Calculus I revealed that failure rates were significantly lower when an active learning model was implemented in the mathematics department (Norton et al. 2017). Since introductory calculus still functions as a gatekeeper role for STEM majors, more attention needs to be paid to the learning environments that are being provided for these students.

This study will report a piece of a larger mixed methods approach to gain more insight into how instructional practices in introductory calculus are related to students' mathematics identity development. Interviews were conducted to explore students' perceptions of the pedagogy used in their introductory calculus class. Students' descriptions of their mathematics identity, which includes the constructs of interest, recognition, and performance/competence beliefs (Cribbs 2015), will be discussed and compared between an active learning environment and a traditional lecture classroom. Preliminary analysis revealed that the group work provided in the active learning classroom supported students' performance/competence beliefs as well as their feelings of recognition as a mathematics student.

DISA – Digital Self-Assessment for Large University Courses

Jokke Häsä
University of Helsinki

Johanna Rämö
University of Helsinki

Juuso Nieminen
University of Helsinki

*We introduce a model for replacing the course exam with self-assessment on a large undergraduate mathematics course. In our course model, the self-assessment method is seen as a part of new learning environment that enhances the students' reflection skills and encourages them to foster their ownership of their own learning. Self-assessment skills are trained throughout the course and the students receive feedback from multiple sources, including teachers and peers. The DISA model is an important initiative to develop large course pedagogy in the university mathematics setting.*

*Keywords:* Self-Assessment, Reflection, Technology-Enhanced Assessment, Assessment Culture

Improving students' reflection and self-assessment skills is an important goal of university education, as these skills are vital for life-long learning and building a successful career (e.g. Boud, 2000). Self-assessment has been shown  to have a positive effect on learning: It can improve reflection skills (MacDowell, 1995), emphasise learner autonomy and communication skills (Stallings & Tascione, 1996) and be a more effective learning method than studying for an exam (Friess & David 2016). However, self-assessment skills are rarely explicitly taught. In the DISA project, we have replaced the final exam with self-assessment on a large undergraduate mathematics course. At the end of the course, the students assess their own skills based on a detailed assessment rubric, which contains not only content knowledge items but also generic skills such as mathematical writing and discussion. Cheating is controlled by an automatic verification process in which the student's self-assessment is compared to their performance in various tasks during the course. Self-assessment is supported by extensive formative feedback during the course, as well as several self-assessment exercises.

The DISA method has been implemented twice on a first-year course in linear algebra. Based on quantitative and qualitative studies on the course feedback, the self-assessment and removing the course exam have encouraged deeper learning approaches in the students. They also report having “studied for themselves” instead of the course exam. They also mention having been relieved from stress and anxiety related to the final exam. The grades the students assign for themselves have been comparable to a typical grade distribution on the course, with the exception that the students are reluctant to give themselves the lowest grades 1 and 2 (on the scale 1–5).

Using Comparative Judgment to Analyze Precalculus Algebra Exam Tasks

Kaitlyn Stephens Serbin
Virginia Tech

*Mathematics educators hold varying views on the teaching and learning of mathematics. Literature revealed inconsistencies in educators' interpretations of conceptual understanding and procedural fluency. To explore these differences in perspectives, the current study asked mathematics doctoral faculty, college instructors, graduate teaching assistants, and high school teachers to analyze undergraduate Precalculus Algebra final exam items. Participants were asked to compare exam items based on their effectiveness to gauge conceptual understanding, procedural fluency, or differences between students. The method of comparative judgment was used to yield an ordered rank of the items from least effective to most effective, as perceived by the judges. The weak ordinal association between the rankings of the different groups indicated disagreement in educators' judgments. The factors contributing to these differences in perceptions are unknown. Further research includes exploring these discrepancies in item rankings amongst different subgroups of mathematics educators*.

*Keywords*: Precalculus, Task Analysis, Comparative Judgment

College students are expected to develop proficient conceptual understanding and procedural fluency in their mathematics courses (MAA, 2015). Examinations should be designed to measure students' acquisition of such proficiency. Literature revealed inconsistencies in college mathematics instructors' implementation and perceptions of exam tasks according to the tasks' cognitive demand and conceptual orientation (e.g. Tallman, Carlson, Bressoud, & Pearson, 2016; White & Mesa, 2014). This study was designed to investigate the extent to which these differences in perspectives of tasks exist between different groups of math educators.

The study implemented the method of Comparative Judgment, founded on Thurstone's (1927) psychological principle, which asserts that judgments are comparative in nature. Using this principle, a series of pairwise judgments can be used to produce a linear measurement scale. The online comparative judgment application from No More Marking was used to create twelve surveys—three for each of the four groups of math educators: doctoral faculty, college instructors, graduate teaching assistants, and high school teachers. Each survey contained thirty prompts, through which the judges compared two of the forty-two Precalculus Algebra final exam items. The judges were asked which exam item was better at gauging students' conceptual understanding, students' procedural fluency, or differences between students.

No More Marking used the Bradley-Terry probability model to develop twelve rankings of the items, from least effective to most effective, according to their ability to gauge conceptual understanding, procedural fluency, and difference in student performance, based on the math educators' subjective judgment. Kendall's rank correlation coefficient, tau, was used to compare the ordinal association between the ranks. Weak correlations were found between the rankings of tasks by the different groups, indicating disagreement in the mathematics educators' classifications of the tasks. Further research could explore what factors contribute to these differing perceptions of tasks, and which characteristics of mathematical tasks deem them more conceptual versus procedural.

The Development of a Video Coding Instrument for Assessing Instructional Quality in Community College Algebra Classrooms

Dexter Lim[1], Anne Cawley[2], Irene Duranczyk[1], April Ström[3], Vilma Mesa[2], Laura Watkins[4], Nidhi Kohli[1]
[1]University of Minnesota, [2]University of Michigan, [3]Scottsdale Community College, [4]Glendale Community College

*This poster presents the evolution of a video coding protocol for mathematics classroom instruction. We highlight challenges encountered while analyzing 18 hours of pilot data from six community college algebra classrooms, entailing calibration of over 150 episodes.*

*Keywords:* community colleges, algebra, instruction, student success, video coding protocol

Community colleges prepare many students for STEM and other mathematics-based career options. Specifically, in 2010, more than 585,000 students were taking intermediate or college algebra in community colleges (Blair et al., 2013). It is shown that there is a relation between quality of instruction and student learning based on the instructor's knowledge of teaching, content knowledge, and instructional practices in K-12 education (Hill, Rowan, & Ball, 2005). However, there is limited information regarding characteristics of instruction that inform community college student success. Throughout 2016-2017 while working on a federally funded research project (Watkins, Duranczyk, Mesa, Ström, & Kohli*, 2016)*, we attempted to establish a protocol to codify instruction so that we can identify the conditions under which instruction in community college algebra courses associate well with student learning gains and performance. As we began to consider important features of mathematical instruction in community colleges, we looked to research in K-12 mathematics classrooms to identify features of quality instruction. We started by reviewing the Mathematical Quality of Instruction (MQI) (Learning Mathematics for Teaching Project, 2011), a video analysis tool for mathematics instruction in grades K-6. We then adapted the Quality of Instructional Practices in Algebra (QIPA) (Litke, 2015), a tool developed for 9th grade Algebra lessons, to add features that we could not capture with the MQI. Modifications in both protocols were warranted given that the tools (MQI and QIPA) did not clearly provide distinctions or delineations of practices we observed in the community college classroom associated with quality instruction. By adapting these two protocols, we created, developed, and refined a new protocol, Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM) that addresses the complexity of community college mathematics instruction. The videos were segmented into 7.5-minute episodes and distributed among five teams. The teams (at least one community college faculty member per team) using an iterative process of review and calibration coded 18 hours of algebra instruction. We shifted from a 4-point scale with 21 codes to a 5-point scale with 15 codes to record components of quality instruction. This poster will chart our development process and seeks feedback from our peers.

Geometric Reasoning in an Undergraduate on the Autism Spectrum: A Magic Carpet Case

Jeffrey Truman
Virginia Tech

*In this report, I examine the unusually precise geometric reasoning of a student in linear algebra given the beginning of the Magic Carpet sequence outside of their normal curriculum. Analysis of possible reasons for taking this approach and implications for teaching are presented.*

*Keywords:* autism, linear algebra, geometric reasoning

My research attends to mathematical problem solving by adults on the autism spectrum (with a formal diagnosis), particularly those with a relatively strong background in mathematics. In this report, I focus particularly on the case of one student's work on one of the Magic Carpet problems of Wawro, Rasmussen, Zandieh, Sweeney, & Larson (2012).

Much of the research currently done on mathematics learning in people on the autism spectrum is focused on young children (e.g. Klin, Danovitch, Mers & Volkmar, 2010; Simpson, Gaus, Biggs & Williams, 2010; Iuculano et al., 2014) or looks at mostly arithmetic. There is also a notable strain of work done on the population of research mathematicians (e.g. James, 2003; Baron-Cohen, Wheelwright, Burtenshaw & Hobson, 2007), but very little attention is paid to groups in the middle (mainly high school and college students, or adults other than career mathematicians). This is a gap which I have sought to help fill with my own research, including the particular selection which I present here.

The theoretical framework that guides my research is rooted in the work of Vygotsky. I also start from a perspective of neurodiversity, generally referring to a positive and inclusive perspective on not only autism, but also other neurological differences (Silberman, 2015). More specifically, given my interest in focusing in-depth on interviews with a small number of people, I use case studies (Yin, 2009) from these perspectives. I also include Fischbein's notion of intuition (1979, 1982) and Grandin's work on geometric reasoning and autism (1995) to further my analysis.

The data for my study comes from a series of eleven clinical interviews with a university student on the autism spectrum that I conducted, each focusing on a different set of problems. In this report, I focus on the first of several Magic Carpet tasks, introduced by Wawro, Rasmussen, Zandieh, Sweeney, & Larson (2012).

In this specific portion of the data, I have found suggestions of a tendency toward higher precision than typically seen in geometric solutions and inclinations toward systematic rather than intuitive reasoning. The tendency toward geometric solutions generally is also a notable characteristic, but comparison to other participants suggests that this is only part of a tendency among people on the autism spectrum to gravitate toward favored types of solutions.

I also examine possible effects of the tendencies seen in the interview data for instruction, such as on the possibility to avoid intended approaches and topics (such as an algebraic view of vectors) as well as opportunities to take advantage of the unusual approaches of students on the autism spectrum to benefit instruction overall. This highlights the importance of being able to see validity in unusual student work and interacting with students without deficit-based preconceptions, something which holds particular importance across a variety of forms of disability-related education research.

# What are the Functions of Proof in Introduction to Proof Textbooks?

Elizabeth M. Hewer
Texas State University

Kate Melhuish
Texas State University

*The role of proof in mathematics is multifaceted. de Villiers (1990) argues students should be exposed to at least five essential roles: verifying, explaining, systematizing, discovering, and communicating. We analyzed six commonly-used Introduction to Proof (ITP) textbooks for their treatment of the function of proof. We used a thematic analysis approach leveraging de Villiers categorizations. We found that verification was heavily emphasized, while discovery was almost excluded. However, the textbooks emphasized verifying, explaining, systematizing, discovering, and communication in ways that de Villiers did not. For example, de Villiers focused on the global view of systematizing, where the books were more likely to emphasize the local structure of proof.*

*Keywords*: Introduction to Proof, textbook analysis, role of proof

Textbook analysis assesses and provides information of curriculum, which influences the instructor's lessons and thereby students' learning (Stein, Smith, & Remillard, 2007). Further, the textbook itself is a resource that impacts students directly. The ITP course is frequently students' first indoctrination into the mathematical community's proof practices. Each of the ITP books provided commentary and information for students to assimilate the function of proof in mathematics. We focus on the early portion of the texts that explicitly treat function of proof.

*Methods.* We selected textbooks reflecting market-share (David and Zazkis, 2017): Chartrand, Polimeni, and Zhang (2013), Hammack (2013), Smith, Eggen, & St Andre (2006), and Velleman (2006). Additionally, we selected a Mathematical Association of America publication (Hale, 2003) and an international series (Cullinane, 2013). Each book was coded using a thematic analysis (Braun & Clarke, 2006) using first de Villiers' (1990) functions of proof as an initial set of codes: *verification*, *explanation*, *systemization*, *discovery,* and *communication* with a sentence-level unit-of-analysis. For example, "You will learn and apply the methods of thought that mathematicians use to verify theorems [verification], explore mathematical truth [explanation] and create new mathematical theories [discovery]." (Hammack, 2013). Within these categories, we both expanded roles beyond de Villiers' framing and developed a set of sub-classifications capturing additional factors such as intended audience.

*Sample Results.* seen in the table 1, the role of verification dominated the textbook discussion while the role of explaining, systemizing, and discovery were inconsistently treated across textbooks. ITP textbooks may not address important roles of proof. If we want students to learn and appreciate these roles, the impetus may be on instructors to move beyond textbook treatment.

*Table 1. Instances of reference to de Villiers' roles of proof.*

| Book/function | Verify | Explain | Systemize | Discovery | Communicate | total |
|---|---|---|---|---|---|---|
| Smith, et al. (2006) | 4 | 0 | 4 | 0 | 1 | 8 |
| Chartrand et al. (2013) | 10 | 5 | 0 | 4 | 4 | 18 |
| Velleman (2006) | 12 | 1 | 2 | 0 | 5 | 18 |
| Hammack (2013) | 3 | 1 | 1 | 1 | 3 | 7 |
| Hale (2003) | 5 | 2 | 4 | 0 | 6 | 10 |
| Cullinane (2013) | 10 | 9 | 0 | 0 | 2 | 17 |

Mathematics Teaching Assistant Preparation and Support: What Would Piaget, Vygotsky, and Dewey Have to Say?

Nathan Jewkes
North Carolina State University

*The purpose of this paper is to analyze the philosophies of the three foundational learning theorists (Piaget, Vygotsky, and Dewey) and explore what can be learned from these theorists about mathematics teaching assistant-professional development (MTA-PD). I begin by reflecting on the professional development opportunities I personally received as an MTA and by analyzing how well my own experience aligns with each of the three theories. I conclude with an argument, based in the literature, why MTA-PD may best be served by Vygotsky's sociocultural theory.*

*Keywords:* Mathematics Teaching Assistant (MTA), Learning Theories, College Teaching, Professional Development

Since 2009, at the conferences hosted by The Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education, there has been a working group focused on the professional development of college mathematics instructors. One of the group's goals, consistent with my own for writing this paper, is the "development of materials, processes, and *theories* to support the professional development of collegiate mathematics instructors" (Hauk, Deshler, & Speer, 2015, emphasis added).

Piaget (1964/1997) asserts that individuals construct their own knowledge and build on prior knowledge. Dewey (1899/1964) claims that knowledge is generated through problem solving, inquiry, and experimentation. Vygotsky (1978) posits a strong role for social interaction in learning. Which of these theories is most useful for analyzing MTA preparation and support?

Characteristics of successful K-12 teacher professional development include an intensive initial experience, spaced-across-time follow-up, opportunities to analyze student thinking, collaboration in teams to learn about teaching, and working with a mentor through multiple classroom visits and follow-up (Blank & de las Alas, 2009). Research specific to college teaching has revealed important elements of MTA-professional development (MTA-PD). These include a focus on MTAs' mathematical knowledge for teaching (Musgrave & Carlson, 2017; Speer & Wagner, 2009), an overall culture of department support for good teaching (Latulippe, 2009), and opportunities for practice and feedback from a mentor (Ellis, 2014). Since each of these elements involves high levels of social interaction, Vygotsky's sociocultural theory aligns well with successful MTA-PD. Indeed, Vygotsky's (1978) mechanism for learning is *internalization*, or the concept that knowledge is built first *between* individuals and then moves inward to the intrapersonal plane. MTA-PD that involves collaboration in teams, opportunities for practice and feedback from mentors, and a department culture of support for good teaching, therefore aligns well with Vygotsky's theory. His notion of the *zone of proximal development* (Vygotsky, 1978, p. 86) is also salient here, with more capable peers helping MTAs reach higher levels of good teaching that, if left to their own means, they would not be able to reach.

Since many universities rely on MTAs to teach of a wide variety of undergraduate mathematics courses, and because MTAs are "the source of mathematics faculty of the future" (Speer, Gutmann, & Murphy, 2005, p. 76), further analysis of MTA-PD through the lens of the three foundational learning theorists will likely prove important for the success of both present and future undergraduate learners of mathematics.

Research on Concept-based Instruction of Calculus

Xuefen Gao
Mathematics Department, Zhejiang Sci-Tech University, China

*Abstract: This study, involving 254 college-level calculus students and 3 teachers, investigated the misunderstanding of concepts in calculus and designed concept-based instruction to help students understand concepts. Multiple achievement measures were used to determine the degree to which students from different instructional environments had mastered the concepts and the procedures. The midterm examination and the final examination results showed that the students enrolled in the concept-based learning environment scored higher than the students enrolled in the traditional learning environment and the investigation at the end of the semester showed that most of students like the concept-based learning environment.*

*Key words*: Concept-based Instruction, Misunderstandings, Teaching design

In the context of mass higher education, the ability of college freshmen is generally in a lower level than before. Many college students can do simple works on calculus, but they cannot understand the idea behind the concept, and as a result, usually have fuzzy understanding of the relationship between concepts. Therefore, to find the cognitive difficulties of the students on the concepts of calculus and to design the concept instruction are the keys to the reform of the teaching on Calculus.

This research presented a study on calculus course in three freshmen classes by carrying out the teaching design and teaching experiment. Research methods such as design research, questionnaires, interviews and classroom observation were adopted. There were 3 teachers and 254 students participated in the practice. Based on the findings of this study, the following conclusions could be drawn:

Firstly, college students' concept image of the fundamental concepts of calculus was one-sided, and some even wrong. Some students couldn't define the limit by correct words. Most of the students usually thought of the slope of the tangent when seeing the derivative, rather than the rate of change. There was confusion in the understanding of the geometrical meaning of differential and linear approximation. Some students know that the definite integral can express the area, but they can't make sure the area of what region; some students did not know which amount was sliced when they calculated the integral.

Secondly, we constructed principles on concept instruction in calculus as follows: (1) Concepts were introduced and demonstrated in a genetic way. (2) Help students understand the concepts by means of geometric or intuitive examples. (3) Paying attention to the elaboration of the relations of the concept between them. The results of teaching experiment showed that the students enrolled in the concept-based learning environment scored higher (M=34.42) than the students enrolled in the traditional learning environment (M=30.27) on the 40 point Conceptual Understanding Subscale and the students enrolled in the concept-based learning environment scored significantly higher (M=48.68) than the students enrolled in the traditional learning environment (M=42.65) on the 60 point Procedural Skill Subscale in the examination.

Mathematics Tutors' Perceptions of Their Role

Christopher McDonald
Oklahoma State University

Melissa Mills
Oklahoma State University

*Undergraduate students who work as mathematics tutors completed surveys and interviews to assess their attitudes towards mathematics and their beliefs about the roles of a tutor and instructor. Tutors in this study viewed their role as supplementary to that of a teacher, and emphasized tutors' ability to tailor their mathematical content to the individual.*

*Keywords:* mathematics tutors, beliefs, roles

In a recent study, 97% of institutions surveyed offered mathematics tutoring to Calculus students (Bressoud, Mesa, & Rasmussen, 2015), so tutors are a prevalent resource for student learning outside of the classroom. Research on classroom teachers has investigated how teachers' perception of mathematics and their role as a teacher affects instructional practice (Thompson, 1984), and how teachers notice students' mathematical thinking (Jacobs, Lamb, & Philipp, 2010). Similar questions may be asked of mathematics tutors. This study will report on undergraduate mathematics tutors' views of mathematics and their perceptions of their role as a tutor and how that compares to the role of a mathematics instructor.

The participants in this study were undergraduate tutors from drop-in mathematics tutoring centers at one large research university in the Midwestern United States and one small private university in the northwestern United States. Twenty-six tutors were given surveys prior to the start of the Fall 2017 semester asking about their beliefs about mathematics, mathematics instructors, and mathematics tutors. The surveys were made up of items that were modified from the CSPCC math attitudes survey (Bressoud, et al., 2015) and the NCTM Teaching and Learning Beliefs Survey (NCTM, 2014). Additionally, tutors recorded tutoring sessions, answered reflection questions, and were interviewed to allow them to elaborate on their responses.

As an example of the results, one Likert scale survey item asked participants to choose whether an effective mathematics tutor "guides students step by step through problem solving" or "provides students with appropriate challenges, … and supports productive struggle". The same question was asked about effective mathematics instructors. Survey responses revealed that the tutors seem to be split between whether tutors should be a guide or provide challenges. However, most of the tutors believed that instructors should provide challenges to students.

In the interviews, 82% of the tutors made statements that indicated that the instructor is the one who presents the theoretical material and "lays the foundation" while the tutor's role is to work with specific examples and "fill in the gaps." Other themes were tutors' ability to personalize their instruction to meet individual student needs and to offer a different perspective than the instructor. One tutor said that tutors "slow-walk students through a problem by asking simple closed-ended questions." Another tutor said that tutors may have more insight into how the mathematics can be applied to classes in the students' specific majors. Several of the tutors mentioned that tutors are more equipped than instructors to encourage students and attend to affective issues.

Future studies will investigate how these perceived differences between the role of a tutor and instructor impact tutors' noticing of students' mathematical thinking and their attention to student affect, and other aspects of their tutoring practice.

# Exploring Neural Correlates for Levels of Cognitive Load During Justifying Tasks

Shiv Smith Karunakaran
Michigan State University

Abigail Higgins
California State University
Maritime Academy

James Whitbread, Jr.
Washington State University

*A recent special issue of ZDM (June 2016) made the case for increasing the interdisciplinary collaboration between researchers in the fields of mathematics education and cognitive neuroscience. Specifically, Ansari and Lyons (2016) argued for increasing the "ecological validity of the testing situations and specific [neurocognitive] tests used to measure mathematical processing" (pp. 379-380). The study reported on in this poster serves as a "proof-of-concept" for the use of Functional Near-Infrared Spectroscopy (fNIRS) to measure the level of cognitive load of the brain under mathematical justifying. The poster will address the pros and cons of using neurocognitive measures, such as the fNIRS, to measure and examine the physiological stresses of the brain under the complex mathematical process of proving.*

*Keywords:* Mathematical justification; Neurocognition; Cognitive load

In their introductory commentary to the *ZDM* special issue: *Cognitive neuroscience and mathematics learning – revisited after 5 years*, Ansari and Lyons (2016) posit that "much progress has been made in the diversity of topics being investigated that make connections between [the fields of] cognitive neuroscience and mathematics education" (p. 380). This claim is echoed by Norton and Bell (2017) in their chapter about mathematics educational neuroscience. They report on various studies (e.g. Ischebeck, Shocke, & Delazer, 2009; Waisman, Leikin, Shaul, & Leikin, 2014) that fall into the growing intersection between the fields of cognitive neuroscience and psychology, and the field of mathematics education. However, even allowing for the growth of this new intersectional field, there are numerous persistent and pervasive challenges that remain. One of these challenges, as outlined by Norton and Bell (2017), is with regard to the nature of cognitive demanding tasks within mathematics education.

This poster will report on preliminary findings from a study that investigates the following question: What neural correlates, if any, exist between the neurocognitive data that is collected from participants while engaged in justifying tasks, and the self-reported cognitive load requirements by the same participants after engaging in those justifying tasks? The participants in question for this study were undergraduate and graduate students of mathematics at a large public university in the Northwest United States.

The poster will be a methodological presentation that focuses on the design and development of the methodology used to study this question, including the justifying tasks used, the neuroimaging tools used such as the Functional Near-Infrared Spectroscopy (fNIRS), and a detailed description of the experimental procedure used and its rationale. We will also present a glimpse into the nature and impact of the qualitative and quantitative data that was collected. This report on the study aims to serve as a "proof-of-concept" for highlighting the usefulness, as well as the challenges inherent in the intersectionality of the seemingly disparate fields of cognitive neuroscience and psychology, and the field of mathematics education.

**Multivariable Calculus Textbook Analysis Highlights a Lack of Representation for Non-Cartesian Coordinate Systems**

| Chaelee Dalton | Brian Farlow | Warren Christensen |
| --- | --- | --- |
| Pomona College | North Dakota St U | North Dakota St U |

*Upper-division undergraduate physics coursework necessitates a grasp of mathematical knowledge, including an understanding of non-Cartesian coordinate systems. To fully grasp what upper-division physics' students understanding of non-Cartesian coordinates is, it is worthwhile to study the mathematics course where non-Cartesian coordinate systems are taught most extensively, Multivariable Calculus. Seven Multivariable Calculus textbooks were examined using content analysis techniques. Additionally, textbook items in four textbooks were qualitatively coded by coordinate system. Results indicate that there were few instances where non-Cartesian coordinate systems were present. These findings suggest that before upper-division physics coursework, students' instruction on non-Cartesian coordinate systems is minimal and that it might be difficult for students to employ mathematical techniques that involve non-Cartesian coordinates in their upper-division courses.*

*Keywords:* Content Analysis, Non-Cartesian Coordinates, Multivariable Calculus

Understanding non-Cartesian coordinate systems is essential for upper-division physics courses. Published literature suggests that student understanding of non-Cartesian coordinate systems is weak; studies by Moore, Paoletti, and Musgrave (2014) observed mathematics students having continued difficulty with polar coordinates after taking mathematics through Calculus III (Multivariable), and studies by Sayre and Wittman (2007) of junior-level physics students also suggested that students' understanding of the polar coordinate system was still under formation when compared to their understanding of Cartesian coordinate systems. Multivariable Calculus textbooks typically introduce three-dimensional non-Cartesian coordinate systems and study polar coordinate systems at a greater depth. This study examines seven textbooks as sources that can potentially enable or obstruct student understanding of non-Cartesian coordinate systems. To capture a comprehensive examination of these textbooks, qualitative content analysis and quantitative content analysis were performed. Qualitative analysis techniques were used, for example, to examine the coordinate systems new topics were introduced in. Quantitative content analysis categorized examples, definitions, and problems/exercises according to their coordinate system(s). Results demonstrated that non-Cartesian coordinate system representation was minimal. New Multivariable Calculus topics were always introduced in Cartesian coordinates and sometimes did not utilize non-Cartesian coordinates at all. Further, only 21% of textbook chapters included any instance of non-Cartesian coordinates. Of those chapters, 73% of items qualitatively coded according to their coordinate systems were Cartesian. When present, these instances of non-Cartesian coordinate systems often involve simply converting from one coordinate system to another rather than posing questions that elicit a higher level of understanding of when to apply particular coordinate systems. This work implies that Multivariable Calculus textbooks do not require a high level of understanding of non-Cartesian coordinate systems, suggesting that textbooks, which serve as a resource for professors and students, could be part of what limits student understanding and application of non-Cartesian coordinate systems at higher levels of mathematics and physics.

Perspectives in the Use of Primary Sources in Undergraduate Mathematics Education: A Triangulation of Author, Instructor, and Student

Matthew Mauntel
Florida State University

Kathleen M. Clark
Florida State University

*We report on a case study of two different university mathematics classes (both Linear Algebra courses) that implemented the same primary source project (PSP) as part of the Transforming Instruction in Undergraduate Mathematics via Primary Historical Sources (TRIUMPHS) project. One class was taught by the author of the PSP; the other was taught by an instructor at a second university. Data were collected from students in both courses via pre- and post-surveys with Likert items and open-ended items designed to assess their mathematical attitudes and perceived gains. Instructors completed a PSP implementation report and pre-/post-course surveys. In our poster presentation, we provide a triangulation of the data from the perspectives of the author as an instructor, a non-author instructor of a same course (Linear Algebra), and the students.*

*Keywords:* primary source projects, mathematical attitudes, instructor implementation

Mathematics faculty and educational researchers are increasingly recognizing the value of the history of mathematics as a support to student learning. The expanding body of literature in this area includes recent special issues of *Science & Education* and *Problems, Resources and Issues in Undergraduate Mathematics Education* (*PRIMUS*), both of which include direct calls for the use of primary historical sources in teaching mathematics. For many instructors, the current lack of classroom-ready materials poses an obstacle to the incorporation of history into the classroom. As noted by Jankvist (2009), "the 'urgent task' of developing critical implements for using history in the teaching and learning of mathematics" (p. 256) is also essential for further research on the benefits and effectiveness of using the history of mathematics to teach. The collection of PSPs being developed by TRIUMPHS addresses these related concerns.

The TRIUMPHS PSP "Solving a System of Linear Equations using Ancient Chinese Methods" (Flagg, 2017) was first implemented in fall 2017. Survey response data were collected from 11 students in the author's course and 7 in the non-author's course. The pre-course survey included items to determine students' beliefs about mathematics, prior experience with primary source materials, views about mathematics learning and general demographic information. The post-PSP survey contained questions intended to capture students' perceived gains in skills specifically related to linear algebra, general mathematical skills such as reading and writing about mathematics, and attitudes and confidence in mathematics. Other post-PSP survey questions asked about the interaction of students with peers, the instructor, and the primary source material inside and outside of class. Finally, several open-ended questions asked students to reflect upon their experience with the PSP, including their perception of benefits and obstacles of learning mathematics using primary sources, and their attitudes towards using primary sources in a linear algebra course. Implementation reports and pre-/post-course surveys were collected from both instructors, and an instructional guide containing implementation recommendations for instructors was provided by the PSP author.

We will discuss the successes from each implementation from the student and instructor perspectives, the ways in which the two course populations reported similar student gains, and the ways in which students' reported benefits and obstacles for learning with primary source materials can inform future implementations in the TRIUMPHS project.

# Historical Analysis on Predictive Practices: The Case of Chaotic Dynamics

Jesús Enrique Hernández-Zavaleta Ricardo Cantoral
CINVESTAV – IPN

*This poster focuses on the historical analysis of three main characters of the history of chaos: the Poincare's error in his memoire about the three-body problem, the ideas of Edward Lorenz about the deterministic non-periodic flow, and the work of Robert May about the logistic map. This into the Variational Thinking and Language research program from the Socioepistemological Theory. The results show a predictive practice characterized for four main actions: to search periodicities, to recognize the uncertain, to compare temporal states, and to classify kinds of behaviors. We assume that the promotion of landscapes and activities out of school are a way for construct specialized mathematical knowledge, and the incorporation of the ability to wait for the unexpected is necessary for teachers and students living this century.*

*Keywords:* Variation, Chaotic Dynamics, Historical Analysis, Socioepistemology,

## Introduction and motivation

Faced with the lack of meaning in the central ideas of the mathematics of change, mainly with the notion of variation (Carlson, Jacobs, Coe, & Hsu, 2003; Doorman, Drijvers, Gravemeijer, Boon, & Reed, 2012; Thompson, Byerley, & Hatfield, 2013; Tall, 2013; Cuevas, 2014; Moreno, 2014), this research looks at the dynamical systems, focus on chaotic ones, as source of mathematical objects that provides different kind of examples, behaviors and *practices* that, currently, are not part of the scholar context. This work assume that Education is not synonymous of schooling but only an aspect (UNESCO, 2012; Rosas Colin, 2014; Valero, 2015), and the promotion of landscapes and activities out of school are a way to construct specialized mathematical knowledge. In another hand we agree with the Morin's idea about the humans living in an uncertain world and the incorporation of the ability to wait for the unexpected (Morin, 1999), and Ghys' discourse concerning to the necessity of include (not only) in mathematics career specific training to teach topics like chaos theory in order communicate these ideas to other scientist or non-scientist (Ghys, 2015).

The fundamental objective of this study is the *search and characterization of the actions* in the transition from the stable periodicities to unstable ones (transition from predictable to unpredictable), first doing a historical analysis looking for *actions over mathematical objects* and the *description of the phenomena* where this kind of behavior appears, and second recollecting data that supports the actions subtracted from the precedent analysis. This poster focuses on the analysis of three main characters of the history of chaos: the Poincare's error in his memoire about the three-body problem (Poincaré, 1898; Barrow-Green, 1997), the ideas of Edward Lorenz about the deterministic non-periodic flow (Lorenz, 1963; 1993) and the methods and tools used by Robert May in the analysis of the logistic map traying to understand the complicated dynamic from a "simple" mathematical model (May, 1974; 1976).

From the Socioepistemological methodology (Cantoral, 2016) over the historical analysis some results show the evolution of a *predictive practice* that is characterized for four main emergent actions over mathematical and physical objects: to search periodicities, to recognize the uncertain, to compare temporal states, and to classify kinds of behaviors. These actions will lead the construction of an experimental instrument to get data about how students and teachers in the last semester of high school and the first of university in scientific and engineer careers face the chaotic behavior.

# Graduate Teaching Assistants' Evolving Conceptualizations of Active Learning

Elijah S. Meyer, Elizabeth G. Arnold, and Jennifer L. Green
Montana State University

*Graduate teaching assistants (GTAs) play a critical role in undergraduate mathematics education, but most have no experience using active learning to promote higher-order thinking. This research investigates how beginning GTAs conceptualize active learning and how these understandings evolve as they engage in a teaching program. This poster describes the program, as well as the evolution of and variation in GTAs' conceptualizations and uses of active learning.*

*Keywords:* Graduate Teaching Assistants, Teacher Development, Active Learning

Graduate teaching assistants (GTAs) play a key role in lower-division undergraduate mathematics courses (Speer, Gutmann, & Murphy, 2005). With the changing context of education, GTAs need exposure to new pedagogical strategies that may fall outside their prior experiences in order to learn how to effectively teach and create valuable learning opportunities for their students (Deshler, Hauk, & Speer, 2015). As researchers and teacher educators, we need to understand how best to help GTAs develop a refined understanding of how to implement active learning effectively, and explore the ways in which they enact it in their own classrooms. Our objective was to introduce new GTAs to active learning strategies during professional development and to research how their views and uses of active learning evolve. Our research questions were: 1) How do beginning GTAs conceptualize active learning? and 2) How do new GTAs' understandings of active learning evolve during professional development?

We adopt the perception that active learning is an instructional method that engages students in mathematical thinking (CBMS, 2016). Our study draws on Bonwell and Sutherland's (1996) conceptual framework that portrays active learning as a continuum where strategies range in difficulty and engagement. They argue teachers should "consider their course objectives and teaching style and to determine through self-reflection what active learning strategies best meet their individual needs" (p. 4) and where these strategies lie on the continuum.

The participants in this study were new GTAs in the first year of their graduate programs (n=20); 35% were female, and 20% were international students. All participants were assigned to be sole instructors of undergraduate lower-division mathematics courses. They completed a week-long teaching orientation before classes began and attended weekly workshops throughout the fall. The program focused on active learning and engaging students in the classroom.

We administered free response surveys at the beginning, middle and end of the fall semester to collect data on GTAs' descriptions and uses of active learning. We also conducted semi-structured interviews with GTAs, asking them to reflect upon their teaching experiences and how their conceptualizations and uses of active learning changed (if at all) over the semester. Qualitative analyses using Bonwell and Sutherland's (1996) framework are ongoing.

Preliminary results indicate that beginning GTAs varied in how they conceptualized and used active learning throughout the semester. Many associated it with an activity and group work, but others had a more nuanced understanding of the term, discussing the process of engaging and involving students in learning. This suggests GTAs need time to develop as teachers and learn how to effectively incorporate active learning strategies in their classrooms. Further research is needed to examine how GTAs' self-identified views and uses of active learning align with their actual classroom practices and continue to evolve with experience.

# Here's What You Do: Personalization and Ritual in College Students' Algebraic Discourse

Luke C. Farmer
University of Texas at San Antonio

Cody L. Patterson
University of Texas at San Antonio

*We present results of a discourse analysis focused on college algebra students' uses of personal and impersonal language, references to endorsed mathematical routines, and inferences about mathematical objects in responses to a small-group problem-posing activity. We analyze students' responses with respect to selected dimensions of the arithmetical discourse profile of Ben-Yehuda et al., and provide evidence of a positive association between impersonal language and the presence of object-level mathematical statements and precise uses of algebraic terminology.*

*Key words:* College Algebra, Discourse Analysis, Mathematical Routines

Students' comprehension of mathematical ideas is inextricably linked to their processes of communication (Wittgenstein, 1953; Sfard, 2007). Ben-Yehuda et al. (2005) developed the *arithmetical discourse profile* as a tool for describing and analyzing students' use of words, mediators, and routines (Sfard, 2007; 2016) when communicating about mathematical tasks. Statements in mathematical narratives can be classified as *personal* (involving a human actor performing mathematical operations) or *impersonal* (describing mathematical structure without personalization) (Ben-Yehuda et al., 2005). Empirical studies have suggested a negative correlation between the use of personalized language, such as "I" and the past tense, and achievement levels in young children (Bills, 2002). Statements in mathematical narratives can additionally be classified into *object-level* statements about mathematical objects, and *meta-level* statements about the discourse itself (Sfard, 2007). In this study, we explore college algebra students' uses of language in mathematical narratives; in particular, we investigate associations between impersonal descriptions of routines and other features of literate mathematical discourse, such as correct uses of algebraic terminology and object-level statements (such as that when the division $P(x) / (x - a)$ leaves a remainder of zero, $a$ is a zero of $P(x)$).

For this study, students in three large sections of college algebra (total enrollment 327 students) participated in a small-group activity in which each group wrote an open-ended problem that could be used to review for an upcoming exam, and worked together to produce a written solution to the problem they created. Students were permitted to write a problem on any topic covered by the upcoming exam; however, most problems dealt with polynomial functions and their zeroes. We found that students' written solutions were largely governed by routines prescribed by the course text (Abramson, 2012) and endorsed by guided notes published by the course instructors; however, students' descriptions of these routines varied in their use of personal and impersonal language and in their uses of mathematical terminology and reasoning. We hypothesize that in some cases, the use of personal language was dictated by the topic selected for the problem; for example, narratives of synthetic division relied heavily on descriptions of human actions on mediators (e.g., "Make sure to bring down the first coefficient."). For many other topics, uses of personal language by students appeared to mimic uses of personal language in the textbook and guided notes. However, some topics led to greater variation in uses of personal and impersonal language. Our poster will report on this variation and present examples of both personal and impersonal descriptions of algebraic routines, and illustrate instances in which impersonal discourse is associated with greater precision in uses of mathematical terminology and algebraic reasoning.

Adaption of Sherin's Symbolic Forms for the Analysis of Students' Graphical Understanding

Jon-Marc G. Rodriguez — Purdue University
Kinsey Bain — Purdue University
Marcy H. Towns — Purdue University

*We describe a methodological presentation of Sherin's (2001) symbolic forms, discussing adaptions made to the framework to analyze graphical reasoning. Symbolic forms characterize the ideas students associate with patterns in an expression. To expand symbolic forms beyond equations, we supplement it with another framework that considers modeling as discussing mathematical narratives. This affords the language to describe how students think about the process or "story" that could have given rise to a graph. By considering registrations in general terms as structural features students attend to (parts of the "story"), when students assign ideas to registrations (parts of an equation or regions of a graph), they are using symbolic forms.*

*Keywords*: mathematical reasoning, symbolic forms, rates, chemistry

Sherin (2001) developed symbolic forms as a means to characterize how students used mathematical ideas to reason about equations when solving problems in physics. This framework has its roots in the constructivist idea of "phenomenological primitives" (p-prims), which describe intuitive ideas developed based on experience (Bodner, 1986; diSessa, 1993). Symbolic forms can be seen as mathematical p-prims, involving students associating ideas (conceptual schema) with a pattern of symbols (symbol template); for example, students associating the idea of "balancing" with the symbolic form "$\square = \square$", where the boxes are generic placeholders for algebraic terms (Sherin, 2001). This is important because without explicit instruction students associate ideas with patterns that are productive when learning concepts (e.g., opposing forces in physics). This framework has been utilized across different discipline-based education research (DBER) fields to explore student understanding of integration, the differential (*dx)*, area and volume, and mathematical expressions in physics and chemistry (Becker & Towns, 2012; Jones 2013, 2015a, 2015b; Dorko & Speer, 2015; Marredith & Marrongelle, 2008; Von Korff & Rubello, 2014). We assert students have similar ideas about graphs and seek to expand symbolic forms to move beyond equations, which has broad applicability across DBER fields.

A central tenet of our adaption of symbolic forms to graphical reasoning is Nemirovsky's (1996) conceptualization of "mathematical narratives" as the integration of events with symbolic notations (i.e., modeling). Nemirovsky (1996) used mathematical narratives to focus on student descriptions of "stories" that could give rise to a particular graph in the context of graphical representations of velocity, distance, and time. Viewing modeling as "story-telling" is particularly useful when considering students' graphical reasoning because it provides the language to describe students' discussion of the series of events represented by a graph. In the literature "registrations" have been used to describe features students focus on in computer simulations; we adopt this terminology to describe structural features students attend to in representations, and when students "register" or associate specific ideas with these features, they are reasoning using symbolic forms (Roschelle, 1991; Sengupta and Willensky, 2009).

Although it has been suggested that symbolic forms can be adapted to graphical reasoning, in practice it has not yet been taken up in the literature (Izak, 2000; Lee & Sherin, 2006; Sherin, 2001). Our presentation will provide examples of how we functionalize this adapted framework, using chemistry as a rich context to study students' reasoning associated with graphs that describe the rate of change of chemical compounds over time, since research has shown that students have difficulty with ideas related to the derivative and rate (Orton, 1983; Rasmussen, Marrongelle, & Borba, 2014; White & Mitchelmore, 1996).

Design Research in German Mathematics Tertiary Education Focusing on Profession-Specificity

Lena Wessel
University of Education Freiburg, Germany

*The poster proposal presents design research projects in the context of German tertiary education for preservice secondary teachers and service mathematics courses. The approach of design research for university students with a content-specific focus on profession-specificity is exemplified by two concrete design research projects.*

*Keywords:* Design Research, Service Courses, Preservice Secondary Teachers, Calculus

In Germany, due to a growing heterogeneity among university students (Heublein et al., 2012) the need for instructional innovations in mathematics and mathematics-related studies is taken very seriously at the moment. Especially in mathematics, also high rates of drop out (Dieter & Törner, 2012) led to an increasing attention to more adaptive teaching as a means of reacting to students' heterogeneity as well as enhancing their motivation. The poster presents research projects of the researcher and her research group on instructional innovations within preservice secondary teacher education on the one hand and mathematics service courses on the other. Although the target groups of the innovations differ in several ways, Design Research as the common research approach is chosen to meet the innovation needs, which will be lined out and motivated.

Design Research is a widely-established research methodology for enhancing and investigating students' learning. It is especially strong when the two aims 'designing learning arrangements' and 'investigating the initiated learning processes and contributing to local instruction theories' are to be combined (Bakker & van Eerde, 2015). The research projects presented here follow a topic-specific approach with a focus on learning processes (Prediger & Zwetzschler, 2013) which is adapted to designing and researching teaching learning arrangements in mathematics tertiary education. The approach is exemplified by two research projects which foster university students' content knowledge and pedagogical content knowledge with a focus on profession-specificity.

*Example 1*: For preservice secondary teachers, the design research project focuses on pedagogical content knowledge of functional reasoning and calculus. The overarching research question "*How can profession-specific learning tasks be specified and structured and which learning pathways and obstacles can be identified*" is pursued. The Four Component Instructional Design Model by van Merriënboer & Kirschner (2007) builds the instructional framework being implemented in three cycles of design experiments (laboratory setting). At the moment, data analysis of n=26 students' pre- and post written answers of three learning tasks from the second and third design experiment cycle is ongoing by means of qualitative content analysis (Mayring, 2008).

*Example 2*: For fostering first-year students' understanding of functions and calculus (and related procedural knowledge) in mathematics service courses, adaptive online remediation modules are designed and investigated. Profession-specificity of the modules is realized by contexts of applications from the field of studies (natural sciences, engineering). Video-taped design experiments at the computer (laboratory one-on-one and partner setting) and the qualitative analysis of the initiated learning processes are much needed, since little is known about how students work with online remediation material and many questions, e.g. concerning adaptive feedback or relations of usability and conditions of success, are still open.

Constant Rate of Change: The Reasoning of a Former Teacher and Current Doctoral Student

Natalie LF Hobson
Sonoma State University

*In this work, I provide brief illustrations of multiple ways of reasoning about constant rate of change that I observed in a mathematics education doctoral student's activity when tasked to draw graphs relating two varying quantities. These ways of reasoning suggest that textbook authors and instructors critically examine those illustrations and experiences provided to students in order for students to come away from mathematics courses with consistent and productive reasonings about rate of change.*

*Keywords:* Covariational Reasoning, Rate of Change, Calculus

Researchers have reported that a productive meaning for the idea of *rate of change* involves one to conceptualize relationships between two covarying quantities (Thompson, 1994). Covariational reasoning describes the mental actions involved in one coordinating such varying quantities (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). In recent decades, researchers have observed and characterized students' and teachers' mental actions while engaged in tasks to model covarying quantities (Carlson et al., 2002; Castillo-Garsow, 2012; Coe, 2007). Researchers have also identified students and teachers having difficulty with covariational reasoning (Carlson et al., 2002; Johnson, 2015). In particular, Musgrave and Carlson investigated mathematics graduate students' meanings of average rate of change (Musgrave & Carlson, 2016). They found that these students often held non-conceptual meanings for average rate of change that were primarily focused on computations or geometric interpretations involving secant lines on graphs. With the goal of developing students' and teachers' covariational reasoning, it is productive to construct models of individuals' thinking about rate of change as a means for creating rich experiences in which students and teachers can develop sophisticated ways of reasoning. The work of this study contributes to expanding and broadening models of individuals' covariational reasonings by providing insights into those reasoning processes that continued mathematics users (i.e., mathematics teachers turned graduate students) engage in.

In this poster, I present multiple and inconsistent ways of reasoning about constant rate of change that I observed in the activity of one mathematics education doctoral student with high school mathematics teaching experience. The study involved clinical interviews in which I asked the participant to draw graphs relating two varying quantities in an animated situation. The participant's reasonings resulted in inconsistent conclusions and suggest that he did not interpret or describe rate of change covariationally by imagining changes. I characterize these ways of reasoning as tangent line reasoning and constant ratio reasoning. *Tangent lines* involved the participant constructing and reasoning geometrically with tangent lines he constructed on his graph. *Constant ratio* involved the participant identifying that the two accumulated quantities he was graphing could be related computationally by a scale factor of some fixed unit magnitude of each quantity (which he identified as the "constant" in a constant rate of change relationship). These ways of reasoning did not seem productive for the participant and yet seem to be suggestive of certain non-quantitative curricular treatment of rate of change. These illustrations suggest that mathematics educators and textbook authors critically examine those reasonings of their students and the experiences they provide students in order for students to develop more consistent and productive reasoning abilities about rate of change.

Investigating Student Learning and Sense-Making from Instructional Calculus Videos

Aaron Weinberg, Ithaca College
Matthew Thomas, Ithaca College
Jason Martin, Central Arkansas
Michael Tallman, Oklahoma State

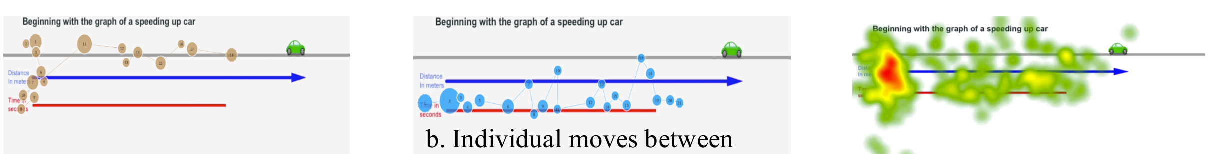
*Growing interest in "flipped" classrooms has made video lessons an increasingly prominent component of post-secondary mathematics curricula. This format, where students watch videos outside of class, can be leveraged to create a more active learning environment during class. Thus, for very challenging but essential classes in STEM, like calculus, the use of video lessons can have a positive impact on student success. However, relatively little is known about how students watch and learn from calculus instructional videos. This research generates knowledge about how students engage with, make sense of, and learn from calculus instructional videos.*

*Keywords:* Calculus, Eye-Tracking, Flipped Classrooms, Sense-Making, Quantitative Reasoning

To help instructors design videos for flipped classrooms, we have collected data from four different calculus classes using instructional videos. Videos used in this study have ranged from innovative approaches to calculus proven successful by supporting students' development of covariational reasoning (e.g., Martin & Oehrtman, 2015; Thompson, Byerley, & Hatfield, 2013) to videos of more traditional whiteboard type lecture. We investigate:

- The ways students interact with video lectures, including how they pause, skip, and re-watch portions of the videos;
- The aspects of the videos students attend to – and report attending to – as they watch;
- The ways students make sense of and learn from these videos, and how this relates the other aspects described above (e.g. Weinberg & Thomas 2016a, 2016b);
- How various ways of structuring the video-watching experience, such as providing an outline, can influence each of these aspects (e.g. Johnson & Mayer, 2009).

Data consists of student responses to mathematical content questions before and after watching videos, timestamps of students' interactions with videos (i.e. playing, pausing, and time-shifting videos), student responses to interview questions as they watch videos, and eye-tracking data from students watching videos. Our analysis yields knowledge about how students learn and interact with these videos. For example, Figure 1a. and b. demonstrates how eye-tracking data shows distinctions between student fixations (the brown and blue circles) while watching a video of a moving car. Figure 1c. indicates how the participant group tended to still be reading the labels when the car started traveling before moving their fixations between the representations for time elapsed, distance traveled, and the moving car.



a. Individual fixates on car　b. Individual moves between representations of quantities　c. Heat map of group fixations

*Figure 1. Eye-tracking data indicating individual and group fixations in the context of a car speeding up.*

Is Mathematics Important for Accounting Learning? – A Study on Students' Attitudes and Beliefs

Ruixue Du | Senfeng Liang | Christine Schalow
University of Wisconsin Stevens Point

*This study examined students' attitudes toward mathematics, and beliefs in mathematics' influence on accounting learning. It also explored how these two factors correlate to students' scores in accounting courses. This study found that students believed that being good at math is a necessary, but not a sufficient, condition for performing well in accounting. Students who performed well in accounting usually showed a relatively positive attitude toward math.*

*Keywords:* accounting performance, attitude toward mathematics, belief in mathematics

## Introduction

Accounting majors usually need to have some mathematics ability before taking accounting courses and may be asked to take courses such as calculus I as prerequisites. Many college professors or researchers think prerequisites in mathematics for the accounting major are well-grounded (Brown, 1962; Collier & McGowan, 1989). However, mathematics' influence on a student's accounting learning is inconsistent. Burdick and Schwartz (1982) found that students' performance in mathematics courses couldn't significantly predict students' scores in accounting courses. Some other studies (Clark & Sweeney, 1985; Collier & McGowan, 1989) found that students' mathematics preparation is positively linked to the accounting coursework performance. It is unclear that in accounting students' perspectives, if mathematics is important for accounting learning. We address two research questions: 1. What are accounting students' attitudes toward mathematics? 2. What are accounting students' beliefs in mathematics' influence on accounting learning?

## Method

This study was conducted in a four-year college in the mid-west area of the United States. Our sample consists of 203 undergraduate students from introductory financial, introductory managerial and intermediate financial accounting courses. Participants completed a consent form to take the study and were asked to finish a survey (23 questions) online toward the end of a semester. Students' scores in the accounting course were collected when the semester ended.

## Data Analysis and Results

Students were asked to respond to questions on their attitudes toward mathematics, and their beliefs in mathematics. The results revealed a positive relationship between a student's attitude toward mathematics and accounting performance. However, no significant relationship was found between a student's belief in the usefulness of mathematics and accounting performance. Students agreed that mathematics was important in accounting learning. However, they did not believe that they were not doing well in accounting because they were not good at math.

## Conclusion

Based on our research, we find our students believe that being good at mathematics is a necessary, but not a sufficient, condition for performing well in accounting. In addition, students who perform well in accounting usually show a relatively positive attitude toward mathematics.

Goals, Resources, and Orientations for Equity in Collegiate Mathematics Education Research

Shandy Hauk
WestEd

Kathleen D'Silva
WestEd

*Though the terms equity, diversity, inclusion, and social justice have entered the research lexicon, we face significant challenges in gaining a nuanced understanding of the various ideas associated with these words and how those ideas are consequential for collegiate mathematics education research. This interactive poster presents a theoretical framework for making sense of (and making sense with) "equity" as an essential component of research. The poster offers tools for thinking and talking about equity and research design, implementation, and reporting. Poster visitors will have an opportunity to contribute questions and observations about the definitions of equity and proposed connections among approaches to courageous conversations about equity in research, self- and other-awareness, and aspects of equity in the mathematics content, curricula, and instruction at the heart of the research.*

*Keywords:* Equity, Social justice, RUME

As people trained in research in undergraduate mathematics education (RUME), we know that our work starts with diagnosing challenges in teaching and learning. As citizens of a first-world country in the 21st century, we are keenly aware of social, political, and economic inequity. And, as a community, we have an opportunity to guide how equity is defined, explored, and addressed in collegiate mathematics education research. Attention to equity has existed for a while (e.g., Aguirre & Civil, 2016; Adiredja, Alexander, & Andrews-Larson, 2015; D'Ambrosio et al., 2013; Davis, Hauk, & Latiolais, 2010; Gutiérrez, 2013; Nasir, 2016).

According to the TODOS-NCSM position paper (2016), three conditions are necessary to establish just and equitable mathematical education for all learners: (1) acknowledging that an unjust social system exists, (2) taking actions to eliminate inequities and establish effective policies, procedures, and practices that ensure just and equitable learning opportunities for all, and (3) being eager for accountability so changes are made and sustained. How do we increase researcher capacity to do these three things? We must address our needs – as researchers – for language, definitions, and awareness-building about equity. This will support us in the inevitable struggle to gain and use pertinent understandings in the design, conduct, and reporting of research. The poster offers key ideas and examples from communication for restorative justice (e.g., Singleton & Hays, 2008) and intercultural orientation development (Bennett, 1993; 2004).

**Questions driving poster conversation:** What questions and observations do RUME researchers have regarding definition(s) of equity and the role of equity in research in collegiate mathematics education? How does equity play into our decisions about who research participants are? How might research be designed to provide evidence that supports action to eliminate an inequity? How might engaging the population we wish to study in the research design and analysis provide new insights into phenomena? How might the research design and analysis be different if the results of the work are to be held accountable by research peers *and* judged in a court of stakeholder opinion that values equity as much as excellence in mathematics education? In what ways is the mathematics implicit in a given research project contributing to inequity and/or equity for participants? How do we pay attention to that in the research goals, resources, and orientations we bring to our work? What are some of the concepts and language from intercultural development that can help us address these questions?

How Diagrams are Leveraged in Introduction to Proof Textbooks

Michael Q. Abili, Elizabeth M. Hewer, Kristen Lew, Kate Melhuish, Robert Sigley
Texas State University

*According to research, diagrams can play a vital role in the constructing and understanding of proofs (Samkoff, Lai, & Weber, 2012). Introduction to Proof (ITP) courses are usually a student's first exposure to proofs. Therefore, the ITP curriculum reflects important opportunities for students to develop proof construction and proof understanding skills. We analyzed how diagrams were presented in the top four market share ITP textbooks across a set of standard topics. Through this process, we categorized the role and nature of diagrams in the curricula. We found that a majority of diagrams were used to illustrate statements and definitions. Other important roles such as supporting proof construction, building conjectures, or finding counterexamples were infrequent.*

*Keywords:* Introduction to Proof, diagrams, textbook analysis

Mathematicians find using diagrams beneficial when constructing and understanding proofs (Samkoff et al., 2012). ITP courses are usually a student's first exposure to proofs. During ITP courses, students develop their proof skills. Textbooks reflect an important component of the intended curriculum and opportunities for students to learn (e.g., Thompson, Senk, & Johnson, 2012). We conducted a textbook analysis to explore how diagrams are leveraged in the curricula. In particular, we investigated how diagrams are used in the proving process in ITP textbooks.

We selected four ITP textbooks to analyze: Chartrand, Polimeni, and Zhang (2012), Hammack (2013), Smith, Eggen, and St. Andre (2010), and Velleman (2006). David and Zazkis (2017) identified these four ITP textbooks as having the top market share use in ITP courses, as well as, covering standard topics for ITP courses: sets, logic, proof techniques, relations, functions, and cardinality. We identified the textbook sections corresponding to these topics then used a thematic analysis (Braun & Clarke, 2006) approach to open-code and develop themes related to the nature and role of diagrams. We coded 173 diagrams across the textbooks.

We identified the following roles of diagrams in ITP textbooks: conjecturing (CJ), identifying counterexamples (CE), instantiating definitions (DEF), instantiating statements (ST), illustrating a procedure (PRO), illustrating the key idea to a proof (KIP), organizing/synthesizing information (ORG), being part of the proof (PP), and other. Most diagrams were used to instantiate definitions and theorems, which only represents a small subset of how mathematicians use diagrams (Samkoff et al., 2012). The poster contains a detailed comparison of same topics across different textbooks.

*Table 1. Frequency of the role of diagrams in the standard ITP topics across four textbooks.*

| Topic | CJ | CE | DEF | ST | PRO | KIP | ORG | PP | OTHER |
|---|---|---|---|---|---|---|---|---|---|
| Sets | 0 | 1 | 38 | 11 | 2 | 3 | 0 | 1 | 5 |
| Cardinality | 3 | 2 | 13 | 5 | 2 | 13 | 0 | 0 | 0 |
| Relations | 0 | 0 | 34 | 1 | 0 | 2 | 3 | 1 | 0 |
| Functions | 2 | 1 | 17 | 5 | 1 | 0 | 2 | 4 | 1 |
| Total | 5 | 4 | 102 | 22 | 5 | 18 | 5 | 6 | 6 |
| Percentage | 2.89% | 2.31% | 58.96% | 12.72% | 2.89% | 10.4% | 2.89% | 3.47% | 3.47% |

Student's Attention to the Conclusion During Proofs

Sindura Subanemy Kandasamy
Texas State University

Kathleen Melhuish
Texas State University

Sean Larsen
Portland State University

Samuel Cook
Wheelock College

*This study investigates students' use of conclusions to structure their proofs for a standard statement in introductory Group Theory. We surveyed 65 students across three classes asking them to evaluate the truth of a statement and provide a proof. We found students tend to use hypothesis-driven second level proof framework (rather than conclusion-driven). These students were then less likely to produce a deductive argument that aligned with the original statement. We conclude with implications for the treatment of proof analysis and proof frameworks to support students' proving activity.*

*Keywords:* Group Theory, Proof Frameworks, Proof Analysis

In courses, such as group theory, students frequently prove statements about structure-preserving properties such as the following statement: Let *f* be an isomorphism from (G, o) to (H, *). If *G* is an abelian group, then *H* is an abelian group. In order to approach such statements, students must structure their proofs around the conclusion to argue about arbitrary elements of *H* rather than arguing about the image of elements in *G.* We designed a study to test the conjecture that students do not necessarily attend to the conclusion when proving. We surveyed 65 students across three group theory classes using either the isomorphism prompt ($n$=32) or an alternate false version with 1-1 homomorphism missing the necessary requirement of onto ($n$=33).

To analyze students' proof approaches, we use two framings: proof frameworks (Selden & Selden, 1995) and proof analysis (c.f., Marchi, 1980; Lakatos, 1976). The proof framework is the "representation of the 'top-level' logical structure of a proof" (p. 129) which is tied directly to the statement to be proven. In order to approach the isomorphism prompt above, one option is to employ the appropriate second-level proof framework (Selden & Selden, 2015): using the conclusion to structure proof (i.e. starting with elements in *H*). An alternate approach would be the selection of a second level proof framework beginning with elements in *G*, arriving at a statement about the images of these elements then using proof analysis (c.f., Marchi, 1980) to recognize that the deductive argument does not align with the statement. We coded surveys based on (1) second-level proof frameworks, (2) validity, and (3) proof corrections.

We found that students used a *G*-first proof framework ($n$=39) compared to *H*-first ($n$=17) at a rate significantly higher than chance ($p$=0.0016). This approach was consistent across the true and false prompt where students produced deductive arguments about the image of *G* rather than *H*. For the true statement, we further analyzed the likelihood of arriving at a valid deductive argument finding that only 2 of 16 *G*-first students arrived at a valid proof with 7 of 9 *H*-first students arriving at a valid proof, a statistically significant difference. Our results reflect that many students are not attending to the conclusion of statements when proving. Instructors may need to work with students to help the students understand the importance of using the conclusion to structure the proof. Further, proof analysis techniques (comparing the statement and deductive proofs, searching for counterexamples) could also support students in producing arguments that better align with original statements.

What Would You Say You Do Here?
Metaphor as a Tool to Characterize Mathematical Practice

Joseph Olsen, Kristen Amman
Rutgers University

Kristen Lew
Texas State University

*In the cognitive science literature, multiple researchers have pointed out the importance of metaphor as a cognitive mechanism for sense-making. In mathematics in particular, metaphor has been shown to be a valuable tool in making sense of and reasoning with mathematics. To our knowledge, there has been no research on the metaphors that professors use when communicating the nature of mathematical practice to students in advanced mathematics lectures. In this poster, we describe the metaphors the research team identified across 11 undergraduate mathematics lectures at the advanced level. We found metaphors used by many lecturers that convey ideas about the nature of mathematical practice. We identified the affordances of these metaphors to better understand the way that mathematicians describe mathematics as a practice to undergraduate students studying advanced mathematics at the undergraduate level.*

*Keywords*: Metaphor, Mathematics education, Advanced mathematics

In the language used in everyday thought and speech, there are large number of expressions whose literal interpretations suggest something other than the intended meaning (Lakoff & Johnson, 1980/2003; Reddy, 1979). In documenting occurrences of these expressions and analyzing their content, researchers have developed the modern theory of metaphor, which has been applied across many disciplines to analyze how we as a species make sense of the world and develop our ideas (Lakoff & Johnson, 2003/1980). In mathematics, it has been argued that metaphors form the foundation of sense making and that we can analyze many important mathematical concepts to identify their metaphorical foundations (Lakoff, 1998; Lakoff & Nuñez, 2000; Nuñez, Edwards, & Matos, 1999; Sfard, 1994)

As the theory of metaphor has developed in a mathematical context, there has been some research documenting the metaphors that mathematicians use to personally make sense of and reason about mathematics (Nathalie & Tabaghi, 2010; Sfard, 1994). Many different types of metaphors have been documented, such as those relying on our conceptions of motion and our experiences with manipulating physical objects (Lakoff & Nuñez, 2000; Nuñez, 2004). Nuñez (2004) found occurrences of motion metaphors in an advanced mathematics lecture.

Through the study of metaphors, we answer the question "How do mathematicians describe their practice to advanced undergraduate students?" To answer this question, we analyzed a corpus of 11 undergraduate mathematics lectures at the advanced level. We found several metaphors that characterize the practice of mathematics (e.g. mathematics as play "*You have to play around* slightly and get three disjoint sets", mathematics as a journey "We have some loose ends in the theory that we won't be able to deal with until we *get to a more advanced place"*). We analyzed the metaphors we found and describe the entailments of these metaphors. Through this lens, we can describe the ways that mathematicians convey the practice of their discipline to students. We may also use this analytical tool as a method of understanding how students conceptualize mathematics.

# Active vs. Traditional Learning in Calculus I

Beth Cory, Ph.D. & Taylor Martin, Ph.D.
Sam Houston State University

*In this poster, we describe an ongoing study on the effect of active learning in Calculus I. We compare the achievement gap between underprepared and prepared students in the active versus traditional setting. Data comes from 16 sections of Calculus I during the 2017 – 2018 academic year, targeting the concepts of limits, continuity, differentiability, and area. We present our study design and initial findings; we look forward to feedback as we enter the latter half of our project.*

*Keywords:* Calculus, Active Learning, STEM, Achievement Gap

Calculus I is a foundational class in the degree plan of nearly all science majors. Calculus is a crucial benchmark in the path to a STEM education; however, many students rely heavily on memorization and repetition as paths to success in mathematics. These techniques fail when they are asked to explore the abstract concepts *of limits, continuity of functions, differentiability,* and *area*. One pedagogical approach to increasing student understanding and mastery is active learning. Active learning activities provide a setting for students to learn in cooperation with others, thus placing them in an excellent environment to construct complex mental frameworks (Bransford et al., 1999; Vygotsky, 1978). Existing literature supports the idea that active learning techniques can increase student learning outcomes significantly (Freeman et. al, 2014; Bressoud, 2011; Haak et. al, 2011; Boaler & Greeno, 2000). In this project, we study active learning specific to the calculus classroom, and target the population of students who enter with deficiencies in algebra, trigonometry, and/or pre-calculus. We explore the following questions:

- Do students who are underprepared for calculus perform better than their calculus-ready peers after learning in an active classroom versus a traditional classroom?
- Does the performance gap between underprepared and calculus-ready students change to a different extent in an active classroom as compared to a traditional classroom?
- Do students identified as underprepared for calculus have a more favorable perception of mathematics after learning in an active classroom as compared to a traditional classroom?
- Do students who learned in an active classroom see more success in Calculus II than those learning in a traditional classroom?

In this study, we compare student learning outcomes in four classrooms employing active techniques to outcomes in four traditional lecture-based classrooms in each of Fall 2017 and Spring 2018. We administer a pre-test assessment and initial survey in each classroom. We use the pre-test to identify students with weak preparation and to gauge students' attitudes and mindsets towards mathematics. The active sections discuss each of our target concepts: limits, continuity, differentiability, and area, using an exploratory activity, discussion, and follow-up assignment. The traditional sections cover the same content, but from a lecture approach. We assess learning outcomes by scoring performance on in-class exams and administer a post-test and survey (Carlson, Oehrtman, & Engelke, 2010). The survey will assess the changes in students' attitudes and mindsets about mathematics, as well as ask them to self-assess their preparedness for Calculus II. We intend to collect data regarding participants' persistence and success in Calculus II. At the conclusion of this project, we hope to better inform teaching practices in calculus at our institution.

# Do Prospective Elementary Teachers Notice Cultural Aspects of Mathematics in a Teaching Scenario?

Jennie Osa
Portland State University

Eva Thanheiser
Portland State University

Brenda Rosencrans
Portland State University

*Many teachers view mathematics as culture-free, which can result in difficulty attending to and valuing the cultural backgrounds of their students. We asked 23 prospective elementary teachers (PTs) to respond to a case that describes a teacher dismissing a third-grade student's solution to a multi-digit subtraction problem, due to the child's use of a nonstandard algorithm. Through a process of open-coding, three themes emerged in the PTs' responses: (1) the PTs would have responded differently/the teacher should have responded differently (22 PTs), (2) the PTs focused on the mathematics and/or on children's mathematical thinking (22 PTs), and (3) the PTs focused on the child's background/culture/family (3 PTs). We examine the differences in response levels between the first two themes and the third. Additional data has been collected and preliminary results show a strong focus on the first two themes, as well as a higher incidence of the third.*

*Keywords:* Prospective Elementary Teachers, Cultural Responsiveness, Elementary Teacher Education, Number and Operation

Although the elementary teacher population in the United States is largely homogenous, the student population is culturally diverse. As such, it can be difficult for teachers to connect to their students' cultural backgrounds (Turner et al., 2014). As mathematics teacher educators, we have a responsibility to help prospective elementary teachers (PTs) learn how to connect with all their students, but to do so we must first explore the ways in which PTs notice cultural aspects of mathematics, as "mathematics is not neutral, is not culture free, and is not value free" (Bishop, 1988). In this poster we will address the following research questions: (1) how do prospective elementary school teachers (in the United States) react to a case of a teacher dismissing a student's nonstandard algorithm?, and (2) do prospective elementary school teachers (in the United States) notice cultural aspects in a mathematics teaching scenario?

Through a process of open-coding, three main themes emerged from the PTs' responses: (1) the PTs would have responded differently/the teacher should have responded differently, (2) the PTs focused on the mathematics and/or children's mathematical thinking, and (3) the PTs focused on the child's background/culture/family. 22 PTs indicated that they would have responded differently and/or the teacher should have responded differently, 22 PTs focused on the mathematics and/or the child's mathematical thinking, and 3 PTs considered the background/culture/family aspect of the case. These results suggest that while PTs attend to and value the child's mathematical thinking, they are less apt to notice or respond to cultural aspects of mathematics in a teaching scenario.

Additional data was collected in Fall 2017 from PTs in the same university which will be analyzed using the same methods as above. This new data will serve to refine the previously found themes, as well as potentially illuminate new themes. Preliminary analysis suggests that a greater number of PTs focused on the child's background/culture/family, indicating that the PTs represented in the second round have more culturally responsive attitudes than those in the initial round of data collection.

Exploring the Role of Active Learning in a Large-Scale Precalculus Class

Gregory A. Downing
North Carolina State University

Brooke A. Outlaw
North Carolina State University

*In a large undergraduate mathematics classroom, introducing evidence based learning practices can be challenging. Due to persisting outdated methods of teaching, results of recent research call for more investigation of active-learning in all STEM classrooms, including large scale ones. Using Fraser's (1989) lens on perception, results from this study indicate that students who participated in Team Activities and other learner-centered activities in a large scale precalculus undergraduate class reported good experiences and are more positive in their attitudes towards mathematics.*

*Keywords*: Large-Scale Classrooms, Precalculus, Evidence-Based Practices

Researchers and curriculum developers have responded to the call for instructional improvements, developing numerous learner-centered curricular innovations particularly using collaborative and open-ended activities. Learner-centered instruction has been shown to support conceptual learning gains (e.g.; Kwon, Rasmussen, & Allen, 2005), diminish the achievement gap (Kogan & Laursen, 2013; Riordan & Noyce, 2001), and improve STEM retention rates (Hutcheson, Pampaka, & Williams 2011; Rasmussen, Ellis, & Bressoud, 2013; Seymour & Hewitt 1997). The objective of this research was to investigate student outcomes from the introduction of a small number of evidence-based active learning practices in a large size Precalculus classroom. For this study, outcomes were defined as students' attitudes towards mathematics and themselves as mathematics learners, interest in mathematics, and self-efficacy. The research question was: "What are students' experiences in a large-sized undergraduate Precalculus class when active learning strategies are present?

Fraser (1989) stated that "the strongest tradition in past classroom environment research has involved investigation of associations between students' cognitive and affective learning outcomes and their perceptions of psychosocial characteristics of their classrooms" (p. 315). We choose to use Fraser's lens to study associations between students' perceptions of a large-scale classroom environment and their cognitive and learning outcomes.

This mixed methodological exploratory research study (Creswell, 2013) was designed to introduce evidence-based instruction to students in order to study how these new practices are implemented and how they affect student outcomes. Data collection included interviews and surveys (pre-and post-) administered to the 14 participants at a very large, public southeastern university. Semi-structured interviews were conducted by the researches and were utilized for students to share their experiences. Video recordings of each interview were then transcribed and coded by the authors. Quantitative analysis was then completed to compare the Likert-scale scores from the pre- and post-surveys. Results will be shown on the poster.

Several themes arose as we analyzed the codes. Overall, (1) students were neutral about math in application, (2) collaboration was important for students, and (3) active learning was important for students. The results are noteworthy as we are finding that it makes a difference even to include just a few instructional strategies that are considered learner-centered even in large scale classrooms. This result leads to a significant question: How important is it to include learner centered instruction fully implemented or can a partial implementation work?

Video Case Analysis of Students' Mathematical Thinking to Support Preservice Teacher Candidates' Functional Reasoning and Professional Noticing

Tatia Totorica
Boise State University

Laurie Cavey
Boise State University

Michele Carney
Boise State University

Patrick Lowenthal
Boise State University

Jason Libberton
Idaho State University

*Using a design-based research approach, we are developing a series of online video-based instructional modules to engage secondary mathematics teacher candidates in case analyses of students' functional reasoning and to improve their own mathematical and pedagogical understandings. We present our project framework for module development, implementation, and revision, with an end goal of identifying preliminary hypothetical learning trajectories for candidates' functional reasoning and professional noticing.*

*Keywords:* Functional Reasoning, Hypothetical Learning Trajectory, Preservice Teacher Preparation, Video-Based Learning, Professional Noticing

## Video Case Analysis of Students' Mathematical Thinking (VCAST) Module Development

To advance student understanding of mathematics, teachers must pay careful attention to and then interpret evidence of student thinking. This requires a specialized mathematical knowledge of common patterns in students' reasoning and how their ideas are related and represented (Ball, Thames, & Phelps, 2008; Stein & Smith, 2011). Video-based modules can offer purposefully selected student evidence (i.e. case studies) to highlight important mathematical ideas.

Our module development process is informed by the literature on functional reasoning (Cooney, Beckmann, Lloyd, & Wilson, 2010; Oerhtman, Carlson, & Thompson, 2008), the use of video to support preservice teacher learning (Coffey, 2014; van Es, Cashen, Barnhart & Auger, 2017), design-based research (Anderson &Shattuck, 2012; Reeves, Herrington, & Oliver, 2005), professional noticing (Jacobs, Lamb, & Philipp, 2010), and hypothetical learning trajectories (HLTs)(Lobato & Waters, 2017; Simon, 1995; Simon & Tzur, 2004).

## Project Framework

We approach our module design through iterative improvement of HLTs while leveraging video cases' affordances for presenting specific episodes of students' reasoning. This entails identifying learning goals for teacher candidates, hypothesizing increasing levels of sophistication in reasoning toward those goals, developing learning activities which target those goals, and iteratively refining each as candidates engage in the modules (see Figure 1).

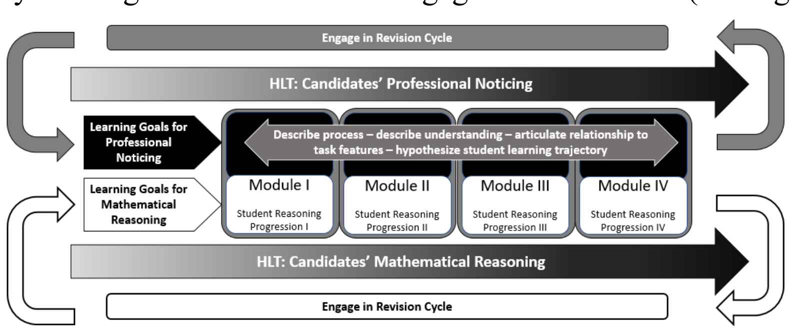

*Figure 1. HLT development in relation to the learning modules built around student reasoning progressions*

# Exploring Pre-service Elementary Teacher's Relationships with Mathematics via Creative Writing and Survey

Taekyoung Kim
Oklahoma State University

*Thirty-two pre-service elementary teachers completed a survey regarding their beliefs and attitudes regarding learning and teaching mathematics and two creative writing tasks. In the writing tasks, participants described their relationship with personified mathematics and introduced personified mathematics to their future students. By interpreting the survey and writings, different aspect of attitudes towards mathematics were discovered.*

*Keywords:* Affect, pre-service teachers, creative writing

Pre-service teachers' relationship with mathematics is important because it can affect how teachers introduce mathematics to their students (Swars, Daane & Giesen, 2006). Existing research has used conventional methods, such as surveys and interviews, to measures preservice and in service teachers' attitude towards mathematics. (Brown, 2007; Raymond, 1997)

Zazkis (2015) used an unconventional method to assess preservice teachers' relationship with mathematics. Zazkis assessed pre-service teachers' attitudes towards mathematics via creative writing task in which they described their relationship with mathematics as though mathematics were a person. Then, he used conceptual blending to interpret participants' human description of mathematics, personification, by mapping their descriptions to corresponding mathematical character.

In this study, we will investigate whether interpreting personification writing tasks using conceptual blending yields the same results as conventional surveys about mathematics attitudes. Thirty-two pre-service teachers completed a 14 question survey assessing their beliefs and attitude regarding learning mathematics. The survey questions were modified from Mathematics Anxiety Rating Scale-abbreviated version (Alexander & Martray, 1989) and Mathematics Teaching Efficacy Belief Instrument (Enochs & Riggs, 2002). They also completed two creative writing tasks. The first one was the same as Zazkis' task, and in the second one, they introduced mathematics to their future students through personifying mathematics.

For one survey item, 68% of participants agreed that "teacher's own feeling about mathematics is related how well a teacher can teach mathematics to students". For example, Alex (pseudonym), who agreed with the statement wrote "sometimes math is a crazy monster that seems to try to make my life so much harder than it needs to be" on task 1 and on task 2 wrote "Math can be scary sometimes because we don't always understand what it is trying to show us" which indicate warning of math to students based on Alex's experience with mathematics.

On the same survey item, Casey selected that "teacher's own feeling about mathematics is independent of a teacher's practice". However, Casey wrote "I found myself face to face with someone(math) I hoped never to see again…" on task 1 and wrote "just remember, he(math) is really never going to be easy to talk to, so always prepare to think when you are around him" on task 2. These responses reflect Casey's relationship with mathematics affecting Casey's portrayal of mathematics to future students, and are contrary to what Casey selected on the survey. Therefore, two writing tasks can offer different view of participants' relationship of math and how it could affect their future teaching.

# Transformers! More than Meets the Eye!

Courtney Simmons
Oklahoma State University

Michael Oehrtman
Oklahoma State University

*In this study, we characterize a conceptual model some students draw upon in their problem-solving activity when engaged in definite integral tasks. We call this model an Integral as a Transformer conception as it is invoked by students as a means to transform a quantitative relationship suitable for constant values into a structure appropriate for co-varying quantities.*

*Keywords:* Definite Integral, Adding Up Pieces, Quantification, Problem-Solving

This poster explores a conceptual model underlying two common misconceptions demonstrated by students attempting to apply definite integrals to problems in context. The literature often distinguishes between these two errors by the symbolic forms (Sherin, 2001) which cued the need for integration (Jones, 2013; Meredith & Marrongelle, 2008; Nguyen & Rebello, 2011). The first error, observed in students cued by the dependence symbolic form, is characterized by a student placing a given, or derived, quantity in for the integrand without consideration for its physical contextual relationship to the differential. The student might omit the differential entirely or only justify its presence as signifying the changing variable within the integrand. Meredith and Marrongelle described this reasoning as a dead end regarding successful student integration when the integrand is not a rate of change or density. When students were instead cued by the parts of a whole symbolic form some were observed to give quantitative meaning to the differential but only viewed the accumulation process as applying to the integrand; Jones described this as Adding up the Integrand. Through classroom observations, we noticed the dependence misunderstanding emerged in some students' reasoning even when they were cued to integrate by the parts of a whole symbolic form. It also appeared this error did not necessarily prevent students from making progress through definite integral tasks. In light of this, we hypothesized there might be an underlying tool (Dewey, 1938; Hickman, 1990) students utilize in their problem-solving process which motivates these misconceptions.

This tool, which we called an Integral as a Transformer conception, entails a student invoking a definite integral to convert a mathematical model that is appropriate for constant values of its constituents (e.g., distance = velocity · time) into a model applicable for contexts in which the constituent quantities co-vary. It should be noted that for a simple rate of change and density problems this conception often provides students with a heuristic for composing correct integral structure despite an incorrect quantitative interpretation.

Planning to challenge this heuristic, we developed our study using Dewey's theory of Inquiry which characterizes knowledge as a byproduct of the dialectic interplay between a student's selection, application, testing, and refinement of a conceptual tool when faced with a problematic situation. We videotaped interviews with nine students, eight in pairs and one alone, as they worked through a series of increasingly difficult contextual definite integral tasks. Our analysis found that every group in the study used the Integral as a Transformer conception at least once in their problem-solving process, despite many pairs also justifying the need for integration in terms of the parts of a whole symbolic form. In our poster presentation, we will discuss the numerous forms in which the Integral as a Transformer conception appeared throughout the interviews, when and how it proved problematic, and more importantly how it interacted with other conceptual tools in students' mathematical modeling activity.

Characterizing Self-explanations for Undergraduate Proof Comprehension

Kristen Amman, Joseph Olsen
Rutgers University

*A study was conducted with 11 undergraduate students in a real analysis course to further investigate important results reported by Hodds, Alcock, and Inglis (2014) on self-explanation and undergraduate proof comprehension, and by Ainsworth, S., & Burcham, S. (2007) on self-explanation and textual coherence. The main product of the current study is a framework of self-explanations in proof comprehension that takes into account students' questions as they self-explain both high and low coherence proofs.*

*Keywords:* Self-explanation, Proof Comprehension, Text Coherence

Self-explanations are explanations of textual material generated *by* the student *for* the student that attempt to aid comprehension. Students can be taught to self-explain and can realize the same benefits as those that do so spontaneously (Chi et al. 1994) especially in domains like mathematics (Rittle-Johnson, B., & Loehr, A. M. 2016). Hodds, Alcock, and Inglis (2014) replicated the self-explanation effect for proof comprehension in undergraduate mathematics. Based on previous research, Hodds et al. described three categories of self explanations (Principle-Based, Goal-Driven, and Noticing Coherence) and four categories of non-explanations (Paraphrasing, False Explanation, Positive Monitoring, and Negative Monitoring).

While these categories reveal important distinctions between undergraduate self-explanations, we argue that they are too broad. Although participants who were trained to self-explain saw greater scores on a proof comprehension test, they still produced the same amount of Paraphrasing and False Explanations as those who were not. Additionally, the proofs provided to participants did not vary in textual coherence (a text can be made more or less coherent depending on the degree to which it makes inferences between ideas and connections to textual goals explicit). While Ainsworth and Burcham (2007) showed that minimally coherent texts elicited different self explanations compared to maximally coherent texts, Hodds, Alcock, and Inglis (2014) used only minimally coherent proofs in their study. However, undergraduate students encounter proofs that are not minimally coherent, particularly in lectures and textbooks.

We explore the following questions: What are some of the different types of questions/self explanations that students generate when reading low- and high-coherence proofs, after going through a self-explanation training? How do these types relate to previous self explanation frameworks? In this study, 11 undergraduate students in a real analysis course received self-explanation training and were audio recorded as they modeled the self-explanation strategy out loud, with both low and high coherence proofs. Their self-explanations and questioning behaviors were used to create a framework based off of Hodds et al. (2014) that allows for a more nuanced consideration of self explanation types. For example, a statement in a proof such as *Since object O has properties A, B, and C,* was often followed by: "I see why we need properties A and B, but why was C necessary?" This kind of self-explanation has attributes of a Goal-Driven self-explanation, but it's not really related to the structure of the proof as a whole (as defined by Hodds et al., 2014). Furthermore, since more coherent proofs would be more likely to include this information, the level of coherence of the proof seemed to influence the extent to which this type of self-explanation was produced.

# Students' Experiences in an Undergraduate Mathematics Class: Case Studies from one Student-Centered Precalculus Course

Brooke A. Outlaw
North Carolina State University

Gregory A. Downing
North Carolina State University

*Using evidence-based practices in a large undergraduate mathematics classroom demands further investigation as there is still not significant work in this area. Results from this case study show that students perceived that their participation in student-centered instruction in an undergraduate Precalculus course, was helpful to their learning. The results also suggest that students demonstrated positive attitudes in regard to the collaborative efforts active learning components including Team Activities were utilized in this course and that the strategies were considered useful and important by the students interviewed.*

*Keywords*: Large Scale Classrooms, Precalculus, Evidence-Based Practices

In general, students have demonstrated greater gains in achievement and positive changes in affect when introduced to student-centered instructional strategies (Freeman et al., 2014; Kwon, Rasmussen, & Keene, 2005). However, there has not been significant work done to give a voice to students in these courses. Being able to show the effects these strategies have on students' perceived experiences in particularly large classes is an important contribution to the RUME community. The goal of this study was to understand the experiences of 5 students in a large-lecture Precalculus course where active learning strategies, such as the use of Team Activities and Clickers, were used. The research question was: What are students' perceptions of their experience in a large-scale Precalculus course where active learning strategies are used?

This is a multiple case study in a large Precalculus course at a southeastern university. The course included lecture and a computer lab component and introduced team activities and conceptual clicker questions designed to be completed in groups. The results are presented as 5 narratives to tell the stories of the students' perceptions of their experiences in this large-scale Precalculus course where student-centered instructional strategies are present (Creswell, 2013). Data collection included interviews and pre- and post-surveys. Interviews were transcribed and then coded using open coding techniques (Strauss & Corbin, 1998). Interview and survey responses were analyzed and reconstructed as a narrative to demonstrate these experiences.

For these 5 participants, it was most common that the Team Activities were classified as the favorite part of the course. Most of the students enjoyed collaborating and problem-solving with their peers. They also liked how it seemed relevant to real-life and was different than the procedural-type learning that they received from lectures and Smart Lab. The students in this study expressed mostly positive attitudes towards these student-centered learning strategies, in addition to demonstrating a similar change in attitude from a pre- to post-survey that was given to them at the beginning and end of the course.

Overall, we found that it is possible to bring student-centered learning strategies to a large-scale undergraduate class. To implement these strategies successfully, we suggest starting with a few activities and then slowly adding more activities to the course.

Gender-based Analysis of Learning Outcomes in Inquiry-Oriented Linear Algebra

Brooke Athey, Matthew Mauntel, Muhammad Haider, and Christine Andrews-Larson
Florida State University

*In order to better understand gender-based differences in learning experiences and outcomes in inquiry-oriented instructional settings, we analyze data from a common end-of-term assessment administered across 7 sections of linear algebra. This analysis focuses on data from 58 students, 22 of whom identified as female and 36 of whom identified as male. Distribution of the 58 students' scores was negatively skewed, similar to that of broader sample of 153 assessment scores (many of which did not have gender information available as that was collected separately from the assessment). A two-tailed t-test with independent samples was administered, revealing that the difference between the scores of the two groups is not statistically significant.*

*Key words:* inquiry-oriented instruction, learning outcomes, gender

Some research suggests that inquiry-based approaches to teaching undergraduate mathematics are likely to "[level] the playing field" between men and women (Laursen, Hassi, Kogan, & Weston, 2014, p. 412). Other research suggests that inquiry-oriented approaches may disproportionately advantage men (Johnson, Andrews-Larson, Keene, Keller, Fortune, & Melhuish, 2017). Inquiry-oriented instruction aims to support students in 'reinventing' important mathematical ideas by first posing challenging problems to students. The instructor's role is to elicit and build on these ideas so as to support the development of more formal langauge and notation that is rooted in students' initial, informal, and intuitive ideas (Rasmussen & Kwon, 2007). In our study, we ask: Are there gender-based difference in learning outcomes among students whose instructors received support to teach inquiry-oriented linear algebra?

Assessment data was collected from 153 students at the end of the term from 7 different classes; instructors of these classes received supports (curricular materials, a 16-hour summer workshop, and facilitated online workgroups for one hour per week during the semester of instruction) to teach inquiry-oriented linear algebra. The assessment consisted of 9 items, including both multiple choice and open-ended response questions, aimed to measure student understanding of key ideas in introductory linear algebra (solutions to linear systems, linear transformations, span and linear independence, and eigenvectors and eigenvalues). We were only able to match 58 of these assessments with gender data gathered as part of a student survey. Of those students, 22 identified as female and 36 identified as male. A team of 3 coders developed and used a rubric for scoring the open-ended assessment questions. After fine-tuning of the rubrics, 13% of the assessments were double coded, with each item requiring at least 80% inter-rater reliability (mean of 91%). Mean scores and standard deviations were computed for students who identified as male and as female; students who identified as other were omitted from this analysis. A two-tailed t-test with independent samples was conducted to determine if the difference of means of male and female TIMES students was statistically significant.

There is not a statistically significant difference between the scores of students who identified as male and female. With 51 points possible, the mean was 38.09 (SD=7.30) for female students and 38.59 (SD=7.67) for male students. There was not a significant effect for gender, $t(57) = .248$, $p = .805$. The effect size between male and female students was .065. A larger sample size is needed to support bolder claims about the generalizability of this finding.

Examining Exams, Evaluating Evaluations: An Alternate Approach Assessed

Kayla K. Blyman
United States Military Academy, West Point

Kristin M. Arney
United States Military Academy, West Point

David del Cuadro-Zimmerman
United States Military Academy, West Point

Lisa Bromberg
United States Military Academy, West Point

*In an attempt to bring a more realistic environment into the classroom during assessments, an alternative form of assessment was piloted during a mathematical modeling course at the United States Military Academy at West Point in the fall of 2017. The "alternate" assessments are primarily conceptual in nature and consist of three parts: a night before read-ahead introducing a new application, an in class individual portion, and an in-class group portion. Through the evaluation of this assessment technique, we hope to determine if it should be expanded to a larger audience in the future. Preliminary finding of this evaluation are presented.*

**Poster Proposal**

Our course has higher-order learning goals for students to learn to think critically, work collaboratively, use technology appropriately and effectively, and to work towards solving real-world problems creatively. While traditional exams are effective at assessing computational lesson objectives, they are limited in their ability to assess a student's growth with regards to these higher-order learning objectives. A desire to more meaningfully challenge students to grow in these ways by requiring them to engage these skills in an assessment setting led us to design and implement this alternate form of assessment.

A sub-movement of the flipped classroom movement that has been growing is team-based learning. The Team-Based Learning Collaborative maintains a list of related publications. These papers ( i.e. Rezaee, Moadeb, & Shokrpour, 2016; Huggins & Stamatel, 2015; Stein, Colyer, & Manning, 2016) focus on team-based learning techniques applied to classroom instruction and how effective it is in comparison with more traditional lecture techniques. While these studies are interesting, the assessment techniques used in these classrooms remain traditional exams. Eric Mazur, the Balkanski Professor of Physics and Applied Physics and Dean of Applied Physics at Harvard University provides a video of a talk on his website entitled *Assessment: The Silent Killer of Learning* in which he claims that the traditional method of assessment is outdated. He claims that we can create assessments in such a way as to encourage the higher-order thinking skills (creating, evaluating, and analyzing) of Anderson & Krathwohl's (2001) revision of Bloom's Taxonomy rather than the traditional assessment which required far more remembering, understanding, and applying.

While Mazur clearly has strong opinions and an abundance of ideas about this topic, we are unaware of any research studies that have addressed the feasibility and effectiveness of such assessments. Consequently, it is the goal of our pilot study to begin to address such questions of feasibility and effectiveness.

Our poster will provide sample assessments and some preliminary findings from our fall pilot. We look forward to discussing the project and potential ways to improve our assessments with conference attendees.

# An Examination of Preservice Mathematics Teachers Using Ratios and Proportions in a Social Justice Context

Brittney L. Black
North Carolina State University

Gregory A. Downing
North Carolina State University

*This study examines ways in which preservice teachers use mathematics in a social justice context. Using a mathematical task and social justice activity adapted from Gutstein and Peterson (2005), participants were asked to respond to questions surrounding their experience with using mathematics topics such as ratios and proportions in a social justice context. Using the preservice teachers' responses from pre- and post-surveys, researchers compared participants initial conceptions of teaching mathematics using a social justice lens to their views after completing a mathematical task involving social justice topics of world wealth and population disparity using ratios and proportions.*

*Keywords*: Algebra, Ratios, Preservice Teachers, Social Justice, Equity and Diversity

When helping develop the knowledge and skills that preservice mathematics teachers need, part of what is needed are mathematical modeling tasks that are designed to elicit thinking and mathematical discourse (Blum & Ferri, 2009; Doerr & English, 2003). There has been a general call for increased quality in science, technology, engineering and math (STEM) undergraduate instruction in the United States due to a fear that the US is falling behind as a professional leader in STEM (Henderson, Beach, & Finkelstein, 2011; Jones & Johnston, 2010). Jones and Johnston (2010) propose that this heavily relies on improved mathematics instruction.

While diversity increases among the student population in public schools, the population of preservice teachers remains homogenous -- predominantly White, female, and middle class (Barnes, 2006; Swartz, 2003). One of the challenges for teacher education preparation programs is preparing preservice teachers to teach diverse student populations. An attitude of *naive egalitarianism* is prevalent among preservice teachers. Causey, Thomas, and Armento (2000) define this as, "[when preservice teachers] believe each person is created equal, should have access to equal resources, and should be treated equally" (p. 34). Preservice teachers with these beliefs may lack an understanding of multicultural issues, as well as disregard effects of past and present discrimination (Causey, Thomas, & Armento, 1999; Finney & Orr, 1995). This study looks at the ways in which preservice teachers viewed mathematics in the context of social justice related issues.

## Study Design

In this study, we provide mathematical tasks for preservice middle and high school teachers (N=40) that aligns with the ideals of teaching mathematics for social justice. We investigated the responses to the mathematical tasks centered around the topics of ratios and proportions. In this mixed methodological study, the researchers observed participants interacting with the tasks, and how they rationalized and reasoned with the material. There was a special emphasis on how the preservice teachers thought about students' misconceptions that the mathematics could possibly trigger and how they would guide these students. Through surveys, quantitative data was collected and will be reported on the poster. One major theme that arose was initial hesitation with the idea of teaching mathematics using a social justice lens, but this later evolved after having taken part in this study.

Connecting Advanced Undergraduate Mathematics to School Mathematics

Elizabeth G. Arnold
Montana State University

James A. Mendoza Álvarez
The University Texas Arlington

*The Mathematical Education of Teachers as an Application of Undergraduate Mathematics (META Math) is a project to create, pilot, and field-test modules for use in undergraduate mathematics and statistics courses taken by pre-service teachers. Materials in calculus, discrete mathematics, algebra, and statistics showcase vital connections between college mathematics and the mathematics taught in high school. Drawing on recommendations in the Mathematical Education of Teachers II and the Statistical Education of Teachers, the project puts attending to the needs of pre-service teachers on par with attending to the needs of other undergraduate students by focusing on applications related to high school mathematics teaching.*

*Keywords:* Pre-service Secondary Teachers, Undergraduate Mathematics, Curriculum Modules

The Mathematical Education of Teachers II (MET II) report (CBMS, 2012) calls for a future in which secondary school students engage in substantive mathematical inquiry, solve non-routine problems, and make deep mathematical connections. The project, "The Mathematical Education of Teachers as an Application of Undergraduate Mathematics" (META Math), draws on the expertise of mathematicians and mathematics education researchers to address the content knowledge needs of undergraduate pre-service teachers, providing faculty with tools to better prepare teachers to contribute to the vision outlined in the MET II report.

The project team developed modules, focusing on four content areas: Calculus, Statistics, Algebra, and Discrete Mathematics. Each module is self-contained and textbook-independent, comprised of materials to assist faculty in seamlessly incorporating content into existing undergraduate courses to meet the specific needs of future teachers and foster deep examination of school mathematics content from the advanced perspective of undergraduate content. We plan to recruit and train a cohort of mathematics faculty to pilot test these modules during the 2018-2019 academic year, collecting research data from their implementation of the modules.

We will test the modules for effectiveness in promoting student understanding of the connections between 7-12 and undergraduate mathematics, investigate effective practices for using these modules, and provide insight into how module usage affects a faculty member's own understanding of school mathematics content from an advanced perspective. To do this, we will employ a qualitative case study approach, in which each content area is a case. We plan to conduct: (1) in-depth qualitative observations of faculty using modules in their classrooms, (2) a preliminary and a follow-up interview with faculty, and (3) cognitive interviews with students.

META Math not only focuses on enhancing pre-service teachers' understanding of the vertical connections from school mathematics through advanced undergraduate mathematics but also awareness of these connections among mathematics majors not intending to teach as a career. This poster presents an overview of the META Math project, including examples of the modules and ways faculty can participate in the field-testing of modules.

# Content Analysis of Introductory Textbooks in Point-Set Topology

Daniel C. Cheshire
Texas State University

Joshua B. Fagan
Texas State University

*This study compared twelve point-set topology textbooks at the introductory level. The goal was to differentiate each textbook according to its overall conceptual approach to the field, as well as its mathematical approach to four fundamental topological ideas. The analysis indicated significant differences in the conceptual and mathematical presentation of those topics among the twelve textbooks. These findings highlight the need for researchers to distinguish between the conceptual and mathematical approaches found in textbooks for proof-intensive courses in undergraduate mathematics education.*

*Keywords:* Concept, Proof, Topology, Textbook analysis

Textbooks play an important role in outlining the learning progressions that students are expected to follow as they first construct their conceptual understanding for new ideas. The purpose of this study was to delineate some of the major conceptual approaches to point-set topology that are introduced by well-known textbooks on the subject, and therefore highlight the ways that students are expected to conceptualize ideas in their undergraduate topology courses.

## Methodology

Twelve introductory textbooks in point-set topology were selected for analysis (see References). The textbook choices were primarily based on the Mathematical Association of America's list of recommendations for undergraduate libraries (MAA, 2017), supplemented by a survey of recommendations published online by authors in the field. The textbooks were chosen to include a variety of conceptual approaches to the topic, but excluded specialized content, outline-style treatments, and out-of-print texts. One popular online textbook was also selected for comparison. The textbooks were examined and compared according to their overall presentation of point-set topology, as well as their approaches to four key analytical and topological concepts. These topics were: open sets, closed sets, sequence/limits, and continuous functions.

## Findings

There were significant differences found among the twelve textbooks, both in terms of the theoretical perspective taken on the field of topology, and in the conceptual progressions that were used to present individual topics. Differences in the textbooks' broad approaches to topology were often reflected in each author's choice of the definitions, theorems, and order of presentation of the concepts screened in the analysis. The textbooks' conceptual approaches to the introduction of topology were grouped into three categories, labelled the *metric-analytic*, *geometric-intuitive*, and *abstract-axiomatic* approaches. Textbooks that followed the *metric-analytic* approach tended to generalize concepts from the study of real analysis, often relying on sequential and metric-based techniques. The *geometric-intuitive* approach tended to focus on low-dimensional surfaces and spatial imagery to establish concepts based on physical intuition. Textbooks that followed the *abstract-axiomatic* approach established definitions and theorems from the topological axioms, employing abstract examples or counterexamples to illustrate concepts. Concept-specific comparisons will be presented in table format on the poster.

Proportional Reasoning Using HLT Instead of Finding 'Missing' Value in Word Problems

Ishtesa Khan
Arizona State University, Arizona, U.S.A.

*Proportional reasoning sounds like finding the missing 'number' when the other three numbers are already given in the context. In this poster we are proposing a Hypothetical Learning Trajectory to achieve some learning goals leveraging proportional reasoning. We also propose effective strategies for solving proportional using graphs and conceptual analysis of proportional reasoning.*

*Keywords:* Proportional Reasoning, Conceptual Analysis, Hypothetical Learning Trajectory

## Introduction and Theoretical Framework

In proportional reasoning we are interested in comparing quantities in relation to one another instead of finding the 'missing' number of given situation. The fundamental concept we need for proportional reasoning is the idea of 'ratio'. A ratio is a binary relation which involves ordered pairs of quantities. (Lesh, Post, & Behr, 1988). According to Thompson (1994), A ratio is the result of comparing two quantities multiplicatively. When we discuss proportionality we not only consider one ratio, we compare two ratios with likely quantities. And the rate of change of both ratios remain same constant in this relationship. By Thompson (1994), a rate is a reflectively abstracted constant ratio. Both definitions of ratio and rate followed by Thompson's 1994 paper is fundamental perspective to look forward to proportional reasoning.

## Conceptual Analysis and Hypothetical Learning Trajectory

A conceptual analysis is a way to describe what students might understand about an idea to reason the way it should be understood (Thompson 2008). To conceptualize and reason proportionality I conjecture that the student will need to achieve seven learning goals I tried to identify in this poster. Simon's (1995) development of hypothetical learning trajectory(HLT) is consist of the goal for the student learning, and hypotheses of the students' learning (Simon, M. & Tzur, R., 2004). Generalizing conceptual analysis (Thompson 2008) and HLT (Simon 1995), this poster is going to present an HLT for proportional reasoning-

1. Students will draw a picture which represents the given situation
2. Students will identify quantities and determine whether they are varying or fixed quantities, and they will always verbalize them with corresponding units.
3. Students will be able to represent the situation graphically with scaled measurements.
4. Students will identify the varying quantities in the given situation and will be able to relate these quantities with the constant rate of change.
5. Students will understand that one quantity is as many times bigger or smaller as the second quantity. If there are more than two quantities in one situation they will be able to understand the relation among them as well.
6. Students will avoid seeing ratio and proportions only as a tool of performing calculations, applying rules and formulae and manipulating numbers and symbols in proportion equations.

# Quantum Physics Students' Reasoning about Eigenvectors and Eigenvalues

*Megan Wawro*
*Virginia Tech*

*Kevin Watson*
*Virginia Tech*

*Warren Christensen*
*North Dakota State University*

*Eigentheory is an important mathematical tool for modeling quantum mechanical systems, but little is known about how physics students reason about eigenvectors and eigenvalues as they transition from linear algebra courses into quantum mechanics. In this poster, we share examples of the resources (elements of students' knowledge) we have identified in physics students' reasoning about the eigenvectors and eigenvalues of real 2x2 matrices, as well as connections among these resources within and across students.*

*Keywords:* Linear Algebra, Eigentheory, Quantum Physics, Student Reasoning, Resources

This work is part of a larger research project that is examining the various ways students reason about and symbolize concepts related to eigentheory in quantum physics, as well as how students' language and symbols for concepts related to eigentheory compare and contrast across mathematics and quantum physics contexts. Expanding on the work done by Henderson, Rasmussen, Zandieh, Wawro, and Sweeney (2010), for this poster we focus on the following research question: What ways of reasoning about eigenvectors and eigenvalues of real 2x2 matrices exist for physics majors at the beginning of a quantum mechanics course?

To operationalize the research question, we use a Resources Framework, a type of fine-grained constructivism (Redish, 2004) initially proposed by Hammer (2000): "A resource is a basic cognitive network that represents an element of student knowledge or a set of knowledge elements that the student tends to consistently activate together" (Sabella & Redish 2007, p. 1018). Resources are activated depending on how individuals frame a given situation; resources can be linked to other resources, in which activation of one resource can promote or demote activation of others; and resources may internally consist of finer-grained resources linked in a particular structure (Sayre & Wittmann, 2008). We seek to identify resources that characterize how our participants reasoned about eigenvectors and eigenvalues of real 2x2 matrices.

Data come from semi-structured (Bernard, 1988) individual interviews conducted in the first week of the semester with eight students enrolled in a senior-level quantum mechanics course at a public research university in the Northeast United States. The linear algebra prerequisite at this university was either a linear algebra or combined differential equations and linear algebra course, both sophomore-level and taught in the mathematics department. The interview question analyzed asked students to reason about the equals sign and solutions to $A\begin{bmatrix}x\\y\end{bmatrix} = 2\begin{bmatrix}x\\y\end{bmatrix}$, where $A$ is a 2x2 matrix, and to find the eigenvectors and eigenvalues of a specific 2x2 matrix.

Each interview was transcribed and then watched independently by the three authors (one physics and two mathematics education researchers) in an attempt to identify students' conceptual and procedural resources (Wittmann & Black, 2015). For example, conceptual resources include eigenvectors being stretched by eigenvalues, scalar multiples of eigenvectors also are eigenvectors, or that the result of the product $A\begin{bmatrix}x\\y\end{bmatrix}$ is the same object as the result of the product $2\begin{bmatrix}x\\y\end{bmatrix}$. Procedural resources include, for example, performing the mathematical steps to rewrite $Ax = \lambda x$ as a system of equations or finding the roots of a characteristic polynomial to find a matrix's eigenvalues. This presentation will feature several examples of these identified resources, along with connections between these resources within and across students.

Bridge Programs for Engineering Calculus Success

Sandra B. Nite and Michael Sallean
Texas A&M University

*Mathematics is often the gatekeeper for students aspiring for a college degree in any field. A precalculus bridge program to improve success in the engineering calculus sequence was initiated at Texas A&M University in summer of 2010. Students who placed into precalculus were offered the program. The program was revised and additional bridges were added. Surveys were administered to examine student beliefs about college level mathematics expectations and requirements. Overall, the programs benefited hundreds of students.*

*Keywords* - calculus, bridge program

Success in engineering programs is highly dependent on mathematics knowledge, but many freshmen entering college lack the preparation needed for success in their college mathematics coursework. This deficiency limits their future career opportunities (Achieve, 2008). Bridge programs have been used to support students' mathematics knowledge and skills during the summer prior to college coursework (Conley, 2008). These programs often cost institutions considerable revenue and staff resources (Kallison & Stader, 2012). Bridge programs were often used to specifically assist first generation college students and those of low socio-economic status (Grimes & David, 1999; Inkelas & McCarron, 2006). Results have been mixed (An, 2012), but positive results have been reported (Gamoran, Porter, Smithson, & White, 1997).

A precalculus bridge program was initiated at Texas A&M University to help engineering students prepare for college level mathematics workloads. The university enrolls about 3,300 freshman engineering students each fall (60% white; 26% Hispanic; 24% female; 76% male). Students who did not meet the cut score on the Mathematics Placement Exam (MPE) for Engineering Calculus I were offered the Personalized Precalculus Program (PPP). Studies for various cohorts have shown improvement on the MPE (Morgan, Nite, Allen, Capraro, Capraro, & Pilant, 2015; Nite, Allen, Morgan, Bicer, & Capraro, 2016) and performed as well in calculus as their peers with similar backgrounds (Nite, Allen, Capraro, Bicer, & Morgan, 2016; Nite, Morgan, Allen, Capraro, Capraro, & Pilant, 2015). Students who spent more time were more successful (Nite & Allen, 2014a; Nite, Allen, Bicer, & Morgan, 2016). Results from surveys identified areas in which students lacked confidence (Nite & Allen, 2014a) and student beliefs and expectations for college mathematics study (Nite, Allen, Bicer, Morgan, & Barroso, 2017).

A bridge to Engineering Calculus II was added for continued support (Nite & Allen, 2014b; Nite, Morgan, Allen, Capraro, & Capraro, 2015), and finally, a precalculus program for students who met the cut score on the MPE (Nite, Morgan, Capraro, Allen, & Capraro, 2014). The overarching question is "What impact did the three bridge programs for engineering calculus courses have on student success in their college mathematics courses?"

Results for the bridge programs have shown a positive impact overall, with statistical significance in MPE improvement ($p < .05$), and course pass rates have been acceptable. Students have difficulty with study behavior and time commitments for college mathematics. Therefore, future bridge programs should consider other factors in addition to mathematics knowledge and skills to improve success for students in college mathematics. Bridge programs to support non-STEM majors in their mathematics could be an effective strategy to improve perseverance toward completing college degrees for at-risk populations.

**A Hypothetical Learning Trajectory (HLT) for Preservice Secondary Teachers' Construction of Congruence Proofs**

Yvonne Lai, University of Nebraska—Lincoln
Rachel Zigterman, University of Nebraska—Lincoln

*With the advent of the Common Core State Standards, there has been renewed interest in teaching geometry from a transformation perspective; however, most geometry teachers are unfamiliar with this approach as they learned geometry from a perspective based on Euclid's Elements. Consequently, there is little knowledge of how teachers who come from this traditional perspective learn geometry from a transformation approach. One major difference that teachers must reconcile is in the construction of congruence and similarity proofs. As such, there is a need to understand how teachers learn these proofs from a transformation perspective. We propose to present a poster reporting a hypothetical learning trajectory (HLT) for preservice teachers' construction of such congruence proofs, based on the coursework of 15 preservice secondary teachers and cognitive interview responses to geometry tasks.*

Keywords: hypothetical learning trajectory, transformational geometry, proofs

Simon (1995) defined a *hypothetical learning trajectory* (HLT) as "the learning goal, the learning activities, and the thinking and learning in which the students might engage" (p. 133). HLTs can be influential in improving curriculum and instruction (e.g., Sztajn et al., 2012) and have been examined extensively for K-8 levels (e.g,, Daro et al., 2011).

We contend that HLTs could be similarly influential in improving the instruction of geometry from a transformation approach, including for pre-service secondary teachers who themselves learned geometry from a more traditional perspective and who may have to teach from a transformation perspective in the future. The central difference distinguishing these two perspectives on geometry is in the construction of congruence and similarity proofs. Thus we address: *What thinking and learning do pre-service teachers progress through while learning to construct congruence proofs?* We focus on congruence as it is typically viewed as a prerequisite for learning similarity.

Based on the mechanism of reflection on activity-effect relationships for generating an HLT (Simon & Tzur, 2004), we identified components of a HLT as specified by Simon (1995). The data for this study are 12 written assignments, selected using Simon and Tzur's (2004) framework, from 15 pre-service teachers (PSTs) (7 white females, 8 white males) enrolled in a course on geometry from a transformation perspective; and 4 students' responses to cognitive interviews. The PSTs are undergraduates at a research-intensive, doctoral granting institution.

The main result of our analysis is an HLT for pre-service secondary teachers' learning to construct congruence proofs. The HLT spans initial learning of rigid motions, to constructing proofs for triangle congruence criterion, to constructing proofs incorporating more complex and/or multi-component geometric objects. Results from this study can be applied to improving undergraduate education of pre-service secondary teachers and potentially informs task design to support concepts of congruence and similarity.

Relationships Between Calculus Students' Ways of Coordinating Units and their Ways of Understanding Integration

Jeffrey Grabhorn
Portland State University

Steven Boyce
Portland State University

Cameron Byerley
Colorado State University

*This poster describes results from a paired-student teaching experiment focused on college calculus students' understandings of integration. Our aim was to model relationships between students' covariational reasoning, quantitative reasoning, and numerical reasoning as they were developing meanings for integration, via teaching sessions that were concurrent but independent from the students' "traditionally-taught" second-term calculus course. We will discuss commonalities between students' ways of reasoning multiplicatively, ways of reasoning about linear rates of change, and ways of understanding integration.*

*Keywords:* Covariational Reasoning, Integration, Numerical Reasoning, Quantitative Reasoning

A key aspect for conceptualizing the fundamental theorem of calculus, the *accumulation function*, $F(x) = \int_a^x f(t)dt$, requires coordinating three varying values: that of an independent variable, *t,* as it varies from *a* to *x,* that of a dependent variable, *f*(*t*), as *t* varies, and that of the accumulation of values of *f*(*t*) as *f*(*t*) and *t* co-vary (Swiden & Yerushalmy, 2016; Thompson, 1994; Thompson & Silverman, 2008). Research with K-12 students points to the necessity of students' construction of a structure for coordinating three *levels of units* for (a) reasoning flexibly with (im)proper fractions, e.g., for thinking of '9/7' as "containing" potential multiplicative relations with '1', '1/7', '1/9' and '7/9', and (b) reasoning flexibly with algebraic equations in the middle grades (Hackenberg & Lee, 2015). Students sometimes experience success in school mathematics if they learn to reason with three levels of units *in activity*, which means they "build" an ephemeral third level of units as part of their way of reasoning rather than assimilating situations with a units (of units (of units)) structure (Ulrich, 2015). Indeed, some students assimilating with two levels of units pursue STEM majors in college: Boyce and Wyld (2017) described constraints in two such differential calculus students' reasoning about function inverses and function composition, and Byerley (2016) described how students' reasoning with fractions was (and was not) associated with their success in different aspects of introductory calculus.

We report on an 8-session constructivist teaching experiment (Steffe & Thompson, 2000) exploring connections between students' units coordination and understandings of integral calculus. Our poster focuses on contrasting the reasoning of a pair of students, one who assimilated with two levels of units and one who could assimilate with three levels of units. Our poster will exemplify contrasts (and commonalities) in (a) their units coordination (b) their ways of reasoning about linear rates of change (c) their meanings for the quantities represented in the statement $F(x) = \int_0^x sin(t)dt$, and (d) their associated justifications for why $\int_0^\pi sin(t)dt = 2$. The results provide conjectures of how differences in the constraints students face in conceptualizing the accumulation function (and fundamental theorem of calculus) may be attributed to differences in their ways of coordinating units.

University of Oklahoma

Stacy Reeder
University of Oklahoma

*Covariational reasoning is at the heart of many pre-calculus concepts and is vital for calculus readiness (Cottrill et al., 1996; cited in Carlson, Jacobs, Coe, Larsen & Hsu, 2002). To explore the efficacy of a game-based learning application to facilitate conceptual understanding of function concepts through covariational reasoning, the University of Oklahoma's Virtual Learning Experience Team developed a digital game titled "Functions of the Machine". In the game, the student plays the role of a scientist tasked with making a complex machine run. The student explores, tests and fixes the machine's moving parts that consist of gears, fluid tanks, and conveyor belt contraptions. Through a series of interactive scaffolded problems, students transition from proportional reasoning to complex covariational reasoning simulations.*

*Keywords:* Covariational Reasoning, Game-Based Learning, College Algebra

According to Carlson, Oehrtman, and Engelk (2010) it has been well established that pre-calculus level students' thought processes for function concepts are primarily procedural and indicative of an action view of functions (Carlson, 1998; cited Carlson et al., 2010). Furthermore, covariational reasoning, described as the ability to interpret the relationship between two varying quantities as they continuously change, has been documented to be a challenge for even "academically talented" undergraduate students (Carlson, 1998; cited in Carlson, Jacobs, Coe, Larsen & Hsu, 2002, p. 353). A meta-analysis conducted by Vogel et al. (2006), reported with high validity that interactive educational computer games were associated with more significant cognitive gains and more desirable learning attitudes compared to traditional teaching methods (Vogel et. al., 2006). The University of Oklahoma Virtual Learning Experience Team developed a digital game titled "Functions of the Machine" to address the following research question: Is a visually dynamic game-based learning environment associated with better cognitive outcomes in covariational reasoning compared to visually static traditional homework or non-game-based covariational homework? It is hypothesized that the visually dynamic game-based learning environment may be better equipped at helping students develop covariational reasoning. A randomized controlled design was used to test this hypothesis. Students enrolled in College Algebra and Pre-Calculus for Business, Life, and Social Sciences at the undergraduate level were recruited and randomly assigned to one of three conditions: digital game play, traditional problems, or covariational problems without a game environment. All three conditions completed demographic and engagement surveys, pre-post assessments, and a subset of items from The Attitudes Toward Mathematics Instrument (Tapia & Marsh, 2004). Data collection and analysis is still ongoing; results will be presented at a later time.

Students' Understanding of Quadratic Equations

Jonathan López Torres
North Carolina State University

Izraim L. Robles Hernández
University of Puerto Rico at Mayagüez

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez

*Action–Process–Object–Schema theory (APOS) was applied to study student understanding of quadratic equations with one variable. This requires proposing a detailed conjecture (called a genetic decomposition) of mental constructions students may use to understand quadratic equations. The genetic decomposition, which was proposed, can contribute to help students achieve an understanding of quadratic equations with improved interrelation of ideas and more flexible application of solution methods. Semi-structured interviews with eight beginning undergraduate students explored which of the mental constructions conjectured in the genetic decomposition students could do, and which they had difficulty doing. Two of the mental constructions that form part of the genetic decomposition are highlighted and corresponding further data was obtained from the written work of 121 undergraduate science and engineering students taking a multivariable calculus course. The results suggest the importance of explicitly considering these two highlighted mental constructions.*

*Keywords:* Quadratic Equations; APOS Theory; Genetic Decomposition; Calculus

Many secondary school students, and undergraduate students, do not truly understand quadratic equations or the rules they use to solve them (Didis, Bas, & Erbas, 2011). Some studies suggest that problems like these may stem from the lack of details in books, which, consequently, teachers tend to not emphasize (Sönnerhead, 2009). Some investigations on student understanding of quadratic equations refer to specific misconceptions (Bossé & Nandakumar, 2005; Ochoviet & Oktac¸ 2009¸ 2011; Vaiyavutjamai, Ellerton, & Clements, 2005). In Puerto Rico, the Department of Education established it is not until tenth grade that students learn how to solve quadratic equations. These quadratic equations are simpler by design, and can be solved using the following techniques: factoring, using square roots, completing the square, the quadratic formula, and by using technology. Given the described context held by incoming first year students attending a Puerto Rican university, this article investigated students' understanding of quadratic equations by: (1) establishing a conjecture of their mental constructions (stated in terms of the constructs of Action–Process–Object–Schema (APOS) theory) that beginning university students may do in order to understand how to solve quadratic equations; (2) using semi-structured interviews in order to investigate which of the conjectured mental constructions students can do and which they have difficulty doing; and (3) using written work from more advanced undergraduate students to investigate their use and understanding of two specific mental constructions conjectured in the genetic decomposition.

## Results and Conclusions

The genetic decomposition and results from this study highlight two specific mental constructions that play a key role in students' understanding of quadratic equations, that students have difficulty doing and that they seem to be overlooked in traditional instruction. Another result of the study underscores the importance of numerical and graphical explorations into the nature of the possible solutions of a quadratic equation.

Using Everyday Examples to Understand the Concept of Basis

Jessica Knapp　Michelle Zandieh　Aditya P. Adiredja
Arizona State University　University of Arizona

*The purpose of this paper is to explore everyday examples given by students to explain the notion of basis. By exploring key aspects of the examples generated by the students we can see what roles and characteristics of basis the students attend to.*

*Keywords:* Examples, Linear Algebra, Basis, Generating Examples

In natural language, it is common to use an everyday example as a conceptual metaphor for abstract ideas. Research suggests that digesting formal definitions can be a stumbling block for students (Edwards & Ward, 2004; Knapp, 2009). Several researchers have studied how students come to understand the concepts of basis, span, and linear (in)dependence (e.g. Aydin, 2014; Stewart & Thomas, 2010; Trigueros & Possani, 2013; Plaxco &Wawro, 2015). Adiredja & Zandieh (2017) developed a framework for exploring students' generation of everyday examples for basis. We use a modified version of this framework to explore student everyday examples.

## Data Collection and Analysis

Data was collected by our second author in Germany with nine Applied Math upper division and masters university students. Interviews were held in English and videotaped by a speaker fluent in English and German. Adiredja & Zandieh (2018) studied ways that students understand the notion of basis in linear algebra. Two aspects of that understanding were how the basis vectors related to the space (*roles*) and the nature of the set of basis vectors (*characteristics*). The roles codes are Generating, Covering, Structuring, Traveling and Supporting. Characteristic codes are Minimal, Essential, Representative, Non-redundant, and Different. We will use the data to illustrate some of these roles and characteristics.

## Results and Discussion

After engaging in mathematical activities on basis, students were asked how they might describe the idea of basis to someone who had not yet learned the concept. The students developed everyday examples as part of their explanation. One student, Andreas, began with a description of a sailboat; however, he decided to think of a different example because the sailboat example had a flaw "[if] you can't assess the point already with one of the other vectors or a combination then it isn't actually a new vector and it can be crossed out or x'ed out from the basis." The student here was attending to the characteristic of non-redundancy. The sailboat example didn't have a mechanism to keep there from being redundant vectors in the basis.

Andreas then chose a star fish to describe basis. "You have sea stars; … they just walk straight in one of those directions." He thought of the star fish legs as the vectors in the basis. "So they just declare one of their legs as front. And then they march on. And so they can access any point on the sea floor which is our plane again." In using the verbs "march, access, move, and walk," Andreas's star fish example illustrates the Traveling code. He reflected on the characteristics of the star fish example, "by moving in those five directions, the question is, is this even necessary to have five directions." Before Andreas was focused on "x-ing out" redundant vectors, now his focus has shifted to consider the minimal amount of legs needed to access the entire sea floor. This illustrates the characteristic of minimal.

**Math Help Centers: Factors that Impact Student Perceptions and Attendance**

Christine Tinsley
University of Oklahoma

Beth Rawlins
University of Oklahoma

Deborah Moore-Russo
University of Oklahoma

Milos Savic
University of Oklahoma

*Mathematics help centers have become more common in post-secondary education, but there is scant research on them. In this study we use data from 1088 students over six academic semesters and grounded theory analysis techniques to study and draw initial conclusions on student perceptions of and reasons for attending a math center.*

*Keywords:* tutoring, university mathematics, support services, help center

Mathematics help centers (or "math centers") typically aim to support undergraduate students in the mathematics courses they take during their freshman and sophomore years of study. These facilities are where students receive a) tutoring, b) access to print resources, c) guidance on use of digital devices and platforms used in mathematics courses, and d) pre-exam review sessions. The increased attention to math centers is evidenced by the new working group in RUME and by a recent handbook for math center directors, which had contributors from 31 institutions ranging from two-year community colleges to liberal arts institutions to large research universities (Coulombe, O'Neill & Shuckers, 2016). This study is an initial foray to consider students' perceptions of and reasons for attending a math center. More specifically, the following open research questions guided the study: *What do students expect from a math center? What are their perceptions of a math center? What impacts students' attendance at a math center?*

This study reports on responses to an online survey with items specifically related to a math center. It was administered over six academic semesters to 1088 students at a large, research university in the southwest United States. The research team used inductive techniques and constant comparison to consider factors that impact students' perceptions of and attendance at a math center.

All quantitative results of the study including information on the sample and the most frequent responses will be reported. Primary findings suggest that math center factors that impact students typically involve the number of staff and student interactions with staff. However, students also commented on issues related to their courses and instructors (e.g., desire for a high grade, perception of instructor deficiencies). Based on the results the research team will offer an initial explanation of the interrelated factors that impact student perceptions of and attendance at a math center in light of expectations of both a) the math center and b) students' courses and instructors.

# Applying Cognitive Learning Theory to Design a Calculus Class for Engineers

Jen French
Massachusetts Institute of Technology

Karene Chu
Massachusetts Institute of Technology

*We describe the methodology used to create a set of interactive online calculus resources for undergraduate engineering students. This content was designed using cognitive learning theory to actively engage students in doing calculus, transfer to engineering courses, and address misconceptions.*

*Keywords:* applied math, calculus, engineering students

Success in calculus has a large effect on success in later engineering courses (Boyajian, 2007). We created a set of interactive online calculus resources that we have used as a free calculus MOOC, as the main course material for a flipped classroom on campus, and for online homework (blended learning) for a traditional lecture course. Here we describe how we design this set of calculus resources to provide motivation, encourage transfer to later engineering courses, and keep students actively engaged with content.

Students learn more when they are motivated. According to Everett et al, 2000, Gagne et al 2004, and Merrill, 2013, motivation is achieved when an instructor provides context for a student to see how the content is relevant to their lives. For each lecture, we created a motivational video that either connected the lecture content with real-life or engineering design problems, or provided big picture connections among calculus concepts, as in Shah, D. et al, 2013. For example, to motivate parametric curves, we showed a student constructed roller coaster with a vertical segment, which cannot be described by a function, but can be by a parametric curve.

To enhance transfer to engineering courses, we introduce linear and quadratic approximations early, immediately after students learn how to differentiate. One of the first problems students work out in the lecture sequence involves using linear approximation and measurement error to design a zipline that is neither too fast nor leaves riders stranded in the middle. Similar problems tying approximations to new content is on almost every problem set throughout the course. By the lecture on Taylor Series, students already have a good sense of the utility of linear and quadratic approximations. This type of interleaving encourages long term retention (Roediger & Butler, 2011), which is necessary for transfer (Halpern & Hakel, 2003).

Unlike a traditional lecture or textbook, each lecture sequence was designed to engage a student in actively working through the content in a manner more similar to a tutorial (Freeman et al, 2014 and Hmelo, Gotterer, & Bransford, 1994). There are 1413 problems interspersed among the 395 short teaching videos and 25 motivational videos. These problems do much more then drill on concepts. Several concept checks are designed to address common misconceptions (Epstein, J. (2007).). Many build upon students' prior knowledge (Roediger & Pyc, 2012). Problems ask students to set up problems rather than do rote computations. These problems all offer immediate feedback (Bransford, Brown, & Cocking, 2000, and Hattie & Timperley, 2007), including feedback on hand drawn graphs (French et al, 2016). The solutions provided after a student has gotten a problem correct or has run out of attempts often contain much of the teaching content and offer an expert perspective. The student is truly learning by doing: *Mens et Manus,* the MIT motto.

# Teachers' Reasoning with Frames of Reference in US and Korea

Surani Joshua, Pat Thompson
Arizona State University

*We gave approximately 180 US and 380 Korean teachers frame of reference tasks, and coded the open responses with rubrics intended to rank responses by the extent to which their responses demonstrated conceptualized and coordinated frames of reference. In both countries less than half of teachers scored at the highest level on almost every task, showing that teachers frequently struggle to keep track of quantities within a frame of reference in a meaningful way. Our US-Korean comparison also shows that US teachers struggle on most of these tasks significantly more than Korean teachers.*

*Keywords:* Frames of Reference, Secondary Teachers, International Comparison

## Theoretical Perspective

When we speak of frame of reference, we mean that an individual can think of a measure as merely reflecting the size of an object relative to a unit or he can think of a measure within a system of potential measures and comparisons of measures. An individual conceives of measures as existing within a *frame of reference* if the act of measuring entails: 1) committing to a unit so that all measures are multiplicative comparisons to it, 2) committing to a reference point that gives meaning to a zero measure and all non-zero measures, and 3) committing to a directionality of measure comparison additively, multiplicatively, or both. […] An individual is coordinating two frames of reference if she conceives each frame as a valid frame, stays aware of the need to coordinate quantities' measures within them, and carries out the mental process of finding a relation between the frames while keeping all relative quantities and information in mind (Joshua, Musgrave, Hatfield, & Thompson, 2015).

## Methodology

From 2012 to 2015, the Project Aspire team created the 48-item assessment Mathematical Meanings for Teaching – secondary math (MMTsm). Two items were categorized as frame of reference items: "Willie Chases Robin" and "Nicole Chases Ivonne". We gave them to 177 US and 359 Korean teachers and coded their free-response answers; our poster has both the aggregate data and sample responses.

## Results & Discussion

It is our hope that the data collected will orient professional development leaders to consider their teacher's meanings for the mathematics that they teach, and guide their PD to focus on helping teachers build more productive meanings. While professional development projects continue to administer the MMTsm, the data discussed in our poster is telling. In both countries less than half of teachers scored at the highest level on every task except for Korean teachers on Part A of Willie Chases Robin. There was also a statistically significant difference between US and Korean teachers on every task. Additionally, the Korean data shows us that the US data cannot be ignored simply by arguing that these tasks are inappropriate to give to high school teachers; there are a lot of gains with US teachers that could be made simply up to the current Korean teacher levels. Our data show that the U.S. teachers in our sample are not prepared to help their students reason through tasks involving multiple frames of reference.

**Calculus I Instructors' Desires to Improve Their Teaching**

| Kevin Watson | Sarah Kerrigan | Rachel Rupnow |
|---|---|---|
| *Virginia Tech* | *Virginia Tech* | *Virginia Tech* |

*As calculus is a course required for many undergraduate programs, several studies over the past decade have examined aspects that create successful calculus programs in the United States. While many of these studies have looked at the teaching practices and beliefs of calculus instructors, none have focused on instructors' desires to improve their teaching. The goal of this research is to examine how desires to improve teaching vary among different types of instructors (GTAs, instructors, tenured faculty, etc.), and how institutional or departmental expectations might influence those desires.*

*Keywords:* Calculus, teaching practices, improving teaching, teacher beliefs and desires

Calculus is a common course required for many undergraduate programs, especially science, technology, engineering, and mathematics (STEM) majors, but is often connected to attrition from these programs. In light of this, mathematics education researchers have begun examining aspects that create successful Calculus programs throughout the United States (Bressoud, Mesa, Rasmussen, 2015). One important aspect that has been a focus of some of these studies is the calculus teacher, specifically their beliefs, teaching practices, and interest in teaching Calculus.

Several studies (e.g., Bressoud & Rasmussen, 2015; Sonnert & Saddler, 2015) have examined mathematics teachers' beliefs and instructional practices, including their impact on students' attitudes towards and success in mathematics, but none have looked at instructors' desires to improve their teaching, and the beliefs and institutional expectations that might influence those desires. For this study, we are particularly interested in calculus instructors' interest in improving their teaching and better helping students understand concepts in calculus. The specific research questions for this study are:

1. To what extent are graduate students, faculty, and instructors interested in improving their teaching of Calculus I, and their awareness of student learning of calculus?
2. What supports do they perceive from their institution and department in regards to the scholarship of teaching and learning?
3. Is there a relationship between institutional or departmental support and calculus I instructors' desires to improve their teaching?

To pursue these research questions, we make use of a 2010 national data set collected by the Mathematical Association of America (MAA), with support from the NSF, as part of the "Characteristics of Successful Programs in College Calculus" (CSPCC) study (Bressoud, Mesa, Rasmussen, 2015). We specifically use the pre- and post-surveys given to calculus instructors, focusing on the questions related to their desires to improve their teaching and questions that could conceivably influence those desires (such as institutional or departmental expectations). Our poster will share descriptive statistics to give an overview of which types of instructors of calculus I are most interested in improving their teaching, as well as correlations between variables that may affect instructors' interest in professional development. A future direction for this project is to run more statistical tests to investigate if there are connections between other components, such as gender and type of institution, on instructors' desires to improve their teaching of Calculus I.

# Seminars to Support Learning Assistants in Mathematics

Nancy E. Kress
University of Colorado at Boulder

Daniel Moritz
University of Colorado at Boulder

*Abstract: This poster reports on the design and implementation of a series of seminars to support undergraduate learning assistants (ULAs) working in university mathematics courses. The ULAs participating in this study work as tutors and classroom assistants in early college mathematics courses through Calculus 2. The seminars support ULAs to more fully understand their roles and to consider ways that they can improve equity and access for all students in their classes. The work is grounded in the perspective that learning is a sociocultural process (Lave, 1991) and that students' learning is significantly impacted by opportunities to participate in actively doing mathematics (Laursen, 2014; Freeman et al, 2014). This project strives to answer research questions related to understanding how ULAs conceptualize teaching for equity and access, how conceptualizations change through participation in seminars, and how these conceptualizations are related to students' experiences in mathematics classes.*

*Keywords:* Learning assistants, Calculus, Equity, Active learning, Professional development

## Background and Conceptual Framework

Undergraduate Learning Assistants (ULAs) are employed at University of Colorado at Boulder in mathematics courses ranging from Mathematical Analysis in Business through Functions and Models, which is a post Calculus upper level course. Their roles include acting as classroom assistants and serving as tutors in the mathematics department's academic resource center. These undergraduate students enter their positions because they are interested in helping others learn mathematics. They begin their jobs with little or no prior experience in teaching or tutoring, and they may have limited foundational knowledge of design principles for active learning or strategies for teaching for equity and access. They are enrolled in a course which supports ULAs from a range of math and science subject areas. The seminars on which this study is based support the ULAs specifically within the context of their work in mathematics.

This work is grounded in research on design principles of active learning (Webb, 2016) which demonstrates the effectiveness of active learning for increasing persistence to subsequent mathematics courses (Laursen, 2014; Freeman et al, 2014). The work is also informed by sociocultural learning theory which explains the ways in which learning develops from the conversations and activities in which students take part, as well as their own roles within those conversations (Yackel & Cobb, 1996). The seminars on which this work is focused are designed to increase the degree to which ULAs are able to help cultivate opportunities for students to actively participate in doing mathematics in their college courses.

## Research Methodology, Results and Implications

This poster will report on the design and implementation of seminars to support ULAs in university mathematics classes to better understand their roles in increasing equitable opportunities for students to actively participate in doing mathematics. Results from a survey administered to the ULAs after the seminar will be reported, as well as analysis of those results. Results from interviews conducted with a small group of ULAs will also be included.

The results from this study will serve to inform the research community about ways to support ULAs to maximize their positive impact on opportunities to learn for all students in undergraduate mathematics classes. Specifically, these results will inform further research about how ULAs developing conceptualizations of teaching for equity and access, and how this relates to students' learning opportunities in undergraduate mathematics.

An Instructional Resource for Improving Students' Conceptual Understanding of Functions through Reflective Abstraction

Jessica E. Lajos
University of Oklahoma

Sepideh Stewart
University of Oklahoma

*It has been widely documented that undergraduate-level students' understanding of functions is rigid and indicative of an action view which constrains conceptual understanding (Carlson, Jacobs, Coe, & Hsu, 2002). Duval affirms that, "to understand the difficulties that many students have with comprehension of mathematics, we must determine the cognitive functioning underlying the diversity of mathematical processes" (2006, p.103). What are the underlying cognitive skills students need to gain a better conceptual understanding of functions? How should instruction of function content and training in these cognitive skills be combined? We propose the theoretical model "Structural-Schema Development for a Function", to address these questions. This model defines developmental stages students pass through to form a global view for the function concept, identifies underlying cognitive mechanisms involved in each stage, and develops instructional exercises that combine content with cognitive skills training for these cognitive mechanisms.*

*Keywords:* Schema, Functions, Understanding, Reflective Abstraction, Structuralism

The proposed model in this study is influenced by Duval's (2006) framework for *Treatments and Conversion* and Piaget's theory *Reflective Abstraction* (Arnon et. al., 2014; Dubinsky & Lewin, 1986). In Dubinsky and Lewin's view, "reflective abstraction includes the act of reflecting on one's cognitive action and coming to perceive a collection of thoughts as a structured whole" (1986, p.63). It can also be thought of as coordinating multiple lower-level structures and reflecting on these structures to combine them into a new higher-level structure (Dubinsky & Lewin). This is the glue that binds the four developmental stages of this model: Identification, Informal Classification, Formal Classification and Ordering. Students who reach the Identification stage can identify whether or not some object satisfies the formal definition of a function. Once students have identified enough objects that are elements of a function space they can begin to construct informal properties of these elements and classify them based on informal properties. Students who can describe a collection of functions as sharing the same informal properties (i.e. these functions are all smooth, these functions have jumps, etc.) have reached the Informal Classification Stage. These informal classifications can then become updated content on which formal classifications are either constructed or presented. These classifications are then coordinated for Ordering. The Ordering stage is reached when students can make substructures within the structure by ordering or nesting classifications using set relations and intuitions guided by informal classifications. Formation of a student's structural-schema for a function can occur in any of the developmental stages. The stage that a student reaches determines a threshold for how rich their structural schema has the potential to be. The student's structural-schema continually undergoes Maintenance through *assimilation* and *accommodation*. The proposed model anticipates to offer instructional resources designed to promote the skills students need to reach higher level developmental stages and ultimately gain a better conceptual understanding of functions.

**Student reasoning with complex numbers in upper-division physics**

Michael Loverude, Department of Physics
California State University Fullerton

Abstract: *Students encounter complex numbers in many physics courses. In particular physics uses complex exponentials to describe oscillatory phenomena and requires that students use multiple representations (algebraic, x vs t graphs, complex plane). In this poster we will examine student responses suggesting difficulties with the connection between complex numbers and oscillation, drawn from students in upper-division physics courses in math methods.*

## Description

This work is part of a collaboration to investigate student learning and application of mathematics in the context of upper-division physics courses. In particular the project focuses on a course required by most physics departments focusing on developing mathematical methods for upper-division physics. Throughout, we seek to go beyond procedures and to probe conceptual understanding and the development of quantitative reasoning skills.

Results suggest that procedural understanding of complex algebra is often not enough for students to connect mathematics with relevant physics contexts. Students had difficulty in relating complex numbers to oscillatory phenomena. It was not immediately clear whether incorrect responses reflected difficulties with procedures or conceptual understanding. For example, students were asked on a course exam to show, using expressions with complex exponentials, how two waves would destructively interfere given a $\pi$ phase difference. Of ten students answering after instruction, only three gave correct answers, none using polar form.

To probe student reasoning, we have used a variety of tasks including both procedural symbolic manipulations and more conceptual questions. While students were largely successful on procedural tasks, their responses suggested a key disconnect with the use of complex numbers to describe oscillations. For example, students were asked to sketch the real part of the function $Ae^{iwt}$ (8 sections, $N = 107$). Student written responses were examined and coded based on correctness and the explanation; the relevant codes after several iterations included the overall graph template (oscillatory / exponential / linear), the value of the function at t = 0, and, in the case of oscillatory sketches, whether the amplitude was constant or changing. Figure 1 shows a correct response and one showing exponential growth.

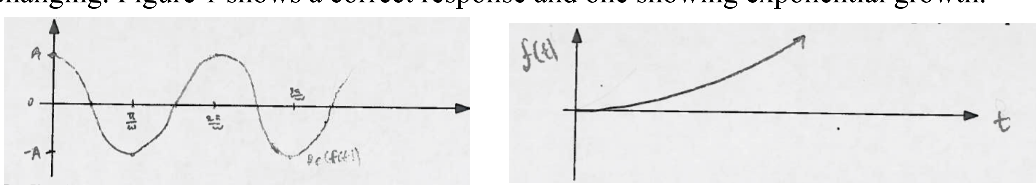

**Figure 1** Scans of student sketches of the real part of the function $Ae^{iwt}$. About a third of students sketched responses like the second example, showing exponential growth.

About 28% of responses were categorized as correct and another 15% showed an oscillatory function with incorrect features (e.g., phase shift or decreasing amplitude). Many responses, however, did not show oscillation; 33% of responses were categorized as showing exponential *growth*. Sadaghiani (2005) reported similar confusion between $e^{kx}$ and $e^{ikx}$ in quantum mechanics examples.

In this context and others, our data suggest that experience with mathematical procedures is not sufficient for students to make sense of the meaning of the procedures and apply them to physics contexts. The course text includes only procedural exercises with a handful of applications, including oscillations, separated into a later section at the end of the relevant chapter. We believe students need dedicated curricular materials focusing on these ideas.

Using Catan as a Vehicle for Engaging Students in Mathematical Sense-Making

Dr. Susanna Molitoris Miller Dr. Amy Hillen
Kennesaw State University

*Catan is an increasingly popular board game which is rich with opportunities for mathematical applications. The research presented in this poster demonstrates how Catan served as an effective vehicle for engaging students enrolled in a freshman learning community. Students engaged with various mathematical concepts involving probability, combinatorics, and game theory.*

*Keywords:* student engagement, motivation, mathematical reasoning, combinatorics, games

Games provide unique opportunities for students to engage in mathematical reasoning (Canada and Goering, 2008; Capaldi and Kolba, 2017). Using games in teaching applies to all four components of Keller's ARCS model of Motivation Design Thoery (1987). Catan is a property development and trading-based game with a board which is set-up differently every time you play. This dynamic board and other aspects of the game provide several opportunities for students to engage in mathematical reasoning to improve their chances of winning (Austin and Molitoris-Miller, 2015). Players place settlements and roll dice to collect resources from resource tiles adjacent to their settlements. Resources are used to build more structures which increase card production or score points. In this study we explored the ways in which using Catan in a general education course for freshmen affected their engagement and motivation.

Participants were freshman students from a variety of majors enrolled in a freshman seminar course which was part of a learning community coupled with a section of pre-calculus. The course consisted of general college skills as well as opportunities to play Catan and discuss the related mathematics. Data were collected throughout the course of a semester in the form of written class work, homework, projects, exam items, and two online surveys.

Preliminary analysis of the data indicates that the game supported students' engagement in mathematical reasoning around a variety of ideas. The use of two different color dice in the game helped clarify justification behind the probability of rolling 2 through 12 using two standard six-sided dice. Determining which player to rob one resource card from in order to maximize the chance of obtaining a desired resource supported reasoning about probability and fraction comparison. Evaluating which locations to choose for initial settlements invoked various considerations of expected value including: the value of each resource based on production costs, the value of each resource based on rarity on a particular board, the probability of a settlement location producing a card, and the probability of a settlement location producing a rare resource. They also deduced results related to Bayes' Theorem by exploring if a particular resource is produced, what is the probability it came from a certain location. Survey results indicate that students saw value in learning mathematics in the context of Catan. 70% of students either agreed or strongly agreed that they enjoy using Catan to learn about mathematics. 75% of students either agreed or strongly agreed to "I understand mathematics best when I use an example or tool to figure it out."

These findings are aligned with other work which highlights the important links between games and mathematical reasoning. By utilizing Catan in this setting with freshman non-mathematics majors we have identified a creative way to make mathematics fun, engaging and accessible to students with a variety of mathematical backgrounds.

# Teachers’ Knowledge of Fraction Arithmetic with Measured Quantities

Sheri E. Johnson, University of Georgia
Merve Nur Kursav, Michigan State University

Abstract: *A national sample of 990 middle grades teachers completed a knowledge assessment aimed at measuring teachers’ knowledge of fraction arithmetic using measured quantities. Utilizing a simple measurement of the percentage of items answered correctly, middle grades teachers scored significantly different based on their undergraduate major. These findings reveal the importance of developing instruction for undergraduates focused on developing their multiplicative reasoning with measured quantities, especially fractions.*

**Keywords: Mathematical knowledge for teaching, Fractions, Multiplicative Reasoning**

The skills of multiplicative reasoning are important because their development can greatly influence success for students in later mathematics (Beckmann & Izsák, 2015). Common Core (2010) stresses the importance of reasoning with fractions as measured quantities. Middle grades teachers are required to reason multiplicatively using fractional amounts with designated units, and researchers have developed instruments to measure this specific content knowledge needed for teaching (Izsák, Jacobson & Bradshaw, in press; Jacobson & Izsák, 2015; Izsák, Jacobson, de Araujo & Orrill, 2012). The present study investigates how undergraduates with different majors who become middle grades teachers perform on a knowledge assessment of reasoning with fraction multiplication of measured quantities. Based on a sample of 990 middle grades teachers, undergraduate engineering majors scored higher on average than any other major, although this was not deemed statistically significant due to the small number (n=23) and variability. Mathematics majors had mean scores significantly higher than teachers who reported the category of “Other”. Izsák et al (in press) reports similar results. Since Business and other STEM majors comprised approximately a quarter and the “Other” category included almost half of the participants, the data were recoded into different categories (see Table 1).

*Table 1. Frequency of undergraduate majors*

| Undergraduate Major | Counts | Percentage |
|---|---|---|
| Business or STEM | 256 | 26% |
| Elementary Education | 240 | 24% |
| Mathematics Education | 169 | 17% |
| Other | 325 | 33% |
| **Total** | 990 | 100% |

At least one of the undergraduate majors has a statistically significant mean score according to a one-way analysis (p-value of less than 0.0001). Furthermore, a Tukey-HSD analysis reveals that teachers with an undergraduate major of Elementary Education and “Other” scored significantly lower than those with a Business or STEM degree. Teachers with an undergraduate degree in Mathematics Education cannot be differentiated from other majors. Middle grades content of multiplicative and proportional reasoning with fractions in context continues to be difficult for many people beyond their K-12 and college education. Business and STEM majors require more advanced mathematics than other majors and it follows they would have more opportunities to apply these skills across a wider variety of contexts and develop mastery.

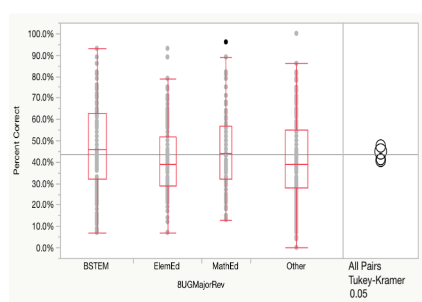

Figure 1

These findings reveal the importance of developing a deep understanding of multiplicative reasoning with measured quantities, especially fractions. Implications are especially important for the undergraduate teaching of our future teachers, who should possess a more robust understanding of this content in order to scaffold their future students learning.

# Student Resources for Unit and Position Vectors in Cartesian and Non-Cartesian Coordinate Systems

| Warren Christensen | Brian Farlow | Marlene Vega | Michael Loverude |
|---|---|---|---|
| North Dakota St U | North Dakota St U | Cal St U – Fullerton | Cal St U - Fullerton |

*As part of a broader study into students' understanding of students' use of mathematics in upper-division physics courses, this study investigates how students conceptualize unit and position vectors in Non-Cartesian Coordinate Systems using a theoretical framework of resources. We present a case study of Mark, a Senior physics major, and identify the resources that Mark activates while answering conceptual questions without a direct physics context during a one-on-one interview protocol. This analysis identifies specific resources that Mark brings to bear when reasoning about vectors. The results of this case study provide a guide for analyzing additional interviews and allow us to pursue the long-term goal of curriculum development that can be used to improve students' use and understanding of non-Cartesian coordinate systems.*

*Keywords:* Vector Calculus, Resources, Student Reasoning, Physics

Using non-Cartesian coordinate systems is a challenge for undergraduate mathematics students [Paoletti, Moore, Gammaro, and Musgrave, 2013; Montiel, Vidakovic, and Kabael, 2008] and this challenge continues into upper-division physics courses where application becomes increasingly important [Hinrichs, 2010; Sayre and Wittman, 2008]. As part of a broader study to develop research-based curriculum materials for physics courses that bridge the gap between middle-division mathematics and upper-division physics courses, this work attempts to shed light on student thinking about vectors in Cartesian and Non-Cartesian coordinate systems through the use of a Resources Framework [Hammer, Elby, Scherr, and Redish, 2005]. The research presented explores the thinking of a single student—Mark–as revealed during a semi-structured, one-on-one interview, and identifies the student's thinking as activated conceptual and procedural resources. Mark is a high-achieving, senior-level physics major, and was selected for detailed analysis due to the clear explanation of his thinking. From Mark's data, identified resources can be grouped into clusters based on the content of the student's thinking [Vega, et al., 2016]. Examples of such clusters are basis unit vectors, position vectors, and velocity vectors. Connections between these resources are also observed, allowing a mapping of the student's thinking as the student works through a series of questions.

In this poster, we present a map of Mark's activated resources and, based on the data, the connections between those resources to understand Mark's complicated thought process. This detailed analysis provides insight into the kinds of ideas undergraduates might activate when faced with questions about unit vectors and position vectors, in Cartesian and non-Cartesian coordinate systems. For instance, Mark initially demonstrates a clear understanding of unit vectors in polar coordinates. He notes that unit vectors are of unit length, and point in the direction of increasing coordinate, in this case, increasing r and theta. These are both identified as specific resources within the unit vector cluster. Later in the interview, Mark activates additional resources that conflict with these unit vector resources, namely, that the unit vectors of r and theta can be written in terms of the unit vectors of Cartesian coordinates. This conflict demonstrates a potential area of interest for curriculum development.

Development of Reasoning about Rate of Change, Based on Quantitative and Qualitative Analysis

Inyoung Lee
Arizona State University

*Pre-calculus and Calculus are two big compartments as we consider their developmental and complemental attribute. I analyzed data quantitatively from a series of pre-calculus assessments conducted in a large public university 2017 fall, then investigated the result and its impacts qualitatively in calculus context focused on rate of change. The two-part analysis consists of discerning intrinsic factors in the assessment items that have a large effect on overall performance followed by clinical interviews about meaning of the Fundamental Theorem of Calculus and its applications. The results support my claim that the ability to conceptualize constant rate of change has a considerably positive effect on students' reasoning about rate of change and the Fundamental Theorem of Calculus as well.*

*Keywords:* Quantitative Analysis, Constant Rate of Change, Rate of Change, Fundamental Theorem of Calculus

Quantitative analysis on pre-calculus assessment with reform curricula (Carlson, Oehrtman et al. 2013) shows that 34 items in the assessment have 11 principal components by factor analysis and each item assesses students' understanding independently by regression analysis. I focused on items in the first component since they have a huge impact on students' overall performance, coding them with $R_i$(reasoning abilities), $F_i$(understandings of various function types), $U_i$(understandings of various concepts), and $A_i$(other abilities) suggested from CCR (The Calculus Concept Readiness) taxonomy (Carlson, Madison et al. 2015). It turns out that the combination of R3 (Quantitative and covariational Reasoning), U3(Constant rate of change) and A4(Understand and use function notation to express one quantity in terms of another) becomes a critical factor to students' conceptualization in terms of their further learning.

The result mentioned above and my experiences of teaching pre-calculus and working with DIRACC (Developing and Investigating A Rigorous Approach to Conceptual Calculus) project led me to ponder on what would be the most problematic part for students as connecting the two compartments of pre-calculus and calculus. I hypothesize that student struggles stem from fragmented interpretations on constant rate of change and the fragmented knowledge hinders comprehensive understanding of rate of change and the Fundamental Theorem of Calculus. Accordingly, I elaborately devised open-ended interview items so that each item could reflect developmental aspects by inquiring on constant rate of change, rate of change, net change, and meaning of fundamental theorem of calculus.

Qualitative analysis on the interview shows that the way of students' reasoning on constant rate of change has different layers in various contexts of graphical, verbal, physical, and symbolic representations based on the framework for the concept of derivative (Zandieth, M. 2000). Also, it supports that each layer becomes distinct pivots of their interpretation on rate of change, having a large effect on the way of reasoning the Fundamental Theorem of Calculus as a continuum of rate of change. I believe that the results from my two-part study will be of interest to the mathematic education community because students' conceptualization on rate of change will be a foundation to the next step of learning.

If $f(2) = 8$ then $f'(2) = 0$: A Common Misconception, Part 2

Alison Mirin and Stephen Shaffer
Arizona State University

*This study reports calculus students' failure to differentiate the cubing function when represented piecewise: $f(x) = x^3$ if $x \neq 2$, $f(x) = 8$ if $x = 2$. The data reported here suggest that students did not fail simply due to inattention to the function definition; when reminded that 2 cubed is 8 and prompted to compare the graph of f to that of the cubing function, student performance did not increase in a statistically significant way, suggesting the presence of deep-seated misunderstandings.*

*Keywords:* function, derivative, calculus, representation

Harel and Kaput (1991) observed a troubling phenomenon among calculus students. Students claimed that for $g(x) = sin(x)$ if $x \neq 0$, $g(x) = 1$ if $x = 0$ , then $g'(0) = 0$ (due to the constant rule). To these students, the only aspect of the representation as relevant for determining the value of $g'(0)$ is the second line of the piecewise function definition. It seems reasonable to believe that if the definition of $g$ were modified to instead have $g(x) = 0$ if $x = 0$ (resulting in a nonstandard representation of the sine function) students would answer identically. However, given the anecdotal nature of Harel and Kaput's claim, there is no data available to substantiate how common such errors are or why they occur. A study I presented at RUME 2017 addresses how common this sort of error is (Mirin, 2017) by discussing student performance on the task of evaluating $f'(2)$ when $f(x) = x^3$ if $x \neq 2$, $f(x) = 8$ if $x = 2$. The poster describes a follow-up investigation that begins to address why students perform so poorly at that task (henceforth called "The Task").

A participant at RUME 2017 observed that the piecewise definition of *f* was rather contrived and therefore students might simply assume that *f* is a discontinuous function without realizing that *f* and the cubing function agree on $x = 2$. In the original study, several students provided a graph with a single point discontinuity and answered in a way consistent with presuming that 2 cubed is not 8. Hence, it seems that inattention, rather than a major conceptual misunderstanding, was at fault in *some* students' responses. Utilizing the data from the 2017 open-ended version, I re-administered The Task in multiple choice form in 2018, first prompting students to calculate $2^3$ , and then, next to a graph of the cubing function, provide a graph of *f*.

The data reveal no evidence to support that inattention could account for student responses. Although there was a slight improvement in correctness rate from 2017 to 2018, this improvement was not statistically significant ($\chi^2$=1.21, p>.05). In other words, prompting students to compare the graph of $y = f(x)$ to that of $y = x^3$ *did not* appear to cause improvement, suggesting that students did not err simply due to inattention to the function's graph. Moreover, the students in 2018 who answered "12" were no more likely than the students in 2017 who answered "12" to draw an explicit comparison between *f* and the cubing function (4.2% of year-2017 students who answered 12 did, whereas only 2.9% of year-2018 students did so).

These results suggest that prompting students to compare *f* to the cubing function did not appear to encourage them to infer that *f* and the cubing function share a derivative at 2.

**Cooperative Learning and its Impact in Developmental Mathematics Courses: A Case Study in a Minority-Serving Institution**

Eyob Demeke
Cal State LA

Alyssa Lawson
Cal State LA

Kimberly Samaniego
UCSD

*In this poster, we report on the evolution of developmental students' mathematics background knowledge after a four-week long course that emphasized active learning. The research took place at a large Hispanic serving institution in the state of California. Students' progress or lack thereof was measured using a diagnostic test developed by the Mathematics Diagnostic Testing Project (MDTP). These students were initially considered not ready for college level mathematics course work and were subsequently enrolled, in a four-week summer course which is designed to prepare them for a college level math course. During each class, students would spend at least 30 minutes engaging in cooperative learning that utilizes active learning strategies such as think-pair share, peer lesson, and wait time. A pre/posttest analysis of SYART showed that these students showed a statistically significant growth, leading us to conclude that the four-week intervention in math remediation had a considerable impact.*

*Key words:* Developmental Mathematics, Cooperative Learning, College Algebra.

Far too many students began their postsecondary mathematics education in remedial mathematics (Bailey, 2009, Schwartz, 2007). Within the California State University (CSU) System, approximately a third of incoming freshmen are considered unprepared for college level mathematics courses (CSU, 2012). For some CSU students, a year will elapse before they can enroll in a college level mathematics course. Across the CSUs, unless exempted, every admitted student is required to take the Entry Level Mathematics (ELM) test, which aims to measure proficiency in basic skills need to succeed in a college level mathematics course. 50 on the ELM is a cutoff score that determines whether a student needs mathematics remediation or not.

It is important to note that the ELM is not a diagnostic test; as such, it does not shed light on specific contents that students are struggling with. To that end, in this study, we used Second Year Algebra Readiness Test (SYART) to understand the mathematical background knowledge of 1100 students who received a score below 50 on their ELM test. These students were enrolled in a two, four-week courses designed to prepare them for a college math course: beginning algebra and intermediate algebra. In both classes, students met their instructor five times a week, and every class, except exam days, they would spend approximately 30 minutes in cooperative learning that utilizes active learning strategies such as *think-pair share, peer lesson,* and *wait time*. A pre/posttest analysis of SYART showed that students' overall score improved significantly. On average, beginning algebra students' SYART score improved by approximately 39.5%. Using a two-sample t-test, session one witnessed a statistically significant growth with a *p-value of* $3.3 * 10^{-63}$.

To summarize, students improved their performance in several topics of the test. However, the biggest growth were observed in the following topics: Exponents and square roots; Scientific notation, Linear equations and inequalities, Polynomial and quadratic equations. However, several students were still below a critical level in some topics. Specifically, students continue to struggle in graphical representation of solution of equations and inequalities. Still, there is a strong evidence to conclude that the four-week intervention in math remediation has a considerable impact.
