February 22-24, 2018

Presented by
The Special Interest Group of the Mathematical Association of America (SIGMAA) for Research in Undergraduate Mathematics Education

CITATION: In (Eds.) A. Weinberg, C. Rasmussen, J. Rabin, M. Wawro, and S. Brown, Proceedings of the 21st Annual Conference on Research in Undergraduate Mathematics Education, San Diego, California.

# Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-first annual Conference on Research in Undergraduate Mathematics Education in San Diego, California from February 22 - 24, 2018.

The program included plenary addresses by Dr. Joanne Lobato, Dr. Marcy Towns, and Dr. Juan Pablo Mejia Ramos and the presentation of 158 contributed, preliminary, and theoretical research reports and 95 posters.

The conference is organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in the field of undergraduate mathematics education, each of which underwent a rigorous review by two or more reviewers:

- Conference Papers are elaborations of selected RUME Conference Reports
- Contributed Research Reports describe completed research studies
- Preliminary Research Reports describe ongoing research projects in early stages of analysis
- Theoretical Research Reports describe new theoretical perspectives for research
- Posters are 1-page summaries of work that was presented in poster format

The proceedings begin with the winner of the best paper award, the paper receiving honorable mention, and the paper receiving meritorious citation; these awards are bestowed upon papers that make a substantial contribution to the field in terms of raising new questions or providing significant or unique insights into existing research programs. These papers are followed by the pre-journal award winner, which was selected based on its potential to make a substantial contribution to the field; this award is limited to authorship teams that only include graduate students, recent PhDs (within 2 years of graduation), and/or mathematicians who are transitioning to mathematics education research.

The conference was hosted by San Diego State Univerisity and the University of California San Diego. Their faculty and students provided many hours of volunteer work that made the conference possible and pleasurable, and we greatly thank them for their support.

Many members of the RUME community volunteered to review submissions before the conference and during the review of the conference papers. We sincerely appreciate all of their hard work.

We wish to acknowledge the conference program committee for their substantial contributions to RUME and our institutions. Without their support, the conference would not exist.

Aaron Weinberg RUME Conference Organizer
Chris Rasmussen & Jeffrey Rabin, RUME Conference Local Organizers
Megan Wawro, RUME Program Chair
Stacy Brown, RUME Coordinator

## Program Committee

| | |
|---|---|
| *Chairperson* | |
| Aaron Weinberg | Ithaca College |
| | |
| *Local Organizers* | |
| Chris Rasmussen | San Diego State University |
| Jeffrey Rabin | University of California San Diego |
| | |
| *Committee Members* | |
| Stacy Brown | California State Polytechnic University Pomona |
| John Paul Cook | Oklahoma State University |
| Paul Dawkins | Northern Illinois University |
| Tim Fukawa-Connelly | Temple University |
| Shandy Hauk | WestEd |
| Estrella Johnson | Virginia Tech |
| Luis Leyva | Vanderbilt |
| Elise Lockwood | Oregon State University |
| Jason Martin | University of Central Arkansas |
| Pablo Mejia-Ramos | Rutgers University |
| Kevin Moore | University of Georgia |
| Jason Samuels | City University of New York |
| Annie Selden | New Mexico State University |
| April Strom | Scottsdale Community College |
| Hortensia Soto | University of Northern Colorado |
| Nick Wasserman | Columbia University |
| Megan Wawro | Virginia Tech |
| Michelle Zandieh | Arizona State University |

# E-IBL: An Exploration of Theoretical Relationships Between Equity-Oriented Instruction and Inquiry-based Learning[1,2]

Stacy Brown
California State Polytechnic University, Pomona

*The purpose of this theoretical report is to further current discussions of the relationships between Equity-Oriented Instruction (EOI) and Inquiry Based Learning (IBL) pedagogies. Specifically, it proposes a framing of Equity-Oriented Inquiry Based Learning (E-IBL) that foregrounds equitable practice, as opposed to viewing equitable practice as a gratuitous outcome of IBL pedagogies. Drawing on data from teaching experiments conducted in IBL-Introduction to Proof courses, the inter-relationships between knowledge, identity and practice (Boaler, 2002), Pickering's 'dance of agency,' Gutiérrez's dimensions of equity, and Bourdieu's notion of habitus, this paper explores why intentional attention towards the critical axis of equity – that which links identity and power – is necessary, if IBL pedagogies are to promote equity.*

*Key words*: Inquiry based learning, equity oriented instruction, identity, agency

## A Question and Some Answers

At the end of the academic term, students in an Inquiry Based Learning (IBL) Introduction to Proof course were asked: *Imagine you are talking to another student and that they've asked you, "What's it like being in an IBL course?" What would you say?* Below are five responses.

> *Student 1*: It may seem that group work may be tedious and unwanting but for [Intro to Proof] it works very well. You get to meet other individuals that interpret the course material differently, which leads to a better understanding of the class. Plus, you may end up making genuine friends. Again, it works well and I don't think I'd be performing as well if I didn't have group members.

> *Student 2*: IBL classes are really, really fun! It makes it so you're not bored with listening to a professor talking for two hours. Although it disturbs nap time in class, you do learn quite a lot more. If you enjoy working in groups and not listening to someone talk for two hours, these types of classes are perfect.

> Student 3: Me gusta. It's fun, engaging and effective. Keeps me involved and learning from my and other people's mistakes. A lot of people can help.

> Student 4: As an introvert, I hate groupwork. I would rather learn based off the book than being forced to talk.

> *Student 5*: I don't like it […]. I feel like I'm thrown to the wolves and told to just figure it out with no guidance to start me off. I think if I had been aware I would be taking an IBL class, I would've tried to do one that wasn't.

---

[1] This paper came about, in part, from conversations with Aditya Adiredja, Luis Leyva, and William Zahner. I would like to thank them, Gail Tang, Robin Wilson, Tim Fukawa-Connelly, Darryl Yong, and the Equity Working Group for their feedback during the early stages of this work.
[2] I dedicate this paper to Uri Treisman, for seeing potential in a nearly illiterate, blue collar first-gen kid from LA and for teaching her how to engage in critical inquiry around questions of equity in and out of the mathematics classroom.

These responses are of interest for two reasons. First, the students were enrolled in the same IBL class. Second, the worrisome responses, those of students 4 and 5, were from female minorities. Thus, the comments came from students who are, statistically speaking, the least likely to complete a mathematics degree (NSF, Science & Engineering Indicators, 2016). And, I have shared them here not to argue that the remarks represent the views of all female minorities in IBL Introduction to Proof Courses but rather as a rationale for exploring the theoretical relationships between *Inquiry Based Learning* (IBL) and *Equity-Oriented Instruction* (EOI).

## The Purpose of the Paper

The purpose of this theoretical report is to further current discussions about the relationships between *Equity-Oriented Instruction* (EOI) and *Inquiry Based Learning* (IBL) pedagogies. Specifically, this report proposes a framing of *Equity-Oriented Inquiry Based Learning* (E-IBL) pedagogies that foregrounds issues of equity, as opposed to viewing equity as a gratuitous outcome of IBL. To understand this framing, current characterizations of EOI and IBL are considered and used to explore rationales for viewing IBL as a pedagogy that promotes equity. Then, drawing on data and field notes from teaching experiments in IBL courses, I examine why efforts to co-enact IBL and EOI pedagogies might create tensions and, therefore, dilemmas for instructors. The paper concludes with a framing of E-IBL.

## A Framing of Equity-Oriented Instruction

Over the past two decades, researchers interested in student learning in school contexts have begun to reconceptualize equity in mathematics education. These researchers (Gutiérrez, 2008; Martin, 2009) challenge our practice of "gap gazing" and argue for the *de-essentialization* of disparities in students' academic achievement; i.e., against "the framing of mathematics achievement …(as) a kind of individualistic accomplishment" (Gutiérrez, 2008, p. 361). Indeed, drawing on Bourdieu's notion of habitus[3] (Bourdieu, 1984), researchers are illustrating the ways in which practices of structural exclusion enacted in students' mathematics education function to marginalize working-class and culturally diverse students (Jorgensen, Gates, & Roper, 2014). This marginalization occurs through schooling practices that align with the habitus of some students but not others by requiring the linguistic capital and practices of particular classes.

Working in ways that align with arguments both for de-essentialization and attention to habitus, Boaler (2002a) has sought to describe the situated nature of learning in schools, arguing not only that students' knowledge, practices and identity are inter-related (Figure 1) but that these inter-relationships "constitute the learning experience." This model of the inter-relationships between identity, practice, and knowledge emerged through Boaler's studies of learning in diverse school settings. It posits that one's knowledge is interactively constituted with one's practices. In particular, Boaler found "practices such as working through textbook exercises, in one school, or discussing and using mathematical ideas, in the other, were not merely vehicles for the development of more or less knowledge, they shaped the forms of knowledge produced" (p. 43). Speaking to the different instructional practices employed in schools and students' identities, Boaler notes that direct instruction places the student in a hierarchical relationship with the teacher, where the teacher is the authority and the students are "received knowers" (Boaler, 2002). In contrast, in discussion oriented classrooms students are

[3] The term *habitus* refers to the informal knowledge and skills that are developed through one's socialization "within the family, home, and immediate environment" so that one learns how to "act in and interpret their worlds" (Jorgensen, Gates, & Roper, 2014, p. 223). *Habitus* is sometimes thought of as, 'the way society becomes deposited in persons in the form of lasting dispositions, or trained capacities and structured propensities to think, feel and act in determinant ways, which then guide them" (Wacquant 2004, p. 316, cited in Navarro 2006, p. 16).

called on to engage in acts of interpretation, expression, and agency. Hence, the practices do not promote students' passive acceptance of mathematical ideas but rather called on them to "contribute to the judgment of validity, and to generate questions and ideas." Thus, enacted practices fostered distinct relationships between students' identities and the "knowledge to be taught." Drawing on Wenger (1998), Boaler argued these findings exemplify his claim that "learning transforms who we are and what we can do, it is an experience of identity" (p. 215).

Beyond those practices enacted in the classroom and the ways they involve an inherent positioning of students, one must consider the possibility that the discipline itself can foster particular disciplinary relationships and, therefore, identities. This point was made both by Boaler (2002) and Pickering (1995), who argue learning involves a *dance of agency*: an interplay of human and disciplinary agency. Specifically, while disciplinary agency refers to the ways that established practices and artifacts (e.g., proving practices, linguistic conventions, syntax, etc.) interact with and affect one's work with mathematics, human agency refers to the ideas, symbols, terms and practices humans develop that impact the discipline. Engaging in mathematics therefore involves a dance of agency in which one both asserts agency on the discipline and surrenders to the "agency of the discipline" (Boaler, 2002, p. 49). And, it is by consideration of disciplinary relationships that we see yet again the ways in which the inter-relationships between identity, knowledge, and practice constitute the learning experience.

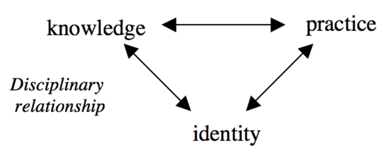

Figure 1. Adapted from Boaler (2002a).

Taken together the works of Gutiérrez (2008), Jorgensen, Gates, & Roper (2014), Bourdieu (1984), Boaler (2002), and Wenger (1998) collectively point to several key tenets of *Equity-Oriented Instruction* (EOI). EOI necessarily disrupts the reproduction of the structural inequities that are shored up and replicated through students' mathematics education. Intentionally, it attends to and broadens the forms of habitus that afford participation in schooling by valuing, among other things, the practices and "linguistic repertoires," that is the social *capital* (Bourdieu, 1984), of those who are further marginalized by schooling (Jorgensen, Gates, & Roper, 2014). It affords the development of identities that enable rather than inhibit participation in the dance of agency and, therefore, students' engagement in authentic mathematical practices. As practices are enacted in discourses (Gee, 2001), EOI requires students be afforded opportunities to engage in work that forestalls the impact of one's social capital while also affording access to rich mathematics. It requires instructors avoid essentializing students while working to provide students with "opportunities to draw upon their cultural and linguistic resources (e.g., other languages and dialects, algorithms from other countries, different frames of reference) when doing mathematics, paying attention to the contexts of schooling and to whose perspectives and practices are 'socially valorized' (Abreu & Cline, 2007; Civil, 2006)" (Gutiérrez, 2009, p. 5).

## A Framing of Inquiry Based Learning Pedagogies

Inquiry Based Learning (IBL) pedagogies have been defined in a variety of ways. Often IBL pedagogies are defined as any form of instruction in which students actively pursue knowledge through activities and discussions (Rasmussen & Kwon, 2007). According to the *Academy for inquiry based learning,* IBL is a "big tent" term for, "Teaching methods in mathematics courses

… where students are (a) deeply engaged in rich mathematical tasks, and (b) have ample opportunities to collaborate with peers (where collaboration is defined broadly)."[4]

IBL pedagogies differ in (at least) two key ways from traditional, lecture-based mathematics instruction.[5] First, curricular activities are often inverted. By this I mean that rather than introducing institutionalized knowledge and having students practice using that knowledge, IBL curricular tasks elicit students' ways of understanding[6] and then through task sequences provide opportunities for students to accommodate their understandings and develop disciplinary practices. The introduction of institutionalized knowledge is the final rather than first step in learning. Second, students are expected and encouraged to act with intellectual autonomy within collaborative settings. In other words, they are called on to engage in specific forms of human agency: (a) generating and proposing problem solving strategies; (b) comparing and contrasting approaches; and (c) justifying and validating solutions. Lastly, it is important to note in relation to these forms of agency, the instructor is expected to elicit, build on, and manage individual student contributions, student-to-student interactions, and whole class discussions.

## Why researchers have argued IBL promotes EOI

The association between active learning and equity has a long and well warranted history. The results of the Treisman (1992) studies demonstrated to many in the mathematics community that opportunities to collaborate around rich mathematical tasks could change the outcomes of students who are disadvantaged by structural inequities. More recently, Freeman et al. (2014) conducted a meta-analysis of 225 studies that compared active learning pedagogies to lecture-based instruction. They found that active learning pedagogies significantly decreased failure rates and that "active learning confers disproportionate benefits for STEM students from disadvantaged backgrounds and for female students in male-dominated fields." In a study that specifically focused on IBL pedagogies, Laursen et al. (2014) found not only did enrollment in IBL classes positively impact student success in subsequent courses but also that the IBL courses reduced the gender gap, with female students not only showing equal or greater learning gains but also higher levels of intention to persist than those in non-IBL courses.

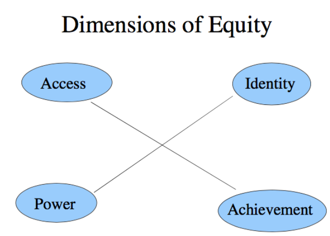

Figure 2. Gutiérrez's (2009) Dimensions of Equity.

Beyond these empirical studies, supports for IBL's potential to promote equitable outcomes can be found in recent theoretical analyses. Tang, Savic, El Turkey, Karakok, Cilli-Turner, and Plaxco (2017) provide a detailed analysis of IBL and its relationship to the dimensions of equity proposed by Gutiérrez (2009) (See Figure 2). Specifically, Tang et al. argue that in collaborative learning environments, *all* students are invited to engage in the "doing, discussing, and

[4] Retrieved from http://www.inquirybasedlearning.org on July 29, 2017.

[5] Kuster and Johnson (2016) proposed a four-component model of IBL that aligns with that proposed here. Cook, Murphy and Fukawa-Connelly (2016) have proposed a six-component model. Due to space limitations, these models are not discussed in this theoretical report.

[6] I am not using the phrase *ways of understanding* as it is used by Harel (1998, 2005) but rather to collectively refer to students' knowings, their ways of inscribing and their ways of discussing the mathematics at hand.

presenting" of mathematics. The implication here is that IBL pedagogies increase access to rich mathematics, while also promoting achievement (Freeman et al., 2014; Laursen et al., 2014). Thus, IBL pedagogies act along the dominant *access-achievement* axis. Building on the findings of Hassi's (2015) qualitative study, Tang et al. also discuss how collaborative learning environments in which students assert agency, foster growth in self-esteem and self-confidence and, therefore, students' sense of power. Thus, according to Tang et al., IBL pedagogies act not only along the dominant axis but also the critical *identity-power* axis.

## Why IBL might not gratuitously promote EOI

> *… identity has as much to do with others as it does with self … A large part of who we are is learned from how others interact and engage with us.*
> *(Pierson Bishop, 2012, p. 38)*

It is not the purpose of this section to argue that IBL pedagogies do not promote more equitable learning *outcomes* than traditional lecture-oriented pedagogies. Certainly, it would be a fool's errand to do so given recent research (e.g. Laursen et al., 2014). Instead, the purpose is to argue that IBL pedagogies are not necessarily EOI pedagogies and, consequently, do not produce equitable learning *environments* "for free." Instead, intentional attention to equity is required.

To explore the ways in which IBL might fail to function as a form of EOI, I will discuss three data excerpts drawn from field notes and student work samples collected during a series of five IBL teaching experiments. These experiments occurred in IBL-*Introduction to Proof* courses taught at a designated Hispanic-serving university, where the majority are first generation students eligible for need-based financial assistance. The classes were majority-minority classrooms: on average 67% were ethnic minorities and one-third were students who identify as female. Students classified as Hispanic by institutional categories were the dominant minority group, with many preferring the terms Latino/Latina or Chicano/Chicana rather than Hispanic.[7]

### The First Example

The first example is drawn from field notes. It concerns an event of *othering*: viewing or treating an individual as distinct from or alien to oneself or one's group (possibly without intent).

**Field Notes Excerpt.** The class begins with a whole class discussion about the theorems the class will focus on proving that day and a target time for discussing their proofs. Students are asked to move into their small groups, which have been assigned by students counting off the numbers 1 through 7. Mariella[8], a Latina, begins to move her desk towards her group. She stops a few feet short of her group because the other members (three male students) have already moved their desks together and left no space for her desk (as shown in Figure 2). She works quietly on her own, occasionally looking at the male students who do not appear to notice her exclusion.

The instructor observes Mariella's situation for approximately 20 minutes in an effort to provide adequate time for someone, either Mariella or the male group members, to rectify the exclusionary situation. The instructor speaks with Mariella to confirm that the group of three male students is, in fact, her assigned group. Mariella requests of the instructor that she be allowed to work alone. The instructor respects her request, observing that she is uncomfortable. The classroom learning assistant (an advanced undergraduate) is asked by the instructor to check

---

[7] Following Gutiérrez (2013), I use the terms Chicano/Chicana to refer to people with indigenous ancestry in the western United States. I recognize its use by students (and researchers) as intentional and political. Hence forth, I will use the gender-neutral terms Chicanx and Latinx.
[8] All names are pseudonyms.

in with Mariella periodically. Several extended mathematical conversations are observed between them. The instructor also checks in with Mariella (it is a 2-hour class so there is time for both to visit without "hovering" around her). After the class, the instructor speaks with two other female students individually and asks each how she would prefer instructors respond in such situations. Unprompted, both of the female students share similar experiences where they were either physically excluded or "invisible" during group work. Both suggest moving Mariella to a group with another female.

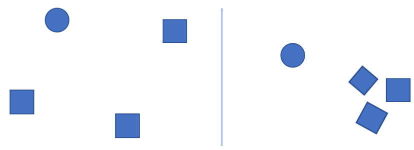

Figure 2. Pre- and post-grouping desk arrangements (Mariella's desk is shown as a circle)

**Post Observation Notes:** The next day Mariella is asked to change her group and, shortly thereafter, observed assisting the other female student. Instances of Mariella actively engaging with her new group while engaging in proving efforts are observed in several subsequent classes.

**Discussion of the Excerpt.** Why is this an instance of IBL not gratuitously promoting EOI? To be certain, some might argue that the students described in the vignette were not engaging in IBL because a central tenet of IBL is collaboration and the students weren't collaborating. There are two issues with this response. First, the male students were collaborating. Second, Mariella had tried to join the group to collaborate but had been excluded. Another critique might center on the fact that the instructor could have remedied the situation by reminding the male students of the participation norms that were discussed extensively at the beginning of the course or that Mariella should have acted to end her exclusion, since participation is an expectation of *all* IBL students. Such responses, however, assume that the tenets of IBL (e.g., collaboration) should be privileged to such an extent that they are enacted in lieu of the tenets of EOI (e.g., practices focused on supporting and valuing students' identities). Instead, they ignore the costs marginalized students pay to participate when students are called on to enforce IBL practices (or be the object of an enforcement) and, potentially, act against their own identities, dispositions, or cultural practices. Moreover, privileging collaboration while ignoring these potential costs does little to mitigate marginalized students' sense of exclusion or the potential for acts of enforcement to create the *illusion of participation*. And it is here that the problem lies. Even if *all* IBL students are expected to advocate for their own participation it is not the case that *all* students are called on to do so (often again and again). More importantly, it is not the case that *all* will have the cultural habitus, disposition, or identity that will support them doing so. Indeed, a post-class discussion with Mariella confirmed after she was publicly othered that she felt extremely uncomfortable "forcing" herself into the group and preferred to work alone.

I will conclude this example with a note of caution: *The purpose of the first example was not to suggest that instructors move othered students to a new group. The purpose was not to suggest a quick fix for the manifestation of exclusionary practices in our institutional spaces.* The purpose was to highlight a classroom situation in which those seeking to co-enact IBL and EOI pedagogies may feel an irreconcilable tension between the two and, necessarily, feel they have to decide whose tenets are privileged.

## The Second Example

LANGUAGE*: a system of verbal symbols through which humans communicate ideas, feelings, experiences. Through language these can be accumulated and transmitted across generations. Language is not only a tool, or a means of expression, but it also structures and shapes our experiences of the world and what we see around us. (Sibley, 2003, p. 1)*

*Mom, how do you say quesadilla in Spanish?*
*-Sebastian, Age 7*

As noted above, EOI requires students be afforded opportunities to engage in collaborative work that supports students' identities through the broadening of the forms of social capital that are recognized and valued. The position taken in this paper is that one's linguistic practices are not secondary to one's identity but rather are an integral component (Bishop, 2012; Gee, 2001, 2005). The extent to which one's language, culture, and practices are valued in an environment determines the extent to which one's identity is valued. Since 1998, Latinx and Chicanx students have had to deal with the educational fallout of California Proposition 227.[9] This proposition codified a stance towards bilingualism that views students' use of non-English languages as a deficit rather than an asset to the students and their communities. It is one of the reasons Californian dialects that heavily integrate Spanish words are often practiced without speakers recognizing their use of another language – a point illustrated by Sebastian's remarks.

Gee (2001, 2005) and Sfard and Prusak (2005) argue that identities are constructed through discourse. Others, such as Bishop (2012), argue discourses "play a critical role in enacting identities" (p. 44). Most who have taught university mathematics courses in environments where the majority of students are first generation urban students can readily attest to the varied and at times colorful dialects used. These languages stand in stark contrast to that employed with relative continuity for thousands of years among the practitioners of the discipline of mathematics, especially when writing proofs. To illustrate this continuity, I ask the reader to consider the resemblance between linguistic practices evident in the two proofs in Figure 3. The first is from *Euclid's Elements* (c. 350 BCE, T.L. Heath's 1909 translation) and the second is from *Mathematical Proofs: A Transition to Advanced Mathematics* by Chartrand, Polimni, and Zhang (2008) (see pp. 145-6). This continuity is highlighted here to provide some evidence for the claim that a disciplinary discourse exists, which members adopt as they are enculturated into the discipline of mathematics.

|---|---|
| ***I.6 If in a triangle two angles be equal to one another, the sides which subtend the equal angles will also be equal to one another.***<br><br>***Proof:*** Let ABC be a triangle having the angle ABC equal to the angle ACB; I say that the side AB is also equal to the side AC. For if AB is unequal to AC, one of them is greater. Let AB be greater; and from AB the greater let DB be cut off equal to AC the less; let DC be joined. Then since DB is equal to AC, and BC is common, the two sides DB, BC are equal to the two sides AC, CB respectively; and the angle DBC is equal to the angle ACB; therefore, the base DC is equal to the base AB, and the triangle DBC is will be equal to the triangle ACB, the less to the greater: which is absurd. Therefore, AB is not unequal to AC; it is therefore equal to it. ■ | ***6.17 For every nonnegative integer n, $3 \mid (2^{2n}-1)$.***<br><br>***Proof***: Assume, to the contrary, that there are nonnegative integers $n$ for which $3 \nmid (2^{2n}-1)$. By Theorem 6.7, there is a smallest nonnegative integer $n$ such that $3 \nmid (2^{2n}-1)$. Denote this integer by $m$. Thus $3 \nmid (2^{2m}-1)$ and $3 \mid (2^{2n}-1)$ for all integers $n$ for which $0 \le n < m$. Since $3 \mid (2^{2n}-1)$ when $n = 0$ it follows that $m \ge 1$. Hence, $m = k+1$, where $0 \le k < m$. Thus $3 \mid (2^{2k}-1)$ which implies that $2^{2k} - 1 = 3x$ for some integer $x$. Consequently, $2^{2k} = 3x + 1$. Observe that $2^{2m}-1 = 2^{2(k+1)}-1 = 2^{2k+2}-1 = 2^2 \cdot 2^{2k}-1 = 4(3x+1) - 1 = 12x + 3 = 3(4x + 1)$ Since $4x+1$ is an integer $3 \mid (2^{2m}-1)$, which produces a contradiction.<br>■ |

Figure 3. Proofs from Euclid (c. 350 BCE; 1909 translation) and Chartrand et al (2008).

[9] After its long and damaging reign, CA Proposition 227 was repealed in the late fall of 2017 after this paper was submitted.

How is this point related to IBL pedagogies and their goals in *Introduction to Proof* classrooms? If our goal in the IBL *Introduction to Proof* classroom is to inquire into the practice of proving and in so doing enculturate students into the discipline of mathematics then our goal is to foster students' growth by developing their awareness of and capacity to engage in disciplinary practices. One of the ways we do this is through our efforts to move students' discursive practices towards disciplinary discursive practices. We argue that students' informal language develops as students work collaboratively, gradually refining their discourse into that of the discipline. We aim to create institutional spaces where the unrefined can interactively be transformed into the refined as students acquire the necessary "cultural dispositions through enmeshment in a cultural community" (Kirshner, 2004; see also Kirshner, 2002). And it is here that a tension between EOI and IBL arises. IBL pedagogies are necessarily unidirectional *enculturation pedagogies* (Kirshner, 2004), which implicitly enact discourse hierarchies by positioning the students' discourses as that which is to be "transformed" and "developed." This point is illustrated in Kuster and Johnson's (2016) discussion of IBL pedagogies:

> 2) *Teachers support formalizing of student ideas/contributions*. In inquiry-oriented instruction, as the students reinvent the mathematics, their reinventions build to be commensurate with formal mathematical ideas. The instructor must be able to promote the students' ability to connect their mathematical ideas to more formal mathematics.

Yet, what of the constitutive role of discourses in relation to students' identities? If discourses are constitutive of identities are we not, in fact, placing students' identities in a hierarchy?

To see how this issue manifests itself in the IBL *Introduction to Proof* classroom, I ask that the reader consider two classroom artifacts. These artifacts were selected because they are examples of the students' own discourses – those which were not taught in but rather brought into the mathematics classroom –and considered in relation to the students' identities. When considering these artifacts, I ask that the reader pay careful attention to his or her initial reactions, thoughts and physical responses.

**Classroom Artifact 1.** The first artifact is from a brief survey administered prior to students' IBL activities focused on standard mathematical logic. The survey was meant to elicit students' ways of thinking and definitions prior to working towards shared definitions that would not only aid communication in the classroom but also develop into the definitions used in the discipline.

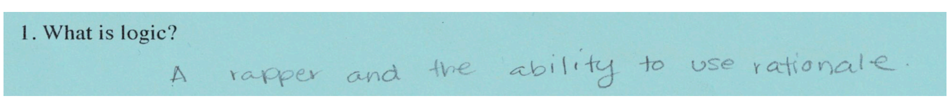

Figure 4. Student Survey Response

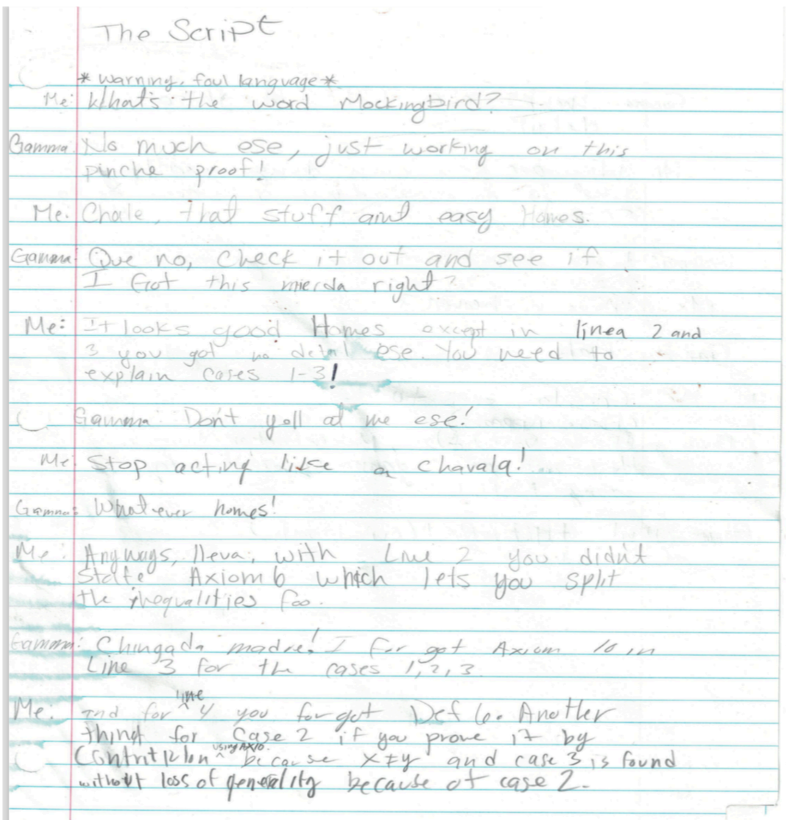
In my experience, many laugh when they read this response. Why is it humorous? In the worst-case scenario, it is because the response "a rapper" is viewed as absurd. In the best, it is because we are surprised and entertained by the unexpected. Thus, the laughter is not necessarily a positioning of the student's response in the realm of the ridiculous. It depends. Furthermore, it is possible our laughter is an intended outcome of the student – a purposeful breaching of norms (Herbst & Chazen, 2011). Then again, it may be that the humor was unintentional and that we are witnessing a moment of deliberate candor. It may be that, regardless of the costs that can arise from revealing one's identity through discourse, the student is in fact declaring: "these are my meanings, in my world, in my everyday life." In this case, when the response is shared and laughter is heard, what do students learn about their meanings? And, what do they learn as their meanings are placed in a discursive hierarchy that relegates certain forms of social capital to the realm of that which must be changed?

**Classroom Artifact 2.** The second classroom artifact is a student proof script drawn from a sample of 43 *proof scripts*: written dialogs in which a student and a fictional peer discuss a proof so as to promote the peer's understanding of any gaps or key points in the proof (See Appendix A). This particular proof script (Figure 5) was chosen because it exemplifies one of the many instances of students describing deep mathematics using their own discursive practices and is reflective of the spoken discourses observed in the IBL *Introduction to Proof* course. Indeed, field notes indicate that throughout the IBL *Introduction to Proof* course students grew increasingly accustomed to intensely discussing proofs in their everyday vernaculars.



The Script

*warning, foul language*

Me: What's the word Mockingbird?

Gamma: No much ese, just working on this pinche proof!

Me. Chale, that stuff and easy Homes.

Gamma: Que no, Check it out and see if I Got this mierda right?

Me: It looks good Homes except in linea 2 and 3 you got no detail ese. You need to explain cases 1-3!

Gamma: Don't yell at me ese!

Me: Stop acting like a chavala!

Gamma: Whatever homes!

Me: Anyways, lleva, with Line 2 you didn't state Axiom 6 which lets you split the inequalities too.

Gamma: Chingada madre! I forgot Axiom 10 in Line 3 for the cases 1,2,3.

Me: And for line 4 you forgot Def 6. Another thing for Case 2 if you prove it by Contradiction using Ax10. because $x \neq y$ and case 3 is found without loss of generality because of case 2.

Figure 5. Joseph's Proof Script Excerpt[10]

The point here is that if one looks at the script and expects to see a student's engagement in the valorized discourse – the disciplinary discourse – then one will find a bar that has not been reached. Yet, if we step away from the hierarchy and de-hegemonize the discourses, we see something else. We see an instance of a student *enculturating mathematics*. And in so doing, we can recognize a dialog focused on accounting for mathematical acts that are not only non-trivial for novices but are also valued by the discipline. Take for example the reference to Axiom 6 in the eighth stanza,[11] where we find the student employing the disjunctive definition of ≤ as a warrant for the use of cases – a mathematical act that is non-trivial at this stage of development. Consider also the last stanza. Here we are provided a rationale for why one of the cases is not

[10] At the time of data collection, I was unaware of the potential exclusionary effect of choosing a Greek letter, *Gamma*, as the student name.
[11] The student meant Definition 6, as indicated by subsequent remarks. This typo is not a point of concern in this paper.

needed; namely, that due to similarities in the logic structure we can argue "without loss of generality." And, it is by seeking an enculturated mathematics, rather than a student's enculturation, that we are afforded an opportunity to recognize the pervasive code-switching as exemplifying a student's masterful *blending* of two dialects – the personal and the mathematical – rather than as indicating a lack of participation in implicitly demanded, disciplinary discourse practices. This is *his dance of agency*.

Having witnessed his dance of agency we can ask, like we did with the first artifact, was the unexpected breaching of norms meant to be humorous? Certainly, this is a possibility. It is also possible, however, that humor was not his primary aim but rather was something secondary to asserting agency over that which seeks to place his discourse and, therefore, his identity in a hierarchy. It is because of the latter possibility that I ask again: What do students learn as their discourses (and therefore, their identities) are placed in a hierarchy that relegates their social capital to the realm of that which must be changed during their enculturation into mathematics?

**Discussion of the Artifacts.** The two student artifacts were shared due to their similarity to students' in-situ spoken discourses and in an effort to demonstrate a tension between IBL and EOI. A key tenet of IBL is that students' move towards institutionalized knowledge (and therefore, normative disciplinary discursive practices) through their collaborative activities (Kuster & Johnson, 2016; Cook, Murphy, & Fukawa-Connelly, 2016). It privileges mathematical discourses by calling on instructors to enact discourse hierarchies in lieu of attending to the integral role discourses play with respect to students' identities. Consequently, enacting IBL pedagogies means working to modify students' discourses, as they progress towards a valorized discourse. In contrast, practitioners who privilege EOI practices over those central to IBL must attempt to navigate a precarious balance between respecting students' means of expressing identity and supporting their development of disciplinary discursive practices. Hence, privileging EOI means rejecting discourse hierarchies while simultaneously providing students opportunities to become knowledgeable of disciplinary discourses through their own *dance of agency*. Thus, drawing on Gutiérrez (2009), this paper argues that privileging EOI when enacting IBL means valuing instances when students "change the game" (e.g., by valuing the student's *bridging* of his own and disciplinary vernaculars and his enculturation of mathematics) while also valuing the student's success "playing the game" (e.g., by valuing the mathematical sophistication that underlies the detailed and precise mathematical refinements embedded in the student's dialog). It means creating institutional spaces where *reciprocal enculturation* is possible.

As with the first example, I will conclude this example with a note of caution: *The purpose of the second example and its discussion of the student artifacts was not to suggest that we create classrooms were anything goes. It was not a call to discard disciplinary discourse practices.* Instead, the purpose was to argue for a rejection of discourse hierarchies and to call for forms of praxis that de-hegemonize our institutional spaces. Implementing such praxis is likely to be difficult and requires further exploration. Moreover, such praxis is likely to defy efforts towards lists of "good teaching practices" since, in essence, it is calling for instructors to enact something akin to a *pedagogy of solidarity* (Gaztambide-Fernández, 2012). Consequently, it requires the enactment of practices and perspectives that attend to past histories of colonization and oppression and are, therefore, not only highly situated and temporal, but also critically intertwined with who we (ourselves) are in relation to others.

### The Third Example

*Competence:* the ability to do something well. Synonyms: skill, talent and ability
– Cambridge Dictionary

*I am invisible, understand, simply because people refuse to see me.*
– Ralph Ellison, The Invisible Man

The third example is drawn from field notes. It is like the first example in that it can be interpreted as an instance of othering. It is not, however, an instance of othering through physical exclusion. Instead, it is an instance that brings to our attention the possibility of othering obscured by the illusion of participation. With this said, the purpose is not to illustrate this difference. The purpose is to consider (hopefully with care) the ways in which IBL classroom environments may create spaces where students, who have been marginalized and oppressed through schooling and other facets of our society, can face *demands for competency* – demands that are not experienced by all who enter these spaces.

**Field Notes Excerpt:** The students have counted off, moved their desks, and are working on Propositions 20-25. In the center aisle is a group that has arranged their desks in a triangular formation. All of the students in the group are male, one is Black. His name is Maxwell.[12] He is the only Black male in the class. The instructor checks on the group while circulating around the room and notices Maxwell is not working on the same tasks as the other two in his group. Though from afar the group was observed talking periodically, up close it is observed they are not collaborating around a task but instead occasionally checking in by asking "where are you at?" The instructor encourages the group to work on the same task and reminds them why this is important. The instructor observes that the situation does not change. The students are sitting together but not working together.

**Post Observation Notes:** Throughout the term, reincarnations of the situation are observed, not with every group but in more than one. In some groups, Maxwell and his groupmates collaborate, in others either he is excluded or isolates himself. It is not clear which is the case. Maxwell periodically attends office hours and asks good questions. From the instructor's viewpoint, Maxwell is a good student, he works hard and cares about his academic performance.

**Discussion of Excerpt.** Why is this an instance of IBL not gratuitously promoting equity? The answer to this question is long and I ask that the reader bear with me. As noted in relation to the first example, one might argue that the students described in the vignette were not engaging in IBL because a central tenet of IBL is collaboration and the students weren't collaborating in the ways expected. But rather than rehash issues related to the costs some pay to participate and rather than hypothesize about the potential reasons for the recurring instances of Maxwell's isolation (be they voluntary or involuntary), I ask that the reader consider another issue – one which may be observed in IBL classrooms but may remain unobserved in lectures. In most areas of America, societal structures are in place that lead to people's homes and K-12 schools being separated along racial and socio-economic lines. By experience and habitus people become accustom to separation. One consequence of this separation is that we can fail to grow in ways that foster the dispositions and perspectives necessary to bridge and move past our recurring experiences of separation and societal messages of difference. Placing students in multi-racial (or multi-religion or multi-gendered, etc.,) groups in a university class and expecting students to

[12] All names are pseudonyms.

freely collaborate, therefore, is in essence calling on students, if they have not yet already done so, to spontaneously generate the dispositions and perspectives necessary to bridge their recurring experiences of separation. While we can argue that it is by calling on students to do so that we begin to foster that which is necessary for students to collaborate across societal divides, (and I agree with this claim) we must also recognize that there are grounds for asking, "Is calling on students to do so enough to promote more equitable institutional spaces?"

Those whose habitus and practices have been valorized need not worry about the isolation and/or exclusion of *othered* individuals, for they can rest assured that they will not be excluded in the grand scheme of things. Neither isolation nor exclusion are part of their prevailing storyline. Consequently, changing the prevailing storyline from one of exclusion and isolation to one of inclusion and collaboration often falls on the *othered* individuals. This can take the form of having to prove one's competence in settings where one must overcome harmful stereotypes. While inquiry, discussion, and the sharing of ideas (activities promoted in IBL environments) provide more opportunities for one to demonstrate one's competence than do lectures, they can also heighten the need for some students to exhibit and establish competence if they are to participate. Thus, it can be the case that the demands placed on *othered* students are not the same as those who are not *othered* in our institutional spaces. When recognized, instructors can support *othered* students by "assigning competence" to them (Cohen & Lotan, 1995) but such actions only further the *othered* students' efforts to meet *the demand to establish competency*. These actions do not mitigate the fact that *othered* students face this demand – that they are called on, often again and again, to establish their competence.

Thus, it is by applying an EOI lens that we recognize collaborative learning environments may place different demands on marginalized students than those who are not marginalized. We recognize that the situation described in this excerpt may or may not have been due to racism, while at the same time recognizing that some of our students (our students of color, our religious minorities, our LGBQT+ students, …) are more likely to experience exclusionary situations repeatedly. The playing field is not level. There are forces inside and outside of the classroom that work to maintain this disequilibrium. We can work to mitigate the impact of these forces while at the same time recognizing they are unlikely to go away easily or be susceptible to quick fixes. Moreover, such work may entail allowing a student to opt-out and focus on a different task rather than engage, yet again, in the fight against the forces that continually seek to make some students invisible. Or, it may entail something else. The point isn't to find answers (or quick fixes) but rather to argue that privileging EOI when engaging in IBL rather than assuming IBL is gratuitously equitable may mean enacting a perspective and praxis that does not privilege collaboration at the expense of ignoring the demands some face when asked to "participate."

## A framing of E-IBL

In this paper, I call into question the assumption that IBL pedagogies gratuitously promote EOI and argue E-IBL requires intentional attention to equity. I posit that intentional attention to equity calls on practitioners to employ EOI as a lens when viewing IBL learning environments. Applying such a lens necessarily entails foregrounding issues of structural exclusion and acting to disrupt the social mechanisms that result in their reproduction in institutional spaces (Jorgensen, Gates, & Roper, 2014; Battey & Leyva, 2016). It means privileging students' identities and habitus when IBL practices call on students to act against either; e.g., by valuing varied forms of social capital (e.g., linguistic resources (Zahner & Moschkovich, 2011)) or addressing instances of *othering* by first attending to students' identities and habitus and to the costs and demands some students face. At its core, this framing posits E-IBL instructors must be willing to recognize that, as argued by Wenger (1998), learning is "an experience of identity" and that identity and power are negotiated in institutional contexts (Adiredja & Andrews-Larsen, 2017). Consequently, privileging the demands of EOI over the tenets of IBL, may require instructors to navigate the tensions present in institutional spaces that support students not only "playing the game" but also "changing the game" (Gutiérrez, 2009) by pushing back against the costs and demands they face or asserting agency through acts of *reciprocal enculturation*.

Lastly, the purpose of this theoretical report was to further current discussions of the relationships between EOI and IBL pedagogies by examining the ways in which IBL pedagogies might not gratuitously promote equitable learning environments. Here is it important to note that I have NOT argued that IBL pedagogies are inequitable. To say that the paper argues so is to deeply misinterpret what was written. Instead, the point is to highlight how persistent broader inequities which are an artifact of our societal structures and practices can manifest themselves in the IBL classroom. Indeed, as argued by Tang (2017),[13] "IBL may not be causing these situations but rather may be making them visible." And, it is through our intentional attention that we can see this visibility and begin to question and explore what it means to enact an equity-oriented IBL pedagogy, which attends to the potential tensions between *Equity-Oriented Instruction* and *Inquiry Based Learning*.

## Appendix A.

**The Script Assignment**

***Instructions*:** You are being asked to create a 1- 2 page dialog between two students, you and a mathematics student named Gamma, who is not enrolled in MATH 310. In the dialog you and Gamma should discuss the proof provided below. Your goal is to help Gamma understand the proposed proof and why it is or is not a valid proof.

***Assignment:***
***Part 1***. Start by reading the proof and identifying what you believe are the "*problematic points*" for a learner when attempting to understand the theorem and its proof. A *problematic point* is anything you think is incorrect, is confusing, or is correct but warrants further discussion. List these "*problematic points*" in a bulleted list.

***Part 2***. Write a dialogue between you and Gamma in which you and Gamma discuss the theorem and its proof. The dialog should address the *problematic points* you identified and listed in your bulleted list through questions posed either by you or Gamma.

***Theorem*:** For any real numbers $x$ and $y$, if $x \leq y$ and $y \leq x$ then $x = y$.

***Proof*:**
1) Assume $x$ and $y$ are real numbers such that $x \leq y$ and $y \leq x$.
2) Then ($x < y$ or $x = y$) and ($y < x$ or $y = x$).
3) We will consider four cases
   Case 1. $x < y$ and $y < x$.
   Case 2. $x < y$ and $y = x$.
   Case 3. $x = y$ and $y < x$.
   Case 4. $x = y$ and $y = x$.
4) In Cases 1 through 3 our assumptions contradict the Law of Trichotomy.
5) We are left with Case 4.
6) Case 4. $x = y$ and $y = x$.
7) Therefore, $x = y$.
8) The result follows. ♦

Self-Regulation in Calculus I

Carolyn Johns
The Ohio State University

*Improving STEM retention is a major focus of universities and studies have shown calculus to be a barrier for STEM intending students. Prior to this study, local data indicated students did not pursue STEM fields because they were not passing calculus. In this work, I report on factors that impacted student success in Calculus I. In particular, I examined the relationship between final grades and self-reported self-regulatory aptitudes after accounting for incoming math aptitude. Results indicate self-regulatory aptitudes predict final grades above and beyond math aptitude. In addition, measures of self-regulation differed amongst high and under achievers as well as low and over achievers. This indicates self-regulation plays a role in student success. Furthermore, gender differences were present in measures of self-regulation which may be of importance for improving retention of women in STEM.*

*Keywords:* Calculus, Motivation, Self-Regulation

Calculus I is known to be a barrier to success for students desiring a career in science, technology, engineering, and mathematics (STEM) fields (National Academies of Sciences, Engineering, and Medicine, 2016). Recent national data shows that little more than half of students in calculus I receive a grade of an A or B and DFW rates are around 22-38% depending on the type of institution in which the course is taken (Bressoud, 2015). Of particular concern is the number of women who do not persist into calculus II with 20.1% of females switching their calculus II intention at the end of calculus I while only 11.1% of males switch their calculus II intention (Ellis, Kelton, & Rasmussen, 2014).

Research has correlated student self-regulation with final grades (Pintrich P. R., Smith, Garcia, & McKeachie, 1991). Self-regulation can broadly be defined as the planning, monitoring, controlling, and reflection on one's progress toward a goal in the areas of cognition, motivation/affect, environment, or behavior (Pintrich, 2000). With particular reference to calculus, recent studies have shown self-regulation measures can predict exam scores in Calculus I (Worthley, 2013) and a calculus based engineering analysis course (Hieb, Lyle, Ralston, & Chariker, 2015). This suggests that addressing self-regulation factors may be important aspects of the curriculum that could potentially improve success for some. However, there is a gap in the literature regarding achievement group differences in self-regulatory aptitudes. Prior regression models indicate self-regulation predicts grades above and beyond incoming math aptitude when considering the sample as one group (Hieb, et al., 2015; Worthley, 2013). However, when classified into four achievement groups based on performance relative to the median incoming math aptitude and median final grade (see Figure 1), it is not known if achievement groups report the same type of self-regulation. In a similar study on college chemistry students, Yu (1996) found many differences in self-regulation amongst achievement groups. The same may be true for calculus.

Furthermore, it remains unclear what role gender may play in the relationship between self-regulatory aptitudes and final grades in Calculus I. Prior studies have shown gender differences among self-regulatory aptitude measures (Pintrich & DeGroot, 1990; Zimmerman & Martinez Pons, 1990; Yu, 1996). In addition, although prior studies have shown aspects of self-regulation impacts success after taking into account incoming math ability, there is a gap in the literature regarding if a model of success for males would differ from a model for females. Better understanding of differences in performance according to gender and achievement groups can aid in designing interventions that cater to specific student populations. To address these gaps in the literature, three main research questions guided data analysis for the current study:

1) Are gender differences present in self-reports of self-regulation among students enrolled in Calculus 1?
2) Is there a relationship between final grades and self-regulation according to gender?
3) How do achievement groups differ in their self-reports of self-regulation?

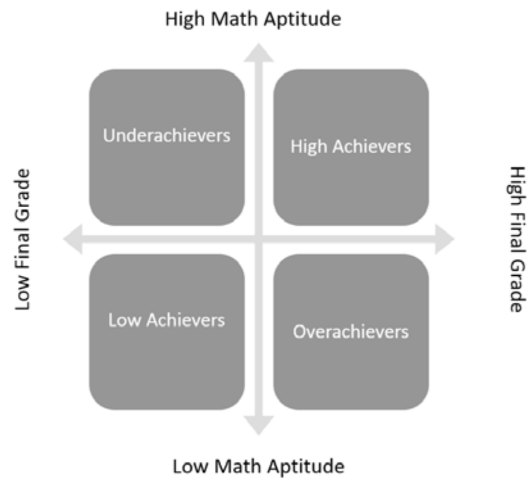

*Figure 1. Achievement groups in calculus. High achievers scored above the median on both math aptitude and final grade. Overachievers scored below the median on math aptitude but above the median on final grade. Underachievers scored above median on math aptitude but below median on final grade. Low achievers scored below median on both math aptitude and final grade.*

## Theoretical Framework and Literature Review

Broadly, self-regulation involves setting a standard or goal, monitoring progress toward the goal, controlling oneself to make adjustments if needed, and reflecting on one's performance (Pintrich, 2004). Self-regulation is rooted in social cognitive theory, examining reciprocal interactions between the individual, their behavior, and their environment (Zimmerman, 1989). Specific to the academic context, Pintrich and Zusho (2007) argue classroom contexts such as academic tasks and instructor behavior impact students' self-regulatory processes which in turn impacts student outcomes. For example, the individual may realize they are not making adequate progress toward their goal leading them to put forth more effort (behavior) or change their study location (environment). Reciprocally, the tasks one is provided to work on (environment) changes the way one cognitively engages with a course and the study strategies and effort (behavior) one engages in, impacts learning.

This study draws upon Pintrich and Zusho's (2007) and Pintrich's (2004) frameworks for self-regulation. Pintrich and Zusho's model places self-regulation within the context of the classroom. They argue students' personal characteristics and the classroom context impact students' motivational and self-regulatory processes. While some self-regulation models consider motivation to fall under self-regulation, Pintrich and Zusho distinguish motivational processes from self-regulatory processes. They argue motivation only becomes self-regulatory when there are active attempts to monitor and control motivation. In Pintrich and Zusho's model, motivational and self-regulatory processes then affect student outcomes. The outcomes feed back into the model to impact future classroom context, motivation, and self-regulatory processes. According to Pintrich and Zusho's model, interventions to alter the classroom context could lead to changes in motivational and self-regulatory processes. However, it must first be understood which motivational and self-regulatory processes are impacting outcomes.

Pintrich's (2004) framework provides a means of examining motivational and self-regulatory processes within categories. Pintrich classifies self-regulation as occurring in four areas: cognition, motivation, behavior, and environment. In addition, he considers self-regulation to occur over four phases: forethought and planning, monitoring, control, and reflection. While Pintrich acknowledges that self-regulation does not necessarily occur linearly through the phases and some aspects of self-regulation don't neatly fit into one area, thinking of self-regulation in terms of phases and areas does allow for distinction among self-regulation processes.

Pintrich's (2004) framework stems from his work developing the Motivated Strategies for Learning Questionnaire (MSLQ). The MSLQ is a questionnaire designed to measure students' course specific self-regulatory aptitudes (Duncan & McKeachie, 2005). The MSLQ has 15 subscales which Pintrich (2004) later mapped onto his classification framework.

In recent years researchers have used the MSLQ to consider the role of self-regulation in success among calculus students. In particular, some studies have attempted to utilize models that predict student success in calculus considering variables such as self-regulatory factors. For instance, Worthley (2013) and Hieb, et al. (2015) used subscales of the MSLQ in their models. Worthley found MSLQ subscales of test anxiety and self-efficacy for learning and performance were good predictors of first midterm grades when combined with math placement test results. Hieb, et al. found that of the select MSLQ subscales administered to their subjects, time and study environment management, internal goal orientation, and test anxiety were good predictors of exam scores. These studies indicate self-regulatory factors play a role in student success and should be examined in more detail.

Furthermore, studies have shown males and females differ in their mathematics interest and self-efficacy beliefs as early as middle school (Pajares, 2005) and the trend continues into college (Pajares & Miller, 1994). In addition, females maintain higher test anxiety than males (Hong, O'Neil, & Feldon, 2005; Pajares & Miller, 1994). Considering these results, it seems plausible that different gender groups may need attention on different areas of self-regulation. Thus it is necessary to examine whether the impact of self-regulation aptitudes on grades vary by gender.

## Method

### Participants

All autumn 2016 Calculus I students at a large Midwestern university were invited to participate in the study. All students, regardless of consent to participate in the study, were given the opportunity to complete all measures. The Calculus Concept Readiness test was a graded quiz assessment for the course. The Motivated Strategies Learning Questionnaire was one of the three surveys given during the course. Students were required to complete all three surveys to earn bonus points. No credit was given to students for consenting to allow their data to be used for the study.

Of the 2539 students enrolled in the course on the 15$^{th}$ day of class, 603 consented to have their data be used in research. Among these 603 students, 29 withdrew from the course. Of the 573 remaining students, 36% ($n$ = 149) of students had missing data leaving a complete data set for 424 students. Of the 424 remaining students, 50.5% ($N$ = 214) were female and 49.5% ($N$ = 210) were male.

### Measures and Procedure

This study consists of five measures: the Calculus Concept Readiness (CCR) assessment (Carlson, Madison, & West, 2015), ACT/SAT Math scores, scores on the Motivated Strategies for Learning Questionnaire (Pintrich P. R., Smith, Garcia, & McKeachie, 1991), and students' final course grades. All sections of the Calculus 1 course were coordinated meaning all students completed the same quizzes, midterm exams, and final exams which minimizes grade differences between sections. The CCR assessment and ACT/SAT math scores were used as a measurement of students' incoming math ability. The MSLQ was used to measure students' motivation and use of cognitive, behavior, and environment self-regulation. Final grades were used as an outcome measure of success in calculus.

**Missing data and insufficient effort response.** Of the 573 students who consented to participate in the study and finished the course, math aptitude scores are missing for 15.9% ($n$ = 91) students due to either a missing ACT/SAT Math score or a missing CCR score. For the MSLQ subscales, scores on each subscale were averaged and thus a student who missed, for example, one question on a subscale, still had a computed average score. However, 9.6% ($N$ = 55) students did not take the MSLQ. An additional 4% ($N$ = 23) students had their MSLQ scores removed due to an insufficient effort response indication of spending less than 3 seconds per question (Kong, Wise, & Bhola, 2007). Overall, examining list-wise missingness, 36% ($n$ = 149) of students have missing data leaving a complete data set for 424 students.

**Calculus Concept Readiness assessment.** The Calculus Concept Readiness (CCR) assessment is a research-based instrument developed with an aim to assess the reasoning and understandings required for Calculus I (Carlson, Madison, & West, 2015). The CCR stands in contrast to many placement exams as the CCR focuses on conceptual understanding rather than procedural knowledge. The assessment consists of 25 multiple choice items which focus on covariational reasoning, the function concept, proportional relationships, angle measure, and trigonometric functions (Carlson, Madison, & West, 2015). The instrument has established reliability as well as internal and criterion validity (Carlson et al., 2015).

The Calculus Concept Readiness assessment was administered to students in the first week of class. Students took the assessment in a timed online environment. While the assessment consists of 25 items, due to error, the first item was omitted leaving an assessment of 24 items.

A Q-Q plot confirmed normality of CCR scores. The average CCR score was $M = 13.37$ ($SD = 3.87$). On average, males ($M = 14.35$, $SD = 3.80$) performed better than females ($M = 12.41$, $SD = 3.71$) on the CCR. This difference, 1.94, BCa 95% CI [1.30, 2.69], was significant $t(422) = 5.32$, $p < .001$ and represents a medium effect size $d = .52$.

**ACT/SAT Math scores.** Student ACT and SAT Math scores were collected from the university's database system. For students with no ACT Math score but with an SAT Math score, SAT Math scores were converted to ACT Math equivalent scores (Dorans, 1999). A Q-Q plot indicated scores are normally distributed. The average ACT/SAT math scores was $M = 29.63$ ($SD = 2.77$). On average, males ($M = 30.08$, $SD = 2.84$) performed better than females ($M = 29.20$, $SD = 2.64$) on the ACT/SAT math test. This difference, .88, BCa 95% CI [.31, 1.42], was significant $t(422) = 3.29$, $p = .001$ and represents a small effect size $d = .32$.

**Math aptitude.** In order to create a single composite incoming math aptitude score, ACT/SAT math and CCR scores were combined. ACT/SAT math and CCR scores were chosen as math aptitude measures due to their correlation with final grade. There was a significant relationship between CCR scores and finals grades, $r = .525$, $p < .001$ as well as between ACT/SAT math scores and final grades, $r = .487$, $p < .001$.

University Math Placement test scores were also considered as an additional component to the incoming math ability score. Math placement test scores were significantly related to final grades, $r = .186$, $p < .001$. However, a hierarchical regression showed math placement test scores did not significantly contribute to the model after accounting for ACT/SAT math scores (Table 1). In the model, ACT/SAT math scores were input as the first step since they are known to be correlated to math grades. Math placement and CCR scores were entered in the second block using forced entry. Due to the non-significant contribution of math placement scores, math placement scores were not included in composite math aptitude score. The CCR scores contributed significantly to the model even after accounting for ACT/SAT Math scores.

*Table 1. Linear model of predictors of final grades, with 95% bias corrected and accelerated confidence intervals.*

| Model | | B | Bootstrap[a] | | | | |
|---|---|---|---|---|---|---|---|
| | | | Bias | Std. Error | Sig. (2-tailed) | 95% Confidence Interval | |
| | | | | | | Lower | Upper |
| 1 | (Constant) | .048 | -.003 | .073 | .509 | -.103 | .190 |
| | ACT/SAT Math | .025 | <.001 | .002 | .001 | .020 | .030 |
| 2 | (Constant) | .106 | -.005 | .066 | .105 | -.034 | .228 |
| | ACT/SAT Math | .016 | <-.001 | .002 | .001 | .011 | .021 |
| | CCR Score | .013 | <.001 | .002 | .001 | .010 | .016 |
| | Math Placement D Score | .001 | .000 | .001 | .226 | .000 | .003 |

a. Unless otherwise noted, bootstrap results are based on 1000 bootstrap samples

The composite math aptitude score was computed by transforming scores on the CCR and ACT/SAT math test into z-scores and then summing the scores. These composite math aptitude scores ranged from -5.24 to 4.00 with an average of $M = .068$ ($SD = 1.65$).

On average, male math aptitude scores ($M = .467$, $SD = 1.65$) were higher than female scores ($M = -.324$, $SD = 1.55$). This difference, .791, BCa 95% CI [.480, 1.095], was significant $t(422) = 5.073$, $p <.001$ and represents a medium effect size $d = .49$.

**Motivated Strategies for Learning Questionnaire.** Students completed 12 of the 15 Motivated Strategies for Learning Questionnaire (MSLQ) subscales during the fifth week of the semester. The MSLQ is a self-report questionnaire designed to measure students' motivation and learning strategy use (Pintrich, Smith, Garcia, & McKeachie, 1991). Three of the original subscales were excluded due to a combination of both low inter-item reliability and final grade correlation as originally reported by Pintrich et al.. All other subscales have reasonable reliability and predictive validity (Pintrich, Smith, Garcia, & McKeachie, 1993). Of the 81 original items on the questionnaire, this left 69 items.

The first section of the MSLQ focuses on student motivations as measured by the subscales of intrinsic motivation, task value, control of learning beliefs, self-efficacy, and test anxiety. Intrinsic motivation is measured by four items such as "In a class like this, I prefer course material that really challenges me so I can learn new things". Students who are intrinsically motivated seek learning opportunities for the sake of learning rather than solely for a grade. Task value is measured by six items and seeks to determine if a student finds the course material interesting and useful through items such as, "I think I will be able to use what I learn in this course in other courses" and, "I like the subject matter of this course". Control of learning beliefs is comprised of four items such as "It is my own fault if I don't learn the material in this class". Students with high control of learning beliefs believe they can succeed through effort. They attribute their success or failures to effort rather than uncontrollable attributes such as innate ability or the instructor. Self-efficacy is measured by eight items asking students about their confidence and belief that they learn the material and do well in the class. Two examples of a self-efficacy items are, "I'm confident I can understand the basic concepts taught in this course" and, "I expect to do well in this class". The final motivation scale is test anxiety. The five items ask students about their anxiety during testing with such questions as, "When I take tests I think of the consequences of failing" or "I have an uneasy, upset feeling when I take an exam". These five motivational subscales assess the inner-person motivational or affective aspects of self-regulation.

The second section of the MSLQ focuses on learning strategy use. These four scales are designed to measure use of cognitive and metacognitive strategies; elaboration, organization, critical thinking, and metacognitive self-regulation. The elaboration subscale is comprised of six questions asking students if they try to make connections between what they are learning and prior knowledge. For example, "I try to relate ideas in this subject to those in other courses whenever possible" or "When I study for this class, I pull together information from different sources, such as lectures, readings, and discussions". The organization subscale's four questions ask students if they attempt to organize their thinking through use of outlines, diagrams, and other organizational techniques. The five items on the critical thinking subscale ask students if they try to think beyond and question what they have learned. Two examples of a critical thinking item are, "Whenever I read or hear an assertion or conclusion in this class I think about possible alternatives" and, "I treat the course material as a starting point and try to develop my own ideas about it". Finally, the metacognitive self-regulation subscale contains 13 items asking if students monitor their understanding. This can take the form of losing focus, "During class time I often miss important points because I'm thinking of other things", or attempts to change strategy when losing focus or not comprehending the material, "If I get confused taking notes in class, I make sure I sort it out afterwards". These subscales focus on the inner cognitive aspects of self-regulation such as monitoring understanding and strategy use.

The second set of learning strategies subscales relates to resource management. The three scales are time and study environment, effort regulation, and peer learning. The time and study management subscale's eight questions asks students if they attend class, keep up with assignments, and study where they can concentrate. The four effort regulation subscales ask students how much effort they put into the class when they find it boring or hard. Finally, the peer learning subscale is comprised on three items asking if they work with their peers when studying. For example, "When studying for this course, I often try to explain the material to a classmate or friend". These subscales address students' attempts to regulate their environment and behavior as they learn.

**Final grades.** Final grades as a decimal percentage were collected from the university's learning management system gradebook. The average final grade was $M = .791$, $SD = .125$. A Q-Q plot gives some indication of non-normality, however, given the large dataset ($N = 424$), the Central Limit Theorem applies. On average, male final grades ($M = .805$, $SD = .126$) were higher than female final grades ($M = .777$, $SD = .124$). This difference, .028, was significant $t(422) = 2.28$, $p = .023$ and represents a small effect size $d = .22$.

## Results

This study examines two phenomena. First, gender differences in motivation and self-regulation self-reports as well as gender differences in how these self-reports impact success in calculus. Second, how self-reports of self-regulation differ amongst achievement groups.

### Gender Differences

A multivariate analysis of variance (MANOVA) was performed to determine gender differences in MSLQ subscale scores. Using a Wilks's Lambda, there was a significant effect of gender on MSLQ subscales, $\Lambda = .800$, $F(12,411) = 8.548$, $p < .001$. The MANOVA was followed up with one-way ANOVAs. Adjusting for Bonferroni's correction, significant differences in gender were found on intrinsic motivation, self-efficacy, test anxiety, critical thinking, organization, intrinsic motivation, and time and study environment (*ps* < .004) (Table 2). Females reported significantly lower intrinsic motivation, self-efficacy, and critical thinking than males. Females reported significantly higher test anxiety, organization, and time and study environment structuring than males.

*Table 2. Univariate effects for gender*

| Dependent Variable | df | df error | F | Sig. | Gender | Mean | 95% Confidence Interval Lower Bound | 95% Confidence Interval Upper Bound |
|---|---|---|---|---|---|---|---|---|
| Intrinsic Motivation | 422 | 1 | 12.543 | <.001 | Female | 4.437 | 4.278 | 4.596 |
| | | | | | Male | 4.844 | 4.683 | 5.004 |
| Task Value | 422 | 1 | 4.829 | .029 | Female | 4.981 | 4.809 | 5.154 |
| | | | | | Male | 5.256 | 5.082 | 5.430 |
| Control | 422 | 1 | .146 | .703 | Female | 5.406 | 5.273 | 5.539 |
| | | | | | Male | 5.443 | 5.309 | 5.577 |
| Self-Efficacy | 422 | 1 | 21.045 | <.001 | Female | 4.841 | 4.671 | 5.010 |
| | | | | | Male | 5.403 | 5.232 | 5.574 |
| Test Anxiety | 422 | 1 | 13.368 | <.001 | Female | 4.545 | 4.349 | 4.741 |
| | | | | | Male | 4.027 | 3.830 | 4.225 |
| Elaboration | 422 | 1 | .221 | .638 | Female | 4.575 | 4.429 | 4.721 |
| | | | | | Male | 4.525 | 4.378 | 4.673 |
| Organization | 422 | 1 | 16.318 | <.001 | Female | 4.479 | 4.312 | 4.645 |
| | | | | | Male | 3.992 | 3.824 | 4.161 |
| Critical Thinking | 422 | 1 | 26.816 | <.001 | Female | 3.221 | 3.053 | 3.390 |
| | | | | | Male | 3.852 | 3.682 | 4.022 |
| Metacognitive Self-Regulation | 422 | 1 | .079 | .779 | Female | 4.564 | 4.453 | 4.675 |
| | | | | | Male | 4.541 | 4.429 | 4.654 |
| Time and Study Environment | 422 | 1 | 10.014 | .002 | Female | 5.488 | 5.376 | 5.600 |
| | | | | | Male | 5.232 | 5.119 | 5.345 |

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Effort Regulation | 422 | 1 | 1.142 | .286 | Female | 5.726 | 5.595 | 5.856 |
| | | | | | Male | 5.625 | 5.493 | 5.757 |
| Peer Learning | 422 | 1 | .000 | .987 | Female | 3.548 | 3.352 | 3.745 |
| | | | | | Male | 3.546 | 3.347 | 3.745 |

A hierarchical regression was performed in order to determine predictability of final course grade. Math aptitude was entered in the first step. Then all ten MSLQ subscale scores were entered in the second step via forced entry. Finally, gender was entered as the third step. In the first step, math aptitude was a significant predictor of final grades, $R^2 = .352$, $F(1,422) = 228.82$, $p < .001$. In the second step, the MSLQ subscales were added to the model and contributed a significant change in $\Delta R^2 = .136$, $F(12,410) = 9.076$, $p < .001$, for a total model $R^2 = .488$. The third step, entering gender, did not result in a significant change in $R^2$ ($\Delta R^2 = .002$, $F(1,409) = 1.534$, $p = .216$). This final step indicates that after accounting for math ability and MSLQ scores, gender does not significantly predict final grade.

In addition, a secondary analysis was applied to determine if the same hierarchical regression model, with predictors of math aptitude and MSLQ subscales and outcome final grades, works equally well for men and women. To compare the fit of the model, $R^2$ values were compared. The hierarchical regression was run for only males and only females. Then, Fisher's Z-test ($z = 1.45$, $p = .147$) compared the $R^2$ values of the models. The results were not statistically significant indicating that the predictors work equally well for men and women. Next, the structure of the models was compared using Steiger's Z. Using the hierarchical regression model for males, expected female outcomes, final grades, were calculated. Correlations between observed final grades and expected final grades for men and women, using the model based on male data, were then compared using Steiger's Z, ($Z_H = -2.11$, $p = .034$) with correlation between male and female expected grade used as the third correlation in the test. The results of Steiger's Z indicate the structure of the hierarchical regression model is not significantly different for both men and women.

**Achievement Level Differences**

In order to determine how self-regulation may differ amongst achievement groups, students were categorized into four clusters. Students were ranked according to both their math aptitude and final grade scores. Students below the median in math aptitude and final grade were categorized as low achievers. Overachievers were those students below the median in math aptitude but above the median in final grade. Students above the median in math aptitude but below the median in final grade were categorized as underachievers. Finally, students above the median in math aptitude and above the median in final grade were categorized as high achievers (Figure 1).

There were 167 low achievers, 73 overachievers, 67 underachievers, and 176 high achievers in the sample. The average math ability score for low achievers was $M = -1.50$ ($SD = 1.00$) with an average final grade of $M = .6555$ ($SD = .123$). For overachievers, the average math ability score was $M = -.973$ ($SD = .768$) with an average final grade of $M = .8552$ ($SD = .038$). The average math ability score for underachievers was $M = .94$ ($SD = .83$) with an average final grade of $M = .7178$ ($SD = .0762$). For high achievers, the average math ability score was $M = 1.52$ ($SD = 1.12$) with an average final grade of $M = .8893$ ($SD = .0521$).

A multivariate analysis of variance (MANOVA) was performed to determine achievement group differences on MSLQ subscale scores. Using a Wilks's Lambda, there was a significant effect of achievement group on MSLQ subscales ($\Lambda = .699$, $F(36,1209) = 4.336$, $p < .001$). The MANOVA was followed up by post hoc Hochberg's GT2 tests and confirmed with Games-Howell tests. Group differences at a $p < .05$ level are indicated in Figure 2. When comparing to low achievers the post hoc tests indicate both high achievers and overachievers have greater intrinsic motivation, task value, and self-efficacy but lower test anxiety. Only high achievers have greater metacognitive self-regulation and control of learning beliefs than low achievers. When comparing underachievers, both high achievers and over achievers have greater task value, self-efficacy, time and study management, and effort regulation. Only high achievers have greater intrinsic motivation and metacognitive regulation but lower test anxiety than underachievers. At a $p < .05$ level, no statistically significant differences were found between high achievers and over achievers or under achievers and low (Figure 2).

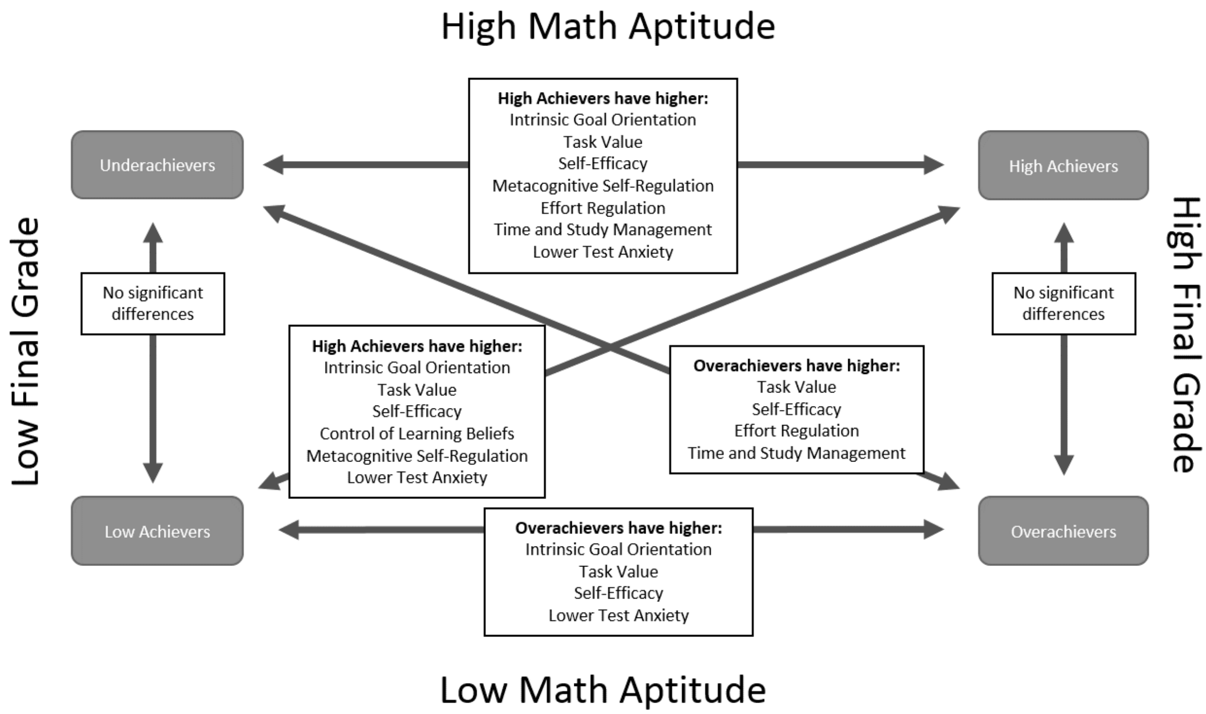

*Figure 2. Differences in MSLQ subscales by achievement group, Group differences significant at p<.05 level.*

## Discussion

Results indicate that the CCR adds significant predictive power when used in combination with ACT/SAT math scores. Combined, these scores can account for 32% of variance in final grades. In addition, adding MSLQ measures of self-regulation, the model accounts for 48% of variance in final grades. This indicates that self-regulation attributes are important for success in calculus I. Incoming math aptitude or pre-requisite knowledge are not enough to ensure success. This assertion is supported by the differences in MSLQ scores amongst achievement groups. While both high achievers and underachievers came in with above median math aptitude, underachievers ended the course with a grade below the median. Differences in self-regulation may account for the underperformance of underachievers as these students differed significantly on several MSLQ subscales compared to high achievers. Furthermore, low incoming math aptitude does not necessarily doom a student to failure. Self-regulation may again play a role as overachievers and low achievers scored significantly differently on several MSLQ subscales.

In particular, the motivational scales seem to play a role in student achievement. The only differences between low achievers and overachievers were in motivational areas. Overachievers reported higher intrinsic motivation, task value, self-efficacy, and lower test anxiety than low achievers. The same subscales, in the same direction, distinguish high achievers from both underachievers and low achievers. However, overachievers only reported higher task value and self-efficacy than underachievers. This indicates that students who are motivated to learn the material for the sake of learning rather than, or at least in addition to, for a grade, do better in the course. In addition, students who see the value in learning the material and how it will relate to other course work or their career perform better. Further, students who believe they can learn the material and believe they can perform well in the class achieve higher grades. Finally, test anxiety plagued both groups who finished the course below the median. However, there was no significant difference between overachievers and underachievers on test anxiety and intrinsic motivation. This indicates that while test anxiety and intrinsic motivation may be important factors for success, they are not the only reason for underperformance.

In fact, effort and time and study regulation may play a larger role in underperformance than anxiety. Both high achievers and overachievers reported higher effort and time and study regulation than underachievers. Students who performed well in the course were able to continue working even when they found assignments boring, plan their time wisely, and find environment conducive to studying. The overachievers scored highest on both the effort regulation and time and study environment subscales followed by high achievers, low achievers, and underachievers. This seems to indicate overachievers may have been able to surpass underachievers via their persistence in the face of boredom, elimination of distractions, and planning of their time. Given that the other significant subscale differences between overachievers and underachievers were task value and self-efficacy, it is possible overachievers persisted because they felt their effort would be fruitful both in terms of their efforts leading to immediate success in the class and the long term benefits of the course.

Finally, metacognitive self-regulation, monitoring one's own understanding, was the only cognitive learning strategy subscale which differed amongst achievement groups. High achievers reported higher metacognitive self-regulation than either underachievers or low achievers. This indicates the ability to accurately monitor one's understanding of the material and then take steps to correct misunderstandings contributes to calculus I success.

One of the most surprising results of this study is the lack of differentiation in learning strategies (elaboration, organization, and critical thinking) amongst achievement groups. These learning strategies are meant to promote deep, conceptual learning in which students take the knowledge they are learning and integrate it into their previous knowledge by making connections, organizing the information, and thinking about whether or not it makes sense given what they already know. The low mean scores for these scales indicates students may not be not be engaging in these learning strategies. This seems to lead to two possible conclusions. Either the coursework does not require students to engage in deeper learning, or the items on the questionnaire do not appropriately measure the constructs of elaboration, organization, and critical thinking as they apply to mathematics and calculus I in particular.

Additionally, organization showed a non-significant yet negative correlation to final grade. Many of the questions related to organization deal with underlining and highlighting of information. It may be the case that students who engage in these types of activities do so because they understand themselves to be weaker students and these are known strategies for learning. On the other hand, students may be engaging in ineffective underlining and highlighting strategies but yet believe themselves to be using productive strategies for learning, which leads to low scores despite what they perceive as effort. This may be particularly troublesome given females reported higher use of organization strategies.

Results show that after taking into account incoming math ability and MSLQ scores, there are no additional significant gender effects on final grade. In addition, math aptitude and MSLQ scores predicts final grades for men and women equally well and the structure of a hierarchical regression model for women is not be significantly different than a model for men. This indicates that gender is not an interaction variable that affects the strength or direction of the relationship between the predictors (math aptitude and MSLQ scores) and final grade.

However, woman entered the course with lower math ability scores than men. This means females are more likely to be below the median in math ability starting them in the low ability or overachiever group. However, females also reported lower intrinsic motivation, self-efficacy, and time and study environment management, as well as high test anxiety than men. Given the results on the relationship between self-regulation and achievement group, this means females are likely to remain in the low achievement group.

## Conclusions

Overall, results show incoming math ability is not enough to guarantee either success or failure. Students' motivations, cognitive learning strategies, and resource management also play a role in their course outcome. As such, any efforts to improve student success in calculus I should address students' self-regulation as well as pre-requisite mathematical understandings. In fact, it is not only students who enter with low math ability who are at risk of failure and need self-regulation addressed. Results indicate the difference in a high math ability students' outcome may also be attributable to self-regulation. Furthermore, addressing self-regulation may be particularly helpful for females whose self-reports are lower than their male counterparts. Efforts to increase women in STEM must take into account self-regulation.

Given that the majority of differences between achievement groups were not in cognitive strategies (i.e. elaboration, organization, critical thinking), addressing cognitive skills or learning strategies, which have often been the focus of self-regulation interventions (Hattie, Biggs, and Purdie, 1996), does not seem warranted. In addition, general study skills courses (e.g. Hofer, Yu, & Pintich, 1998) might not provide students with the domain-specific skills they need. Current research emphasizes the need for curricular integration of self-regulation and classrooms (Boekaerts & Corno, 2005; De Corte, 2000; Schunk, 2005). Therefore, efforts to address self-regulation in calculus should be integrated with the course.

Supplemental instruction models in which self-regulatory needs are addressed directly in relation to the mathematics content (Peterfeund, et al., 2007) may be beneficial. However, these programs may not adequately support underachievers who, according to their incoming math ability, may not believe they need the extra assistance upon entering the course. Furthermore, due to their low effort regulation, underachievers may not put forth the effort to partake in extra programs.

Addressing self-regulation within the classroom may have greater potential to reach underachieving students. For example, Cook, Kennedy, and McGuire (2013) found spending a lecture directly discussing self-regulation in a chemistry course significantly improved final grades for students who attended the lecture. Alternatively, De Corte, et al. (2011) advocate for an even deeper integration of self-regulation into the mathematics classroom creating what they call "powerful learning environments for self-regulation and constructive beliefs" (p. 163).

These powerful learning environments include variation in teaching methods and learning activities as well as a classroom culture that encourages active problem solving and self-regulated learning. Working with elementary school children on mathematics, Schunk's (1998) intervention incorporating these features led to increased achievement beliefs, including self-efficacy. Given self-efficacy was a distinguishing characteristic amongst achievement groups, this type of learning environment shows promise.

**Limitations**

The sample for the study leads to issues of external validity. The sample is from one university, during one semester, during which all students completed the same assignments. In particular, the exams which were 80% of the final grade were identical, only with slight form variations. Additional sampling from other universities would strengthen the conclusions of this study.

In addition, only 603 of the 2539 students in the course consented to participate in research. It is unknown if there was bias in students' self-selection into the study. Additionally, 29.68% ($N = 179$) students in the study were missing data. Withdrawn students were removed so the power of the math aptitude and MSLQ results to predict students to withdraw is unknown. In addition, much of the missing data is due to student lack of completing surveys or insufficient effort in responding to the MSLQ. These behaviors may indicate that a certain subpopulation of students who are unwilling to put forth effort were missing from the study. Given that assessing student effort is part of this study, missing this subgroup could potentially decrease validity.

**Future Research**

One area for future research is understanding why certain subscales do not show strong correlations with final grade. According to self-regulation theory, all of these subscales should be tied to final grades and learning gains. Why is it that the cognitive learning strategy scales have such low correlations with final grade? Future research could couple use of MSLQ subscales in a course with exams known to be conceptual in nature. In addition, future research should examine the MSLQ subscales themselves to determine if they are measuring elaboration, organization, and critical thinking as they apply to mathematics. The MSLQ was designed to measure self-regulation in any subject but it could be the case that mathematics requires skills that are not captured in the general language. The original MSLQ study showed higher final grade correlations on all three subscales when used with students from 14 different subjects. However, none of these subjects were mathematics. It appears as though work may need to be done on domain specific learning strategies.

Finally, how can self-regulated learning be supported in the calculus classroom? There is existing research on interventions for non-domain specific self-regulation instruction as well as interventions for elementary school mathematics (Hofer, Yu, & Pintrich, 1998; Schunk, 1998). Which of these interventions are transferable to the calculus classroom? What additional interventions may be successful? It is not enough to know that motivations, learning strategies, and resource management leads to better grades. The community must be able to intervene with students in order to help them develop these dispositions.

## Acknowledgements

I would like to acknowledge The Ohio State University Calculus Design Team, as this study is part of a larger effort to better understand our calculus students and how to best support them.

How Positioning as Teacher or Student May Change Validation of the Same Proofs

Erin E. Baldinger
University of Minnesota

Yvonne Lai
University of Nebraska-Lincoln

*Recent results such as by Wasserman, Weber, and McGuffey (2017) show the promise of using a particular type of task in undergraduate mathematics courses for secondary teachers: tasks that situate mathematics in pedagogical context. Yet their design deviated from previous recommendations that tasks necessitate pedagogical knowledge; some of their tasks can be solved with purely mathematical knowledge, even if pedagogical knowledge may be beneficial. We examine the phenomenon they observed, that the presence of pedagogical context appears to change the work of a mathematical task. We presented 17 practicing secondary teachers with the same set of proofs to validate, once in the context of teaching secondary mathematics, and then in taking a university mathematics course. We argue that the construct of social positioning – as a student or teacher – explains differences in secondary teachers' proof validations as well as the problem of disconnect between undergraduate mathematics and secondary teaching.*

*Keywords:* Mathematical Knowledge for Teaching, Proof Validation, Secondary Teachers

One enduring question of undergraduate programs for preparing secondary teachers is: how do undergraduate mathematics experiences inform future secondary teaching? As Felix Klein lamented in 1908, for the typical schoolteacher, "university studies remained only a more or less pleasant memory which had no influence upon his teaching" (Klein, 1932, p. 1). Many teachers of this century, particularly secondary teachers, may still concur that undergraduate mathematics do not much impact their current teaching (Goulding, Hatch, & Rodd, 2003; Ticknor, 2012; Zazkis & Leikin, 2010), whether or not they agree that undergraduate studies were "pleasant".

To mend the discontinuity between undergraduate mathematics preparation and teaching practice, mathematics educators advocate for using tasks that situate mathematics in pedagogical contexts. The recommendation spans elementary (e.g., Stylianides & Stylianides, 2010) and secondary levels (e.g., Lai & Howell, 2016; Wasserman, Fukawa-Connelly, Villanueva, Mejía-Ramos, & Weber, 2016). Empirically, pilot programs based on this recommendation show promise, with teachers perceiving undergraduate mathematical content and practices as relevant (Wasserman, Weber, & McGuffey, 2017), and teachers doing mathematics that may not have happened without a pedagogical context (Stylianides & Stylianides, 2010). From these authors' work, along with others (e.g., Biza, Nardi, & Zachariades, 2007), we can conclude that pedagogical context does draw out mathematical reasoning and utility in a way that tasks without pedagogical context do not.

What mechanism lies behind these optimistic results, especially in face of prior findings of teachers' perceptions that their undergraduate preparation is inapplicable to their teaching? One explanation is the process of mathematization, meaning that teachers derive from the pedagogical context a "set of conditions with which a possible solution to a task needs to comply" and reason through these constraints mathematically (Stylianides & Stylianides, 2010, pp. 164–165). Figure 1(a) shows an example of a task featured in their study, on judging the appropriateness of a definition of even number. Doing this task well involves coordinating mathematical reasoning, such as about characteristics of a good mathematical definition, with pedagogical reasoning, such as about what is developmentally or curricularly appropriate for students. It is impossible to do the tasks without bringing in some pedagogical knowledge.

Stylianides and Stylianides argued that the necessity of both mathematical and pedagogical reasoning motivates teachers to see mathematical knowledge as useful for and usable in teaching.

Yet mathematization due to the necessity of pedagogical reasoning cannot explain the results of Wasserman et al. (2017), whose tasks do not require pedagogical reasoning, even if it may be beneficial. A representative task from their study is shown in Figure 1(b), on constructing examples with particular mathematical properties. It is possible for a teacher to respond to this task based on knowledge of the curriculum; however, it is also possible that the teacher can rely strictly on mathematical knowledge accrued through standard secondary and undergraduate coursework. To explain why working on such tasks helped to convince teachers of the utility of undergraduate mathematics, Wasserman and colleagues cited Lobato's (2012) conceptualization of transfer. Wasserman and colleagues argued that tasks that situate mathematical practices in teaching scenarios help teachers see the practices as part of teaching. Consequently, in accordance with Lobato's (2012) theory, Wasserman and colleagues' findings that teachers did knowingly transfer mathematical ideas from undergraduate mathematics to teaching practice was possible because they perceived these mathematical ideas as applicable to their teaching.

(a)
Use the two considerations [of continuity of mathematics in the curriculum, and of intellectual honesty, meaning honest to mathematics as a discipline and honoring of students as learners] to discuss the appropriateness of the following textbook definitions for elementary school students:

(1) An even number is a number of the form $2k$, where $k$ is an integer.
(2) An even number is a whole number that it is a whole number times 2.
(3) An even number is a natural number that is divisible by 2.
(4) An even number is a number that has 0, 2, 4, 6, or 8 in the ones place.
(5) An even number ends in 0, 2, 4, 6, or 8.
(6) An even number is a number that is not odd.
(7) A whole number is even if it is another whole number times 2.

Stylianides and Stylianides (2010, pp. 167–168)

(b)
[Consider each statement, made by a teacher:]

- "The perimeter is just the sum of all side lengths"
- "Remember, to multiply a number by ten, just add a 0 to the end"

Determine for what set(s) of objects the statement is true. If there are any, provide an example of a set(s) of objects for which the statement is not true.

Discuss in what mathematical contexts might the statement by the teacher be appropriate, if ever? When might it be inappropriate, if ever?

Wasserman, Weber, and McGuffey (2017, p. 9)

*Figure 1. Examples of tasks with pedagogical context, from (a) Stylianides and Stylianides (2010) and (b) Wasserman, Weber, and McGuffey (2017).*

The common feature of both the above studies is tasks that place mathematics in the context of teaching. Stylianides and Stylianides contended that for tasks to promote mathematical knowledge as applicable to teaching, solutions "cannot be sought in a purely mathematical space, but rather in a space that intertwines content and pedagogy" (p. 164). However, Wasserman and colleagues' tasks do not satisfy this criterion, while still resulting in teachers seeing mathematical knowledge as applicable to teaching. *The differences in their tasks raises the question of whether the most salient characteristic of tasks with pedagogical context is that they have pedagogical contex*t. In other words, it may be possible that simply placing a task in pedagogical context is enough to change how a teacher perceives the work of the task.

## The Present Study

Our purpose is to investigate the phenomenon that *the presence of pedagogical context changes the work of a mathematics task*. We approach the problem of disconnection between undergraduate mathematics preparation and secondary teaching practice by seeking to understand why being situated in teaching appears to make a difference, even when the task does not necessitate pedagogical reasoning. Throughout this paper, we use *pedagogical context* refer to contextual elements of teaching practice, such as as student talk or curriculum materials. In contrast we use *university context* to refer to tasks that are set in the context of an undergraduate mathematics course, and do not have contextual elements related to teaching. Distinguishing these two contexts explicitly highlights the potential differences in teachers' undergraduate mathematical preparation and the mathematical work of their teaching.

We conducted an interview-based study in which we presented 17 practicing secondary teachers with two parallel tasks, one in the context of teaching high school mathematics, and one in the context of taking a university mathematics course. The prompt for the tasks are shown in Figure 2. Although neither version requires pedagogical reasoning, we hypothesized that the presence of pedagogical context would prompt teachers to activate different resources due to norms and expectations of either teaching or mathematics. Our research questions were: (1) *In what ways does the presence of pedagogical context change teachers' reasoning on a mathematics task?* (2) *What norms and expectations are used in reasoning about these tasks, and in what ways do these norms and expectations relate to the context of learning undergraduate mathematics or teaching secondary mathematics?*

| Below are three responses. Determine whether each *student's proof* is valid. | Below are three responses. Determine whether each *proof* is valid. |

*Figure 2. Tasks used in the present study. Three candidate proofs of the statement were provided to participants, labeled as "Kate's answer", "Leon's answer", and "Maria's answer" in Task (a), and labeled as "1", "2", and "3" in Task (b). The same candidate proofs were presented both times. Differences in the tasks are indicated using italics here; they were presented without emphasis in the study.*

Based on the results of these interviews, we argue that *social positioning* – as a student or as a teacher – can influence teachers' reasoning on a mathematical task. We elaborate two key implications of this phenomenon for research and practice.. The implication for research, particularly on teachers' knowledge of mathematics, is that researchers should be alert to how priming as a teacher education student or as a practicing teacher can shape the way that mathematical knowledge is activated. Researchers must consider the potential effects of positioning in designing protocols and in interpreting the resulting data; the validity of conclusions drawn may depend on how teachers understand the purpose of a task. The implication for the practice of teacher education is that teachers' thinking in mathematics coursework may not predict how teachers' mathematical knowledge for teaching is activated in the classroom, even when the content is directly related to what they teach. Instructors of mathematics courses for teachers should attend to how teachers' responses may prioritize perceptions of what is "expected" in a mathematics course and how these expectations may contrast with expectations for K-12 teaching and the instructor's intended expectations.

Below, we begin with an overview of the construct of position and then discuss why proof validation tasks were a strategic choice for this investigation. We then review literature on teachers' conceptions of proof, focusing particularly on studies where secondary teachers were asked to validate proofs. After discussing our data, methods, and results, we turn to how our finding of the role of position can be used to explain results of prior literature, and we conclude with implications for research and practice.

## Theoretical Perspective

### Position

To interpret responses to the tasks in this study, we turn to the construct of *position*, as it is used in the theory of practical rationality. Herbst and Chazan (2003) introduced the term *practical rationality* to describe the grounds on which teachers' actions can be justified or critiqued. As they observed, the rationality behind teachers' actions "cannot be reduced to individual wisdom, gift, sensibility or skill, since these are common to people who perform the same job; yet they are not all part of the explicit regulations that describe this job" (p. 2); actions in teaching are shaped by combination of sources including teachers' own convictions and knowledge – and also, importantly, the demands that their *instructional system* places on the persons who take on the *position* of teacher and student.

The notions of instructional system and position are both relevant to our work. As Herbst and Chazan conceptualize it, an *instructional system* involves teachers taking student work on a task and assigning value to it in terms of the mathematical knowledge it represents. For example, a student's work on a proof task might represent knowledge of a specific proof technique, ability to cite a particular theorem correctly, or perhaps understanding of what constitutes proof. It is up to the teacher to determine what knowledge the student's work can represent and to what degree.

**Position of teacher.** No matter the instructional system, a person's position is defined by the social rules they must adhere to. Based on empirical work, Herbst and Chazan (2011) argued that the social rules for teachers come from four main obligations: the *discipline* of the subject taught, the *individual* students, the *interpersonal* culture of the class, and the *institution* where the teacher teaches. In brief, the disciplinary obligation demands that a teacher's actions are consistent with the practices of mathematics as a discipline; the individual obligation says that every student has the right to be treated according to their individual being and feeling; the interpersonal obligation asks that the teacher share the class space in culturally appropriate ways; and the institutional obligation demands that the teacher comply with the norms and expectations of their department, school, district, or any larger system such as professional unions.

**Position as student.** While Herbst and colleagues have focused primarily on identifying and describing the practical rationality of teachers, Aaron has built on this work to develop a theory of practical rationality of students. Aaron (2011) argued that being a student is itself a cultural practice and proposed four key obligations of the position of student. Three coincide with Herbst and Chazan's (2011) obligations: *individual*, *interpersonal,* and *institutional*. However, because students are learning the discipline, they are unlikely to be committed to the discipline; however, they are committed to *truth* based on personal notions of true and false.

**Activities concerning proof and their subjectivity**

Mathematical proof is a predominant focus of many undergraduate mathematics courses, including those required for secondary teachers (Conference Board of the Mathematical Sciences, 2012; Tatto et al., 2012). Proof-based courses may also be where secondary teachers feel most disconnected to future teaching (e.g., Ticknor, 2012; Wasserman et al., 2016), despite the centrality of proof and formal reasoning to secondary mathematics (National Council of Teachers of Mathematics, 2000). For our study, tasks with proof activities are a strategic site for studying the influence of pedagogical context because of the potential for connection to teaching, the empirical documentation of disconnection, and also – as we discuss next – the inherent subjectivity of proof activities. Subjectivity is key to this study as it means that judgement can be shaped by a person's norms and expectations, which are shaped by that person's position..

In a review of literature on mathematical proof, Inglis and Mejía-Ramos (2009) organized mathematical activities concerning proof into three categories. These activities are constructing proof; reading proof, consisting of comprehending and validating a purported proof; and presenting proof. As Selden and Selden (2003) argued, validation – determining whether a purported proof of a statement actually establishes that statement mathematically – is "inextricably linked" to constructing proof as well as presenting a proof; both the latter activities involve the ability to determine whether a statement is adequately justified (p. 9).

Understanding the process of proof validation is helpful for understanding mathematics learning and teaching from a socio-cultural perspective. How students and teachers determine what constitutes an acceptable mathematical explanation and justification is at least in part socially negotiated (Yackel & Cobb, 1996). Recent studies have demonstrated the subjectivity of validation across different populations, including mathematicians (Mejía-Ramos & Inglis, 2009; Miller, Infante, & Weber, 2018). These studies call attention to how validation is shaped by how much expertise or competence is attributed to the author who produced the proof. As Weber and Alcock (2005) argued, "Determining whether a warrant would be considered acceptable by the mathematical community may inherently involve a degree of subjectivity" (p. 38).

It has been claimed that mathematical truth is objective, because deductive reasoning is purely analytic (e.g., Hempel, 1945). From this perspective, then, why has proof validation been shown empirically to be subjective? One explanation is how proof validation is operationalized, as observed by Bass (2015). Even if there is such a thing as an ideal proof,

> For mathematical claims of any reasonable complexity, mathematicians virtually never produce complete formal proofs. Indeed, requiring that they do so would cause the whole enterprise to grind to a halt ... Proving a claim is, for a mathematician, an act of producing, for an audience of peer experts, an argument to convince them that a proof of the claim exists. (Bass, 2015, p. 5)

In sum, we hypothesize that validation of proofs with potential gaps, such as those produced by students, would be particularly susceptible to subjectivity. Moreover, reading and validating student work is an inherent part of teaching. For these reasons, we designed the present study around validation of student proofs.

## Literature Review

Prior research has demonstrated that teachers have wide variation in their conceptions of proof. For example, teachers may emphasize different criteria when determining whether or not an argument counts as a proof (Knuth, 2002a), and these conceptions may change when intentionally set in a school context (Knuth, 2002b). Buchbinder (2018) suggested that teachers are likely to bring both mathematical and pedagogical considerations to bear when evaluating proofs. Three factors appear to be particularly salient in influencing teachers' conceptions of and validations of proof: (1) the presence or absence of algebraic notation; (2) the use of verbal representations; and (3) the use of examples in proof.

**Presence or Absence of Algebraic Notation.** Both students and teachers have expressed sensitivity to algebraic notation in proofs in particular contexts. Healy and Hoyles (2000) found that students believed that proofs with algebraic notation would receive the best scores from their teachers, even though it was not the type of proof they would have written for themselves. When asked to predict what their students would value in proof, teachers "appeared to overestimate the extent to which their students would make judgments that were based on mathematical content rather than simply on form" (p. 407).

Algebraic notation can give proofs a recognizable form or structure, and it can also contribute to proofs being perceived as general. Tabach et al. (2011) found that some teachers ascribed more generality to a proof when it was represented using algebraic notation than verbal representations. This emphasis on algebraic notation, expressed by teachers, highlights the implicit values of structure and generality. In the case of the students in Healy and Hoyles' (2000) study, it also highlights their perception that more explanatory proofs were less valued by their teachers, as these students did not perceive the algebraic notation as being helpful in understanding a proof.

Investigating the relative value placed on algebraic notation in different contexts using parallel tasks would shed light on the ways in which these views about algebraic notation may relate to proof validation.

**Use of Verbal Representations.** Despite believing that algebraic notation would earn the highest scores, students may acknowledge their own preference for verbal proofs, which they saw as being more explanatory (Healy & Hoyles, 2000). Yet Tabach et al. (2010) found that teachers tended to treat verbal proofs as "mere examples" and did not necessarily recognize explanatory value that students saw in them. One hypothesis is that teachers found the verbal proofs less transparent than algebraic proofs (Tabach et al., 2011). However, most teachers in Healy and Hoyles' (2000) study selected a verbal representation as the way they would approach a particular proof. In interviews, they expressed that "it was more important that the argument was clear and uncomplicated than that it included any algebra" (p. 413).

These somewhat contradictory results related to the role of verbal representation in proof leads to a question about how context may influence teachers' values related to the purpose of proof, and, in turn, their approach to proof validation.

**Use of Examples.** Teachers and students also attend to the role examples play in proof. The students in Healy and Hoyles' (2000) study found examples to be helpful in developing understanding, even while they recognized them as not sufficient for proof. Buchbinder (2018) investigated both students' and pre-service teachers' perceptions of the role of examples in proofs in the context of proving or refuting universal statements. She found that the pre-service teachers valued student work that tested multiple examples, even while acknowledging the limitations of that approach.

We explore these factors influencing proof validation by engaging in a direct comparison of tasks situated in pedagogical and university contexts. To our knowledge, no existing study of proof validation compares reasoning about the same proofs across different contexts. Such a comparison may shed light on how previous results on proof validation by teachers fit together.

## Data & Method

### Rationale

To determine the ways in which the presence of pedagogical context changes teachers' reasoning on mathematics tasks, we asked teachers to each work on the same set of parallel tasks. One task featured the pedagogical context of teaching secondary mathematics; the other situated the participant as a student in a university mathematics course. We chose to contrast the pedagogical secondary context with a university context because the most recent and intensive context in which secondary teachers experience proofs is as university students. These two contexts thus serve as productive contrasts to inform future work in teacher education.

Figure 3 shows the set of tasks used to address the research questions. The university context could be considered a pedagogical tertiary context; however, we note that the task situates the participant as a student, not a professor. Moreover, responses from our participants indicate that they were reasoning from the stance of student, not university instructor.

| Set of Tasks with Pedagogical Context | Set of Tasks with University Context |
|---|---|
| In a unit on mathematical justification, you ask your high school students to prove the following statement:<br>*When you multiply 3 consecutive natural numbers, the product is a multiple of 6.*<br>Below are three responses. Determine whether each student's proof is valid. | In a unit on mathematical justification, your mathematics professor asks you to consider proofs of the following statement:<br>*When you multiply 3 consecutive natural numbers, the product is a multiple of 6.*<br>Below are three responses. Determine whether each proof is valid. |
| **Kate's Answer**<br>A multiple of 6 must have factors of 3 and 2. If you have three consecutive numbers, one will be a multiple of 3. Also, at least one number will be even and all even numbers are multiples of 2. If you multiply the three consecutive numbers together the answer must have at least one factor of 3 and one factor of 2. | **1.**<br>A multiple of 6 must have factors of 3 and 2. If you have three consecutive numbers, one will be a multiple of 3. Also, at least one number will be even and all even numbers are multiples of 2. If you multiply the three consecutive numbers together the answer must have at least one factor of 3 and one factor of 2. |
| **Leon's Answer**<br>$1 \times 2 \times 3 = 6$.<br>$2 \times 3 \times 4 = 24 = 6 \times 4$.<br>$4 \times 5 \times 6 = 120 = 6 \times 20$.<br>$6 \times 7 \times 8 = 336 = 6 \times 56$. | **2.**<br>$1 \times 2 \times 3 = 6$.<br>$2 \times 3 \times 4 = 24 = 6 \times 4$.<br>$4 \times 5 \times 6 = 120 = 6 \times 20$.<br>$6 \times 7 \times 8 = 336 = 6 \times 56$. |
| **Maria's Answer**<br>$n$ is any whole number.<br>$n \times (n + 1) \times (n + 2) = (n^2 + n) \times (n + 2)$<br>$= n^3 + n^2 + 2n^2 + 2n$<br>Cancelling the n's gives $1 + 1 + 2 + 2 = 6$. | **3.**<br>$n$ is any whole number.<br>$n \times (n + 1) \times (n + 2) = (n^2 + n) \times (n + 2)$<br>$= n^3 + n^2 + 2n^2 + 2n$<br>Cancelling the n's gives $1 + 1 + 2 + 2 = 6$. |

### Data Source

**Participants.** We interviewed 17 practicing secondary mathematics teachers who had 1 to 14 years of experience teaching, and who had worked with a variety of grade levels and courses. These teachers represent a convenience sample across two sites. We, the two authors, conducted interviews at our own sites, and we each had pre-existing relationships with or connections to the interview participants. As such, we acknowledge the role these relationships may have played in our data collection. We both identify as mathematics educators, but we take on different roles in that space. The first author interviewed ten participants and was a mathematics methods instructor for nine of these participants during their teacher preparation program. The tenth participant was a cooperating teacher at a partner school site. The second author interviewed seven participants and was a mathematics content course instructor for five of these participants. The other participants taught in the same department as one of the second author's former students. Throughout the paper, we refer to participants from the first site using the letter A (e.g., A07) and from the second site using the letter B (e.g., B02).

**Tasks.** To ensure that the pedagogical context was realistic, we used existing tasks that had been extensively reviewed as representing mathematical knowledge for teaching. For the research question reported, we used tasks, shown in Figure 3, based on the TEDS-M released item #MFC709 (TEDS-M International Study Center, 2010), which represents pedagogical content knowledge (Tatto et al., 2008). Healy and Hoyles (2000) used a similar task in their interviews about proof validation with secondary students and their teachers. Healy and Hoyles' (2000) use of the task shows the potential inherent in the task for illuminating different values and norms that might influence proof validation.

**Protocol.** All participants completed the pedagogical context first and the university context second, with personal questions before each context to prime their identities in that context. Prior to the tasks with pedagogical context, we asked the participants how many years they had taught and what courses they were currently teaching. Then, after the tasks with pedagogical context and before the university contexts, we asked participants to name the courses they took in university and identify their favorite course. In each context, after the initial validation of the proofs, we asked parallel follow-up questions to probe participants' thinking further. Two questions we asked included: (1) Would you judge the proof as "partially" valid or invalid? [If the participant concurred] What makes this judgement better than "valid" or "not valid"? (2) Would you agree or disagree with the statement, "Kate's Answer/Proof 1 is less valid because it does not use algebraic notation." This question targeted potential belief in the importance of algebraic notation in proof (e.g., Knuth, 2002a, 2002b; Tabach et al., 2011).

### Data Analysis

Our analysis occurred in four phases. We first coded all of the interview responses related to the pedagogical context. We identified the reason each proof was judged valid or invalid, and reasons for agreement or disagreement about the role of algebraic notation in proof. We developed codes based on existing literature and discussion of interviews from each site. During the coding process, any cases that were unclear were discussed and consensus was reached on all codes. The second phase of analysis involved applying the same coding process to all interview responses related to the university context. Coding each context separately enabled us to interpret the reasoning expressed in each context independently, rather than inferring a participant's reasoning in the university context based on the reasoning they expressed in the pedagogical context. In the third phase of analysis, we looked across contexts for differences in the determinations about the proofs, participants' reasoning, and agreement or disagreement about the role of algebraic notation. We identified changes at the level of considering all participants and at the level of individual participants. Finally, we used the patterns evident in the third phase of analysis to generate themes connected to the research questions.

## Findings

Clear differences emerged in teachers' validations of proof based on context. First, we report teachers' validations of the empirical proof. Next, we explore the role explanation might play in proof validation. Third, we unpack teachers' validations of verbal proofs. Finally, we describe the importance of algebraic notation in proof by context.

**Examples are Not Proof**

As shown in Table 1, teachers consistently judged Leon's Answer/Proof 2 to be not valid in both contexts. They reasoned that even though the examples he selected were correct, examples were not sufficient for provide the statement in all cases.

*Table 1. Validation of Leon's Answer/Proof 2, by context*

| | Pedagogical Context | University Context | Total |
|---|---|---|---|
| Valid | 3 | 0 | 3 |
| Not Valid | 14 | 17 | 31 |
| Other | 0 | 0 | 0 |
| Total | 17 | 17 | 34 |

The teachers who judged Leon's Answer valid in the pedagogical context did so because they wanted to give Leon credit for the elements of the proof that were correct, while acknowledging that it was not a general proof. For example, one teacher said, "It's valid for what he did, but not valid for every number" (A07). Another said,

> It's not a proof *per se* but giving multiple examples and showing that they are all correct, and unfolding them, showing that 24 is 6 times 4, I just find that his reasoning is very strong. It's like induction. I would absolutely consider both of these [Kate and Leon] to be equally strong, but that they are different thinkers. (B02)

The third teacher in this category said, "Leon had concrete examples but didn't generalize it. He didn't take it a step further and show why it always works." This participant continued:

> I'm used to grading on, "You've got a good start," but I guess if I had to grade on a passing/not passing, then I'd have to have a better idea of the expectations for this class? You know, there's times that at the beginning, I'd say, "Yes! Good job! You're showing instances, you're understanding the concept." (B07)

In terms of the professional obligations identified by Herbst and Chazan, these responses negotiate between the obligation to the *individual* student and the obligation to the *discipline*. The three teachers wanted to give credit to Leon for the aspects of his work that were correct, while also acknowledging that in mathematics, empirical proof schemes do not establish a mathematical statement. In the university context, there is no obligation to fellow students, as the proofs were presented without authorship; however, the universal judgment of Proof 2 as not valid can be interpreted as obligation to the *truth*.

This was emphasized further by teachers who expressed a reluctance to commit to calling a proof either valid or not valid. When given the choice, many teachers revised their judgements from valid or not valid to partially valid or invalid. For example, one teacher who judged Leon's Answer to be invalid in the context of teaching when forced to choose between just valid and invalid described more of a middle ground when given the opportunity. Almost none of the teachers revised their response to partial validity in the university context.

**Role of Explanation Varies by Context**

Teachers' validations of Maria's Answer/Proof 3 revealed interesting differences around the reasons for judging the proof to be valid or invalid. For the most part, as shown in Table 2, participants in both contexts found this proof to be invalid. Those who judged this proof to be valid still identified problematic elements of the proof.

*Table 2. Validations of Maria's Answer/Proof 3, by context*

| | Pedagogical context | University Context | Total |
|---|---|---|---|
| Valid | 2 | 3 | 5 |
| Not Valid | 14 | 14 | 28 |
| Other | 1 | 0 | 1 |
| Total | 17 | 17 | 34 |

Looking more closely into the reasons participants judged these proofs to be invalid, we found variation by context. As shown in Table 3, in the pedagogical context, the teachers focused primarily on the incorrect algebraic step of "canceling the *n*'s". In the university context, the lack of explanation of steps in the proof became more salient. This difference could be explained by an obligation to the *institution*, which determines curricular expectations. Algebraic properties are developed in middle school and secondary mathematics, whereas proof-based courses in university may emphasize justifying steps of deductive arguments more than particular algebraic properties. These changes in rationale demonstrate the potential for pedagogical context to influence the process of validation, as well as suggest how position may influence reasoning.

*Table 3. Reasons given for judging Maria's Answer/Proof 3 to be invalid, by context*

| Not valid because… | Pedagogical context | University Context | Total |
|---|---|---|---|
| Incorrect algebraic step ("canceling") | 11 | 6 | 17 |
| Does not explain all the steps | 1 | 4 | 5 |
| Incorrect algebra AND does not explain all the steps | 0 | 1 | 1 |
| Participant assumed algebra would eventually work out, but not enough steps are shown | 1 | 2 | 3 |
| Other reason | 1 | 1 | 2 |
| Total | 14 | 14 | 28 |

**Role of Algebraic Notation Varies by Context**

The majority of participants changed their validations for Kate's Answer/Proof 1 based on context. Overall, participants found the proof valid in the pedagogical context and not valid in the university context. Table 4 shows these shifts. Ten teachers changed from valid in the pedagogical context to invalid in the university context. Among remaining participants, five judged the proof valid in both contexts, and one judged the proof invalid in both contexts.

*Table 4. Validations of Kate's Answer/Proof 1, by context*

| | Pedagogical context | University Context | Total |
|---|---|---|---|
| Valid | 16 | 5 | 21 |
| Not Valid | 1 | 11 | 12 |
| Other | 0 | 1 | 1 |
| Total | 17 | 17 | 34 |

The most common rationale for determining the proof was valid in the pedagogical context was that teachers judged each part of Kate's reasoning to be true (11 participants). As one teacher said, "The argument's pretty solid, talking about the different factors and what it means to be consecutive numbers and why there has to be a multiple of 2 and a multiple of 3" (A03).

In the university context, of the 11 participants determining the proof was invalid, 8 participants reasoned that the proof was invalid because it did not contain algebraic notation. As one participant said,

> Even though I know what's going on, in general terms, at a college level you should use general terms, your *n*, *n* + 1, *n* + 2 ... So, I know the understanding's there, but *at the college level, I feel like your ability to prove things formally is more at stake*. (A09, emphasis ours)

Participants A09 shows sensitivity to the obligation of *institution*, that in the university context, what is expected of students is proving things formally.

We now report the results of asking participants whether they agreed or disagreed with the statement that "Kate's Answer/Proof 1 is less valid because it does not use algebraic notation". Participants' responses to this question also varied by context. Table 5 shows these results.

*Table 5. Teachers' views on whether "Kate's Answer/Proof 1 is less valid because it does not use algebraic notation", by context*

| | **Pedagogical context** | **University Context** | **Total** |
|---|---|---|---|
| Agree: The proof is less valid | 1 | 10 | 11 |
| Disagree: The proof is NOT less valid | 15 | 5 | 20 |
| Other | 1 | 2 | 3 |
| Total | 17 | 17 | 34 |

These responses show the strong role that algebraic notation played in judgements about Kate's Answer/Proof 1. In the pedagogical context, one participant said "The whole point of doing proofs *in high school* is that they know the math, *the goal isn't to show the algebra*. Normally for me, it's *more about the explanation* being the important part of what they are doing" (A02, emphasis ours). This teacher and others explained that their goal for proofs is not having students state formal theorems or use particular mathematical notation. Instead, they are interested in the logical and explanation the student provides. The theme of the logic of the argument as distinguished from the notation used, in the pedagogical context, is echoed in Healy and Hoyles' (2000) findings, where teachers prioritized the meaning of the argument above the notation, due to the obligation to *individual* students. In their study, teachers justified their preference for Kate's proof by saying the explanation would likely make most sense to students.

In the university context, participants in our study reasoned differently about algebraic notation. As A05 said, "I feel like that *by the time you get to a university math course* your algebra skills are already there, you're strong with algebra, so *you should be able to manipulate the numbers and variables* so you could do that" (emphasis ours). A05 is saying that algebraic notation should be understood by the time a person was in college math. Other participants emphasized the perceived judgements of their own university professors: "In the college level, I would agree with that. *I don't think any of my college professors would have given me credit for something without algebraic notation*" (B07, emphasis ours). These responses parallel that of Healy and Hoyles' (2000) secondary students participants, who estimated that their teachers would award more credit to proofs with algebraic notation.

The university context also revealed a sense of negotiating between the obligation to *truth* and the obligation to *institution* expectations. One teacher said of Proof 1, "I think it's valid. But a college professor would call it invalid" (A06). This teacher judged Kate's Answer valid and Proof 1 as not valid. As another participant with the same validation responses put it, "It's very much playing the game of how your professor likes proofs" (B02).

The teachers' recognized that they had different responses for different contexts. For example, one said,

> *Knowing what was expected of me at that level*, *I would agree with that, because it doesn't have formal use of variables and notation*. It's hard to say because *I disagree so much at the high school level*. I agree with it because when you get into that level of mathematics, the thinking should be there for sure, but knowing how to formally construct a proof I think is one of the expectations you need to follow. *That doesn't take away from how important I think the understanding is.* (A09, emphasis ours)

These responses reflect different obligations as a university student as opposed to a secondary mathematics teacher.

Some teachers were mostly comfortable with how their opinions had changed based on the context, because they felt that it was appropriate to have different expectations. For instance, one participant said, "I want to have high expectations for high school students, *but they haven't seen this kind of reasoning before*, whereas university students should be more familiar for this, at least in theory. So there needs to be a higher expectation there" (B03). This response can be seen as based on teachers' obligation to the *individual* students in the pedagogical context.

## Discussion

Our findings corroborate previous findings that pedagogical context does change the work of a mathematics task, and in particular, that they influence the process of proof validation. We make three points in this discussion. First, the construct of position, from the theory of practical rationality, can be used to explain differences in proof validations, both in our own findings and in the literature. Second, to researchers, we suggest how and why the role of position must be taken into account in both research design and data interpretation. Finally, to instructors of mathematics courses for teachers, we suggest why position may play an important role in secondary teachers' perception of disconnect between their university mathematics experiences and their teaching practice.

In the theory of practical rationality, a person is subject to the obligations of their context and must sometimes negotiate between them. In this study, when participants were positioned as teachers, they negotiated between obligations to *individual* students and to the *discipline*, and at times brought in obligations to the *institution*. When participants were positioned as university students, they negotiated between obligations to *truth* and obligations to *institution*. The different sets of obligations led the participants to come to different conclusions about the validity of proofs in different contexts.

The results related to Leon's Answer/Proof 2 highlight the tendency of teachers, especially in a pedagogical context, to draw on pedagogical considerations for an individual student when they are thinking about validity. Many teachers talked about valuing what was correct in Leon's work, even while acknowledging it was not a proof. This difficulty with the binary scale of valid or invalid for judging proofs connects to findings from Buchbinder (2018). Including the option of partial validity highlights some of the pedagogical considerations teachers recognize when doing proof validations. This result is even more striking because almost none of the teachers opted to judge proofs as partially valid in the university context. Participants' discussions of

Maria's Answer/Proof 2 reveal what teachers perceive is valued by the *institution* of university, and how this differs from teaching. While in the pedagogical context teachers wanted to acknowledge individual students' progress, in the university context they were much stricter in their validations. Many participants talked about how Proof 1 needed "more math". This is another way in which position influences validation. The cultural expectation of proofs requiring particular organizational structures or particular notations, especially in the *institution* of university, plays a role in validation separate from judging the mathematical content.

The role of cultural expectations brings us to the importance of position in research design and data interpretation. Cultural expectations by position explain differences between our findings and those of Tabach and colleagues who found that teachers rejected proofs written with verbal representation (Tabach et al., 2010), and over-valued proofs with algebraic notation while under-valuing verbal proofs (Tabach et al., 2011). Our results from the university context corroborate theirs, and contradict theirs in the pedagogical context. An analysis of the protocols in both these studies suggests that the teachers may have been put in the position of student, or at the very least, participants were *not* positioned as teachers. In these studies, teachers began their participation by solving pure mathematics problems, and then asked to validate proofs.

It is well-known that stereotype threat can impact results in mathematics education studies, due to invoking beliefs about identity; similarly, we argue that positioning can impact results, as shown in our study where we asked participants to validate the same set of proofs and only varied the task by position. The different positions activated different obligations, which led to judging mathematical arguments differently. In research in undergraduate education, findings about future teachers as undergraduate students are often used to draw conclusions about what teachers are capable of doing in the field. If it is unclear how participants are positioned by the research design, the conclusions drawn about the teachers may well be incorrect.

Finally, the construct of position may be used to make sense of the problem of disconnection between the undergraduate mathematics experiences and teaching practice of secondary teachers. The obligations that an undergraduate mathematics student is subject to may be very different from the obligations of a secondary teacher. Our findings suggest that when engaging in validation, a proof activity that is vital to success in any proof-based course, teachers may interpret the activity differently in different contexts. Thus the reasoning that future secondary teachers use in undergraduate coursework, and thus the reasoning that instructors are evaluating, may not actually predict how the teachers would reason when they are teaching a high school class. In personal conversations with mathematicians, the authors of this paper have heard laments that undergraduate students, including future secondary teachers, exaggerate the importance of algebraic notation and do not focus enough on the logic of an argument. What if this behavior is more due to expectation than to inclination or ability?

Our findings underscore and qualify the promise of using tasks with pedagogical context to bridge the gap between undergraduate mathematics experience and secondary teaching practice. Positioning future teachers as teachers engages them in reasoning that may be more predictive of how they reason when they teach. This means that the feedback that they receive on these tasks is more likely to be beneficial and influential to their future teaching. At the same time, there is also more work to be done to understand how future teachers, who do not yet have experience teaching, interpret the obligations of pedagogical context, as well as how pedagogical context layered into a university context may differ from the pedagogical context of actual teaching.

Red X's and Green Checks: A Preliminary Study of Student Learning from Online Homework

Allison Dorko
Oklahoma State University

*Homework is thought to play an important role in learning of mathematics. Undergraduate mathematics students spend more time doing homework than they do in class. Many students' homework is at least partially online. Because homework accounts for the majority of students' interaction with content, it has the potential to be a rich learning environment. However, we know little about the nature of students' activity as they complete online homework. This paper proposes an empirically-based model of students' activity in an online homework context. The model was developed from analyses of (1) video recordings of 9 calculus II students completing an online homework assignment about sequences and (2) follow-up interviews with those students regarding their activity. The model characterizes nuances in students' activity regarding reasoning that leads to their answers, the points at which they submit parts or the whole problem and why, and how they leverage immediate feedback.*

*Keywords:* online homework, instructional triangle, didactic contract

## Introduction and Background Literature

Homework is thought to play an important role in students' learning of mathematics. University calculus I students spend more time doing homework than they do in class (Ellis et al., 2015; Krause & Putnam, 2016). Many students' math homework is at least partially online. Because homework accounts for the majority of students' interaction with content, it has the potential to be a rich learning environment.

Most research about online homework has had an achievement focus. LaRose (2010) found that online homework increases students' procedural competence on integration problems. Researchers have sought to determine if differences in homework formats (online, written, or a combination) affects course and/or exam grades. A preponderance of evidence indicates an online homework format has either a slight positive effect or no effect on student exam grades and course grades (Dedic, Rosenfield, & Ivanov, 2008; Halcrow & Dunnigan, 2012; Hauk & Segalla, 2005; Hirsch & Wiebel, 2003; LaRose, 2010). However, researchers have found that students are more likely to complete online homework than they are pencil-and-paper homework (Halcrow & Dunnigan, 2012; Hauk & Segalla, 2005; Hirsch & Weibel, 2003; LaRose, 2010; Roth, Ivanchenko, & Record, 2008).

Perhaps in part as a result of findings that online and written formats are comparable in terms of student achievement, and that students generally seem to like online homework systems and find them helpful for their learning (Halcrow & Dunnigan, 2012; Hauk & Segalla, 2002; Krause & Putnam, 2016; Roth, Ivanchenko, & Record, 2008), online homework systems have proliferated. Their use will likely continue to expand. However, beyond achievement studies and some information about students' perceptions of online homework, we know little about how students engage with these systems and what benefits they might derive from them. Given that homework represents a majority of the time that students interact with content, research about student thinking and learning in an online context can go a long way toward bolstering student learning outcomes. As such, this paper seeks to answer the following research question: what is the nature of calculus II students' activity as they complete an online homework assignment about sequences?

## Theoretical Framework

Homework is one component of an instructional system (Ellis et al., 2015; Figure 1). Ellis et al. (2015) build on Herbst and Chazan's (2012) elaboration of the instructional triangle to describe the relationships between teachers, students and knowledge at stake (content). Online homework is a milieu, or an environment through which students can learn knowledge at stake and through which students receive feedback on their actions (Artigue, Haspekian, & Corblin-Lenfant, 2014; Herbst & Chazan, 2012).

The didactic contract (Brousseau, 1997) governs the interactions between components of the instructional system. The didactic contract is "a set of reciprocal obligations and mutual expectations [that is] the result of an often implicit negotiation" (Artigue, Haspekian, & Corblin-Lenfant, 2014, p. 53). For example, students are expected to do homework, and the instructor is expected to provide opportunities for them to learn the knowledge at stake (via homework or other milieu).

This framework is useful for the study at hand because the nature of students' activity while doing homework is likely influenced by other components of an instructional system, such as what they might learn in other milieu (e.g., class) and what expectations students might have for an online homework assignment. Additionally, the idea of a milieu as a feedback-providing environment aligns with a distinguishing feature of an online homework system: the immediate feedback it provides for each problem. The research question about the nature of students' activity in the context of an online homework system, then, focuses primarily on elaborating what occurs in the arrow between 'student' and 'milieu' in Figure 1, while acknowledging the other facets of an instructional system that influence that activity.

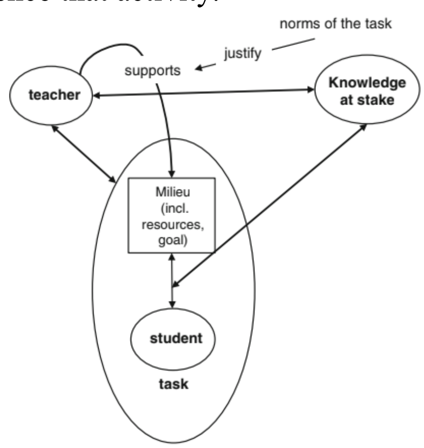

*Figure 1. Instructional triangle (Ellis et al., 2015, p. 270)*

## Data Collection and Analysis Methods

The data presented here come from video recordings and follow-up interviews with 9 calculus II students who completed an online homework assignment about sequences. The data were collected in the fall and spring semesters at a large public university in the US. Calculus II at this university is a coordinated course and so while the students were from five different sections, each with a different instructor, they all completed the same online homework assignment. The homework assignment used the platform WebAssign, and corresponded to section 10.1, sequences, from Rogawski and Adams' (2015) *Calculus: Early Transcendentals*. The problems students answered are shown in Table 1; numerical values in all but Q1 were randomized such that students had the same questions with slightly different numbers. The students had three attempts to answer each question that required a numerical value (e.g., Q4) and one attempt for each multiple choice question that asked if a sequence converged or diverged (e.g., Q7). The course coordinator had disabled the 'try a similar problem' feature. Once a student submitted an answer, the online platform provided a green check mark to indicate a correct answer and a red X to indicate an incorrect answer.

Table 1. Selected WebAssign questions from section 10.1, sequences

| Name | Question |
|---|---|
| Q1 | Match each sequence with its general term. (Assume $n \geq 1$)<br>(a) $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \ldots$ (b) -1, 1, -1, 1, … (c) 1, -1, 1, -1, … (d) $\frac{1}{2}, \frac{2}{4}, \frac{6}{8}, \frac{24}{16}, \ldots$<br><br>*(Each part had the following multiple-choice answers)*<br>$\cos(n\pi)$ $\frac{n!}{2^n}$ $\frac{n}{n+1}$ $\sin(n\pi)$ $(-1)^{n+1}$<br><br>*(Note: students could submit each a, b, c, and d individually)* |
| Q2 | Let $a_n = \frac{1}{2n-1}$ for n = 1, 2, 3, … . Write out the first three terms of the following sequences.<br><br>(a) $b_n = a_{n+1}$ $b_1 =$ _____ $b_2 =$ _____ $b_3 =$ ______<br><br>(b) $c_n = a_{n+3}$ $c_1 =$ _____ $c_2 =$ _____ $c_3 =$ ______<br><br>*(Note: students could submit each $b_1$, $b_2$, $b_3$, $c_1$, $c_2$, and $c_3$ individually)* |
| Q3 | Calculate the first four terms of the sequence, starting with n = 1. $c_n = \frac{5^n}{n!}$<br><br>$c_1 =$ _____ $c_2 =$ _____ $c_3 =$ ______ $c_4 =$ _____<br><br>*(Note: students could submit each $c_1$, $c_2$, $c_3$, and $c_4$ individually)* |
| Q4 | Calculate the first four terms of the given sequence, starting with n = 1.<br>$$c_n = \frac{1}{5} + \frac{1}{8} + \frac{1}{11} + \cdots + \frac{1}{3n+2}$$<br>$c_1 =$ _____ $c_2 =$ _____ $c_3 =$ ______ $c_4 =$ _____<br><br>*(Note: students could submit each $c_1$, $c_2$, $c_3$, and $c_4$ individually)* |
| Q5 | Find a formula for the $n^{th}$ term of the following sequences (with a starting index of n = 1)<br>(a) $6, -\frac{7}{8}, \frac{8}{27}, \ldots$ $a_n =$ ______________<br><br>(b) $\frac{6}{5}, \frac{10}{9}, \frac{14}{13}, \ldots$ $a_n =$ ______________ |
| Q6 | Determine the limit of the sequence and state if the sequence converges or diverges.<br>$$a_n = \frac{7 + n - 3n^2}{12n^2 + 1}$$<br>$$\lim_{n\to\infty} a_n = \_\_\_\_\_\_\_$$<br>___ The sequence converges.<br>___ The sequence diverges. |

| | |
|---|---|
| | *(Note: students could submit the limit and the 'converges / diverges' part individually. The converges/diverges part was a multiple-choice question in which students selected one of the two answers.)* |
| Q7 | Determine the limit of the sequence and state if the sequence converges or diverges. $$a_n = \left(\frac{2}{3}\right)^n$$ $$\lim_{n\to\infty} a_n = \_\_\_\_\_\_\_\_$$ ___ The sequence converges.<br>___ The sequence diverges.<br><br>*(Note: see note for Q6.)* |
| Q8 | Determine the limit of the sequence and state if the sequence converges or diverges. $$a_n = -\left(\frac{5}{8}\right)^{-n}$$ $$\lim_{n\to\infty} a_n = \_\_\_\_\_\_\_\_$$ ___ The sequence converges.<br>___ The sequence diverges.<br><br>*(Note: see note for Q6.)* |
| Q9 | Determine the limit of the sequence and state if the sequence converges or diverges. $$a_n = \frac{n}{\sqrt{n^3+2}}$$ $$\lim_{n\to\infty} a_n = \_\_\_\_\_\_\_\_$$ ___ The sequence converges.<br>___ The sequence diverges.<br><br>*(Note: see note for Q6)* |
| Q10 | Determine the limit of the sequence and state if the sequence converges or diverges. $$a_n = \ln\left(\frac{11n+2}{-9+6n}\right)$$ $$\lim_{n\to\infty} a_n = \_\_\_\_\_\_\_\_$$ ___ The sequence converges.<br>___ The sequence diverges.<br><br>*(Note: see note for Q6.)* |
| Q11 | Use the appropriate limit laws and theorems to determine the limit of the sequence or show that it diverges. (If the quantity diverges, enter DIVERGES). $$c_n = 1.01^n$$ $$\lim_{n\to\infty} c_n = \_\_\_\_\_\_\_\_$$ |
| Q12 | Use the appropriate limit laws and theorems to determine the limit of the sequence or show that it diverges. (If the quantity diverges, enter DIVERGES). $$b_n = n^{2/n}$$ |

| | |
|---|---|
| | $\lim_{n\to\infty} b_n =$ ________ |
| Q13 | Use the appropriate limit laws and theorems to determine the limit of the sequence or show that it diverges. (If the quantity diverges, enter DIVERGES). $$c_n = \frac{10^n}{n!}$$ $\lim_{n\to\infty} c_n =$ ________ |
| Q14 | Use the appropriate limit laws and theorems to determine the limit of the sequence or show that it diverges. (If the quantity diverges, enter DIVERGES). $$b_n = \ln(n^2+5) - \ln(n^2-1)$$ $\lim_{n\to\infty} d_n =$ ________ |

The data were collected in two phases. First, I video-recorded each student as (s)he completed the homework. I made copies of students' scratchwork, class notes, and any other materials they referred to while completing the assignment. I then watched each video and took notes about students' observable actions (e.g., what they wrote for scratchwork, what they typed into calculators, what they submitted for answers, and when these actions occurred in relation to one another). This formed the first phase of data analysis. Most broadly, all students' interactions with any given problem fell into three components: pre-answer submission, answer submission, and post- answer submission. For the pre-answer submission component of each problem, I made notes about what the students did before submitting an answer (e.g., computed terms of a sequence, looked at class notes). This portion of students' activity represents their first interactions with the knowledge at stake.

For the answer submission component, I made notes about what the student submitted. Because most questions had multiple parts, the "what students submitted" focused on which part(s) of the question and the student's actual numerical answer. This was important because it forms what students received feedback on, and feedback is a component of the homework as a milieu. My notes about post- answer submission focused on whether the answer was correct or incorrect and what the student did following that feedback. This was important because it represents another opportunity in which students might (re)-engage with the knowledge at stake.

In the second phase of data collection, the student and I watched the video and I asked questions pertaining to my notes. I asked questions such as "can you explain how you arrived at that answer?" to gain insight into the pre-submission component of students' work. To gain insight into how students made use of the immediate feedback, I asked questions such as "can you explain why you submitted just this part of the question?" or "can you explain why you submitted all of these parts at once?" and "what did you think when you saw that your answer was correct/incorrect?" This interview was also video-recorded and was transcribed for analysis.

The data were analyzed via a constant comparative analysis (Strauss & Corbin, 1994). I sought to elaborate the students' activity in the previously-identified pre-answer submission, answer submission, and post- answer submission components of the students' work. Using my initial notes and the transcripts, I first sought to categorize what students did before submitting an answer. The themes that emerged were that students did some mathematical thinking (e.g., computing terms), formed guesses, or engaged in a combination of the two. In the answer submission component of students' work, I observed that sometimes students submitted parts of a question and sometimes they submitted all parts at once. Because questions had multiple parts, the feedback students received could be [fully] correct, partially correct, or incorrect. Further, because students had multiple tries on most questions, the feedback could be intermediate (if students had more tries on any part of the question) or final (if students had all parts of the question correct, or if they had run out of tries). Per the post- answer submission component, I observed the students continuing to work on the question, guessing an answer without doing more work, and moving to the next question. Based on students' answers to interview questions, I was able to categorize these as students cycling forward, cycling back, or not cycling (defined below). I made each of these themes into a code, then went through all of the data applying these codes. This allowed me to refine them and 'collapse' them into the model presented in the results section. Finally, I re-coded all of the data using this model to ensure that the model accurately accounted for the phenomena observed in the data. The result, presented in the next section, is an empirically-based model that describes the nature of these students' activity in an online homework context.

## Results: Preliminary Model of the Nature of Students' Activity While Completing Online Homework

In this section, I present the result of this study: an empirically-based, preliminary model of the nature of students' activity while completing online homework. I then provide examples of different paths through the model.

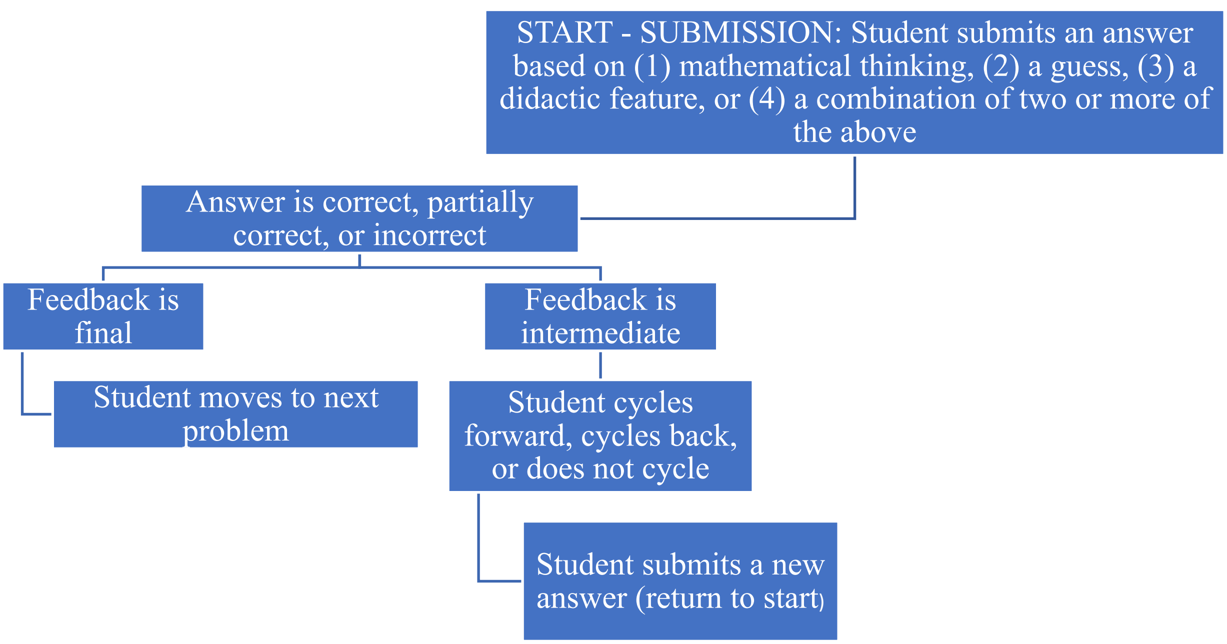

*Figure 2. Preliminary model of the nature of students' activity while completing online homework*

## Unit of analysis

The first step in coding was to determine the unit of analysis. I made this decision by question type. Question 1 was analyzed as one unit, since the multiple choice answers were the same for each sequence. In questions 2 and 5, parts A and B were coded separately because they were fairly distinct problems. Questions 3 and 4 were each treated as a single unit. For example, if a student submitted a value for $c_1$ but not $c_2$, $c_3$, or $c_3$, that was coded as 'intermediate' feedback because there were more parts of the question. This decision was informed in part by the fact that students frequently described submitting an answer to one part of a question to make sure they were on the right track; that is, the students saw $c_1$ as a fraction of a question, not an entire problem in itself. Similarly, for a multi-part problem like questions 6, 7, 8, 9, and 10, the two parts were considered together. For example, if a student submitted the value of the limit (but not the converge/diverge part) and it was correct, the feedback was coded as intermediate. Questions 11, 12, 13, and 14 were each a single unit in analysis.

## Submission

The data indicated that students submitted answers based on either mathematical thinking, guessing, a combination of mathematical thinking and guessing, or didactic features. *Mathematical thinking* is characterized as applying a general principle that is within the learning objectives of the course to a specific problem. Examples include applying a theorem, creating a graph, computing, doing algebraic manipulation, differentiating, and symbolizing. I defined mathematical thinking in terms of applying principles within the learning objectives of the course to exclude reasoning such as 'I submitted 0 because sequences often converge to 0'. While we might argue that a student has engaged in generalizing based on their experience, and generalization is a critical component of mathematical thought, I wanted the definition of mathematical thinking to reflect the particular mathematics we might want students to engage in for these problems; noticing that many of the sequences they saw converged to 0 was not a goal of the course.

Submitting an answer based on *didactic features* means that rather than focusing on the mathematics, the student reasons about what she is 'supposed to learn'. This follows from the idea of the didactic contract as a set of mutual obligations and expectations; according to the theory framing the study, students have particular expectations about the opportunities to learn provided to them in a homework assignment. I follow Merriam-Webster's definition of *guessing* as 'estimating or suppose (something) without sufficient information to be sure of being correct.'

## Feedback

Feedback is *final* if the student does not submit another answer for a problem, and *intermediate* otherwise. A student might obtain a correct answer and move to the next problem, in which case the green check is final feedback. If a student runs out of attempts on a problem, the green check or red X corresponding to the last attempt is final feedback.

It might seem that a correct answer would be final feedback because a student is unlikely to submit another answer. However, I repeatedly observed students submitting each part of a multi-part question individually and explaining that they did so because they could use the feedback to guide their work on other parts of the question. Correct answers in these cases affirmed for students that they had the right method for solving the problem. Hence a key finding is that one way students interact with an online homework system is that they use the feedback as formative assessment. As such, it is important to distinguish between types of feedback within the model.

## Cycling forward / cycling back / not cycling

One emergent theme in the data was that students often submitted one part of a multi-part problem to obtain feedback regarding whether they were on the right track. In some cases, if the answer were correct (such as having computed a term correctly), they took the green check mark as evidence that they had the correct method, and they applied that method to the remainder of the problem. In other cases, such as submitting the correct numerical value for a limit but not the multiple choice converge/diverge, students would interpret a green check mark as evidence that they understood the problem at hand, then submit the multiple choice part. Contrastingly, students often interpreted a red X as meaning they needed to find a new process. Finally, one students obtained a red X and appeared to guess a new answer without considering any mathematics (see Example 2).

I borrow from Carlson and Bloom (2005) problem-solving taxonomy in characterizing these actions as *cycling forward* and *cycling back*. Carlson and Bloom (2005) observed that mathematicians' problem-solving involved a 'checking' phase in which they "verified the correctness of their computations and results" (p. 63). The mathematicians would then "accept the result and move to the next phase of the solution" (*cycle forward*) or "reject the [incorrect] result and cycle back" (Carlson & Bloom, 2005, p. 63). The online homework system does the verification for students, who then made decisions to cycle forward, cycle forward, or not cycle.

The next section provides examples of student activity as framed in this model.

## Examples of Student Activity in Online Homework Problems

In each example below, the header represents the code for the reasoning behind a student's initial submission; the parentheses indicate the students' name[1] and the question number. The first paragraph lists the codes for the student's work on the question. Subsequent paragraphs provide details and evidence that support the codes. These examples contain quotes from only three of the nine students, but they are representative of the ways in which all the students acted. By focusing on three students, I hoped to allow the reader to compare how one student had different 'paths' through the model for different problems (e.g., in Example 1 we see how Susie relied on mathematical thinking on Q10, and in Example 2 and 3 we see multiple reasons she combined mathematical thinking and guessing). The final example is meant to demonstrate the ways in which students leveraged immediate, intermediate feedback, and how important it was for them in their thinking.

## Example 1: Mathematical thinking (Susie Q10)

Susie's work on Q10 (Figure 2) is coded as: student submits answer based on mathematical reasoning, answer is partially correct; feedback is intermediate; the student cycled forward; the student submitted a new answer based on mathematical thinking; the answer was incorrect (because of the format); feedback is intermediate; the student cycled forward; the student submitted a new answer based on mathematical thinking; the answer was incorrect (again because of the format); feedback is intermediate; the student cycled forward; the student submitted a new answer based on mathematical thinking; the answer was incorrect (again because of the format); feedback is final; the student moved to the next question.

---

[1] Names are gender-preserving pseudonyms based on students' self-identified gender on a demographic survey completed at the end of the study.

Susie began this problem by computing $a_2 = 2.08$, $a_4 = 1.12$, $a_6 = 0.92$, and $a_8 = 0.83$. She submitted $\lim_{n\to\infty} a_n = 0$ and 'converges' at the same time; WebAssign marked the former as incorrect and the latter as correct, meaning in the model we code this as *partially correct*. Susie described that she reasoned the limit was 0 "because like on the previous ones like if they continually decrease, they all went to 0. But this one that wasn't the case." Susie's computations and comment about paying attention to the trend are evidence that she submitted her answer based on *mathematical thinking*. The feedback was *intermediate* because Susie tried the problem again. She *cycled back*. As evidence of this, she described in the second interview

*Interviewer*: And can you tell me about, so here we have part of the question right, so you know it converges, but you didn't know what the limit was. Can you tell me what you were thinking?

*Susie*: That I needed to find, I needed to go further down in like the n values.

Susie computed $a_{12} = 0.75$, $a_{100} = 0.62$, and $a_{1000} = 0.607$. This, taken with her comment that she needed to 'go further down in like the n values', is evidence of mathematical thinking. Susie submitted 0.6 as an answer. Because WebAssign wanted the exact answer ln(11/6), the system marked this *incorrect*. The feedback was *intermediate* because Susie tried the problem again, submitting 0.607 (*incorrect*). While finding these decimals, Susie *cycled forward.* She explained in the second interview, after viewing her third incorrect submission *(final feedback)*,

*Interviewer*: Do you feel like you understood what was going on?

*Participant*: I thought so, but then I got it wrong, so I wasn't sure what it was converging to…

*Interviewer*: So you kept trying bigger and bigger values…

*Participant*: I felt like it was a good method but, so then I thought it was just like the decimals, so it might be a fraction. But yeah natural logs are not my forte.

These quotes are evidence that Susie cycled forward. She felt her method was appropriate, and she continued to try larger values of n. However, she submitted another decimal when the system wanted an exact answer, and obtained a red X. This feedback was final because Susie was out of attempts and moved to the next problem.

Like example 5 (below), this example demonstrates how students leverage immediate, intermediate feedback. Susie had a green check mark for the 'converge' part. She said this told her "I needed to go further down in the n values". That is, she leveraged this feedback by coupling it with her prior work and using it as a hint toward what future action she should take. Students did this frequently, both with the questions that had a converge/diverge multiple choice part and with questions that required them to compute terms (See Example 5).

**Example 2: Mathematical thinking and guessing (Susie, Q1)**

Susie's work on Q1 is coded as: student submits answer based on a combination of mathematical thinking and guessing; answer is partially correct; feedback is intermediate; the student did not cycle; the student submitted a new answer based on a guess; the answer is correct; the feedback is final.

Susie's first attempt at question 1 involved a *combination of mathematical thinking and guessing*. She correctly wrote the first term or two for the given general terms $\frac{n}{n+1}$, $\frac{n!}{2^n}$, and $(-1)^{n+1}$ and these computations are evidence of mathematical thinking. However, she made some errors in writing the values of trig functions, which resulted in her guessing for one part of the question. Susie wrote, $\sin(\pi) = 0$ , $\sin(2\pi) = 1$, $\cos(\pi) = -1$ and $\cos(2\pi) = 0$. Susie then matched the terms she wrote to the given sequences. Her work corresponded exactly for 1a, 1c, and 1d.

However, on 1b, because the incorrect terms for the trig functions did not match any of the sequences, Susie guessed between the two remaining answer choices. Watching the video of herself doing the problem, Susie explained "I knew it was between one of those two [sine and cosine] but apparently I couldn't figure out which one it was… but I mean I like multiple choice because you can free guess."

Susie submitted all four parts of the problem at once. Her submission and the feedback she received are shown in Table 2. Because the feedback was a mix of correct and incorrect responses, this is coded as *partially correct*. Susie submitted a different answer to 1b after obtaining this feedback, so the feedback shown in Table 1 was *intermediate*.

Table 2. Susie's first submission for Q1

| Problem | 1a | 1b | 1c | 1d |
|---|---|---|---|---|
| Sequence | $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \dots$ | -1, 1, -1, 1, … | 1, -1, 1, -1, … | $\frac{1}{2}, \frac{2}{4}, \frac{6}{8}, \frac{24}{16}, \dots$ |
| Susie's submission | $\frac{n}{n+1}$ | $\sin(n\pi)$ | $(-1)^{n+1}$ | $\frac{n!}{2^n}$ |
| Feedback[2] | Correct | Incorrect | Correct | Correct |

When Susie saw that her answer to 1b was incorrect, she immediately clicked $\cos(n\pi)$, submitted the answer, and moved to the next problem. Hence she *did not cycle*. The evidence for this is twofold. First, there was a four-second gap between when the red X appeared on her screen for 1b and her clicking and submitting $\cos(n\pi)$. Second, she did not return to her scratchwork to re-compute any values of cosine. This submission, then, was based on a *guess* because Susie did not have sufficient information to be sure she was correct. Her answer was correct, and the feedback was *final* because Susie did not submit any more answers. Susie's guessing was an affordance of the multiple-choice nature of the question. The next example describes guessing as an affordance of the number of chances students are allowed.

**Example 3: Mathematical thinking and guessing (Susie, Q12 and Calvin, Q4)**

Susie's work on Q12, $\lim_{n\to\infty} b_n$ where $b_n = n^{3/n}$, was coded as: student submits answer based on a combination of mathematical thinking and a guess; answer is correct; feedback is final.

Susie computed $b_2$, $b_{10}$, $b_{20}$, and $b_{50}$. She submitted the answer $\lim_{n\to\infty} b_n = 1$, which was correct. In the second interview, Susie explained her thinking as she was computing the terms.

*Susie*: I think I was starting [inaudible] if it was diverging to 1 or 0.

*Interviewer*: Okay, so when you typed 1 here [in the answer box] -

*Susie*: I was, I was thinking it was 1, but it could have also been 0 if you went down further…

*Interviewer*: So was this, do you think this was one of those things where you like have three chances, so –

*Susie*: Yeah.

*Interviewer*: - try one and then –

*Susie*: If it's wrong try another one… cuz like just a lot of graphs converges [sic] to 0. But it was, like it was going to 1, like it had 1 point something, so I figured it was 1, but there was also the possibility that if you went further if it was going to converge to 0 or not.

[2] The students see a green check mark for a correct answer and a red X for an incorrect answer, not the word 'correct' or 'incorrect'.

*Interviewer*: So it sounds like you were paying attention to both number patterns like the 1 and the experience that things go to 0 often.

*Susie*: Yeah.

Susie's computation of $b_2$, $b_{10}$, $b_{20}$, and $b_{50}$ and attention to the fact that the values were decreasing to 1 is evidence of mathematical thinking. Her comments about submitting 1 and then submitting 0 if the 1 were wrong are evidence of guessing. This example sheds some light on student guessing behavior. First, Susie guessed in part because the particular constraints of the system afforded a guess or two. That is, Susie had three chances to obtain full credit for the problem, and this made her feel comfortable guessing. Second, the example highlights that students' guesses may be based on some sort of reasoning (as opposed to guessing random numbers). Susie had in mind 0 and 1 because she had noticed that in her experience, sequences frequently converge to those numbers.

Another question in which guessing was afforded by multiple chances per problem, and based on some sort of sensemaking, was in question 4. Several students submitted $c_1 = 1/3$, $c_2 = 1/5$, $c_3 = 1/7$, $c_4 = 1/9$. Calvin, one of the students who did this, described

*Calvin*: I looked at it and it looked like they were just asking me to write down what they had already typed out. So I was a little confused on why it was so easy. So I just, since I knew I had multiple tries, I just decided let's just go with it, assuming that I understood it right.

Calvin's submission of $c_1 = 1/3$, $c_2 = 1/5$, $c_3 = 1/7$, $c_4 = 1/9$ was based in part on mathematical thinking, as evidence by his comments that "it looked like…" and "assuming that I understood it right." These comments show that he had engaged in some sensemaking about what the problem was asking. However, he guessed because he did not have sufficient information to be sure he was correct. We know he was unsure because he said he was "confused on why it was so easy" and he was "assuming he understood it." Calvin's comments about multiple tries indicates that he guessed in part because the system afforded it. Like Susie, he felt the multiple tries allowed for guessing. The feedback Calvin obtained for these answers was partially correct ($c_1$ was correct and the others were incorrect). He cycled back, as he describes below:

*Interviewer:* So one was right, and three of them were wrong… do you remember what you were thinking?

*Calvin:* This isn't as easy as it looks.

*Interviewer:* So I'm pretty sure here you were just looking at the computer screen… do you remember what you were looking at or trying to figure out?

*Calvin:* I was just trying to soak up as much information from the problem to figure out what I was supposed to do. I probably re-read the question and then made sure I understood what the question was asking and then I went back to the equation or numbers they gave and tried to figure out what part I wasn't understanding… I think I figured out that the terms were, like they were trying to get me to add the previous term to it.

Here, the immediate feedback was a cue for Calvin that he did not understand what was going on (as he had assumed), and he needed to think through the question in a different way. He realized that he might need to add the terms, and computed $c_2 = 1/5 + 1/8$. He submitted $c_2 = 13/40$. He submitted just that one answer because

*Calvin:* I knew I only had two tries for all three of them… I figured if I did one of them I'd limit the amount of tries I lost.

This is evidence that the number of tries influenced the way in which Calvin worked, but it is also evidence that the multiple tries allowed Calvin to try an idea. While in some cases the multiple chances afforded guessing, in many more cases, students used the multiple chances to submit answers as multiple chances with which to engage in the mathematics.

**Example 4: Mathematical thinking, guessing, and didactic features (Rosalyn, Q11) and Guessing and didactic features (Rosalyn, Q12)**

Rosalyn's work on questions 11 and 12 show evidence of attending to the didactic contract when submitting answers in online homework.

In Q11, Susie's work is coded as: submitted an answer based on mathematical thinking, guessing, and the didactic contract; the answer was correct; the feedback was final; the student moved on to the next problem. In the next question (Q12), Rosalyn's second submission involved guessing based on attention to didactic features. Her work in this question is coded as: submitting an answer based on mathematical thinking; answer is incorrect; feedback is intermediate; the student did not cycle; the student submitted an answer based on a guess and didactic features; the answer was incorrect; feedback is intermediate; and the student stopped working on the question (she wanted to ask for help, and saved her last attempt for later).

In question 11, Rosalyn appeared to have (mis)applied the power rule to take a derivative. She wrote $\lim_{n\to\infty} 1.02^n = \lim_{x\to\infty} 1.02^x = \lim_{n\to\infty} x(1.02)^{x-1} = \infty^{\infty-1}$. She then said,

*Rosalyn*: Infinity to the infinity minus 1 would be, that doesn't make any sense. I'm going to enter diverges and hopefully that's it. [Submits 'DIVERGES', which is correct] Okay, it diverged. I don't know how to solve it, but I guessed. So – and probably one more of these diverges. Don't know which one though but most likely.

*Interviewer*: Why do you think probably one more diverges?

*Rosalyn*: Usually like in WebAssign like the fact that there's four of them [problems that read 'If the quantity diverges, enter DIVERGES] I want to say like probably at least another one diverges… because the whole point is you know you learn like, you know a little bit of each. So I feel like if they have one that diverges they most likely will have another one diverges.

Although Rosalyn said she "guessed," I coded the submission as involving mathematical thinking because Rosalyn did some computation and I believe the $\infty^{\infty-1}$ may have influenced her decision to guess 'diverge'. This guess also appears to have been influenced by Rosalyn's expectation that some of the sequences diverge, as evidenced by her comment that "the whole point is… you know a little bit of each." Rosalyn appeared to believe that if diverging was something she was supposed to learn, it would be an answer to at least one problem. She applied this reasoning in the next question.

Rosalyn's first submission on question 12 was $\lim_{n\to\infty} b_n = 2$. This was based on mathematical reasoning because she did some (incorrect) algebra, either trying to simplify $n^{2/n}$ or take a derivative, and writing $\lim_{n\to\infty} \frac{2}{n} * n = \lim_{n\to\infty} 2 = 2$. She submitted 2, which was incorrect. Rosalyn explained,

*Rosalyn*: I don't know this one, and I'm going back to the whole I'm-hoping-two-of-them-diverge, so I'm going to check if it diverges.

She then typed in 'diverge' without doing any additional scratchwork. This was a guess because she did not have sufficient evidence to be sure that it diverged. It was a guess based on a didactic feature because she relied on her reasoning in question 11: divergence was something she was supposed to learn, so she expected 'diverge' would be a correct answer for at least one question.

**Example 5: Mathematical thinking (Calvin, Q2A and Q8)**

Calvin's work on questions 2 and 8 provide evidence of solving problems by engaging in mathematical thinking and leveraging immediate, intermediate feedback to support his solution attempts. Calvin's work on Q2 and Q8 followed the same coding: submitting an answer based on mathematical thinking; the answer was correct; the feedback was intermediate; he cycled forward; he submitted more answers based on mathematical thinking; those answers were correct; and the feedback was final.

On Q2, Calvin wrote $b_1 = a_2$. He described,

*Calvin*: I was just writing out what I was thinking… $b_n$ is $a_{n+1}$ so if you have $b_1$ you have to add one when you're doing $a_n$ so it's going to be $a_2$. [Submitted $b_1 = 1/3$]

*Interviewer*: I noticed here that this question has 3 boxes to fill in [points to part A] and you filled in one and then submitted it. Do you remember why you did that?

*Calvin*: Just to make sure I was doing it right.

Submitting one term to check that they were on the right track was very common; nearly all students did this. In particular, here Calvin did some mathematical thinking (as evidenced by his sensemaking of how $a_n$ and $b_n$ were related), submitted one answer, and obtained the intermediate feedback that it was correct. He reflected on the fact that his method was correct and went on to submit the correct answers for $b_2$ and $b_3$ (cycling forward)

In Q8, Calvin did some algebra, writing $-(8/5)^n$. He described, "to remove that negative from the exponent, you just flip whatever the coefficient is." Calvin engaged in mathematical thinking because he was doing algebraic manipulation and paid attention to the magnitude of the fraction (see below). He then clicked the 'diverge' multiple choice box, but not the numerical limit. He explained,

Calvin: I saw that the fraction was greater than 1 so I was like okay it has to diverge. But I wanted to make sure. But I don't know why I did it with that [the multiple choice part] because I only have one shot.

Calvin then submitted $-\infty$ in the box for the numerical limit, which was correct. Like question 2, he described that he employed the immediate feedback as a 'check.' The comment about being unsure why he submitted the multiple choice part (for which he had one chance), instead of the numerical limit (for which he had three chances) is evidence of one of the ways in which the structure of the homework system influences students' work. Like Susie and Rosalyn, Calvin felt the multiple chances afforded trying answers he was unsure of. Moreover, in many cases, these students and the others in the study felt the multiple chances afforded feedback on their work that they could, and often did, employ in directing their future work.

## Discussion

I have proposed a preliminary, empirically-based model of the nature of students' activity while completing online homework. The components of this model are (1) the basis of the student's answer submission, (2) the correctness of the submission, (3) whether the feedback is immediate or final, (4) whether the student cycles forward, back, or does not cycle and (5) whether or not the student submits a new answer. It is my hope that this model serves as an entry point for others studying student thinking and learning in the context of homework. Because homework forms the majority of students' interaction with content (Ellis et al., 2015; Krause & Putnam, 2016), it is a rich area for studying student thinking and learning. It is also an area in which we may be able to employ particular structures that engender desired action. For example, a key finding in this study is that students often employed their multiple chances per problem as ways to obtain feedback on their thinking. That feedback served as a formative assessment. This finding supports allowing students more than one attempt on 'open-ended' online homework problems.

One key finding is that in coding the data, I found that most students' initial submissions, and re-submissions, were based at least partially on mathematical thinking. In future work, I intend to attempt to quantify this more specifically. Another key finding in this study relates to why students guess. The students in this study only guessed randomly in multiple-choice settings (e.g., Susie's guess described in Example 2). Their guesses had some sort of reasoning behind them, such as a generalization based on experience that 'sequences often converge to 0', or an implicit understanding of the didactic contract that they would be provided with problems that represented the scope of knowledge at stake. These findings support looking at student activity in homework as part of an instructional triangle, as Ellis et al. (2015) propose.

These findings raise a number of avenues for future research. First, this study was done with a very specific population of students. An important question is whether or not the model accurately represents the nature of *other* students' online homework activity. Do students in different courses interact with an online homework assignment in similar ways? Another avenue for research is further investigation in the number of attempts students have per problem. My findings support allowing students multiple tries. However, is a particular number of tries better than some other number? How, if at all, would the nature of students' activity change if they had unlimited tries? Finally, the students in this study had particular constraints built into their WebAssign system, one of which was that the instructor had disabled the 'see similar example' feature. Is the nature of students' activity different when they have access to a 'try a similar problem' or 'see similar example' feature? How do students make use of such features? Answering these questions can tell us what conditions and resources within an online homework system promote desirable student activity such as engaging in and reflecting on mathematical thinking.

# An APOS Study on Undergraduates' Understanding of Direct Variation: Mental Constructions and the Influence of Computer Programming

Cynthia L Stenger James A Jerkins Jessica E Stovall Janet T Jenkins
University of North Alabama

*This study explores undergraduates' understanding of direct variation before and after instruction using computer programming to teach generalization over the concept. Based on an initial genetic decomposition for direct variation, the four math/CS researchers developed a research design that included lessons featuring computer programming and mathematical proof writing activities. This study shares results from an application of the instructional research design to N=33 undergraduates interested in teaching. Lessons were from a secondary education math methods course. Follow up interviews were conducted with seven participants. The analysis, using APOS as a framework, categorized mathematical behaviors at the Action, Process or Object level. The study identified obstacles that may have prevented progression through deeper levels of understanding such as deficient prerequisite skills and an affinity for routine algebraic manipulation rather than considering underlying relationships. The student data demonstrated how computer programming activities influenced undergraduates' mental images.*

*Key words:* Direct Variation, Generalization, Computer Programming, Pre-Service Teachers

## Introduction

The ability to generalize is considered an essential skill for reasoning about and deeply understanding mathematical concepts by mathematics education researchers. Many researchers have investigated how to explicitly induce students to develop generalizations in the context of mathematical explorations (Tall et al., 1991). In this paper, we extend our previously published preliminary study into student's understanding of direct variation using computer programming exercises (Stenger et al., 2017). Many mathematics education researchers believe that using computer programming activities designed to parallel the construction of an underlying mathematical process may stimulate or accelerate the development of the associated mathematical construction (Dubinsky and Tall, 2002; Jenkins et al., 2012). In prior work, we developed an explicit method for motivating students to generalize into mathematical constructions using computer programming exercises and proof writing based on the theoretical perspective of APOS theory (Stenger et al, 2017). The research questions we investigate are: (1) Does our genetic decomposition of direct variation adequately describe the observed students' constructions; and (2) Do our instructional treatment's computer programming activities influence students' mental constructions as described in the genetic decomposition?

## Proportional Reasoning

The ability to reason using proportions is an important and pervasive requisite for many academic and daily pursuits. In developmental psychology, proportional reasoning is considered "a major landmark in the passage from concrete operational to formal operational thinking" (Light, et. al., 2016; Inhelder and Piaget, 1958). Consequently, investigating how learners acquire and practice proportional reasoning has been the subject of numerous studies. Lessons on proportions are typically considered the responsibility of middle school mathematics educators, yet proportional reasoning problems occur and cause difficulties for students throughout their academic and non-academic life (Ben-Chaim, 2012; Hilton, 2016). Scenarios that are addressed by proportional reasoning are not only math classroom problems, they also appear in other STEM classes in a wide range of scientific contexts, including, for example, trajectories, fuel consumption and the expansion of gases (Light, 2016), as well as economics and geography (Hilton, 2016). Additionally, professions such as architecture, nursing, and pharmacy require the ability to reason proportionally (Hilton, 2016). The necessity to employ proportional reasoning skills in increasingly complex and diverse problem solving situations continues to present a teaching and learning challenge for mathematics educators and students.

Mathematics education researchers have dedicated considerable energy to proportional reasoning with elementary and middle school students, high school students, undergraduates and graduates. Collectively these researchers have shown that students and adults have difficulty with problems involving proportional reasoning (Noelting 1980; Vergnaud, 1983; Hart, 1988; Lesh et al., 1988; Caput and West, 1994). When proportions are "treated as procedural computational problems where the goal is to find missing values using a certain technique, such as 'cross-multiplication'" (Warshauer, 2014; Heinz and Sterba-Boatwright, 2008), students may be missing the appropriate struggle required for deeper learning (Warshauer, 2014; Liu, 2013). Frith, et. al. (2016) performed a study among undergraduate law students that suggests that even semester-long interventions may make only modest improvements in understanding. Ben-Chaim, et. al. (2012) noted that often both pre-service and in-service teachers have insufficient understanding for subjects taught in elementary and middle schools. Courtney-Clarke and Wessels (2014) found that in a study of pre-service teachers in Namibia, only 25% could determine the "relative size of two common fractions (a comparison problem)."

There is widespread recognition that proportional reasoning is important and students and teachers may struggle. We found that explanations for the difficulties undergraduates experience with the concept of direct variation are sparse in existing literature. Hence this study will contribute to the literature on how undergraduates' understand direct variation by examining student's mental constructions and exploring how computer programming activities support the development of mathematical constructs.

## Theoretical Framework

The theory of reflective abstraction was described by Piaget (1985) as a two-step process, beginning with reflection on one's existing knowledge, followed by a projection of one's existing knowledge onto a higher plane of thought. Further, Piaget (1985) and Dubinsky et al. (2005a, 2005b) wrote that during the process of cognitive development, reflective abstraction could lead to the construction of logico-mathematical structures by the learner. The conviction that reflective abstraction could serve as a powerful tool to describe the mental structures of a mathematical concept led Dubinsky to develop APOS theory.

In APOS theory the mental structures are Action, Process, Object, and Schema. A mathematical concept develops as one acts to transform existing physical or mental objects. Actions are interiorized as Processes and Processes are encapsulated to mental Objects. It is tempting to view the progression as linear, but APOS practitioners hold that learners move back and forth between levels and hold positions between and partially on levels. In other words, the progression is not linear. This nonlinear behavior and the resulting mental structures may explain the different ways learners respond to a mathematical situation (Arnon et al., 2014).

## Genetic Decomposition for Direct Variation

The genetic decomposition was developed as a conjecture of the mental constructions, Actions, Processes, and Objects, that may describe the construction of mental schema for the concept of direct variation as it develops in the mind of the learner. The genetic decomposition served as a model for the design of this research study as well as the analysis of the results. It was also the basis for the computer activities in the lessons that were developed for the students. The pervasive impact of the genetic decomposition is consistent with an APOS theoretical framework (Asiala, et al., 1996).

The prerequisite concepts to start the construction of direct variation are an Object conception of multiples of a number, a Process conception of a variable and an Object conception of constant. The notion of equality (=) needs to be used as a relation between corresponding elements of two sets. The learner must have a Process level conception of one-to-one correspondence between two sets X and Y, and be able to recognize and compare corresponding members.

### Action

The Actions needed are simple algebraic manipulations involving division and/or multiplication of numbers. The learner will apply the Actions to substitute in known values and solve for an unknown value in the equation. For example, she or he might find a constant ($k$) by dividing the first value ($x$) by the second value ($y$), and then multiply a subsequent number by $k$ to find the answer. Each activity is viewed by the learner as a single instance, isolated from subsequent similar instances. At this level, $k$ is viewed as a specific value, not as an arbitrary constant. The learner may or may not see the relationship between $x$ and $y$, they may work several examples without seeing a general pattern.

The same Actions described above can take place in different settings with different representations of the relation, such as a table, mapping, graph, and an analytical example.

### Process

These Actions are interiorized into Processes as the learner repeats the Action with different values of $k$ or different values of $x$ or $y$. They might iterate through values of $x$, but instead of checking specific numbers, the student can determine in general and in his or her imagination, for example, that as values of $x$ increase, corresponding values of $y$ will increase. The learner recognizes a general behavior that $x$ and $y$ vary.

As the learner iterates over $x$, this Process with $x$, $y$, and $k$ is coordinated into a new Process where the learner can view a sequence of numbers X and can determine if elements $x$ in a set X vary with corresponding values $y$ in a set Y without multiplying each value of $x$ by $k$ but by imagining each value of $x$ as a multiple of its corresponding value of $y$. While they imagine multiplying by $k$ or dividing by $x$ and $y$ to get $k$, they may not see that $y$ is locked into a value by $x$ and $k$, into a pattern that is carried out no matter what value is given. They may or may not see the rate of variation as a constant rate.

### Object

The Process of checking if elements of a sequence of numbers X are equal to a constant multiple $k$ of corresponding values of Y, (or quotient of $x$ and $y$ is constant) encapsulates into an Object when the individual is able to apply Actions or Processes to it. The Actions that can be carried out on the Process conception of direct variation include comparing and contrasting it with other generalized properties of multiples such as doubling or halving, and to interpret the role of varies directly in the possibility that the two sets X and Y have a constant $k$ when any corresponding elements are divided. For example, they may understand that the ratio between corresponding elements of X and Y is a constant $k$. They may double the values in X and observe that values in Y are doubled. Then they may halve the values in X and observe that values in Y are halved, and so on. The learner may generalize the process that the subsequent values are determined by $k$, the constant of proportionality, locked in a pattern that is carried out no matter what value of $x$ you select. Another Action on the process may be reversing the process to determine X when $k$ and Y are known.

## Instructional Treatment Overview

We have developed an explicit approach to teaching abstraction and generalization in the mathematics classroom using computer programming exercises (Jenkins et al., 2012). The instructional treatment is grounded in APOS theory and considers the mental processes by which abstract concepts are acquired and utilized in mathematics (Dubinsky, 1984). Dubinsky is an advocate of students writing computer programs where the constructs in the program parallel the constructs of a mathematical topic under inquiry. By using computer programming exercises where the programming activity specifies the procedure for the computer to carry out, the student is motivated to reflect upon the enactment of the concept. Dubinsky states that the act of programming is a generic process which carries out what may be viewed as a more general construct in specific cases and induces the student to move towards a generic abstraction of the concept (Tall et al., 2002). Our instructional treatment is built upon this notion that programming is a vehicle for building abstractions in the mind of the learner. Numerous researchers in APOS theory have shown that computer programming is a viable tactic for teaching a variety of topics in undergraduate mathematics (Asiala et al., 1998, Weller et al., 2008). Consequently, it is a commonly held belief that computer constructions are an intermediary between concrete objects and abstract entities (Dubinsky, 2000; Asiala et al., 1996; Dubinsky, 1995).

Our instructional treatment is composed of four primary phases: essential characteristics (ESS), programming activities (PROG), general expressions (GEN), and conjectures and convincing arguments (CA). This structure is depicted in the flowchart shown in Figure 1. Designing a lesson using the instructional treatment begins with an initial, naive genetic decomposition of the concept. The essential characteristics the learner needs to understand are identified and decomposed. Using the prerequisites identified in the ESS stage, programming activities and motivating questions are documented. These are used to create a guided lesson with response sheets for the PROG phase. During the PROG stage, participants are taught how to recognize general expressions in their programs and employ them as they explore the lesson topic. The PROG and GEN steps are iterated an appropriate number of times based on the requirements identified in the ESS phase. Each iteration results in the learner identifying additional general expressions. The participants are taught to write the generalizations as mathematical statements leading to more general expressions and generalizations. Finally, learners are motivated to make conjectures about relationships between concepts using the discovered general expressions and make convincing arguments using what they've discovered. Throughout the PROG, GEN, and CA phases data is collected in the form of participant response sheets. Participants are pre-tested and post-tested over the lesson concept. All of the collected data is analyzed using the APOS framework. Our instructional treatment has been applied to a variety of mathematics concepts such as parity of integers, functions, and proportional reasoning (Stenger et al., 2016).

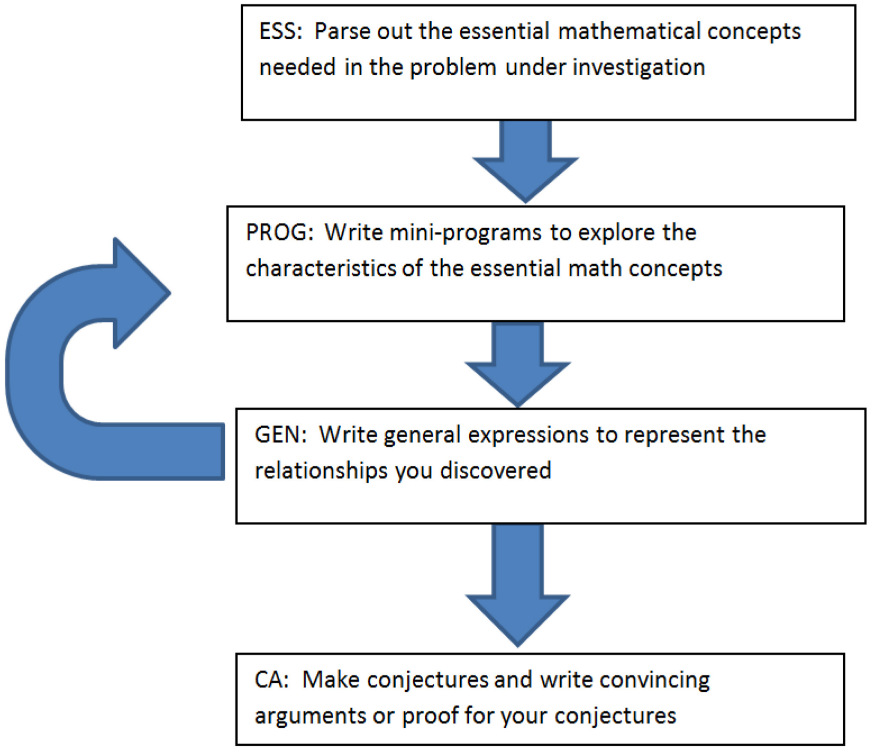

*Figure 1. The four phases of the Instructional Treatment*

## Methodology

We applied our instructional treatment to the concept of direct variation for this study. Our investigation was carried out with 33 upper level undergraduates who were interested in teaching mathematics. Each subject participated in a complete lesson including the pre-test, response sheets, and post-test. The format of the lesson was as follows. A brief introduction to the programming environment was given along with the code template shown in Figure 2. A cursory review of the relationship distance is rate times time ($d=rt$) was also presented. Using the code template with an increasing rate and fixed time, participants were asked to complete the program to output the associated distance. Learners were encouraged to experiment with their computer programs and make observations about any relationships. Once this initial table was constructed, the participants were ushered through a series of program modifications and written responses. For example, they were asked to add columns to their programs to depict the doubling or halving of the rate with time fixed and the resulting distance. Programs were modified to show the results of doubling, tripling, and halving the rate with time fixed. Written responses to questions and reflections on their observations were recorded by the participants on their response sheets including generalizations of behavior. Observations on variation and direct variation were solicited as general expressions and participants were taught how to denote the general expressions in mathematical language. For example, participants might observe that if rate doubles and time is fixed, then distance doubles. The instructional treatment was designed so that repetition with various program modifications would stimulate the desire to generalize the observed behavior and make conjectures about the mathematical construct. The final stage of the lesson involved making conjectures and convincing arguments. Participants were shown how to use general expressions to support, or refute, a conjecture using mathematical language. They were then asked to attempt their own convincing arguments with the general expressions they recorded during their inquiry. All of the participant's responses were collected on written response sheets during the lesson. Additional data was collected in the form of interviews. We recorded interviews with seven of the participants which were then transcribed and analyzed. All of the collected data was reviewed and scored using APOS theory. We devised a ranked set of scores to denote pre-action, action, process, and object levels for the direct variation concept based on our genetic decomposition and recorded scores for each subject's pre-test, response sheets, post-test, and where applicable interview data. In the event that authors disagreed, a discussion and further analysis of the data was used to reach consensus.

```
print("r", "t", "d", sep="\t")
t = 5
r = 1
while r < 11:
  print(r, t, "?", sep="\t")
  r = r + 1
```

*Figure 2. Computer programming template for lesson*

## Results

For ease of reporting and discussing results we have adapted the following convention. When referring to elements from a first set , say X, that vary with elements of a second set, say Y, we call values in the first set x and the corresponding values in the second set y.

In the discussion that follows, R denotes the researchers and U0001 to U0033 identify undergraduates. Results are presented that show how student mathematical behavior correlated to the genetic decomposition. Results also illustrate the influence of computer programming on students' ability to generalize over the concept of direct variation.

### Overall Results

Table 1 shows the number of undergraduates who were rated at the Pre-Action, Process, and Object level prior to instruction and after instruction. Forty-two percent of the students were at the process level prior to instruction. (14/33). Seventy-six percent (25/33) were either Action or Process. Only two students demonstrated an Object conception before instruction. Table 1 shows the number of undergraduates who were rated at the Pre-Action, Process, and Object level prior to instruction and after instruction. Forty-two percent of the students were at the process level prior to instruction. (14/33). Seventy-six percent (25/33) were either Action or Process. Only two students demonstrated an Object conception before instruction.

| | Before Instruction | After Instruction |
|---|---|---|
| Pre-Action | 6 | 0 |
| Action | 11 | 5 |
| Process | 14 | 9 |
| Object | 2 | 19 |

*Table. APOS level before and after instruction*

**Action**

Student responses to questions were scored at Action level based on the description in the genetic decomposition. Action level responses were analyzed by the authors for common mathematical behaviors. Student responses during the lesson and in interviews following the lesson fell into three categories of mathematical behavior:

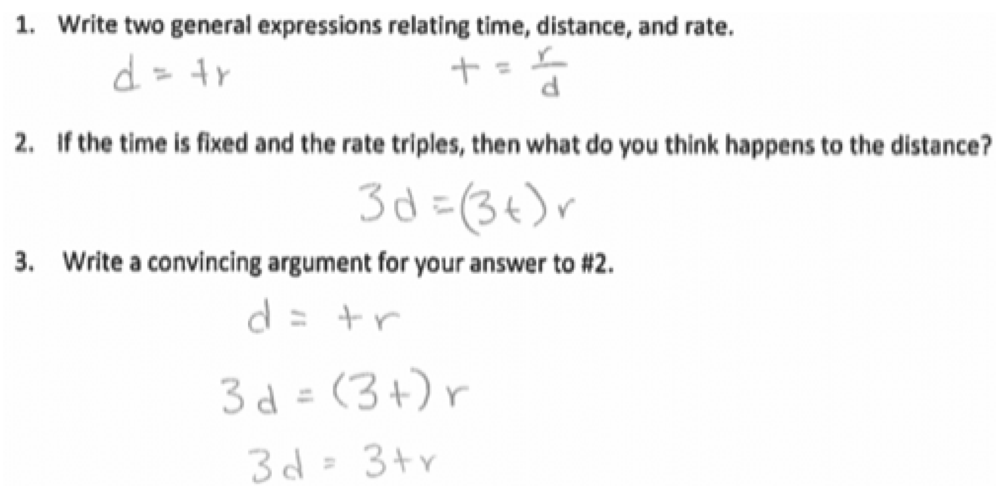
- Category 1. Using specific values or thinking about specific instance
- Category 2. Balancing the equation
- Category 3. Substituting a value in the equation

**Using Specific Values or thinking about specific instance.** In the follow-up interview, the researcher asked the student to explain their thinking on a response.

R: What were your thoughts on this? (pointing to post-test response)

U0001: I like having values just cause[sic] it helps distinguish what we're already going over like variables are fine but when I actually have a number to place with the variable it makes it easier to keep up with where I'm going and what I'm doing. So I would place a random value somewhere just so I know how to get from point A to point B.

**Algebraic manipulations of a general expression.** It is not unexpected that students at the Action level for a concept would use specific values to direct their problem solving. Surprisingly, this study found that ten of the eleven Action level students did not rely on specific values but performed algebraic manipulations on a general formula. What looked like a general argument, which might imply an Object conception, was instead an explicit, step-by-step procedure to balance the equation. This is similar to Frith, et al. (2016) who found students could work proportion problems applying "mechanical knowledge or algorithmic procedures" without actually reasoning about the relationship. Mechanics of algebra included either trying to balance the equation (9 instances) or to substitute general expressions into the equation (8 instances). Students at this level did not meet the prerequisite skills, as defined in the genetic decomposition, two students were at the pre-action level for the concept of multiples, eight did not meet the prerequisite process level for the concept of variable, two did not meet the prerequisite for constant, and one did not meet the prerequisite for the concept of one-to-one correspondence.



1. Write two general expressions relating time, distance, and rate.

$d = tr$ $\quad$ $t = \frac{r}{d}$

2. If the time is fixed and the rate triples, then what do you think happens to the distance?

$3d = (3t)r$

3. Write a convincing argument for your answer to #2.

$d = tr$

$3d = (3t)r$

$3d = 3tr$

*Figure 3. Action Category 2 – Balancing the equation*

**Balancing the equation.** The snip of student U0005 in Figure 3 shows a typical response in Action Category (2). The student carried out the step by step procedure, multiplying both sides of the equation by a constant, e.g., if $d=tr$ then $3d=(3t)r$. This student wrote in their response of a "need to balance", as they multiplied both sides by 3.

**Substituting a value in the equation.** The snip of student U0029 in Figure 4 shows a typical response in Action Category (3). The student carried out the step-by-step procedure, substituting $3r$ for $r$ in the equation $d=rt$. This work demonstrates a lack of the prerequisite requirement for a process understanding of variable, as $d$ takes on the role of the first distance and the second distance.

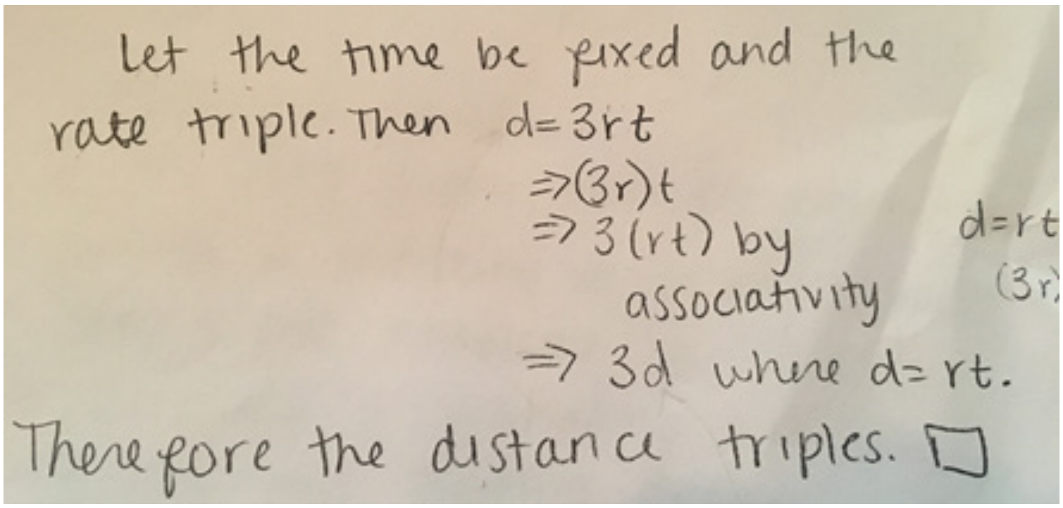


*Figure 4. Action Category 3 – Substitution*

**Process**

Of the 14 students at the process level, 10 demonstrated the notion of varies without demonstrating a notion of varies directly. Students' concept of varies fell in two categories:

- Category 1. Varies - $x$ increased (or decreased) then $y$ increased (or decreased)
- Category 2. Varies by some multiple - $x$ increased (or decreased) by some multiple, then $y$ increased (or decreased)

In either case, whether or not they repeated the given information about $x$, for their part in the solution they did not mention the multiple. They did not indicate an awareness of the "locked relationship" between $x$ and $y$ that is determined by the constant of proportionality $k$.

**Varies.** The snip of work from U0003 in Figure 5 below shows a typical response for varies in Process Category (1). The student described a dependence between rate and distance where the rate increased then the corresponding distance "will increase as well". The parenthetical statement by the student "The same time frame in a quick pace" indicated they were imagining a process in their mind, where rate and distance varied in a coordinated way.

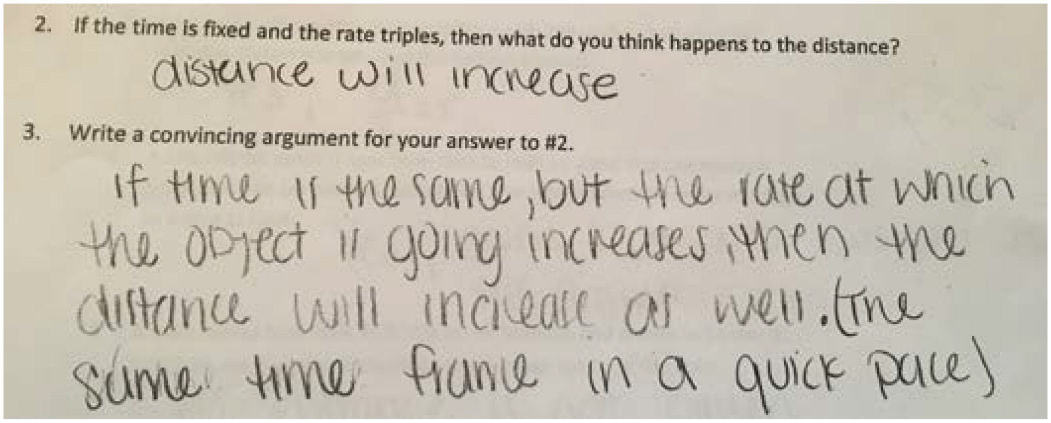

*Figure 5. Varies – Process Category (1)*

**Varies by some multiple.** The snip of work from U0007 in Figure 6 shows a typical response for varies in Process Category (2). The student described a dependence between rate and distance where the rate tripled then the corresponding distance traveled increased. They are imagining a process where an object is moving at a faster speed so "a greater distance would be covered in a fixed amount of time". There was a Process in their mind where rate and distance varied in a coordinated way.

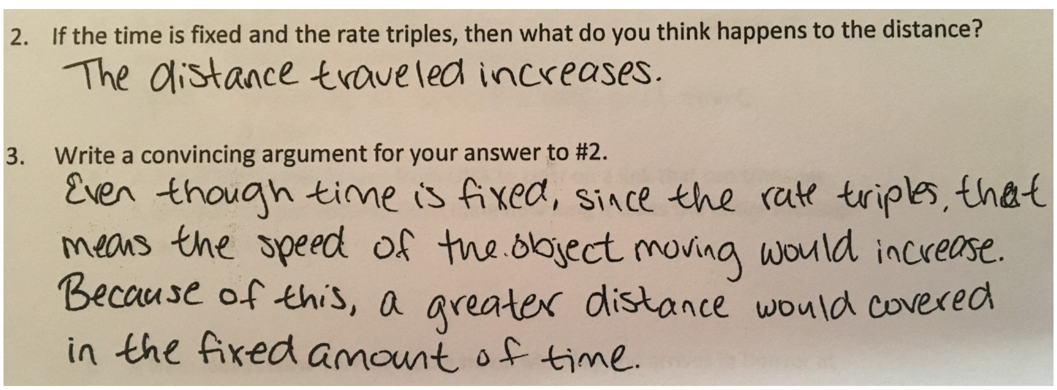

*Figure 6. Process Category (2) - Varies*

In neither case did the students in Process Category (2) demonstrate a knowledge of the "locked in" relationship between $x$ and $y$ that is a part of direct variation and is fully determined by the constant of proportionality.

The other mathematical behavior that was common among students at the process level was incorrect use of substitution. Students were stuck performing learned, routine algebraic manipulations and did not look for a general relationship. When they engaged in computer activities designed to act on the varies relationship such as doubling or halving elements of X, they did not see the effect on the relationship between corresponding elements in Y as locked in place by $k$. Eight students used flawed substitution to attempt to solve the general expression algebraically, in the same manner observed in Action level students (see Figure 4 above).

**Object**

The responses that indicated Object level understanding of direct variation, according to our genetic decomposition, fell in two categories:

- Category 1. Relationship between X and Y locked in place by $k$

- Category 2. Elements of X were dependent on values in Y and the dependency determined by *k*

Verschaffel et al. (2000) found that students' natural, naïve understanding of proportions were a hindrance to deeper understanding of the concept. Although 32 of our 33 students correctly identified two general expressions relating *d*, *r*, and *t*, only two students demonstrated an Object level knowledge of the fixed relationship between X and Y, determined by *k*, before the instructional treatment.

**Influence of Computer Programming on Generalization**

The influence of writing computer programs to explore the concept of direct variation was demonstrated by 16 of the 33 students. These students referenced their programming activities in their responses, in multiple instances, even though neither the question (nor the instructor) suggested responding with program code. Students naturally and intuitively adopted language from their programs. Twelve of the sixteen, who referenced programming in their responses concerning general expressions, improved at least one level during the instructional treatment, while two stayed the same and two went down a level. The students who referenced their programs when asked to give a general expression fell into two categories: (1) Computer Input: Print Statements and (2) Computer Output. In both cases illustrated below by typical responses, the students imagined generating code in their mind, and copied their imagined code onto their response sheet.

The response from Student U0007 in Figure 7 shows a typical response for Computer Category (1). The student imagined writing a computer program with the displayed print statement as an input statement. The response below was after the first computer programming activity. The print statement was stuck in between the answers for Response #3 and Response #4. It appears as a transition between the English statement "the distance is also doubled" and the general expression *(2r)t*. The transitory work is seen as the student wrote "*d = r2*t*" above the print statement "*(r*2)*5"*.

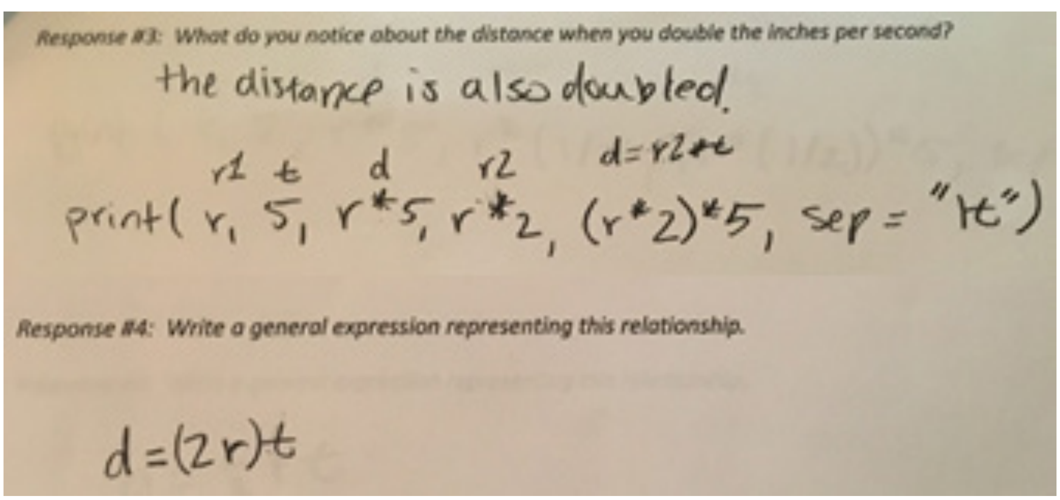

*Figure 7. Category (1) – Computer program*

Two students demonstrated evidence that running a computer program in their mind and reflecting on the output in table form was a transition from English language to mathematical language. The response from Student U0002 demonstrated the typical response for Computer

Category (2) by constructing a table for Response #5 in the left margin after concluding, "halving the rate also halves the distance". The same student then responded in Response #6 with "d2 = $\frac{rt}{2}$.".

The response from Student U0002 in Figure 8 shows the typical response for computer category (2). The student wrote the table over to the side of Response #5 and appeared to use it as a transition between the responses. This student worked #3 and #4 in a similar manner, using a table from a computer program they ran in their imagination.

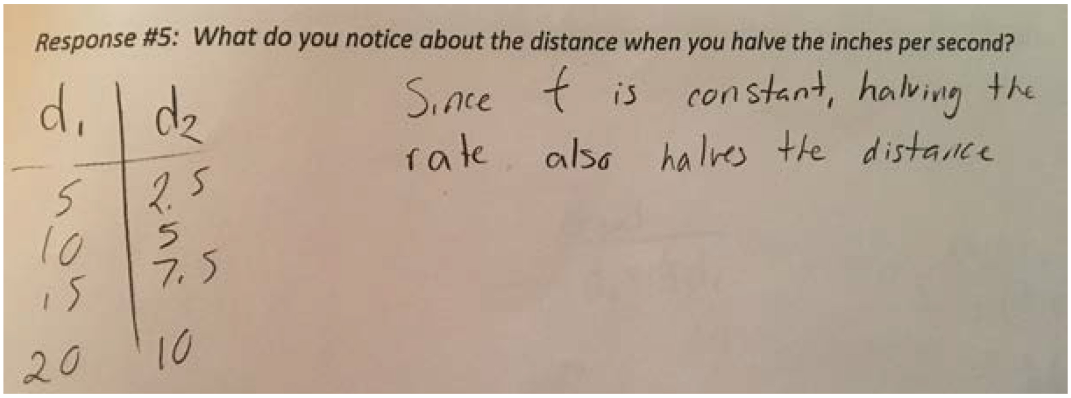

*Figure 8. Computer Program – Category (1)*

Students U0006 and U0007 were probed about the relevance of the programming in a follow-up interview:

R: Did you think the programing and the coding helped with the proofs and seeing the general expressions? Do you feel like it contributed in any way?
U0007: I was it does make it easier to look at because you can see everything broke[sic] down and spread out.
U0006: I agree, totally.

In the following interview snip, U0004 described how they developed a "mindset of generalizing" during the instruction. They did not demonstrate a general notion using variables in their expression until after the first programming activity.

R: Just describe when you were writing the last couple of proofs or either one of the proofs
U004: I was thinking more of just the letters and generalizing it after we had done those together and the ones on the other response sheets because I think I was in a mindset of generalizing it…
R: Right
S: So the way I wrote it out, I put more notation the second time on the post-test.

## Conclusion

In this study, students explored direct variation through an explicit method for teaching generalization that uses computer programming and convincing arguments. The researchers found that scoring and assessing undergraduates' conception of direct variation was complex due to the task-dependent and context-dependent nature of conception. The genetic decomposition adequately described the students' constructions observed in the data. We noticed students at the

Action level tended to manipulate algebraic expressions without understanding the underlying structure. We found many students in our study have a notion of vary but not directly varies. We observed some students who needed to construct the property vary, at the Process level, before constructing the property varies directly, at the Object level and conjectured that a notion of vary is a prerequisite to directly vary. Therefore, we have modified our genetic decomposition to account for this in future studies. We found that prerequisite deficiencies corresponded with the inability to progress through levels of understanding as measured by APOS. We found that students naturally turned to their computer programs to help find general expressions for the concept. Some students considered the inputs to their programs and others reflected on the outputs of their programs when asked to write general expressions for observed relationships. The programming activities influenced students and served as a catalyst to move from purely English descriptions of their conceptions to using mathematical symbols and a "mindset of generalizing". The results of this study can facilitate further analysis of using computer programming and proof writing to overcome cognitive obstacles in undergraduates' understanding of proportional reasoning.

**First-generation Low-income College Student Perceptions about First Year Calculus**

Gaye DiGregorio and Jess Ellis, Colorado State University

## Abstract

*The purpose of this study was to explore first-generation low-income students' experiences with first-year calculus, including their self-belief in being successful in math. As part of the Progress though Calculus project, one STEM-focused institution was studied with survey results from students enrolled in first year calculus, and interviews and a focus group of three first-generation low-income students who completed first year calculus. Quantitative results illustrated similar rates of faculty and student interaction and increased self belief in being successful in math while taking first year calculus for first-generation students, in comparison to their continued generation peers. Qualitative findings emphasized the value of creating interactions with faculty and other students, and faculty's impact on students' sense of belief in being successful in calculus. Promoting non-cognitive factors such as student support and self-belief in math success may influence math completion of first-generation low-income students.*

**Key Words**: First-generation low-income students, self-belief, first year calculus

Along with innovative pedagogies and curriculum enhancements to improve math education, it is also important to consider the increasingly diverse student population, gaps of math completion among marginalized students, and the impact of non-cognitive factors such as self belief and support networks as part of the formula for student success in mathematics. In this study I explore the experiences of first-generation low-income students in first year mathematics from an asset approach, meaning I focus on what these students bring from their identities to support their success, as well as attending to barriers these students face. For decades college administrators and researchers have viewed the first-generation and low-income identities as "at risk", which is reinforced by the well documented national graduation gaps of these students. For instance, among 4.5 million college students from 1995-2002, six-year graduation rates for first-generation low-income students were 44% lower than continuing-generation higher-income students (Engle & Tinto, 2008).

To address these graduation gaps and move beyond the focus on the disparities of underserved students as a disadvantage to being successful in college, a paradigm shift is needed to to support students that attend college rather than require students to adapt to college. One way to provide support is focusing on first-year mathematics completion since it is highly correlated to graduation rates (Colorado State University, 2015). By understanding what assets students bring to first-year mathematics success, we can better understand how to support a higher graduation rate among this population.

## Shifting to an Asset Approach to Understanding First-generation Low-income Students

Nationally, 28% of all undergraduate college students are first-generation, and 27% are low-income (Cook & King, 2007). Most prominent research on first-generation low-income students has focused on deficits of this student population, as a disadvantage to being successful in college. Academic deficiencies of these students include: higher need for remedial courses (Chen & Carroll, 2005), undeveloped student success skill sets (Collier & Morgan, 2008), less academic and co-curricular engagement (Pascarella, Pierson, Wolniak, & Terenzini, 2004; Warpole, 2003), and lower educational aspirations (Pike & Kuh, 2005). For example, in considering the success in math of first-generation low-income students, lower levels of math completion have been documented. An analysis of first-generation student college transcripts from 1992 to 2000 shared that 55% of first-generation students took at least one math course in college compared to 81% of students whose parents had a bachelor's degree (Chen & Carroll, 2005). Additionally, at Colorado State University (2016) after controlling for prior academic preparation, first-generation, students of color, and Pell eligible students were significantly less likely to place into college algebra and to complete three credits of math in the first year compared to their peers. Non-cognitive disparities include a lack of parental support (Ward, 2012), not as much social capital (Lin, 2011), lower levels of a sense of belonging (Aires & Seider, 2005; Ward, 2012), and a cultural mismatch with the university (Roberts & Rosenwald, 2001; Stephens, Fryberg, Markus, Johnson, & Covarrubias, 2012).

A different approach to defining deficits and expecting students to compensate for deficits is research done within the perspective of promoting the strengths and assets of students as an advantage for collegiate success. Although not as prevalent, research within an asset framework focused on higher self-authorship with first-generation students, which is a transition from relying on others to defining oneself to more internal thinking in determining one's life path (Pizzolato, 2003), high levels of motivation to attend college with an emphasis on hard work (Martin, 2012) , and a desire to contribute to society (Olive, 2009).

Research has also shown the importance of meaningful individual connections to support first-generation low-income students. For instance, a strong network of faculty who care and have high expectations plus peers who offer encouragement has been found to help first-generation college students transition to college (Coffman, 2011), and obtain a college degree (Lourdes, 2015).

Broader interventions that centered on creating an institutional culture to support these students' success have also been impactful. This supportive culture was promoted by emphasizing interdependence of being part of a community, which positively impacted first-generation students' academic performance prior to the fall semester (Stephens et al., 2012). This research represents a paradigm shift of supporting students that attend college rather than requiring students to adapt to college, has been defined as becoming a student ready college (Brown McNair, Albertine, Cooper, McDonald, & Major, 2016) .

## Self-belief Factors Affecting Math Completion

To begin to reflect on ways to enhance math completion with first-generation low-income students, one non-cognitive factor to consider is self-belief based on the power of positive psychology, which is the study of conditions that influence the optimal functioning of people (Gable & Haidt, 2005). Theories to inform this perspective of developing student assets are stereotype threat (Steele, 1997), which challenges college success, and self-belief (Bandura, 1977; Dweck, 2006), which can potentially mediate challenges and promote academic success. Stereotype threat theory asserts that negative stereotypes of one's performance based on his or her social group can put individuals at risk of lower performance (Steele, 1997).

In response to the negative influences of stereotype threat, positive psychology theories of self-belief are used with Bandara's theory of self-efficacy and Dweck's theory of a growth mindset. Bandara's theory of self-efficacy is a social cognitive theory based on the belief that one can achieve his or her goals (Bandura, 1977). Expanding upon self-efficacy is growth mindset, which is the belief that one may improve through engagement with the learning process (Dweck, 2006).

### Self-belief and Math Achievement

Research on the relationship of self-efficacy and math achievement is evident both with students who have not performed well in math along with engineering students with high levels of math performance. Investigating students who were repeating a developmental math course, they identified high self-efficacy as the essence of their persistence despite a low self-concept in mathematics (Canfield, 2013). For engineering students who usually excel in math, self-efficacy was correlated with mathematics achievement scores and cumulative grade point averages (Loo & Choy, 2013).

Research has demonstrated greater course completion rates in challenging math courses (Yeager & Dweck, 2012), which supports an approach emphasizing a growth mindset. Many studies have also focused on the growth mindset as a mediating factor to stereotype type threat of marginalized populations in math performance. Dar-Nimrod and Heine (2006) studied math achievement and gender, and illustrated that females with a growth mindset performed better than females with a fixed mindset on math assessments similar to the Graduate Record Examination.

### Purpose of this study

Lower math completion rates of first-generation low-income students along with the positive impact of self-belief and math achievement, warrant further investigation into ways that self-belief can enhance success in mathematics. The purpose of this study is to explore first-generation low-income students' experiences with first-year calculus, with particular focus on their self-belief in being successful in math. First-generation students are defined, using the TRIO definition, as students whose parents have not obtained a college degree (Nunez, Cuccaro-Alamin, & Carroll, 1998), and low-income is defined as Pell recipients, which are government grants for college students with exceptional financial need (Dynarski & Scott-Clayton, 2013)

Specifically, the following research questions guide this work: (1) How do first-generation low-income college students experience first year calculus at a STEM focused institution? (2) How does first year calculus influence the self-belief of first-generation low-income college students to be successful in math?

### Methodology

To provide context of this research, a broad overview of the Project through Calculus (PtC) research that is studying ways to enhance student calculus completion rates is summarized. A part of the PtC research was a pilot study at one STEM institution, which is the focus of this paper.

#### Progress through Calculus Research

The Progress through Calculus study is sponsored by the Mathematical Association of America and funded by the National Science Foundation (NSF) to research student success in calculus. Twelve higher education institutions were identified by the research project team as institutions using structural, procedural, curricular, and pedagogical approaches to the pre-calculus and calculus program that has been successful in higher math completion rates, especially with underrepresented students. Specific approaches include math placement, course structure, active learning, student support, instructor coordination, graduate teaching assistant training, integration between math and other STEM disciplines, and local data analysis. Prior to researching the twelve institutions, three pilot studies were held at institutions based on geography, convenience, and access; to refine data collection content and procedures.

One of the pilot studies as the focus of this study was done at an institution that implemented initiatives including developing a teaching faculty track, coordinating efforts with calculus faculty, and implementing active learning practices in calculus courses. Additionally, this institution was of interest since the first year calculus D FW rates have decreased from 22% in fall 2006 to 10% in spring 2015.

**Research Approach**

This case study mixed methods design was used as a means to understand a complex social unit problem holistically (Merriam, 1988) which for this research was student experiences in math, and to study "how" and "why" questions (Yin, 2003) that informed these experiences. This study utilized multiple sources (Merriam, 1988), focused on the contextual environment (Fryvbjerg, 2011), and gained multiple perspectives with a progressive focus reconsidering issues throughout the research process (Stake, 1995). Multiple data sources, varying perspectives, and in-depth information for this study included student interviews, a student focus group, and a student survey. Additional contextual information about the environment was gathered through faculty interviews, classroom observations, and information from the local coordinator. The mixed methods design was a convergent parallel design with both interviews/focus group and survey results gathered and analyzed independently, and then the results interpreted together (Creswell & Plano Clark, 2011).

**Study Participants and Data Collection**

In spring 2017, this pilot study took place at a four year public STEM focused institution (4,600 undergraduate students, 11% first-generation, 11% Pell recipients, and 26% students of color) with a two day site visit. Students that participated in the interviews and focus group were recruited with assistance from the multicultural support program director. Three first-generation low-income (defined as financial struggles being central to their college experience) students participated including a first year white female majoring in engineering, a third year African American female majoring in computer science, and a third year Asian male majoring in computer science. The student survey was developed by the Progress through Calculus Research team, and questions on self-belief and resources for academic success from students enrolled in first-year calculus were utilized for this study.

The data collection is outlined in Table 1 focusing on one hour individual interviews at mid-semester and one focus group with the same three students at the end of the semester. The interview responses and institutional context informed the focus group questions by developing both themes and areas of differing perspectives. Two researchers were present at the focus group, with one facilitator and one who took reflective notes. The math instructors facilitated the completion of the student surveys during one class period.

**Table 1. Data Collection Process**

| Data Method | Data Means | Data Collection Timeline |
|---|---|---|
| Student Interviews | Audio-recorded and notes | Mar-17 |
| Institution context | Faculty & Staff interviews<br>Classroom Observations | Mar-17 |
| Student Focus Group | Audio recorded and notes | Apr-17 |
| Student Survey | Completed in class | Apr-17 |

### Data Analysis

Qualtrics survey results on student self-belief and interactions with faculty and peers as support resources were analyzed with SPSS using chi-square analysis. For the interviews and focus group, holistic data analysis was accomplished with an inductive process to identify relevant emerging themes (Yin, 2003), making sense out of the data collection (Miles, Huberman, & Saldana, 1994).

The interviews and focus groups were transcribed and then coded with MaxQDA, a qualitative coding software program. The researcher began with a first-cycle coding process and then reviewed each code and coded segment to illuminate connections between the categories in the second-cycle coding process, and used a second coder to review the coding process (Miles et al., 1994). Throughout the data analysis process, high quality data verification was implemented including attending to all the data, and using the researcher's expert knowledge (Yin, 2003). For instance, the researcher's expertise of creating generalizations was balanced with including description of vicarious experiences (Stake, 1995). Collectively the data analysis of breaking apart and piecing together data themes, illuminated further understanding of the math experiences of first-generation low-income students (Merriam, 1988).

### Trustworthiness

The core principles of trustworthiness for this study were triangulation of data sources, incorporation of various evaluators with different theoretical perspectives, and continual maintenance of a chain of evidence (Yin, 2003). Triangulation of multiple sources including interviews, focus groups, and survey data enhanced the richness of the study. Additionally, working together with four researchers with mathematics backgrounds provided an additional perspective to my higher education background, which broadened the collective lens of this research. Field notes were taken by all the researchers and compared to each other's documents for a collective chain of evidence.

## Quantitative Survey Results

On the survey, there were 335 respondents, with a 69% response rate. Demographics of the students were first year 317(95%), first-generation 36 (11%), and Pell eligible 44 (13%). The questions analyzed in this study asked about faculty and student interactions, and self-belief in mathematics.

## Faculty and Student Interaction

Focusing on faculty interaction outside of class, survey frequencies found similar percentages of first-generation students ≈20% (7) compared to continuing generation students (57). Concerning interactions with peers for all students, there were higher percentages of working with peers outside of class than instructors, and similar percentages with first-generation ≈58% (21) compared to their continuing generation (173). In general low income students had similar percentages than first-generation students.

## Student Self-Belief

Aspects of self-belief studied were confidence, ability to do math, and growth mindset. The survey results indicated that most first- generation ≈65% (24), and continuing generation ≈62% (184) significantly or moderately increased their confidence in math by taking calculus, which are similar percentages amongst first-generation and continuing generation students.

Along with confidence, findings about a student's ability to learn mathematics revealed that most first-generation students ≈72% (26) said that their math ability "moderately or significantly increased" with taking calculus, which was slightly higher than continuing generation students ≈67% (198). Additionally, ≈ 75% (27) first- generation students shared that their growth mindset "significantly or moderately increased" while taking first year calculus, which again was slightly higher than continuing education students ≈70% (208). In general, low income students had similar percentages than first-generation students. Overall there were fairly similar percentages of student self-belief in math success with first-generation and continuing education students.

# Qualitative Interview and Focus Group Results

The interview and focus group results emphasized the importance of interactions with faculty and students, highlighted faculty's impact on students' sense of belief and students growth mindset in being successful in math, and explored students' identities around generational and income status.

## Faculty Interaction

In exploring faculty interactions, key factors that emerged were the importance of how faculty responded to questions, and the value of small individual interactions. An example of how faculty reacted positively to questions is illustrated by the following statement by one student, "When you ask a question and a faculty member is really supportive and they don't look down on what you ask, they just answer this is what it is." A less supportive response is illustrated by the statement by another student, "if we ask a question that is dumb he looks down on us, so it's really intimidating."

In addition to responding to questions, short interactions with faculty had a big impact on the student's experiences in math courses. One student illustrated the impact of a faculty interaction as being the most positive experience in calculus.

> "My math teacher was sitting outside on one of the picnic tables and I didn't want to sit with him and talk about math….so I sat on a bench …. He was going back into his office and he stopped by and was talking to me….How are your classes going? Then he said he didn't care about the other classes just mine, it kinda made me laugh… It was kinda of like your cool and we joke around now. I feel like I know him a lot better. Listening to him lecture I have that connection: you know what you're talking about I will believe what you are saying. I

mean I guess it showed because I did a lot better on my last test. That was the best positive experience that I have had in calculus. It was getting that connection."

**Student Interaction**

Along with faculty interactions, the importance of peer support was highlighted, describing how students worked with other students in math courses. Two students shared that they looked for students that were doing better than them, and then would ask them to be in a study group. Another example was a network of students beginning with two students working together, each branching out to other friends, and then coming back together to complete the homework. Illustrating the interdependence of working with another student and becoming more of an independent learner is illustrated below.

> "Last semester I had that one student who was really good at math I feel that she pushed me along and unfortunately I'm not in the same section with her this semester, kinda of realizing that I'm alone here. I need to figure it out but we still meet up to do the homework since we have the same class. I've been able to go, I solved 1 and 2 what did you get? Seeing if we have the same answers really helped me to learn more, being able to say I learned this so I can tell her I learned it."

A common theme of their math experiences was the major significance of working with faculty and other students outside of class.

**Faculty Impact on Student Self-Belief**

The other prominent research finding was the tremendous impact that faculty had on student's self-belief in being successful illustrated by the quote below.

> "I went in [to her office] and said I can't do Calc II, I'm a fraud, and she said yes you can. She said we are going to sit down and go through this exam and she went question by question and she said what did you do wrong? It's not like you don't understand what's going on sometimes you are reading the question incorrectly. You know the material you just need to interpret the question and answer it correctly. Okay that clicks. She didn't give up she didn't brush me aside as one of twenty students. She remembered my name which was important."

**Growth Mindset**

Beyond faculty and peer support, another theme of all of the student's experiences was some sort of struggle in a course. Strategies of how they responded to academic struggles were studying earlier before a test, and going to office hours. More importantly was the constructive reflection from those experiences. Two students shared,

> "Failing, it gives me more motivation. I can't study one week in advance, let's go 2 weeks. Question yourself and say I did that wrong, you kinda go through with that self evaluation I know what I did wrong and I know how to improve after a bad test".
>
> "I know how to pick myself up. It's not something that is going to crush me and I am going to succeed. Where other people have dropped out because they earned their first B on an exam, I was just bewildered, so I definitely know how to push through the hurt".

These reflections illustrated a growth mindset valuing the importance of continued engagement in the learning process to improve performance.

**First-generation Low-income Identities**

One of the interesting aspects of the first-generation identity is that it may be an emerging identity that becomes apparent as a young adult differing from a lifelong identity. For instance one student in this study shared that she learned about first-generation from a TRIO staff member who said that being first-generation would help her get to college, and another student discovered that he was first-generation from his high school principal. In reflecting on this newly discovered first-generation identity, a student described first-generation with two words, story and determination. "Where you come from is your story and where you go is your determination."

In addition to the first-generation identity, all of the students spoke about financial struggles, which was a more long-standing identity when growing up. A high saliency was shared that being first-generation and low-income impacted how they experienced college in terms of navigating this new adventure, working experiences, and living arrangements. Additionally other intersecting identities such as being a student of color, and having immigrant parents were also interwoven into their perceptions and experiences.

Overall, the students' comments about being first-generation and low-income were more focused on the assets of these identities rather than the deficits. Advantages of being first-generation included having more "ump" to get through school, being acknowledged by career representatives as being hard workers, and having more job experiences. One student shared below that as a low-income student she had better work experience than her higher income peers.

> "We say we wish we had rich folks and then we say no we don't because we know where we would be at. We would take things for granted… I finally got an internship but I had experiences that other students didn't. I have had a job for 4 years and worked with teams, and other students that come from a linage family you have never had to work. You don't know what it means to really work."

The challenges of being first-generation low-income students focused on the uncertainty of college, and dealing with the imposter syndrome of questioning the capability of being successful. Beyond the internal reflections about being first-generation low-income students, there was also a theme that continuing higher income students were not only unaware of these identities, but lacked an appreciation that some students may be different from the majority identities as illustrated below.

> "Everyone thinks that their parents are the same as theirs. That they came from a good family, parents that went to college have good jobs. I think that is why a lot of students who do have that- think that everyone else has it. Predominately like the continuing generation students here look down upon other students."

These results illustrate increased self belief in mathematics at this institution, the power of faculty and student interactions as integral to first-generation low-income student experiences in math, and especially the impact of faculty believing in student success.

## Discussion

A major highlight of this research was the positive impact that calculus had on students' increased confidence in math, their ability to learn mathematics, and their sense of hope in being successful in calculus, which was mostly similar for first-generation low-income in comparison to their continued higher income peers. Additionally students illustrated a growth mindset in sharing the ability to bounce back from academic struggles. All of these factors may suggest a positive impact on the self-belief in being successful in math for these first-generation low-income students at this institution. This is an important finding considering stereotype threat which is well documented with students having marginalized identities in negatively impacting students beginning with studying women's performance in math (Spencer, Steele, & Quinn, 1999), African Americans' performance on intelligence exams (Steele & Aronson, 1995), and intellectual achievement of low-income students (Croizet & Claire, 1998). Learning even more about how faculty and institutions can provide an environment for enhancing student self-belief is recommended.

Another highlight of this study was the importance of faculty and student interactions. Although strong faculty and student interactions reinforce well established high quality teaching practices, it is an important reminder to keep these qualities at the forefront especially in college courses. It is also essential to note that faculty interaction was similar for first-generation students compared to continuing generation students. This finding conflicts with predominate research that suggests less curricular engagement among marginalized identities, such as first-generation and low-income. For instance, Soriaa and Stebleton (2012) found less academic engagement with first-generation students measured by faculty interactions and contributions to class discussions, and Goodman et al. (2006) found that low income students did not experience faculty contact and active learning at the same levels as higher-income students. Ensuring faculty interaction may be even more imperative for first-generation low-income students, which is reinforced by Lohfink and Paulsen (2005) who found that first-generation student participants who had higher levels of academic engagement focusing on faculty-student interaction persisted in college at higher rates than students with lower levels of academic engagement.

Additionally, in light of the research findings that first-generation low-income students are working with peers outside of class at higher rates than instructors, perhaps more intentional integration of student study groups would be impactful. The impact of faculty and student interactions found in this study may be an illustration of a supportive culture that fosters academic success.

In regard to first-generation and low-income identities, students focused on the advantages of being first-generation low-income students including increased motivation, more work experiences, and being acknowledged by others as hard workers. There was also a theme that continuing higher income students lacked an understanding of first-generation low-income identities. Consequently, it may be important for institutions to strategize ways that encourage all students to gain a stronger appreciation of varying student identities and to emphasize how diverse intersecting identities contribute to the campus community.

Repeating this same study at other institutions as part of the Progress through Calculus research project with larger sample sizes, will provide cross institutional results and additional insights. Although this study illustrates some promising results in enhanced student self-belief in math at one institution, additional more comprehensive findings will continue to explore ways to create an environment that promotes self belief in math in developing the talent of first-generation low-income students.

Conventions or Constraints? Pre-service and In-service Teachers' Understandings

Teo Paoletti, Montclair State U.
Kevin C. Moore, University of Georgia
Jason Silverman, Drexel University

Zareen Rahman, Montclair State U.

*We draw on data from pre-service (PST) and in-service (IST) teachers to characterize relationships between what we perceive to be conventions common to U.S. school mathematics and individuals' meanings for graphs and related topics. We use PST responses during clinical interviews to illustrate three themes: (a) some PST responses implied that things we perceive to be conventions were instead inherent aspects of PSTs' meanings (habitual use of "conventions"); (b) some PST responses implied they understood certain practices as customary choices not necessary to represent particular mathematical ideas (conventions qua conventions); and (c) some PST responses exhibited what we perceive to be contradictory actions and claims. We then focus on data collected with ISTs against the backdrop of these themes to highlight similarities across these populations and to provide implications of our findings.*

Keywords: Conventions, Graphs, Preservice Teacher Education, In-service Teacher Education

Hewitt (1999, 2001) distinguished between arbitrary and necessary information in mathematics curriculum and learning. He described arbitrary information as that which students need to be informed about by an external source (e.g., the name of an object or representational conventions), whereas necessary information students can deduce for themselves. In addressing graphs and coordinate systems, Hewitt (1999) described aspects of coordinate systems that are necessary (e.g., the need for a starting point or origin) and noted:

> These are some aspects of where mathematics lies within the topic of co-ordinates, rather than with the practising of conventions. I am not saying that the acceptance and adoption of conventions is not important within mathematics classrooms, but that it needs to be realised that this is not where mathematics lies. So I am left wondering about the amount of classroom time given over to the arbitrary compared with where the mathematics actually lies. (p. 5)

Whereas we imagine mathematicians and mathematics educators likely agree with Hewitt's distinction, the extent to which students and teachers hold meanings consistent with his description is an open question. Hence, in this report, we address the question, "In what ways do pre-service and in-service teachers understand graphing conventions?" Specifically, we highlight the extent to which what we perceive to be conventions are pervasive in PSTs' and ISTs' meanings for graphs and related ideas (i.e., function).

## Theoretical Perspective: Conventions, Constraints, and Habits

Conventions—or those practices an individual perceives as customary choices within a community of individuals—play an important role in mathematics, with notable examples including notational systems (e.g., function notation), order of operations, and representational systems (e.g., the Cartesian coordinate system). With respect to representational or notational systems, a primary reason individuals in a community establish or adopt conventions is that conventions afford consistent, simplified, or efficient ways to capture, convey, and constrain aspects of ideas and reasoning. Hewitt (2001), however, noted, "The learning of names and conventions plays a vital role in engaging with mathematics and communicating with others about mathematics, but is not mathematics itself" (p. 44).

The conventions established by a community typically do not originate at the community level, and for this reason the emergence and use of conventions cannot be reduced to strictly issues of notation and communication. Conventions predominantly emerge through a process of negotiation, wherein a community collectively adopts, rejects, or modifies the ways in which *individuals* originally attempt to capture and convey aspects of their thinking (Ball, 1893; Cajori, 1993; Eves, 1990; Menninger, 1969). Importantly, negotiation at the community level is not only about a choice of physical notation or representation, but it is also a negotiation of interpretation and meaning (Thompson, 1992, 1995). The emergence of conventions involves individuals of a community simultaneously negotiating, clarifying, and choosing customary forms of expression *and* intended constraints on the interpretations of those expressions. An implication of this is that when an individual enters a community, to understand something as a convention of that community requires that the individual address issues of notation and representation while simultaneously becoming aware of the implied constraints on interpretations and meanings. Although it is easy to speak of conventions as if they exist in a community independent of a knower, we contend conventions are personal constructs. A *person* understands something as a convention of a community when *that person* understands something as a customary or arbitrary choice made by some perceived community and with respect to some idea or concept.

When discussing students' use of notation and representational systems, Thompson (1992) described two ways in which an individual can use a convention: (a) using a convention unthinkingly and possibly unknowingly and (b) using a convention with an awareness that she is conforming to a convention (i.e., convention *qua* convention). Thompson (1992) elaborated, "To understand a convention *qua* convention, one must understand that approaches other than the one adopted could be taken with equal validity. It is this understanding that separates convention from ritual" (pp. 124-125). We leverage Thompson's distinction in the context of teachers' graphing activity, arguing a teacher's use of graphs entails a *convention qua convention* if the teacher's meaning includes an *awareness* of maintaining a convention (i.e., understands the convention as one way to represent some idea among other *equally valid* choices). We claim a teacher's use of graphs entails the *habitual use of "convention"* if the "convention" is a necessary or inherent aspect of a teacher's meanings. In this case, what we as researchers perceive to be a convention is not a convention qua convention with respect to that teacher's meanings; hence, we intentionally use quotations to indicate this difference in perception. As we illustrate in the results section, what an observer understands to be a convention can instead be habitual to a PST's or IST's use of graphs to the extent that the teacher unknowingly assimilates situations in ways that entail the "convention". Alternatively, the teacher might consider using graphs in some different way, but the teacher does not conceive such a way equally valid due to her or his system of meanings necessitating that the "convention" be maintained.

## Relevant Literature

Speaking on various conventions practiced in U.S. and international school mathematics, Mamolo and Zazkis (Mamolo & Zazkis, 2012; Zazkis, 2008) argued that students (and teachers) are not supported in understanding certain conventions as customary choices if educators unquestionably maintain particular conventions. Mamolo and Zazkis hypothesized that a potential outcome of educators unquestionably maintaining conventions is that students do not develop meanings that enable them to understand novel and unconventional situations (e.g., alternative coordinate systems). Mamolo and Zazkis's stance echoes Thompson's (1992) claim, "to ignore convention in our teaching can lead students to think of mathematics ritualistically" (1992, p. 125).

International and U.S. education researchers who have investigated students' meanings for function and other related areas have reported findings that are compatible with Mamolo, Zazkis, and Thompson's sentiments. Researchers (Akkoc & Tall, 2005; Even, 1993; Montiel, Vidakovic, & Kabael, 2008; Oehrtman, Carlson, & Thompson, 2008) have documented that students' meanings for function foregrounds the ritual application of the *vertical line test*. Montiel et al. (2008) identified students who applied the vertical line test when investigating relationships in the polar coordinate system. Doing so resulted in those students claiming that relationships such as $r = 2$ do not define a function. In this, and other (i.e., Breidenbach et al., 1992) examples, the researchers posed graphs that they understood to be representative of functions, yet the students' meanings for functions and their graphs did not afford their assimilating the graphs as such.

Our purpose here is not to rehash the documented claim that students often understand function in ways constrained to the application of the vertical line test (see Leinhardt, Zaslavsky, and Stein (1990) and Oehrtman et al. (2008) for more extensive reviews). Rather, our purpose is to draw attention to a particular feature of students' meanings that, as we illustrate in subsequent sections, is more deep-rooted and wide-spread than researchers have previously reported. Namely, we infer that one explanation for the students' actions in our colleagues' studies is that the students drew on meanings in which a particular coordinate system and what we perceive to be conventions of that coordinate system had become intrinsic to and inseparable from those meanings. For instance, what we perceive to be the convention of representing a function's input along the Cartesian horizontal axis did not appear to be a convention to those students reported on by Breidenbach and colleagues (i.e. habitual use of "convention").

We interpret several other researchers' findings to imply students' habitual use of "convention". For instance, Sajka (2003) detailed a student's use of function notation. Sajka argued that, to the student, function notation was more about what "we usually write" (2003, p. 247) than about using the notation to represent her ideas and reasoning. Using Thompson's (1992) language, the student was more focused on a ritualistic use of notation than on using notation as an act of personally expressing meaning under certain constraints. A consequence of this was that the student deemed examples that did not conform to her image of what "we usually write" as incorrect. Or, the student assimilated examples in ways that were consistent with her image of what "we usually write" but inconsistent with or inattentive to the researcher's intentions. Sajka noted that by conflating what "we usually write" and essential aspects of a mathematical idea, the student produced numerous inconsistencies in her use of function notation, some of which the student was aware of and others that were only inconsistencies from the researcher's perspective. As another example that we interpret to imply some students' habitual use of "convention", Moore, Paoletti, and Musgrave (2014) discussed how students' meanings for the polar coordinate system can be influenced by "conventions" of the Cartesian coordinate system. Notably, the students involved in their study were perturbed by contradictions in their reasoning that stemmed from coordinate pairs in the Cartesian coordinate system being conventionally of the form $(x, y)$ :(input, output), whereas coordinate pairs are conventionally of the form $(r, \theta)$ :(output, input) in the polar coordinate system.

## Methods

We interpret the collection of findings discussed above to indicate the need for a deeper examination of the extent to which individuals', and especially teachers', meanings entail the habitual use of "convention" versus a convention *qua* convention. In cases that teachers' meanings entail the habitual use of "convention", we would expect that their meanings become problematic in situations that an observer considers to break particular conventions or consist of alternative representational systems (Moore, Paoletti, et al. (2014) and Breidenbach, Dubinsky, Hawks, and Nichols (1992)). We would also expect them to (consciously or subconsciously) impose particular "conventions" in order to make sense of their experiences (Montiel et al. (2008) and Sajka (2003)). In order to explore and better understand this phenomenon in the context of teachers' meanings for graphs, we designed and conducted task-based semi-structured clinical interviews with PSTs (Ginsburg, 1997). We used similar tasks in an on-line open-ended survey to explore the extent to which ISTs held meanings compatible with those of the PSTs.

### Participants and Setting

Our work with PSTs involved 31 participants enrolled at a large state university in the U.S. The PSTs were entering their first semester in a four-semester preparation program for secondary mathematics teachers. Each PST began the program during her or his junior year (in credits), and each PST had completed at least two mathematics courses past Calculus II before beginning the program. We chose the PSTs by asking for volunteers from their initial meetings of a secondary mathematics content course. We drew participants from four different sections of the course.

In order to better understand teachers' meanings, we gathered similar data from ISTs. We adapted our interview tasks for an on-line survey completed by 45 ISTs enrolled in a fully online graduate mathematics course at a private U.S. research university as part of a master's degree program in mathematics education. The ISTs were geographically distributed across the U.S. They all had more than three years of experience teaching middle or secondary mathematics and had completed at least one mathematics course beyond Calculus III. All students in the program were invited to complete the survey during their third quarter in the program.

We worked with both undergraduate PSTs and ISTs due to our interest in understanding relationships between individuals' meanings and what we perceive to be conventions common to U.S. instruction. Because the chosen teacher populations had completed at least 14 years of mathematics schooling and, in the case of the ISTs, at least three years of teaching, we conjectured that we would gain insights into the extent to which teachers' meanings entail the habitual use of "convention" or convention *qua* convention. We note that we extended our work to include ISTs in order to explore if the themes identified with PSTs: (i) were similar to those of the ISTs, (ii) could viably explain ISTs' responses to an on-line survey, and (iii) would be ameliorated or otherwise affected by middle or high school teaching experience.

### Data Collection and Analysis

In the initial study with PSTs, we conducted task-based semi-structured clinical interviews (Ginsburg, 1997) during which the PSTs worked on tasks we had designed as discussed in the next section. Each PST participated in one interview lasting approximately 90-120 minutes, with the interview occurring during the first two weeks of the content course. During the interviews, a member of the author team asked that the PSTs verbalize their thinking as much as possible. Although we designed each interview task with particular purposes, the clinical interviews were semi-structured in that we asked questions formulated in the moment and on the basis of our interpretations of a PST's response (Merriam & Tisdell, 2005). We posed follow-up questions for the purpose of gaining deeper insights into the PST's thinking while also attempting to minimize shifts in the PST's thinking due to the researchers' questioning.

We videotaped each interview and digitized all written work. We analyzed the data following a selective open and axial analysis approach (Strauss & Corbin, 1998) for the purpose of modeling the PSTs' thinking on the basis of their utterances and observable actions, which Thompson (2008) described as a conceptual analysis. This process first involved identifying instances of PST activity that offered insights into his or her meanings. We used these instances to develop hypothesized models of the PST's meanings. With these initial models developed, we compared a PST's activity across instances and tasks in order to test and improve our interpretations of her or his activity, including identifying themes across instances and tasks. Lastly, we compared across PSTs to identify compatible and contrasting aspects of their meanings. The research team met throughout the data analysis phase in order to discuss analysis efforts, including differences, uncertainties, and refinements in interpretations of PSTs' activity.

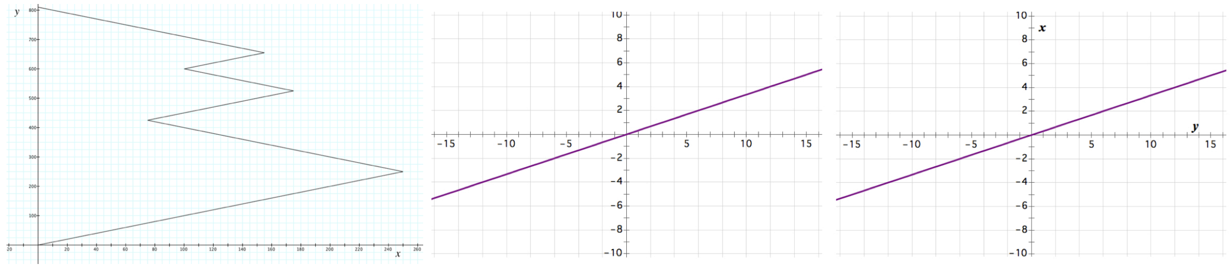
IST responses to the online survey items were analyzed through an iterative process that began with a first review of the entire data corpus and the subsequent development of a coding scheme heavily informed by our work with the PSTs. Members of the research team analyzed a subset of the ISTs' responses and we met to discuss our observations, identify commonalities across ISTs' responses, and adapt or create new codes to capture more ISTs' responses. We iterated this process four times as we refined our codes to capture all ISTs' responses. After obtaining final codes, a second researcher recoded approximately 65% of the data to check for inter-rater reliability. We obtained Cohen Kappa values of 0.78 and 0.85, indicating a high level of agreement, for the two tasks we present in this paper, described in more detail below.

**Task Design**

We designed each task to include what we perceive to be an unconventional feature with respect to the use of graphs in U.S. school mathematics. Although we designed these tasks to be unconventional, we also intended each task to include a graph that is mathematically viable as presented with respect to a particular claim (i.e. a graph in its *given orientation*). Because we did not expect the PSTs or ISTs to spontaneously interpret the displayed graphs as entailing unconventional aspects, we designed tasks to include specific claims (e.g., hypothetical student responses) with respect to features that we intended to be unconventional. By including hypothetical responses focused on such features, we were able to infer the extent that something was an inherent or habitual aspect of the PSTs' and ISTs' uses of graphs.

To illustrate, we provided the graph in *Figure 1a* and posed a variant of, "What about a student who claims that this graph represents $x$ is a function of $y$?" With respect to *Figure 1b*, we presented the graph as the work of a hypothetical student who graphed the relationship $y = 3x$. We asked the participants to describe how the hypothetical student might have been thinking when creating the graph. The follow-up prompt included a graph with the axes labeled (*Figure 1c*), and we explained that a hypothetical student clarified his graph of $y = 3x$ by labeling the axes as given in the second graph (i.e. $x$ on the vertical axis and $y$ on the horizontal axis). Both tasks illustrate our intent on designing graphs that can be conceived as mathematically viable (albeit unconventional) as presented with respect to the given prompts and claims.

The IST online survey was modeled after the PST interview protocol using virtually identical prompts. Due to the temporal nature of the images and prompts, multiple part items were displayed on multiple pages. Following the format of the PST interview, online survey participants were initially shown the graph in *Figure 1a* and asked "Is the following graph a function? Why or why not?". They were subsequently presented with the student response, "Sure, it can be a function… $x$ is a function of $y$", and asked to provide a response to the student.



(a) (b) (c)

*Figure 1.* (a) Is x a function of y? (b)-(c) A hypothetical student's work to graphing y = 3x.

## Results

We structure the results section around the teachers' responses to the two aforementioned tasks due to the teachers' responses being salient representations of their responses to other tasks. For each task, we first provide excerpts to illustrate themes in the PSTs' responses to the tasks. We also present summative PST data for each task to offer the reader a sense of the variety of PST responses. We then highlight instances in which teachers' actions indicated particular contradictions, as we describe below. We then provide results from our analysis of the ISTs' responses and compare the PSTs' and ISTs' propensity to respond in certain ways.

### *x* is a Function of *y*

We asked 25 of the 31 PSTs the entire sequence of prompts associated with *Figure 1a*. On the initial pass, 24 of 25 PSTs claimed that the graph did not represent a function either because of the graph not passing the vertical line test, the graph failing to have a unique $y$ value for each $x$ value, or a combination of the two. The remaining PST claimed that the graph did not represent a function because, "I don't like it [*referring to the cusps*]." With respect to the subsequent prompt (i.e. "Is there some way that we or a student could consider the graph as representative of a function?"), we provide a summary of the PST responses in Table 1. We draw attention to the fact that no PST provided a viable way to think about the graph as representative of a function in the *given* orientation. In Table 2, we present a summary of the PST responses to the student's claim that the graph is a function as, "$x$ is a function of $y$." In the sections that follow we discuss themes in the PST responses to this claim.

Table 1
*PST responses to the question, "Is there some way that we or a student could consider the graph as representative of a function?"*

| PST Response Category | # out of 25 |
|---|---|
| Yes, if rotated counter-clockwise 90-degrees | 6 |
| Yes, if rotated counter-clockwise 90-degrees and axes relabeled so that $y$ and $x$ were represented along the vertical and horizontal axes, respectively, in the new orientation | 5 |
| Did not determine how a hypothetical student might claim that the graph represents a function; maintained that the graph does not represent a function | 14 |

Table 2
*PST responses to the statement, "x is a function of y."*

| Category code | PST Response Category | # out of 25 |
|---|---|---|
| Habitual use of "convention" | Unsure | 1 |
| | Not true | 9 |
| | True, if graph is rotated counterclockwise 90-degrees | 7 |
| | True, if rotated counterclockwise 90-degrees and axes relabeled so that *y* and *x* were represented along the vertical and horizontal axes, respectively, in the new orientation | 1 |
| Convention *qua* convention | True | 7 |

**Convention *qua* convention.** We interpreted 7 of the 25 PSTs' responses to suggest that they did not require *x* or the horizontal axis to represent a function's input. Although 5 of these PSTs described they had a tendency to imagine the graph oriented so that the values defined as the function's input were represented along the horizontal axis, ultimately, each of the seven PSTs understood the graph *as given* to be consistent with the claim "*x* is a function of *y*" (*Excerpts **1***).

*Excerpts 1. x is a function of y; convention qua convention.* [1]

S1: I want to look at this and say this is a function *y* of *x* because that's how I would traditionally view a graph but I think it's valid to view it as *x* of *y*. And then you're still [*pause*] obeying what a function is. But you just have to be cognizant that your axes have changed so I guess it's like, valid.

S13: Rather than *y* being a function of *x*…Yeah I guess if you do it this way [*writes* '*x*(*y*)' *on paper*] …for every *y* there is exactly one *x*. And for every *y* [*puts marker on vertical axis on graph and moves it horizontally to a point where it hits the curve*] yeah, there's exactly one *x*…I've never thought about it that way but yeah, he's right.

**Habitual use of "convention".** Two notable characteristics emerged from our analyses of the PST responses to the sequence of prompts associated with *Figure 1a*: 16 of the PSTs either maintained *x* as representing input values *or* maintained the horizontal axis as representative of input values. These characteristics of the PSTs' meanings were most apparent when we posed the claim, "*x* is a function of *y*."

Collectively, 11 of the 25 ('Not true', 'Unsure', and 'True, if rotated counterclockwise 90-degrees and axes relabeled') PST responses suggested they assimilated the phrase "*x* is a function of *y*" no differently than "*y* is a function of *x*" (*Excerpts **2***). More specifically, these PSTs maintained that the graph does not represent a function because the graph does not pass the vertical line test, because there exists *x*-values for which there is not a uniquely associated *y*-value, or a combination of the two. To each of these 11 PSTs, "function" drew to mind an action that entailed treating (implicitly or explicitly) *x* and the quantity represented along the horizontal axis as the input quantity (i.e. habitual use of "convention").

*Excerpts 2. x is a function of y; habitual use of "convention".*

S7: Okay. Um [*pause*] *x* is a function of *y*. [*long pause*] …Well you know something's not a function if [*placing her marker in a vertical line over the given graph*], two different outputs can give you the same, I mean if two different inputs can give you the same output… Which you have here obviously that, you know, these one two three four five six *x*-values give you different *y*-values [*using her marker to mark points on the graph in a vertical line*]. I mean these, the same *x*-value can give you six different *y*-values.

[1] For space purposes, we use "…" to indicate the removal of spoken words and actions that we did not interpret to alter our interpretation of the PSTs' activity.

S24: [*laughing*] Oh gosh, um, well [*pause*] if $x$ is a function of $y$, well you can't [*pause*] for it to be a function you can't have more than one $y$-value for the $x$ [*motioning the marker over the graph indicating points vertically from one another*]. So, like if I wanted to know what, umm [*pause*] $f$ of one hundred was, or something, like I would get a bunch of different [*begins to mark points on the graph for a specific x-value*], I mean, yeah I would get a bunch of different $y$-values for it, you know [*has marked multiple points on the graph with the same x-value*] …you can't get more than one $y$-value per $x$-value. It's not a function.

Turning our attention to the 7 PSTs who maintained that the statement "$x$ is a function of $y$" is true only on the condition that the graph is rotated 90-degrees counterclockwise and axes *not* relabeled (Table 2), these PSTs understood the statement "$x$ is a function of $y$" in two parts. The phrase both defined the axes orientation and presented a statement to be considered with respect to a relationship between paired values (*Excerpts **3***). Because they understood the given phrase to necessitate a particular axes orientation—an orientation in which input values are represented horizontally—they required that the graph be rotated to orient $y$-values horizontally before considering the validity of the claim with respect to properties of the $x$-$y$ pairing (i.e. habitual use of "convention").

*Excerpts 3. x is a function of y; habitual use of "convention".*

S4: I guess she doesn't understand what graphs represent…so she said $x$ is a function of $y$. That'd be, that'd be looking at it this way [*turning the paper 90-degrees counterclockwise*] and saying look there's no [*motioning hand over the graph as if doing the vertical line test*], there's no crossing…you'd have to flip the whole graph… [*redraws graph in rotated orientation, labeling the horizontal axis as y and the vertical axis as x*] That'd be $y$ and that'd be $x$. So $x$ is a function of $y$. And that's a function… [*Interviewer returns S4's attention to the graph in its given orientation*] No, because $x$ isn't a function of $y$. This is the graph of $y$ as a function of $x$ [*motioning to her sketch*].

S14: Okay so $x$ is a function of $y$. That's trueeee [*turning the paper 90-degrees counterclockwise*]. [*Turning the paper back to the given orientation*] But $y$ is not, $y$ is not a function of $x$…That's what we're looking at here…So you want $y$ is a function of $x$. Is that what you said to me, no you said $x$ is a function of $y$…That's backwards [*laughing*]…because like $x$ is a function of $y$, so that, I think of that as, like the graph like kinda this way [*turning the paper 90-degrees counterclockwise*] … [*motioning over the horizontal–now y–axis*] like if this is our horizontal that's true. Because for every $y$ [*pointing to y-label on horizontal axis of turned graph*] there is one unique $x$ [*pointing to x-label on vertical axis of turned graph*] but [*turns the paper back to given orientation*] for every $x$ [*pointing to x-label on horizontal axis*] there is not [*pointing to y-label on vertical axis*] one unique $y$… she's incorrect because it's like backwards…that's not what we're looking at [*referring to graph in given orientation*].

**A Graph of $y = 3x$**

We asked all 31 PSTs the sequence of prompts associated with *Figure 1b* and *c*. With respect to the first prompt (*Figure 1b*), we provide a summary of their responses in Table 3. No PST encountered difficulty attributing a viable approach to producing the hypothetical solution. Several PSTs provided multiple explanations as to how a student might create the graph.

Table 3

*PST responses to the prompt and graph associated with Figure 1b.*

| PST Response Category | # out of 31 |
|---|---|
| Hypothetical student held some misunderstanding of slope (e.g., 'rising 1 and running 3') | 16 |

| | |
|---|---|
| Hypothetical student graphed $x = 3y$, $y = (1/3)\,x$, or interpreted the equation to mean $x$ is three times as large as $y$ (e.g., variables as literal objects) | 13 |
| Hypothetical student graphed $y$ on the horizontal axis and $x$ on the vertical axis | 13 |

When we presented *Figure 1c* and asked the PSTs to interpret the hypothetical solution, we asked them to comment on the correctness of the solution (i.e. "Does the graph represent $y = 3x$?") in order to gain insights into the extent to which they considered the graph a viable representation of $y = 3x$. We summarize their responses in Table 4. In the sections that follow we discuss themes in the PST responses to the graph and prompts.

Table 4

*PST responses to the prompt and graph associated with Figure 1c.*

| Category code | PST Response Category | # out of 31 |
|---|---|---|
| Habitual use of "convention" | Hypothetical student did not construct a correct graph | 5 |
| | Hypothetical student constructed a graph that is both correct and incorrect | 11 |
| | Uncertain if the hypothetical student constructed a correct graph | 4 |
| Convention *qua* convention | Hypothetical student unquestionably constructed a correct graph | 11 |

**Convention *qua* convention.** 11 PSTs maintained that the graph as oriented in *Figure 1c* unquestionably represents $y = 3x$ (*Excerpts **4***). These PSTs identified the graph's departure from convention, and specifically its departure from a customary axes orientation. They also claimed that the departure does not influence the correctness of the represented relationship between $x$ and $y$ (i.e. convention *qua* convention). Several of the PSTs mentioned the creativity of the hypothetical student's solution (see S30).

*Excerpts 4. A graph of $y = 3x$; convention qua convention.*

S21: Ohhhh…this graph is saying…$y$ is three times bigger than $x$…so where $x$ is one, $y$ is three times bigger [*checking graph*]. Yes. Where $x$ is two, $y$ is three times bigger [*checking graph*]. So this graph is correct… $y$ is three times bigger than $x$.

S30: He graphed it completely right. That's $y$ equals three $x$…he's not wrong. He just has a different perspective than the traditional $x$-$y$…that's just counter to tradition and normal classroom settings. But I think it's smart of him to understand that it's not glued.

**Habitual use of "convention".** We interpreted 20 PSTs (Table 5, first three response categories) who deemed *Figure 1c* incorrect or who expressed uncertainty about the hypothetical solution to hold meanings that entailed the habitual use of "convention". These "conventions" included assigning $x$-values to the horizontal axis, maintaining particular axes directions for positive and negative values (which arose after rotating the graph to obtain $x$-values oriented horizontally), using the horizontal axis to represent a function's "input" (and inferring the given graph contradicted an equation defining $x$ values as "input"), or a combination of these (*Excerpts 5 Excerpts 5*). In some cases, PSTs discarded the hypothetical student's solution or deemed the solution incorrect because of its departure from these "conventions", thus treating "conventions" as unquestionable rules of a coordinate system and graphing (see S20). In other cases, PST responses to the hypothetical solution suggested they drew on meanings for slope or rate in which the habitual use of a particular Cartesian orientation was embedded (see S23). For instance, after rotating the graph 90-degrees counterclockwise so that the $x$-axis was oriented horizontally, some PSTs understood the slope as negative because the line is directed downward left-to-right. This statement is true under conventional Cartesian orientations.

*Excerpts 5. A graph of $y = 3x$; habitual use of "convention".*

S19: I feel like you should know your $x$ and $y$, and like, know which one is which. And, yeah, you're going to get it all wrong I think.

S20: The horizontal axis should always be $x$ and the vertical axis should always be $y$.

S23: Because if you turn it this way [*referring to graph rotated 90-degrees counterclockwise*] then this [*traces left to right along the x-axis which is now oriented horizontally*] and this [*traces top to bottom along the y-axis*] and it would be still not right though…this [*laying the marker on the line which is sloping downward left-to-right*] is negative slope. So I would…show them like the difference between positive and negative slopes also. Because that's something that, like, when I was in middle school we, like, learned kind of like a trick to remember positive, negative, no slope, and zero [*making hand motions to indicate a direction of line for each*].

**PSTs' Contradicting Actions and Claims Across Both Tasks**

Returning to the task associated with *Figure 1a*, we draw attention to S4 and S14's responses (*Excerpts **3***). S4 and S14 claimed the graph as given was not such that $x$ is a function of $y$, and they claimed the rotated graph was such that $x$ is a function of $y$. From our perspective, there is a contradiction that exists in their responses: the graph is such that each $y$-value has a uniquely associated $x$-value no matter the rotated orientation of the paper. But, we stress that the PSTs' responses were not a contradiction from their perspective. As we described above, we infer that these PSTs' meanings for functions and their graphs were such that the ways they conceived $x$-$y$ pairings were dependent on the axes orientations (i.e. habitual use of "convention"). The variable values represented along the horizontal axis were necessarily representative of a function's input, even when presented with interviewer utterances asking them to consider otherwise.

More generally, several cases entailing their habitual use of "convention" included the PSTs exhibiting contradicting actions and claims. We focus on the task associated with *Figure 1a* to provide additional illustrations this phenomenon. First, we note the contradiction an observer can perceive when PSTs claim that rotating the given graph changes the represented relationship or slope (see Excerpt 5, S23). Regardless of orientation, an observer can understand the graph so that each $y$-value is three times as large as the associated $x$-value and that any change in $y$ is three times as large as the change in $x$. To S23, however, slope was as much, or more, an indicator of direction constrained to particular Cartesian "conventions". Thus, they did not perceive a contradiction in claiming that the "slope" changes as the given graph and paper is rotated.

Second, numerous PSTs claimed that the graph in *Figure 1c* was *both* correct and incorrect in its representation of $y = 3x$. In some cases, a PST claiming that the graph is both correct and incorrect was only a contradiction from our perspective. Those PSTs held meanings that enabled them to claim the graph is both correct and incorrect without experiencing a sense of perturbation (*Excerpts **6***, S2 and S9). Namely, the PSTs understood that the graph as given entailed coordinate points satisfying $y = 3x$. At the same time, they held meanings for coordinate systems that entailed the habitual use of "convention" in the form of axes orientations, thus requiring those orientations in order to claim a graph is how it "should be written."

In other cases, PSTs experienced a perturbation that stemmed from their awareness of claiming that the graph satisfies the equation $y = 3x$ but that it is incorrect due to its orientation (*Excerpts **6***, S17). These PSTs did not resolve their perturbation during the interviews, which led to each PST expressing uncertainty about whether particular axes orientations must be maintained in order to have a solution that is mathematically correct.

*Excerpts 6. A Graph of y = 3x; contradicting actions and claims.*

S2: [*S2 is addressing how he would respond to the student who produced Figure 1c*]… I mean I would tell him that this is the correct graph because it technically is. But I would just explain to him, and I don't know how I would explain but how, like when graphing functions $y$ is always going to be the vertical axes and $x$ is always going to be the horizontal axis… explain to him that next time he needs to change his axis. And why [the graph] is right but wrong at the same time.

S9: It's wrong with like how we normally write graphs…So he should lose points because he wrote the graph in like really incorrectly to what, how the graph should be written. Like the horizontal axis should always be $x$ and the vertical axis should always be $y$. But if you're looking at it based on did he understand that, when $y$ equals three, $x$ equals one, like he understood that, um, relationship between $x$ and $y$.

S17: He got them mixed up… So he did the problem correctly…he didn't understand how the graph worked…that the $x$ is always on this [*referring to the horizontal axis*], and $y$ is always on the vertical axis…[his graph] is correct [*making finger quotations surrounding correct*] but it's not mathematically correct. [*S17 then draws canonical graph and illustrates how the graph is correct using points*]…it's not wrong, it's just not what graphs are supposed to be…I don't know. I've always just done what I was told. I don't really know why it has to be that way…I never really questioned why $x$ is there and $y$ is there.

**IST Responses**

We do not present the IST responses to each task as they are compatible with the PST responses. Table 5 provides codes we created to characterize the IST responses to the last stage of hypothetical student work for both tasks, example responses to the hypothetical student prompt associated with *Figure 1a*, and counts of the number of IST responses coded within each category for each task. 12 of the 45 IST responses for the task associated with *Figure 1a* indicate the ISTs understood a convention *qua* convention. 25 IST responses for the task associated with *Figure 1c* indicate the ISTs understood a convention *qua* convention. The remaining 33 and 20 ISTs, respectively, maintained meanings which entailed a habitual use of "convention".

Table 5
*Codes description, counts, and sample responses of IST online survey (n = 45).*

| Convention category | Code | Example Responses to the task in *Figure 1a* | *Figure 1a* | *Figure 1c* |
|---|---|---|---|---|
| Convention *qua* convention | The student's mathematical statement is correct despite breaking from conventions. | That's great! I am so glad you were able to apply the "vertical line test" in a horizontal orientation and realize that you would have a function. You are correct in saying that $x$ is a function of $y$. | 12 | 25 |
| Habitual use of "convention" | The student's mathematical statement is true but the student is incorrect because he/she broke from conventions. (contradicting actions and claims) | I think the student is understanding that $x$ can be a function of $y$ but they are not displaying it correctly through the graph. | 9 | 7 |
| | The student's mathematical statement is incorrect or the IST did not address the student's mathematical statement. | It was not a good explanation and $x$ is not a function of $y$, $y$ is a function of $x$. The value of $y$ depends on $x$. They also did not describe what would make it a function. | 24 | 13 |

**Comparing PST and IST Responses**

To identify similarities between PST and IST responses, and to consider the possible persistence of PST meanings into teachers' professional careers, we assigned numerical values to the two convention categories within each coding scheme (Convention *qua* convention a value of 1, and habitual use of "convention" a value of 2). Table 6 provides the average scores for PSTs and ISTs across both tasks. We used a two-tailed Mann-Whitney U-test to examine the coded responses from the PST and IST populations. Analysis indicates no statistically significant difference between the populations for either task ($p > 0.05$ in both cases), meaning that there is no evidence that PSTs and ISTs provide different responses in relation to the tasks used in our study. Hence, it appears that these meanings for graphing conventions (or "conventions") likely persist into teachers' professional careers, highlighting that experience teaching does not necessarily support shifts in teachers' conceptions of graphing conventions (or "conventions").

Table 6
*Average scores of PST and IST responses and p-values obtained from a Mann-Whitney U-test.*

| | *Figure 1a* | *Figure 1c* |
|---|---|---|
| PSTs | 1.72 | 1.65 |
| ISTs | 1.73 | 1.44 |
| *p*-value | 0.9283 | 0.1416 |

## Discussion and Concluding Remarks

Our analysis provides inferences relative to the meanings teachers maintain in relation to particular graphing conventions (or "conventions"). Our analysis also highlights the pervasiveness of such meanings in both PSTs and ISTs. We interpret our findings to underscore the importance of future work that supports students and teachers in developing meanings that differentiate between what is critical to a mathematical idea and what is customary or arbitrary.

**Significance of Findings**

Our results support the claims of Breidenbach et al. (1992), Montiel et al. (2008), and Sajka (2003), who provided data that we interpret to imply their participants' meanings of function and their graphs entailed the habitual use of particular coordinate systems, orientations, or variable symbols. Our work extends their work in an important way. We are not aware of other researchers who have used task-based clinical interviews or on-line surveys (as opposed to an instructional setting) to present participants explicit claims—through written or spoken words—designed to be unconventional with respect to the notation and coordinate orientations used here. Our findings in this regard shed insights into the extent that some teachers have (or have not) differentiated what we perceive to be conventions from essential aspects of particular mathematical ideas and representational systems. Most notably, we show that despite providing explicit claims and ideas represented in ways compatible with these claims, many of the teachers assimilated the situations in ways that implied their habitual use of "convention". The persistence of some teachers' habitual use of "convention" after a repeated sequence of interview questions and explicit prompts addressing the same "convention" is particularly noteworthy.

At the most fundamental level, it is significant that both PSTs and ISTs—who have completed advanced mathematics courses and many of whom have several years of teaching experience—have developed mathematical meanings that, at best, limit their ability to attribute mathematical viability to school mathematics ideas presented in unconventional formats. Also significant is that some teachers (or soon be teachers) held meanings that led to claims and actions that, although potentially internally viable to the teachers, were contradictory from our perspective and suggested their habitual use of “convention”.

In our study, it was clear that when conventions (or “conventions”) were not violated, the PSTs and ISTs were able to respond in ways that were sensitive to the mathematical viability of students’ solutions. However, this study reveals, perhaps unsurprisingly, that being able to respond appropriately in one context does not necessarily indicate coherence in teachers’ mathematical meanings. Specifically, we document that in many cases, particular aspects of teachers’ meanings were not apparent until their engagement in tasks that we designed to be unconventional. That is, it was not until we violated particular “conventions” that we were able to gain insights into the extent that particular representational features were inherent to teachers’ meanings (i.e. the habitual use of “convention”). We argue that a significant contribution of this paper is that it provides a mechanism to identify previously invisible aspects of learners’ meanings of core mathematical ideas. This is important as it is only when these aspects of meanings are identified that there will there be a chance of supporting learners’—including teachers—development of internally consistent, coherent and generative mathematical meanings.

**Future Work**

Our current work indicates that a non-insignificant number of PST meanings entail the habitual use of “convention”, with some of these cases involving their exhibiting contradicting claims or actions. This trend is consistent with the participating ISTs, suggesting that classroom experience with students does not ameliorate the issue. If we accept that teachers (and students) understanding mathematical ideas in ways that entail conventions *qua* conventions is desirable, then an important question for teacher education is *how might the desired meanings develop?* We believe that our work, in combination with that by previous researchers (Mamolo & Zazkis, 2012; Thompson, 1995; Zazkis, 2008), provides initial guidance in this area. Specifically, for teachers holding meanings that entail the habitual use of “convention”, we hypothesize that one way to support the transition to understanding convention *qua* convention is to develop instruction that supports teachers in raising and reconciling contradictions between claims and actions. Examples provided in this paper provide some viable contexts for these conversations. Moore, Silverman, Paoletti, and LaForest (2014) and Johnson (2015) share additional strategies that speak to Thompson’s (1995) suggestion of placing an emphasis on synthesizing issues of convention, quantitative reasoning, and notation. Mamolo and Zazkis (Mamolo & Zazkis, 2012; Zazkis, 2008) provide other examples that include using unfamiliar coordinate systems. Each of these strategies can be used as design and implementation principles for teacher educators and researchers interested in supporting and understanding PSTs’ and ISTs’ development of meanings that are consistent with convention *qua* convention.

Before closing, we acknowledge the limitations of using on-line survey data to draw inferences about IST meanings. We also acknowledge that our work with PSTs was limited to one university, thus limiting the diversity of the participant pool. There is thus a need for additional studies into both PST and IST populations, and we suggest that investigations of IST populations include other qualitative methods (e.g., various forms of clinical interviews) in order to provide nuanced insights into their meanings, particularly when confronted with contradicting actions and claims. The PSTs in our study did not reconcile these contradictions when they became aware of them. It remains to be seen if other PST and IST populations do so or if interventions are necessary to support their reconciliation of these contradictions.

## Closing Remarks

We close by underscoring that we do not intend to discredit conventions, nor to convey that conventions are unimportant. We hope we have been clear that a convention is important to the extent an individual understands it as a convention *qua* convention. We also do not contend that educators, whether teachers or curricula designers, can realistically address every convention they perceive to constitute some mathematical community. We argue, however, that our results respond to and strengthen calls for a more detailed consideration of how educators and researchers treat and understand conventions (or "conventions"). We agree with Thompson's claim, "…[we] can attempt to make explicit those conventions that are assumed and treated as given, those conventions that are assumed and presented as conventions, and those conventions that are meant for students to recreate or to create in some idiosyncratic form" (1992, p. 125). Educators and researchers must be sensitive to the negotiation of conventions among students, teachers, and any member of a perceived community. Given the complexity of learning and teaching, understanding what this sensitivity might look like will take concerted efforts at many levels with particular emphasis given to students' meaningful creation and use of notation and representations (e.g., diSessa, Hammer, Sherin, & Kolpakowski, 1991; Meira, 1995; Thompson, 1995; Tillema & Hackenberg, 2011). In short, if students and teachers are to understand a convention *qua* convention, then they need opportunities to come to understand mathematical ideas in ways that include the negotiation of customary choices within the context of those ideas that remain invariant among those choices.

*Navigating the transition from computing to proof remains a key challenge for mathematics departments and undergraduate students. Many departments have developed courses to introduce students to proof and proving (David & Zazkis, 2017), but research on the impact of these courses has just begun. This paper reports the experience of four mathematics majors in a semester of real analysis. Each participated in our prior study of students' experience in the introduction to proof course. Where the students' work in that course supported their success in real analysis, they experienced real analysis in quite different ways. Two recognized and exploited the structures common to real analysis proofs; the other two relied on extensive practice with example problems. The results have re-oriented our view of the computation-to-proof transition and where and how students experience proof as problem solving.*

*Keywords*: Transition to Proof, Real Analysis, Students' Experience, Qualitative Analysis

This paper extends our prior research that examined undergraduate students' experience in one introduction to proof course taught at a research-intensive university (Smith, Levin, Bae, Satyam, & Voogt, 2017). Most of the N = 14 participants in that study clearly indicated that they found the work to write proofs different from their prior mathematical work to compute numerical or symbolic answers. Where the majority found proof writing challenging, most were relatively successful in the course, as judged by final grades and self-reports. But the success of courses designed to introduce students to proof and proof-writing cannot be judged locally. As the goal for such courses is to increase learning and achievement in upper-division mathematics, success depends on how well students learn and perform in subsequent proof-focused courses that explore major areas of mathematics (e.g., analysis and algebra).

Here we report on the experience of four "graduates" of an introduction to proof course in their first semester of real analysis. All were successful in that course, as judged by both grades and self-reports. But their descriptions of their work in real analysis, offered in comparison to the introduction to proof course and prior mathematical work through calculus, revealed a more complex pattern of similarities and differences in how students see and carry out mathematics work. For some students, the differences between following procedures to compute answers and writing effective proofs in real analysis were less stark than we initially conjectured—and than they experienced in their introduction to proof course. If true for a small sample, analyses characterizing students' transition to proof and subsequent mathematical development may need to attend to important *continuities* as well as *discontinuities* with prior mathematical work through calculus.

## The Transition to Proof and Proving

Understanding the challenges that undergraduate students face in learning to prove (or disprove) mathematical statements and designing courses and experiences that support their efforts to address those challenges have become major foci of research in undergraduate mathematics education. Recent work has focused on the nature and diversity of courses intended to introduce students to proof and proving (David & Zazkis, 2017; Selden, 2012), specific cognitive challenges in understanding and writing proofs (Antonini & Mariotti, 2008; Selden & Selden, 2003; 2013; Sellers, Roh, David, & D'Amours, 2017; Weber & Alcock, 2004; Zandieh, Roh, & Knapp, 2014), and following students' proving work and reasoning after an initial introduction to proof (Benkhalti, Selden, & Selden, 2017; Weber, Brophy, & Lin, 2008). In this regard, real analysis, which is one of the first proof-based content courses taken by students after introduction to proof, has been investigated by researchers interested in development of students' understanding of particular concepts in real analysis such as the epsilon-delta definition of limits (e.g., Alcock & Simpson, 2005; Oehrtman, Swinyard, & Martin, 2013, Swinyard & Larsen, 2014), and understanding and improving teaching practices of real analysis courses (e.g., Weber, 2004; Pinto, 2013; Wasserman, Weber, & McGuffey, 2017). In particular, some studies have reported students' experiences in real analysis in terms of how they adjusted in new learning environments and changed their learning activities. For example, Weber (2008) interviewed a student in a real analysis course bi-weekly throughout the semester and reported changes in her emotional states in relation to changes in learning strategies. Specifically, the student entered with a rote learning strategy and negative experience with proving from her introduction to proof course. This study described how she changed her learning strategy to an understanding-oriented approach and began to enjoy proving work in the real analysis course through social interactions with peers and the instructor.

As a contribution to this growing literature, we previously interviewed N = 14 undergraduate students after they completed a one-semester introduction to proof course. Our analysis focused on four issues: (1) how the students saw the introduction to proof course as different from prior courses, (2) the activities they reported undertaking to learn the course content, (3) how they characterized their thinking during work on proof (proof reasoning), and (4) their sense of success in the course (Smith et al., 2017). None reported any prior work on proof in high school or their calculus sequence. Most were clear that the course made different demands than their prior work in mathematics, and in response, many initiated new patterns of work. Despite the challenges they reported, most completed the course relatively successfully, leading us to conclude that this particular introduction to proof had successfully brought these students up to and through the doorway to proof. In particular, the course placed students into the work of solving mathematical problems—tasks for which a solution path is not immediately clear (Schoenfeld, 1992)—and supported their adjustment to that work.

But the merit and impact of introduction to proof courses lie as much—if not more—in how students perform *after* they complete such courses. Introduction to proof courses typically emphasize foundational issues of logic and syntax (the grammar of mathematics) and introduce different methods of proof but either cover no additional topics from specific mathematics content or simply provide an introduction to the advanced topics near the end of the semester (David & Zazkis, 2017). The main task of working in proof and proving to understand more about the fundamental structure of a specific domain of mathematics lies ahead of them. If the gap between carrying out known procedures to compute numerical and symbolic answers and proving statements is wide and deep (Selden & Selden, 2013), the transition to proof and proving will not be accomplished in a single semester. Consequently, it makes sense to follow successful introduction to proof "graduates" into their content-specific proof-based courses: Where does reasonable initial success with proof lead? How do students experience their first proof-based course situated in a particular content area? How do they compare their experience in that course to their "preparation" in the introduction to proof course and to their prior mathematical experience? Is it possible to chart students' experience, work, and views of mathematics from computing to proving at a reasonable level of precision, to understand more specifically the challenges that undergraduate students face?

## Conceptual Framework

As in our prior study, the theoretical stance that framed this study was constructivist. From this perspective, students bring forward mathematical "resources" (knowledge, skills, learning practices) developed and proven useful in prior courses and attempt to use the resources to address the tasks of their present courses. Some resources are individual in nature (e.g., students' understanding and mastery of mathematical induction); other resources are inherently social and interpersonal (e.g., how students organize their work with peers outside of class). New challenges, at any scale, mean that some resources will work well as is, some must be adapted, and some must be developed, more or less *de novo*, in the new setting. The view of students as agents in their own learning is also central to our perspective, especially with respect to learning activities outside of class.

The present analysis was more specifically structured by the main concepts that oriented our prior work (Smith et al., 2017). Informed by prior work to understand pre-college and college students' experience of work in "reform" and "traditional" courses (e.g., Smith & Star, 2007), we expected the shift from computing single answers to proving statements to set the stage for major transitions in students' experience of mathematics, where their understanding of the nature of their work, how they feel about their experience and their abilities, and what they do to carry out that work would change in quite substantial ways. Where mathematical transitions are not determined by the external environment, some features of the environment make them more likely, such as the presentation of fundamentally new types of mathematical tasks and solutions. Our prior study conceptualized students' experiences in terms of (a) the differences they saw between the work in their introduction to proof course and their prior mathematics, (b) their sense of the task of writing proofs, (c) their learning activity, in and outside of class, and (d) their subjective "sense of success" in the course.

In the present study, we focused on students' experience in real analysis in relation to their work in the introduction to proof class a year earlier. The above four foci again informed the development of our interview questions and the direction of our analysis. For the first focus (differences with prior courses), we were particularly interested in how students compared the introduction to proof course to real analysis.

Both our prior and present studies foreground what may seem like a vague psychological notion—*students' experience*. Where it is arguably less analytic than more familiar constructs of knowledge and skills that can structure studies of proof learning and understanding (e.g., students' understanding of and ability to use a particular proof method), the broader notion of experience merits researchers' attention. Following Dewey (1916, 1938), we see experience as reflective, interpretive, and consequential for students' engagement in mathematics. In contrast to experiences (plural) that are more particular and happen daily, experience (singular) is inherently summative, formed by students reflecting back and interpreting a corpus of many experiences over time. Experience is interpretive in the sense that its truth depends on how the student herself has read and made sense of her experiences. It is consequential because the narrative of experience that students construct for themselves from their aggregate experiences orients their subsequent activity. For example, mathematics students' experience in proof-based mathematics is consequential for their choices and commitments to complete their major and their thinking and decision-making about post-college work.

## The Program, Courses, and Participants

In the university where our research was conducted, undergraduates—both mathematics majors and minors—complete a calculus sequence, the introduction to proof course, a linear algebra course, and two or more proof-focused content courses. After a linear algebra that does not emphasize proof, the first semester of real analysis and the first semester of abstract algebra are two common sites where students experience proof-intensive work in a specific content area. These two courses are required for both majors and minors, and both require successful completion of the introduction to proof course. Majors are required to complete additional proof-based courses, including the second semester of both real analysis and abstract algebra, as well as other courses—some of which are proof-based.

In the semester of our study, two sections of real analysis were taught by different instructors; both sections used the same text (Kenneth Ross, *Elementary analysis: The theory of calculus*, 2nd edition, 2013). The two sections differed somewhat in their in-class activities, homework, and assessments. In this department, real analysis is widely seen by students, instructors, and advisors as among the most, if not the most challenging undergraduate course. One of the two instructors this semester stated this explicitly to her students in class early in the semester.

In Spring 2017, six of the 14 student participants in our previous study responded positively to our invitation to participate in a follow-up study. All six were mathematics majors or minors and had taken the first semester of real analysis and/or abstract algebra in 2016-17. The other eight initial participants either did not respond or indicated they had taken neither course, had changed majors, or left the university. Two respondents took both real analysis and abstract algebra; the other four took only one. For those who had taken both courses, our interview focused on the more recent course (either real analysis or abstract algebra) to reduce concerns about (re)constructed memory. With four participants, the interview focused on real analysis; with the other two, on abstract algebra. In this paper, we will focus on the former group, who are described in Table 1 below.

*Table 1. Overview of participants*

| Student | Gender | Standing | Home | Major | Career Obj. | Other proof-based courses |
|---|---|---|---|---|---|---|
| S1 | Female | 3 | US | Mathematics | Teaching | Higher geometry (F16) |
| S2 | Female | 3 | US | Mathematics | Actuary | None |
| S3 | Female | 3 | US | Mathematics | Uncertain | None |
| S4 | Male | 4 | Int. | Mathematics | Grad school | Abstract algebra I (F16)<br>Abstract algebra II (Sp17) |

All four participants took the first semester of real analysis in the same semester (Spring 2017), and we interviewed them just after they completed it. S1, S2, and S3 had the same instructor; S4 was taught by the other instructor. Though we did not directly observe either instructor's teaching as we had in the previous study, we asked all students a series of questions about the nature of their in-class activities—both what the instructor did and what students did.

S1, S2, and S3 provided very consistent descriptions of their course, their instructor's teaching, the assigned homework, the use of the text, and the course assessments.

The interviews were semi-structured around focal questions, about an hour in duration, and conducted either face-to-face or via video conference. In two cases (S1 and S3), a follow-up interview was used to clarify students' responses from the first (for S1) or to pose all the questions we needed to ask (for S3). The overall goal of the interviews was to understand students' experience in real analysis relative to their experience in the introduction to proof course—with particular attention to the task of writing effective proofs.

After checking basic information (e.g., major/minor, standing, career plan, other math courses), we asked about the students' sense of how well the introduction to proof course prepared them for the real analysis course (and any other proof-based courses they had taken). Making no assumptions about how participants saw other mathematics courses they took that year (e.g., linear algebra), we asked how they viewed each such course relative to its focus on proof (very little, somewhat, strongly). All four participants indicated that real analysis was strongly proof-based. For the course(s) characterized as somewhat or strongly proof-based, we asked students to compare the difficulty of that course(s) to the introduction to proof course.

Then we explored their experience in each course, but with greater attention to real analysis. For that class, we asked specifically about assignments and instruction, learning activities in class (e.g., group work) and outside of class (e.g., work with peers in any context), and their view of proof tasks and work to produce acceptable proofs. These interviews also provided the opportunity to return to the students' presentation of their experience in the introduction to proof course reported in our prior study, affording a check on consistency in their characterizations.

Toward the end of the interview, we asked them to draw a Confidence Graph to represent the contours of their confidence with that semester of real analysis. As in the prior study (Smith et al., 2017), these graphs helped us understand the challenges participants faced at different points in the course and how they addressed the challenges. The graphing activity was useful because, in addition to the graphical representation it provided of one affective component of students' experience, it also created more space for students to relay their experience verbally, as they explained the features (e.g., location and rate of change) of their graphs.

Figure 1 below represents the comparisons of the different mathematical experience that were supported in the two studies, the previous (Phase 1) and the present (Phase 2). The interviews in the present study supported comparisons between real analysis and the introduction to proof course, but also with participants' experience prior to the introduction to proof course.

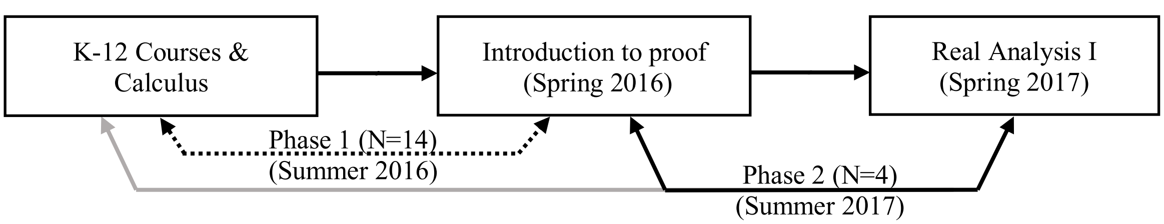

*Figure 1. The previous (Phase 1) and present (Phase 2) studies across the sequence of the courses*

## Results

All four students reported success in real analysis, represented both in final grades (all received 4.0) and their sense of having mastered the content. Also, as indicated in Table 2 below, all four acknowledged and valued the preparation for real analysis they received in the introduction to proof course. However, S1 and S3 made a stronger case for their preparation in the introduction to proof course, where S2 and S4 indicated they did not learn some things that they wished they had. S2 stated that she was not required and taught how to build up the structure of a proof; S4 stated that some methods (e.g., epsilon-delta proofs) were not taught in sufficient detail in the introduction to proof course. All four participants noted that the introduction to proof course moved frequently between content areas (making the course more difficult in the process), where real analysis focused on one set of related ideas. S1, S2, and S3 each indicated that they appreciated learning in real analysis why theorems and rules they learned in calculus were true.

*Table 2. Summary of students' sense of preparation of the introduction to proof course for Real Analysis I*

| Student | Preparation | Relative Difficulty |
|---|---|---|
| S1 | Very well | Introduction to proof > Real analysis |
| S2 | Well | Real analysis > Introduction to proof |
| S3 | Very well | Introduction to proof > Real analysis |
| S4 | Well | Real analysis > Introduction to proof |

Because the interviews at the end of real analysis provided an appropriate context, we also asked the students to compare the difficulty of real analysis to that of the introduction to proof course. S1 and S3 judged the latter as more difficult than real analysis, despite the fact that prior reports led both to expect that real analysis would be very challenging. In contrast, S2 and S4 indicated that real analysis was more difficult than the introduction to proof but cited different reasons for their judgments. S4 indicated that insufficient example problems in real analysis contributed significantly to its difficulty, where S2 found the concepts as well as proof construction in real analysis was more challenging than it was in the introduction to proof. Beyond these top-level judgments about "preparation," we found the two pairs of the participants (S1 & S3 and S2 & S4) provided two quite different narratives about the challenges of the course and how they had worked to address the challenges.

**The Introduction to Proof Course as Preparation for Real Analysis**

Before characterizing the differential experience of the two pairs of students in real analysis, we first buttress our claim that the introduction to proof course provided these students with a reasonable preparation for the challenge of real analysis. Here we summarize evidence that have we reported in greater detail elsewhere (Smith, et al., 2017). Our core argument is that the introduction to proof course represented a relatively rigorous entry into a very different form of mathematical work than the students had experienced in prior coursework. First, none of the four students reported any experience with proof prior to that course (i.e., either in their high school mathematics courses or their university mathematics—that was for most, their calculus sequence). Consequently, all four described how the work in the course seemed quite different from that in their prior courses. They all cited important differences between computing particular answers and constructing proofs of general statements. With different degrees of explicitness, each cited the difficulty involving in learning this new form of mathematical thinking. S3 was most explicit about this challenge, telling us in both interviews that she felt she had "no idea what she was doing" in the beginning of introduction to proof course. They all reported that because of that challenge, they undertook new learning activities outside of class (e.g., attending the Math Learning Center for the first time). Three of the four (S1, S2, and S3) received lower grades (3.0 out of 4.0 for all three) than they had in their previous mathematics courses. Substantively, they all reported learning specific proof methods (e.g., mathematical induction) and working for a few weeks on issues in real analysis (e.g., the convergence [or not] of sequences) in the introduction to proof course. We concluded that the course prepared these students reasonably well for real analysis because (1) the challenge of learning to prove statements in any mathematical domain was important preparation for work in real analysis, (2) the students addressed this challenge in their work and earned reasonable grades, and (3) the tools and content of the introduction to proof course were specific preparation for work in real analysis.

**The Introduction to Proof Course Was Helpful in Different Ways**

As we described in the previous section, all four participants reported that they agreed with the crucial role of the introduction to proof course in preparing for their success in real analysis. Interestingly, however, they seemed to have benefitted from that preparation in different ways, as they sustained or adjusted their learning activities formed in the introduction to proof course and prior mathematics courses.

**S1 and S3: Work together and exploit similarity across tasks.** In explaining their success in real analysis, S1 and S3 both emphasized the quality of their instructor's teaching, citing four main similarities to instruction in their introduction to proof course: (a) group work in class, (b) regularly assigned and graded homework, (c) weekly quizzes, and (d) the instructor's encouragement. Both S1 and S3 also reported they could reasonably predict the general nature of exam questions that were aligned with the regular homework and weekly quizzes. They completed their homework each week, whose content predicted the weekly quizzes, which in turn predicted the content of exams. Their instructor also gave a practice final exam, described to resemble the actual final. But this shared experience with instruction was coupled with changes in their learning activity. Whereas both S1 and S3 attended the Math Learning Center (MLC) at the university for the first time during their introduction to proof course and benefited from the activities and relationships supported there, neither attended in the MLC during real analysis. Instead, they worked remotely outside of class with the other members of their classroom small group that they maintained for the entire semester. When they got stuck on homework problems, they messaged with each other, sent pictures of the status of their solution attempts, and asked each other for suggestions.

Their voluntary group work outside of class in real analysis was influenced by their positive experience of social interactions in the introduction to proof course. Describing the different nature of the introduction to proof course in our prior study, both S1 and S3 reported that social and interpersonal resources were one of the key factors of their success in that course. S1 stressed the interaction with her peers and the instructor in and outside of class to be successful in the course.

> *Interviewer*: Okay. So, what do you think it takes to be successful in [the introduction to proof course]?
>
> *S1*: […] And I think it definitely helps to make friends and connect to other people who are in the classroom, or other people who have that class that you know and work together. Because you might not notice little errors in your proof, but they would. Like you can help compare. (Introduction to proof course, Summer 2016)

In addition to getting help from others on homework, the regular small group work in the introduction to proof course provided her with emotional support. She felt "more like high school classes with the interaction between the students and the professor" in comparison to her calculus classes in large lecture halls. She enjoyed the introduction to proof course because "there is a lot of interaction between everyone in the class." Similarly, S3 stated that the MLC provided opportunities to form a learning community supporting her success in the introduction to proof course. In our prior study, she stated that she "became friends" with others who regularly visited the MLC from her section and other sections of the course and worked together with them on weekly homework problems. Though she did not find tutors or peers at the MLC for real analysis, her prior experience in the introduction to proof course influenced her strong belief in collaboration with peers on mathematical work and confidence in real analysis.

> S3: It's okay if, you know, if they don't know something and if you don't know something because then you talk about it and then figure it out. So yeah, I mean if you had a group of people that were always on their phones, like you probably would be a little bit screwed over but if you talk things out and take all of your notes and just be like, okay let's figure this out. Three, four brains working on it, like everyone's in this class for a reason, we got here somehow.

In sum, the positive experience from the social and interpersonal resources of the introduction to proof course transferred to real analysis. Although they reported fewer resources in real analysis (e.g., less intensive group work in class, no TAs at MLC for real analysis) than there had been in the introduction to proof course, they adjusted to the new environment by finding a group of students who wanted to work together and support each other. They strongly endorsed the importance of collaboration with their peers and interactions with the instructor including her feedback and encouragement.

**S2 and S4: Work independently on lots of examples.** In contrast, S2 and S4 emphasized the importance of repeated practice on numerous example problems for each course topic, as practice increased the likelihood of mastery and success on course assessments. In addition, both carried out this practice-focused work on their own. S4 expressed frustration that his real analysis instructor (different from S1-S3's) did not provide a sufficient number of examples comparable to his experience in the introduction to proof course. Instead, he actively searched the internet for examples, explaining that he looked for problems that were related to those worked in class and had complete solutions (proofs). He would then work the problem and compare his proof to the one provided. If he was unsure how to start, he reviewed the provided proof and then attempted to complete it on his own—comparing his proof to the one provided when he finished. He never went to the MLC during real analysis (in part because he did not think that Center personnel were prepared to help with that content), though he had done so regularly during his introduction to proof course. Also, he stated that he did not need to get help from MLC or office hours to complete the homework problems in real analysis, which are similar to what his instructor showed in class. By contrast, he reported in the prior study that he was not able even to start some of the homework problems in the introduction to proof so he had to go to the MLC.

S2 did not complain about the supply of example problems; she found the combination of problems worked in class, homework problems, and problems in the text not assigned for homework sufficient. Though she was part of the in-class group that S1 and S3 cited as important, S2 seldom contacted her group outside of class and solved most course problems on her own. She described her method of study for exams to involve "just doing lots of problems." Like her peers, S2 did not attend the MLC during real analysis, though she had done so repeatedly and productively during her introduction to proof course. She was also able to complete almost all the homework problems using what her instructor showed her in class, whereas she reported that in the introduction to proof course there were significant gaps between problems worked in class and homework and between homework and exam problems.

**Common Structure Among Real Analysis Proofs**

One common thread in these results is the importance of noticing and abstracting a structure common to many real analysis proofs (what Selden & Selden [2013] have called a "proof framework"). Although S1 and S2 took different approaches to their work in real analysis, principally in how they engaged their peers, both spoke to the common structure they saw among the real analysis proofs their instructor and they produced. S4 spoke to this issue in different terms, and S3 did so only obliquely and without emphasis.

S1 saw the common structure among epsilon methods with some variation (e.g., epsilon-delta, epsilon-N) depending on the concepts involved in the statements (e.g., functions, sequences, and series). She learned to always start with specific sentences in the structured way of proving the statements using the epsilon methods.

> *S1*: In 320 [real analysis] so it's always epsilon greater than zero be given and then, you know, use the definition. So we did plenty of examples to know the structure of that, so in that case, she [her instructor] would, she would always tell us this is how you should write it, I guess.

She liked her instructor's practice of assigning similar problems using same approach/structure in the homework and stated that her instructor's proof writing in class emphasized this pattern. Her perception of common structure contributed substantially to her confidence going into major course assessments. It is notable that she found the introduction to proof course difficult partly because she saw no explicit common structure among the proofs she wrote. She addressed this issue at the interview in our prior study where she just finished the introduction to proof course.

> *Interviewer*: But was there any variation in your sense of the difficulty on the final exam by content? Or was it mostly just problem-by-problem; it wasn't so much whether it was number theory or sequences and series or whatever the content was?
>
> *S1*: It was more problem-by-problem. I was just afraid there was gonna be one I would look at [on the final exam] and just not know how to start. Because that's how a few of the homework problems had gone before. So that's what I was worried about. (Introduction to proof course, Summer 2016)

S2 also stated that the real analysis proofs were a lot more structured than those in her introduction to proof course. She asserted this pattern ("the proof was basically the same for every type of like, every type of problem") and indicated that real analysis proofs had an "introduction" that stated an arbitrary epsilon, the body of the proof, and a "conclusion" that related the particular case to the definition. In particular, her description of this structure corresponds to how Selden and Selden (2013) described the proof framework— "the part of a proof that depends only on unpacking and using the logical structure of the statement of the theorem, associated definitions, and earlier results" (p. 308).

S4 did not specifically describe common structural aspects among real analysis proofs like S1 and S2 did but instead emphasized the epsilon-delta method in real analysis. He responded that he thinks it is really important because "320 [real analysis] is all about that [epsilon-delta method]." Contrasting to other participants, S4 also described the process of completing a real analysis proof after setting up its structure as "computation." He used that term to indicate the repeated process of determining appropriate values for delta or N in epsilon arguments. Though he used different terms than S1 and S2, we interpret his assertion as similar to theirs: All three are citing structural regularities across many different real analysis proofs.

**Decrease in Problem-Solving Activity**

This abstraction of common structure across many different proofs is significant for many reasons, not the least of which is that it narrows considerably the "problem solving space" students found themselves in during course work. In describing their work in proof production in real analysis, none of the participants except S4 spoke to specific challenges in "filling in the blanks" of the common structure proof—Selden and Selden's (2013) "problem-centered part" of a proof.

S1 identified her work in proof production as executing known procedures on familiar tasks and connected to mathematical work prior to the introduction to proof course. Though she mentioned the variations in the common structure of epsilon methods according to different definitions being used (e.g., limit of a sequence, limit of a function at a point, etc.), she did not report specific challenges after setting up such structures in proof production. Rather she emphasized the importance of access to this common structure, compared to her proof work in the higher geometry course she took concurrently with real analysis.

> *S1*: And looking at the problems [in real analysis], you kind of had an idea already about what kind of structure you could use or you had several options whatever one you wanted to but in higher geometry, sometimes it was a lot harder to just look at a problem you didn't really know what kind of structure and do the proof. It wasn't a whole lot. It wasn't like use contradiction to prove this, it was just prove the statement. You know, there wasn't a lot of certain structure to it.

Although we did not ask her in detail about her work in higher geometry, the instructional style, or course content, it is notable that she characterized her reasoning involved in producing analysis proofs as relying on the explicit connection between the statements to be proven and the common argument structures introduced in the course. Comparing her work in real analysis to her prior work before the introduction to proof course, she did not dispute the parallel between "common structure" in real analysis proof and procedural work through in her prior calculus courses.

S4 described his struggles with proof production, even after setting up common structures. Responding to our question about the emphasis on proof in real analysis, he described the mathematical work in that course as "half proof, half calculation." Later in the interview describing his struggles in proof production, his response indicated what he meant by the calculation in real analysis as follows.

*S4*: The epsilon-delta method, the proof was kind of confusing and also the calculation part was kind of tricky sometimes. Because when you see it, like it's not obvious because you have to think about you're gonna use the ratio test or … like comparison test, that wasn't obvious, so you need to think a bit.

S4 specifically indicated that choosing an appropriate test among the series convergence tests taught in the course (e.g., ratio test, comparison test, root test, integral test) was a "tricky" part for him because it was not procedural and forced him to "think a bit." The reasoning involved in this calculation part corresponds to the problem-centered part of a proof in the sense that it may call on students' mathematical intuition with respect to the particular examples of the concepts (e.g., series or functions) given in the problem (Selden & Selden, 2009). Though his description of the calculation part indicates that he recognized a problem-solving aspect of proof production in real analysis, he seemed to distinguish this part from what he originally described as "problem-solving" nature of his prior work in the introduction to proof course. In our prior study when he was interviewed after the course, he emphasized a role of conceptual understanding in proof writing that differed from procedural work in prior calculus course.

*S4*: It's important to understand for the calculus is really important but even without understanding, you can just get used to do it, how to solve the problems, for calculus courses so, but for 299 [the introduction to proof course], you have to understand it. That's the difference. (Introduction to proof course, Summer 2016)

He recognized a problem-solving aspect of proof production in the introduction to proof course that necessitated understanding key concepts in the statements to be proven. He described this crucial role of understanding in characterizing the different nature of mathematical work in moving from calculus to the proof and proving work. On the other hand, he did not emphasize conceptual understanding for proof production in real analysis, rather stressed the importance of repeated practices that cover various examples.

## Discussion

This study produced three main results; all concern transition to proof "outcomes" from one introduction to proof course. First, the introduction to proof course prepared all four participants relatively well for proof-based work in real analysis, one major content area of advanced mathematics. If the goal of introduction to proof courses is to increase students' achievement in upper-level coursework, this course succeeded, at least for some students. Note that the introduction to proof course covered the basics of proof and proving and situated students' work in three different content areas. As such it fell into David and Zazkis's (2017) "Standard + Sampler" category of such courses. Only five of the 176 courses they reviewed across the R1/R2 institutions in the U.S. were of this type.

Second, even in our small sample, we have examples of students pursuing and achieving success in real analysis in different ways, even after "the same" introduction to proof. In particular, our four students took up group-work from their introduction to proof course in quite different ways—from substantially to not at all. The changes in how they used the resources of other people in real analysis appeared to depend jointly on (a) the absence of expertise in real analysis in the MLC, (b) the perceived ease or difficulty of real analysis problems, and (c) the individual orientations of the four students.

Third, returning to our opening metaphor of proof as a doorway, mathematical work on the other side of that door can be similar in important ways to the computational focus of prior mathematics work. Three of the four participants reported regularities across real analysis proofs that resemble in some ways the mathematical work that preceded the focus on proof—to recognize problems and apply the appropriate procedure to produce answers without significant effortful problem-solving. Though their introduction to proof course regularly asked these students to solve real problems (that is, tasks that were problematic for them), the tasks in real analysis significantly reduced the problematic nature of their mathematical work, as noted by S1, S2, and S4.

One major limitation of this study is our small and "correlated" sample. Three of the four participants experienced real analysis with the same instructor and engaged each other in the same small group—though they indicated no knowledge of their joint participation in the study. Our two different approaches to mastery (engage one's peers vs. repeated individual practice) are likely not the only narratives of mastering real analysis. Variation among students (e.g., in prior mastery experiences) and among instructors both likely contribute to the diversity of students' experience in real analysis. A second limitation leads to our next steps in this research: Most of the "graduates" of the introduction to proof course in this study have thus far had only modest experience in proof-based courses. Their journey will continue into new content areas and under the direction of different instructors. In the next phases of the research, we intend to track their experience in these new contexts (e.g., abstract algebra, real analysis II) and extend the reflective comparison of present and past experiences that we initiated in this study. We also hope to increase our sample size as more participants in our previous study enroll in proof-based content courses.

# Mathematical Reasoning and Proving for Prospective Secondary Teachers

Orly Buchbinder
University of New Hampshire

Sharon McCrone
University of New Hampshire

*The design-based research approach was used to develop and study a novel capstone course: Mathematical Reasoning and Proving for Secondary Teachers. The course aimed to enhance prospective secondary teachers' (PSTs) content and pedagogical knowledge by emphasizing reasoning and proving as an overarching approach for teaching mathematics at all levels. The course focused on four proof-themes: quantified statements, conditional statements, direct proof and indirect reasoning. The PSTs strengthened their own knowledge of these themes, and then developed and taught in local schools a lesson incorporating the proof-theme within an ongoing mathematical topic. Analysis of the first-year data shows enhancements of PSTs' content and pedagogical knowledge specific to proving.*

*Keywords:* Reasoning and Proving, Preservice Secondary Teachers, Design-Based Research

Mathematics educators and education researchers agree on the importance of teaching mathematics in ways that emphasize sense making, reasoning and proving. In fact, teaching practices that emphasize mathematical reasoning have been shown to be more equitable, and associated with higher knowledge retention (Boaler & Staples, 2008; Harel, 2013). These practices encompass a wide range of processes such as exploring, conjecturing, generalizing, justifying and evaluating mathematical arguments (Hanna & deVillers, 2012; Ellis, Bieda & Knuth, 2012). Policy documents also encourage integrating reasoning and proving throughout grade levels and mathematical topics (CCSSI, 2010; NCTM, 2009). However, the reality of many mathematics classrooms has been far from the vision put forth by researchers and policy makers. Reasoning and proof is often confined to high school geometry, tied to a particular format and used to show already known results. Consequently, students and teachers alike often view proof as redundant, rather than a means of deepening mathematical understanding (Knuth, 2002). Although teachers often recognize the importance of reasoning and proof beyond high school geometry, they tend to choose skills-oriented activities over proof-oriented ones for their own classrooms (Kotelawala, 2016). One reason for this might be, as Bieda (2010) found, that even experienced teachers struggle to implement reasoning and proving in their classrooms.

These studies suggest that enacting teaching practices that emphasize reasoning and proof is a complex process that requires awareness and intentionality on behalf of the teacher. Preparing teachers who are capable of implementing such teaching practices and cultivating positive attitudes towards mathematical reasoning and proving is a critical objective of teacher preparation programs (AMTE, 2017). Yet, the theoretical and practical knowledge in this area of teacher preparation has been scarce (e.g., Ko, 2010; Stylianides & Stylianides, 2015).

To address this knowledge gap, we utilized a design-based-research approach (Edelson, 2000) to develop and study a novel capstone course *Mathematical Reasoning and Proving for Secondary Teachers*. The goals of the course were to improve the PSTs mathematical knowledge for teaching proving, including subject matter knowledge and pedagogical content knowledge. The goals of the research study were to (a) explore how PSTs' knowledge and dispositions towards the teaching and learning of reasoning and proof developed as a result of participating in the capstone course, and (b) to identify course design principles that afforded PSTs' learning. In this paper, we illustrate the overall structure of the course; we describe in greater detail one of the four modules, specifically, the module on Conditional Statements (CS); and we provide details on how PSTs interacted with the components of the CS module. We also show evidence of growth of PSTs' mathematical knowledge for teaching proof, following the completion of the course.

### Theoretical Framework and the Course Design

Researchers have conjectured that engaging students in reasoning and proving, that is, exploring, generalizing, conjecturing and justifying, might require a special type of teacher knowledge: Mathematical Knowledge for Teaching of Proof (MKT-P) (e.g., Lesseig, 2016; Stylianides, 2011). Building on their work, we theorize that MKT-P consists of four interrelated types of knowledge, two specific to content, and two related to pedagogy (Fig. 1).

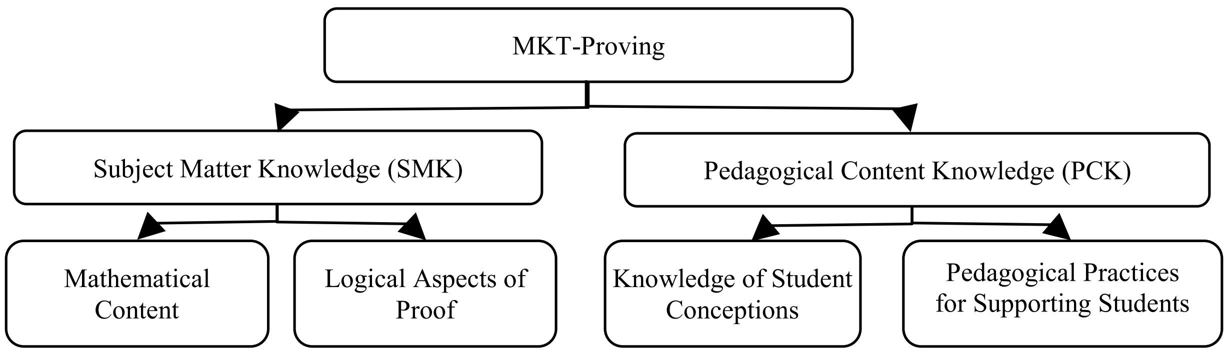

**Figure 1.** Mathematical Knowledge for Teaching of Proving (Buchbinder & Cook, 2018)

As suggested in Figure 1, to enact reasoning and proving in their classrooms, we hypothesize that teachers must have robust Subject Matter Knowledge (SMK) of mathematical concepts and principles, and also knowledge of the logical aspects of proof, which includes knowledge of different types of arguments, proof techniques, knowledge of logical connections, valid and invalid modes of reasoning, the functions of proof, and the role of examples and counterexamples in proving (Hanna & deVillers, 2012). Teachers also need strong Pedagogical Content Knowledge (PCK) specific to proving, such as knowledge of students' proof-related conceptions and common mistakes, and knowledge of pedagogical strategies for supporting students' proof activities. Thus, we built into the course structure opportunities for PSTs to develop and practice these four types of knowledge (Fig. 1).

The course consists of four modules, each three-weeks long, corresponding to four proof-themes: quantified statements, conditional statements, direct proof and indirect reasoning. These themes were identified in the literature as challenging for students and PSTs (Antonini & Mariotti, 2008; Weber, 2010). Thus, each module was designed with activities to enhance PSTs' knowledge of the logical aspects of proof related to the proof themes, followed by developing and teaching lessons at a local school integrating that proof-theme with current mathematical topics. This combination of the activities was intended to address both subject matter knowledge and pedagogical knowledge specific to proving, as mentioned above. Figure 2 shows the structure of the course (top) and the general structure of a single course module (bottom).

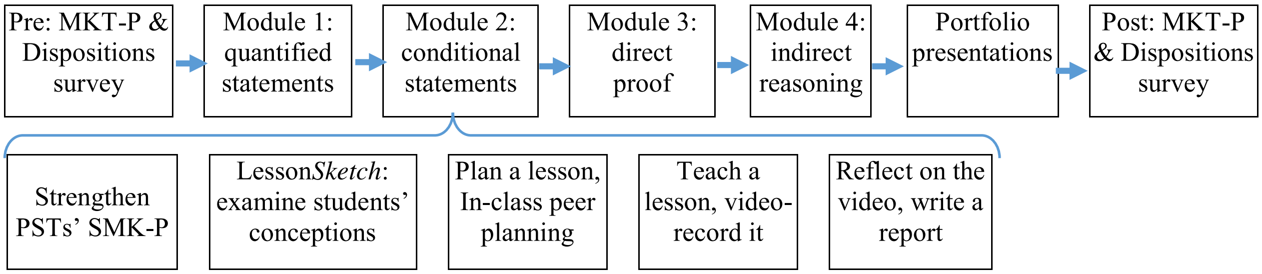

**Figure 2.** Design of the course *Mathematical Reasoning and Proving for Secondary Teachers*.

The theoretical background underlying the course design also draws on a situated perspective of learning (Peressini, Borko, Romagnano, Knuth, & Willis, 2004) which views learning as patterned participation in social contexts. In particular, Borko et al. (2000) assert that learning to teach occurs across multiple settings through active participation in the social contexts embedded in them, and should not be confined to a university classroom. Building on the literature on practice-based teacher education (e.g., Ball & Forzani, 2011; Grossman, Hammerness & McDonald, 2009) we designed opportunities for PSTs to enhance their proof-related pedagogical knowledge in an environment of reduced complexity and risk, through the virtual learning platform Lesson*Sketch* (Herbst, Chazan, Chieu, Milewski, Kosko, & Aaron, 2016). The learning experiences created and administered through this platform allowed the PSTs to engage in practices such as interpreting sample student work, identifying students' conceptions of proof, evaluating students' mathematical arguments, and envisioning responding to them in ways that challenge and advance students' thinking. We also engaged PSTs in planning and implementing, in local schools, lessons that combine the proof themes with the regular mathematical content. We see this as a critical component and the unique feature of our course design, that aims to bring together the aspects of proof and secondary curriculum.

As PSTs enacted their lesson, they recorded it using 360° video cameras, which captured simultaneously the PSTs' teaching performance and the school students' engagement with proof-oriented lessons. PSTs then watched and analyzed their lesson, wrote a reflection report and received feedback from the course instructor to inform future lesson planning.

The design-based research format of this project requires that we take a careful look at the various course components and the participants' interaction with them. Thus, in the methods and results sections below, we describe one module, Conditional Statements (CS), in order to demonstrate how we address the first goal of our project: to develop and study the capstone course. We focus on the following research questions:

1. *How did the PSTs interact with the CS module?*
2. *What mathematical and pedagogical ideas addressed in the CS module were implemented in the PSTs' lessons?*

At the same time, a second main goal of our project was to improve the preservice teachers' knowledge of and disposition toward teaching proof and reasoning through this course. Thus, we explored the research question:

3. *How did the PSTs' MKT-P and dispositions toward proof develop throughout the course?*

## Methods

Participants in the first iteration of the course were 15 PSTs in their senior year (4 middle-school, and 11 high-school track; 6 males and 9 females). The PSTs had completed the majority of their extensive mathematical coursework, and two educational methods courses, one focused on general mathematics education topics that are common across grade levels, and one specific to teaching secondary mathematics.

Multiple measures were used to collect data on PSTs interaction with the CS module. We collected and analyzed PSTs' responses to home- and in-class assignments, and video-recordings of all in-class sessions to answer the first research question. To answer the second question, we analyzed the PSTs' cumulative teaching portfolios containing four lesson plans, video-records of the lessons taught, reflection reports, and sample school students' work. We used a modification of Schoenfeld's (2013) TRU Math rubric to analyze 360° video-records of the PSTs' lessons.

In addition, we investigated how PSTs' knowledge of content and pedagogy, and their dispositions towards proof evolved throughout the course. For that, we used two instruments: pre- and post- measures of mathematical knowledge for teaching proof - the MKT-P questionnaire, and dispositions towards proving survey. Prior to the study, we identified four existing instruments from the literature (Corleis et al., 2008; Kotelawala, 2016; Lesseig, 2016; Nyaumwe & Buzuzi, 2007), that partially matched our research focus. We combined elements of those instruments and supplemented with our own items to create an MKT-P instrument containing four sets of questions corresponding to the four types of MKT-P (Fig. 1). The dispositions towards proof survey included six sets of questions, some open and some closed, addressing PSTs' notions of proof, the purpose and usefulness of proof, suitability of proof for secondary students, PSTs' own confidence and comfort with proving, as well as confidence in teaching proof to students. The survey questions were a combination of items from related instruments (e.g., McCrone & Martin, 2004; Nyaumwe & Buzuzi, 2007). Both the MKT-P instrument and the dispositions survey were reviewed and analyzed by experts in educational assessment. The data collected with the MKT-P questionnaire and dispositions towards proof survey were analyzed quantitatively to answer the third research question.

## Results

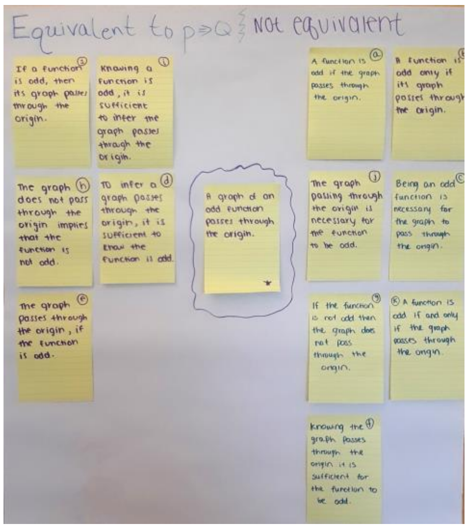
### PSTs' Interaction with the Conditional Statements Module

In this section we take a closer look at the Conditional Statements (CS) module and the PSTs interaction with the module components. The Conditional Statements module comprised the following activities: (1) sorting conditional statements, (2) Lesson*Sketch* experience *Who is right?*, (3) analysis of conditional statements in the secondary curriculum, (4) planning and implementing a lesson that incorporates some ideas about conditional statements, and (5) implementation reflection.

#### Sorting Conditional Statements.

For this in-class activity, PSTs broke up into three groups and each group received one conditional statement. Their task was to identify the statements' hypothesis $P$ and conclusion $Q$, and use the $P$ and $Q$ to write statements in 11 logical forms such as: $P\ if\ Q$, $P\ only\ if\ Q$, $If\ {\sim}P\ then\ {\sim}Q$, and others. The PSTs were to write each statement on an index card using different colors for true and false statements, and then sort the cards into statements equivalent to $P \Rightarrow Q$, and non-equivalent to it. The original statements given to the groups were: "A graph of an odd function, defined at zero, passes through the origin" (group 1), "A number that is divisible by six is divisible by three" (group 2), and "Diagonals of a rectangle are congruent to each other" (group 3).

Each group created a poster showing how they sorted the cards, and presented their work to others. Figure 3 shows a poster by group 1. The statements on the cards (Fig. 3-a) are written in terms of the original statement, which is located in the middle of the poster. Figure 3-b shows which logical forms PSTs identified as equivalent or non-equivalent to $P \Rightarrow Q$, the incorrect answers are marked with *. Note that the PSTs correctly identified all equivalent forms and all non-equivalent forms. However, they also wrongly identified two equivalent forms (j) and (b) as non-equivalent.



(a)

Types of statements as sorted on the poster.
P: $f$ *is an odd function, defined at zero*
Q: *the graph of* $f$ *passes through the origin*

Equivalent to $P \Rightarrow Q$:
If P then Q.
d) To infer Q, it is sufficient to know P
e) Q if P
h) Not Q implies not P
i) P is sufficient to infer Q

Nonequivalent:
a) P if Q
c) P is necessary for Q
f) Q is sufficient for P
g) If not P then not Q
k) P if and only if Q
j) Q is necessary for P*
b) P only if Q*

(b)

**Figure 3.** (a) Group 1 poster, sorting equivalent and non-equivalent statements; the original statement is in the middle; (b) logical forms represented on the poster.

The form that the PSTs in all three groups found most challenging to interpret was $P$ *only if* $Q$. Some PSTs realized that it is equivalent to a contrapositive, $\sim Q \Longrightarrow \sim P$, and therefore equivalent to the original statement. But other PSTs rejected this idea by arguing that $P$ can be true "not only when $Q$ is true", concluding that $P$ *only if* $Q$ is not equivalent to $P \Longrightarrow Q$. Group 2 argued that a statement "A number is divisible by 6 only if it is divisible by 3" is both untrue and non-equivalent to the original statement, because a number is divisible by 6 *not only* when it is divisible by 3, but also when it is divisible by 2. Since the PSTs found the arguments for equivalence and non-equivalence of the two statements to be equally appealing, it required facilitator intervention to clarify the equivalence using the contrapositive argument. In this explanation, the abstract logical notation appeared to be more useful than the contextualized one.

After all groups presented their posters and the discrepancies were discussed and resolved, PSTs received additional prompts to grapple with, such as: What is the relationship between truth-value of a statement and equivalence of statements? Identify inverse and converse among the given forms, and rewrite the language of necessary and sufficient conditions symbolically. PSTs discussed these prompts in their groups first, and then as a whole class. The follow-up homework assignment (discussed below) introduced the PSTs to students' conceptions of conditional statements.

**LessonSketch experience *Who is Right*?**

Lesson*Sketch*.org is an interactive-media web-based platform for teacher education, which allows a teacher educator to represent classroom interactions as cartoon sketches, which PSTs can analyze. Such representations preserve much of the authenticity of the real classroom, but allow PSTs more time to interpret student thinking and plan a response (Herbst et al., 2016). The interactive tools of Lesson*Sketch* allow teacher educators to create rich learning experiences for PSTs, that provide PSTs with opportunities to experience situations that resemble classroom interactions, and envision themselves participating in them as teachers. These experiences can involve analyzing samples of student work; watching classroom scenarios in the form of video, animation or story board; responding to prompts about these scenarios; creating their own depictions of classroom interactions; and participating in discussion forums.

The experience *Who is right?* is based on real student data, and was field-tested in prior studies (Buchbinder, 2018). In this experience the PSTs were presented with a false mathematical statement: "If $n$ is a natural number, then $n^2 + n + 17$ is prime," and asked whether it is true, false, sometimes true, or cannot be determined. It is important to note that although a mathematical statement can only be true or false, we discovered in pilot implementations of the experience that PSTs struggled to commit to a dichotomous answer. Instead, they were trying to hedge their responses in the comment box. This tendency to avoid a dichotomous response is reminiscent of "fuzzy logic" (Zazkis, 1995), the form of reasoning that allows one to assign to a statement a value that qualifies one's confidence in its correctness. By providing PSTs four, rather than two, options to choose from when evaluating the truth-value of the statement, we allowed greater flexibility for PSTs to respond to the prompt. As researchers and teacher educators, we were able to assess who among our PSTs had not yet developed bivalent logical reasoning, which aligns with conventional mathematical logic.

After PSTs evaluated the statement on their own, they viewed a set of slides depicting arguments of five pairs of students evaluating the truth-value of that given statement. The arguments were developed to reflect common student misconceptions about conditional statements. For example, "proving" the statement by testing a set of strategically chosen examples, requesting more than one counterexample to disprove a statement, asserting that the truth-value of a statement cannot be determined when both supportive examples and counterexamples exist (Buchbinder & Zaslavsky, 2013). The PSTs' task was to evaluate the correctness of these five students' arguments, identify instances of expertise and gaps in student reasoning and pose questions to advance or challenge that reasoning. In a similar vein, we provided four, rather than two, response options for evaluating students' arguments: correct, more correct than incorrect, more incorrect than correct and incorrect. The design decision to allow PSTs to assign partial correctness to student arguments stemmed from pilot implementations of this Lesson*Sketch* experience (Buchbinder, 2018).

Figure 4 shows the distribution of PSTs' ratings of each of the five arguments. Each row corresponds to one of the five arguments, and the numbers in the rows correspond to the number of PSTs choosing a particular rating (incorrect, more incorrect than correct, more correct than incorrect, or correct). To validate the numerical data, we examined PSTs' justifications of their ratings, which revealed that that PSTs scores are not solely dependent on mathematical correctness of the evaluated argument, but are strongly influenced by pedagogical considerations.

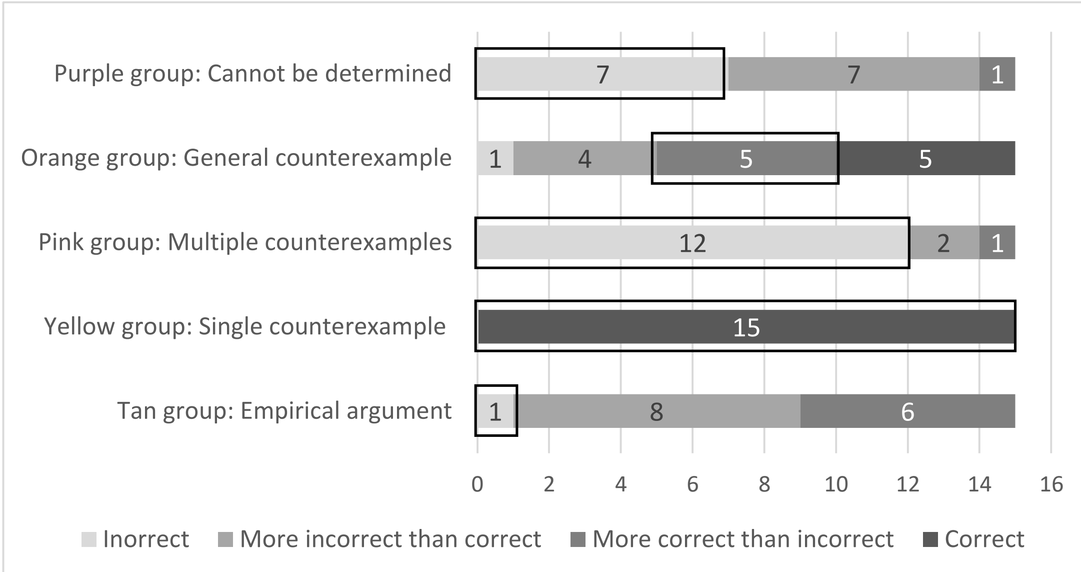


**Figure 4:** Distribution of PSTs' ratings of five student arguments in the LessonSketch experience *Who is right?* The dark frame indicates expected correct answer.

Figure 4 shows that all PSTs accepted a disproof by a single counterexample, and the vast majority of PSTs rated as incorrect the request for multiple counterexamples. Also, 14 out of 15 PSTs rated negatively the assertion that the truth-value cannot be determined when both supportive and counterexamples exist. The one PST who rated this student response as more correct than incorrect justified it with a pedagogical consideration. She wrote:

> This statement should be written with a universal quantifier to make it easier for students to understand it, but since it is not I can see where the students are confused and are not sure if they can prove the statement true or false. However, finding one counterexample is enough to prove this statement false, which they don't understand yet.

This kind of response from the PSTs was not an isolated instance. Overall, across all PSTs' responses to the variety of student arguments we observed that mathematical correctness of the argument was not the ultimate evaluation criterion; PSTs' evaluations were strongly affected by pedagogical considerations, reflecting the PSTs' desire to award partial credit for correct students' work or computation. In particular, the eight PSTs who rated Tan group's empirical argument as more incorrect than correct, noted that it is not an appropriate way to prove a conditional statement, but acknowledged the correctness of student calculations and validated their efforts.

We note that that while valuing student contributions is an important pedagogical practice, it is crucial for PSTs to recognize which arguments are mathematically valid, and help students to progress towards more mathematically accepted logical arguments. This is, however, heavily dependent on the PSTs' own mathematical reasoning. In our sample, there were five PSTs who believed the given statement to be true because they, themselves, could not find a counterexample. These PSTs also rated the students' empirical argument as more correct than incorrect, mimicking their own invalid reasoning.

PSTs completed the *Who is right?* activity at home, and then shared and discussed their responses as a whole class. The main focus of the discussion was on the students' conceptions of proof and the type of evidence needed to determine the truth-value of conditional statements.

PSTs also discussed the ways to acknowledge student effort, while pointing students towards more valid modes of argumentation.

**Conditional statements in the secondary curriculum.**

The final in-class activity in the Conditional Statements module focused on analyzing where conditional statements appear in the secondary curriculum. Working in groups, PSTs analyzed excerpts from glossary sections in a few textbooks. Their task was to write some of the rules or theorems stated there in the form of conditional statements or in some of the equivalent forms. The goals of this activity were (1) to demonstrate the prevalence of conditional statements in high school mathematics curricula aside from geometry, and (2) to anticipate student difficulties in reasoning about such statements. The discussion questions for this activity addressed the importance of understanding conditional statements, potential student difficulties related to conditional statements and brainstorming ways to support student thinking.

**Planning and implementing a lesson on conditional statements.**

The lesson planning process included several steps. About a week prior to the lesson, PSTs contacted their cooperating teacher to find out the mathematical topic for their lesson. Based on this information, the PSTs developed a lesson incorporating that topic with some ideas about conditional statements. During an in-class session, the PSTs worked in small groups sharing the lesson plans, testing out ideas, giving and receiving feedback with their peers and the course instructor. After improving the lesson plans through this process, the PSTs implemented their lessons in middle school and high school classrooms participating in the study.

PSTs in the middle school worked with one teacher and class, throughout the semester. These PSTs could develop closer relationships with the students, but all their lessons were tied to one mathematical unit, namely exponents. The high school track PSTs rotated among different classrooms and teachers. This allowed exposure to a variety of mathematical topics, but limited the PSTs ability to establish long-term connections with students. This also complicated their lesson planning, since the PSTs struggled to envision the students' mathematical background. The high school track PSTs taught lessons in Pre-algebra, Algebra 1, and Geometry on a range of topics such as order of operations, variable expressions, linear equations, classifying triangles, and parallel lines.

The analysis of PSTs' lesson plans showed that PSTs came up with a variety of creative ways to integrate conditional statements in their lessons while appropriately adjusting them to the students' level. Almost all PSTs used real-world examples, such as, "If I do my homework, I will get good grades" to introduce students to the general structure of a conditional statement, and to identify the hypothesis ($P$) and the conclusion ($Q$). One of the PSTs, Sam, came up with a particularly creative way to introduce conditional statements: She showed students a few product advertisements, asked them to turn the slogans into conditional statements and analyze their structure in terms of $P$ and $Q$.

There was a great variation among PSTs' use of mathematical vocabulary in the lessons. For example, although both Cindy and Audrey developed a lesson on exponents asking 8$^{th}$ grade students to evaluate the truth-value of several conditional statements, Cindy did not introduce any vocabulary in her lesson, while Audrey mentioned explicitly conditional statements, and used $P$ and $Q$ notation. Nate, who taught 10$^{th}$ grade geometry, included in his lesson on parallel lines the definitions of converse, inverse and contrapositive. The majority of PSTs used a softer approach, explaining that statements of the form "if__then__" are called conditional statements, and used language of given and claim, instead of hypothesis and conclusion for P and Q. These kinds of adjustments were discussed by PSTs throughout the in-class sessions of the module as possible ways to support students' engagement with proof, particularly at the lower grade levels.

The most utilized types of tasks implemented by the PSTs were True or False, and Always-Sometimes-Never, in which the PSTs had students identify the hypothesis and the conclusion in each statement, determine whether the statement is true or false, and provide justifications or counterexamples. But there were other types of tasks utilized by the PSTs. For example, Bill created two sets of notecards: one set contained hypotheses (e.g., a triangle is not equilateral) and another set contained conclusions (e.g., a triangle is isosceles). First, Bill asked his students to match hypotheses to conclusions to produce conditional statements about triangles. After determining as a group which statements are true and which are false, Bill asked the students to change the order of cards by physically switching between the hypothesis and the conclusion. Then he had students examine the relationship between the converse and the original statement.

Another PST, Logan, modified a common Algebra 1 task into a proof-related activity on conditional statements. First, he asked his Algebra 1 students to produce an algebraic expression describing a certain sequence of operations: pick a number, quadruple it, subtract 6 and divide the result by 2. Then, he asked students to determine the truth value of several statements about the resulting expression, for example: "If your output is 34, then your input had to have been 8," or "If your input is even, then your output will be odd." Overall, except for four PSTs who only minimally addressed conditional statements, the majority of PSTs successfully and creatively integrated conditional statements in their lessons.

**Reflection on lesson implementation.**

As mentioned above, the PSTs recorded their lessons using 360° cameras to capture both the teacher and the student interactions. Each PST watched and reflected on their video by (a) annotating it, and (b) writing a report on how the lesson went, according to a given set of prompts. To support their claims, PSTs were required to provide time-stamps in the video. Some reflection prompts were common across all lessons, such as the following questions: In what ways did you engage students in making sense of mathematics? What aspects of students' thinking did you find particularly interesting or surprising? On the scale 1 (low) – 5 (high) evaluate your own performance in the lesson and explain the rating. In addition, each module had questions specific to the proof-theme. In the CS module, the PSTs were asked to reflect on aspects of their lessons that were specific to conditional statements. The following excerpt is taken from Grace's reflection report in which she responded to a prompt: What ideas about conditional statements do you think students understood by the end of your lesson? How do you know? Grace wrote:

> The pair work allowed [the students] to bounce ideas off each other and I could tell that they understood how to write the converse and contrapositive based on their discussions. For example, I overheard things like, "Converse, ok we need Q then P" or "This is the contrapositive, right? … If not Q, then not P?" I was happy to hear these conversations because not only were the students engaged in the activity, but they were working and communicating well together.

Reflecting on the video-recording of the lesson was quite a time consuming process, however when asked to reflect on this aspect of the course at the end of the semester, the majority of PSTs indicated that this contributed to their learning. In the summative course evaluation Ellen wrote:

> I felt that the video recordings were extremely beneficial for my learning. Even when there were parts of the lesson that I thought went very smooth at the time, I later found when watching the videos that things did not always go as smooth as I had thought.

This idea of occasional mismatch between one's feeling of their teaching performance and the lesson as recorded on camera was a recurring theme in our data. For example, Audrey, who was initially happy with her lesson, wrote after watching the video: "I realized that I am so quick to answer students' questions, that I am not stepping back and asking for other students' ideas." And concluded: "I want to make sure I am reaching all my students." Overall, the 360° video capturing allowed the PSTs to see how students reacted to their teaching in general, and to the specific proof-theme.

**Evidence of PSTs' Learning**

In this section we provide data from the MKT-P and disposition questionnaires to examine research question three: *How did the PSTs' MKT-P and dispositions toward proof develop throughout the course?* To trace changes in PSTs' knowledge and dispositions as a result of the course, we administered pre- and post- measures of MKT-P and pre- and post-surveys on dispositions towards proof (Fig. 2). The MKT-P contained 12 questions, 3 in each of the four areas of MKT-P (Fig. 1). In line with Hill and Ball (2004) all MKT-P items were embedded in pedagogical contexts, that is, as representing student mathematical work. The items in our measures, therefore, called for analyzing, interpreting and responding to students' conceptions of proof, similar to activities described above in the CS module.

Out of the three items measuring PSTs' Knowledge of the Logical Aspects of Proof (or Logical Knowledge, LK, for a shorthand), two items addressed knowledge related to conditional statements. In one item, a geometrical statement about quadrilaterals, and its converse were given, accompanied by a set of four claims about these statements, for example, "to prove statement (1) is false it is sufficient to prove statement (2) is false", or "to prove statement (2) is true, it is sufficient to prove statement (2) is false". The task for PSTs was to identify the correct claim about the given pair of statements. Almost all PSTs performed well on this item in both pre- and post- questionnaires, indicating that the item was too easy for PSTs in our sample, and did not sufficiently discriminate among them. We plan to modify this item in the future.

The second item dealing with conditional statements had several parts. It first introduced four statements about real numbers: (a) If $x < 1$, then $x^2 < x$, (b) If $x^2 < x$ , then $x < 1$, (c) If $x^2 > x$ , then $x > 1$, and (d) If $x > 1$ then $x^2 > x$ . PSTs were asked for each statement to determine whether it is true or false, and if false, provide a counterexample. Next, we referred to statement (a) as "If P then Q", and asked the PSTs to identify the logical form of the rest of the statements, accordingly. Lastly, we asked the PSTs to identify an equivalent statement to (a) from a given list of distractors. Across all parts of the item, we documented a 14% score increase from pre- to post-test, with most gains occurring in identifying equivalent statements.

Overall, the data analysis revealed that PSTs had relatively high initial scores on three out of four types of MKT-P, that is Knowledge of Logical Aspects of Proof, Knowledge of Students' Conception of proof, and Knowledge of Pedagogical Practices for supporting students (Fig. 5). Because of the high initial scores we calculated the calculated the percentage of possible growth in lieu of examining the point increase. That is, we calculated what percent of the possible growth (difference of maximum score and pre-test score average) constitutes the observed growth (difference in post-test and pre-test averages). For example, although the increase in the Knowledge of Logical Aspects of Proof was only 1.15 points, it constitutes 48% of possible 2.4

points needed to obtain the maximum score. The highest gain of 66% occurred in the Knowledge of Pedagogical Practices for supporting students' learning of proof. This was reflected in the items, among others, that called for interpreting students' conceptions of proof related to activities from the CS module.

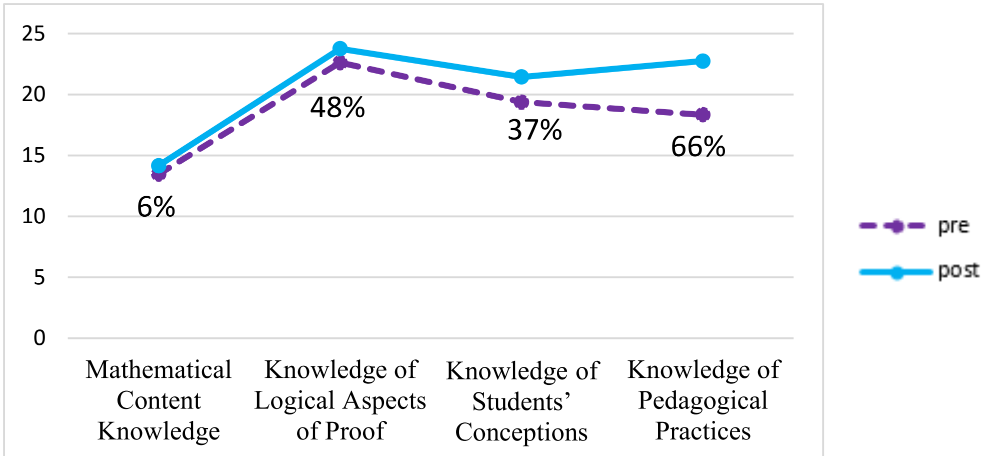

**Figure 5:** Sub-score averages across all participants (out of 25 points) for the four components of the MKT-P survey, with percent increase.

The dispositions towards proof survey included five categories of questions: (1) the PSTs' notions of a proof, (2) the purpose and usefulness of proof, (3) confidence and comfort with proving, (4) the suitability of proof in the school curriculum, and (5) confidence in and knowledge about teaching proof to students. In general, the pre- and post-test results did not show much change in the PSTs' thinking around categories 1, 2 and 4, but a few noteworthy results had to do with categories 3 and 5. Prior to the course, about 65% of the PSTs agreed or strongly agreed that they felt confident in their ability to prove mathematical results from the school curriculum, whereas 92% responded positively after completing the course. A slightly greater change was noted in confidence of teaching proof to students, from 50% agreement in the pretest responses to 84% agreement in post-test responses. The fact that PSTs' overall growth of dispositions was relatively modest may be attributed to the not necessarily justifiable feeling of confidence at the start of the semester due to the PSTs' prior mathematical coursework.

## Discussion

This paper described the first iteration of a 3-year design-based-research project aimed to enhance PSTs' knowledge and dispositions for teaching proof at the secondary level. We have described the overall structure of the course *Mathematical Reasoning and Proving for Secondary Teachers*, the theoretical underpinnings of its design, and provided details on the Conditional Statements module, one of four course modules. Our first two goals in this paper were to describe how PSTs interacted with the Conditional Statements module, and to examine what mathematical and pedagogical ideas addressed in the Conditional Statements module were implemented in PSTs' lessons. Towards this end we provided descriptions of the various components of the module, such as an activity on sorting conditional statements and the Lesson*Sketch* experience *Who is right?* which required the PSTs to evaluate the logical reasoning of students in relation to determining the validity of a conditional statement. We also presented data on how the PSTs interacted with these components of the module, and identified particular strengths and weaknesses in PSTs' knowledge. Our data show that PSTs interacted with different components of the CS module in productive and meaningful ways. Although the scope of the paper does not allow presenting the full detail of the interactions, the analysis of classroom videos showed that PSTs engaged in rich discussions around the logical aspects of conditional statements actively seeking to clarify their meaning, especially when presented in the alternative forms to "If P then Q". The PSTs also were deeply concerned with the pedagogical side of teaching middle- or high-school students about conditional statements, as their lesson plans and reflections attest.

The data on PSTs' interactions with the CS module serve as a backdrop for understanding the gains in PSTs' content and pedagogical knowledge of proof, following their participation in the capstone course. The comparison of PSTs' performance on pre- and post- measures of MKT-P shows that the areas in which the PSTs' growth of MKT-P was most evident are those that were emphasized in the course, namely, the logical aspects of proof and pedagogical knowledge specific to proving. Due to the small sample size we were unable to test whether the gains were statistically significant, however, we are encouraged by these outcomes, especially since they are based on evidence beyond PSTs' self-report.

One of the critical elements of design-based-research, according to Edelson (2002), is to treat a particular study as an instance of a more general phenomena to develop educational design theories that go beyond the specific research context. This can be achieved by examining the relationship between the design features of the intervention – the capstone course – and the PSTs' learning. In the descriptions above we highlighted the range of practice-based elements in the course design: Analyzing students' conceptions of proof; devoting course time and resources to lesson planning and sharing; teaching in middle school and high school classrooms; and reflecting on one's teaching, supported by video technology. We assert that all these elements contributed to enhancement of PSTs' MKT-P and dispositions towards proof. One particular aspect where this can be seen is the PSTs' pedagogical knowledge for proving. Throughout the course, and in the final course reflection, many PSTs acknowledged that they often found it challenging to integrate the proof-themes with pedagogical practices. However, as we showed in the case of CS module above, the PSTs' lesson plans and classroom implementations clearly reflect the proof-themes addressed in the course (although there was obvious variation among the PSTs). This is also visible in the increased PSTs' scores on the MKT-P portion related to the Pedagogical Aspects of Proof. This suggests to us, that the repeated cycles of lesson development, implementation and video-supported reflection contributed to PSTs' pedagogical knowledge for proving.

Our data analysis is still ongoing, as we examine video of on-campus sessions and of the PSTs' teaching to create a more fine-grained description of how PSTs' content and pedagogical knowledge evolved throughout the course, and to match this growth to the design principles of the course. The results of this analysis will inform future iterations of our project. In particular, we plan to further conceptualize and enhance instructional scaffolding of the course in the subsequent iterations of the study, to better support PSTs' learning.

Through our data analysis we seek to generate an evidence-based instructional model, and four proof-modules that can be adopted by other courses or institutions to improve preparation of secondary mathematics teachers, and, potentially advance the field's understanding of how to support PSTs' development of mathematical knowledge for teaching proof.

# Exploring Pre-service Elementary Teacher's Relationships with Mathematics via Creative Writing and Survey

Taekyoung Kim
Oklahoma State University

*Thirty-two pre-service elementary teachers completed a survey regarding their beliefs and attitudes towards learning and teaching mathematics and two creative writing tasks. In the first writing task participants described their personal relationship with personified mathematics and in the second, they introduced personified mathematics to their future students. By interpreting the survey and writings, different aspect of attitudes towards mathematics were discovered. A main finding was that the two writing tasks were able to provide a more nuanced view of how pre-service teachers' beliefs about mathematics changed over time. We found that their past experiences with mathematics often affected the way that they talked about mathematics to their students, though they did attempt to suppress their negative experiences when introducing mathematics to their students.*

*Keywords*: affect, pre-service teachers, creative writing

## Introduction

Negative experiences in learning mathematics can cause a person to develop mathematics anxiety. Unfortunately, research suggests that teachers can contribute to these negative experiences, which can have an adverse effect on a student's learning (Bekdemir, 2010). Therefore, the mathematical experiences of pre-service teachers are critical not only for themselves but also for their future students.

In addition to mathematical content knowledge, teachers' views, beliefs, and preferences about mathematics influence their instructional practice (Thompson 1984). While surveys can measure pre-service teachers' views and attitudes toward mathematics, they can be limited because participants are responding to specific items rather than expressing their own thoughts. Creative writing tasks in which participants write about their experience with mathematics can provide researchers with information about different aspects of their attitudes and beliefs about mathematics. Using Zazkis' (2015) method of eliciting personification, I gave thirty-two pre-service teachers opportunities to describe their relationship with mathematics as though mathematics were a person in two creative writing tasks. The first writing task was the same as Zazkis' task in which they tell about their personal relationship with mathematics, and in the second one, they introduced mathematics to their future students. Participants also completed a 14 question survey assessing their beliefs and attitudes regarding mathematics. The survey questions were modified from the Mathematics Anxiety Rating Scale (MARS)-abbreviated version (Alexander & Martray, 1989) and the Mathematics Teaching Efficacy Belief Instrument (Enochs & Riggs, 2002).

I analyzed these two writing tasks using conceptual blending (Fauconnier & Turner 2003) to explore pre-service teachers' beliefs about mathematics and how it could affect their teaching. Moreover, using a survey about their beliefs about mathematics, I saw how two different types of tasks could bring some common ideas and different perspectives regarding beliefs and attitudes toward mathematics.

## Literature Review

Several studies used conventional surveys to measure pre-service teachers' perception of mathematics. Survey methods were used to investigate both the relationship between participants' attitudes and anxiety level of mathematics and to see how those results are related to their teaching of mathematics.

A teacher's personal mathematics anxiety can affect their anxiety about teaching mathematics. Hadley & Dorward (2011), surveyed 692 elementary school teachers in a three-part survey. The first part was MARS-R (MARS-Revised) and the second part consisted of 12 Likert-scale items which mirrored the MARS items but assessed anxiety about *teaching* mathematics. The third part of the survey asked about the elementary teachers' mathematics instructional practices. It included questions regarding how the teachers use writing mathematics in class, manipulatives, group work and so forth. Also to investigate relationship between teachers' mathematics anxiety level and student achievement, the class average scores on the state mathematics test for each teacher was collected. The result showed that teachers who were anxious about mathematics tended to also be anxious about teaching mathematics. However, upon further analysis the data indicated that for teachers with higher levels of anxiety about mathematics, there was no relationship with anxiety about teaching mathematics. Some of these teachers had very high anxiety about teaching mathematics, while others had moderate or even low anxiety about teaching mathematics. Some low anxiety teachers were experienced teachers. The study also found that regardless of teachers' anxiety level, when teachers were comfortable teaching mathematics, students achieved somewhat higher test scores. No relationship was found between anxiety about teaching mathematics and mathematics instructional practices.

Mathematics anxiety also influences confidence in teaching mathematics. Bursal & Paznokas (2006) measured sixty five pre-service elementary teachers' math anxiety levels and confidence levels for teaching elementary mathematics and science. They used Revised-Mathematics Anxiety Survey (R-MANX), and the Math Teaching Efficacy Belief Instrument (MTEBI) for mathematics. The result showed that participants who scored low and moderate mathematics anxiety showed confidence in teaching mathematics and participants who scored high mathematics disagree with MTEBI statements.

Teachers' prior experiences with mathematics can influence their beliefs more than their teacher education programs. Raymond (1997) observed six first and second year elementary school teachers for 10 months to see the relationship between mathematics beliefs and teaching practice. The study involved observing and interviewing six teachers to categorize their beliefs about mathematics, beliefs about learning mathematics, beliefs about teaching mathematics, and teaching mathematics. He evaluated each teacher as "traditional", "nontraditional" or "even mix" for each category. All six teachers named their prior school experiences of mathematics being the main influence on their beliefs about mathematics and teaching experiences. Teacher education programs were viewed as having a slight influence on their teaching and beliefs about mathematics. This showed how beliefs about mathematics are affected by prior school experiences, and for teacher how it could affect their teaching practice. In addition, the study showed that the effectiveness of a teacher education program had on teachers' beliefs about mathematics. The authors mentioned that it is possible that a teacher education program cannot directly affect teaching practices beyond certain level. Therefore, the result of the study suggests that focusing on pre-service teachers' beliefs about mathematics could indirectly affect pre-service teachers practice.

These studies highlight the current issue of pre-service teachers' relationship with mathematics and the effects that could have on their teaching mathematics. Having mathematics anxiety can affect how a teacher teaches mathematics and the teacher's level of comfort with teaching math can affect student learning. It is also evident that a teacher's personal beliefs about mathematics have an effect on his or her teaching. Therefore, having less mathematics anxiety, being comfortable teaching mathematics, and general positive relationships with mathematics are important for pre-service teachers to gain in order to become better mathematics educators.

Non-standard methods were used in some studies to investigate people's perception of mathematics. Zazkis (2015) assessed pre-service teachers' attitudes towards mathematics by using a creative writing task in which they described their relationship with mathematics as though mathematics were a person. Then, he used conceptual blending to interpret participants' human description of mathematics by mapping their descriptions from the human relationship space to the corresponding characteristic in the mathematics space. This method of data collection and analysis provided a "vivid window" into the beliefs of the pre-service teachers.

Stereotypes about what kind of people do mathematics can play into students' beliefs about mathematics. Picker and Berry (2000) asked 12-13 year olds in five countries to draw a mathematician. By analyzing the drawings, they found that children of this age relied on stereotypical images from the media to portray a mathematician. Students who possess these beliefs may feel mathematics anxiety if they do not conform to the stereotype.

Several studies regarding students' relationship or view about mathematics have been measured by some kind of survey. Survey methods are limited because a participant has prescribed choices for the items. It is possible that the way she or he expresses anxiety about mathematics could be different from the wording of the survey items. Hence, chosen vocabularies in a survey could limit participants' ways of expressing views on mathematics. Likert-like surveys have similar limitations. It could be ambiguous for a person to describe their anxiety on a numerical scale. Therefore, using two writing tasks, I explored pre-service teachers' relationships with mathematics through concepts and feelings they portrayed to gain a different perspective of preservice teachers' relationship with mathematics.

## Methodology

### Data Collection: Personification of Mathematics and Survey

Before we make an effort to change a pre-service teacher's beliefs about mathematics, we need to be able to assess their relationship with mathematics. In a study of pre-service teachers' beliefs, Zazkis (2015) utilized the method of eliciting personification when he had 36 pre-service teachers write a story about their relationship with mathematics. The data were analyzed with conceptual blending. Conceptual blending involves taking the elements of two mental spaces and blending them together to form a new space. Through conceptual blending, Zazkis made connections between the personal relationship space and the mathematics space to form relationship with mathematics space. For example, a student described math as a "terrible beast" which can be connected to one's level on enjoyment of mathematics. Then using conceptual blending, Zazkis identified that a "terrible beast" in the relationship space maps to their level of enjoyment in the mathematics space, which implies a fear of mathematics of that student possess in the combined space. Zazkis concluded that personification is not a replacement for the methodology of past studies but it offers a vivid window into study participants' relationships with mathematics.

In my study, using Zazkis' method of eliciting personification, I explored thirty-two pre-service elementary school teachers' relationships with mathematics and how these relationships could affect the way that they teach mathematics to their future students. Thirty-two pre-service elementary teachers completed a survey assessing their beliefs and attitudes regarding the learning and teaching of mathematics along with two creative writing tasks (see Table 1). The survey questions were modified from Mathematics Anxiety Rating Scale-abbreviated version (Alexander & Martray, 1989) and Mathematics Teaching Efficacy Belief Instrument (Enochs & Riggs, 2002).

*Table 1: Writing Tasks*

| Writing Task 1 Prompt (W1) | Writing Task 2 Prompt (W2) |
|---|---|
| Your assignment is to personify Math. Write a paragraph about who Math is. This paragraph should address things such as: How long have you known each other? What does he/she/it look like? What does he/she/it act like? How has your relationship with Math changed over time? These questions are intended to help you get started. They should not constrain that you choose to write about. | You are introducing Math for the first time to children. Describe who Math is as a character to children using following questions as guidelines. What kind of Personality does it/she/he has? What does Math look like? What does Math act like? How one can get along with Math? How one can get to know Math? How should one treat Math? These questions are intended to help you get started. These should not constrain that you choose to write about. |

Using conceptual blending, I formed connections between the pre-service teachers' relationships with mathematics to their portrayal of mathematics to their students. The results of this study display how teaching mathematics and relationships with mathematics are related without using a quantitative survey. I also compared my analysis of written assignments with the survey to find relationships between the two different data collection methods. I found a "vivid window" to investigate pre-service teachers' self-reflections on mathematics and their portrayal of mathematics for their future students so that they can be aware of the potential conflict.

**Data Analysis: Conceptual Blending**

Conceptual blending is a basic mental operation that leads to new meaning, global insight, and conceptual compressions useful for memory and manipulation of otherwise diffuse ranges of meaning. (Turner & Fauconnier, 2003, p.57). We can bring two things together mentally in various ways. For example, consider "land yacht" as a reference to a large, luxurious automobile. The word "land" and "yacht" come from different domains. But combination of two words from different domain provides a different but relatable meaning. Despite the fact that "yacht" is associated with water, it gives large luxurious meaning to the "land yacht". And the "land" implies that the vehicle moves on the ground which gives the meaning of automobile. Notice that blending two spaces enable us to relate land and yacht to what we already had an idea of, which is a large, luxurious automobile. In this paper, using conceptual blending, I attempted to connect the participants' written product and mathematical level to view their relationships with mathematics. Moreover, I assessed participants' relationships with mathematics and their portrayal of mathematics for children through conceptual blending.

## Results

The results are separated into three different categories describing how the writing tasks and survey relate to each other, and one case study of a participant in which we highlight the different contributions of the two data collection methods.

### Category 1: W1 and W2 Offered a Different View

A significant portion of students described mathematics differently between personification of mathematics and portrayal of mathematics. Most of the data in this category showed that pre-service teachers had a negative personal relationship with mathematics but portrayed mathematics positively to children.

Mary wrote on W1 that her relationship with mathematics is changing as she encounters math but when reflecting upon taking a statistics course in college she concludes “math betrayed me once again and made me feel inadequate.” Her expression of “betrayal” in the human relationship space is connected to level of enjoyment in mathematics space. By connecting human relationship space and mathematics space, Mary’s relationship with mathematics appeared to be negative. But despite her disappointing encounter with math, on her W2 she wrote “Things may not go your way when associating with Math, but it always has your best interest in mind”. Her portrayal of mathematics having “your best interest in mind” corresponds to level of importance of mathematics in mathematics space which leads to value of mathematics in Portrayal of mathematics space. This shows a hope that she wants children to have a positive experience with math, though she did not appear to have a positive experience with math.

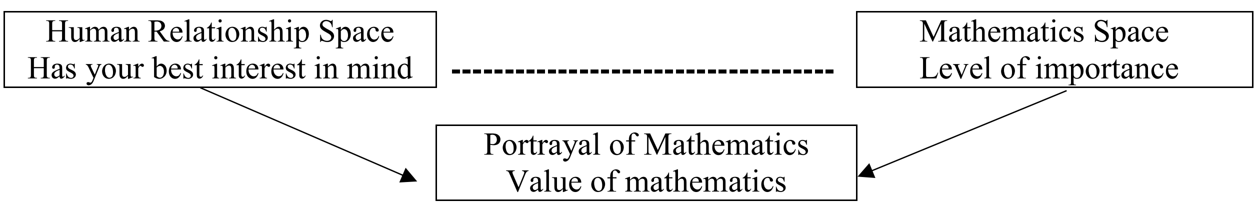

*Figure 1. “Best interest in mind” conceptual blending diagram.*

Jamie described math as a “scary monster that thrives on the tears of children” and extended her bad relationship with math by adding “I have never understood the purpose of forcing kids to take math classes throughout their entire school careers”. But on W2, she wrote “Math is a super chill dude. Do not be afraid to laugh with math and ask questions because math is always there. Math actually gets excited when you ask questions because that means you are learning.” Her W2 describes positive characters of math despite her bad relationship with math from W1.

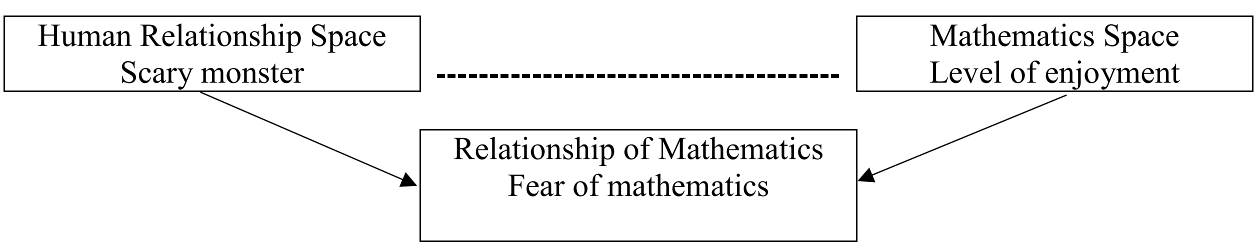

*Figure 2. “Scary monster” conceptual blending diagram.*

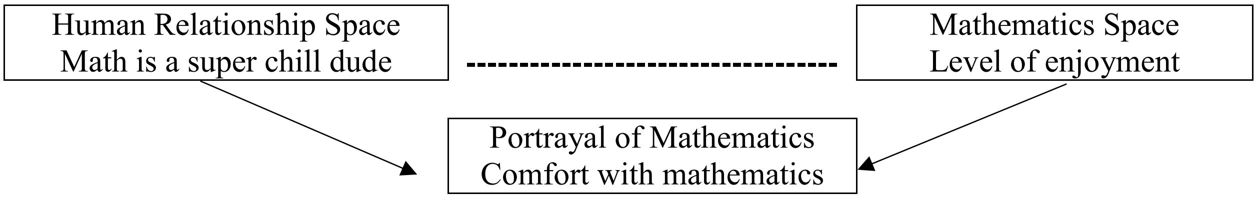

*Figure 3. "Super chill dude" conceptual blending diagram.*

A surprising finding here is that Jamie's personal level of enjoyment of mathematics appears to be completely opposite of her portrayal of mathematics to her students. Even more interestingly, she understood no benefits of kids learning math in W1, but on W2 she encourages kids to ask questions to math emphasizing learning.

**Category 2: W1, W2 and Survey Offered Similar Views**

It was common for participants to have similar views on mathematics on W1 and W2. It appeared that a student's experience with mathematics affects when she or he introduces mathematics to children in below examples.

Fiona described her challenging relationships with mathematics on W1 and added "I still try to make things better between us, because clearly this isn't at all my fault" then concluded by saying "I still have hope that I'll at least understand him one day, especially in the days that I have to introduce to him others" Then on W2, she portrayed mathematics with fearful caution for children. She wrote "listen closely, and if you still have questions, ask him! However don't speak negatively of him as that will affect your relationship with him." Fiona's experience with mathematics directly impacts her portrayal of mathematics. Then she concluded W2 by saying "My poor friend-such a bad reputation for such a useful skill" There writings align with her responses in the survey as she indicated that solving a problem that involves mathematical reasoning is a frustrating experience.

Jamie indicated on a survey response that "Learning mathematics requires a special talent." On W1 she wrote that having a good relationship with math is like having a "magic power." The description of "magic power" corresponds to complexity in the mathematics space which shows her relationship with mathematics was difficult due to her perception of mathematics being complex. She also agreed that "Solving a mathematics problem more than once is a waste of time" and "reasoning skills that are taught in mathematics course can be helpful to me if I were to major in math or a related field" on the survey.

**Category 3: W1 and W2 Offered Something Different From Survey**

There were a few examples of when two writing tasks differed from the survey responses. Bailey indicated that "a teacher's own feelings about mathematics are independent of a teacher's teaching practice" on the survey, but her writing tasks showed that her personal beliefs did affect her portrayal of mathematics to students. On her W1, she wrote "math is picky and I wish that he and I could get along better, math is too confusing for me to be around for long periods of time, so I can only handle him in small doses". On her W2 she wrote "as you both grow up, it will be harder to build a strong relationship with him (math)." She also portrayed math as more of a self-centered character by saying "He loves to talk about himself, and likes to joke with you and often tries to trick you" Which shows Bailey's challenging relationship with mathematics impacting on her portrait of math to children.

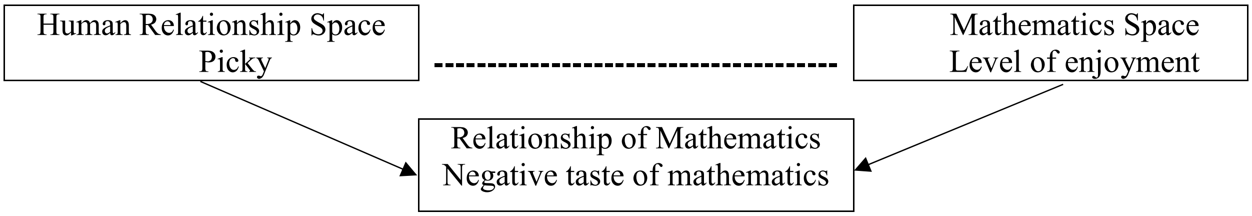

*Figure 4. "Picky" conceptual blending diagram.*

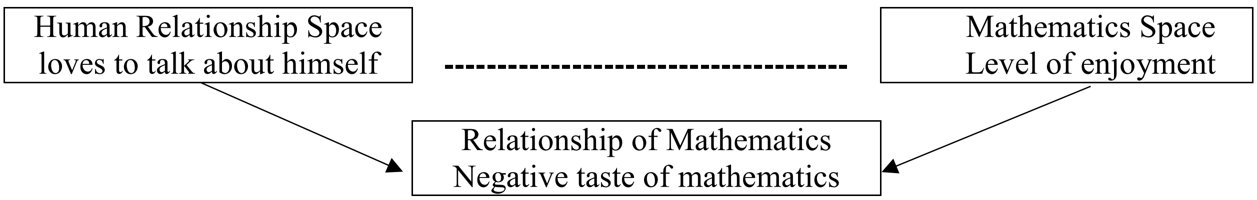

*Figure 5. "Self-Centered" conceptual blending diagram.*

Gabby also indicated that "a teacher's own feelings about mathematics are independent of a teacher's teaching practice" on her survey. But on her W1 she expressed that she and math did not get along. On W2, her introduction of math to children was a warning in which she said "you may get tired of seeing math everyday but make the most of it" and "Math does get harder as time goes on and the friendship will get more complicated."

Jamie indicated that that "a teacher's own feelings about mathematics are related to how well a teacher can teach mathematics to students." But her negative experiences with mathematics on W1 did not seem to affect her portrayal of mathematics on W2 which was more optimistic and positive. It appeared that Jamie's personification of mathematics on W1 seemed completely different from her portrayal of mathematics on W2 as we saw in Figures 2 and 3.

**The Case of Emily**

Zazkis (2015) claimed that the method of eliciting personification of mathematics through writing cannot replace survey methods, but can offer a different viewpoint. Here we will discuss the case of Emily, in which we can clearly see that the survey and writing tasks assessed different aspects of her beliefs.

Emily indicated on the survey that "solving a problem that involves mathematical reasoning is an enjoyable experience". Several of her survey responses indicated that she has positive views about mathematics. Then she personified mathematics using four different descriptions:

> Math has the "bad boy" look – tattoos that you don't understand, chains with missing links, and he always has an answer for everything. He's kind of a dork with his dark rimmed glasses and a shaggy hair cut. Math is as wide as he is tall, and you would think he was a linebacker for the school football team. He looks mean, but she's really a big teddy bear.

These personifications shows the changes in her relationship with mathematics over time. She indicated that at first mathematics appears mysterious and intimidating, but after learning more about mathematics that view changed. The diagram for these character traits are shown in Figures 6 and 7. Elsewhere in her writing she clearly stated that "Math used to scare me and I dreaded the time of day when I had to spend an hour with him, After years of dreading him, I finally knew it was time to get to know the real him, once I did, I really found my time with him to be fun and interesting."

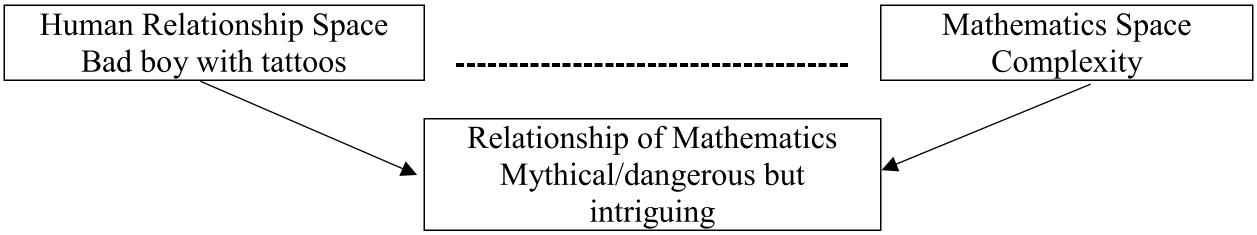

*Figure 6. "Bad boy" conceptual blending diagram.*

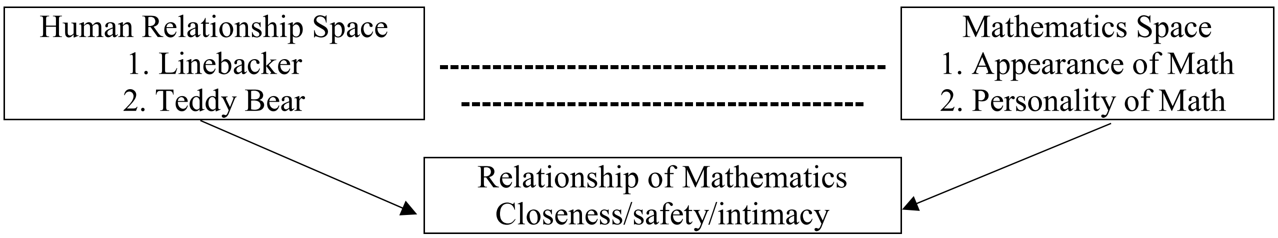

*Figure 7. "Teddy bear" conceptual blending diagram.*

Understanding Emily's struggle in the past with mathematics helps us analyze what she wrote on W2; "He thinks it's funny but does not realize he's scary. You might see one of Math's problems and it might look very scary because you don't understand it! But don't worry!" She expressed caution to children based on her experience. It also appears that her overcoming struggles with mathematics on W1 contributed to her positive attitude towards mathematics in W2; "He wants you to understand all of his different identities and for you to enjoy spending time with him!" This could explain why her portrayal of mathematics for her future children was different in W2 because of her current positive views of mathematics. She portrayed mathematics by saying "Math is like a superhero too! He can do almost ANYTHING!"

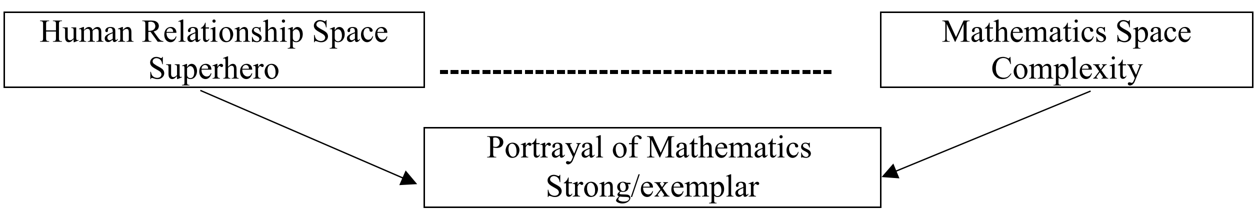

*Figure 8: "Superhero" conceptual blending diagram*

As shown above, W1 and W2 offered more than the survey item since it showed Emily's past relationship with mathematics and how that changed over time. Survey questions are often not designed to capture this type of change in a person's relationship with mathematics, but only how a person currently feels about mathematics.

There were also aspects of her relationship with mathematics that appeared on the survey but were not captured in her written assignment. On the survey, she indicated that "learning mathematics requires special talent" and "For me, doing well in mathematics course depends on how well the teacher explain things in class." These two ideas were not presented in her writings. This result provides more evidence that the two writing tasks do not provide the same information as the survey when measuring beliefs and attitudes towards mathematics.

**Notable Trends**

Thirty-two percent of participants agreed that “teacher’s own feeling about mathematics is independent of a teacher’s practice.” However, among that 32%, some participants’ two writing tasks were not completely independent. It appeared that their own experience with mathematics affect how they portray mathematics for children.

Thirty-four percent of participants agreed that “Reasoning skills that are taught in mathematics courses can be helpful to me if I were to major in mathematics or a related field” contrary to “in my everyday life” Despite this response rate, almost all of the participants wrote something on W2 emphasizing how children should get along with mathematics because it is good for them. But it is notable to point out that significant number students did not write anything on W1 regarding usefulness of mathematics. W1 mostly described their relationship with mathematics respect to their performance or understanding of mathematics.

If W1 showed positive relationship with mathematics, W2 also showed positive attitudes towards mathematics when introducing to children. For example, Emily wrote “I really found my time with math to be fun and interesting!” and then introduced math by saying “I would like to introduce to you my favorite, dear, friend, Math!” then she explained how math can do anything and how a great guy he is.

Most of the participants expressed importance of mathematics in W1 and W2 regardless of their past experience with mathematics. Many of the participants wrote something close to “you should try to get along with him because it is good for you,” which shows that they value mathematics. Although many of participants mentioned why mathematics is important, some of them did not specify the reason why children should get along with mathematics.

## Discussion and Further Research

Zazkis (2015) concluded in his paper that the tool of personifying mathematics in writing offers another perspective of pre-service teachers’ relationship with mathematics than previous data collection methods. This study has given evidence that the two writing tasks did offer a different perspective than the survey. Although some of the participants showed similar views on all three tasks, other participants showed a different and more detailed attitude towards mathematics and portraying mathematics in the two writing tasks. In particular, the case of Emily showed that the writing tasks can capture the changes in a pre-service teacher’s relationship with mathematics over time, whereas many of the existing mathematics attitude surveys designed to measure a person’s current beliefs about mathematics. On the other hand, because of the open-ended nature of the writing tasks, there may be survey items that would address particular aspects of a person’s beliefs about mathematics that they might not think to include in their writing.

Another contribution of this study is the comparison between the writing task in which they described their own relationship with mathematics (W1) and the writing task in which they introduced mathematics to their students (W2). The most common difference that we found was that the teachers would have a more positive attitude about mathematics when presenting it to children, although we did see that their prior experiences affected the way that they would talk about mathematics to their future students.

Further investigation on factors that cause pre-services teacher’s beliefs and attitudes toward mathematics is necessary to improve their views about mathematics that could impact their teaching practice. Although many of the participants express the value of mathematics on W2, it was unclear in many cases if the valuing mathematics was because they wanted to prevent frustration for students struggling with mathematics or because they believed in the benefits of mathematics as a discipline.

# Supporting Prospective Teachers' Understanding of Triangle Congruence Criteria

Steven Boyce
Portland State University

Priya V. Prasad
University of Texas, San Antonio

*We report on the results of pre-post written assessments of our college geometry students' justifying SAS to a hypothetical 10th grade student. We hypothesized that investigating transformations in the taxicab metric would perturb students' understandings of the relationships between triangle congruence criteria and isometries, so they would more explicitly identify the properties of transformations as a necessary part of their justifications of triangle congruence criteria. We describe how the ways our geometry students' responses on the pre/post assessments did not reveal the understandings we anticipated. We discuss conjectures of ways of introducing transformations and sojourning to taxicab geometry that might be more productive.*

*Keywords:* Geometry, Congruence, Mathematical Knowledge for Teaching

## Introduction

Research has demonstrated that supporting college geometry students' understandings of transformational geometry remains a challenge (e.g., Hegg & Fukawa-Connelly, 2017). Because many of our college geometry students are prospective secondary teachers, supporting their mathematical knowledge for teaching secondary geometry is an important course goal. The United States' Common Core State Standards for Mathematics [CCSS-M] state that high school geometry students should be able to justify triangle congruence criteria (angle-side-angle, side-angle-side, side-side-side) as a consequence of properties of rigid motions (NGACBP/CCSSO, 2010). Hegg and Fukawa-Connelly (2017) found that college geometry students struggle with explicitly using relevant properties of transformations in such justifications, and they suggest that "asking for the kinds of explanations of ideas that [college geometry students] would give [secondary geometry] students has value in both giving researchers insight into their understanding of the content and giving policy-makers a better understanding of what additional supports will be needed going forward" (p. 8). This paper presents a study that investigated an instructional intervention aimed at perturbing preservice secondary teachers' understandings of congruence in order to better support their understanding of transformational proofs for the triangle congruence criteria. The assessment we used followed the suggestion by Hegg and Fukawa-Connelly by situating a question about justifying the side-angle-side triangle congruence criteria in a classroom scenario.

## Theoretical Background

### Transformations and Intellectual Need

The CCSS-M advocate for a definition of congruence that is based on the rigid motions of the plane (i.e. isometries in Euclidean geometry) (NGACBP/CCSSO, 2010). The standards then call for the development of congruence criteria for triangles to follow from this definition of congruence. According to the CCSS-M, a *transformations-first* approach would develop ideas of geometric congruence in the following ways:

1. Use geometric descriptions of rigid motions to transform figures and to predict the effect of a given rigid motion on a given figure; given two figures, use the definition of congruence in terms of rigid motions to decide if they are congruent.

2. Use the definition of congruence in terms of rigid motions to show that two triangles are congruent if and only if corresponding pairs of sides and corresponding pairs of angles are congruent.
3. Explain how the criteria for triangle congruence (ASA, SAS, and SSS) follow from the definition of congruence in terms of rigid motions. (NGACBP/CCSSO, 2010)

While there is some historical precedent to this pedagogical approach (Sinha, 1986), this approach has been little researched in the mathematics education literature (Jones & Tzekaki, 2016). It should be noted that this is a slight departure from the development of geometry as presented in Euclid's *Elements*, since Euclid himself did not have the tools to define rigid motions, but defining congruence as a result of rigid motions is roughly mathematically equivalent to Euclid's approach of defining congruence through superposition in Euclidean geometry (Sinha, 1986). Moreover, most students experience an approach to Euclidean geometry in high school that relies on the (mathematically flawed) axiomatic system developed by Euclid himself in the Elements, with the possible addition of the SAS criterion for triangle congruence to his original five axioms (Portnoy, Grundmeier, & Graham, 2006). However, as Portnoy and colleagues found, students struggle to construct proofs using geometric transformations. Specifically, students often focus less on the properties of rigid motions and instead view them as actions that they can perform with geometric objects. Students also often view the result of a transformation as the resulting image of the geometric figure, instead of the result of transforming the entire plane (Hollebrands, 2003). Nevertheless, a transformations-first approach to geometry can provide accessibility for students to reason about their own actions (Simon, 1996). Moreover, connections between synthetic (Euclidean) and analytic (transformational) geometry can help students eventually reason about calculus (Hollebrands, 2003).

We identified the CCSS-M approach to introducing triangle congruence criteria due to properties of rigid motions as potentially problematic for our students. We had encountered SAS as a postulate in our own high school teaching and learning experiences. Anticipating that our students' encounters with SAS would likely also be as a postulate, we were concerned about motivating a justification for congruence criteria based on properties of transformations. After all, if two triangles in the plane are congruent, there is a rigid motion that maps one to the other that preserves *all* corresponding side lengths and angle measures. How might we motivate them to consider a justification for congruence *criteria* based on *properties* of a *composition* of isometries?

Harel (2014) emphasizes this problem for secondary students learning geometry in his discussion of the CCSS-M's transformations-first approach:

> In the [CCSS-M's] approach the transition from middle school geometry to high school geometry is to be carried out through the rigid motions of translation, reflection, and rotation and the motion of dilation. In middle school geometry, these motions are delivered informally, and in high school they are defined as functions on the plane. In both levels, the motions are merely described, not intellectually necessitated through problems the students understand and appreciate… (p. 26).

Harel discusses the lack of *intellectual need* for using transformations as a method of justification for K-12 students. Harel informally defines intellectual need as follows:

> When people encounter a situation that is incompatible with or presents a problem that is unsolvable by their existing knowledge, they are likely to search for a resolution or a solution and construct, as a result, new knowledge. Such knowledge is meaningful to

them because it is a product of their personal need and connects to their prior experience. (p. 23.)

Keeping in mind that the prospective teachers in our courses were likely not exposed to this approach in school, we investigated tasks and approaches that might provide this intellectual need.

**Taxicab Geometry**

Taxicab geometry is an excellent non-Euclidean geometry to introduce as students' first experience outside of Euclidean geometry. It has an axiomatic structure that is close to Euclidean geometry (Krause, 1986), it has real-world applications, and it is close enough to Euclidean geometry to allow for students' to retain and apply some intuitive and embodied understandings from Euclidean geometry. Taxicab geometry develops from changing the metric for measuring distance between two points $(x_1, y_1)$ and $(x_2, y_2)$ on the Cartesian coordinate plane from the traditional Euclidean metric, $d_E = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$, to the taxicab metric, $d_T = |x_1 - x_2| + |y_1 - y_2|$. An important consequence of changing the metric in this way is that not every "rigid motion" in taxicab geometry is also a taxicab *isometry* (that is, not every rigid transformation in taxicab geometry preserves distance). Moreover, two segments of the same length under the taxicab metric may not be congruent, if there does not exist an isometry that maps one to the other (see Figure 1).

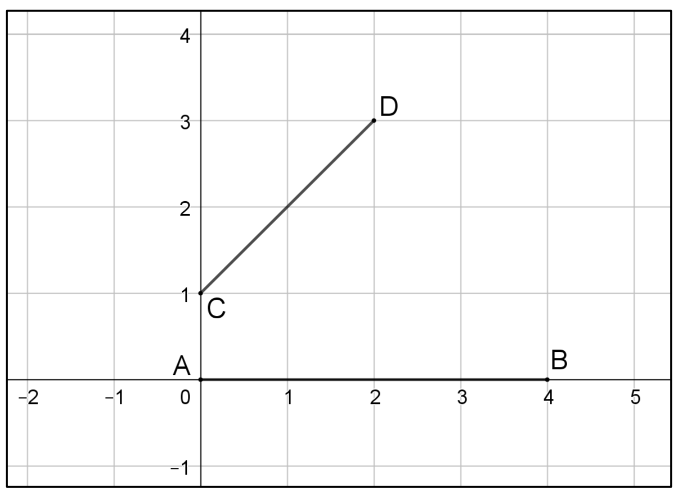

*Figure 1. In the taxicab metric, AB and CD have the same length, but there is no isometry mapping AB to CD.*

One important aspect of taxicab geometry to note is that in an internally consistent treatment of taxicab geometry, taxicab angles do not necessarily have the same measure as Euclidean angles. Thompson and Dray (2000) describe how taxicab angles may be defined in relation to Euclidean angles to support taxicab trigonometry. However, a right angle in taxicab geometry is the same as a right angle in Euclidean geometry. By focusing on transformations of right triangles, discussion of taxicab geometry does not need to include this added complication.

Thus, working in taxicab geometry provides a rich context for problematizing students' association of congruence with equal measure in a way that working in Euclidean geometry cannot. Since it is a theorem of geometry under the Euclidean metric for distance that two segments have the same measure if and only if they are congruent, students can assume that having the same measure implies congruence without referring to a definition of congruence which relies on isometries. However, this conflation of equal measures and congruence may lead a student to assume that Figure 2 shows a counterexample to the SAS triangle congruence criterion in taxicab geometry (lengths are labeled based on the taxicab metric). In fact, there is no taxicab isometry that will take one of the legs of one of the right triangles to either of the legs of the other right triangle, so there are no corresponding sides of these triangles that are congruent. Hence, the SAS triangle congruence criterion does not apply, although students who continue to associate congruence with equal measure will think it does.

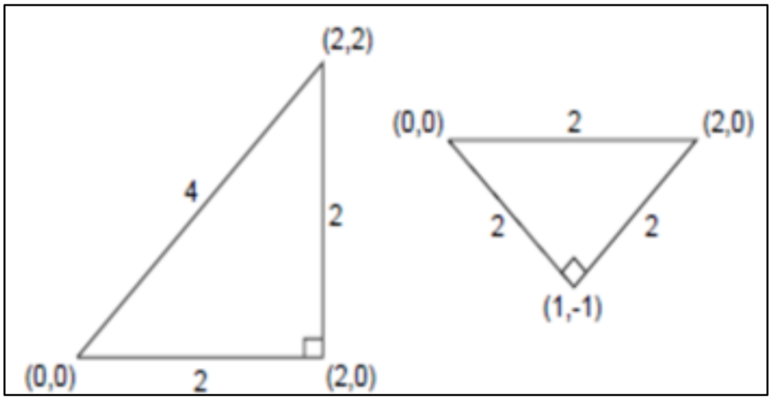

*Figure 2. In the taxicab metric, these pair of triangles appear to violate the SAS criterion*

In this way, taxicab geometry provides a context in which students can establish an intellectual need (Harel, 2013) to separate their notions of congruence and measurement, and therefore appeal to other notions (such as transformations) to find justifications for the triangle congruence criteria.

## Research Question

We theorized that we could provide an intellectual need for our students to reconsider their understanding of congruence by prompting them to explore the possible ways in which a rigid motion may not preserve distance. After such an experience, in our thinking, students would understand congruence (and therefore triangle congruence criteria) in Euclidean geometry as depending on the *properties* of the transformations and thus be better-prepared to support future secondary students' in constructing that way of thinking about triangle congruence. Thus, our goal was not to teach them a technique or procedure; rather our goal was for them to realize that their preconceptions of triangle congruence criteria would not always hold if one figure was the image of another under a transformation that was not an isometry. We viewed this as foundational for motivating a disposition to teach their students to justify triangle congruence criteria as a result of properties of isometries. However, since all rigid motions are isometries in Euclidean geometry, we created an instructional intervention using taxicab geometry to serve as this perturbation. We anticipated that while students would begin to understand congruence as properties of compositions of translations, rotations, and reflections, they would not attend to the importance of these rigid motions preserving distance (that is, that they are isometries). By moving to the context of taxicab geometry wherein not all rigid motions preserve distance, they must attend more closely to the analytic concepts of distance preservation, they cannot just rely on their intuitive notions of superposition.

## Methods

### Study Setting

We were motivated to collaborate in designing instruction as we were each preparing to teach a Spring 2017 course that would satisfy the geometry content knowledge requirement for teaching licensure programs at our institutions. Prasad taught Fundamentals of Geometry, a junior-level course required for prospective middle and high school teachers with 41 students. Boyce taught College Geometry, a junior-level course required for prospective high school mathematics teachers with 29 students. Both courses also served as math electives for other math majors. Boyce's course was four credits, taught in the ten week quarter system, whereas Prasad's course was three semester credits. Thus, Boyce's course began when Prasad's course was approximately halfway complete. Neither of the courses included a "transition to proof" course as a prerequisite. The topics of both courses included Euclidean and transformational geometry, as well as non-Euclidean (hyperbolic and taxicab geometry).

### Instructional Sequence

Our approach was to first introduce SAS as a postulate in Euclidean geometry. Because this was likely to be PTs own experience with SAS prior to the course, and the perspective of a majority of colleagues, parents, and even curricula likely to be encountered in their teaching, we felt it was important for them to first understand the meaning and application of the SAS congruence criterion. At the beginning of our courses, students completed Euclidean proofs about properties of isosceles triangles and quadrilaterals by relying on triangle congruence criteria. We later introduced plane transformational geometry, emphasizing the definition of an isometry as a distance-preserving automorphism (of the Euclidean plane) rather than a mapping from one domain to a distinct domain. In both courses students explored fixed point and orientation properties, the results of composing isometries, and analytic formulas for particular plane isometries using Cartesian coordinates. See sample tasks in Figure 3.

- Let line $m$ be the positive x-axis and let the line $k$ be the line $y = x$. If $R_{C,\alpha} = r_k \circ r_m$ is the rotation resulting from reflection across the line $m$ followed by reflection across the line $k$, then find the center $C$ and angle α of this rotation.
- How could you describe a translation as a composition of two reflections? Provide an example to illustrate your reasoning.
- How could you describe a translation as a composition of two rotations? Provide an example to illustrate your reasoning.
- Recall that we left congruence as an undefined term. In Common Core Geometry, two geometric objects are defined to be congruent if there is an isometry that maps one figure to the other. How might you prove two triangles are congruent using isometries? Create an example.
- Let *S* be the square with vertices (-1,1), (1, 1), (1, -1), (-1, -1). Identify the 8 isometries that leave S invariant (the *symmetries* of the square).

*Figure 3.Sample tasks in transformational geometry*

At this point in our courses we administered a written task prompting our college geometry students to justify SAS to a hypothetical 10th grade student (see Figure 4). Our aim was to assess how and whether students would evoke reasoning about isometries in their explanations. Students in Boyce's course were assigned the task as a homework assignment, for which they were accustomed to working in groups but submitting an individual write-up, whereas Prasad's students were instructed to complete the prompt individually.

> You are teaching your tenth-grade class about the SAS Congruence and after the lesson, a student comes up to you to tell you that he is still struggling with understanding why it works. *Even though you may be treating it in class as a postulate (thereby just assuming that it is true), how could you help your student better justify SAS Congruence?*

*Figure 4.Task prompt for eliciting reasoning about transformations*

We then embarked upon a week-long introduction to taxicab geometry. After introducing the taxicab metric, students explored relationships between Euclidean and taxicab geometry. As part of their explorations, students were tasked with determining whether triangles congruent in Euclidean geometry would be congruent in taxicab, and vice versa. As part of this process, students explored which Euclidean transformations would preserve taxicab distance and thus be taxicab isometries.

- Identify all taxicab isometries
- How can we define congruence in taxicab geometry?
- Come up with examples of each, or explain why such an example is not possible:
    - 2 triangles that are congruent in both Euclidean geometry and Taxicab geometry
    - 2 triangles that are congruent in Euclidean geometry but not in Taxicab geometry
    - 2 triangles that are congruent in Taxicab geometry but not in Euclidean geometry

*Figure 5.Sample tasks in taxicab geometry*

**Data Sources and Coding**

Following the week-long unit on taxicab geometry, we administered a follow-up prompt, again tasking students with explaining how they might help a 10th grade student justify the SAS criteria. In both classes, the length of time between the pre-assessment and post-assessment was between two and three weeks. However, because of the staggered implementation of assessments and the course sequences, Boyce administered the post-assessment to his class weeks after Prasad had finished this project with her class. Since both authors had analyzed the post-assessment responses from Prasad's class by then, Boyce decided to slightly modify the post-assessment prompt (this is discussed further in the Results section). On the post-assessment, both groups of students completed the assignment individually. The sequence of data collection and analysis is displayed in Figure 6.

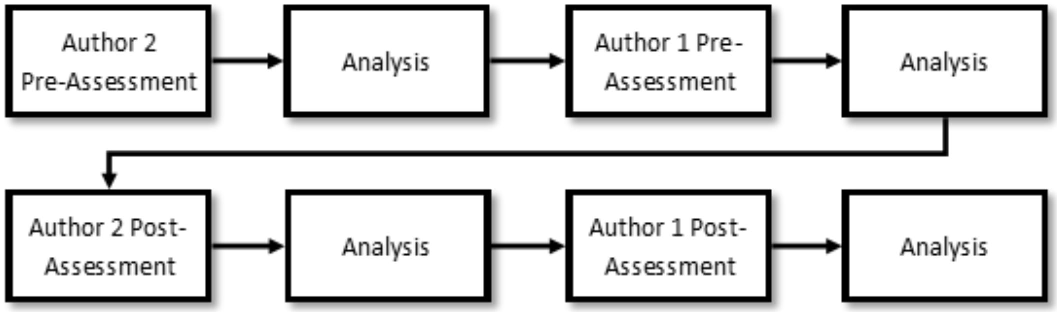

*Figure 6. Sequence of data analysis*

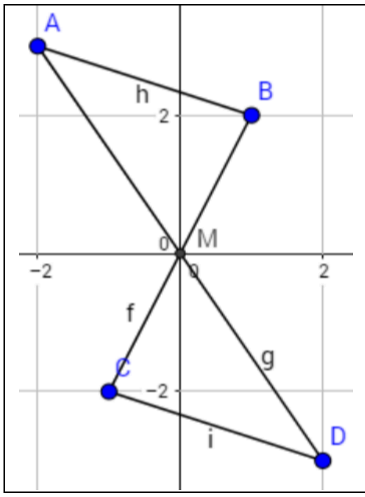
Prasad's course started approximately 8 weeks before Boyce's, thus her students completed the written assessments first. We coded the responses to this first set of assessments independently, using the constant comparison method (Glaser, 1965), before Boyce's class completed the same prompt for the pre-assessment. We selected 10 of the 34 responses to code independently, and we then met to discuss commonalities in our codes and developed a shared set of codes and meanings. After some additional codes were added after coding the remaining assessments (as well as Boyce's pre-assessments) there were eighteen different codes.

For example, one student responded on the pretest,

*I would grab two sticks and hold them together at a single angle and ask students if there was any way to make two triangles out of it. If need be I would grab two more of the same length and show that there is still only one triangle that can be formed. If I can't find sticks I can draw it out.*

This student's response was coded as having an *instructor orientation*. This code meant that the prospective teacher (PT) focused upon hypothetical interactions with a student in their response. The PT *understood the premise and conclusion of SAS*, but their *justification was missing* – the PT seemed to infer that the hypothetical student in the prompt would be convinced by lack of counterexamples. Their response was also coded as referring to *construction*, since the PT modeled one way of constructing a figure to address the prompt.

Other students' responses indicated understanding of the meaning of the SAS congruence criterion, and attempted to justify SAS by referring to other Euclidean theorems or axioms, such as the SSS criterion. The response depicted in Figure 7 was coded this way as well, as the student referred to vertical angles and the alternate interior angles theorem. This student *created a specific example* to discuss and *provided a figure* to reference. This student did not have an instructor orientation and did not describe a construction.



Let $M$ be the midpoint of $\overline{AD}$ and $\overline{BC}$. Then $\overline{AM} \cong \overline{DM}$ and $\overline{BM} \cong \overline{CM}$. Then, by the vertical angle theorem, $\angle AMB \cong \angle DMC$. By SAS, $\Delta ABM \cong \Delta DCM$. Since corresponding parts of congruent triangles are congruent, $\overline{AB} \parallel \overline{CD}$ and $\overline{AB} \cong \overline{CD}$, and by the alternate interior angles theorem, $\angle BAM \cong \angle CDM$ and $\angle ABM \cong \angle DCM$.

*Figure 7. Student response on pre-assessment showing justification of SAS using other Euclidean theorems*

After we had completed coding Boyce's pre-assessments, we collapsed some of the initial eighteen codes, using axial coding (Charmaz, 2006). For instance, we originally had separate codes for whether students responses demonstrated understanding the premise of SAS, whether students demonstrated understanding the conclusion of SAS, whether students' attempted to justify SAS, and whether students attempted to justify something. After axial coding, we created a new code, whether students' understood the premises and conclusions of SAS.

**Coding schemes**

We focused on the following aspects: (a) whether students focused their responses on hypothetical interactions with a 10th grade student, (b) students' understanding of the premises and conclusions of SAS, (c) students' describing a construction to justify SAS, (d) students' use of other Euclidean axioms or theorems to justify SAS, such as SSS, and (e) students' use of transformations to justify SAS.

Prasad's class took the post-assessment next. As discussed in the Results section, we modified the task prompt before Boyce's class completed the post-assessment (see Figure 10). We coded the results on each of our post-assessments using the codes (a) - (e) listed above, marking in a spreadsheet whether or not they were exhibited with 1s or 0s. We then reconciled our codes so that each student had single indicator of '1' or '0' for each of the five codes.

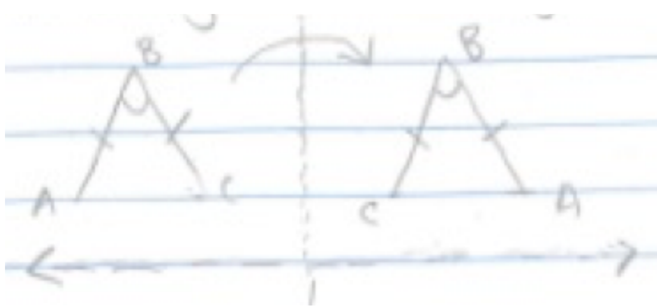
Following the administration of the post-assessments, we returned to the data to focus more closely on how students were using transformations in their justifications. For this purpose, we developed the following rubric:

(1) substantive, valid, and precise justification
(2) substantive, mostly valid, missing some precision
(3) correct, but imprecise and lack of attention to SAS
(4) describes transformations, but informal and not specific
(5) scant or incorrect use of isometries
(6) no mention of isometries

We independently rated each of the responses across all four assessments using this rubric to understand whether students' experiences with taxicab geometry influenced not only the frequency, but the qualities, of their justifications for SAS involving transformations. We coded "use of transformations" quite broadly, to include situations in which a transformation was described informally (e.g., a description of "moving" triangles akin to Euclid's superposition principle) as well as situations in which the name for a transformation (e.g., translation) was used, however inappropriately or without details.

**Coding examples**

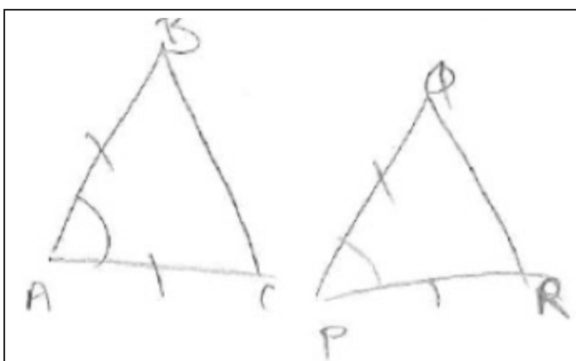
Figures 8-10 exemplify our coding of students' use of transformations in their justifications. In Figure 8, the student describes a reflection as preserving distances and angles, but the justification of SAS is about the (in)ability to manipulate sides or angles rather than relying on properties of reflections. The student also labels corresponding sides and points imprecisely. This response was coded as justifying SAS using transformations, but informally and not specifically.



*"If I reflect the vertices A, B, and C over the y-axis, I preserve the distance between the points and the shape of the figure.* By preserving the distance between the points we get that all the sides and angles are congruent. If I preserve two sides and an angle between them, there is no way for me to manipulate the last side or the other two angles without changing the entire triangle."

*Figure 8. Pre-assessment response coded as (4), describes transformations, but informal and not specific*

The response in Figure 9 exemplifies an instructor orientation, as the focus of the response includes choice of manipulatives and explicit attention to students' thinking. In contrast to the response in Figure x, the student describes a particular example for which a translation maps, not one triangle to another, but the pairs of sides and their included angle to corresponding pairs of sides and an included angle. Although the response was imprecise, it shows attention to the premise of SAS and was thus coded as (2).

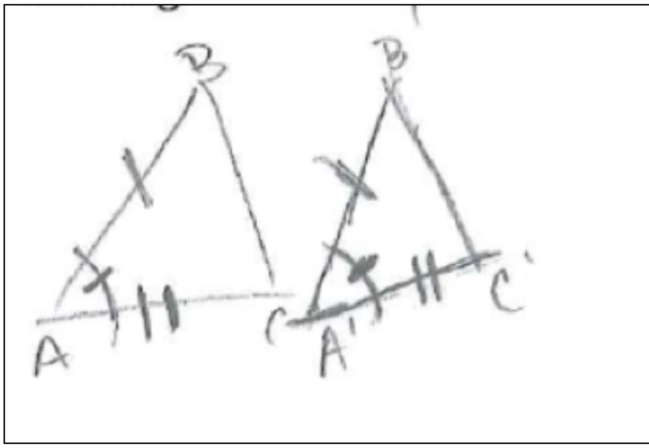


I could do a similar example like we just did in class. We could draw a triangle on a transparency and *notice if we do a translation then the two sides and angle we are claiming to be congruent will line up.* This could help them see that the two triangles are congruent given that two sides and the angle they share are congruent.

*Figure 9. Pre-assessment response coded as (2), substantive, mostly valid, missing some precision*

The response depicted in Figure 10 is in some ways more precise than that of Figure 9 – the student chose a more generic, scalene triangle as an example and described the premises of the

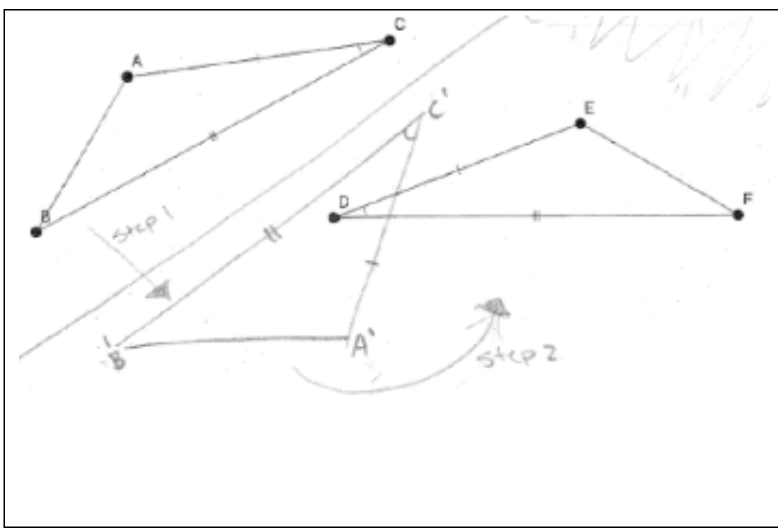
SAS postulate. However, as was also exhibited in the response in Figure 8, the student's description of the transformation involves mapping one triangle to another triangle. There is no justification for why the isometry that maps AB to A'B', AC to A'C', and ∠BAC to B′A′C would necessarily map the remaining sides and angles of $\Delta ABC$ to the corresponding sides and angles of $\Delta A'B'C'$.



Well if we assume/use SAS Congruence as a postulate, we would know that AB≅A′ B′, AC≅A′C′, and ∠BAC≅∠B′A′C′. We could show that *if we translate triangle* $\Delta ABC$ *onto* $\Delta A'B'C'$ *that the sides and angles in fact are all congruent to their counterpart.* Thus proving that SAS holds true.

*Figure 10. Post-assessment response coded as (3), correct, but imprecise and lack of attention to SAS*

The response depicted in Figure 11 does not indicate an instructor orientation. The student first states that isometries preserve angles and side lengths, and then proceeds to describe a sequence of three isometries that map one triangle to another. There are several aspects of precision missing. For one, the conclusion should be that $\Delta ABC$ is mapped to $\Delta EFD$, rather than $\Delta EDF$. More substantively, the student does not provide justification for the existence and uniqueness of parallel lines that underlie their approach, and their description of isometries refers to a sequence of transformations of triangles, rather than transformations of the entire plane.



I would explain SAS by using isometries since isometries preserve distance in Euclidean geometry. The angles and side lengths will stay the same. *First I would reflect* $\Delta ABC$ *over a line parallel to BC.* Now I have ΔA′B′C′. *If I take* $\Delta A'B'C'$ *and rotate it till C′B′ is parallel to DF and then translate it so all the points overlap with* $\Delta EDF$, then I can show the triangles are congruent.

*Figure 11. Post-assessment response coded as (2), substantive, mostly valid, missing some precision*

### Analysis of Coding Across Pre/Post Assessments

After completing the coding of the results, we examined the corpus of data to look for common patterns and themes across pre/post assessments within each class or within pre/post assessments across classes. In particular, we tested whether there was an increase in students' substantive use of transformations in justifying SAS across pre/post assessments. For example, consider that the response depicted in Figure 7 includes an example for which the properties of rotation centered at *M* could justify the congruence criteria. Might we find more instances of substantive justifications using transformation criteria in the post-assessment, following the introduction of taxicab geometry?

## Results

### Pre-assessment Results

On the pre-assessment, the majority of our students focused on how they would interact with hypothetical secondary students in their responses. They described details such as the particular triangular examples or manipulatives they might introduce (e.g., Figure 7). When students included justifications, they were as apt to focus on constructions, or on justifications of SAS using SSS, as they were to describe transformations (see Table 1). This was the case across both of our courses. Students in Prasad's class were more likely to respond with a focus on interacting with a hypothetical student to the extent that they did not provide a justification for SAS (23/34 students versus 6/18 students). However, some of the students in Boyce's class provided multiple ways they might respond to the prompt, reflecting that they had discussed the task with classmates prior to writing up their responses.

*Table 1. General coding results*

| General Results Across Pre/Post Assessments | | | | |
|---|---|---|---|---|
| Codes | Prasad (pre) N=34 | Prasad (post) N=34 | Boyce (pre) N=18 | Boyce (post) N=25 |
| Instructor orientation | 17 | 20 | 12 | 3 |
| Did not justify SAS | 23 | 22 | 6 | 2 |
| Described a construction | 4 | 4 | 5 | 7 |
| Used other Euclidean axioms/theorems | 5 | 6 | 2 | 4 |
| Use of transformations | 3 | 7 | 6 | 16 |

*Note:* There were three students in Prasad's class that completed only the pre-assessment, three students in Prasad's class that completed only the post-assessment, one student in Boyce's class that completed only the pre-assessment, and eight students in Boyce's class that completed only the post-assessment.

### Post-assessment Results

After Prasad administered the post-assessment in her class and examined the results, she noticed that although there was an increase in the number of students mentioning transformations in their responses, it seemed the majority of students responded in a similar manner on the pre-assessment as the post-assessment. There were still many students who did not provide a justification of SAS as part of their response to the prompt, and the majority of students maintained an instructor orientation.

One of the issues with eliciting a response including transformational reasoning was that the examples that students chose to include often involved cases for which a single translation, rotation, or reflection would map one triangle to another, or an example involving isosceles triangles (e.g., Figure 10). We modified the task prompt for Boyce's post-assessment to include more explicit directions that the prospective teacher was to provide a justification by referring to particular diagram that involved mapping an (ostensibly) scalene triangle to an image that would require consideration of a *composition* of translations, reflections, or rotations (see Figure 12).

Boyce's students were not able to collaborate on the post-assessment, as they had on the pre-assessment, as the task appeared on their final exam. Only 3/25 students adopted an instructor orientation, suggesting that the revised prompt suggested that they focus more on describing a justification for SAS rather than describing how they would help a hypothetical student. That 23/25 of the students provided a justification for SAS also suggests that revisiting triangle congruence criteria in the context of taxicab geometry may have supported their understanding of the premises and conclusions of SAS. The majority of students in Prasad's class (16/25) used transformations to provide a justification on the post-assessment, suggesting that students may have been more apt to consider transformational reasoning as well. However, as we discuss in the next section, many of the justifications using transformations were lacking substance and precision.

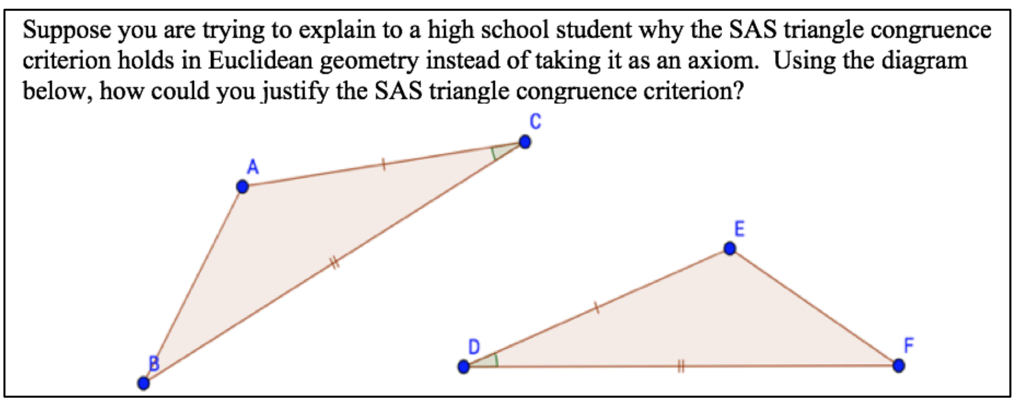


*Figure 12. Revised task prompt for eliciting reasoning about transformations*

**Use of Transformations**

When we revisited the data to rate the use of transformations in our students' justifications, we conceived of several aspects we valued: substance, precision, and validity. When we compared our independent ratings of the 32 responses that had been coded by either of us as having something to do with transformations, we considered the robustness and granularity of our rating scheme. After calculating inter-rater agreement ($\kappa = 0.6118$, using linear weighting), we found our rating scheme to be on the borderline of moderately/substantially useful (Landis & Koch, 1977). By collapsing codes to (1-2), (3-4-5), and (6), we found agreement in all but 4 of 32 cases. After reconciling these 4 cases, we considered the results across the pre/post assessments.

The results depicted in Table 2 show greater substantive use of transformations in PTs' justifications in response to the revised task prompt. On the pre-assessment, only 1 of the 6 responses mentioning transformations in Boyce's class had been rated as '1' or '2', whereas on the post-assessment 8/16 of responses had such ratings. Still, only about a third of the responses to the revised task prompt included substantive justifications of the SAS using properties of transformations (8/25). Although there were also more PTs in Prasad's class that mentioned transformations on the post-assessment than the pre-assessment, their justifications in response to the original prompt tended to be less precise and more informal—none of the responses were rated as '1' or '2'.

*Table 2. Transformation coding results*

| Transformational Reasoning Across Pre/Post | | | | |
|---|---|---|---|---|
| Codes | Prasad (pre) N=3 | Prasad (post) N=7 | Boyce (pre) N=6 | Boyce (post) N=16 |
| 1 or 2 (substantive) | 1 | 0 | 1 | 8 |
| 3, 4, or 5 | 1 | 5 | 5 | 5 |
| 6 (lack of isometries) | 1 | 2 | 0 | 3 |

## Conclusions

The premise of our study was that after our students' explorations in taxicab, they would be more likely to describe properties of transformations in their justifications of SAS. We were surprised that on the pre-assessment, before exploration of taxicab geometry, there were so few students providing a valid justification for SAS or even attempting to justify SAS (as opposed to using it to justify something else). With consideration that our students were assigned the prompt directly after explorations with isometries, we had anticipated that more students would provide justifications that referred to translations, rotations, or reflections, at least informally. Our students interpreted the assessment prompt in interrelated ways that potentially obscured their mathematical thinking: using transformations to prove a congruence theorem, how to justify a theorem in a mathematically valid way, and what forms of justification are appropriate for secondary students.

The revised post-assessment seemed to shift their focus away from the third interpretation, but it was also less likely to elicit how they would operationalize their knowledge of transformations in a classroom situation. Still, there were enough promising answers to the pre-assessment to suggest that perhaps shifting to taxicab geometry might not be the most effective way to perturb their understanding of congruence – instead of providing intellectual need for properties of isometries, it may have just confused them. Although we observed many interesting features of students' thinking about transformations, justifications, and triangle congruence criteria, the results of this study have made it clear that investigating students' justifications of triangle congruence criteria was too broad an assessment for the learning goal of perturbing their understandings of congruence.

## Discussion

The results of this study and our more broad discussion about taxicab geometry suggest a clear axiomatic system that includes the isometries as axioms may be fruitful for engendering college students' justifications for triangle congruence criteria. While transformational reasoning has long been considered a part of analytic geometry (which is perhaps emphasized in K-12 more than it is in college-level geometry), a reliance on an axiomatic system usually paves the way to synthetic geometry in curricula. However, since the CCSS-M relies on the isometries to be treated as axioms, we believe that the resultant axiomatic system needs to be explicitly defined for teachers who are expected to follow the CCSS-M. If mathematics teacher educators are to expect preservice teachers to spontaneously call upon properties of transformations to justify congruence criteria, it also seems we may need to spend more time focused on applying transformational reasoning in our courses, further necessitating a well-defined axiomatic system within analytic geometry.

Moreover, such an axiomatic system has the advantage of connecting clearly to the axiomatic system that underlies taxicab geometry: instead of taking it as axiomatic that every rigid motion is an isometry, taxicab geometry restricts the possible rotations and reflections that can axiomatically be considered isometries. Thus, an excursion into taxicab geometry may focus students' attention more clearly on the consequences of defining congruence as the result of compositions of isometries. For the next step of our investigation, we would like to run another iteration of tasks (revised again) the next time we have the opportunity to teach these courses, perhaps exploring a more elementary idea of using taxicab isometries to perturb the notion of what it means for two segments to be congruent.

A Preservice Mathematics Teacher's Covariational Reasoning as Mediator for Understanding Global Warming

Dario Gonzalez
University of Georgia
darioagm@uga.edu

*In this paper, I discuss the role of covariational reasoning in mediating one preservice mathematics teacher's (PST's) understanding of the link between carbon dioxide ($CO_2$) pollution and global warming. I used Thompson and Carlson's (2017) levels of covariational reasoning to inform the discussion of the results. Jodi, the PST, completed a mathematical task I created for the study during an individual, task-based interview. The analysis of Jodi's responses revealed that Jodi's covariational reasoning supported increasingly sophisticated images of the link between $CO_2$ pollution and global warming as it developed from No Coordination Level to Chunky Continuous Level. My findings also suggest that covariational reasoning can involve two quantities changing simultaneously but in different intervals of conceptual time, which I have not seen previously reported in the literature. Finally, the study suggests that the implemented task is a suitable point of entry to study the mathematics of global warming.*

*Keywords:* Covariational Reasoning, Global Warming, Preservice Teachers, Modeling

## Introduction

Global warming refers to an increase in the mean global surface temperature caused by human emissions of greenhouse gases. This phenomenon is a contemporary and pressing issue with important social, economic, and ecological consequences around the world (Intergovernmental Panel on Climate Change [IPCC], 2013). Global warming also offers a potentially motivating and engaging context to learn integrated mathematics and science. The planetary scale of global warming, however, makes it difficult for a single person to experience such phenomenon in its entirety. Mathematical modeling can provide students and teachers with more easily accessible representations and objects such as quantities, graphs, or equations, that they can manipulate and reason with in order to further their understanding of the phenomenon (Barwell & Suurtamm, 2011; Barwell, 2013a, 2013b; Mackenzie, 2007). Mathematics teachers, however, are unlikely to incorporate global warming into their instruction. They may believe it is too politically charged, be unfamiliar with concepts related to climate science and global warming, or feel unprepared to teach the mathematics of global warming (Dahlberg, 2001; Lambert & Bleicher, 2013; Leiserowitz, Smith, & Marlon, 2010; Pruneau, Khattabi, & Demers, 2010). Therefore, there are both societal and cognitive needs for studies regarding global warming and mathematical reasoning.

In my research, I investigate how preservice teachers (PSTs) make sense of introductory mathematical models for global warming in which the mathematics involved can be accessible to high school students. The models require PSTs to think about a dynamic situation in terms co-variation between quantities. Existing research in mathematics education has demonstrated that students and future mathematics teachers can have persistent difficulties comprehending and mathematically expressing co-variation between quantities (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Johnson, 2012; Oehrtman, Carlson, Thompson, 2008; Thompson, 2011). In this paper, I discuss the role of one PST's covariational reasoning in mediating her understanding of the Earth's energy budget and the link between carbon dioxide pollution and global warming.

## Background Information

The Earth's climate system is powered by the sun, and there is a continuous exchange of heat between the sun, the planet's surface, and the atmosphere. The *Earth's energy budget* accounts for the direction and magnitude of this continuous heat exchange (Figure 1). The sun warms the planet's surface at a relatively constant rate S. As the surface warms up, it radiates (infrared) energy to the atmosphere at a rate R. A small portion L = (1 – g) × R escapes to space, while the majority B = g × R is absorbed by *greenhouse gases* (GHG) in the atmosphere such as water vapor ($H_2O$), carbon dioxide ($CO_2$), and methane ($CH_4$). The atmosphere re-radiates the absorbed heat in both directions toward space and toward the surface, at a rate A. The continuous heat exchange between the surface and the atmosphere is known as the *greenhouse effect* and influences the planet's mean surface temperature. The rates of radiation or heat exchange S, R, B, L, and A (Figure 1) are usually measured in Joules per second per square meter ($J/s/m^2$), while the concentration of GHG in the atmosphere is usually measured in the same units of volume (e.g., $m^3/m^3$) or in parts per million by volume (ppmv). The parameter $0 \leq g \leq 1$ is related to the greenhouse effect and represents the proportion of surface radiation absorbed by GHG in the atmosphere. Quantifying changes in heat exchange due to changes in the concentration of GHG is central to accurately model global warming. My study focuses on how an instantaneous increase in the atmospheric $CO_2$ concentration produces variation in heat exchange over time, and how that variation affects the planet's mean surface temperature.

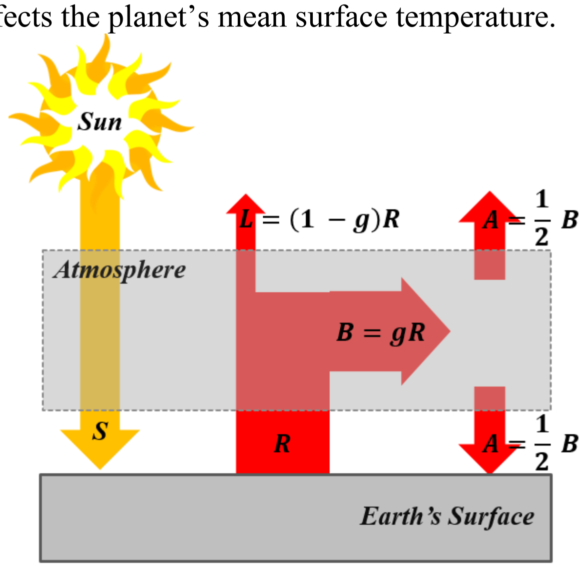

*Figure 1: The Earth's energy budget, assuming a single-layered atmosphere*

The *planetary energy imbalance function* N(t) is a measure of the energy imbalance in the Earth's energy budget over time. In particular, N(t) can be defined as a difference between the rate of downward radiation and the rate of upward radiation at the planet's surface, or mathematically N(t) = (S + A(t)) – R(t). The Earth's energy budget is said to be in *radiative equilibrium* when N(t) = 0 (rate of downward radiation equals rate of upward radiation), which implies that the *planet's mean surface temperature function* T(t) remains constant. However, there are factors or *forcing agents* that can push the energy budget out of equilibrium, producing N(t) ≠ 0. The present study focuses on how N(t) and T(t) vary over time after an instantaneous increase in the atmospheric $CO_2$ concentration at t = 0. Such increase would result in an atmosphere with more capacity to absorb radiation or heat from the surface. This translates into a value for B(0), and consequently A(0), such that N(0) = (S + A(0)) – R(0) > 0; this is known as a *positive forcing by $CO_2$*. Since the rate of downward radiation exceeds the rate of upward radiation, the planet's surface starts warming up as time increases (T(t) increases); a hotter surface radiates heat at a higher rate (R(t) increases). Since the surface is radiating heat at a higher rate, the atmosphere absorbs heat at a higher rate (B(t) increases). As a result, the atmosphere starts radiating heat back to the surface at a higher rate (A(t) increases), further warming the surface. The planet's mean surface temperature T(t) and the rate of radiation R(t) will continue to increase until a new radiative equilibrium is reached. Notice that the latter implies that N(t) will decrease towards zero as time increases. By using the equality $A(t) = \frac{g}{2}R(t)$ (Figure 1), the expression N(t) = (S + A(t)) – R(t) can be reduced to N(t) = S – $\beta$R(t), where S is the solar constant and $\beta = 1 - g/2$. That expression shows that N(t) decreases as R(t) increases. This variation indicates that the planet's mean surface temperature T(t) increases at a decreasing rate and asymptotically approaches to a new equilibrium value. As long as N(t) > 0, T(t) would increase because the rate of downward radiation S + A(t) exceeds the rate of upward radiation R(t). Since N(t) is decreasing, T(t) would slow down as it increases.

## Literature Review

Thompson (1994a) used *image* to refer to a set of fragments of experiences involving sensory-motor inputs (e.g. vision, smell, movements, touch, taste, etc.), affective states (e.g. fear, joy, struggle, etc.), and cognitive process (e.g. imagining, inferring, deciding, etc.), that one collects and coordinates when reasoning in particular ways about particular situations. In the context of co-variation, talking about an image allows us to elaborate upon that "something" in the student's mind when the student talks about something changing or something accumulating.

*Co-variation* refers to two quantities changing simultaneously and interdependently. Thompson (2011) provided a definition of co-variation in terms of a person's images of variation. For Thomson, to say that a quantity's value varies "is to say that one anticipates its measure having different values at different moments in time. So a varying quantity's value might be represented as $x = x(t)$, where t represents (conceptual) time" (p. 46). Variation therefore always occurs over an interval. The student anticipates D = domain(t), the values of *conceptual time* over which t ranges, as covered by intervals of length ε. Then, the variation in quantity $x$ can be represented with $x_\varepsilon = x(t_\varepsilon)$, where $t_\varepsilon$ represents the interval [t , t + ε) and t can be any value of conceptual time. The student envisions $x$ varying in intervals of conceptual time with the understanding that the quantity also varies within any interval of completed variation. Co-variation can then be defined by extending that definition of variation. Co-variation can be represented as $(x_\varepsilon , y_\varepsilon) = \big(x(t_\varepsilon) , y(t_\varepsilon)\big)$, where the pair $(x_\varepsilon , y_\varepsilon)$ represents a student's image of uniting in mind two quantities, and then varying them simultaneously over intervals of conceptual time.

Co-variation represents a more intuitive approach to teaching and learning functional relationships (Thompson, 1994b). Researchers in mathematics education use the term covariational reasoning to refer to someone's ability to envision co-variation. Saldanha and Thompson (1998) have defined covariational reasoning as:

> Someone holding in mind a sustained image of two quantities' values (magnitudes) simultaneously. It entails coupling the two quantities, so that, in one's understanding, a multiplicative object is formed of the two. As a multiplicative object, one tracks either

quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value. (pp. 299).

Saldanha and Thompson also conjectured that someone's images of co-variation or covariational reasoning undergoes several developmental stages. Carlson and colleagues (Carlson et al., 2002) build upon Saldanha and Thompson's conjecture. They developed the Covariation Framework as a theoretical instrument to examine and assess a student's covariational reasoning abilities. The framework describes five levels of development, each more sophisticated than and built upon the previous one: *Dependency of Change* or Level 1 ($y$ changes when $x$ changes), *Direction of Change* or Level 2 ($y$ increases as $x$ increases), *Amounts of Change* or Level 3 (a change $\Delta y$ in $y$ correspond to a change of $\Delta x$ in $x$), *Average Rate of Change* or Level 4 ($y$ increases more rapidly for successive changes $\Delta x$ in $x$), and *Instantaneous Rate of Change* or Level 5 ($y$ increases more rapidly as $x$ continuously increases). Carlson and colleagues emphasized that if a student's covariational reasoning was classified at a particular level, then it is implied that the student's covariational reasoning can also operate at any of the previous levels.

The way that a student might perceive a quantity's value varying can shape their covariational reasoning. Castillo-Garsow and colleagues (Castillo-Garsow, Johnson, & Moore, 2013) theorized that students can develop two different types of images of variation: *chunky images* and *smooth images*. The chunky thinker's way of envisioning variation has two main features: (a) a unit or chunk building up the variation through iteration and (b) no variation occurs within this unit or chunk. The chunky thinker reasons in discrete or atomic units (chunks) and only attends to what is *happening* at the chunk's ends (what an observer would describe as the lower and upper limit of the interval) so that no variation occurs within the chunk. Castillo-Garsow and colleagues argued that this way of envisioning variation "makes it seemingly impossible for a student using chunky thinking to imagine a situation dynamically while simultaneously imagining the mathematics of it" (p. 34). In contrast, the smooth thinker can envision ongoing change as occurring progressively and continuously.

> Ongoing change is generated by conceptualizing a variable as always taking on values in the continuous, experiential flow of time. A smooth variable is always in flux. The change has a beginning point, but no end point. As soon as an endpoint is reached, the change is no longer in progress. (Castillo-Garsow et al., 2013, p. 34)

The smooth thinker can also envision ongoing change in chunks but, unlike the chunky thinker, the smooth thinker can envision change occurring within the chunk. Castillo-Garsow and colleagues emphasized that smooth images are not a refinement of chunky images; the chunky thinker will not develop smooth images by solely considering smaller and smaller chunks in the independent variable.

The literature discussed in this section have introduced important aspects regarding a person's covariational reasoning. First, covariational reasoning is recursive since change is envisioned in intervals and within intervals (Thompson, 2011). Covariational reasoning also involves the development of a multiplicative object linking change between two quantities (Saldanha & Thompson, 1998). In addition, covariational reasoning develops through levels, each more sophisticated than and built upon the previous levels (Carlson et al., 2002). Finally, envisioning variation can involve two different types of images: chunky images or smooth images. These images may support or constrain the way that co-variation is envisioned (Castillo-Garsow et al., 2013).

## Conceptual Framework

I make use of Thompson and Carlson's (2017) levels of covariational reasoning to inform the discussion of the study's results. They suggested that "a researcher could use [the levels] to describe a class of behaviors, or she could use it as a characteristic of a person's capacity to reason … covariationally." For the current study, I used the framework as a way to characterize Jodi's covariational reasoning relative to a particular mathematical task involving two quantities—planetary energy imbalance and mean surface temperature—varying over time. Thompson and Carlson describe six distinctive levels of covariational reasoning (Table 1), each more sophisticated than and encompassing the previous levels.

*Table 1. Major levels of covariational reasoning*

| Level | Description |
|---|---|
| Smooth continuous covariation | The person envisions increases or decreases (hereafter, changes) in one quantity's or variable's value (hereafter, variable) as happening simultaneously with changes in another variable's value, and the person envisions both variables varying smoothly and continuously. |
| Chunky continuous covariation | The person envisions changes in one variable's value as happening simultaneously with changes in another variable's value, and they envision both variables changing by intervals of a fixed size (not necessarily of the same size). The person imagines, for example, the variable's value varying from 0 to 1, from 1 to 2, from 2 to 3 (and so on), like laying a ruler. Values between 0 and 1, between 1 and 2, between 2 and 3, and so on, "come along" by virtue of each being part of a chunk—like numbers on a ruler—but the person does not envision that the quantity has these values in the same way it has 0, 1, 2, and so on, as values. |
| Coordination of values | The person coordinates the values of one variable (x) with values of another variable (y) with the anticipation of creating a discrete collection of pairs (x, y). |
| Gross coordination of values | The person forms a gross image of quantities' values varying together, such as "this quantity increases while that quantity decreases." The person does not envision that individual values of quantities go together. Instead, the person envisions a loose, nonmultiplicative link between the overall changes in two quantities' values. |
| Preccordination of values | The person envisions two variables' values varying, but asynchronously—one variable changes, then the second variable changes, then the first, and so on. The person does not anticipate creating pairs of values as multiplicative objects. |
| No coordination | The person has no image of variables varying together. The person focuses on one or another variable's variation with no coordination of values. |

## Methods

### Context and Purpose

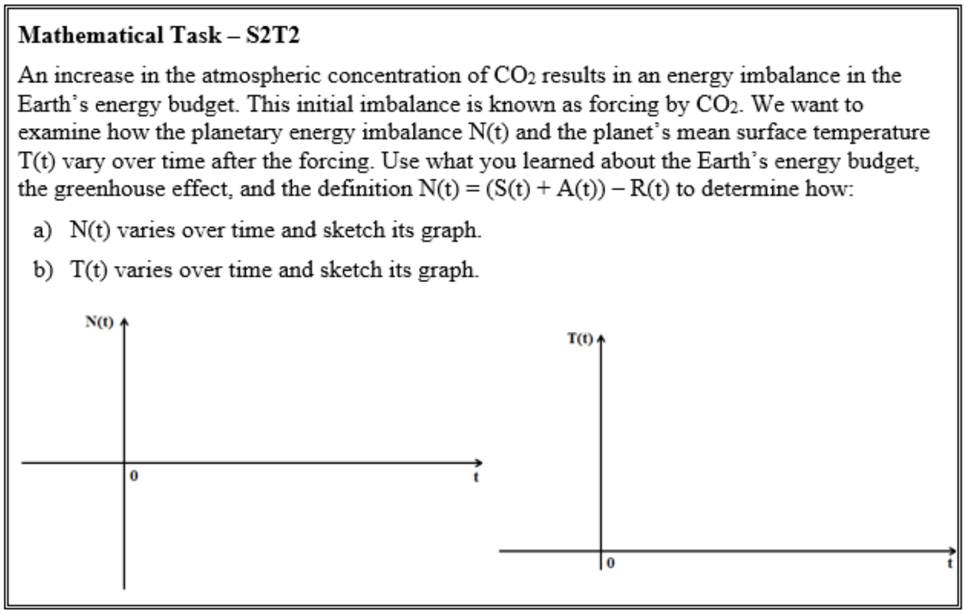
The current study is part of a larger research project that investigated how PSTs made sense of introductory mathematical models for global warming. The research project was conducted in two stages. The first stage was an exploration of the PSTs' conceptions of three quantities commonly used to model global warming: concentration, energy density, and heat flux density. The second stage was an examination of the role of covariational reasoning in making sense of three functions commonly used to model global warming: the forcing by $CO_2$ function F(C), the planetary energy imbalance function N(t), and the mean surface temperature function T(t). To accomplish the research goals, I created an original sequence of six mathematical tasks, four regarding the quantities and two regarding the functions previously mentioned. I then conducted four individual, task-based interviews with each PST as they worked through each task in the sequence. The current study focuses on the case of one PST, Jodi, and her responses to one mathematical task regarding the functions N(t) and T(t).

### Participants

Three PSTs enrolled in a secondary mathematics education program at a large Southeastern university participated in the larger research project. The PSTs have completed two calculus courses covering topics such as limits, derivatives, linear approximation, curve sketching, optimization, indeterminate forms, integrals, Fundamental Theorem of Calculus, areas, volumes, arclength, techniques of integration, Taylor series, and separable differential equations. In addition to calculus, the PSTs completed an Introduction to Higher Mathematics course covering topics such as logic, sets and relations, functions, and proof writing. The PSTs were also completing the course Connections in Secondary Mathematics, which covered topics in secondary mathematics such as algebra, functions, conics, linear systems, and sequences and series. The sequence of tasks designed for the research project required PSTs to reason about ratios, rate of change, functions, curve sketching, and modeling. Therefore, participants with experience in these topics were preferred. All three PSTs had no previous experience learning about concepts related to global warming. They, nonetheless, believed that global warming was real and that human activity was at least partially responsible for it. All three PSTs completed all six mathematical tasks in the sequence. The current study focuses on Jodi's responses to the sixth mathematical task. I chose Jodi's case because: (a) her responses were markedly different from her peers, which represents a unique case for discussion, and (b) her case provided explicit examples of how covariational reasoning can mediate the understanding of global warming.

### Data Collection

The second stage of the larger research project included two tasks (the fifth and sixth tasks) involving function commonly used to model global warming. The fifth task required Jodi to make sense of the forcing by $CO_2$ function F(C), while the sixth task described a situation in which the planetary energy imbalance function N(t) and the mean surface temperature function T(t) were involved. Before Jodi began working on those two tasks, I showed her a 7-minute long video introducing the concepts of *Earth's energy budget*, *radiative equilibrium*, and *greenhouse effect*. The video was retrieve from the NASA YouTube channel *NASAEarthObservatory*. Once the video ended, I answered any questions that Jodi had concerning the concepts discussed in the video. I then presented Jodi with the fifth task. The goal of that task was for Jodi to make sense of the forcing by $CO_2$ function, F(C). F represents the energy imbalance caused by an instantaneous increase in the atmospheric $CO_2$ concentration C. Thus, the value of F depends on the value of C. Jodi was tasked with sketching the graph of that relationship. A week later, Jodi participated in another individual interview in which she completed the sixth task in the sequence (Figure 2). The current study focuses on Jodi's responses to that sixth task.



**Mathematical Task – S2T2**

An increase in the atmospheric concentration of $CO_2$ results in an energy imbalance in the Earth's energy budget. This initial imbalance is known as forcing by $CO_2$. We want to examine how the planetary energy imbalance N(t) and the planet's mean surface temperature T(t) vary over time after the forcing. Use what you learned about the Earth's energy budget, the greenhouse effect, and the definition $N(t) = (S(t) + A(t)) - R(t)$ to determine how:

a) N(t) varies over time and sketch its graph.

b) T(t) varies over time and sketch its graph.

*Figure 2. The sixth mathematical task in the sequence.*

Jodi completed the task during a 60-minute, semi-structured, task-based interview (Goldin, 2000). I created interview protocols containing pre-defined questions to guide the interview process and to ensure all participants received similar probes during the interviews (structured part). Additionally, I spontaneously reacted to participants' responses and reasoning by asking additional follow-up questions not included on the protocols (unstructured part). Throughout the interview, I adopted a facilitator role, avoiding intervening in their reasoning or directing their thinking in any particular way. I carefully listened to their responses and asked for clarifications, further explanation, or arguments for their claims. The interview was video recorded and transcribed for analysis. All of Jodi's work on paper was collected as well.

**Data Analysis**

Videos and transcripts were analyzed through Framework Analysis (FA) method; this method consists of five inter-related stages: familiarization with data, developing an analytic framework, indexing and pilot charting, summarizing data in the analytic framework, and synthesizing data by mapping and interpreting (Ward, Furber, Tierney, & Swallow, 2013). Through these stages, the researcher creates and refines framework analysis' distinctive feature: the *matrix output*, a table arrangement into which the researcher systematically reduces, summarizes, and analyzes the data. I began the analysis by watching the interview videos. While watching the videos, I took notes regarding the video's general content at different moments in the interview and moments when the conversation changed topics (familiarization with data). I used the notes to focus my analysis on the episodes of the videos showing information relevant to the larger research project's goals. I then watched those particular episodes and coded them using the major levels of covariational reasoning described by Thompson and Carlson (2017) as themes (developing analytic framework). I then transcribed these episodes and organized text excerpts according to levels of covariational reasoning. I next read all text excerpts categorized under a particular level, selecting the excerpts that were more representative of each particular level (indexing and pilot charting). I repeated this process until I selected representative excerpts for each level the participants demonstrated. Then, all selected excerpts were organized into a matrix output containing six columns –one for each level– and two rows: one for N(t) and another for T(t) (summarizing data in analytic framework). Charting data in the matrix output allowed me to observe and analyze Jodi's responses in light of: (a) her level of covariational reasoning, (b) moments when her covariational reasoning advanced or progressed, and (c) her images of the Earth's energy budget and the link between $CO_2$ pollution and global warming (synthesizing data by mapping and interpreting).

## Results

Jodi's responses to the task suggest her level of covariational reasoning served as mediator of her understanding of the link between carbon dioxide ($CO_2$) pollution and global warming. In this section, I present and discuss the evidence supporting that finding. I divided the result section into two subsections: Part 1 refers to Jodi's construction of the graph of N(t), while Part 2 refers to Jodi's construction of the graph of T(t).

### Part 1: Sketching the Graph of The Planetary Energy Imbalance N(t)

During the first part, Jodi's covariational reasoning advanced from No Coordination Level to Coordination Level. At the beginning of the interview, I was interested in assessing whether Jodi could reason about the situation in a non-numeric and dynamic way. I thus asked Jodi to think about and describe how N(t) would be varying after a positive forcing without using particular values of N. Jodi's response suggested a covariational reasoning at the No Coordination Level; she had not yet developed images of values of N and values of time varying together. She stated the following regarding the variation of N(t):

> I think that the value of N will stay the same after we have [*pauses*]. If we increase [the concentration of $CO_2$] by just some number, then we would increase N by some number. And, it wouldn't increase or decrease if $CO_2$ is kept stable.

In a previous interview, Jodi worked on the task involving the forcing by $CO_2$ function F(C), where C represented the atmospheric $CO_2$ concentration. F(C) measures a change in the planetary energy imbalance caused by changes in C. The task assumed a single increased in atmospheric $CO_2$ concentration at t = 0, hence F(C) = N(0). Jodi's response suggests she has not yet made that distinction between F(C) and N(t). This might explain why Jodi did not think of N as a function of time and imagined N remaining constant if the atmospheric $CO_2$ concentration remained constant. Jodi's image of the energy budget involved realizing that a change in atmospheric $CO_2$ concentration would produce an energy imbalance. Because she did not coordinate N with t.

I decided to let Jodi use particular values to assess whether she could develop images of N and t varying together. I showed her a diagram of the Earth's energy budget with the initial values S = 240 J/m$^2$/s, R(0) = 390 J/m$^2$/s, B(0) = 300 J/m$^2$/s, and A(0) = 150 J/m$^2$/s to illustrate the idea of radiative equilibrium –notice that N(0) = (S + A(0)) – R(0) = (240 + 150) – 390 = 0. Next, I explained that an instantaneous increase in atmospheric $CO_2$ concentration at t = 0 would result in different initial values for B(0) and A(0). I showed Jodi a different diagram with the new values B(0) = 310 J/m$^2$/s and A(0) = 155 J/m$^2$/s to illustrate the idea of departing from radiative equilibrium – notice the positive forcing F = N(0) = (S + A(0)) – R(0) = (240 + 155) – 390 = 5. To further assists Jodi, I told her to use the following recursive rules: $B_i = 0.794 \times R_i$, $A_i = 0.5 \times B_i$, and $R_{i+1} = S + A_i$ for i = 0, 1, 2, … . The recursive rules shaped the way Jodi visualized variation in the rates of radiation R(t), B(t), and A(t). In particular, Jodi envisioned these rates varying one after the other –B(t) would vary first, then A(t), and finally R(t)– all occurring during a single time interval of fixed length h. She conceived of these intervals as chunks of time and referred to them as *cycles* or *revolutions* –probably because the order in which the rules are used resembled a cyclic process: determine R(t), then A(t), then R(t), then back to B(t) and so on. Jodi registered the values of R(t), B(t), and A(t) on the diagram of the energy budget (Figure 3).

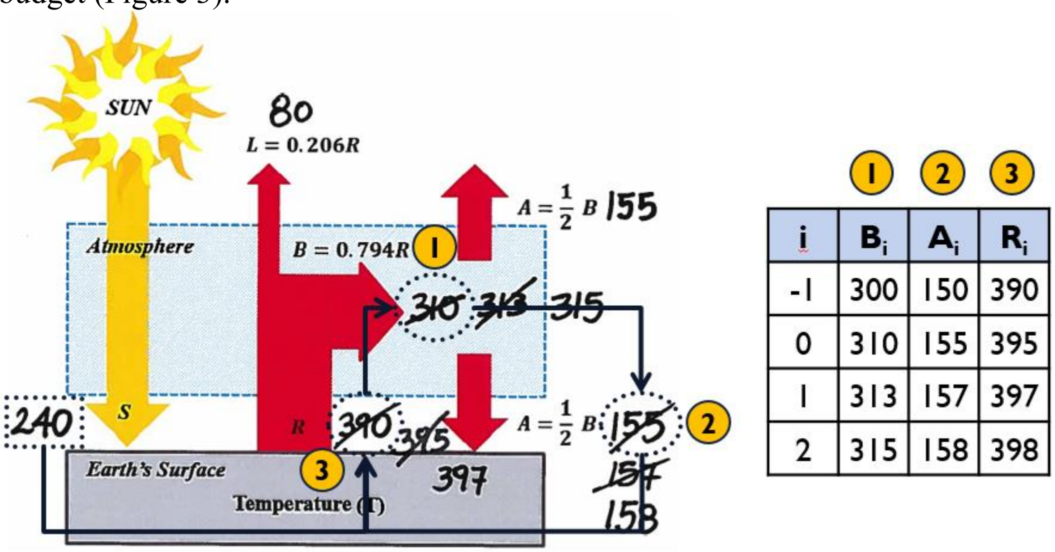


*Figure 3. The way Jodi determined the values of the rates of radiation in the diagram of the energy budget.*

Since Jodi determined particular values for the rates of radiation for three different cycles, I decided to assess whether she could describe how N(t) was varying as time increases. When asked, Jodi replied "N [was] increasing as time goes on," without attempting to determine values of N(t) and to coordinate them with values of time. Although Jodi incorrectly anticipated that N(t) would increase over time, her response unveiled that she developed a gross image involving values of N and t varying together. This Gross Coordination Level supported the notion of N(t) varying as time increases, even if the atmospheric $CO_2$ concentration was to remained constant after its initial instantaneous increase. Jodi's image of the energy budget expanded to include the idea of variation after a change in atmospheric $CO_2$ concentration (forcing). In other words, Jodi can envision an energy budget *doing something* or changing (as opposed to statically remaining out of equilibrium) after a forcing.

Jodi did not demonstrate envisioning individual values of N and t going together. Therefore, I asked Jodi to use the rule $N_i = (S + A_i) - R_i$ to determine individual values of N(t) (S is assumed to be constant). Jodi determined the values $N_0 = 5$ J/m$^2$/s, $N_1 = 2$ J/m$^2$/s, and $N_2 = 1$ J/m$^2$/s. She used these values to create a discrete collection of pairs (i , $N_i$); she represented each pair as a point in the coordinate plane and join all points by a concave-up, decreasing curve in order to draw the graph of N(t) (Figure 4). The way Jodi constructed the graph of N(t) suggests she coordinated individual values of N(t) with individual values of time. I should clarify that, for Jodi, an individual value of time can be described (from the point of view of an observer) as a time interval of fixed length. This Coordination Level allowed Jodi to realize that N(t) was decreasing as time increased, a fact that she was not expecting as suggested by her statement "I thought N would be larger." When I asked her to interpret her graph, Jodi stated that "[The graph means] that we are going back to an equilibrium, or we are not as far from equilibrium as we were." Jodi's interpretation of her graph appeared to be a product of *discovering* that N(t) was actually decreasing as time increased. She anticipated that N(t) would be increasing. When she saw a decreasing graph of N(t), Jodi had to make sense of the situation by relating the graph to the idea of radiative equilibrium: N(t) is decreasing to show that the energy budget is *returning* to an equilibrium. I used the word *returning* to indicate that Jodi envisioned the energy budget as *going back* to the original radiative equilibrium (i.e., before the forcing occurs at t = 0), rather than reaching a new one. This conjecture is further supported when I asked Jodi to interpret her graph in terms of how the heat content in the surface was varying over time. Jodi stated that the heat content was decreasing since "we would need to be losing energy so that we can go back to equilibrium." Jodi's image of the energy budget expanded to include the idea of moving towards radiative equilibrium. Jodi envisioned an energy budget *returning* to the original radiative equilibrium as time increased (after the forcing occurred at t = 0).

| i | $N_i = (S + A_i) - R_i$ |
|---|---|
| 0 | (240 + 155) – 390 = 5 |
| 1 | (240 + 157) – 395 = 2 |
| 2 | (240 + 158) – 397 = 1 |

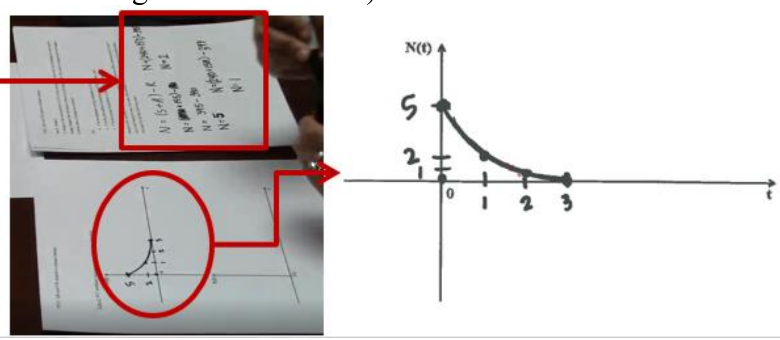

*Figure 4. Jodi's construction of the graph of the planetary energy imbalance N(t)*

Jodi's responses suggest that her covariational reasoning developed from the No Coordination Level toward the Coordination Level as she worked through Part 1 of the task. Initially, Jodi did not demonstrate an image of N and t varying together. This No Coordination Level supported an image of the energy budget involving the realization that a change in $CO_2$ concentration produce an energy imbalance (forcing). The image, however, did not include envisioning an energy budget changing after the forcing occurred. The use of recursive rules to determine individual values for the rates of radiation R(t), B(t), and A(t) appeared to help Jodi develop a gross image of N and t varying together. This Gross Coordination Level supported an image of the energy budget involving change after a forcing: the budget did not statically remain out of equilibrium after a forcing but changed as time increased. Once Jodi determined individual values for N(t), she was able to coordinate them with values of time, creating a discrete collection of pair. The Coordination Level was followed by the realization that N(t) was decreasing as time increased. It also supported an image of the energy budget returning toward radiative equilibrium after a forcing.

**Part 2: Sketching the Graph of The Mean Surface Temperature T(t)**

During the second part, Jodi demonstrated covariational reasoning at the Chunky Continuous Level. Jodi envisioned the rates R(t), B(t), and A(t) varying one at a time within a single time interval of fixed length h (cycle): B(t) would vary first, then A(t), and finally R(t), all occurring during a single cycle. She would repeat this reasoning for three cycles in order to visualize how the energy budget was changing over time. Jodi followed the same strategy to reason about how the planet's mean surface temperature T(t) was varying as time increased. This time Jodi attended to the amounts by which R(t) and A(t) were increasing from cycle to cycle.

*Jodi*: Well, I don't expect the temperature of the Earth to be zero. So, I wouldn't think it would start here [*points at the origin*] … Let's say that the temperature of the Earth is like here [*points at the middle of the vertical axis*]. So, the temperature of the Earth at equilibrium is there [*makes a mark on the vertical axis*].

*Interviewer*: So, is that the initial surface temperature?

*Jodi*: Uh-huh. I am trying to look at the differences. So here, the change was five (A increased from 150 to 155). Then, the change was two (A increased from 155 to 157). [*Long pause*] is it not changing?

*Interviewer*: What isn't changing?

*Jodi*: [The heat content] increased by five (A increased from 150 to 155), then it decreased by five (R increased from 390 to 395). Then, it increased by two, and then it decreased by two [*pauses*]. So, it is almost as if there was no change in temperature because I associate energy as kind of having a relationship with temperature. So, if the energy increases, then the temperature increases. But, in this scenario, an equal change in energy [input] was an equal change in [energy] output [*simultaneously points at A and R*].

*Interviewer*: Would you be able to draw the graph of the surface temperature now?

*Jodi*: I want to say that [T(t)] stays the same, but maybe it like [*pauses*]. OK, [a] cycle started here [*points at B*], and here the Earth's temperature would've been something … So, when the cycle started, there was an input, and then it got released [*circles her hand over the diagram in the B-A-R direction*]. Then, another cycle starts: input of energy, release of energy. So, it would almost be like [*draws a periodic curve (Figure 5)*]

The excerpt above unveils two interesting aspects of Jodi's reasoning regarding the situation. One aspect is the way she envisioned variation in the rates of radiation as time increased. Specifically, the order in which Jodi used the rules $B_i = 0.794 \times R_i$, $A_i = 0.5 \times B_i$, and $R_{i+1} = S + A_i$ shaped the way she envisions such variation. When using the rules, Jodi started by determining a value of B(t) (first rule), then a value of A(t) (second rule), and finally a value of R(t) (third rule). Jodi envisioned the rates varying one after the other in the B-A-R direction. A second aspect involved Jodi's conception of R(t) and A(t). In particular, Jodi appeared to conceive of A(t) and R(t) as heat entering and leaving the surface, respectively. This may explain why Jodi attended to the amounts by which A(t) and R(t) were increasing rather than the values they took. Let $\Delta_i A$ and $\Delta_i R$ be the amount by which A(t) and R(t) increased within Jodi's cycle i, respectively. From Jodi's perspective, the heat content is increasing during the *first half* of the cycle (when she perceived A(t) increasing), and then decreasing during the *second half* of it (when she perceived R(t) increasing). Since she noticed that $\Delta_i A = \Delta_i R$, Jodi envisioned the heat content having the same value at the beginning and at the end of the cycle. Jodi therefore envisioned T(t) varying in the same way: T(t) would increase during the first half of the cycle and decrease during the second half of it such that T(t) would take the equilibrium value T(0) at the beginning and end of the cycle. Jodi represented this variation in T(t) with a periodic curve (Figure 5).

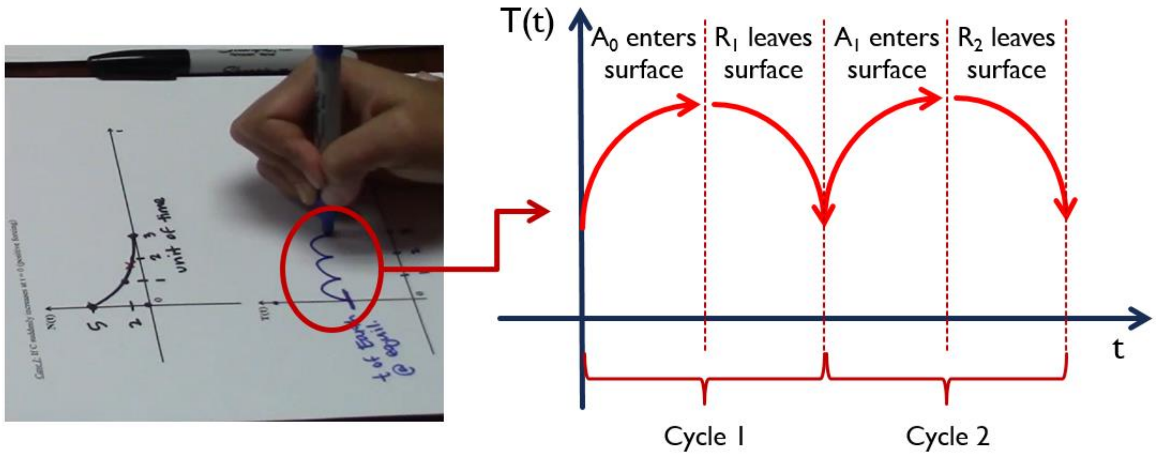

*Figure 5. Jodi's first periodic curve to represent T(t) (left) and the way she constructed that curve (right).*

Jodi drew three different curves representing T(t): *Periodic Curve 1*, *Periodic Curve 2*, and a *Quasi-periodic Curve* (Figure 6). Jodi drew Periodic Curve 1 in the way described in the previous paragraph. Periodic Curve 2 was the result of Jodi changing the way she defined a cycle. Jodi stated that if a cycle is defined in the R-B-A direction, then T(t) would increase throughout a cycle and would return to equilibrium value T(0) at the beginning of the next cycle.

> If we started the cycle here [*points at R*], then it would be like zero cycle. [*Circles her hand in the R-B-A direction*]. At the end of cycle 1, we would have an increased temperature. But then, we would go back and it would almost be something that looks like this [*draws Periodic Curve 2*], where at the beginning of a cycle, we will be back to a normal temperature, equilibrium temperature.

Unfortunately, I did not ask Jodi to explain why she drew linear segments to represent the variation in T(t). I, however, do not think that Jodi drew a linear segment to represent T(t) increasing at a constant rate during a cycle. She did not seem to attribute such meaning to her curve choice (linear versus non-linear) since she unproblematically moved from non-linear (Periodic Curve 1), to linear (Periodic Curve 2), and back to non-linear (Quasi-periodic Curve) as she drew the graph of T(t) (Figure 6).

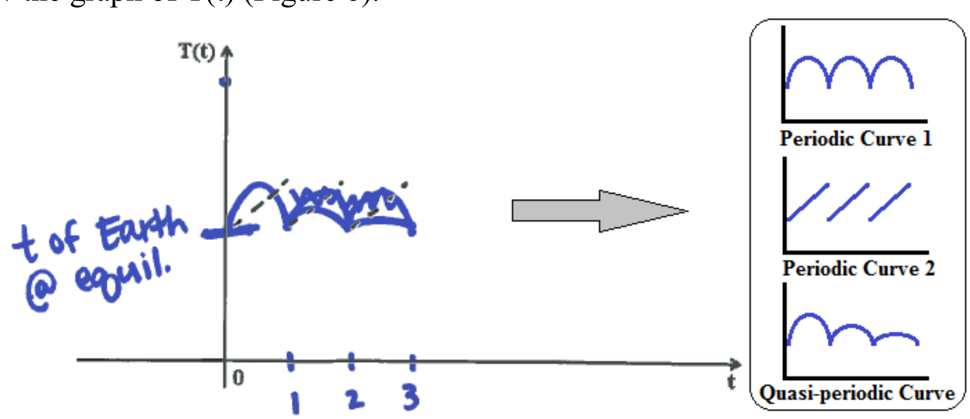

*Figure 6. Jodi drew three different curves for T(t): two periodic curves and one quasi-periodic curve*

The Quasi-periodic Curve was the result of Jodi attending to the variation in the amounts $\Delta_i B$ by which B(t) was increasing from one cycle to the next. Jodi conceived of $\Delta_i B$ as measures of (what an observer would describe as) the largest difference $\Delta_i T = \max\ \{T(t) - T(0)\}$ for Jodi's cycle i or, put in another way, the amplitude of the *arc* for that cycle i. The amounts $\Delta_i B$ were decreasing from one cycle to the next. Jodi interpreted that variation as indicating that T(t) was quasi-periodically approaching to the original equilibrium value T(0).

> The amount of [heat] was decreasing, like each time. Because in here, [B(t)] increased 10, then 3, and then 2 (B(t) took the values 300, 310, 313, and 315). So, maybe [the arcs] should be like smaller [*points at Periodic Curve 1*]. You know, like they wouldn't be the same size. Because, the Earth's temperature wouldn't increase that much [*draws the Quasi-periodic Curve*]. Because the increases in temperature are smaller during the cycles.

Regardless of the type of curve, Jodi demonstrated Chunky Continuous Level of covariational reasoning while constructing the graph of T(t). Jodi envisioned changes in T(t) are occurring simultaneously with changes in time (i.e., T(t) taking particular values for particular values of time). Jodi also envisioned changes in T(t) and changes in time as happening in intervals of fixed size. For instance, for Periodic Curve 1, T(t) increased by an amount $\Delta T$ during the *first half* of a cycle and then decrease by $\Delta T$ during the *second half* of the cycle. Thus, T(t) varies in intervals of fixed length $\Delta T$. The time t also increased in intervals of fixed length $h > 0$, where h is the duration of a Jodi's cycle. This Chunky Continuous Level supported an image of the planet's surface returning to its original equilibrium temperature as time increased (i.e., after the forcing occurred at $t = 0$). Jodi may have seen the variation in $\Delta_i B$ as consistent with her image of the energy budget returning to its original radiative equilibrium. Notice that Jodi's conclusion contradicts the notion that an increased in atmospheric $CO_2$ concentration would result in a warming effect over the planet's surface. This may become an obstacle to understand the link between $CO_2$ pollution and global warming.

## Conclusions

The study's findings suggest that Jodi's covariational reasoning mediates her understanding of the Earth's energy budget and the link between carbon dioxide pollution and global warming. Jodi's responses suggest that her covariational reasoning developed from the No Coordination Level toward the Coordination Level as she constructed the graph of N(t) (Part 1 of the task). Initially, Jodi did not demonstrate an image of N and t varying together. This No Coordination Level supported an image of the energy budget involving the realization that a change in $CO_2$ concentration produce an energy imbalance (forcing). The image, however, did not include envisioning an energy budget changing after the forcing occurred. The use of recursive rules to determine individual values for the rates of radiation R(t), B(t), and A(t) appeared to help Jodi develop a gross image of N and t varying together. This Gross Coordination Level supported an image of the energy budget involving change after a forcing: the budget did not statically remain out of equilibrium after a forcing but changed as time increased. Once Jodi determined individual values for N(t), she was able to coordinate them with values of time, creating a discrete collection of pair. The Coordination Level was followed by the realization that N(t) was decreasing as time increased. It also supported an image of the energy budget returning to the original radiative equilibrium after a forcing.

Jodi demonstrated a Chunky Continuous Level of covariational reasoning as she constructed the graph of T(t) (Part 2 of the task). Her Chunky Continuous Level was characterized by: (a) the order in which Jodi imagined the rates of radiation taking values, (b) Jodi's conception of A(t) and R(t), and (c) the way she envisioned T(t) and t varying in different intervals of conceptual time. Jodi imagined the rates B(t), A(t), and R(t) as taking values one after the other –same order as the recursive rules $B_i = 0.794 \times R_i$, $A_i = 0.5 \times B_i$, and $R_{i+1} = S + A_i$. For instance, R(t) could take a value *only after* A(t) had already taken a value. Determine the values of these rates in the B-A-R direction represented a Jodi's cycle. Jodi conceived of A(t) and R(t) as heat *entering* and *leaving* the planet's surface, respectively. Jodi thus imagined the surface heat content *first* increasing by $\Delta_i A$ *and then* decreasing by $\Delta_i R = \Delta_i A$. For Jodi, this meant that T(t) was *first* increasing *and then* decreasing within a single Jodi's cycle. In particular, T(t) would increase during the *first half* of a cycle and then decrease during the *second half* of it. Using Thompson's (2011) definition of co-variation, I describe Jodi's image of co-variation between T(t) and t in the following way. If τ represents conceptual time, then a Jodi's cycle can be denoted as $t_\varepsilon = t(\tau_\varepsilon)$ where $\tau_\varepsilon$ represents the interval $[\tau, \tau + \varepsilon)$ for $\varepsilon > 0$. Similarly, the mean surface temperature can be denoted as $T_{\varepsilon/2} = T(\tau_{\varepsilon/2})$. Thus, $(t_\varepsilon, T_{\varepsilon/2})$ represents Jodi's image of uniting in mind t and T(t), and then varying them simultaneously over different intervals of conceptual time. This finding, to the extent of my knowledge, has not been previously reported in the literature regarding covariational reasoning. Jodi's Chunky Continuous Level supported an image of the planet's surface as cooling down after the atmospheric $CO_2$ concentration increased (positive forcing). In particular, she imagined the surface returning to its original equilibrium temperature as time increased. Jodi may have found this consistent with her image of the energy budget returning toward radiative equilibrium after a positive forcing. This images contradict the long-term impact of $CO_2$ emissions on the planet's mean surface temperature, which increases as a response to an increase in atmospheric $CO_2$ concentration.

The study's results also suggest that modeling the dynamics of the Earth's energy budget can be a suitable point of entry to teach mathematics of global warming. Jodi identified relevant quantities and established quantitative relationship between them as she modeled the dynamics of the budget. The results, however, suggest two modifications might be needed for future implementations of the task. First, avoid using recursive rules to explore variation in the energy budget. Such rules appeared to have been an obstacle for Jodi envisioning smooth co-variation. Second, explicitly relate change in N(t) with change in T(t). This may have helped Jodi see that the rate of change of T(t) is proportional to N(t) (Widiasih, 2013). Nonetheless, the study offers a way in which mathematics and science can be studied together in the context of global warming.

# The Sierpinski smoothie: Blending area and perimeter

Naneh Apkarian[1], Chris Rasmussen[1], Michal Tabach[2], & Tommy Dreyfus[2]
San Diego State University[1], Tel Aviv University[2]

## Abstract

In this report, we present an analysis of 10 individual interviews with graduate mathematics education students about the area and perimeter of the Sierpinski triangle (ST) and the resulting paradoxical situation. We use conceptual blending as a theoretical and methodological tool for analyzing students' reasoning to investigate how students encounter and cope with the ST having zero area and infinite perimeter. Our analysis documents the diverse ways in which the students reasoned about the situation. Results suggest that an infinite perimeter is more accessible to these students than zero area, that encountering the paradox is dependent on how blends are composed, and that resolution of the paradox comes through completion and elaboration. The analysis contributes to what we know about how students think about infinite limit processes and furthers the theoretical/methodological framing of conceptual blending as a useful tool for revealing the structure and process of student reasoning.

**Keywords:** Conceptual blending, Infinite processes, Fractal, Paradox, Student thinking

*It's still hard for me to wrap my mind around the Sierpinski triangle, and that there's infinite perimeter and no area. It makes sense to me individually, but both together at once, I'm still, it's still mind-boggling. – Carmen, graduate mathematics education student*

## Introduction

Straightforward notions of the area and perimeter of geometric shapes are first learned in elementary school, and are revisited and leveraged throughout secondary and postsecondary mathematics. Despite such familiarity, counterintuitive situations involving these ideas can arise when working with fractals. One such situation, a region with zero area and an infinitely long perimeter, was encountered by a class of mathematics education master's students in a chaos and fractals course when investigating the Sierpinski Triangle (ST). As seen in Carmen's introductory quote, this was a non-trivial exercise and caused some students serious consternation.

The ST is a fractal, and is the result of an infinite iterative process that begins with an equilateral triangle. Connecting the midpoints of its sides results in another equilateral triangle with sides half the length of the original's and area that is one-fourth of the original's, which is then removed. Repeating this process on the remaining three triangles and so on, ad infinitum, results in the ST (Figure 1). At each step of the process, the area of the object shrinks by a factor of 3/4 and the perimeter grows by a factor of 3/2. Thus, the ST has a perimeter of infinite length and an area of zero. This counterintuitive situation is a consequence of the fact that it is a fractal with Hausdorff dimension $\log_2(3)$, putting it between one- and two-dimensions.

We chose to focus on student reasoning about the ST for three reasons. First, the familiar concepts of equilateral triangle, area, and perimeter are central to the ST which makes it a mathematical object accessible to a wide range of students, while at the same time offering opportunities for quite sophisticated analyses including self-similarity, fractal dimension, infinite processes, and a paradoxical situation. Second, there is little research on ho about the ST, despite its mathematical significance and prominence. Third, of student work on the ST illuminated the surprising complexity of student and what happens "at the end".

To investigate student reasoning about the ST we conducted individual interviews about three weeks after the in-class investigation of the ST in a chaos and fractals course. Based on the interview data, and using the ideas of conceptual blending, we address the following two related research questions: (1) How do students make sense of (a) area and (b) perimeter of the ST? (2) How do students coordinate the area and perimeter of the ST and cope with the resulting paradoxical situation?

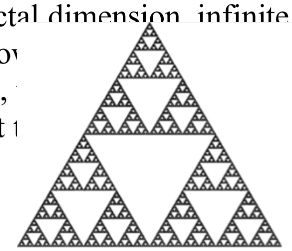

*Figure* 1. *The ST*

## Theoretical Background and Literature Review

### Infinity and Paradoxes

One of the first places students are asked to work with the infinite is when they are introduced to limits. Convergence and limits, especially related to sequences and series, are a notoriously challenging topic for students, and many believe that impoverished understandings of infinity contribute to that challenge. Many researchers have made use of paradoxical tasks to investigate and promote student understandings of infinity (e.g., Dubinsky et al., 2005ab; Ely, 2011; Radu & Weber, 2011; Wijeratne & Zazkis, 2015).

The relevant paradoxes that have been used in mathematics education research are infinite iterative tasks. The combination of physical steps (e.g., moving halfway to the door, drawing a triangle) with something physically impossible to complete is a situation which is not easily resolved, even by students with extensive mathematics training (Ely, 2011). The above research in this area has revealed potential infinity conceptions, the projection of finite patterns onto the completed state, conceptions of limits as unreachable, and an urge to preserve consistency with the physical world.

### Conceptual Blending

We use conceptual blending theory (Fauconnier & Turner, 2002) as a theoretical and methodological tool for analyzing students' coordination of two infinite processes, one increasing (perimeter) and one decreasing (area). Blending is based on the notion of mental spaces, which are "small conceptual packets constructed as we think and talk, for the purposes of local understanding and action" (p. 40). According to the theory, these mental spaces "organize the processes that take place behind the scenes as we think and talk" (p. 51). Conceptual blending is defined as the conceptual integration of two or more mental spaces to produce a new, *blended,* mental space. An important feature of this new blended space is that it develops an emergent structure that is not explicit in either of the input mental spaces. This emergent structure is generated by three processes: composition, completion, and elaboration.

*Composition* is the selective projection of elements from input spaces into a common space. During composition, distinct elements may be projected on top of each other or *fused,* and common elements may be projected separately. The composition process develops a new space, with the potential for structure not available in either input space. *Completion* is the process of recruiting familiar frames to the blended space, along with their entailments. That is, an individual recognizes certain aspects of a blended space as parts of a familiar frame and brings in additional knowledge, scripts, assumptions, etc., to complete the frame and prescribe structure for the blended space. These frames can serve as tools for *elaboration*, which is sometimes called *running the blend*. Elaboration is the process that leads to the emergence of something new within the blended space, using the tools of the completion process and the elements that compose the blend. These processes, composition, completion, and elaboration, do not necessarily take place sequentially.

This theory has been applied to the learning of mathematics by a number of researchers. For example, Lakoff and Núñez (2000) propose that most of the important ideas in mathematics are metaphorical conceptual blends. Alexander (2011) goes further and discusses how one can see conceptual blending within the formal structure of mathematics, and that the actualization of blends is a cognitively challenging but critical part of the evolution of the discipline. However, while a number of researchers have used conceptual blending to explain mathematics and mathematical thinking in general, it has been only minimally used in empirical studies of student thinking.

The few examples of empirical studies include the work of Edwards (2009) and (Yoon, Thomas, & Dreyfus, 2011) who analyzed how people invest their real gesture space with mathematical meaning; the use of grounded blends and physical space separates that work from what we present here. Gerson and Walter (2008) used the theory to look at the emergence of calculus concepts for individuals during small group work, but did not leverage the elements of the blending process as we do. Megowan and Zandieh (2005) and Zandieh, Roh, and Knapp (2014) do leverage the processes of composition, completion, and elaboration to investigate students' reasoning and proving activities in a geometry course, but they used small groups as their unit of analysis while we saw distinctions between groupmates. As these are the most relevant studies we could find, we situate our work as part of a new movement to leverage conceptual blending as an analytic tool in empirical mathematics education research.

## Methods

### Setting and Participants

The study took place in a graduate level mathematics course of 11 students (10 of whom participated in individual interviews). All students in the course were instructors and/or tutors of secondary or tertiary mathematics. Their master's degree program required a substantial mathematics component, and the chaos and fractals course studied here fulfilled part of that requirement. The course was taught by one of the research team members. Students sat in four groups throughout the course: 1) Carmen, Joy, and Jackie (Jackie did not participate in interviews); 2) Shani, Soo, and Kay; 3) Mia, Kevin, and Elise; 4) Sam and Curtis. Students regularly worked on mathematical tasks during class time in their groups and then discussed their thinking with the whole class. Data was collected as part of a larger study and included video-recordings of each class session, individual task-based interviews conducted at the middle and end of the semester, and copies of all student work.

### Methods for Data Collection

The focus of the analysis in this paper are students' responses to the following question from the mid-semester interview: *In class, we discussed the Sierpinski Triangle. How do you think about* *what happens to the perimeter and the area of the ST as the number of iterations tends to infinity?* This question was accompanied by a printout of the ST (as seen in Figure 1), with a follow-up prompt to tell us what they thought about the following claim of a fictitious student, "Fred": The computation shows that the perimeter goes to infinity because the perimeter is given by $3 \times (\frac{3}{2})^n$ which increases to infinity as n tends to infinity. But, the perimeter can't really be infinitely long, because there is nothing left to draw a perimeter around, since the area goes to zero.

This interview task was designed based on the classroom discussion of the ST. At that time, students seemed to agree that the area went to zero but were unsure of what happened to the perimeter. They publicly considered the possibilities that it went to infinity, converged to some value, or did not exist because there was nothing left for a perimeter to go around. We included a sequential expression for the perimeter in the hopes of foregrounding the paradoxical situation by helping students see that the perimeter diverges. The interview was structured so that we would first gain insight into the students' reasoning about the area and perimeter of the ST, followed by an opportunity for them to respond to Fred's claim. All interviews were conducted by the same member of the research team, with one of the other researchers present to video-record and ask occasional follow-up questions. Each interview lasted roughly an hour, 5-20 minutes of which were spent on the ST segment.

As noted, Fred's claim is based on an argument heard in class, presented first by Carmen, amended to include a (correct) algebraic expression. This ensured that the argument did not feel contrived to the students, and in fact several of them recognized this and noted that some students in class struggled with this same scenario. So, students had previously seen the ST and considered, to some extent, the same paradoxical situation we brought up in Fred's argument. This means that when we consider students' thinking in the interviews, we are gaining access to a semi-retrospective account of their original thinking. As conceptual blending is not a linear process, and in fact mental spaces coexist for extended periods of time, this gave us a better chance of seeing fully blended spaces, but reduced our ability to access the completion process or identify failed blends along the way.

**Methods for Analysis**

The transcripts and student work produced during the interviews were coded and organized in two rounds. The first round consisted of identifying the elements of each student's input spaces and blended space, extending and expanding our previous work (Rasmussen, Apkarian, Dreyfus, & Voigt, 2016). The second round was a fine-grained analysis of the blended spaces to identify the blending processes.

To identify a student's input space for area (similarly for perimeter), we first marked which of their utterances were about the area. Next, we categorized these utterances into sets of ideas about the area of the ST - including the process by which it is created and the resulting product. In the spirit of grounded theory (Strauss & Corbin, 1998), these ideas were coded and compared iteratively until a coherent set of idea codes emerged. The interviews were divided into two groups and analyzed by different members of the research team. These analyses were then swapped, compared, and vetted. The multiple, iterative bouts of discussion among the research team members provided many occasions to share and defend interpretations, thereby minimizing individual bias and keeping interpretations grounded in the data.

We investigated students' blending by identifying each of the three processes: composition, elaboration, and completion. To see how a student's blend was composed, we identified which elements of the student's input spaces were brought up as they considered the coordination of area and perimeter (prompted by Fred's paradox). We identified the ways students elaborated their blended spaces by identifying ideas which were not in the input spaces, but emerged as they worked to make sense of the task. For completion, we asked ourselves what frames (and entailed tools) students used (other than input space elements) in order to make their elaborations. The analysis of the composition of blended spaces was carried out in the same fashion as identifying the input space elements. Interpretation of completion and elaboration was done first as a group, with all four authors debating each point, then a more detailed pass was made by two members of the team in close comparison with the transcripts, and these analyses were then discussed again among the four authors until agreement was reached.

## Results

In this section, we address our two research questions. We begin with the first: how students made sense of (a) area and (b) perimeter of the ST. In particular, we specify the various elements of students' respective input spaces for area and perimeter, including both their conclusions about the area and perimeter as well as the ideas they use to justify their conclusions. These results are organized by idea, with mention of how widespread they are, rather than by student. Following this analysis, we present results for the second research question: how students cope with the paradoxical situation that arises from coordinating area and perimeter for the ST. We address this question by considering students' blending processes. These processes were individualized, and hence we present these analyses organized by student rather than process. In doing so, we present blending diagrams and note the composition of blends from students' input spaces, discuss the completions we were able to see, and identify the resulting elaborations.

### Results 1: Area and Perimeter

During the in-class discussions about the ST there was widespread agreement that the area would go to zero but less agreement that the perimeter would diverge to infinity. We expected similar claims in the interview, and were surprised to find that only six of the ten students concluded that the area of the ST goes to zero. Soo indicated that area shrinks unendingly but was adamant it would never actually reach zero; Shani and Kay said that the area converges to something nonzero; and Kevin said only that it converged, but he had not worked out what it converged to. On the other hand, all ten students concluded that the perimeter tends to infinity.

Among students' justifications for their conclusions, we identified seven qualitatively different mental space elements for area and seven qualitatively different mental space elements for perimeter. We display these different mental space elements side-by-side, with descriptions of the elements and, in most cases, illustrative quotes. This is intended to highlight the parallel nature of these ideas and to relate to the diagrams (Figures 2-7) that accompany the blending results.

| **Area** | **Perimeter** |
|---|---|
| <u>Infinite decreasing process</u><br>Common among all 10 students was the element that area is the result of an infinite, decreasing process. For example: | <u>Infinite increasing process</u><br>All 10 students conceived of the perimeter of the ST as the result of an infinite |

| | |
|---|---|
| Carmen: *So, ok eventually the area gets to zero, but that's if you could do it infinitely many times. And if you actually conceptualize doing infinitely many times you're never gonna stop.* | increasing process. Elise's reasoning is typical of this thinking:<br><br>Elise: *You're just like forever adding length to your perimeter, so I feel like your perimeter is forever increasing.* |
| <u>Area removed at each step</u><br>All students except Curtis there was explicit use of the justification that area is removed at each step. Two students computed the first few steps during their interviews.<br><br>Kay: *We're always taking out the middle triangle of each equilateral triangles and we're doing that infinitely so it's like we're taking away area with each iteration.* | <u>Perimeter is added at each step</u><br>All students except Curtis also pointed to the fact that perimeter is added at each step. Four students accompanied this with computation for the first few iterations.<br><br>Joy: *I think it goes towards infinity because each iteration you're creating more triangles and so you're creating, you're adding to the perimeter.* |
| <u>Change in the rate of change</u><br>Shani and Kay, who were in the same group, were the only two students who concluded that the area tended to something non-zero. They were also the only two who shared what we refer to as the change in the rate of change for area element, as exemplified in this excerpt.<br><br>Shani: *As we keep taking off little pieces and more become white, it's getting smaller and smaller. Or the amount that it's increasing is getting smaller and smaller and smaller.* | <u>Change in the rate of change</u><br>Two other students, Elise and Carmen, gave some consideration to the rate at which the perimeter increases and to changes in this rate. For example, Elise argued that<br><br>Elise: *Every time after the first iteration I'm adding more perimeter than I added before. So if I keep adding more then I think it's going to keep going to infinity because I'm just going to keep adding bigger and bigger.* |
| <u>Each step decreases by a factor of ¾</u><br>Only one student, Curtis, reasoned about the area in a multiplicative manner. All other students focused on the removal of area at each step, which suggests an additive conception.<br><br>Curtis: *Each time, [the area is] 3/4 the previous, so, I mean, I know that when you keep multiplying 3/4 by itself you get, you get zero out.* | <u>Each step increases by a factor of $^3/_2$</u><br>Only two of the 10 students, Curtis and Carmen, pointed to the fact that at each step the perimeter increases by a factor of 3/2. Curtis went further and expressed this formally with a limit as follows:<br><br>Curtis: *The whole thing increases by three-halves at each stage. So, you can just say that's three-halves to the n give you the perimeter at n.* |

Three other pairs of mental space elements were identified, but as they were used infrequently we mention them only briefly. Curtis was the only student to express a conception of area and perimeter as each composed of congruent components, not just as numeric sequences. This way of reasoning coincides with him being the only student to describe the area as decreasing by a factor of 3/4 at each step and one of only two who described perimeter increasing by a factor of 3/2 at each step. Kevin and Mia (groupmates) both indicated that "r>1" indicated divergence and "r<1" indicated convergence, with Kevin explicitly motivated by conceptualizing perimeter and area as geometric series. Finally, Mia conceived of the area of the ST as computed from "leftover" triangles and the perimeter as computed from "removed" triangles during the recursive creation process explored in class. In her interview, she drew these sets of triangles as distinct figures from which to compute area and perimeter.

**Summary for RQ1: Making sense of area and perimeter**

Students made sense of the area and perimeter of the ST, first and foremost, as infinite iterative processes. This in and of itself is no surprise, given the construction process students were introduced to in class. What *did* surprise is the fact that, except for Curtis, students used informal additive reasoning to reach their conclusions. The few students who did some computations did so only for the first few iterations and did not generalize the adding of perimeter or removal of area into algebraic expressions from which to take limits. While some students used limit language or referred to convergence criteria, it was not done concretely, despite their mathematics experience.

Given students' informal ways of reasoning, the parallelism between area and perimeter ideas is noteworthy. As seen in the previous section, each element of reasoning about area had a corresponding element of reasoning about perimeter. While some of these ideas were common (infinite processes, adding area, removing perimeter), others were not. In several cases students' idiosyncratic ways of thinking were consistent within students across area and perimeter. Curtis is the most obvious case, standing out by using multiplicative and more formal reasoning than the other students, but also Kevin's mentioning of geometric series, and Mia's reference to a convergence test. However, there were some discrepancies. For example, the two students who referred to change in the rate of change of area did not refer to it in the case of perimeter, whereas two students who referred to it in the case of perimeter did not refer to it in the case of area.

Despite the idiosyncrasies, there was quite a lot of consistency in ways of reasoning across students, both with respect to area and with respect to perimeter. Based on the fact that the students had previously discussed the area and perimeter of the ST in class, this might have been expected; however, we note that the interviews presented substantial differences to what we expected on the basis of the classroom discussions. Further investigation is needed to conclusively explain these shifts, but we speculate that conceptualizing the infinitely large (e.g., ST perimeter) may be easier than the infinitely small (e.g., ST area).

The two students who claimed that the area tended to something non-zero had been in the same group; they were also the only two students taking change in the rate of change into account when discussing area, and they might have discussed these issues at some stage. While a causal claim between this justification and conclusion that the area tends to something non-zero is not warranted, we suspect that focusing on the relative size of pieces removed suggested for these two students coupled with a strong grounding in the figure itself (as opposed to the result of an infinite process) contributed to their conclusion of non-zero area. On the other hand, the two students who referred to change in the rate of change regarding perimeter were in different groups. We also note that the two who referred to a convergence test (r >1, r<1) were in the same group, though Kevin was more specific than Mia. Themes within group members' reasoning are also seen in the following blending section, but again they are not totally consistent.

## Results 2: Blending Area and Perimeter

As the previous section detailed the input space elements, we do not revisit the nature of those elements in any detail but instead focus on the blended spaces. One element appears in each student's blended space which did not appear in the area/perimeter section: *infinite creation process*. This element is a result of fusion, wherein two input space elements (here, infinite increasing and infinite decreasing) are projected onto one element. As students were introduced to the ST as something created through an iterative, recursive process affecting both area and perimeter, in a sense the students are re-fusing elements which they originally separated. To organize these ideas, a three-part diagram is used: rectangles represent mental spaces, with the upper rectangles representing the input mental spaces and the lower rectangle representing the blended mental space, and the lines show mappings between the spaces (Figures 2-7).

**Joy.** We gained access to Joy's blending process primarily through her response to Fred's argument. Her blended space (Figure 2) is composed of the infinite process of creating the Sierpinski Triangle, the area tending to zero, and perimeter tending to infinity. Completion brought into the blended space a metaphor of *perimeter as fence*, along with several entailments. One such entailment is that fences should remain, even if the space they enclose is no longer there. Part of Joy's elaboration based on this frame, as she worked to resolve Fred's paradox, was to say that "we don't count their space, but there is still a perimeter associated with it." Another entailment of the fence framing is that not only do fences have length, but they also take up space. This contributed to another element of Joy's elaboration, that the perimeter will fill in the Sierpinski Triangle, "so eventually in a sense it's all fence." Some parts of Joy's elaboration were grounded in a physical metaphor, and she recognized this when responding to Fred. She added to her elaboration that the Sierpinski Triangle is "not a real object," and identified the juxtaposition of an infinite mathematical process with the physical world as "where the disconnect is."

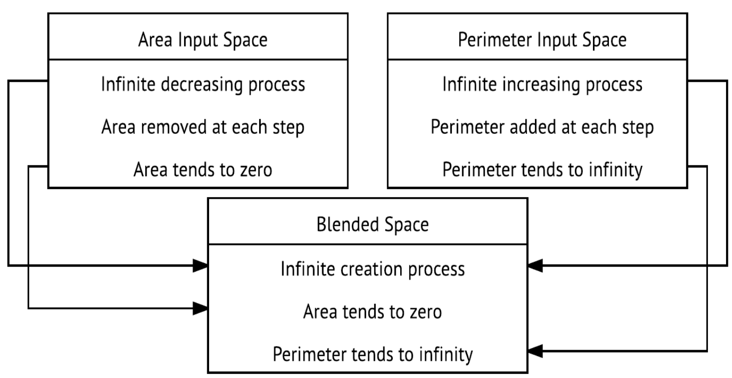

*Figure 2. Blending diagram for Joy's reasoning.*

**Elise.** Like Joy, Elise's blended space is composed of the infinite process of creation for the

ST, perimeter tending to infinity, and area tending to zero (Figure 3). However, the framing metaphor that completes Elise's space is one of a skeleton, not a fence. She elaborated her blend, saying, "I'm thinking of our perimeter as like, like I guess I think at the end of this I have this skeleton, so I have no area, nothing is left inside" This skeleton metaphor brings with it entailments of bones remaining when flesh has gone, clearly mapping perimeter to bones and area to flesh. In addition, we note that Elise mentioned "at the end" in her elaboration, perhaps hinting that she sees the ST as an abstract object at the end of a generating process.

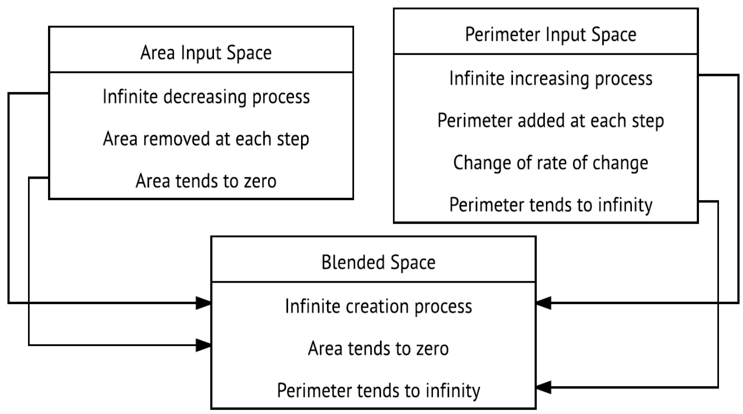

*Figure 3. Blending diagram for Elise's reasoning.*

**Curtis.** As with Elise and Joy, Curtis's blended space is composed of an infinite creation process, perimeter tending to infinity, and area tending to zero (Figure 4). Unique to his blended space, however, is his formulation of these tendencies. He wrote area as $lim_{n\to\infty}\ (\frac{3}{4})^n$ and perimeter as $lim_{n\to\infty}\ (\frac{3}{2})^n$ and computed the limits of each sequence, obtaining 0 and $+\infty$ respectively. The completion process brought in a zooming frame, saying, "we could say you could zoom in for infinitely, as much as you want, and you could get like these as tiny and tiny as you want, there's still more perimeter to draw" when prompted with Fred's paradox. The second frame we saw Curtis leverage is one related to mathematics classes (e.g., Calculus, Analysis) where symbolic manipulations are sufficient. Evidence of this comes from the fact that Curtis did not encounter a paradox when considering an object with zero area and an infinite perimeter on his own, something he elaborated by saying "this isn't like, not physically drawing something like a perimeter, it's kind of just a concept."

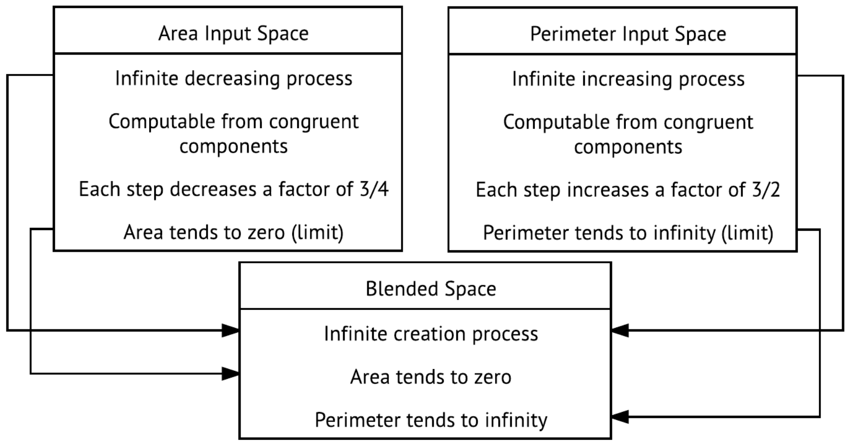

*Figure 4. Blending diagram for Curtis's reasoning.*

**Carmen.** Carmen's blended space is, like several others', composed of an infinite process of creation, area tending to zero, and perimeter tending to infinity (Figure 5). The completion of her blend, however, was particularly distinct. She brought in a calculus frame and identified "analogies to calculus or real analysis," including Riemann sums, that she saw as similar to Fred's paradox. The "calculus arguments" that she referenced seem to imply, to Carmen, that Fred's paradox is like other paradoxical situations that she has seen in previous mathematics courses. Upon reading Fred's arguments during the interview, Carmen stops to query whether "the perimeter can't really be infinitely long" implies zero perimeter or some non-zero finite length (for Fred). She proceeds to resolve the dilemma by eliminating each, leaving only the possibility that the perimeter is indeed infinite and Fred is wrong. During this episode, two more frames appeared. Like Joy, she brought in a fence metaphor for the perimeter and the entailment that fencing should remain, but did not use the idea that fences take up space. Her elaboration using the fence frame, "you have sort of your old triangle fences that you had before [...] we still have this fence around, that big triangle and the center, and we still have those other ones we made before," is how she argued that the perimeter of the ST cannot be zero. Finally, she brought the frame of self-similarity, with the entailment that "we can keep zooming in." The elaboration using this frame was that the perimeter cannot be a finite value, which she explained using a contradiction. Carmen said, "I think if we could [stop] then you could say ok it's this number," but the zooming goes on forever, "so that's kind of why it can't be a number."

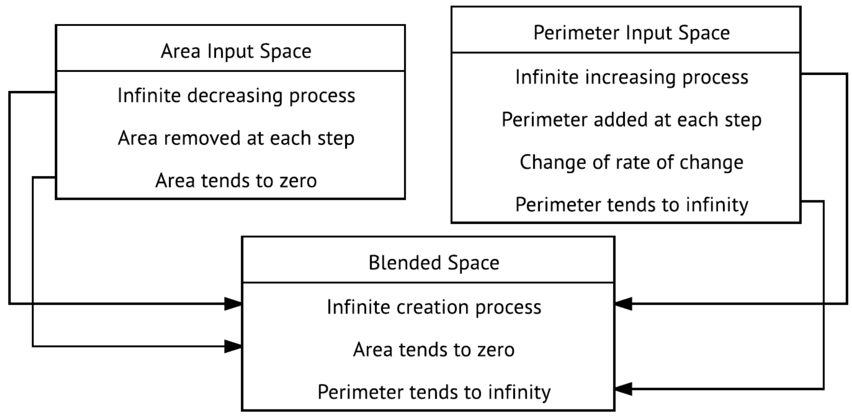

*Figure 5. Blending diagram for Carmen's reasoning.*

**Sam.** Sam's blended space is composed of the infinite process of creation, area tending to zero, and perimeter tending to infinity (Figure 6). The composition also includes a unique fusion of removing area at each step and adding perimeter at each step, so that one element of his blended space is the *simultaneous* addition of perimeter and removal of area. He clearly said that "as you keep adding triangles you're taking chunks from the area [...] and because you keep taking chunks out of it you're adding triangles you're adding perimeter." Sam completed his blend by bringing in a frame about the nature of infinity and infinite iterative processes, saying about area that "*at infinity* it's going to 0. It's not before infinity." These tools allow him to elaborate his blend, establishing that Fred's paradox only exists if the process stops at a finite stage, or "if it's before infinity [Fred's] statement will be right."

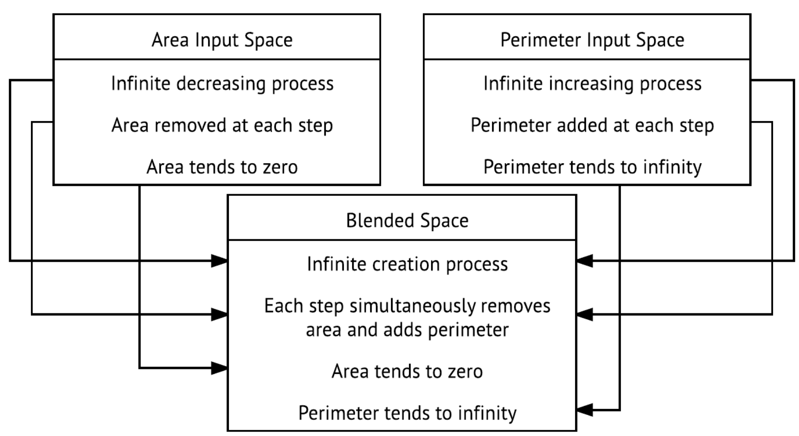

*Figure 6. Blending diagram for Sam's reasoning.*

**Kevin.** Kevin's blended space is composed of the infinite process of creation, the perimeter tending to infinity, and an area that converges without committing to a value (Figure 7). When asked about the area and perimeter of the ST in the interview, Kevin immediately responded with: "perimeter can be defined as a geometric series that diverges, and then the area converge and to me that indicates it's not dimension 1 or 2 but somewhere in between." Kevin's thinking was difficult to unpack, particularly differentiating between the completion and elaboration of his blend. We have evidence that he saw a relationship between Fred's paradox and the non-integer dimension of the ST, which is an irregular object - but is difficult to say what is the frame and what is the elaboration. Kevin is one of the students whose blending process was difficult to access, maybe because it had solidified in the time between the class activity and the interview. Nevertheless, we can see the results of the blending process. The blend we can identify supports his interpretation of the root of the paradox, explaining that "it seems like Fred is assuming that [the ST] has to be a natural number dimension. So, if it has no area, then it can't have a perimeter because it wouldn't make sense for it to have one, but not the other."

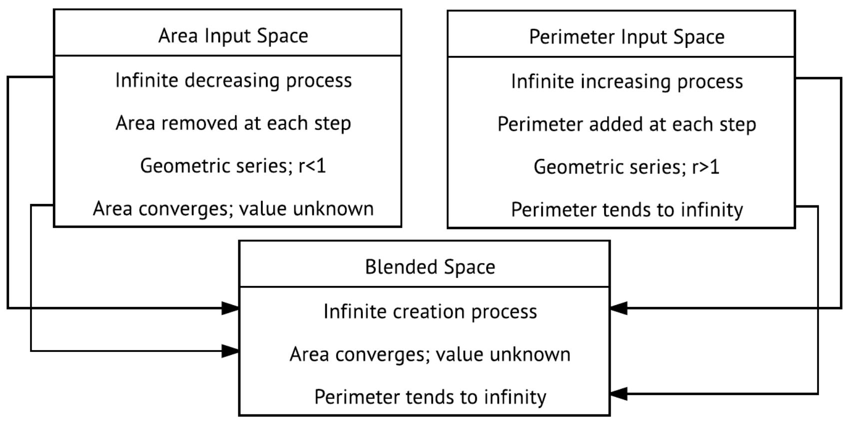

*Figure 7. Blending diagram for Kevin's reasoning.*

**Shani, Kay, and Soo.** The group of Shani, Kay, and Soo had similar blending processes and so we address them together. In particular, this group saw the perimeter as infinitely decreasing, but not converging to zero. Shani and Kay described perimeter as converging to some "infinitely small" yet nonzero value, while Soo described an unending decreasing process which never reaches zero. While researchers can see the nuanced differences between these two conceptualizations, both resulted in students composing similar blended spaces that did not include "zero area," and this contributed to the fact that none of the three encountered Fred's paradox. Shani and Soo's completion processes were framed by their understanding that the process does not end, and we have no evidence of elaboration on their part. Kay's completion, however, brought in a frame of perimeter with the entailment that "a perimeter encloses something."

These different frames were particularly evident in their responses to the interviewer's prompt to consider, as a thought experiment, whether or not Fred's argument would make sense *if* he was correct that the perimeter "went to zero." Shani did not engage with the thought experiment, instead returning to her statement that the area of the ST did not go to zero. Kay engaged with this, and her frame of perimeter as something that encloses led her to an elaboration that "[the perimeter] could be just kind of wrapping either around itself or so kind of close together, it basically is like almost a single line or something." Soo, however, more deeply considered the possibility of the perimeter going to zero and in fact displayed a second round of conceptual blending. This second round, which included the idea that the area of the ST goes to zero, triggered a different completion process of regular and irregular triangles, in which she declared that "[Fred's argument] doesn't make sense in general if you are looking at just regular triangle and then see perimeter and then area relationship. But we are looking at Sierpinski triangle." While she engaged with Fred, and was the only one of her group who recognized and grappled with the paradox, we saw no further elaboration.

**Mia.** Mia was a special case. As noted in the discussion of the first research question, she conceptualized the ST as two figures: the triangles that remain and the triangles which were removed during the recursive creation process. In talking about the coordination of area and perimeter, she clearly stated that "when we're talking about the perimeter, we're looking at the triangles that we're taking out, and when we're looking at the area, we're looking at the area of the triangles that are left over," and accompanied this with sketches of both 'sets' of triangles. This composition, with two distinct figures, does not seem to make sense to Mia - she was unable to move past this contradiction, she did not engage with Fred's paradox, and we did not identify any completion or elaboration.

**Summary for RQ 2: Coordinating area and perimeter and coping with the paradox**

Our analysis of students' blending processes, especially as provoked by encountering Fred's argument, revealed how students deal with the paradox of coordinating infinite perimeter and zero area associated with the ST, and how they cope with, or resolve, the cognitive dissonance it provokes. It was sometimes challenging to unpack and distinguish the completion and elaboration processes. We attribute this difficulty in part to the fact that this was the second opportunity in which the students were prompted by Fred's paradox. Having detailed each individual student's blend previously, we now comment on what we learned.

All students *composed* a blended space from their area and perimeter input spaces following Fred's prompt, and most of them also *completed* their blended space with additional frames, which then supported *elaboration* of the blend - leading to new implications. In two students' interviews we saw evidence of completion but not elaboration (Shani and Soo); only for one student (Mia) we do not have evidence of completion.

We saw one commonality across all students' composition processes: the fusion of *infinite (increasing) process* and *infinite (decreasing) process* into a unified *infinite creation process* for the stepwise creation of the ST. This is not to say that there was a shared conception of exactly what happens at each step, only that the process is infinite. This can explicitly be seen in the case of Mia, who envisioned an infinite process that created two separate figures. We purposefully refer to these elements as *infinite*, with all the ambiguity about potential/actual infinity it entails, because our data does not support conclusions about the nature of students' conception of the infinite.

We found that four students did not encounter the paradox on their own, and this seems related to the composition of their blended spaces. That Mia's blend was composed of processes based on two distinct figures (removed vs. leftover triangles) prevented her from encountering a paradox, since she did not see one figure with infinite perimeter and zero area. Shani and Kay's input spaces for area included a non-zero limit for area, and their completions allowed them to coordinate this without experiencing a paradox. Soo is the fourth who did not encounter the paradox on her own, because she did not see an end where area would equal zero, but she was able to entertain the idea of an object where the paradox might exist.

While composition is an important part of the coordination of area and perimeter, and explained who encountered the paradox or not, it was not enough to explain students' different ways of reasoning. For example, the blending spaces of Joy, Elise, Curtis, and Carmen included the same three elements, but they completed these spaces with different frames and/or different entailments of similar frames. For each student (except Mia), we have evidence of 1-3 distinct frames being used to complete their blended spaces. In all the cases, one of the frames has to do with the nature of mathematics – e.g., the nature of infinite processes. This might be expected, as the paradox itself is rooted in a mathematical context. However, four students also used physical frames (fence, skeleton, zooming-in) and their entailments to coordinate area and perimeter and to make sense of that coordination.

Elaboration of the blend was the most varied of the processes we analyzed, due in part to its dependence on both the composition and completion of the blended spaces. We observe that students could arrive at similar conclusions based on very different lines of reasoning (e.g., Joy and Curtis concluding that the ST is a mathematical concept, not a real object) and that students with superficially similar starting points could bring in different frames and reach different conceptualizations. Our approach, using conceptual blending, allowed us to see these nuances as students' lines of reasoning separated and coalesced in a non-deterministic way.

## Discussion

The in-class Sierpinski Triangle activity was intended to be a brief interlude, a relatively simple yet interesting task that would serve as motivation for a discussion about self-similarity and later fractal dimension. However, it proved to be challenging for the students. The classroom discussion, and the interview question it prompted us to ask, proved very rich for exploring how students reason about features of the ST.

The design of our interview question sequence is worth revisiting. We included an actual classroom episode as a hypothetical question about Fred's claim for students to engage with. This allowed us to investigate the extent to which students maintained the ideas expressed in a classroom discussion, pick out nuances of individual thinking that were not accessible in the larger group, and see how students would defend and elaborate their ideas in the face of an alternative view (Rasmussen, Apkarian, Dreyfus, & Voigt, 2016). Students' responses to Fred's argument were, in general, deeper than their original responses to the interview task. This may be a function of our participants' career paths as instructors, their enculturation into a classroom where mathematical arguments were normative, or something else entirely – nevertheless it was a rich source of data about students' reasoning and understanding of the topic.

As the 10 students we interviewed were in the same graduate program, part of the same class, had worked together and discussed the Sierpinski Triangle (including Fred's argument), we expected to see some consistency in their responses. As seen at every stage of our analysis, this was not the case. To be sure, some ideas about the nature of the infinite iterative process were present in all interviews. But while in class students seemed comfortable with the idea that the area of the ST goes to zero, and concerned about what happens to the perimeter, *all* students' input spaces for perimeter included that it was infinite, and only six of the ten spaces included area going to zero. There were other idiosyncratic elements present in students' input spaces such as Curtis's multiplicative reasoning about components and Mia's conceptualization of the ST as two separate figures.

There were also idiosyncrasies in terms of the composition of blended spaces. Though most students had the ideas of perimeter being added and area being removed at each step, only Sam fused these ideas and mapped them to his blended space. While several students had blended spaces composed of the same elements, the development of those spaces showed more variation. Some students completed their blends with ideas from calculus or analysis (e.g., Carmen, Curtis), fractal dimension (e.g., Kevin), and metaphors (e.g., Joy, Elise). These frames resulted in varied elaborations. Some related to the nature of the ST, such as "it's not a real object" (Joy), its non-integer dimension (Kevin), or that is only the remaining outline (Elise's skeleton, Carmen's fence); others framed the nature of the paradox itself, such Sam's statement that the paradox only exists "before" infinity.

Some of the less common elements of students' mental spaces may be attributable to groupwork. Kay and Shani were the only two to insist that area converged to a nonzero value, and the third member of their group, Soo, was not entirely certain; Kevin and Mia are the two who mentioned "r>1 and r<1;" Carmen and Joy are the two who used a fence metaphor. However, groupmates' blending processes were not always parallel in structure. While Carmen and Joy both use a fence metaphor to complete their blends, the entailments of that metaphor and how they elaborated using that frame were markedly different. Altogether, we conclude that while classroom conversations and small group work affected students' thinking about the ST, there are individual idiosyncrasies that cannot be attributed to these collaborative efforts.

More generally, our analysis methods allow us to point to some of the precise points of departure, from initial ideas to completing frames and final elaborations, one of the methodological implications of our work for future researchers. Along with Zandieh et al. (2014), our articulation of the component process of conceptual blending in a mathematical context allow for nuanced analysis of students' reasoning – though they looked at group blends and types of blends, while we look at more individualistic reasoning. This is particularly relevant for situations where students must bring together multiple ideas. Identifying all three processes - composition, completion, and elaboration - allows us to examine not only the main ideas students mention, but how they are used and enacted, or what leverage they give students in thinking about mathematical objects. This is in contrast to other lenses which make claims about the level of students' understanding, the extent to which their ideas are normative, or the conceptual structures that they might "possess." We are particularly impressed with the analytic power of the completion process, allowing us to articulate the tools by which students elaborate their blends. Thus, our analyses lie fully within the domain of enacting ideas.

Our use of these processes as analytic tools allowed us insight into student thinking that, on the surface, appeared as a jumble of ideas and conclusions with little connection. We further see that the completion process, that of recognizing elements and bringing in a frame and its entailments, was critical in students' ability to think deeply about the ST. Regardless of how a blended space is composed, it was completion which allowed for elaboration and the formation of new understandings.

Graduate Student Instructors' Growth as Teachers: A Review of the Literature

Erica R. Miller, Karina Uhing, Meggan Hass, Rachel Zigterman,
Kelsey Quigley, Nathan Wakefield & Yvonne Lai
University of Nebraska-Lincoln

*In recent years, providing teaching professional development for graduate student instructors has become more common in mathematics departments in the US. Following this trend, mathematics education researchers have begun to conduct studies on professional development programs and on graduate students as future mathematics faculty. The purpose of this literature review is to examine the current status of research in this field and make recommendations for future research on graduate student instructors and professional development. In examining the literature, we found that there are few studies that have researched graduate student instructors' growth as teachers. However, those studies that do address growth attend to it in three ways: by examining growth over time, by taking a stance on what constitutes desirable growth, and by using models or theories of growth.*

*Keywords:* Graduate Student Instructors, Professional Development, Teacher Growth, Literature Review

## Introduction

In recent years, undergraduate mathematics educators have focused on helping graduate students develop as teachers. Most large universities rely on graduate students as an integral part of their teaching staff and therefore, many undergraduate students are impacted by the quality of their teaching (Belnap & Allred, 2009). Additionally, many graduate students go on to teach after graduation; hence we can view graduate school as a training ground for their work as teachers as well as researchers. To help prepare graduate students as teachers, an increasing number of mathematics departments across the U.S. have begun designing professional development programs specifically focused on teaching.

Indeed, at the 2017 Conference for Research on Undergraduate Mathematics Education there were at least eight different presentations on graduate student instructor (GSI) professional development. A striking aspect of these presentations was the variety of approaches, methodologies, and theories used. One theme we noted in many of the presentations was a focus on how graduate students grow as teachers over time[1].

With this in mind, we reviewed the research literature on how mathematics GSIs learn to teach. Our goal was to identify and characterize the models and theories that have informed studies of GSIs' growth as teachers. We sought to take stock of what is known about improving GSIs' teaching, what gaps there may be, and how to move forward. To do this, we asked: *How have researchers studied mathematics GSIs' growth as teachers?*

In this literature review we report on the results of a Grounded Theory analysis of three major research databases from 2005 to 2016: Education Resources Information Center (ERIC), PsycINFO, and Web of Science, as well as the RUME proceedings from 2010 to 2016 and the AMS Notices from 2005 to 2016. We describe the current state of research in the field of

[1] Here we define growth as the process of changing along an identifiable trajectory. For something to be considered growth, it must be true *that* something has changed and that exactly what has changed can be *identified.*

mathematics GSI professional development, describe emergent themes, and discuss the implications of these themes for future research. Finally, we make the central claim: *graduate student instructors' growth as teachers is a largely unexamined practice*.

## Using a Grounded Theory Approach

We felt that grounded theory was the most appropriate research design to answer our research question. According to Creswell (2013), "the intent of a grounded theory study is to move beyond description and to generate or discover a theory, a 'unified theoretical explanation' (Corbin & Strauss, 2007, p. 107) for a process or action" (p. 83). We chose this design because we wanted our review to move beyond just describing the literature on GSIs' growth as teachers and generate a theory for how researchers have studied GSIs' growth. In other words, the process or action that we wish to study is the ways in which researchers study growth.

### Need for Theory Development

A key aspect of grounded theory research is that "this theory development does not come 'off the shelf,' but rather is generated or grounded in data from participants who have experienced the process" (Creswell, 2013, p. 83). There has been an increase in the number of researchers studying GSIs' growth as teachers, but researchers have examined this phenomenon in very different ways. While studying a phenomenon from different perspectives can bring light to different aspects, it is also important for research to be connected and not isolated. Therefore, we thought it was important to conduct this literature review in order to examine and build these connections.

### Researcher Positioning

Researcher positioning, or reflexivity, is another important characteristic of grounded theory research. In order to make it clear how the researchers are positioned in the study, they should "convey...their background (e.g., work experiences, cultural experiences history), how it informs their interpretations of the information in the study, and what they have to gain from the study" (Creswell, 2013, 47). Our background, as a research team, is in studying how professional development impacts graduate students' growth as teachers. Therefore, we are particularly interested in and aware of research in this area. This personal interest influences how we interpret the literature and our sensitivity to ways in which our research is similar to and different from other, related, research. While one of the articles included in our literature review was co-authored by a member of the authorship team, this individual was not responsible for coding this article. Also, the work that we have published together was not included in the review, since it was published in 2017.

### Sampling

Another key aspect of conducting grounded theory research is utilizing theoretical sampling. Since the purpose of grounded theory is to develop a theory of a process or action, theoretical sampling is used to choose participants that would best help the researcher form the theory (Creswell, 2013). In our study, we started by sampling from databases that index the major peer-reviewed publications in mathematics education. When this sampling did not return as many results as we expected, we decided to sample from some other peer-reviewed publications that we knew published research on GSIs' growth as teachers but were not indexed by the original databases that we searched.

## Coding

Open coding is an essential part of grounded theory analyses. Open coding refers to "coding the data for its major categories of information" and then using constant comparison to identify and refine emergent themes (Creswell, 2013, p. 86). Once we identified articles that studied GSIs' growth as teachers, we open coded them using descriptive codes (Miles, Huberman, & Saldaña, 2014) in order to summarize how researchers were studying GSIs' growth as teachers. After this first cycle of coding, we went through a second cycle of pattern coding in order to group the summaries produced by the first cycle of open coding "into a smaller number of categories, themes, or constructs" (Miles, Huberman, & Saldaña, 2014, p. 86). Finally, we shared the memo summaries that we wrote for each article with the original authors in order to conduct member checking and validate that our interpretation of the article matched their original intent.

## Methods

All articles considered for inclusion in the review were peer-reviewed and contained at least one search term from each of the following four categories: teaching, domain, level, and participants (see Table 1 for exact search terms). This yielded 1,889 articles. We read each abstract to determine if an article could reasonably address our research questions. We double-coded until we reached consensus on the criteria for inclusion, with an inter-rater reliability of 97%. After discussion, we agreed to include only articles that focused on novice instructors teaching collegiate mathematics. This excluded, for example, articles that discussed GSIs teaching STEM classes in general. As a result, we identified seven articles that were relevant. To capture other relevant research on this topic, we then turned to the proceedings of the RUME conferences, as we were aware that relevant articles were published there. We read the abstracts of the RUME proceedings for the years 2010 through 2016 (we restricted our time frame due to infrequency of relevant articles), again coding for inclusion, and found 17 relevant articles. Finally, we searched the AMS Notices using an advanced Google Scholar search for the years 2005 through 2016 using the same search terms in Table 1 but excluding the "domain" category. This yielded an additional two articles, which gave us a total of 26 articles that focused on novice instructors teaching collegiate mathematics.

Each article was then open coded for teaching practices and whether or not the authors used an explicit or implicit model or theory of how GSIs grow as teachers. Six articles were double-coded, at which point the team discussed preliminary findings and how to adjust the coding procedure. After consensus was reached, the rest of the articles were coded.

*Table 1. Search Terms*

| Category | Terms |
|---|---|
| Teaching | teach*, instruct*, "professional development", PD, training, TD |
| Domain | STEM, math* |
| Level | undergrad*, collegiate, tertiary, college |
| Participants | "graduate student", novice*, "future faculty", beginning, GST, GSI, GI, GTA, TA |

## Findings

Of the 26 articles that addressed novice mathematics GSIs' teaching, 16 addressed some aspect of growth. Among these 16 articles, three themes regarding growth emerged: studying growth over time, taking a stance on growth, and using a model or theory of growth. The "studying growth over time" theme took the form of studies that addressed some change in teaching over time among GSIs. In accordance with our definition of growth, these articles both *identified* something that changed and described *how* it changed. The second theme, which we call "taking a stance," can be described as any article that explicitly stated what sort of change would be desirable among GSIs. It is important to note that some articles that addressed change over time did not take a stance on growth. Lastly, the theme called "using a model or theory of growth" describes the papers that call upon theoretical or empirical models of growth from the literature to support their arguments about growth in teaching. We will elaborate on these three themes below by providing thick descriptions of articles that illustrate each theme.

**Studying Growth Over Time**

In total, ten of the 26 articles (38.5%) addressed growth over time. These studies addressed a range of topics, including change in beliefs, knowledge, and teaching practices. Here, we describe three of them. First, in 2005, Speer, Gutmann, and Murphy called upon the community to produce more longitudinal research to examine how GSI's instructional practices, beliefs and expectations evolved over time. In an effort to foster collaborations between K-12 and undergraduate mathematics education, the authors reviewed work related to GSI professional development and drew parallels to work in K-12 teacher education. The authors emphasized the importance of GSIs in undergraduate mathematics education, reviewed current trends and developments in GSI professional development programs, drew connections to K-12 research, highlighted research in progress on GSI professional development, and provided suggestions for future directions of research. While these authors did not use the language of growth, their discussion of identifying and advocating for change in teaching is compatible with the definition of growth used in this literature review.

Another example of an article addressing growth over time is Raychaudhuri and Hsu's (2012) longitudinal study. The authors explored how math GSIs' ontological and pedagogical beliefs regarding mathematics changed over the course of teaching for a year. Their initial findings indicated that these two types of beliefs could conflict with one another. In their paper, they argue that GSIs' knowledge of students can be classified as behaviorist-teacher-centered or constructivist-student-centered. Again, we see the authors identifying and studying an aspect of teaching that changed over time; in this case, the focus was on GSIs' beliefs about teaching and learning.

More recently, in 2016, Musgrave and Carlson showed that GSIs can develop deeper conceptual mathematical knowledge, which they argue helps them to become better teachers. In particular, the authors looked at how GSIs conceptualize average rate of change (AROC) before and after a professional development intervention. The authors found that before participating in the intervention, GSIs focused on computational or geometric interpretations of AROC. After the intervention, some GSIs were able to express a more conceptual understanding of AROC. We view this as an example of studying how knowledge can grow over time. Notably, these authors also take a stance on knowledge, claiming that deeper conceptual knowledge of AROC is desirable; we explore this theme more thoroughly next.

**Taking a Stance on Desirable Growth**

Eleven of the 26 articles (42.3%) took a stance regarding desirable growth. Many authors drew upon established frameworks or standards for teaching in order to form their stance. For example, in their 2005 *AMS Notices* article, Deshler, Hauk, and Speer advocated for increased pedagogical content knowledge. In this theoretical article, the authors summarized different types of GSI professional development and provided suggestions for what it should include. In their model for GSI professional development, they recommend an initial "intensive" experience followed by sustained follow up sessions spaced out across time. The authors argue that developing pedagogical content knowledge is a key part of effective instruction as it helps GSIs to anticipate and use student thinking, attend to both computational and conceptual understanding, and orchestrate productive class discussions. Finally, the authors emphasize that in order to evaluate GSI professional development, it is important to pay attention to the changes in GSIs' knowledge and beliefs about teaching, learning, and doing mathematics.

Yee, Rogers, and Sharghi (2016) studied the development of GSIs' teaching practices by comparing them to the NCTM's *Principles to Actions* (2014). They used these teaching practices because they "provide a framework for strengthening the teaching and learning of mathematics" (NCTM, 2014, p. 9). In this qualitative multiple case study, the authors examine the teaching practices of ten GSIs as they implemented an intensive iterative lesson study process across two universities. Yee et al. examined whether or not GSIs' mathematical teaching practices evolved over the span of a two-week involvement in an iterative lesson study process and used their stance regarding the development of teaching practices to argue that Lesson Study was a useful form of GSI professional development.

Finally, Friedberg (2005) argued in his theoretical article that while the primary focus of math graduate school is for students to become mathematicians, it is also important that students also become effective communicators and teachers of math. Working under the presumption that "the analysis of experience can contribute to good judgment" in teaching, Friedberg argues that case studies provide an opportunity for math GSIs to improve their judgment in teaching-related issues. He and his colleagues developed 14 different case studies as part of the Boston College Mathematics Case Studies Project. In the article, Friedberg discusses some of the GSIs' experiences learning from the case studies and reiterates how important it is for GSIs to improve their teaching, since developing the communication, listening, and group work skills required for effective teaching is important for their future careers. Ultimately, Friedberg takes the stance that mathematics graduate students should grow in their ability to effectively communicate mathematics.

**Using a Model or Theory of Growth**

Three of the 26 articles (11.5%) called upon a model or theory of growth; we will describe each of them here to illustrate this theme. First, a 2011 study by Beisiegel investigated obstacles to teacher education among GSIs. In this empirical qualitative study, the author sought to uncover issues and difficulties that impact mathematics graduate students' views of their role as an undergraduate instructor. The author found that graduate students feel the need to replicate teaching practices and emulate the identities of other members of the mathematics teaching community, which results in feelings of resignation. Using Lave and Wenger's (1991) theory of legitimate peripheral participation in relation to communities of practice, the author argues that the attention to legitimate peripheral participation in a mathematics department prevented graduate students from adopting alternate modes of teaching. Here, we see the author explicitly drawing upon a theory of growth to inform the arguments made in the study. A stance regarding growth is also taken; the author argues that novices should gain knowledge and understanding about the practices of a community (desirable growth) but that legitimate peripheral participation prevents graduate students from adopting alternate modes of teaching (undesirable growth).

Both of the remaining articles that use a model or theory of growth were written by Nepal (2014; 2015). In the earlier article, Nepal studied graduate students who were not yet teaching a course and investigated how their teaching philosophies changed over a semester of professional development. The author found that all of the beliefs that were present at the beginning of the semester were still present at the end, but that new beliefs were also formed throughout the semester. The second article extended this work by following the GSIs through their first three semesters of teaching and investigated how their beliefs changed during this period of time. The author argued that while beliefs changed little during the pre-service phase of professional development, more significant changes occurred during the in-service phase; specifically, several of the GSIs expressed a belief that they should become more authoritative in the classroom. In both of these studies, Nepal framed his studies around context-based adult learning theory, which is an extension of Vygotsky's (1978) sociocultural theory. He claims that GSIs' beliefs are "developed, changed, or reinforced as they learn more about teaching and learning, and these changes are reflected in their teaching philosophies" (Nepal, 2014). As in Beisiegel's article, an explicit reference to models or theories of growth is made in order to support the overall arguments that are made.

Above we gave in-depth descriptions of the three themes; our overall findings are summarized in Table 2. Note that ten of the articles in the original pool did not address growth at all and are therefore not included in this table.

*Table 2. Articles Addressing Growth*

| Authors and Date | Type | Growth Over Time | Stance | Model or Theory |
|---|---|---|---|---|
| Speer, Gutmann & Murphy (2005) | Theoretical | 1 | 0 | 0 |
| Friedberg (2005) | Theoretical | 0 | 1 | 0 |
| Soto-Johnson, King & Haley (2010) | Empirical (Quant) | 0 | 1 | 0 |
| Beisiegel, (2011) | Empirical (Qual) | 0 | 1 | 1 |
| Raychaudhuri & Hsu (2012) | Empirical (Qual) | 1 | 0 | 0 |
| Speer & Firouzian (2014) | Empirical (Qual) | 0 | 1 | 0 |
| Miller & Wakefield (2014) | Empirical (Qual) | 1 | 0 | 0 |
| Nepal (2014) | Empirical (Qual) | 1 | 0 | 1 |
| Firouzian (2014) | Empirical (Qual) | 0 | 1 | 0 |
| Deshler, Hauk & Speer (2015) | Theoretical | 1 | 1 | 0 |
| Nepal (2015) | Empirical (Qual) | 1 | 0 | 1 |
| Firouzian & Speer (2015) | Empirical (Qual) | 0 | 1 | 0 |
| Reinholz, Cox, & Croke (2015) | Empirical (Qual) | 1 | 1 | 0 |
| Yee, Rogers & Sharghi (2016) | Empirical (Qual) | 1 | 1 | 0 |
| Musgrave & Carlson (2016) | Empirical (Qual) | 1 | 1 | 0 |
| Duncan (2016) | Empirical (Qual) | 1 | 1 | 0 |
| Totals | | 10 (38.5%) | 11 (42.3%) | 3 (11.5%) |

## Discussion

In 2005 Speer, Gutmann, and Murphy called on the community to conduct more longitudinal research on GSIs. One means of conducting further longitudinal research is by looking at how GSIs grow as teachers. In our literature review, we found only 26 articles that address novice mathematics GSIs' teaching. Of that small pool, ten of these articles (38.5%) did not focus on growth at all. Of the 16 articles that addressed growth in some way, none of them reflected all three emergent themes:  growth over time, taking a stance on growth, and the use of a model or theory of growth. Moreover, only three of the articles called on explicit models or theories of growth to support their arguments. It is important to note that ten of the studies addressing growth over time also demonstrated that growth is possible. Considering the importance of such results and the relatively small number of studies examining GSI growth, it is evident that more research is required to understand this phenomenon.

**Limitations**

While we made an effort to find as much of the literature on GSI professional development as possible, there are some limitations of our search that warrant discussion. We searched major research databases (ERIC, PsycINFO, Web Of Science) for peer reviewed articles as well as the RUME proceedings and *AMS Notices*; however, there are journals and proceedings from other conferences that are not included in these indices. We are also aware of other publications that are relevant, but they were included in books, which we did not include in our search. Another limitation is that we realized recently that we did not include the terms "post-secondary" and "postsecondary" in our search, so we may have missed some relevant articles.

**Recommendations for the Field**

Consistent with Speer, Gutmann, and Murphy (2005), we suggest that the field would be greatly enhanced by additional longitudinal studies exploring how GSIs grow as teachers. In addition, it would be beneficial to begin developing an accepted definition of GSI growth. We argue that part of this process is clearly articulating our stances as a research field on teaching quality and how they relate to models or theories of growth in teaching. It is striking that only one article took an explicit stance on both teaching quality and called on an existing model or theory of growth. We call for future research to take an explicit stance on teaching quality and how teaching quality is related to models and theories of GSI growth to better inform professional development for GSIs.

Finally, our findings suggest the need to develop explicit models or theories of growth in teaching that are linked to stances on teaching quality. There has been some progress on this (e.g., development of MKT by Thompson, Carlson, & Silverman, 2007), but more development is needed. We call for the research community to begin developing models of growth that will allow research on GSI professional development to grow into a richer body of literature.

## Annotated Bibliography[2]

*This article provides an overview of professional development efforts for mathematics GSIs in the US. The authors summarize different types of professional development models being used and provide suggestions for what it should include. In their model for professional development, they recommend that an initial "intensive" experience followed by sustained follow up sessions spaced out across time. The authors also highlight the importance of extending and adapting results from the K-12 literature on good instructional practices and teacher knowledge development to help inform research at the undergraduate level. In addition, they argue that developing pedagogical content knowledge is a key part of effective instruction as it helps GSIs to anticipate and use student thinking, attend to both computational and conceptual understanding, and orchestrate productive class discussions. Finally, the authors emphasize that in order to evaluate GSI professional development, it is important to pay attention to the changes in GSIs' knowledge and beliefs about teaching, learning, and doing mathematics.*

Duncan, A. (2016). Investigating a mathematics graduate students' construction of a hypothetical learning trajectory. In T. Fukawa-Connelly, N. E. Infante, M. Wawro, & S. Brown (Eds.), *Proceedings of the 19th Annual Conference on Research in Undergraduate Mathematics Education,* (pp. 696-703), Pittsburg, PA. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*In this report Duncan investigates how a GSI's instructional planning decisions and mathematical conceptions about angles and angle measurement changed as she worked through a provided hypothetical learning trajectory (HLT), and then created one for her students. The researcher began by using the literature to generate a HLT involving angle, angle measurement, and radius. She then used an initial interview to probe into the GSI's mathematical conceptions of these topics and modify the HLT accordingly. In two additional interviews she had the GSI work through the HLT, and then in a final interview she had the GSI create her own HLT that could be used in a lesson on angle and angle measurement. Duncan found that the GSI's conceptions of angle and angle measurement evolved as she worked through the HLT, and that these informed her construction of an HLT for her own students. From these results Duncan highlights that in order to improve instruction teacher educators must take into account teachers' prior mathematical meanings. Moreover, she argues that this process of having a GSI work through an HLT and then create one themselves can be useful in helping GSIs make accommodations to their conceptions of math and use this to better inform their instructional goals.*

Firouzian, S. S. (2014). Graduate students' integrated mathematics and science knowledge for teaching. In T. Fukawa-Connelly, G. Karakok, K. Keene, & M. Zandieh (Eds.), *Proceedings of the 17th Annual Conference on Research in Undergraduate Mathematics Education*, (pp. 617-623), Denver, CO. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*In this report Firouzian examines how GSIs use their mathematical and scientific knowledge when teaching the concept of derivative, as well as applied derivative problems. Using the results from two task-based interviews, Firouzian describes how the calculus GSIs utilized "integrated knowledge" of math and science when completing the teaching tasks. The purpose of this study was to determine whether this knowledge fits within existing frameworks for teachers' mathematical knowledge; in particular Firouzian draws upon Ball, Thames, and Phelps' (2008) egg model when making this determination. He found that this framework "did not capture all the elements of the GSIs' mathematical knowledge for teaching," but rather that the graduate students also utilized their knowledge for teaching science in responding to the interview tasks. Firouzian concludes by proposing that professional education for math GSIs should include opportunities for students to improve their scientific and mathematical knowledge for teaching.*

Firouzian, S., & Speer, N. (2015). Integrated mathematics and science knowledge for teaching framework. In T. Fukawa-Connelly, N. E. Infante, K. Keene, & M. Zandieh (Eds.), *Proceedings of the 18th Annual Conference on Research in Undergraduate Mathematics Education*, (pp. 524-536), Pittsburgh, PA. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*In this study Firouzian and Speer examined math GSIs' knowledge of student thinking when solving applied derivative problems. They interviewed eight math GSIs using a task-based protocol. In these interviews GSIs discussed difficulties students might encounter in a given applied derivative problem, as well as analyzed sample student work illustrating typical difficulties. Throughout the interview the GSIs were asked various questions meant to elucidate what type of knowledge they used in their responses. When analyzing these responses, Firouzian and Speer found that Ball, et al.'s (2008) MKT framework did not capture all of the knowledge for teaching that the math GSIs used. They instead offer preliminary theoretical constructs that might be useful to classify such knowledge, and call for more research into the nature of this knowledge. They conclude with a recommendation that GSI professional development programs include examples of student work on applied problems, and incorporate information on non-mathematical content knowledge needed to teach applications to science.*

Friedberg, S. (2005). Teaching mathematics graduate students how to teach. *Notices of the AMS, 52*(8), 842-847.

*In this article Friedberg introduces case studies as a tool for helping mathematics graduate students develop their teaching and communication skills. Working under the presumption that "the analysis of experience can contribute to good judgment" in teaching (p. 843), Friedberg argues that case studies provide an opportunity for math GSIs to improve their judgment in teaching-related issues. He and his colleagues developed 14 different case studies as part of the Boston College Mathematics Case Studies Project (published in the CBMS). These materials were then piloted at around 20 different post-secondary institutions. The goal of these materials was to provide GSIs with the opportunity to discuss teaching*

*issues with others, especially more experienced graduate students who could enrich the discussions by sharing their own experiences. The project received positive feedback from graduate students and faculty, and the materials have since been published. Friedberg concludes the article by reiterating how important it is for GSIs to improve their teaching, as the communication, listening, and group work skills required to teach effectively will be important in their future careers.*

Miller, N., & Wakefield, N. (2014). A mentoring program for inquiry-based teaching in a college geometry class. *International Journal of Education in Mathematics, Science and Technology, 2*, 266-272.

*This paper describes a mentoring process that took place over two consecutive semesters between an experienced teacher (an associate professor) and a novice GSI. During the first semester, the GSI observed an inquiry based learning (IBL) class that was taught by the professor, helped GSI for the class by holding office hours and grading papers, and taught a few lessons. During the second semester, the GSI was responsible for teaching the course while the professor attended the class and observed his teaching interactions. The professor and GSI would then meet weekly to discuss how the class was going. The experience changed how the GSI viewed teaching and learning and provided him with an opportunity to use IBL while being mentored by an experienced teacher. In addition to moving from lecture-based teaching to a more inquiry based teaching style, the GSI also changed the types of questions he used while helping students work. Overall, the mentoring experience helped the GSI develop as a teacher and influenced both the GSIs' teaching practices and beliefs about teaching and learning mathematics.*

Musgrave, S., & Carlson, M. P. (2016). Understanding and advancing graduate teaching assistants' mathematical knowledge for teaching. *The Journal for Mathematical Behavior, 45,* 137-149.

*This study investigated how mathematics GSIs conceptualize average rate of change before and after a professional development intervention. The authors found that before participating in the intervention, GSIs' focused on computational or geometric interpretations of average rate of change. After the intervention, GSIs were able to express a more conceptual understanding of average rate of change, suggesting that the intervention was somewhat effective in shifting GSIs' meanings for average rate of change. However, GSIs still varied in their ability to fluently express the meaning behind average rate of change, which led the authors to conclude that the impact of the intervention was not "uniform" across the GSIs.*

Nepal, K. (2014). An exploration of mathematics graduate teaching assistants' teaching philosophies. In T. Fukawa-Connelly, G. Karakok, K. Keene, & M. Zandieh (Eds.), *Proceedings of the 17th Annual Conference on Research in Undergraduate Mathematics*

*Education,* (pp. 942-946), Denver, CO. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*This study examined teaching statements from four different GSIs during a semester-long professional development program. Three teaching statements from each GSI were analyzed (written at the beginning, middle, and end of the program). None of the GSIs were teaching during the semester in which they participated in this professional development program. A fundamental assumption of this study was that GSIs' beliefs are "developed, changed or reinforced as the learn more about teaching and learning, and these changes are reflected in their teaching philosophies" (p. 942). Preliminary findings showed that the four GSIs expressed varying beliefs about teaching and learning with some common themes appearing, such as having high expectations for students and encouraging them to work hard, having a positive attitude toward teaching, and relating mathematics to real life problems. Common themes expressed in the teaching philosophies of the two international GSIs were that teachers should treat their students equally and that teachers' content knowledge is key to their success. Common themes present in the teaching philosophies of the two domestic GSIs were that instructors should keep students engaged and motivate their students to think, learn, and succeed rather than just transferring their own knowledge to students. None of the GSIs changed their earlier opinions from their first teaching statements, but they did express additional opinions in their second and third teaching statements. In addition, "all the [GSIs] were influenced more than anything by the teaching they had experienced during their undergraduate or high school times, especially by the role model teachers they had" (p. 945).*

Nepal, K. (2015). An investigation of beginning mathematics graduate teaching assistants' teaching philosophies. In T. Fukawa-Connelly, N. E. Infante, K. Keene, & M. Zandieh (Eds.), *Proceedings of the 18th Annual Conference on Research in Undergraduate Mathematics Education,* (pp. 830-837), Pittsburgh, PA. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*This study examined both pre-service and in-service teaching philosophies from four different GSIs during a semester-long pre-service professional development class and their first three semesters of teaching. GSIs beliefs evolved from the pre-service phase to the in-service phase. The main factor that influenced their pre-service teaching philosophies were their past experiences as students, while the main factor influencing their in-service teaching philosophies was their experiences as teachers. During the pre-service phase, GSIs held simplistic views of teaching and wrote very little that was specific to mathematics teaching. They also mainly described the teaching behaviors of their past teachers rather than writing about their own beliefs and opinions. Overall, the teaching philosophies of the GSIs changed very little during the pre-service professional development program. During the in-service phase, a major change that was detected was that GSIs said they would like to become more authoritative to gain the respect of their students. In addition, several of the expressed beliefs from the pre-service phase carried over into the in-service phase.*

Raychaudhuri, D., & Hsu, E. (2012). A longitudinal study of mathematics graduate teaching assistants' beliefs about the nature of mathematics and their pedagogical approaches toward teaching mathematics. In S. Brown, S. Larsen, K. Marrongelle, & M. Oehrtman (Eds.), *Proceedings of the 15th Annual Conference on Research in Undergraduate Mathematics*

*Education,* (pp. 522-525), Portland, OR. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*This preliminary study explored how math GSIs' ontological and pedagogical beliefs regarding mathematics changed over the course of a year. Initial findings indicate that these two types of beliefs can conflict with one another. The authors plan on conducting further analysis to examine how this affects a GSI's instructional approach. Moreover, they found that GSIs' knowledge of students can be classified as behaviorist-teacher-centered, or constructivist-student centered. The authors hope to examine how a constructivist approach affects the GSI's teaching practice with regards to planning, performing, and assessing.*

Reinholz, D. L., Cox, M., & Croke, R. (2015). Supporting graduate student instructors in calculus. *International Journal for the Scholarship of Teaching and Learning, 9*, 1-8.

*This report presents how the instruction of two GSIs teaching changed over the course of a semester while using the Peer-Assisted-Reflection (PAR) method of teaching. The PAR method has students solve difficult problems, reflect on their work, provide feedback on their peers' work, and revise their own work using their peers' feedback. The GSIs facilitated this work in their recitations (there were 14 PAR assignments in one semester), as well as met with a working group six times in the semester to discuss instructional goals related to PAR: developing students' communication, collaboration, and persistence. This group focused on using student-centered strategies for instruction. In their analysis the authors focused on two GSIs: Beth (who changed her instruction from lecture-based to more student-centered) and Wong (who attempted to do so, but still retained a teacher-focused practice). Using interviews with the GSIs, the authors argue that this discrepancy may be due to differing GSIs' beliefs about the nature of learning (traditional view vs. reformed view) as well as prior teaching experiences (Wong had more teaching experience than Beth, and so it's possible that his teaching practice was more established than hers). The report concludes by stating that the PAR method can be useful in developing GSI's student centered teaching, and that even inexperienced GSIs can successfully implement PAR assignments in the classroom.*

Soto-Johnson, H., King, K., & Haley, C. (2010). Does mentoring a graduate student effect student achievement? *Proceedings of the 13th Annual Conference on Research in Undergraduate Mathematics Education*, 1-16. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*The authors conducted a quantitative study in order to explore the relationship between the mentoring status of instructors and their students' performance. The study included one graduate student who was being mentored while teaching a course for preservice elementary teachers. In designing their study, the authors took the stance that having a teaching mentor should result in improved student achievement. To verify this hypothesis, they conducted a Chi-Squared test on the students' course grades as well as an ANOVA test on the students' final exam grades. While the Chi-Squared test did not reveal any differences, the ANOVA did indicate that there was a statistical significance difference in the final exam grades for students who had an instructor that was being mentored.*

Speer, N., & Firouzian, S. S. (2014). Current and future faculty members' mathematical knowledge for teaching calculus. In T. Fukawa-Connelly, G. Karakok, K. Keene, & M. Zandieh (Eds.), *Proceedings of the 17th Annual Conference on Research in Undergraduate*

*Mathematics Education,* (pp. 1052-1057), Denver, CO. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*In this grounded theory study, the authors examine mathematicians' and graduate students' knowledge of student thinking about core calculus concepts. While they do not study the process of growth, they do take the stance that graduate students should be developing mathematical knowledge for teaching, and knowledge of students in particular. As a result of their analysis, they found that mathematicians were more able to identify known student difficulties and describe common student strategies.*

Yee, S., Rogers, K., & Sharghi, S. (2016). Graduate students' pedagogical changes using iterative lesson study. In T. Fukawa-Connelly, N. E. Infante, M. Wawro, & S. Brown (Eds.), *Proceedings of the 19th Annual Conference on Research in Undergraduate Mathematics Education,* (pp. 1458-1466), Pittsburgh, PA. Retrieved from http://sigmaa.maa.org/rume/Site/Proceedings.html

*In this qualitative multiple case study, the authors examine the teaching practices of ten GSIs as they implemented an intensive iterative lesson study process across two universities. In particular, the authors identified mathematical teaching practices from the NCTM* Principles to Actions *(2014) used in the revision process of lesson study. The authors chose these practices, in particular, because they "provide a framework for strengthening the teaching and learning of mathematics" (p. 1461). As a result of their study, they found that there were mathematical teaching practices that GSIs both used consistently and revised throughout the study and that Lesson Study was an engaging form of professional development for GSIs.*

## Here's What You Do: Personalization and Ritual in College Students' Algebraic Discourse

Cody L. Patterson
University of Texas at San Antonio

Luke C. Farmer
University of Texas at San Antonio

*We present results of a discourse analysis focused on college algebra students' uses of personal and impersonal language, references to endorsed mathematical routines, and inferences about mathematical objects in responses to a small-group problem-posing activity. We analyze students' responses with respect to selected dimensions of the arithmetical discourse profile of Ben-Yehuda et al., and provide evidence of a positive association between impersonal language and the presence of statements about mathematical objects and their relationships. We also study the relationship between the mathematical discourse of students and the discourse espoused by curricular resources used in the course.*

*Key words:* College Algebra, Discourse Analysis, Mathematical Routines

At many colleges and universities in the United States, college algebra courses act as gateways into science, technology, engineering, and mathematics (STEM) disciplines. Although students in non-STEM disciplines continue to take college algebra in large numbers, the broad consensus of the mathematical profession is that the primary function of college algebra is to prepare students for success in calculus courses (Herriott & Dunbar, 2009). Research in mathematics education has identified ways of thinking that are propitious for learning concepts and solving problems in calculus, such as attending to algebraic structure (Linchevski & Livneh, 1999; Hoch & Dreyfus, 2004) and reasoning covariationally about functions (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Thompson & Carlson, 2017); college algebra presents some opportunities to develop these ways of thinking if they are addressed intentionally and skillfully. More broadly, some educators aligned with the reform movement in algebra education view algebra courses as responsible for developing "strategic problem solving and reasoning skills, symbol sense and flexibility, rather than procedural fluency" (Drijvers, Goddijn, & Kindt, 2011, p. 4). The report *Adding it up* (National Research Council, 2001) takes a more moderate stance, positing conceptual understanding, strategic competence, and procedural fluency as intertwined strands of mathematical proficiency that develop simultaneously and interdependently. However, there is broad agreement that students' work in college algebra should go beyond the development of rules for manipulating symbols in expressions, equations, and inequalities. Yet Kaput (1995) argues that the content of algebra courses "has evolved historically into the manipulation of strings of alphanumeric characters guided by various syntactical principles and conventions" (p. 71). Though Kaput's assessment is over two decades old and pertains to algebra at both the secondary and postsecondary levels, we hypothesize that it still bears some fidelity to the experience of students who take college algebra.

We are interested in investigating opportunities for students in college algebra courses to explore mathematical objects and their properties and relationships rather than simply performing scripted routines endorsed by a course text or instructor. In this study, we use elements of the *arithmetical discourse profile* of Ben-Yehuda, Lavy, Linchevski, and Sfard (2005) perform a discourse analysis of students' solutions to algebra problems, focusing on how and whether students use routines and how they describe properties of, and actions on, mathematical objects and mediators. We argue that students' uses of language – including both mathematical language and references to human actors and actions – give us insight into their understandings of algebraic objects and relationships. We then compare and contrast students' discourse with the discourse modeled by the course text and comment on how college algebra courses might create additional space for development of conceptual understanding and flexible problem-solving skills.

## Theoretical Perspective and Related Research

In this study, we take a commognitive perspective (Sfard, 2007) in which we regard thinking as a form of communication, and learning as the modification and expansion of one's discourse. Wittgenstein (1953) describes communication as a game in which participants exchange ideas according to certain rules and norms; a *community of discourse* forms when a group of people exchanges ideas under a common set of rules and norms, even if not all members of the group communicate directly with one another. In addition to using words, participants in a community of discourse use *visual mediators*, such as symbols, formulas, and graphs, to identify the objects of discourse and facilitate communication.

Prior research has offered several complementary arguments for the importance of attention to language in classroom instruction in mathematics and science. Chapin, O'Connor, O'Connor, and Anderson (2009) showed that classroom discussions of mathematical concepts and procedures can enhance student learning and provide windows into students' thinking for teachers. Studies in cognitive science have shown that encouraging students to engage in self-explanation while reading examples in mathematics and science texts can enhance the development of problem-solving skills and conceptual understanding (Chi, Bassok, Lewis, Reimann, & Glaser, 1989; Chi, De Leeuw, Chiu, & LaVancher, 1994). Thier (2002) argues that learning of science and development of literacy are interconnected; Fellows (1994) suggests that the process of writing "may force integration of new ideas and relationships with prior knowledge."

Ben-Yehuda, Lavy, Linchevski, and Sfard (2005) developed the *arithmetical discourse profile* as an analytical tool for identifying features of students' mathematical discourse that may facilitate or inhibit their access to rich mathematical thinking. Ben-Yehuda and colleagues divide discourse into a *subject dimension* in which communication focuses primarily on the author of the discourse and an *object dimension* in which communication refers to an external object, as constructed by the speaker. Within the object dimension, the authors analyze learners' word use, use of mediators, use of routines, and inclusion and production of *endorsed narratives*, mathematical facts (as understood or constructed by the speaker) that may be used in exploration. In analyzing word use, the authors consider the extent to which learners engage in *objectifying talk*, mentally constructing intangible, external objects for which mediators (such as numerals, expressions, and formulas) serve as visible "avatars." The authors also analyze the degree of *personalization* in learners' mathematical talk; that is, the extent to which learners' mathematical statements invoke human actors and actions on signifiers. As support for the relevance of personalization as a feature of mathematical talk, the authors cite a large-scale study by Bills (2002) suggesting a negative correlation between mathematics achievement and the use of personal identifiers and past-tense verbs to describe operations.

Subsequent research on students' mathematical discourse has highlighted other salient aspects of the language with which students express mathematical ideas. Sfard (2016) marks a distinction between *ritualized* and *explorative* mathematical discourse. Ritualized discourse has as its primary goal the satisfaction of an external need; this type of discourse typically engages in rote application of routines endorsed by an external source, and utilizes signifiers and mediators without attention to the mathematical objects to which they refer. Explorative discourse, on the other hand, serves the primary goal of knowing more about mathematical objects; participants in this discourse use routines and narratives flexibly and inquire about the source of their endorsement, and engage in *objectifying* talk, referring directly to mathematical objects and their properties. Sfard points out that learners assimilate themselves into these discourses largely through reflective imitation, observing the talk and actions of experts and then studying what aspects of these actions are adaptable to other situations and what aspects must be changed. In an analysis of student discourse about rational functions and their asymptotes, Mpofu and Pournara (2017) suggest that a lack of reflective imitation on the part of learners may lead to incomplete or flawed understandings of mathematical concepts. They observe that while the high school students in their study are able to produce graphs for rational functions correctly, their narratives about these mediators are mostly visual and dependent upon memorized routines, suggesting a ritualized understanding of asymptotes.

Like the authors of prior studies on students' mathematical discourse, we hypothesize that ritualized mathematical discourse – in student talk, in teacher talk, and in curricular materials – may bar students' access to mathematical exploration and understanding. In this study, we analyze specific features of the discourse of college algebra students in response to a problem-posing activity, the discourse of course instructors and curriculum authors in materials used in the class, and similarities and differences between the two. In particular, we investigate the following questions:

1. How do college algebra students use routines endorsed by their textbook or course notes in explaining solutions to problems that they have generated?
2. To what degree do college algebra students' explanations of solutions engage in personalized discourse, referring to human actions on mediators for mathematical objects, and to what degree do they make impersonal statements about mathematical objects and their properties and relationships?
3. What influences might the course text and notes have on students' mathematical discourse?

## Method of Study

### Study Setting and Population

This study was conducted in three large-enrollment sections (with 102, 115, and 114 students, respectively) of a college algebra course for STEM majors at a public university in the south central United States. At this university, most freshmen in science and engineering majors must take the college algebra course as a prerequisite for precalculus and most entry-level chemistry and physics courses. At the time of this study, the college algebra course was the target of a reform effort to shift instruction toward an emporium model (though with some elements of a large-lecture course still in use) and improve student retention and success rates. Students in the course attended class for three hours per week; prior to each class session they were expected to complete a set of "guided notes" in which they copied definitions and procedures and completed example problems from the course text (Abramson et al., 2012). Both the course text and guided notes frequently provided endorsed routines consisting of numbered lists of steps that prescribed how students should approach certain classes of problems.

Even though class sessions took place in a large lecture hall, sessions focused heavily on small-group activities in which students applied procedures to solve problems. For our study, we used a small-group activity because students were accustomed to small-group work and because we anticipated that collaborative work on the activity might lead to greater elaboration in students' solutions.

**Data Collection**

For this study, students in the three sections of college algebra participated in a small-group activity in which each group wrote a free-response algebra problem, including a solution. Students organized themselves into groups, usually based on their location within the lecture hall; groups typically consisted of two to five students. After groups formed, the authors distributed one copy of the Question Posing Activity (Figure 1) to each group. The Question Posing Activity asked each group to identify a mathematics concept covered in class since the first midterm exam and write a question on that concept that could be used as a test question or to review for the upcoming second midterm.[1] Each group was also asked to write a complete solution to that problem that could be understood by other students. Most groups appointed one student to record the group's ideas on the activity sheet. The researchers and college algebra instructors did not intervene in students' work on the activity; if a group asked for assistance or guidance, the researchers and instructors simply reiterated the instructions for the activity.

**Question Posing Activity**

**Names of Students in your Group:**

**Mathematics Concept:**

**Please write a question on this concept that could be used as a question on the upcoming test, or a question that could be used to study for the test:**

**Write a solution to your question using sentences, formulas, and key words that can easily be understood by fellow students. Please write your finished solution here; we've left some room on the back of this page for you to work out your problem and plan what you want to say.**

*Figure 1.* The Question Posing Activity given to study participants.

[1] Students were assured prior to the activity that the questions they wrote would not in fact be used on exams; our purpose in framing the activity in this way was to encourage students to write questions that would have well-defined mathematical solutions.

In posing the activity, we allowed students latitude to select from a variety of algebraic topics and problem types. We designed the activity to be open-ended so that students could select topics and problems that were comfortably within the scope of their understanding and on which they could produce elaborate and clearly written solutions. We anticipated that while responses would cover a variety of topics, the richness of the solutions would afford us greater opportunity to study how students write about mathematical problems that they understand relatively well. Students were allowed to use their notes during the Question Posing Activity, including the guided notes they had completed; however, they were permitted to write questions in their own words and approach problems in ways not specifically endorsed by the notes if they wished.

Over three sections, a total of 72 groups submitted responses to the Question Posing Activity, which we scanned and analyzed. We categorized a response as posing a well-defined algebraic problem if question prompted the reader to answer a mathematical question having a specific solution that could be found using ideas taught in the college algebra course prior to the study. The question itself did not have to follow specific guidelines in sentence structure or phrasing to be considered a question. Of the 72 responses, 70 posed well-defined algebraic problems; of the other two, one asked a question about a general strategy for a broad class of problems ("How do you find rational zeros of a polynomial?") and one wrote a formula for a cubic function but did not ask a question about the function. We limited our analysis to the other 70 responses.

**Data Analysis**

In analyzing the 70 responses that posed well-defined problems, we wished to characterize the mathematical topics addressed by the problems, the ways in which students employed routines from the course text and guided notes in their solutions, and the extent to which students used personal or impersonal discourse in their explanation of the solutions. We developed a three-part coding scheme to address these dimensions of each response.

In order to categorize the questions posed by mathematical topic, we used an open coding scheme to develop an ordered list of topics (Table 1) addressed in the questions that students posed:

Table 1
*Hierarchical list of question topics*

| Abbreviation | Topic |
|---|---|
| **LF** | Linear functions and equations |
| **ARoC** | (Average) Rate of change |
| **QF** | Quadratic functions and equations |
| **FT** | Factor theorem and zeroes of polynomials |
| **FP** | Factoring polynomials |
| **PD** | Polynomial division |
| **PM** | Polynomial multiplication |
| **GP** | Graphs and intercepts of polynomials |
| **O** | Other |

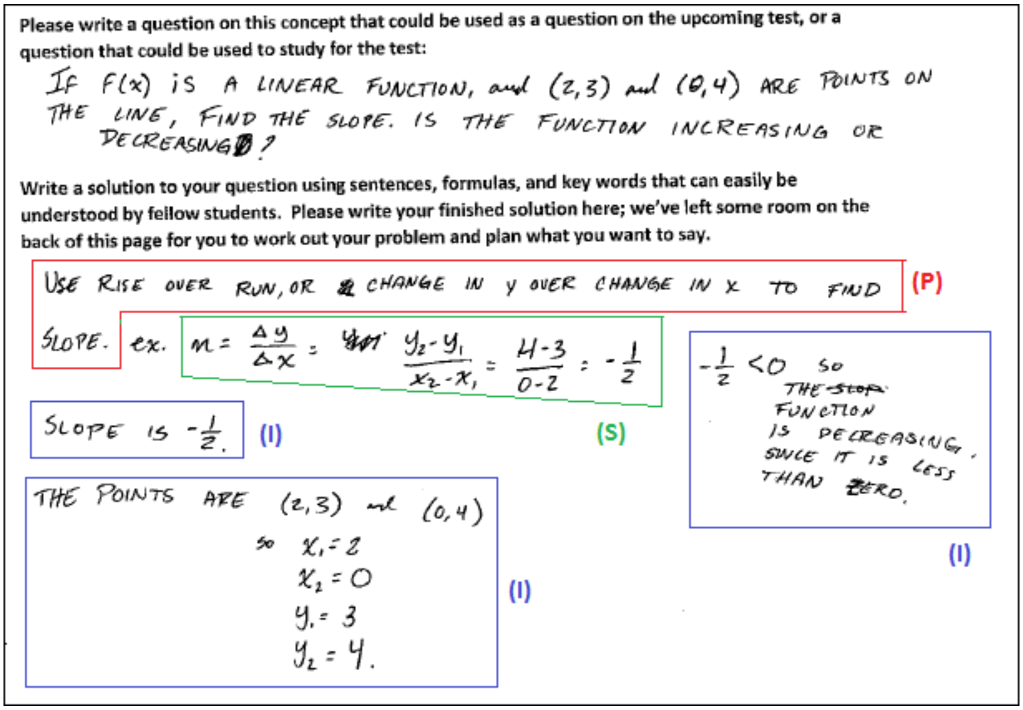
If a question addressed more than one topic in the table, we assigned it the first topic in the table that was relevant to the problem posed. Our rationale for the hierarchical listing of topics was that some topics encompassed others; for example, questions that addressed the factor theorem (FT) tended to address factoring polynomials (FP) as well. However, some questions addressed broader factoring techniques without using the factor theorem; we generally categorized these as FP. We created a separate category for quadratic functions and equations (QF) separate from the category on factoring polynomials; we assigned this topic higher priority because we observed, based on the course text, that factoring of quadratic functions was taken up separately from factoring of general polynomials and at an earlier point in the course.

We also categorized each solution according to its use of a routine from the guided notes or course text and how the routine was presented; we thus coded each response along two dimensions. Each solution was first assigned a code for *routine format*, based on whether the routine used to solve the problem was not explicitly described in the solution (N), was presented as a numbered list or bullet list of discrete steps (L), or was described in paragraph form (P). If a solution did not appear to make clear use of any endorsed routine from the course text or notes, we coded the routine format as (X). For coding reliability, we used symbolic markers to distinguish lists of discrete steps from paragraph descriptions of routines; if a solution presented a routine as a sequence of plain-language statements describing steps without numbering or bulleting the steps, we coded the routine format as (P) regardless of the flow of the steps.

Each solution that used a routine was also assigned a code for *routine fidelity*, based on whether the solution used or described an endorsed routine exactly as presented in the textbook and notes (1), used the same steps as the endorsed routine but reworded some steps (2), consolidated, split, or reordered steps in an endorsed routine but did not introduce any steps not in the endorsed routine (3), or introduced at least one step not in the course text's endorsed routine (4). We thus assigned a composite code, consisting of a letter and a digit, to each response that used a routine from the textbook, based on both routine format and routine fidelity.

Finally, we assigned a *personalization* code to every statement in each written solution. For this analysis, we coded a sentence or phrase in a solution as a *statement* if it expressed a complete thought and served the purpose of explaining or describing a step of the solution. We coded a statement as personal (P) if it invoked a human actor, whether explicit or implied through a description of an action on a signifier, and impersonal (I) if it did not invoke a human actor. We separately coded symbolic (S) statements (equations and inequalities) that occurred "in the flow" of an explanation of a solution that were not part of the scratchwork explained by the written statements. For example, Response 013G (Figure 2) contains one statement that instructs the reader to use a specific formula (P), an in-the-flow symbolic calculation determining the slope of a line (S), a statement of the slope of the line (I), a statement connecting the line's slope to the function's decreasing behavior (I), and a statement explaining how two given points are used in the slope formula (I). We coded this response as (PSIII); because some responses did not readily lend themselves to a linear ordering of statements, we did not perform any analysis based on the ordering of personal, impersonal, and symbolic statements within a solution. Perhaps more notably, we did not conduct any analysis of whether the language in students' statements was mathematically correct or precise; for example, our analysis did not take into account that Response 013G claimed that "the function is decreasing, since it is less than zero," and did not clearly indicate to what object the pronoun "it" referred. Our only aim in this part of the coding process was to capture the extent to which participants' writing referred to human actors or actions on mediators.

When assigning topic, routine, and personalization codes, each author coded each response independently; disagreements were resolved through discussion, which led to iterative refinements of each coding scheme. After these refinements, inter-rater agreement on topic codes, routine codes, and personalization codes reached 100%, 76%, and 88%, respectively. The primary obstacle to inter-rater reliability on assignment of routine codes was the process of deciding whether a step in a student explanation of a routine that differed from a step in the course text's endorsed routine constituted a new step not in the endorsed routine, a consolidation of two steps in the endorsed routine, or a rewording of a step in the endorsed routine.



Please write a question on this concept that could be used as a question on the upcoming test, or a question that could be used to study for the test:

IF F(x) IS A LINEAR FUNCTION, and (2,3) and (0,4) ARE POINTS ON THE LINE, FIND THE SLOPE. IS THE FUNCTION INCREASING OR DECREASING?

Write a solution to your question using sentences, formulas, and key words that can easily be understood by fellow students. Please write your finished solution here; we've left some room on the back of this page for you to work out your problem and plan what you want to say.

USE RISE OVER RUN, OR CHANGE IN y OVER CHANGE IN x TO FIND SLOPE. (P)

ex. $m = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1} = \frac{4-3}{0-2} = -\frac{1}{2}$ (S)

SLOPE IS $-\frac{1}{2}$. (I)

THE POINTS ARE (2,3) and (0,4) so $x_1 = 2$, $x_2 = 0$, $y_1 = 3$, $y_2 = 4$. (I)

$-\frac{1}{2} < 0$ so ~~THE SLOPE~~ FUNCTION IS DECREASING, SINCE IT IS LESS THAN ZERO. (I)

*Figure 2.* Personal, impersonal, and symbolic statements in Response 013G.

In categorizing responses by topic, we anticipated that some categories of responses would be more likely to contain impersonal discourse than others. For example, we hypothesized that questions dealing primarily with synthetic division would typically have a higher concentration of personalized discourse, since synthetic division is a procedure that distills the work done in certain cases of polynomial long division into actions on mediators that can be performed rapidly; that is, the goal of synthetic division is to permit the user to compute a quotient and remainder without actively attending to algebraic relationships among the polynomials being divided. On the other hand, we anticipated that responses having to do with the factor theorem might contain more impersonal statements, since in using the factor theorem one makes a connection between a polynomial's zeroes and its factors, and this connection can readily be described in terms of algebraic objects.

## Results

### Students' uses of routines

Responses to the Question Posing Activity addressed a variety of algebraic topics; the topics that occurred the most frequently were polynomial division (PD, 40 responses) and the factor theorem (FT, 10 responses). In discussion with the instructors of the college algebra classes we studied, we determined that students had most recently learned how to use synthetic division to find factors of polynomials; this may account for the high frequency of these topics.

Composite codes for descriptions of routines, along with the frequency of each code, are given in Table 2. Of responses that provided written narratives of routines in their solutions, remarkably few (4 out of 49) described routines exactly as they appeared in the course text, with or without minor rewording. An excerpt of such a response on synthetic division is shown in Figure 3; the textbook's endorsed routine for synthetic division is shown in Figure 4 for comparison. Most responses to the activity either consolidated multiple steps into a single step, split one step into multiple steps, omitted a step, or introduced a step that was not in the endorsed routine provided by the textbook.

Table 2
*Codes for Descriptions of Routines in Solutions*

| Routine Format | Routine Fidelity | | | |
|---|---|---|---|---|
| No clear usage of routine: X (4) | Same as endorsed routine in course text | Rewording of endorsed routine | Consolidates, splits, or omits steps | Includes a step not in endorsed routine |
| Routine not explicitly stated | N1 (13) | N2 (0) | N3 (1) | N4 (3) |
| Number or bullet list | L1 (2) | L2 (1) | L3 (10) | L4 (14) |
| Paragraph form | P1 (0) | P2 (1) | P3 (5) | P4 (16) |

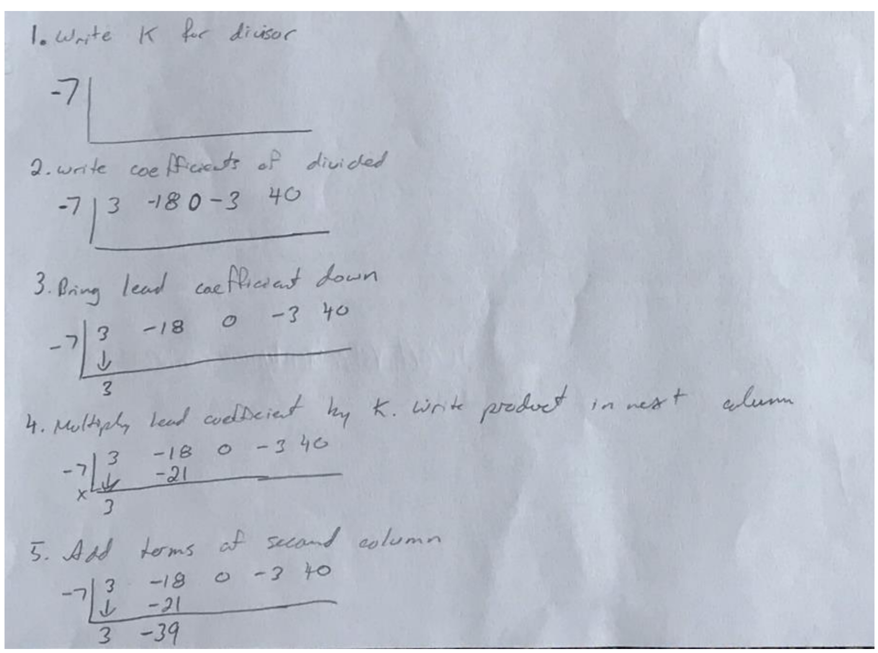


*Figure 3.* Response 009Y, a solution to a synthetic division problem.

*How To...*

Given two polynomials, use synthetic division to divide.

1. Write $k$ for the divisor.
2. Write the coefficients of the dividend.
3. Bring the lead coefficient down.
4. Multiply the lead coefficient by $k$. Write the product in the next column.
5. Add the terms of the second column.
6. Multiply the result by $k$. Write the product in the next column.
7. Repeat steps 5 and 6 for the remaining columns.
8. Use the bottom numbers to write the quotient. The number in the last column is the remainder and has degree 0, the next number from the right has degree 1, the next number from the right has degree 2, and so on.

*Figure 4.* The textbook-endorsed routine for synthetic division.

Consistent with Sfard's view of learning as the expansion of learners' discourse to include elements of expert discourse (2016), we frame instances in which a routine is not reproduced with perfect fidelity as possible instances of reflective imitation; that is, instances in which a group of students might decide that a routine as presented in a course text is insufficient or inefficient, and make adaptations to a routine appropriate for a given problem-solving scenario. To investigate this possibility, we performed further analysis on the 16 responses on polynomial division with routine codes of L4 or P4 to determine what additional steps or insights the students added beyond those included in the endorsed routines. We compared each response to the "How To" instructions on synthetic division found in the course text (Figure 4). We found that these 16 responses typically went beyond the textbook-endorsed routine in two ways:

1. Some responses added description of when or how to start the procedure of synthetic division; some described applicability conditions (Ben-Yehuda et al., 2005, p. 203) for synthetic division, and many focused on how to find the constant $k$ that corresponds to the linear divisor.
2. Some responses elaborated on the mathematical significance of the remainder obtained in the synthetic division procedure, stating conditions under which the divisor is a factor of the dividend, or conditions under which the value $k$ in the divisor $(x - k)$ is a zero of the dividend.

As illustrated in Table 3, which shows all polynomial division solutions from one section of the course that were coded L4 or P4, the syntax and wording of these additional contributions were varied; for this reason, we suspect that while students likely had these additional insights as a result of their interaction with the course text or lectures, these contributions were not scripted. As the students' responses suggest, while most students incorporated endorsed routines from the course text into their explanations of solutions, many also took up opportunities to elaborate on the routines by noting key features of problems they created or implications of the outputs of routines they used.

Table 3
*Students' Enhancements of the Endorsed Routine for Synthetic Division*

| Response | Beginning of Procedure | Interpretation of Results of Procedure |
|---|---|---|
| 013D | "Set ($x + 2$) equal to zero to see what you are dividing by. ($x + 2$) set equal to zero is -2." | "set remainder over dividend ($x + 2$)" |
| 013I | "($x + 3$) $\rightarrow x = -3$"<br>"Because our divisor is in ($x - k$) form, where $k$ is a real number, we are able to use synthetic division as a shortcut to divide polynomials." | |
| 013K | | "Put remainder over $x - k$ and simplify." |
| 013L | "First solve for $x$ for the factor ($3x - 1$), which = 1/3" | "If not place remainder over factor ($3x - 1$)" |
| 013M | | "If the last sum is zero, the divisor is a factor. If it is non-zero, it is not." |
| 013O | "It is -7 because $x + 7 = 0 \rightarrow x = -7$" | "If the remainder is zero, then the equation is a factor of the divisor, in this case our remainder was 1090, so it is not a factor of ($x + 7$)" |
| 013Q | "First off, find a number that makes $x + 2 = 0$ (which is -2)." | "Put the bottom numbers into an equation and the last number (if it $\neq 0$) over the root ($x + 2$)" |
| 013V | | "Yes, $x - 2$ is a factor of $2x^4 - 3x^3 - 15x^2 + 32x - 12$ because the remainder is zero."<br>"If there is no remainder, $k$ is a factor. If there is a remainder, $k$ is not a factor." |

**Personalization in students' word use**

In reviewing personalization codes for the 60 solutions that contained at least one verbal statement (coded (P) or (I)), we found that the majority of students' statements were personal (250 personal statements; 38 impersonal statements). For each of these 60 responses, we tallied the number of impersonal statements in the response as well as the percentage of statements that were impersonal. Results of this analysis are shown in Table 4.

Table 4
*Number and Relative Frequency of Impersonal Statements in Verbal Responses*

| Number of impersonal statements | Number of responses | Relative frequency of impersonal statements | Number of responses |
|---|---|---|---|
| 0 | 36 | 0% | 36 |
| 1 | 16 | (0%, 25%] | 9 |
| 2 | 6 | (25%, 75%) | 7 |
| 3 | 4 | [75%, 100%) | 2 |
| More than 3 | 0 | 100% | 6 |

Of the 60 solutions that contained verbal statements, 45 contained at most 25% impersonal statements. In our initial analysis of the data, we anticipated that responses containing a high volume of impersonal statements would be likely to contain objectifying talk; that is, statements about algebraic objects and their properties (as opposed to talk about actions on mediators, such as "bring lead coefficient down" or "Create an 'L' shape and add and multiply the answer given by -2"). To test this hypothesis, we performed an additional analysis on the 38 impersonal statements in the solutions submitted to determine whether each statement, in our judgment, was primarily intended to describe properties of or relationships among mathematical objects (objectifying talk), or to describe the role of an object or mediator in a routine performed by a human (operational talk; Ben-Yehuda et al., 2005, p. 198). Of the 38 statements analyzed, we categorized 25 as objectifying talk and 13 as operational talk; some examples from responses dealing with polynomial division are presented in Table 5.

Table 5
*Examples of Objectifying Talk and Operational Talk in Impersonal Statements*

| Objectifying Talk | Operational Talk |
|---|---|
| "The solution will be $x - 2 - 4/(6x + 2)$, which also proves that $6x + 2$ is not a factor of $6x^2 - 10x - 8$." (009N)<br>"These 3 numbers represent zeros of the polynomial in the problem." (012J)<br>"If the remainder is zero then the $x$ value is also a zero." (012K) | "$k$ is the divisor $x - 6$" (009E)<br>"last number is the remainder over factor" (009R)<br>"$x + 4 = x - k$ which means $k = -4$." (012G)<br>"It is -7 because $x + 7 = 0 \rightarrow x = -7$" (013O) |

As the examples in Table 5 illustrate, students who posed and solved problems on polynomial division frequently made objectifying comments connecting the remainder obtained from the division algorithm to the question of whether the divisor is a factor of the dividend, and connecting factors of polynomials to zeroes of polynomials. On the other hand, some of the impersonal statements they wrote appeared to have the purpose of clarifying the role of the zero of the linear divisor ($x - k$) in the synthetic division routine; we classified these as operational talk since their primary purpose seemed to be to justify the use of a mediator in the routine.

To test our hypothesis that problems on the factor theorem would call for more deductive reasoning and therefore engender greater degrees of objectifying talk, we analyzed the 10 responses that addressed the topic of the factor theorem for their uses of personal and impersonal language in explanations of solutions. Of these 10 responses, only two contained at least one impersonal statement. We observed that in most of the responses on the factor theorem, participants solved a problem that might call for attending to mathematical relationships (such as that between factors and zeroes) and deductive reasoning (for example, ruling out possible rational roots of a polynomial) in a way that suggested the use of a routine, and their description of this routine consisted entirely of personal statements. For example, Response 012D (Figure 5) uses an endorsed routine from the course text to find the zeroes of the polynomial $f(x) = x^4 + x^3 - 13x^2 - x + 12$. This response makes a connection not visible in the endorsed routine (Figure 6); namely, that the purpose of using synthetic division is to find factors that can be used to decompose the original polynomial. On the other hand, it misses some subtleties in this routine; for example, that a fourth-degree polynomial may not split (over the rationals) into linear and quadratic factors. We hypothesize that because the course text's instructions merely suggest that students continue until the quotient is a quadratic "if possible," the object-based reasons for this potential complication are not explored. Thus while the students' response contains some insight not found in the endorsed routine, it largely reflects the operational and personal discourse presented in the course text, and misses a potentially important mathematical understanding as a result.

zeros: -1, 1, -4, 3

Steps:

① Use rational zero theorm to determine possible zeros.

② Pick from list of $\frac{p}{q}$ values and synthetically divide to find factors.

③ Repeat step 2 until you are left with a quadratic function

④ Factor quadratic or use quadratic function

⑤ Set all factors equal to zero and solve.

*Figure 5.* Response 012D describes how to factor a fourth-degree polynomial.

*How To...*

Given a polynomial function *f*, use synthetic division to find its zeros.

1. Use the Rational Zero Theorem to list all possible rational zeros of the function.
2. Use synthetic division to evaluate a given possible zero by synthetically dividing the candidate into the polynomial. If the remainder is 0, the candidate is a zero. If the remainder is not zero, discard the candidate.
3. Repeat step two using the quotient found with synthetic division. If possible, continue until the quotient is a quadratic.
4. Find the zeros of the quadratic function. Two possible methods for solving quadratics are factoring and using the quadratic formula.

*Figure 6.* The textbook-endorsed routine used in Response 012D.

## Discussion

In our analysis of student responses to the Question Posing Activity, we found that students frequently used endorsed routines from the course text and notes as templates for their solutions, even though they often made adaptations to the routines based on the specifics of the problems they were solving. We also observed that personalized mathematical discourse was prevalent in most of the students' solutions; in most of the responses, the majority of written statements contained references to human actors or human actions on mediators. A closer analysis of impersonal statements in students' solutions revealed that the majority of these were mathematical statements about algebraic objects (such as functions, equations, and solutions) and their properties. We found that solutions that avoided impersonal talk often referred to mathematical objects in ways that would seem vague to a third-party reader (for example, referring to mediators without clarifying the objects they represent), and sometimes obscured algebraic ideas that might have led to deeper understanding of the problems they addressed.

While recognizing the limitations of our study, which was situated in a specific instructional context in which student discourse was influenced by a common set of curricular resources and likely by specific teaching practices that were not fully visible to us, we suggest that a prevalence of personalized discourse at the expense of impersonal and objectifying talk may inhibit students' access to certain worthwhile mathematical ideas. We do not mean to suggest that personal statements in a written solution to a problem are indicative of an impoverished understanding of the underlying mathematics; indeed, we expect that virtually any explanation of an algorithm such as synthetic division would contain some description of actions on mediators, since the effective use of mediators is key to the efficiency of a written algorithm. Rather, we wish to suggest that mathematical talk can be enriched with substantive discussion of the mathematical objects to which mediators refer, and that impersonal statements can focus attention on these objects.

In observing students' responses to the activity, we also found that the mathematical discourse of students often resembled the discourse exemplified by the course text and guided notes, though with some modifications. On the one hand, we found that students often made adjustments to the textbook's endorsed routines that added meaning and context; for example, many student solutions to polynomial division problems went further in analyzing the output of the division algorithm and its relation to factors and roots of polynomials than the textbook's description of the routine did. On the other, students frequently incorporated all of the steps in the textbook's endorsed routine into a solution (while possibly consolidating or splitting some steps or providing additional detail), and in doing so they rarely described mathematical objects with any more clarity than the book's explanation contained. This suggests that in a course in which students are required to interact regularly with an assigned text, the text serves as an important influence in the development of students' mathematical discourse. In our commognitive perspective, in which the expansion of mathematical understanding is the expansion of discourse, the discursive norms and practices of a textbook set standards for students' understanding and for the epistemic approach students should take in assimilating new knowledge. While instructors can supplement textbooks with additional explanation, more explorative activities, or richer assessments, a textbook presents a permanent physical artifact of ways in which students are expected to understand the mathematics they know. A textbook that promotes explorative discourse can serve as a resource that helps acquaint students with the objects of the mathematical activity in a course and invites students to participate actively in the development of mathematical ideas. If students have opportunities to engage in mathematical exploration in which they have access to the objects of study and motivation to articulate relationships among these objects, they can develop ways of thinking and explaining that can be distilled into personalized and ritualized mathematical talk – but of whose rituals they are the developers and owners.

# Assessing the Development of Students' Mathematical Competencies: An Information Entropy Approach

Yannis Liakos
University of Agder, Norway

Yuriy Rogovchenko
University of Agder, Norway

*We report on the use of a modification of the Danish KOM framework of mathematical competencies for monitoring the development of mathematical competencies of freshmen biology students at a Norwegian university. Preliminary analysis of the data indicated the need for the adjustment of the original framework and development of the appropriate scaling for competencies' intensity which may differ significantly even within one session. We retain only five out of eight groups of competencies in the KOM framework and suggest the scaling scheme for the strength of each of the sixteen competencies in the five groups. In addition, three different dimensions for each competency are introduced and scaled. After all the data have been processed, the need for the development of techniques for processing large data sets arose. We started by converting a large corpus of qualitative data into quantitative data and used recent developments in the information theory to initiate the discussion regarding monitoring of the development of students' mathematical competencies.*

*Keywords:* mathematical modeling, competencies, quantitative data, scaling and evaluation tools, information entropy.

## Introduction

What exactly do we mean by saying "he/she knows" mathematics? One may attempt to answer this question by viewing mathematical knowledge as a complex combination of a number of complementary mathematical competencies. An individual possessing all (or some) competencies at certain levels could be considered as the one possessing some mathematical knowledge. For this purpose, we need: (i) to define what is meant by a mathematical competency; and (ii) to explain how these competencies can be meaningfully assessed.

A mathematical competency should be clearly recognizable and distinct as one of the constituents of the overall mathematical competence. Different approaches to this operationalization have been proposed in the literature by Boesen et al, 2014, Maaß 2006, Niss, 1999, Weinert, 2001 and others. We follow Niss (1999) who suggested the framing of a set of mathematical competencies within the KOM-project (KOM: Competencies and the Learning of Mathematics), initiated by the Ministry of Education and other official bodies for reforming Danish mathematics education. The main objective in the KOM project was to replace traditionally expressed lists of topics, concepts and results in mathematics curricula with a list of mathematical competencies students should possess. The eight groups of competencies suggested in Niss (1999) are: (1) thinking mathematically; (2) posing and solving mathematical problems; (3) modelling mathematically; (4) reasoning mathematically; (5) representing mathematical entities; (6) handling mathematical symbols and formalisms; (7) communicating in, with, and about mathematics; (8) making use of aids and tools (IT included). The twenty four competencies in these eight groups are further classified with regard to abilities "to ask and answer questions in and with mathematics" (1-4) and "to deal with and manage mathematical language and tools" (5-8).

The purpose of this paper is to address the following questions. (1) How efficiently can the KOM framework of mathematical competencies be used for monitoring and assessing the development of mathematical competencies of freshmen biology students? (2) How can information entropy be used to facilitate the process of big data analysis?

## Research setting

This research took place in a department of biology at a Norwegian university. Two Norwegian centres for excellence in higher education, the Centre for Research, Innovation and Coordination of Mathematics Teaching (MatRIC) and the Centre for Excellence in Biology Education (bioCEED), developed a joint project aimed at improving biology students' motivation for, interest in, and perceived relevance of mathematics in biological studies using mathematical modeling activities. The project addresses serious concerns regarding mathematical education of future biologists raised recently in the literature. As mentioned by Bialek & Botstein (2004), "The fragmented teaching of science in our universities still leaves biology outside the quantitative and mathematical culture that has come to define the physical sciences and engineering. Even though most biology students take several years of prerequisite courses in mathematics and physical sciences, these students have too little education and experience in quantitative thinking and computation to prepare them to participate in the new world of quantitative biology." A similar concern has been also expressed by Gross, Brent, & Hoy (2004) who pointed out that "the need for basic mathematical and computer science (CS) literacy among biologists has never been greater."

The teaching was planned and performed by MatRIC researchers, whereas bioCEED took care of all organizational aspects and helped with the recruitment of biology students. MatRIC researchers suggested to use biologically meaningful modelling tasks for demonstrating possible uses of mathematics in life sciences and encouraging better engagement of students in learning mathematics. To this end, the first author prepared teaching materials for eight complementary sessions and conducted teaching once a week over a period of two months in addition to the regular lectures and seminars in their standard mathematics freshmen course for natural sciences students.

*Table 1. Task example 1*

| Adam & Eve |
|---|
| How long it takes for a pair of individuals (one may think, for instance, of Adam and Eve) to produce the world population of today (about 6 billion people) at the present rate of growth $r = 2\%$ per year? |

The topics discussed in the eight sessions were: periodic functions (2 sessions), exponential growth and regression (2 sessions), population dynamics (2 sessions), integrals and modeling (2 sessions). Usually students were given two tasks, the first to "warm up" and the second, main task, to see how well they understood main ideas and techniques. Examples of two tasks from one of the sessions (the first session on population dynamics) are provided in Tables 1 and 2.

*Table 2. Task example 2*

| The Andromeda Strain |
| --- |
| Uncontrolled geometric growth of the bacteria *Escherichia coli (E. Coli)* is the theme of the best-selling Michael Crichton's science fiction thriller *The Andromeda Strain*. In a single day, one cell of *E. Coli* could produce a super-colony equal in size and weight to the entire planet Earth. If a single cell of the bacterium *E. Coli* divides every 20 minutes, how many *E. Coli* would be there in 24 hours? The mass of an *E. Coli* bacterium is $1.7 \times 10^{-12} g$, while the mass of the Earth is $6.0 \times 10^{27} g$. Is Crichton's claim accurate? If not, how much time should be allowed for this statement to be correct? |

In addition to our attempt to engage biology students into more active learning of mathematics through the work on modeling tasks with biological content, the goals of this intervention were to create mathematical competencies profiles for individual learners and to follow their development from session to session and in the long run.

## Data collection

Data collection methods included video recordings of participants, researcher's observation/field notes and students' written material obtained using *Livescribe 3* smart pens and notebooks. One group in each classroom was the "focus group" with a camera recording students' work using a vertical view; this enabled the capture of all written actions. A *GoPro* camera with a panoramic view facing the whiteboard and the groups was used to record all interactions in the classroom, including teacher's involvement and groups' activities. All audio recordings were obtained from the two cameras and then transcribed. Some studies (e.g. Spradley, 1980) criticized this method for researcher's involvement and intrusiveness due to the camera's and his/her presence during the data collection. However, since the researcher was also the teacher at the same time, this made him an integral part of the study in terms of involvement. Furthermore, "the effect of video becomes negligible in most situations after a certain phase of habituation" (Knoblauch, Schnettler & Raab, 2006) and the camera's intrusiveness gradually fades away. An important part of data is the written work produced by students during the sessions using smart pens and notebooks.

## Mathematical competencies framework

In 2016, the first author conducted a "pilot analysis" to test the functionality of the KOM mathematical competencies framework with a group of biology students. The very first analysis of the data brought to light several episodes where the competencies significantly overlapped. As mentioned by Niss, "The competencies are closely related - they form a continuum of overlapping clusters - yet they are distinct in the sense that their centres of gravity are clearly delineated and disjoint" (Niss, 2003, p. 9). This indicates a potential problem with the inter-coder reliability which may arise with the adoption of the KOM framework for tracking the development of student's competencies. In order to maximally avoid possible complications with coding, we retain only five basic groups of mathematical competencies (16 competencies in total) out of the eight suggested in KOM: thinking/acting mathematically, modeling mathematically, representing and manipulating symbolic forms, communicating/reasoning mathematically, and making use of aids and tools. All sixteen competencies in these five groups are described below.

*Thinking/acting mathematically*

i. pose questions that are characteristic of mathematics, know possible answers that mathematics may offer;
ii. understand and handle the scope and limitations of a given concept;
iii. attack (take actions towards a solution) mathematical problems.

*Mathematical modeling*

i. assess the range and validity of existing models;
ii. interpret and translate elements of a model during the mapping process;
iii. interpret mathematical results in an extra-mathematical context and generalize solutions developed for a special task or situation;
iv. criticize the model by reviewing, reflecting and questioning results;
v. search for available information differentiating between relevant and irrelevant information;
vi. choose appropriate mathematical notation, represent situations graphically.

*Representing and manipulating symbolic forms*

i. choose a representation;
ii. switch between representations;
iii. manipulate within a representation.

*Reasoning and communicating*

i. understand others' written, visual or oral information having mathematical content; follow and assess chains of arguments put forward by others;
ii. express oneself in oral, visual or written form in mathematical context; provide explanations or justifications to support own results and ideas.

Aids and tools

i. know different tools and aids for mathematical activity and their properties;
ii. use appropriate aids and tools to develop insight or intuition.

Each of sixteen competencies was coded separately and tested for reliability by requiring three researchers to code the same transcript and verifying consistency of their coding by direct comparison. When all data were collected, an initial data analysis took place focusing on the first three sessions and the work of two students, J and E. This preliminary analysis brought to light an important finding that, in addition to a number of instances when a certain competency was activated, its strength at each instance should also be recorded. Even though the same codes appear within the same session at chronologically different solution stages, they do not exhibit the same intensity in terms of competency activation. A positive impact of this adjustment is that by assessing the strength of each competency at each occasion we improve validity and reliability of our research. On the other hand, this approach demands a much more careful treatment of the data which, in our case, includes the need for the analysis of large sets of qualitative data.

Figure 1 provides an extract from the transcript of the third session which we use to illustrate the coding procedure. The group comprised of two students, J and E, and the first author. Since the video recordings were split in three parts, a, b, and c, we use, for instance, the notation 3b for the part b of the recordings of the work of the third group of students. The figure shows the time, names of the actors, extracts from the transcript of the episode (with clarifications, whenever necessary) and the code for each activated competency (in this example, just P.Q., which stands for "posing questions which are characteristic for mathematics"). Since we focus our attention on students' discourse, the codes are assigned only to students. Assignment of codes for the tutor's (researcher's) discourse is a part of the task analysis and is beyond the scope of this paper.

| Time | Who | What was said | Code |
|---|---|---|---|
| 01:30 (3a) | Y | So, what do we count as part of Norway's population in 2017? (pointing to: $N_{t+1} = N_t + B + D + I - E$, where $N_{t+1}$ : the population at $t+1$ year, $N_t$ : the population at $t$ year, $B$: the number of births, $D$: the number of deaths, $I$ : number of people immigrated and $E$ : the number of people emigrated) | |
| | J | Why do we have "+" at deaths? | P.Q. |
| 12:27 (3a) | J | Don't we use ln for all sides so we get $t$ down? (He refers to this equation $N_t = N_0 * e^{rt}$) | P.Q. |
| 16:16 (3a) | J | Since we have ln $e$ can we just delete it? | P.Q. |
| 17:40 (3a) | J | Can I take this down now? (J is writing down the following: $\ln(N_t) = \ln(N_o) + \ln e^{rt}$, and he is asking about the "$rt$" part) | P.Q. |
| 02:12 (3b) | J | Shouldn't we use the same method we used last Monday? (This question was posed when Y introduced the main task for the first time) | P.Q. |
| 07:30 (3b) | Y | How many doublings do we have? | |
| | J | 24 hours divided by 20 minutes? | P.Q. |

*Figure 1. Part of a modeling session transcription. The columns represent the timing, the name of the participant, the transcription and the competency code.*

**Dimensions and scaling**

The example shows that in the transcript of the session we came across the code P.Q. six times, but the frequency gives us little information, if any. The P.Q. code is one of the aspects of mathematical thinking and acting competency and even though all questions asked by the students in the episode clearly exhibit mathematical characteristics, not all of them have the same depth and targeting. Therefore, the need for certain "scaling" became obvious. The authors started with a “rough” scaling (beginning – developing –accomplished – exemplary) for each of the three dimensions described below (task solving vision, use of mathematical language/vocabulary) and proceeded with its further refinement.

| | | GRADING/SCALING | | | |
|---|---|---|---|---|---|
| | | **Exemplary (A+)** | **Accomplished (A)** | **Developing (B)** | **Beginning (C)** |
| DIMENSIONS | **Task Solving Vision** | Activation of the competency with a meta-reflective perspective towards the final solution | Full vision of task solving process with possibly minor inaccuracies | Occasional, regular or consistent mid-range perspective towards the final solution | No clear perspective or short-range perspective towards the final solution |
| | **Use of Mathematical Language/Vocabulary (Flexibility)** | Worthy of imitation, serving as model | Proficiency of mathematical language with possibly some minor omissions | Basic, occasional confident or regular use | Familiar, everyday expressions or gestures |
| | **Prompting** | The student often “replaces” the tutor during the solving process | The student works independently or needs minor hints to bring the competency into action | Prompted adequately (1 to 4 questions) or indirectly to bring the competency into action | Continuous prompting to bring the competency into action |

*Figure 2. The scaling system: the columns represent the levels of competency intensity and the rows the dimensions of the competency*

**Task Solving Vision**

This dimension focuses on the depth of student’s understanding of the task’s solving steps and his/her perspective towards the solution of the task; it also helps to relate the activation of a given competency with actual steps towards solution. The findings from the preliminary data analysis led to the conclusion that there are episodes where a student may activate a particular competency which, however, has no relation with the solution of a given task. On the other hand, at other instances students exhibited specific competencies in combination with clear ideas at all times of how to solve the problem. Developments in competency strength are not linear and differ depending on the moment of activation, task's type, its difficulty, and other factors. Using the data from the preliminary analysis and synthesizing the second author's teaching experience, we decided to further differentiate the beginning, developing and advanced levels coming up with the refined scaling system presented in Figure 3.

| Scaling | Rating | Description |
|---|---|---|
| Beginning | C1 | Students activate the competency having no clear perspective towards the solution. |
| | C2 | Initial signs of short-range perspective towards the solution. |
| Developing | B1 | Occasional signs of mid-range perspective towards the solution. |
| | B2 | Regular signs which indicate that the student activates the competency having in mind future steps of the solution. |
| | B3 | Consistent signs of mid-range perspective towards many steps of the solution. |
| Accomplished | A1 | Evident signs of long-range perspective towards the final solution. Full vision of the process with minor inaccuracies. |
| | A2 | The student's actions during all steps of the solving process are directed by his/her perspective towards the final solution. Full vision of the process. |
| Exemplary | A+ | In addition to A2, the student exhibits non-standard approach(es) to solution synthesizing ideas and techniques beyond the topic and subject discussed. |

*Figure 3. The sub-levels of the Task Solving Vision*

**Mathematical Language and Vocabulary**

Concepts, algorithms, procedures, computation, problem solving, and language are some of critical component skills that should be combined to achieve certain proficiency in mathematics (Riccomini, Sanders, & Jones, 2008). The language of mathematics can be confusing, especially for students who do not have mathematics as their main subject of study (Rubenstein & Thompson, 2002). However, even these students should communicate their mathematical ideas organizing them in some form of reasoning. There is a significant difference between getting the right answer and explaining how one got it. Students can use a vocabulary enriched with mathematical terms or just utilize familiar, everyday expressions and gestures. An undeveloped mathematical language can be the reason for the overall deceleration of their mathematics learning (van der Walt, Maree, & Ellis, 2008). Difficulties with the use and learning of mathematical vocabulary are well documented (Riccomini et al., 2015); language development can be a challenging issue.

| Scaling | Rating | Description |
|---|---|---|
| Beginning | C1 | Use of familiar, everyday expressions with no visible signs of mathematical language knowledge. |
| | C2 | Use of familiar, everyday expressions with gestures that suggest an initial familiarity with mathematical vocabulary. |
| Developing | B1 | Use of basic mathematical expressions at an intermediate level. The student can use simple connected statements while activating the competency. |
| | B2 | Occasional and confident use of mathematical language with a certain degree of fluency, independency and spontaneity. |
| | B3 | Regular and nearly independent use of mathematical vocabulary in a complex context. The student often uses definitions of mathematical notions to express himself/herself. |
| Accomplished | A1 | The student, independently, expresses himself/herself fluently with a rich mathematical vocabulary. |
| | A2 | Proficient use of mathematical language. |
| Exemplary | A+ | In addition to A2, the student expresses himself/herself at a more advanced level beyond the limits of the topic/subject. |

*Figure 4. The sub-levels of Mathematical Language and Vocabulary.*

Communicating mathematically is a demanding task for all students, even for those who display certain familiarity with mathematical concepts and notions. Most of the competencies in our framework are activated through verbal or written communication. Students use mathematical language, for instance, to pose questions (P.Q.) that are characteristic of mathematics or to interpret and translate the elements (Int.El.) of a model during the mapping process. This direct connection between the competencies framework and mathematical language proved to be a decisive reason for introducing mathematical language and vocabulary as the second dimension in our scaling tool.

**Prompting**

During the students' work on the tasks, one has to take into account instructor's involvement in the process assessing the breadth of prompting and scaffolding.

<table>
<tr><th colspan="2">Scaling</th><th>Rating</th><th>Description</th></tr>
<tr><td colspan="2" rowspan="2">Beginning</td><td>C1</td><td>Continuous prompting or use of directive probing question to activate the competency</td></tr>
<tr><td>C2</td><td>Prompting is still continuous but with moments of independence. The student attempts to interrupt guidance.</td></tr>
<tr><td rowspan="3">Developing</td><td rowspan="2">explicit</td><td>B1</td><td>The student needs 3 or 4 basic prompting actions to activate the competency.</td></tr>
<tr><td>B2</td><td>The student needs 1 or 2 basic prompting actions to activate the competency.</td></tr>
<tr><td>non-explicit</td><td>B3</td><td>Indirect prompting, usually through a statement indicating the student what is expected, but not exactly. For example, "What is your next step?" "How can we explain this?"</td></tr>
<tr><td colspan="2" rowspan="2">Accomplished</td><td>A1</td><td>Independent work, the student can perform the task by activating the competency on his/her own, with minor hints.</td></tr>
<tr><td>A2</td><td>Independent work, the student can perform the task by activating the competency on his/her own, with no prompts or assistance.</td></tr>
<tr><td colspan="2">Exemplary</td><td>A+</td><td>In addition to A2, the student anticipates the solution steps constructively "assisting" the lecturer.</td></tr>
</table>

*Figure 5. The sub-levels of Prompting.*

Wood et al. (1976) characterized scaffolding as an interactive system of exchange in which the tutor operates with an implicit theory of the learner's acts to recruit his attention, reduces degrees of freedom in the task to manageable limits, maintains 'direction' in the problem solving, marks critical features, controls frustration and demonstrates solutions when the learner can recognize them (p. 99). They continued by identifying scaffolding as the process that enables a child or novice to solve a problem, carry out a task, or achieve a goal which would be beyond his/her unassisted efforts. The latter definition and especially the expression "beyond his/her unassisted efforts" could raise some justified arguments since one can never be certain about students' responses and reactions to the assigned tasks. Nevertheless, we adopt this definition of scaffolding for the following two reasons: (i) complementary modeling sessions were designed to assist generation of new knowledge; (ii) freshmen biology students had very limited experience with modeling tasks, if at all; they could view many modelling tasks as quite demanding.

The purpose of introducing this dimension is to monitor the extent to which the instructor was using probing questions and assisted students. Bernstein (1967) referred to the importance of reducing the alternative actions during skill acquisition; he considered it as an essential process to adjust and regulate feedback so that it could be used for correction. The latter is strongly related to this study's focus since our goal is to analyze the process of competency acquisition through the solution of modeling problems. We can see in Figure 5 that activation of a competency with low-level prompting results in a high-level competency intensity. Less scaffolding means more stimulation for independent work and thus a higher competency strength.

This dimension has a unique characteristic that distinguishes it in terms of functionality from the other two. In the first two dimensions, we focus attention at a specific discourse episode "cutting it out" from the session. However, scaffolding is a delicate continuous process where one has to choose very carefully both the timing for the intervention and the format of the help offered to students. Even though scaffolding is a rather demanding task, we view it as the only way to achieve prominent levels of trust and credibility for our scaling tool in general and for this dimension in particular.

## Coping with large volume of qualitative data

When the data collected in the sessions are coded, the record of each competency frequency and strength (beginning, intermediate, developed, exemplary) is also kept. This creates a large corpus of qualitative data which we would like to analyze in order to monitor and assess students' competency development. Looking for an appropriate tool to analyze the data, we decided to convert all qualitative data into numerical values (the value 1 is assigned to C1, 2 to C2, 3 to B1, and so on) and employ information entropy for spotting the trends in competencies development.

### What is information entropy?

Entropy is one of the important concepts in thermodynamics characterizing the "amount of disorder" in a system at a given temperature. "Shannon entropy" or "information entropy" is used to evaluate the amount of information encoded in a transmitted message. The Shannon entropy is defined by

$$H(p) = -k \sum_{x_i} p(x_i) \log_b p(x_i) \geq 0,$$

where $p(x_i)$ is a normalized discrete probability distribution function and $k$ is a coefficient (Shannon, 1948).

Some important properties of the information entropy:

- Higher entropy levels correspond to larger disorder in physics and higher information content in information theory.
- Entropy is an extensive property like mass.
- Entropy grows logarithmically with the number of degrees of freedom.

**How do we use entropy to assess competencies' development?**

Step 1. In our example, we follow the development of the three competencies which were evaluated by the lecturer at 10 different instances during one session. We first collect all data in a 10×3 matrix $A$:

$$A^{\mathrm{T}} = \begin{pmatrix} 2 & 2 & 2 & 4 & 3 & 3 & 4 & 4 & 4 & 4 \\ 5 & 3 & 3 & 4 & 6 & 3 & 3 & 3 & 2 & 4 \\ 5 & 5 & 4 & 4 & 3 & 2 & 6 & 6 & 6 & 5 \end{pmatrix}.$$

Step 2. We collect the frequencies of appearance of each of strengths in a table:

| #0 | #1 | #2 | #3 | #4 | #5 | #6 | #7 | #8 |
|---|---|---|---|---|---|---|---|---|
| - | - | 3 | 2 | 5 | - | - | - | - |
| - | - | 1 | 5 | 2 | 1 | 1 | - | - |
| - | - | 1 | 1 | 2 | 3 | 3 | - | - |

Step 3. We fill the table with probability distribution function for each of the three monitored competencies:

| #0 | #1 | #2 | #3 | #4 | #5 | #6 | #7 | #8 |
|---|---|---|---|---|---|---|---|---|
| - | - | 3/10 | 1/5 | 1/2 | - | - | - | - |
| - | - | 1/10 | 1/2 | 1/5 | 1/10 | 1/10 | - | - |
| - | - | 1/10 | 1/10 | 1/5 | 3/10 | 3/10 | - | - |

Step 4. We compute information entropies for each of the three competencies:

$$e_1 = -\frac{1}{\ln 10}\left(3 \cdot \frac{1}{10} \cdot \ln \frac{1}{10} + \frac{1}{5} \cdot \ln \frac{1}{5} + \frac{1}{2} \cdot \ln \frac{1}{2}\right) = 0.44717,$$
$$e_2 = -\frac{1}{\ln 10}\left(3 \cdot \frac{1}{10} \cdot \ln \frac{1}{10} + \frac{1}{2} \cdot \ln \frac{1}{2} + \frac{1}{5} \cdot \ln \frac{1}{5}\right) = 0.59031,$$
$$e_3 = -\frac{1}{\ln 10}\left(2 \cdot \frac{1}{10} \cdot \ln \frac{1}{10} + \frac{1}{5} \cdot \ln \frac{1}{5} + 2 \cdot \frac{3}{10} \cdot \ln \frac{3}{10}\right) = 0.65352.$$

Note that a higher (closer to 1) entropy value indicates larger "impurity" of data and points at a larger volatility in competency strengths.

Step 5. We compute a so called "distinguishing ability" (impact) $\omega_j$ of each competency

$$\omega_1 = \frac{1 - 0.44717}{1 - 0.44717 + 1 - 0.59031 + 1 - 0.65352} = 0.42233,$$
$$\omega_2 = \frac{1 - 0.59031}{1 - 0.44717 + 1 - 0.59031 + 1 - 0.65352} = 0.31298,$$
$$\omega_3 = \frac{1 - 0.65352}{1 - 0.44717 + 1 - 0.59031 + 1 - 0.65352} = 0.26469.$$

Smaller values of the entropy $e_j$ indicate larger impact of the $j$-th competency $\omega_j$ in the overall assessment. In our example, the first competency has the largest impact and the third one the smallest.

Step 6. We compute the consolidated competencies assessment value A for all three competencies as a weighted some of means for the competencies:

$$A = 0.42233 \cdot 3.2 + 0.31298 \cdot 3.6 + 0.26469 \cdot 4.6 = 3.6958.$$

Note that this consolidated weighted assessment value differs from the regular mean value $A = 3.8$. By monitoring the changes in $A$ from session to session and in the long run, we can follow the dynamics of the range of competencies.

## Conclusions and further plans

In this paper, we addressed the question regarding the use of KOM framework for monitoring the development of mathematical competencies of biology students engaged in complementary to the main mathematics course modeling activities. It turned out that the use of a reduced framework with five out of eight groups of competencies is preferable for practical reasons related to overlapping of competencies and coding reliability.

However, the choice of a comprehensive and reliable mathematical competences framework is not sufficient for successful monitoring of the development of students' competencies. It has become clear from the preliminary data analysis that, in addition to the record of the activation of each of the competencies during the teaching sessions, it is very important to develop a solid scaling system for tracing the "strength" (intensity) of each of the competencies which varies significantly at different instants. We believe that the eight-step scaling scheme serves well our purposes for each of the three dimensions; quite significant variations of the scores for different dimensions associated with the same competency confirm our opinion regarding the need of each of them in the analysis and importance of each of these dimensions in its own turn.

The next research question regards processing of large amounts of qualitative data collected in tables with the strength of each competency measured from C1 (the lowest) to A+ (the highest). We decided to convert all data to numerical values and performed preliminary analysis of the data based on the use of information entropy. One of advantages of this approach is related to the possibility to spot competencies with the most "volatile" behavior as those needing more lecturer's attention. We believe that in combination with other indicators (even as simple as median/mean value for the strength of a given competency), a new entropy-based scaling tool opens interesting opportunities for researchers who need a consolidated evaluation for big amounts of data. Information entropy could be efficiently used both to monitor the development of individual students' competencies and to compare performance of different students. One can assign different weights to competencies for monitoring the progress in the development of particular skills. However, using this method of data analysis inevitably leads to the loss of some essential information, the risk we are currently willing to undertake in order to study the potential of this new progress-tracking tool. In our forthcoming research we will test other ways of using information entropy for monitoring the development of students' mathematical competencies, both as a part of an independent scaling tool and in combination with other techniques for the analysis of large data sets (like monotonicity properties of data strings).

Goals, Resources, and Orientations for Equity in Collegiate Mathematics Education Research

Shandy Hauk
WestEd

Kathleen D'Silva
WestEd

*Though the terms equity, diversity, inclusion, and social justice have entered the research lexicon, researchers in collegiate mathematics education face significant challenges in gaining a nuanced understanding of the various ideas associated with these words and how those ideas are consequential for research. This report presents a framework for making sense of (and making sense with) equity as an essential component of research content and conduct. It offers tools for thinking and talking about equity and research design and implementation.*

*Keywords:* Equity, Justice, RUME

People trained in research in undergraduate mathematics education (RUME) know that work in RUME starts with diagnosing challenges in teaching and learning. As citizens of a first-world country in the 21st century, researchers in collegiate mathematics education in the United States are keenly aware of social, political, and economic inequity as challenges in education. And, as a community, researchers have an opportunity to define, explore, and address *equity*, *diversity*, *inclusion*, and *justice* in collegiate mathematics education. Rather than a report of empirical research, this piece is a synthesis of information about professional goals, resources, and orientations for working towards equity as a core aspect of both the content and conduct of research in undergraduate mathematics education. We start with the voices of researchers – the sample quotes in Figure 1 are synthesized from people in the RUME community (mostly attendees at the RUME Conferences in 2017 and 2018) when asked "What does it mean to consider equity in research in collegiate mathematics education?"

**Researchers speak their truths about equity and RUME:**

- I don't have a definition for "equity" and I'm not really sure what you mean by it, so I can't consider it in research.
- I include race and ethnicity in my data, that's how I'm addressing equity.
- My team researches equity in math ed, so of course we're addressing equity in RUME.
- I've faced this my entire professional career; I have done my best to 'fit-in' to have a career.
- We need to help others learn what the RUME ways are to do things, then we would be on a level playing field for research.
- The problem is too big, what can I do about it?
- Others don't want to participate in RUME, why should that change? Yes, it is inequitable, but is that necessarily a bad thing?
- Mathematics operates as whiteness. There is no possibility of equity in RUME until the meaning of the M in RUME is interrogated.
- What you do in math ed is so different from what I do, I couldn't possibly understand, review, and evaluate it.
- Dealing with equity means just doing 'good work,' because good work is bias-free.
- I'm a researcher in math ed that pays attention to equity but I accept that not all of my colleagues are going to be interested in that.
- Equity in education research has undergone a slow evolution. The time for evolution is over, the time for revolution is now.
- For RUME to be rigorous, it has to disrupt the inequitable research status quo.

*Figure 1. Sample of researcher thoughts about equity in RUME.*

**What do Equity, Diversity, and Inclusion mean?**

The difficulty in defining equity is that it involves an attempt to define something we have never seen. In what ways is equity a destination? … a journey? …something else? One can start with the Merriam-Webster dictionary and say, "equity is fairness." A starting point, but it begs the questions: What is fairness? Who decides? In the U.S. we have gotten to the point where we can distinguish between equity and equality: equality is everyone having the same thing while equity is based on a person's current situation and goals and means people have what they need to grow from the one to the other. Also, equity can be partially defined by its complement: inequity. Equity is evidenced by the absence of disparities (e.g., membership in a group that has been historically disadvantaged is in no way correlated to access to opportunities, attainment of educational outcomes, or achievement of life goals). So, tracking change in disparity is a way to measure progress towards equity (by measuring reduction in *in*equity). The distinctions between equity, diversity, and inclusion are a little clearer. Diversity is quantitative - a measure of the variation of particular characteristics of interest across people or groups. Like diversity, inclusion (in a group or structure) may provide a metric related to equity in that inclusion "involves an authentic and empowered participation" (Annie E. Casey Foundation, 2014). At best, however, inclusion may be necessary but is not sufficient for a situation or process to be equitable. As reflected in Figure 1, at this moment in the educational research and practice communities (and more broadly) there is not a well-defined, crisp, and shared definition of equity.

**Social Justice and Education**

Last year two organizations, TODOS: Mathematics for All and the National Council of Supervisors of Mathematics (NCSM), issued a position paper entitled *Mathematics Education Through the Lens of Social Justice: Acknowledgement, Actions, and Accountability*. In it, justice in mathematics education included "fair and equitable teaching practices, high expectations for all students, access to rich, rigorous, and relevant mathematics, and strong family/community relationships to promote positive mathematics learning and achievement" (p. 1). Underlying all of these was a call for attention to the ways power, privilege, and oppressions contribute to and maintain an inequitable educational system.

According to the TODOS-NCSM position paper, three conditions are necessary to establish socially just mathematics education and, we argue, to establish just RUME:

(1) acknowledging that an unjust social system exists,
(2) taking action to eliminate inequities and establish effective policies, procedures, and practices that ensure learning for all, and
(3) managing accountability to monitor progress in and from action, so changes are made and sustained.

How do we increase mathematics education *researcher* capacity to do these three things? In writing this report, we (the authors) claim that one step is meeting researchers where they are, addressing the need for language, definitions, and awareness-building about educational equity. A deep investigation of perceptions in Figure 1 is beyond the scope of this report. As a first step, we have organized this report around: (1) potential *goals* for the RUME community, (2) some *resources* for starting the journey towards equitable research – research that attends to equity in its conduct and its content, and (3) *orientations* for doing this work together with others.

Certainly, significant inequity in the United States is rooted in racism, sexism, and other societally institutionalized -isms that structure opportunity and assign value in ways that disadvantage some people and groups and advantage others for reasons that are (now) anathema to the majority of the population. Acknowledging, unpacking, and addressing the inequitable realities of systemic, professional, and personal biases requires courage.

Cognitive dissonance and disequilibration have come to be valued as opening mental room for the generation of disciplinary learning (Piaget, 1963). Similarly, dissonance and disequilibration related to belief, motivation, culture, and communication can pose opportunities for the creation of new knowledge and ways of thinking. Discomfort is frequently an indicator that we are about to learn something (National Research Council, 2000).

**Speaking Differently in Different Ways**

Mathematics education by its very nature is interdisciplinary, pulling from educational psychology, sociology, and mathematics fields, among others. This means that researchers navigate among different professional cultures. Here, we use the word *culture* to indicate a set of values, beliefs, behaviors, and norms in use by a group that are shared with and taken up by others who become members in the group. Therefore, it may be important for RUME researchers to take note of lessons from researchers in other interdisciplinary groups. It is well documented in the literature that equitable research in other fields is carried out by disciplinary experts in multidisciplinary teams (e.g. see Bililign, 2013). In particular, successful cross-cultural collaboration requires *intercultural sensitivity* (Bennett, 2004) and *responsive communication skills*. The development of these relies on (a) the orientations we have to differences we note in both explicit and implicit values and (b) knowledge and use of variation in norms for communication and resolution of conflict (Bennett, 1993; Hammer, 2009).

International and national variation means factors of ethnic, racial, and other types of group and institutional enculturation and socialization are involved in professional intergroup communication. As an example, consider the work related to gender and communication, both within and across groups. One comparison of African American and European American women found a direct communication style to be more common among African American women than the indirect framing most used by their European American peers. Both groups of women had a goal of reducing potential conflict (or, largely in the case of the European American participants, conflict avoidance), but methods for how to articulate and achieve it were different (Shuter & Turner, 1997). As we have noted before from a gender-as-culture perspective (Hauk & Toney, 2016), communication habits emerge from a childhood and adolescence filled with same-sex conversational partners and a lifetime of social expectation (Maltz & Borker, 1982). Review of the literature on studies of language and gender has found that women may have access to power (and more acceptance) in a majority culture context when using indirect language, uncertainty, and hedges in relatively long sentences: “Well, I was wondering if…,” “Perhaps we might…,” while men fulfill expectations by referencing quantity or judgments with direct assertions: “An evaluation of 3.8…,” “It’s good because…” (Mulac, Bradac, & Gibbons. 2001, p. 125).

The fact that interaction about RUME in most universities occurs in the context of historically male discourse makes every interaction between the sexes a doing of gender in some way (Uchida, 1992). Consequently, gendered communication structures can be (dis)empowering depending on context. Additionally, those whose work focuses on teaching tend to value a pragmatic approach and may seek rewards based on personal motivation rather than external distinction (Wang, Hall, & Rahimi, 2015). Some have written about the importance of women seeking to participate in the career reward structures and other status quo value systems in the academy (Nicholson & de Waal-Andrews 2005; Olsen, Maple, & Stage, 1995). However, embracing the status quo without also attempting to change it has the danger of derailing progress in the intellectual and professional work of RUME.

## Goals

Rigor in research is in its authenticity and trustworthiness (Lewis-Beck, Bryman, & Liao, 2003). Implicit in this assertion are (a) who is making the decision about what is worthy of trust and (b) whose trust needs to be sought. Current research practice common in the United States relies on a closed (and exclusive) system: the people making the decision and whose trust is sought are the extensively educated people doing the research. Yet, research involves humans who are not researchers. The *stakeholders* include researchers *and* those who will be researched as "participants" in the work, colleagues in education who are not researchers (e.g., department chairs, other faculty in the department and university, at other colleges), future audiences for the results of the research, and policy makers who rely on research to inform decisions.

In K-12 education, attention to equity in the focus of research and in the methods and reporting of research, particularly an intention to include views of stakeholders who are not also researchers, has existed for a while. Statements from K-12 about equitable and inclusive mathematics and its teaching might be adapted to be about RUME. In Figure 2, we have "marked up" two statements. One is an existing equitable vision for teaching for robust understanding (TRU, Schoenfeld et al., 2014; 2017) and the other a critical vision for just and inclusive mathematics (Gutierrez, 2012). Each indicates how an adaptation for RUME goals can be stated.

**TRU Framework (Schoenfeld, 2014):** Equitable access to ~~mathematics~~ RUME is the extent to which ~~classroom~~ research activity structures invite and support the active engagement of all of the ~~students~~ stakeholders in the ~~classroom~~ research.

**Gutiérrez (2012):** We seek ~~mathematics~~ RUME that squarely acknowledges the position of ~~students~~ stakeholders as members of a society rife with issues of power and domination. Critical ~~mathematics~~ RUME takes ~~students~~' stakeholders' cultural identities and builds ~~mathematics~~ RUME around them in ways that address social and political issues in society, especially highlighting the perspectives of marginalized groups.

*Figure 2. Examples of two existing goal statements from K-12 education and their adaptation into goal statements for RUME.*

In recent RUME, an inclusive and stakeholder-responsive approach has become more frequent (e.g., Aguirre & Civil, 2016; Adiredja, Alexander, & Andrews-Larson, 2015; D'Ambrosio et al., 2013; Davis, Hauk, & Latiolais, 2010; Nasir, 2016). Change takes time and intentionality (Marshak, 2005). Changing our individual and collective mindsets, behaviors, and approaches related to equity and the work of RUME will not happen as a result of one paper, statement, project or movement. However, "immediate and transformative change is necessary" (TODOS, 2016, p. 1). Aiming for the goals in Figure 2 requires change. How can we achieve this change? On the small scale of a local research project, what is needed to pursue goals like those in Figure 2? Certainly, self-awareness and awareness of others as we plan, act, reflect, and communicate. This occurs in the context of researcher orientation (individual and collective) towards the thing about which the planning, doing, and reflecting is happening.

Regardless of whether research is *about* equity in mathematics teaching and learning, it is time for an "equity lens" to inform research questions, design, methods, and reporting in the focusing and doing of collegiate mathematics education research. In a piece that appeared in the

*Journal for Research in Mathematics Education* (JRME), Aguirre and colleagues (2017) asserted that researchers in K-12 education have a responsibility to challenge the ways in which "power, privilege, and oppression tacitly and explicitly play a role in research programs" (p. 126). The authors also noted that researchers have a choice in moving from the *status quo* to intentional collective responsibility for doing "the right thing for current and future generations" (p. 125). They organize their suggestions as four political acts:

1. Conduct mathematics education research with an equity lens
2. Acquire the knowledge necessary to do genuine equity research work
3. Challenge the false dichotomy between mathematics and equity as research topics
4. Expand the view of what counts as "mathematics."

In this essay, we touch on each of these in the context of RUME with a focus on Political Act 2.

In the next section we offer resources for researcher planning, doing, and reflecting on equity – this includes such things as deciding what to study and how to conduct the research. By no means exhaustive, these resources include existing research reports, frameworks for organizing activity and analysis, and a tool to support purposeful reflection. In the subsequent section, we examine the contextual factor of interpersonal orientation. This report ends with a synthesis across the offered goals, resources, and orientations for working towards equity as we do RUME.

## Resources

Given the nature and foci of research in collegiate mathematics education to date, new ways of thinking and new ways of engaging with topics, participants, structures, mechanisms, and results of research are needed for work with an equity lens. The challenge is how to visualize that world we have not yet seen and traverse with purpose and patience the meandering path to educating ourselves for working towards equity. Crucial to realizing the new view is a re-usable process that supports researchers to detect, discuss, and disrupt inequities within research.

How do we engage in conversations about research in mathematics education that may be challenging and uncomfortable? We offer a few resources here. These have emerged from the authors' own work in critical educational research as well as purposeful conversations with RUME colleagues (e.g., poster-side at conferences, during conference (pre)sessions focused on the topic). We rely on effort to be aware of, and transparent about, our own views as well as active effort to become knowledgeable about views across the gamut of stakeholders in RUME.

In what follows, we have chosen to adapt the engineering design cycle (see e.g., NGSS, 2013) as a way to structure the presentation. We made this choice for two reasons. First, the cycle is cross-cultural. Versions of the design cycle appear across time and societies. Second, it is a framework that has proven useful in many human endeavors with varying numbers of stakeholder groups, from developing a cure for smallpox, to successful moon landing, to organizing effective civil disobedience.

### Research Design Cycle

We propose a process for attending to equity and creating transformative change. The process is based on the design cycle common in engineering and design-based research (e.g., Figure 3, next page). There are many other versions of the design cycle. They share the basic features of a process for defining/understanding the problem, designing/testing solutions, and then iterating the process.

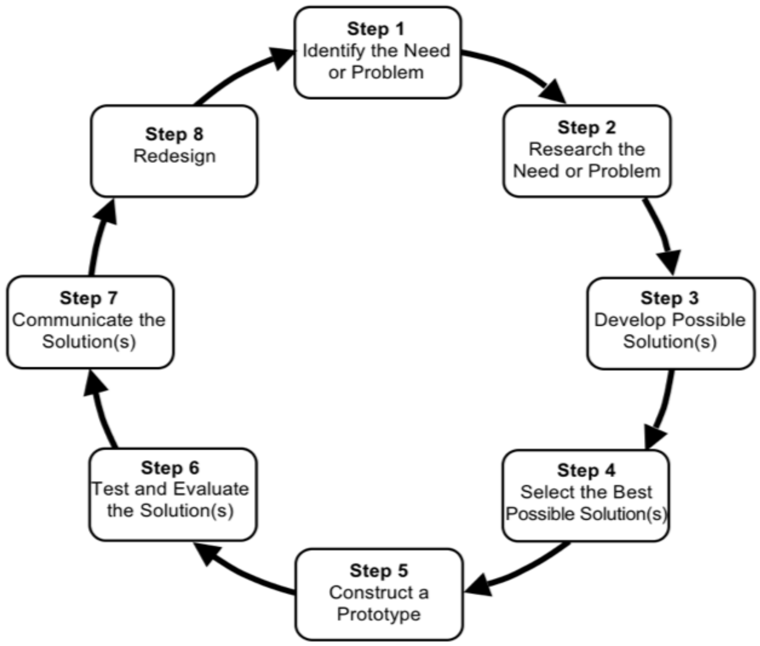

*Figure 3. Example of a design cycle (Massachusetts Department of Education, 2006).*

Just as engineers repeatedly iterate on a design to make a better product or solution, so must we iterate on our strategies, research designs, and methods for creating, using, and reporting on research. Engineers acknowledge there are many different possible solutions and that a solution that meets current needs or goals can always be improved. We also recognize that while there may be many approaches for those attempting research that includes equity as a research focus and/or attends to equity in its conduct, none will be perfect. Individually, and collectively, researchers in collegiate mathematics education must continue to iterate through the cycle. We can pause, but must not become complacent, in the work. Yes, the problem is overwhelming. Yes, it may seem insoluble in our lifetimes. At one point, so was how to create a proof about parallel lines that would stay proved. The important thing is to start, somewhere, and iterate. Intentionally going through the cycle helps to make incremental success visible as we move towards near, subsequent, and far goals.

A design cycle is useful for an individual researcher, in small professional groups, and as a community. However, when they cycle is about work of *research* it is, explicitly, situated in research. No one can do it alone. The researcher version of the design model in Figure 4 (next page) requires at least one thought partner. Keep in mind that in the RUME community, in addition to general opportunities to build professional relationships at the annual conference, there are research working groups. Each of these working groups is a resource. Also, we as the RUME community are stakeholders, and can engage in a cycle to acknowledge, act, and hold ourselves accountable for community progress in making and attaining equity goals.

**Design Cycle Framework as a Researcher Tool**

***Consult with Stakeholders*****:** The cycle begins with developing a focal research goal. A necessary first step is to identify people/organizations that *might be* stakeholders in defining and achieving that goal. Consult with possible stakeholders to determine the degree to which people see themselves as stakeholders and to ask who other stakeholders might be. This consultation is used to shape goals and their framing.

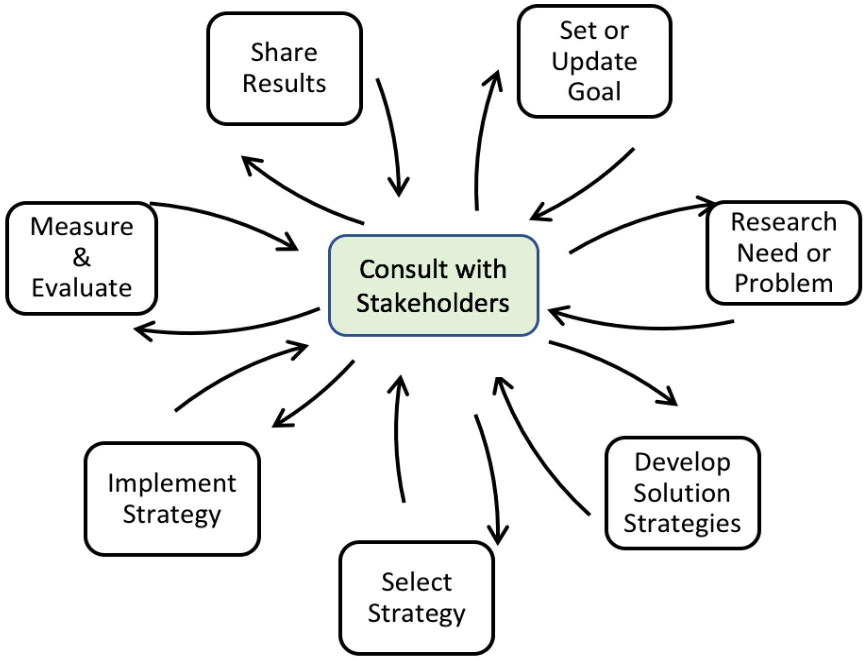

*Figure 4. Research design cycle with centrality of stakeholders.*

For example, is a goal stated as a problem that will be solved, as a situation that will be explored, as a driving question that will be addressed? Also, part of this stakeholder consultation is identification of which mathematics is the mathematics under consideration. Researcher and stakeholder views of what counts as mathematics and what is compelling for research may need considerable negotiation (e.g., determine whose mathematics is the research about and what accountability to stakeholders is explicit in the choice; see, e.g., Balacheff, 2010; Bensimon & Harris, 2012; Sternberg & Ben-Zeev, 1996). Questions about *how to consult with stakeholders* are challenging to pose and to answer. Though in later sections we offer some tools, as noted earlier, this report is an initial tilling of ground for the RUME community. What it means to identify and productively consult with stakeholders will continue to develop as the community builds experience with the idea.

***Set or Update Goal.*** In the context of the acknowledge-act-account framework from TODOS/NCSM, this step acknowledges that there is an issue or area that needs addressing to move towards equity. The goal step also sets up accountability by explicitly stating a goal against which to measure effectiveness. While an overarching goal may be to attend to equity in research in undergraduate mathematics education, it is necessary to create one or more specific goals when engaging in the cycle. In fact, the goals themselves may focus on a target of acknowledgment, action, and accountability. For example, a research team with members across several institutions may set goals to include more about student learning outcomes in the context of student needs, cultures, strengths, and struggles in calculus (generally or, perhaps with a focus on a particularly problematics topic). The research team may have several objectives related to this goal, including (a) focal *research content* that examines what supports equity of outcomes among students (e.g., in addition to equity of opportunities) and (b) situating the research design and implementation in the entirety of student experience as a decision driven by equity in the *conduct of research* (e.g., taking into account the various types of calculus tutoring available to students at each campus, in and outside of the mathematics department; course loads for instructors and students; work hours). Another example, one that is structural, would be setting a goal for the context in which research is conducted and valued. The research team may have the goal of having their respective departments acknowledge, act, and set an accountability structure within the tenure and performance review process, one that incentivizes equitable research practice. Each of these example goals - for professional research design and for professional context design - might be served, together, in the same research project effort. ***Consult with Stakeholders*** to clarify and confirm stakeholder partners/informants and prioritize areas of focus for finding out more (i.e., to prepare for the next step in the cycle). For instance, in the calculus study example, immediate stakeholders would include the researchers on the team, calculus students at each university, those who offer calculus instruction and tutoring to students (e.g., instructors and grad students in the math department, staff at campus cultural centers, fraternities, sororities, publishers, and other sites that may offer in-person or online tutoring services), as well as informants from student services, the office of the Provost (who oversee instructional development), and the office of the Dean of Students (who are familiar with data on course/workload and student support practices that may shape goals).

***Research:*** Once a goal is set, the next step is to engage in background research. This is part of acknowledgement in that one learns about and acknowledges the nuances of issues surrounding a goal. While this step is revisited throughout an entire career, dwell time here depends on context. Do learn enough about the goal-related need, problem, or aim that any subsequent actions have a reasonable likelihood of positive outcomes. This step includes a literature review across stakeholder-relevant literature. The research step also involves learning what resources are available for this work. ***Consult with Stakeholders*** to discuss and negotiate priorities of the needs related to goals. Learn from people, organizations, and other venues what has been done before, what has worked or not, and why. In this step, relationships with critical friends for the project will continue to be negotiated. For example, individuals wanting to learn more about students may consult with someone with expertise in how to develop intercultural competence, a department incentivizing equitable research practices may want to research what other institutions have done in this area, and the RUME community might research the range of practices considered equitable by stakeholder groups. Resources that emerge from this step range from financial to conceptual frameworks. Through this research and stakeholder consulting step, a different or deeper understanding of the need or problem is made possible. Thus, folding back to update goals may be called for before going on to the development of strategies.

***Develop Strategies:*** Equipped with some idea of the nuances, considerations, and resources surrounding a goal, the next phase is to develop possible actions. This is the first step in the cycle directly related to action. It is important in this step to not focus on any one strategy but develop an array of strategies that may work. Also, in this phase are early plans for measuring effectiveness. Some strategies for attaining (and measuring progress towards attaining) goals may arise from research on approaches others have used. ***Consult with Stakeholders*** to develop, in conjunction with them, a pool of possible strategies and an awareness of the situated pros and cons. Several different types of relationships can be built in this step. New critical friends valuable to the project may emerge or need to be sought to answer key questions. Will there be surveys or interviews? Why? Which stakeholders are important to include in the measures? Will the work involve sensitive data? Who defines what is “sensitive” and why do they get to decide? Is permission needed? From whom? What, in context, is ethical? What do stakeholders feel are important measures? Why? The answers will inform prioritization of strategies.

***Select Strategy:*** Decide what action to take. Investigate each of the possible strategies and think about the merits and constraints of each. ***Consult with Stakeholders*** to determine which strategy best meets the need or goal while respecting all persons involved.

***Implement Strategy:*** Often, carrying out an intervention or program is seen as the most important or sole action. This step represents a large and complex set of activities! Something to keep in mind in this step are the importance of establishing and devotedly maintaining open and regular stakeholder communication. ***Consult with Stakeholders***, particularly those identified in earlier steps as (1) valuable critical friends and (2) brokers among stakeholder groups. Note that implementing a strategy is only one step of the cycle. If effective, it can be far-reaching. And, we know from existing research that effective implementations arise from strategies based in a robust theory and rooted in authentic educational settings.

***Measure and Evaluate:*** Measuring outcomes and evaluating effectiveness are central to accountability. Some of this must happen at the same time as implementing the strategy. Data collected throughout the cycle is used to measure progress to goals. ***Consult with Stakeholders*** to select and be guided by resources on formative and summative assessment for projects.

***Communicate Results:*** Once all data are collected for a cycle, analysis, reflection, and synthesis set up the next cycle. The definition of rigor in scholarship includes the expectation of peer review. In research that works towards equity, stakeholders are peers who review. ***Consult with Stakeholders*** by providing and seeking feedback on documentation of results. This is at the foundation of accountability. Keep in mind that "stakeholders" includes researchers! Thus, to "consult with stakeholders by providing and seeking feedback on results" includes submitting articles to peer-reviewed outlets.

Democratic systems function when stakeholders are involved and shape the work. Involving representative stakeholders in every step of the process is essential for developing equitable systems for research. Stakeholder communications holds research efforts accountable at each and every step of the cycle.

**Tool for Sharpening Awareness: Feeling Safe, Comfortable, and/or Brave**

Discerning difference, recognizing pattern, and anchoring new knowledge in those already noted differences and patterns are at the core of all human cognition. In other words, examining and making sense with our experiences are the essentials that allow humans to think, know, and learn. For researchers to engage in equitable, inclusive, and just efforts, means successfully noticing and navigating similarities and differences when collaborating with colleagues and communicating with stakeholders (including those who may identify with culture(s) different from their own). One resource we have found helpful in building awareness and responsiveness to the in-the-moment experiences is the Venn diagram shown in Figure 5 (next page).

The diagram can support self-aware communication about how people experience intellectual, personal, and professional risk. For example, a person may not feel safe having a conversation with (or about) people from other races but can be brave and handle the discomfort in order to stay engaged in a conversation (region *b*). For more on this tool, see Hauk, Toney, Judd, & Salguero (2017; in preparation).

We note here that the terms in Figure 5, and the meanings of the overlaps, must be negotiated between any two people who attempt to use the diagram as a tool in communication. In particular, safety is a characteristic of a person's experience, not a feature of the space. This differs from common (and often inequitable) assertions like, "the classroom should be a safe space." In general, such a statement is made without an accompanying expectation to *consult* *with stakeholders* (e.g., students and teachers) to validate it is possible for every person in the classroom to simultaneously experience the classroom as safe. Unaddressed is what is considered "safe" and who gets to decide (Nasir, 2016).

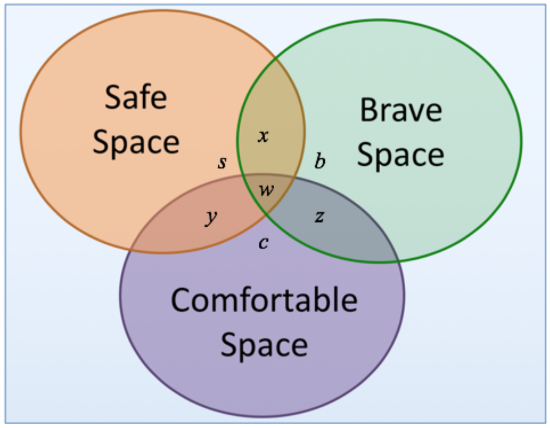

*Figure 5. Juxtaposition of three types of experience related to taking risk.*

As a tool for articulating self-awareness, the Venn diagram in Figure 5 is meant as a way for a person to identify the nature of individual experience in a particular moment. We are not claiming that a thing (e.g., a whole conversation, a research paper, a research design) might be a member of one of the sets or in a region. In fact, in the course of a 3-minute exchange during a research development meeting, one person could experience each of the seven regions in the diagram! To illustrate, a short example (from Hauk, Toney, Judd, & Salguero, in preparation):

***Researcher example.*** Suppose I am a white research faculty member talking with two white graduate students who have been vocal in their deficit views of non-whites as learners. The topic is a new research project they are to work on and my goal is to guide them to readings about how to fruitfully include attention to race and gender in their research. This is familiar and routine advice on my part, I feel comfortable in my role and what I am saying. I am not feeling the need to be brave (yet), because this is an initial conversation (region *y*); continuing conversation after the students have done some reading probably will involve being brave. At the same time, I realize the conversation is becoming professionally risky for me (region *z*) when one of the students says that if I really assign the readings, then he plans to complain to the chair about the assignment. Unsure of my relationship with the chair, I suspect there is a professional risk. At this moment, I would point to region *c* to identify my experience (still comfortable in my role and what I am saying, but not safe and not brave). Meanwhile, the graduate student who asserts, "students whose parents are from Mexico cannot do well because their parents do not value education" may experience the initial conversation from region *y* and rapidly move to region *b*, when his view is not met with the approval he expected.

## Orientations

Equity-aware research is shaped by what a researcher knows or anticipates about others' experiences and how that is communicated. Do we anticipate great risk? Do we have the privilege of assuming safety? Interactions with other people are shaped by the approach we take to the interaction and our orientation to noticing and engaging with difference in context. In this section we offer a framework for each of these. The first is an approach to being self- and other-aware during interactions. The second framework provides language and a developmental model for cross-cultural competence growth.

**Approach to Courageous Conversations**

Over the past 10 years, Singleton and colleagues' (2006, 2008) courageous conversations framework has become a cornerstone in the professional development of teachers. It is built on four agreements made by participants in a conversation before the conversation begins. These agreements contradict some tightly held cultural norms common to many in the U.S. when it comes to talking about interculturally challenging topics. To participate in a "courageous conversation" you agree to:

- stay engaged
- expect to experience discomfort
- speak your truth
- expect and accept a lack of closure.

The details for each of the four agreements are non-trivial. Staying engaged is different from being verbal; staying engaged means persisting as a listener and contributor, making conscious decisions about when to share thoughts aloud and when to reflect or write them down for further personal consideration before sharing. Expecting to experience discomfort also means being aware of one's own behavior and how that may ramp up discomfort for others - self-regulation, particularly for those unaccustomed to exercising it, can be challenging. The aim of a courageous conversation is *not* to convince or persuade others. Rather, the goals are determined (or at least negotiated) by the discussants. "Speak your truth" also means *listening to* the truth of others - this is a different activity from *listening for* echoes of one's own truth in what others say (or do, or value). Finally, the work of a courageous conversation may achieve milestones of agreement of understanding but rarely is the conversation tied off neatly. This is to be expected in a complex situation.

**Framework for Intercultural Orientation Development**

The ways people are aware of and respond to others is a consequence of their intercultural orientation. This is neither a reference to one's beliefs about culture or race nor about views on researching in mathematics education. Rather, intercultural orientation is the perspective about human difference each person brings to interacting with others, in context. For researchers, it includes perceptions about the differences between personal and professional views and values around various types of work in mathematics education, the views of colleagues, and the views of stakeholders in research. Intercultural competence is the capability to shift perspective and appropriately adapt behavior to differences and commonalities (Hammer, 2009).

To build skill at establishing and maintaining relationships in, and exercising judgment relative to, cross-cultural situation requires the development of intercultural sensitivity (Bennett 2004). The developmental continuum for intercultural sensitivity has five milestone orientations to noticing, making sense of, and responding to difference: denial, polarization, minimization, acceptance, and adaptation.

With mindful experience a person can develop from ethnocentric ignoring or denial of differences, moving through an equally ethnocentric polarization orientation of an us-versus-them mindset. With growing awareness of commonality, a person enters the less ethnocentric orientation of minimization of difference, which may over-generalize commonalities. From there, development leads to an ethnorelative acceptance of the existence of intra- and intercultural differences. Further development aims at a highly ethnorelative adaptation orientation in which differences are anticipated and responses to them readily come to mind for effectively brokering cross-cultural interaction. Figure 6 offers a visual summary.

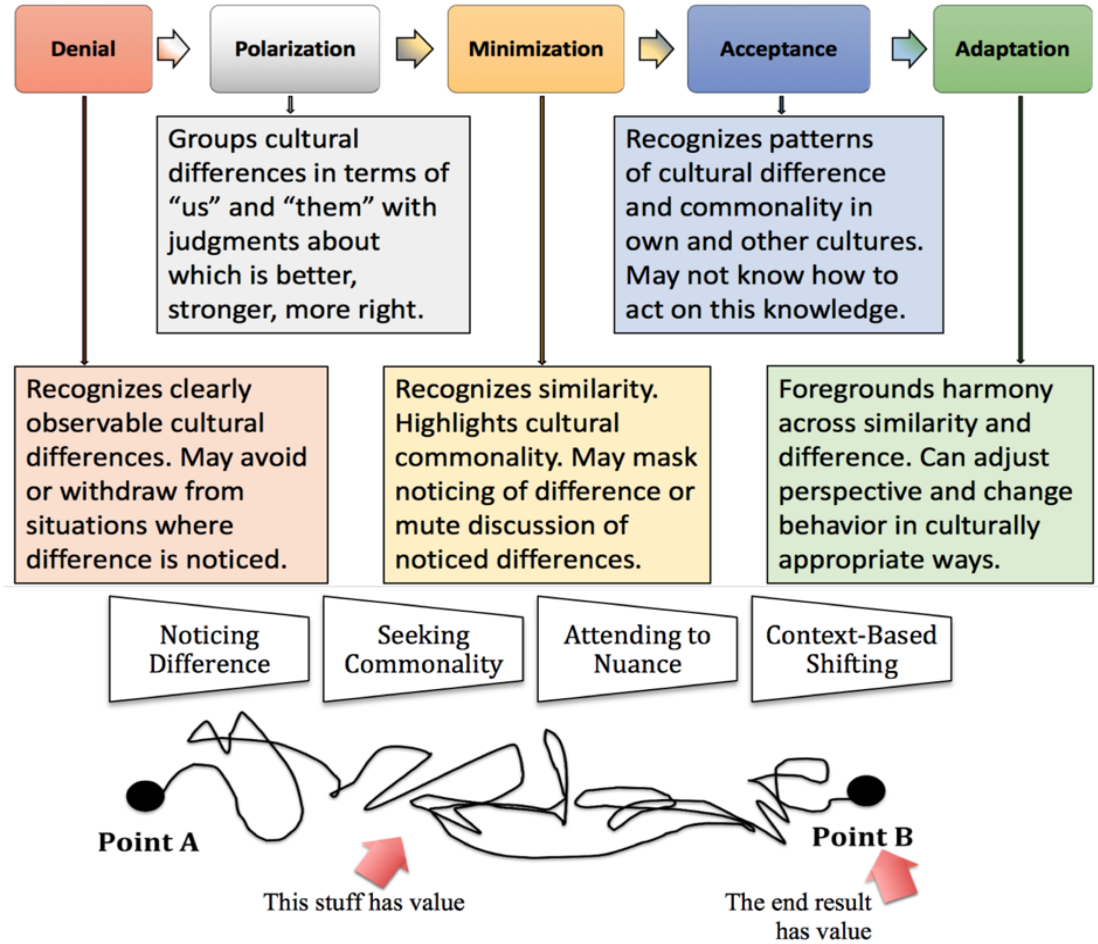

*Figure 6. Diagram summarizing intercultural orientation developmental continuum. One may start at point A and eventually develop to point B, but the path is not linear.*

To meet the goal for this report of synthesizing information that can support researchers in working towards equity as a central feature of RUME, here we have only briefly summarized some of the language and structure for intercultural orientation. We have discussed and illustrated use of this framework at length, particularly in RUME contexts, elsewhere (e.g., Hauk & Toney, 2016; Hauk, at al., 2017; Hauk, Toney, Jackson, Tsay, & Nair, 2014; Hauk, Toney, Nair, Yestness, & Troudt, 2015). Though not yet a common perspective in RUME, understanding oneself and others through the lens of intercultural orientation has proven transformational for the authors in our efforts at acknowledgement, action, and accountability.

The takeaway message about orientations: all the consultative activity at the center of the design cycle involves challenging conversations with people who are different from each other and may have widely varying orientations to those differences (and to research). In particular, an explicit action that can be taken by researchers is seeking agreement to Singleton et al.'s four foundations by participants in challenging conversations (this includes researcher and non-researcher stakeholders; American Evaluation Association, 2011).

## Conclusion

Regular engagement in courageous conversations is required for the kind of stakeholder-communication-centered design cycle described in this report. It takes practice to ensure such conversations are productive and worthwhile for discussants. Encounters with stakeholders, particularly when topics are challenging, requires carefully considered orchestration. Intentional effort is needed to learn to do this. As a community we are still in the early stages of building the necessary knowledge and skills for an equity lens on research. Recently, in their study of successful collaborations between education faculty and science, technology, engineering, and mathematics (STEM) faculty, Bouwma-Gearheart, Perry, and Presley (2014) noted that for experienced *brokers* (i.e., facilitators between two groups) it took multiple semesters of mindful effort to support development away from a polarizing stance (i.e., each group recognizing difference between the two cultures but being overly critical of the other) towards an adaptive orientation in which each accepted the other culture and used differences effectually in collaborative work.

The Venn diagram (and negotiated definitions) for safe, comfortable, and brave space can function as either a personal reflective tool or an explicit, shared, tool for mindful conversation. Use of the tool might help identify how conversations and research designs are courageous (and challenging enough) to meet goals for equity and justice. For example, personal monitoring during a challenging conversation can provide feedback on how and when seeking safety and comfort may interfere with attaining equity goals.

We have illustrated a cyclic framework for setting goals, leveraging resources, and reaching beyond personal orientations for a new and inclusive RUME. A RUME that dismantles inequity. A RUME in which the very definitions of rigor and quality in research unpack the current value set, the *status quo*, in research and make plans for how to rebuild. To make progress, we must embrace the humanity and fallibility of ourselves and of those our research is meant to serve. The interaction between the authors and you, the reader, was an acknowledgment, an action, and an opening for accountability.

When "Negation" Impedes Argumentation: The Case of Dawn

Morgan Sellers
Arizona State University

*Abstract: This study investigates one student's meanings for negations of complex mathematical statements. One student from a Transition-to-Proof course participated in two clinical interviews. The student was first presented with several statements with either one quantifier or one logical connective and asked to negate these statements. Then, the student was presented with statements containing a combination of quantifiers and logical connectives and was asked to negate these statements. Lastly, the student was also presented with several complex Calculus statements and asked to determine if these statements were true or false on a case-by-case basis using a series of graphs. The results reveal that the student used the same rule for negation in both simple and complex mathematical statements when she was asked to negate each statement. However, when the student was asked to determine if statements were true or false, she relied on her meaning for the mathematical statement and formed a mathematically convincing argument.*

*Key words:* Negation, Argumentation, Complex Mathematical Statements, Calculus, Transition-to-Proof

Previous literature shows that students often interpret logical connectives (such as "and" and "or") and quantifiers (such as "for all" and "there exists") in mathematical statements in ways contrary to mathematical convention (Dawkins & Cook, 2017; Dawkins & Roh, 2016; Dubinsky & Yiparaki, 2000; Epp, 2003; Shipman, 2013). Researchers have recently called for others to also focus on the logical structure found within Calculus theorems and definitions (Case, 2015; Sellers, Roh, & David, 2017). Even in introductory Calculus courses, students must reason with logical components, such as quantifiers and logical connectives, in order to verify or refute mathematical claims. However, introductory Calculus textbooks do not discuss the distinctions among different connectives nor do they have a focus on the meaning of quantifiers or logical structure in algebraic expressions, formulas, and equations, even though these components are used in definitions and problem sets (Bittinger, 1996; Larson, 1998; Stewart, 2003).

In undergraduate mathematics courses, including Calculus, students are frequently asked to evaluate the validity (i.e. determine the truth-values) of mathematical conjectures that are complex in nature. By *complex mathematical statements*, I mean statements that have two or more quantifiers and/or logical connectives. For example, the Extreme Value Theorem (EVT) is an example of a complex mathematical statement. This theorem may be stated as follows:

| |
|---|
| If a function is continuous on $[a, b]$, then there exists a $c$ in $[a, b]$ such that for all $x$ in $[a, b]$, $f(c) \geq f(x)$, and there exists a $d$ in $[a, b]$, such that for all $z$ in $[a, b]$, $f(d) \leq f(z)$. |

*Figure 1.* The Extreme Value Theorem (EVT).

The EVT is a complex Calculus statement because it contains multiple quantifiers ("for all" ($\forall$) and "there exists" ($\exists$)) and logical connectives ("and" ($\wedge$) and "if…then…" ($\rightarrow$)).

In order for students to properly justify why complex Calculus statements are true or false, and for students to develop logical proofs, they must be able to describe the relationship between these statements and their negations (Barnard, 1995; Epp 2003). For example, for students to build strong meanings for the EVT, they need to be able to determine when graphs *do* or *do not* have an absolute maximum or minimum. Similarly, students in Calculus, Transition-to-Proof, or

Advanced Calculus may be asked to determine if sequences are convergent *or* divergent, or determine if functions or sequences are bounded *or* unbounded. If students are in a Transition-to-Proof or Advanced Calculus course, they may also need to utilize proof by contradiction, which relies on the ability to assume the negation of a statement is true (Lin, Lee, & Wu, 2003). Thus, we also must explore student meanings for negation in mathematical contexts that they will encounter in their undergraduate courses. Several studies have investigated student meanings for negation (Barnard, 1995; Dubinsky, 1988; Lin et al., 2003), but these studies do not explicitly address complex Calculus statements. In this paper, I will investigate one student's meanings for the negation of various types of mathematical statements as well as how these negation meanings affect her justifications for several Calculus statements. Thus, I seek to investigate the following research questions for this student:

1. *As mathematical statements become increasingly complex, will the student keep the same negation meanings? If some or all of her negation meanings change, which meanings change and how do they change?*
2. *How do the student's meanings for negation affect her evaluations of complex Calculus statements and her justification for these truth-values?*

## Literature Review

In order to better understand students' negations of entire complex mathematical statements, we must first analyze their understanding of quantifiers and logical connectives in given statements before analyzing their negations of the entire complex statement. This manuscript includes a synthesis of the literature on quantifiers and logical connectives, including literature that pertains to negating statements with these logical components.

### Student Treatment and Negations of Quantified Statements

Quantified statements, like statements with logical connectives, elicit a plethora of student meanings that differ from mathematical convention and are found throughout many mathematics courses. Some studies focus on a single quantifier, while others involve statements with multiple quantifiers. I focus attention on each of these trends in literature before summarizing what is known about students' negations of quantified statements.

**Single quantifiers.** Some statements only have one quantifier such as "for all" ($\forall$) or "there exists" ($\exists$). Both universally-quantified statements and existentially-quantified statements may elicit student interpretations that differ from conventional norms. Students often suggest that multiple examples are sufficient justification for universal statements (Healy and Hoyles, 2000). On the other hand, when proving a universally quantified statement false, students often don't believe that only one counterexample is sufficient to prove a universally quantified statement false (Balacheff, 1986; Galbraith, 1981). Some students also reject the notion that one example suffices for proving an existential statement is true (Tirosh & Vinner, 2004). Sellers, Roh, and David (2017) analyzed students' meanings for the individual quantified variables in complex mathematical statements. They found that Calculus students often do not distinguish a difference between "for all" and "there exists" when analyzing the validity of mathematical statements and instead may interchange meanings for "for all" and "there exists." Sellers et al. (ibid) noted that some students appeared to skip over quantifier words in the mathematical statements given, but added their own quantifications based on their meanings for the phrase "$f(c)=N$."

**Multiple quantifiers.** Previous studies also show that students often do not problematize the distinction between "for all… there exists…" ($\forall\exists$) and "there exists… for all…" ($\exists\forall$)

statements, and that ∃∀ statements are frequently misinterpreted as ∀∃ statements (Dubinsky & Yiparaki, 2000; Sellers, et al., 2017). Sellers et al. (2017) also found that one Transition-to-Proof student in their study treated ∀∃ statements like ∃∀ statements. Other studies also note that students may reorder the variables attached to the quantifiers in their explanation of a complex mathematical statement because they do not recognize the independence of the first variable and dependence of the second variable (Dawkins & Roh, 2016; Roh & Lee, 2011). For example, in the Extreme Value Theorem provided in Figure 1, one must consider each value of $c$ before finding the associated $x$ that depends on each $c$.

**Negations of quantified statements.** Since students often interpret quantified statements in unconventional ways, one may not be surprised that they also often negate these statements in unconventional ways. Lin, Lee, and Wu (2003) gave students statements that either had no quantifiers, a universal quantifier, an existential quantifier, or a unique existential quantifier. Students in this study were most successful with negating statements with no quantifiers, followed by the existential quantifier (∃), then the universal quantifier (∀), and finally the unique existential quantifier (∃!). Approximately half of the students correctly negated the universally quantified statements, but less than 20% of the students in the study correctly negated statements with a unique existential quantifier. Barnard (1995) presented students with both colloquial and mathematical statements and asked them to negate the statements. Even the more advanced students negated correctly less than 75% of the time for the seven provided mathematical statements. All student success rates were lower for more logically complex statements, and only 1% of the students answered every one of his 21 negation items correctly. The low success rates on the more complex mathematical statements may be partially attributed to students' emphasis on the negation of one of two quantifiers from the original statement (Barnard, 1995; Dubinsky, Elterman, & Gong, 1988).

These results suggest that students need formal training to properly negate quantified statements. Yet, Dubinsky, Elterman, and Gong (1988) suggest that formal training should not be equated to the teaching and memorization of rules for negation. Dubinsky et al. (ibid) found that students often memorize rules for negation incorrectly, and then proceed to use their own rules when negating statements. In their study, they presented students with two statements with multiple quantifiers. They analyzed students' reasoning about the statements, with a specific aim to analyze their negations of the statements. They mention three types of negation with quantification: *negation by rules* (memorization of rules), *negation by recursion* (parsing a statement and then negating each part appropriately), and *negating meaning* of a statement. Dubinsky et al. claim that negating the meaning of the statement is the most difficult of the three, but that every student that used negation by recursion achieved a correct negation. While students who negated recursively also negated correctly, students who used negation by their own memorized rules often made errors in their negations. Dubinsky et al. claim that these students either did not remember the rules correctly, or in the process of negation, would forget the rule.

### Student Treatment and Negation of Logical Connectives

Complex mathematical statements involve both quantifiers and logical connectives, such as conjunctions (and) and disjunctions (or), which are involved in the complex statements in this study. Both students' interpretations and negations of statements with logical connectives may not follow mathematical convention.

**Conjunctions and disjunctions**. In Dawkins and Cook's (2017) study of student's meanings for statements with disjunctions ("or" statements), teaching experiments were conducted with Calculus 3 students. Students in this study sometimes treated the disjunction (or) as if it were a conjunction (and), and claimed that both parts of the statement would need to be true for the entire statement to be true. Some students would often think that if one part of an "or" statement was false, then the entire statement was false.

Another common issue with disjunctions that has been noted in the literature is students' use of "or" as the *exclusive or* (Dawkins & Cook, 2017; Epp, 2003). Mathematical logic utilizes the *inclusive or,* which means that "or" *includes* the conjunctive case. Students, however, use an *exclusive or* meaning for disjunctions because they often interpret "A or B" as "either A or B," but *exclude* the conjunctive case, "A and B," from their consideration. For example, consider the statement, "All rectangles are parallelograms or have four right angles." Students using the *exclusive or* may consider the statement false because rectangles are *both* parallelograms and have right angles, and students may think that only one of the properties may be true of rectangles for the statement to be true.

**Negations of compound sentences.** Just as students often use unconventional logic such as the *exclusive or* in their interpretation of compound sentences (i.e. statements with more than one subject or predicate), their negations for these compound sentences often follow unconventional logic patterns as well. Students often negate the parts of the statement before and after the logical connective, but retain the logical connective itself (Epp, 2003; Macbeth, Razumiejczyk, del Carmen Crivello, Fioramonti, & Pereyra Girardi, 2013). Epp (2003) claims that in her classes, students often negate "John is tall and John is thin" with the statement "John is not tall and John is not thin" (p. 890). Macbeth et al. (2013) also investigated how students negate statements with conjunctions and disjunctions. Students often retained the conjunction or disjunction in the original statement in their negations, as expected. Macbeth et al. (2013) conjecture that this tendency is due to the brain's attempt to reduce cognitive load. This conjecture aligns with Khemlani, Orenes, and Johnson-Laird's (2012) study, where subjects provided more accurate responses for the denials of disjunctions than conjunctions. Khemlani et al. (ibid) hypothesize that statements with conjunctions are easier to cognitively process and interpret than disjunctions because conjunctions are true if both propositions are true, whereas disjunctions include three combinations for the propositions (TT, TF, and FT) to imply that the overall statement is true. On the other hand, using this theory, negations of conjunctive statements are more cognitively demanding than negations of statements containing a disjunction.

### The Effect of Context on Students' Logic

Some suggest that students may have difficulty with interpreting quantified statements or statements with logical connectives because the use of these phrases may change from colloquial to mathematical contexts. For example, when I colloquially state, "I'll get Chinese or Italian for dinner" I do not intend that I may pick up *both* Italian and Chinese, and thus, use the *exclusive or*. Shipman (2013) discovered that students thought "unique" meant "unequaled" instead of "sole," which also may be a result of colloquial use of the word "unique." Dawkins and Cook (2017) also noted that several of their students also made *semantic substitutions* to sentences. For example, a student may substitute "increasing" with "is not decreasing." However, this substitution is not mathematically valid because one should also consider the case of neither increasing nor decreasing (constant)[1].

Even within mathematical statements, students' logic is often guided by the mathematical content of the statement rather than the logical structure of the statement. Dawkins and Cook (2017) found that students changed their interpretation of statements with a disjunction depending on the mathematical context of the statement. For example, some students deemed "Given an integer number $x$, $x$ is even or odd" true, but "The integer 15 is even or odd" false because they stated that they already knew that 15 was odd.

**Discussion of Literature**

I have detailed issues associated with students' meanings for quantifiers and logical connectives and their negations. However, more work needs to be done to investigate how students may think about statements in the Calculus context that combine quantifiers and logical connectives and how they might negate these statements. In this study, I investigate how one student negates statements with quantifiers and logical connectives, and analyze how her meanings for negation are related to her evaluations of given statements.

## Theoretical Perspective

My perspective throughout this paper is that students construct their own meanings for quantified variables and logical connectives, and they construct their own meanings for the negation of statements with these logical components. These meanings are schemes. A *scheme* is a mental structure that "organize[s] actions[2], operations, images, or other schemes" (Thompson et al., 2014, p. 11). I cannot see a student's schemes, but can only do my best to create a model of students' negation schemes by attending to their words and actions throughout the clinical interview process. Schemes are tools for reasoning that have been built in the mind of the student over time.

My goal in this paper is to describe my best perception of one student's meanings for negations of mathematical statements at different moments. I use the phrase "student meaning" throughout this paper the same way in which Thompson (2013) explains that, from a constructivist viewpoint, an individual constructs his own meanings by assimilation to schemes (Thompson, 2013). When the student *assimilates* a mental object to a scheme, she is "extending scheme[s] to new objects" (Montangero, 1997, p. 71).

Different meanings, which are types of schemes, may be elicited in different moments due to the nature of a given task or question. Thompson et al. (2014) distinguish between *stable meanings* and *meanings in the moment*. Thompson et al. (ibid) describe a *meaning in the moment* as "the space of implications existing at the moment of understanding" (p. 13). Student meanings may change from one moment to the next because particular tasks could elicit different schemes, or the student could be assimilating information in the moment by making changes to their current scheme(s). Thus, I consider several different moments of interaction for each student because different moments of interaction may result in different types of student negation. I aim to describe my view of this particular student's negation schemes for different tasks and to describe how her meanings for negation impact her justifications for her evaluations of various

[1] As one anonymous reviewer astutely noted, this particular semantic substitution may be due to students (or even textbooks) confounding monotonically increasing with strictly increasing.

[2] By action, Thompson is referring to Piaget's meaning for action: "any thought, emotion, or movement that satisfies a need" (Piaget, 1968, p.6).

types of mathematical statements. I also analyze the student across different moments to determine if her meaning for the negation of quantified statements and her meaning for the negation of statements with logical connectives appear to be stable meanings.

While a student's meaning may consist of what the student does with a particular task, a student's *way of thinking* (Harel & Sowder, 2005; Thompson et al., 2014) may be a student's problem-solving process that is used across investigation of many different types of problems. If the student anticipates how she will reason through a negation task before even being provided with a specific statement, this may also be evidence that the student has a way of thinking about negation across different tasks. Dubinsky et al.'s (1988) categories for negation, such as negation by rules, may be characterized as students' ways of thinking about negation, as these categories describe students' general problem-solving strategies for the negations of many types of mathematical statements.

## Methods

This study is part of a larger study that will seek to answer these research questions with undergraduate students from various mathematical levels. For this particular study, I conducted clinical interviews (Clement, 2000) with one student, Dawn, who was currently enrolled in a Transition-to-Proof course at the time of the interview. Dawn completed two clinical interviews that were each two hours long. Both interviews were video-recorded. One camera captured her written work, while another camera captured her gestures. I chose different levels of tasks to determine if Dawn's negations stayed the same or changed across different levels of mathematical complexity.

### Interview Tasks

I first presented Dawn with thirteen statements with either one quantifier or logical connective to address my first research question. Two examples of these statements are shown in Figure 2 (left).

| Statements with One Logical Component | Statement with Two Logical Components |
|---|---|
| 1. Every integer is a real number.<br>2. 12 is even and 12 is prime. | There exists a real number $b$ such that $b$ is odd and negative. |

*Figure 2*. Selected items with either one logical component or two logical components.

Dawn was asked to evaluate (i.e. provide a truth-value) and negate each statement, as well as evaluate her negations. After she completed these tasks, I presented her with a list of possible alternative student negations. I created these hypothetical negations by changing different parts of each statement. These hypothetical negations allowed me to test a wider range of possible negations that Dawn might accept as valid negations.

In the second clinical interview, I first asked Dawn to negate complex mathematical statements with both a quantifier and a logical connective in an attempt to test whether her meanings for negations were stable across different tasks. I presented Dawn with two statements, like the one shown in Figure 2 (right), which involves two logical components (an existential quantifier and either a conjunction or disjunction). I asked Dawn to evaluate and negate these statements in the same manner as she did in the first interview. I used Dawn's negations of the more complex statements along with her negations for the statements with one logical component in the first interview to try to answer my first research question.

During this second interview I also presented Dawn with three complex mathematical statements from Calculus (shown in Figure 3) in order to address my second research question.

Statements 1 and 2 are based on the conclusion of the definition of a bounded function[3] and Statement 3 is based on the conclusion of the Extreme Value Theorem. For the statements and graphs shown in Figure 3, I asked Dawn to evaluate each graph with each statement and determine if a given statement was true or false for each function. The EVT only holds for continuous functions. Since I omitted the hypothesis of the EVT, there are cases where this statement I present is false. These graphs were selected in hopes that the student would use some of these graphs to show that the statements are false in some cases. Then, I used her justifications of why the statements are false to determine how she negated complex statements in the context of her justifications. Finally, I was able to compare these justifications with her previous negations in the first clinical interview.

| **Example Complex Mathematical Statements** | **Graphs** |
|---|---|
| **<u>Statement 1.</u>** There exists a real number $m$ and a real number $M$ such that for all $x$ in [-1, 8.5], $m \le f(x) \le M$.<br><br>**<u>Statement 2.</u>** There exists a real number $m$ such that for all $x$ in [-1, 8.5], $m \le f(x)$, and there exists a real number $M$ such that for all $x$ in [-1, 8.5], $f(x) \le M$.<br><br>**<u>Statement 3.</u>** There exists a $c$ in [-1, 8.5], such that for all $x$ in [-1, 8.5], $f(c) \ge f(x)$, and there exists a $d$ in [-1, 8.5], such that for all $z$ in [-1, 8.5], $f(d) \le f(z)$. |  |

*Figure 3.* Complex statements and graphs used in follow-up interview.

The graphs that I presented and the $\exists\forall$ statements shown in Figure 3 provided opportunities for Dawn's meanings for negation to be elicited with statements from a Calculus context, in hopes of beginning to answer my second research question.

**Data Analysis**

I used grounded theory (Strauss & Corbin, 1998) to analyze videos from Dawn's interview as well as her written work. Hence, findings about Dawn's negation meanings emerged from the data. I identified moments where distinctions could be made about Dawn's negation meanings. A new moment began when Dawn was presented with a new question or task, she changed her evaluation or interpretation of a given statement, or if she changed her argument or negation of a statement in any way. After identifying these moments of interest, I compared Dawn's negations of statements with one quantifier or one logical connective with her negations of statements with both a quantifier and a logical connective. Finally, I compared her negations in the context of her justification for each Calculus statement with all previous negations.

## Results

I noticed a consistent pattern in how Dawn chose to negate the statements when I directly asked her to provide negations. However, when I presented the last three complex mathematical statements along with graphs, and only asked for her to justify why the statement was true or false for each graph, Dawn's negations in her argumentation did not always match her previous

[3] Statements 1 and 2 are mathematically equivalent, but were both given to students to determine if the way in which these statements were structured would change students' interpretations and negations of the statements.

patterns of negation. The mathematical content of the tasks and questions appeared to influence Dawn's patterns for the negation of statements with quantifiers and logical connectives.

## Consistent Negation Patterns

There were patterns in Dawn's thinking about quantifiers and logical connectives and patterns in her negations of statements containing quantifiers and logical connectives. I will highlight general patterns that emerged from my data analysis and show how these patterns remained consistent even with a more complex statement.

**Patterns across all negations.** Dawn stated that all negations were basically the "opposite statements" or the "reverse of what we originally said," but in practice, she pondered what would constitute an opposite meaning of the original statement. For example, when interpreting the statement "Every integer is a real number" she stated that the "opposite of every is none," and wrote the negations, "Every integer is not a real number" and "There is no integer that is a real number." However, in a later moment, she considered that the opposite of "every" may be "some."

While Dawn did not exhibit a consistent use of the word "opposite," she did have a consistent method for negating all the statements given in the first interview. She frequently stated that negations could negate one part of the statement, but not both parts of the statement. Dawn often wrote multiple negations as a result of this way of thinking about negation, changing one part of a given statement, but not both parts. I asked Dawn to explain why she believed she should only change one side of a statement for its negation. She stated, "In general, it's just some kind of rule that I follow, like you only negate one side."

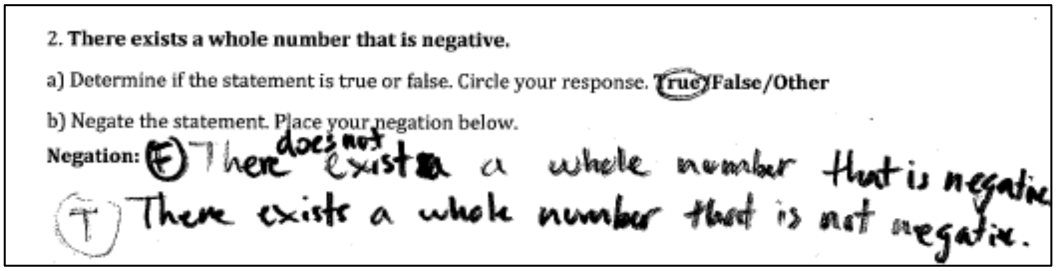
When evaluating the negations she constructed, she often concluded that there could be multiple negations of the same statement, and these negations could have different truth-values. I asked Dawn if two negations could have different truth-values. She replied, "I think it is okay for them to have different truth-values." For one statement where Dawn wrote two negations with different truth-values she also stated, "I don't think they [the two different negations] have the same meaning, but I think they're both valid."

Since Dawn stated that negations could have a variety of different truth-values, and she stated that negation involves changing one part of the statement, the evidence thus far suggests that, for Dawn, "negation" is related to a constructed *procedure* rather than a means for proof or disproof. Thus, the meaning of a statement and *its truth-value had no effect on Dawn's decision about the validity of a negation*; the validity of a negation for Dawn was assessed based on whether or not it followed her procedure.

Dawn's reliance on a rule to change one part of a statement for a negation appeared in statements with both one logical component and with multiple logical components. I will now show how Dawn used her same way of thinking about negation with statements containing an existential quantifier, a conjunction, or both a quantifier and a conjunction.

**Dawn's meaning for "there exists" and its negation**. Dawn consistently interpreted "there exists" as "there is at least one," but her negations for existential statements of the form "There exists an $x$ such that $P(x)$" did not always follow mathematical convention. For statements with an existential quantifier of the form "There exists an $x$ such that $P(x)$," she referred to "There exists $x$" as one part and "such that $P(x)$" as another part of the statement, and claimed that she "could only negate one part of the statement."

For any statement of the form "There exists an $x$ such that $P(x)$," Dawn preferred to start with the negation of the form "There does not exist an $x$ such that $P(x)$," which is a valid negation. However, she also stated that statements of the form "There exists an $x$ such that *not* $P(x)$" were valid negations because this also changed only one part of the statement. For example, for the statement, "There exists a whole number that is negative," Dawn referred to "There exists a whole number" and "that is negative" as two separate parts, and claimed that she could only negate one part of the statement. In Figure 4, Dawn's negations for this statement are provided.



2. **There exists a whole number that is negative.**

a) Determine if the statement is true or false. Circle your response. True/False/Other

b) Negate the statement. Place your negation below.

**Negation:** F There does not exist a whole number that is negative

T There exists a whole number that is not negative.

*Figure 4.* Dawn's negation for a statement with 'there exists.'

I asked Dawn to explain the meaning of each of her negations. She stated that her first negation, "There does not exist a whole number that is negative," means that "there is no whole number that is negative, so every whole number is going to be positive," and that her second negation, "There exists a whole number that is not negative," means that "there is a whole number that is not negative, so there is a whole number that is positive." She later based her evaluations of the statements on these meanings: "For the second one, I would say it is true, but the first one is false, because there does exist a whole number that is negative." I next presented Dawn with hypothetical negations. Even though she said that the meaning of the first negation is the same as "every whole number is going to be positive," she did not select this as a hypothetical negation. Dawn usually did not accept negations of the form $\forall x, \sim P(x)$ for statements with an existential quantifier because she said that changing the "there exists" to "for all" would be "changing too much."

In this example, Dawn evaluated each statement and each of her negations based on her interpretation of each statement and each negation. However, even though Dawn recognized that the meanings of her negations were different, and their truth-values were different, these differences were inconsequential to Dawn. Since these negations followed her rule to change one part of the original statement, she believed that the negations were valid. Her rejection of the hypothetical negation "Every whole number is going to be positive" indicates that she did not find alternative negations with equivalent meanings. Instead, the evidence indicates that she is choosing to follow her negation rule. Additional evidence that Dawn was relying on a rule for negation was found when Dawn negated another quantified statement where she provided two negations. In this moment she stated, "The only thing different [in the two negations] is the quantity [the quantifiers were different], and I don't think that matters, how many" elements satisfy a proposition. Since Dawn used a memorized rule for negation rather than viewing it as a way to prove or disprove the original statement, the number of elements she was referring to in each of her negations became inconsequential to Dawn in light of her rule.

**Dawn's meaning for "and" and its negation**. Dawn's algorithm for negating one part of a statement was also consistent with her negation of statements with a conjunction or disjunction because she still claimed that she could negate one part of a statement, but not both parts. She also continued to write and select negations regardless of their meaning or truth-value. For the statement, "12 is even and 12 is prime," Dawn wrote the negations shown in Figure 5:

8. **12 is even and 12 is prime.**

a) Determine if the statement is true or false. Circle your response. **True/False/Other**

b) Negate the statement. Place your negation below.

**Negation:** F 12 is odd and 12 is prime.

T 12 is even and 12 is not prime.

*Figure 5.* Dawn's negation of a statement with 'and.'

Yet again, Dawn changed one part of the statement for each negation, and again, she had two different negations with varying truth-values. The following dialogue between the interviewer (I) and Dawn (D) emerged after Dawn had created these two negations:

> *I*: Could you say that 12 is odd and 12 is not prime [is a valid negation]?
> *D*: I don't think so.
> *I*: Okay. Why not?
> *D*: You'd be negating both sides of the statement.
> *I*: Okay, and why is it not okay to negate both sides of an "and" statement?
> *D*: I just feel like you could only do one.
> *I*: Do you feel like that's something that you memorized, or are you thinking about this particular statement about evens and primes?
> *D*: In general, it's just some kind of rule that I follow, you can't negate both sides...I just took the original statement and did the opposite of the first part. It's not a true statement, but it *is* a possible negation.

For both of these negations, Dawn retained the logical connective and changed one part of the original statement in each negation. One may notice that Dawn retaining the logical connective is characteristic of shallow processing (Khemlani et al., 2012; Macbeth et al., 2013). However, her rule for changing one part of the statement does not align with shallow-processing expectations of retaining the conjunction and negating both propositions (i.e. accepting 12 is odd and 12 is not prime). Dawn never explained where she learned that she could only change part of the statement, but instead simply stated that she "felt like [she] could only [negate] one" part and that it was a "rule that [she] follow[s]." Even though she noticed that her other negation is true, and the original statement is false, she stated that this "*is* a possible negation," which indicates that, again, the truth-value was inconsequential to her determination about the validity of the negation.

**A combination of negation meanings**. The statement "There exists a real number *b* such that *b* is odd and negative," has two logical components. Dawn interpreted the negation of both the quantifier and the conjunction in this statement in a similar manner as her earlier negations, as seen in her two negations in Figure 6:

There exists a real number ***b*** such that ***b*** is odd and negative. True

**Negation:**

There does not exist a real number b such that b is odd and negative.
False

There exists a real number b such that b is ~~not odd~~ even and negative.
True

*Figure 6.* Dawn's negation for a statement containing both "there exists" & "and."

These negations are similar to the negations Dawn preferred for "there exists" statements in the first interview, as they are also of the form "There does not exist an $x$ such that $P(x)$," and "There exists an $x$ such that *not* $P(x)$" (even though her negation of $P(x)$ is incorrect). Yet again, she did not consider the use of a universal quantifier in her negations and only changed one part of the statement. Dawn also negated the proposition within the statement that contained a conjunction in the same manner that she did with the first set of statements. The phrase "*b* is odd and negative" has its own parts that Dawn also considered. She negated "*b* is odd and negative" as "*b* is even and negative." She verbalized that she could have also used "b is odd and positive" for this part of her second negation. I asked her to consider explaining to a friend why her negation for the first complex statement was valid, to which she replied, "I would tell them that [my negation is correct] because I changed the second half of the statement." This reply suggests that Dawn was assessing the validity of her negation based on her rule for negating one part of the statement, rather than comparing the *meaning* of the negation with the original statement.

From all of the previous example moments, there appears to be sufficient evidence that Dawn's meaning for the negation of statements with quantifiers and her meaning for the negation of statements with a logical connective are both stable meanings. Dawn also appears to have a way of thinking about negation that ties together both of these meanings for negation. She appears to have a way of thinking about negation that is a rule for negation (Dubinsky et al., 1988). This rule appears to be that she can alter one part of a compound phrase or one quantifier, but not more than one part of a given statement.

**Negation in Argumentation: When Negation Isn't Viewed as Negation**

I have already detailed Dawn's treatment of negation for the previous examples where I asked her to provide a negation. In the last set of tasks, I did not ask her to negate, but rather asked her only to determine if the statements were true or false on a case-by-case basis and to justify her claims. For Statement 3, Dawn interpreted the original statement as intended. Dawn explained why the statement shown below is true for the given graph:

| Statement & Graph Presented | Transcript |
|---|---|
| There exists a $c$ in [-1, 8.5], such that for all $x$ in [-1, 8.5], $f(c) \geq f(x)$, and there exists a $d$ in [-1, 8.5], such that for all $z$ in [-1, 8.5], $f(d) \leq f(z)$.<br> | *D*: There is a maximum $y$-value at 3 [$x$=3] and a minimum $y$-value here (points to (8.5, $f$(8.5)). So no matter what $x$ is, this [$f$(8.5)] is going to be the least $y$-value.<br>*I*: So what part of the statement tells you [that] you need to focus on the least $y$-value and the largest $y$-value?<br>*D*: Because we want to pick values for $c$ and $d$ strategically so that they are going to be the maximum and minimum $y$-value.<br>*I*: What part tells us we're going to pick the max and min?<br>*D*: Here, for all $x$, you want it to, no matter what the value of $x$, the value of $f(x)$ is going to change. And you want this statement here, this inequality, to hold true, and there's only one instance where that can be true—at the max or min. |

Dawn exhibited a conventional interpretation for this statement. She expressed that she needed to choose *the* maximum or minimum that works *for all x*. Dawn's meaning for this statement and its negation was also revealed in her explanation of when the statement is not true. In the following example, Dawn claimed that the same statement is false for the given case.

| Statement & Graph Presented | Transcript |
|---|---|
| There exists a $c$ in [-1, 8.5], such that for all $x$ in [-1, 8.5], $f(c) \geq f(x)$, and there exists a $d$ in [-1, 8.5], such that for all $z$ in [-1, 8.5], $f(d) \leq f(z)$.  | *D*: The minimum *y*-value is $^{-}\infty$, so you couldn't pick a value for… *d* that would always make this inequality true (points to $f(d) \leq f(z)$).<br>*I*: Let's say your friend said, "For all the values that I look at, for all the *y*-values that I look at, if I chose *any* value for *d*, then I can always find a smaller value [than *f*(*d*)]..." Would you agree with your friend's argument?<br>*D*: Yeah, I would agree with his argument.<br>*I*: Would you say that his argument is the same as your argument?<br>*D*: Yeah, because I said there isn't a value for *d* where there's the smallest *y*-value. I think that's kind of the same thing. It isn't the smallest because you could always find one smaller. |

Dawn said that she *could not pick* a value for *d* such that this value of *d* would *always* satisfy the inequality. This response is similar to the negation "there *does not exist a d* such that $f(d) \leq f(z)$." Dawn's response was consistent with her prior approach to negate one part of a statement in her negation. I responded by asking Dawn to consider an alternative negation that used a universal quantifier and changed more than one part of the statement to test her meaning for negation of Statement 3 against her previous negations.

In the context of this statement where Dawn was asked about her argument rather than for a negation specifically, she accepted a negation that involved changing more than one part of a statement and she did not mention having an issue with the universal quantifier changing too much of the statement. Her original denial aligns with the argument, "there *does not exist* an *x* with a corresponding minimum *y*-value," but she also recognized that my proposed argument, "for *any x*-value, *d*, a smaller *y*-value than *f*(*d*) can be found," was equivalent to her original denial. Thus, she accepted the argument that aligned with the negation "for *any* value of *d,* there exists a *z* such that $f(z) \leq f(d)$" by stating that this argument was "kind of the same thing" as her argument. She even explained why the logic for the two negations is equivalent: the *y*-value "isn't the smallest because you could always find [a *y*-value] smaller." Even though she had previously rejected alternate negations in the first interview that involved a universal quantifier, in the context of justification for this Calculus statement, she recognized that an alternate negation with a universal quantifier was valid for showing that the statement was false for this graph.

In instances when my question or request omitted the word "negation," Dawn considered the *meaning* of the statement rather than her memorized rule to negate one part of the statement. Dawn considered the truth-value of the graph in relation to the statement first during this portion of the interview, in contrast to previous moments where Dawn used her rule first, and then evaluated the given statements. Her interpretation of a statement and her negation for that statement varied based on the context of my question. These moments in the second interview were characterized by the question, "Is this statement true or false for this graph?" rather than the command "Negate this statement." The word "negation" appeared to alert Dawn to negate only one part of the statement. However, when asked to think about the validity of a statement in a particular context, Dawn's approach was to use her reasoning about the truth of a statement, and apply logical argument to justify her evaluation.

## Conclusion & Discussion

When responding to negation tasks in the first interview, Dawn negated one part of a given statement, but not both parts of a given statement. Her meanings for the negation of quantifiers and logical connectives appeared to be consistent when she analyzed statements with multiple logical components for tasks that also asked her to provide a negation. This finding is similar to Dubinsky et al.'s (1988) finding that students tend to use rules (which may or may not be correct) to negate a statement. Dawn viewed that no matter what type of statement was given, the command to "negate" implied changing one part of the given statement. Her procedural approach for negating a statement could help explain why some students only negate one of two quantifiers when statements with multiple quantifiers (Barnard, 1995; Dubinsky, 1988) and why some often retain disjunctions and conjunctions in their negations (Epp, 2003; Macbeth et al., 2013). In Dawn's words, changing two quantifiers or changing a logical connective might be "changing too much" in the student's view.

Dawn's negations are also consistent with other literature that has claimed that students' logic can change across different tasks (Dawkins & Cook, 2017; Durand-Gurrier, 2003). In this study, I found that Dawn negated by rules when she was commanded to negate. In the second interview, complex statements with quantifiers and logical connectives were given, and Dawn was asked to provide reasons for why a graph made the statement true or false for a given graph. The directive to classify these statements as true or false did not include the word "negation." Dawn accepted different negations as valid in tasks that used the word "negation" than she did when she was asked to justify why a statement was false.

For many students, the word "negation" may be associated with a *procedure* rather than using logical arguments based upon their own *reasoning*. Dubinsky et al. (1988) noted that students in their study often negated by a set of memorized rules that may or may not be correct. This study sheds light on one specific way of thinking about negation, that is, one specific general rule for negation. More importantly, this study also reveals that some students who negate by memorized rules may not negate by rules if the task is changed from "negate" to "justify why the following statement is false." Whenever Dawn was asked to "negate," she appeared to have stable meanings for the negations of quantified statements and statements with logical connectives, even as statements became increasingly complex. However, the command to determine if a statement was true or false actually led her to negate according to mathematical convention. Similarly, her evaluations were more aligned with mathematical convention when she focused on forming arguments based on her evaluations. Students who apply a memorized rule to negate a mathematical statement may have the ability to negate appropriately if the word "negation" does not hinder their argumentation. This procedural emphasis means that students may not even connect the truth-value of a negation as opposite of the original statement.

Instructional considerations should be made as a result of this new information. Phrases like "opposite of the original statement" or "not the original statement" may be vague for students not attending to the elements of a set for which we are considering a proposition. The treatment of negation as a procedure rather than an argumentation tool may cause students to lose sight of the usefulness of a negation. If students are presented with rules for negation but do not have opportunities to construct these rules, they may view these rules as something to memorize for the command "negation" rather than logically derived properties for expressing refutation of a given statement. Students may benefit from tasks that use the command, "Explain why the following statement is true or false" and from negating quantifiers and logical connectives in different mathematical contexts. Then, the students may be asked questions that may help them construct their own rules for negation that are consistent with their argumentation. This study suggests that the word "negation" may be more appropriate to use *after* students have constructed formal rules for negation based on their justifications for why statements are false.

Cognitive Consistency and Its Relationships to
Knowledge of Logical Equivalence and Mathematical Validity

Kyeong Hah Roh
Arizona State University

Yong Hah Lee
Ewha Womans University

*The purpose of this study is to explore how cognitive consistency in logical thinking is related to knowledge of logic and knowledge of mathematical validity. We developed a logic instrument and administered it to forty-seven (47) undergraduate students who enrolled in various sections of a transition-to-proof course. The analysis of the students' scores on the logic instrument indicated that students' knowledge of logical equivalence and their knowledge of mathematical validity were somewhat related to one another. On the other hand, cognitive consistency was not closely related to either student knowledge of logic or knowledge of mathematical validity. Based on these findings, we address the importance of cognitive consistency in logical thinking and discuss implications for the teaching and learning of logic in mathematical contexts.*

*Keywords:* cognitive consistency, logical equivalence, mathematical validity, transition-to-proof

Our society expects people to have ability to make decisions in their workplaces more efficiently by deducing valid inferences from a tremendous amount of information and resources. In fact, a person's logical thinking plays a crucial role in generating valid arguments from the given information as well as in evaluating the validity of others' arguments in workplaces. Hence, training our students as logical thinkers has been a central component in education (NCTM, 2000; NGAC & CCSSO, 2010; NRC, 2005). Many universities offer mathematics courses to introduce logic and various proof structures for valid arguments in mathematical contexts. However, research in mathematics education reports that undergraduate students have weak knowledge of logic and mathematical validity (e.g., Dubinsky, Elterman, & Gong, 1988; Epp, 2003; Inglis & Simpson, 2007; Morris, 2002; Martin & Harel, 1989). Such a deficiency of student knowledge of logic would entail serious difficulties with using logical thinking and deductive reasoning, in particular, to construct valid arguments (Bell, 1976; Coe & Ruthven, 1994; Hanna & Barbeau, 2008; Healy & Hoyles, 2000; Holyes & Küchemann, 2002; Ko & Knuth, 2009; Moore, 1994; Recio & Godino, 2001; Senk, 1989; Weber, 2001), to comprehend or interpret arguments of their teachers or in textbooks (Alcock & Weber, 2005b, Hazzan & Zazkis, 2003; Mamona-Downs & Downs, 2005; Selden & Selden, 1995), or to evaluate the validity and the soundness of someone's arguments (Alcock & Weber, 2005; Ko & Knuth, 2013; Martin & Harel, 1989; Mejia-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012; Selden & Selden, 2003).

With the importance of student knowledge of logic, we also consider *cognitive consistency* as an essential component in logical thinking. Generally, cognitive consistency refers to "an intra-individual psychological pressure to self-organize one's beliefs and identities in a balanced fashion" (Cvencek, Meltzoff, & Kapur, 2014, p.73). Cognitive psychologists explain such a tendency as people behave in ways that maintain cognitive consistency or minimize cognitive dissonance among their interpersonal relations, intrapersonal cognitions, beliefs, feelings, or actions (Bateson, 1972, Festinger, 1957; McGuire, 1966). Similarly, constructivists' theory of learning also posits students' recognition of cognitive inconsistencies as a necessary condition for their learning. Once a student recognizes inconsistencies in his way of thinking of a mathematical problem, he would be situated with a cognitive conflict and get perturbed because he is no longer able to assimilate to his existing scheme. Learning would then occur to the student by his attempt to modify his existing scheme or to construct a new scheme that resolves the cognitive conflicts (Piaget, 1967). For instance, based on his own knowledge and scheme, a student might deduce two statements such as '$x$ is an integer' and '$x$ is not an integer' from given information. Logically speaking, each of these statements contradicts one another, thus two statements cannot be accepted simultaneously. Such a logical contradiction is a fatal flaw that makes the student's entire argument meaningless. Once a student recognizes such a logical contradiction in his argument, he would attempt to find a way to remove it from his argument. On the other hand, if the student does not recognize the contradiction in his argument, he would be still in cognitive inconsistency in his logical thinking.

One's recognition of cognitive inconsistency in his own thinking will be the first step in self-regulating one's own cognition. However, if a student does not recognize cognitive inconsistency in his own belief, attitude, or knowledge structures, the student would not take any effort to change or modify his existing scheme or knowledge structure. Thus, it is very important to train students not only to gain more knowledge of logic but also to maintain cognitive consistency in logical thinking.

At this point, one might expect that the more knowledge of logic students has, they would less likely deduce logical contradictions from given information; or they would recognize logical contradictions if they happen to deduce logical contradictions from given information. It might also be expected that students who do not recognize logical contradictions in their arguments would not be knowledgeable in logic. This study explores *how students' cognitive consistency in logical thinking is related to their knowledge of logic and mathematical validity.* To be more specific, as an exploratory study, we address the following research questions:

1) Do students with more knowledge of logical equivalence tend to have stronger cognitive consistency in logical thinking?
2) Do students with more knowledge of mathematical validity of arguments tend to have stronger cognitive consistency in logical thinking?

For the purpose of this study with the specific research questions, we developed the logic instrument to systematically measure three components of students' logical thinking from student responses to the logic instrument as follows: knowledge of logical equivalence between two statements, knowledge of mathematical validity of arguments, and cognitive consistency in logical thinking. We use the term *Knowledge of logical equivalence* (KoLE) between two statement, or shortly, knowledge of logical equivalence, to refer to knowing a relationship between two statements that have the same truth value in every possible case. *Knowledge of mathematical validity* (KoMV) of arguments, or shortly knowledge of mathematical validity in this paper, refers to knowing that the truth of the premises of an argument in mathematics logically guarantees the truth of the conclusion of the argument. By cognitive consistency in logical thinking (CC), or shortly by *cognitive consistency* in this paper, we mean an individual's psychological pressure to self-organize his/her thinking to have no logical contradiction.

In this study, we shortly use the term cognitive consistency to refer to cognitive consistency *in logical thinking*. While we hope this study provides new insights into the theories of cognitive consistency, our foci are distinct to previous ones from two aspects. First, in exploring the role of cognitive consistency, this study pays more attention to *contexts of mathematical logic* such as logical connectives and quantifiers, rather than focusing on personal or interpersonal attitudes and behaviors in social contexts (c.f., Cooper, 1998; Gawronski & Strack, 2004; Gawronski, Walther, & Blank, 2005; Stone & Cooper, 2001). Second, this study focuses on whether students recognize cognitive inconsistencies in their logical thinking rather than how students reconcile cognitive inconsistencies after recognizing them in their reasoning (c.f., Dawkins & Roh, 2016; Ely, 2010; Oehrtman et al., 2014; Roh & Lee, 2011).

## Research Methodology

This study was conducted in the spring semester of 2014 at a large public university in the United States. Among 137 undergraduate students who were taking an introductory proof course at the semester, forty-seven (47) students voluntarily participated this study to complete the logic instrument that we designed to explore undergraduate students' logical thinking in mathematical contexts. Due to the pre-requisite for the introductory proof course at the university, the participants had already completed at least the first semester calculus course. In addition, as the logic instrument was administered at the last week of the semester when the participants enrolled in the introductory proof course, the participants of this study were those who had already been exposed to the terms used in the questions of the logic instrument, such as equivalent statements, implications, negation, and valid arguments. Twenty-three participants (48%) were mathematics majors whereas twelve participants (26%) were mathematics education majors. The rest of the participants (twelve students, 26%), labeled as others, were students whose major areas of study were neither mathematics nor mathematics education.

### The Logic Instrument

For this study, we developed a logic instrument consisting of twelve questions in total. The first part (seven questions) was designed to test students' knowledge of logical equivalence between two statements. On the other hand, the second part of the logic instrument (five questions) was designed to test students' knowledge of mathematical validity of arguments as well as cognitive consistency. We describe each part of the logic instrument in detail.

**Part 1 of the Logic Instrument** The first part consists of seven multiple choice questions. These questions were designed to assess students' knowledge of logical equivalence amongst conditional statements with/without quantifiers. All questions in Part 1 present one or a pair of statements whose logical forms are frequently found in undergraduate mathematics textbooks from calculus and beyond. See Table 1 for the logical forms of the statements given and the nature of each question in Part 1 of the logic instrument.

*Table 1 Summary of the questions in Part 1 of the logic instrument*

| | LOGICAL FORM OF THE GIVEN STATEMENTS | NATURE OF THE QUESTIONS |
|---|---|---|
| Q1 & Q3 | $P(x) \rightarrow Q(x)$ | Mark off all logically equivalent instances to the given statement |
| Q2 & Q4 | A pair of statements in the forms of $\forall x \exists y P(x, y)$ & $\exists y \forall x P(x, y)$ | Mark off the best description about the logical relationship between the given statements |
| Q5, Q6, & Q7 | $\forall x, P(x) \rightarrow Q(x)$ | Mark off all logically equivalent instances to the negation of the given statements |

Several instances are also presented with the statement(s) in each question and students are asked to mark off all relevant ones among the given instances. For instance, Q1 and Q3 (see Figure 1 for Question 1) presents a conditional statement and asks to mark off O for all its equivalent statements to the conditional statement among the given instances. The main difference between Q1 and Q3 is in the contexts: The statement given in Q1 is from a non-mathematical context (a person SAM) whereas the statement in Q3 is from a mathematical context (real numbers and inequalities between two functions).

*Q1. Consider the following statement* (*) *about a person, SAM:*
(*) *If $f$ is a quadratic function, SAM can solve the equation $f(x) = 0$.*
*For each of the following statements, mark (O) if the statement is equivalent to the statement* (*)*; otherwise mark (X).*
_________ $f$ is a quadratic function and SAM can solve the equation $f(x) = 0$.
(1) _________ $f$ is a quadratic function or SAM cannot solve the equation $f(x) = 0$.
(2) _________ $f$ is not a quadratic function or SAM can solve the equation $f(x) = 0$.
(3) _________ If SAM can solve the equation $f(x) = 0$, $f$ is a quadratic function.
(4) _________ If SAM cannot solve the equation $f(x) = 0$, $f$ is not a quadratic function.
(5) _________ If $f$ is not a quadratic function, SAM cannot solve the equation $f(x) = 0$.

*Figure 1. Q1 in the logic instrument*

Questions 2 and 4 (see Figure 2 for Question 4) both present a pair of statements involving two quantifiers ∀ and ∃ in which the order of quantifiers in one statement is ∀∃ and that in the other statement is ∃∀ while the predicates are the same. These questions ask to mark off the most relevant logical implication between the statements in a pair. The contextual difference between Q2 and Q4 is similar to that between Q1 and Q3.

Q4. *Let $f$ be any function from $\mathbb{R}$ to $\mathbb{R}$. Consider the following two statements* (i) *and* (ii).

(i) *For any $x \in \mathbb{R}$, there exists* $\mathrm{M} > 0$ *such that* $|f(x)| < \mathrm{M}$.
(ii) *There exists* $\mathrm{M} > 0$ *such that for any $x \in \mathbb{R}$,* $|f(x)| < \mathrm{M}$.

*Check the most accurate description about the two statements.*
(a) _________ (i) is equivalent to (ii).
(b) _________ (i) implies (ii) but (ii) does not imply (i).
(c) _________ (ii) implies (i) but (i) does not imply (ii).
(d) _________ None of the above is correct.

*Figure 2. Q4 in the logic instrument*

Q5, Q6, and Q7 present the same conditional statement with a universal quantifier, "for any $x > 0$, if $f(x) \geq g(x)$, then $g(x) < h(x)$" and ask to mark off all statements that are equivalent to the *negation* of the given statement. The difference among these three questions is mainly in the use of quantifiers and the sets of the discourse in given instances. To be more specific, the instances for Q5 remain the universal quantifier 'for any' whereas the instances for both Q6 and Q7 use the existential quantifier 'there exist'; in addition, the instances for both Q5 and Q6 remain the same set of discourse '$x > 0$' to that of the given statement whereas Q7 uses the compliment '$x \leq 0$' of the set of discourse of the given statement. See Figure 3 or the statement and some instances given in these three questions.

All statements given in the questions in Part 1 of the logic instrument are *open* statements involving at least one free variable so that the truth-value of each statement cannot be determined. We purposely created and included *only* open statements to the questions in Part 1 in order to avoid the cases of students who answer to the questions based on their determination of the truth-value of a statement. It is because otherwise students might focus not on the logical structures, but on the truth-values, of the given statements. For instance, the statement (*) given in Q1 "if $f$ is a quadratic function, then SAM can solve the equation $f(x) = 0$" is an open statement with two free variables $f$ and SAM. Since this statement is an open statement, one cannot determine if the statement is true or false unless plugging in specific values for $f$ and SAM. Nonetheless, the logical equivalence between the statement (*) and any of the instances given in Question 1 can be evaluated independently from the determination of the truth-value of the statement or the truth-values of any instances given in Question 1.

Q5.~Q7. Let $f$, $g$, and $h$ be functions from $\mathbb{R}$ to $\mathbb{R}$. Consider the following statement (***):
(***) For any $x > 0$, if $f(x) \geq g(x)$, then $g(x) < h(x)$.
For each of the following statements, mark (O) if the statement is equivalent to the **negation** of the statement (***): otherwise mark (X).

Examples of Instances from Q5:
(3) _______ For any $x > 0$, if $f(x) < g(x)$, then $g(x) \geq h(x)$.
(4) _______ For any $x > 0$, if $g(x) < h(x)$, then $f(x) \geq g(x)$.
(7) _______ For any $x > 0$, $f(x) \geq g(x)$ and $g(x) \geq h(x)$.

Examples of Instances from Q6:
(3) _______ There exists $x > 0$ such that if $f(x) < g(x)$, then $g(x) \geq h(x)$.
(4) _______ There exists $x > 0$ such that if $g(x) < h(x)$, then $f(x) \geq g(x)$.
(7) _______ There exists $x > 0$ such that $f(x) \geq g(x)$ and $g(x) \geq h(x)$.

Examples of Instances from Q7:
(3) _______ There exists $x \leq 0$ such that if $f(x) < g(x)$, then $g(x) \geq h(x)$.
(4) _______ There exists $x \leq 0$ such that if $g(x) < h(x)$, then $f(x) \geq g(x)$.
(7) _______ There exists $x \leq 0$ such that $f(x) \geq g(x)$ and $g(x) \geq h(x)$.

*Figure 3. The statement presented in Questions 5, 6, and 7 and some given instances*

**Part 2 of the Logic Instrument** The second part of the logic instrument (Q8 – Q12) was designed to assess students' knowledge of mathematical validity as well as cognitive consistency. Each question in Part 2 contains a statement and one or two arguments about the statement. Table 2 summarizes the statements and arguments given in the questions in Part 2 in terms of the truth-values of the given statements as well as the structures and validity of the given arguments. Whereas statements presented in the questions in Part 1 of the logic instrument are all open statements, the statements presented in the questions in Part 2 are either true or false statements. In addition, some questions in Part 2 present invalid arguments and the other question presents a valid argument. These arguments are structured by one of the four proof frames, all of which are frequently found in mathematical proofs: direct proof, proof by contradiction, proof by contrapositive, and proof by mathematical induction.

*Table 2.Summary of questions in Part 2of the logic instrument*

| | Statement | Argument Structure | Validity |
|---|---|---|---|
| Q8 | True | Example/counterexample | invalid |
| Q9 | True | Direct proof | invalid |
| Q10 | False | Proof by contradiction | valid |
| Q11 | True | Proof by contrapositive | invalid |
| Q12 | True | Proof by mathematical induction | invalid |

All five questions in Part 2 are set up similarly in the sense that each question asks to (1) determine the truth-value of the given statement; (2) determine if the given argument is either an attempt to prove or an attempt to disprove the given statement; and (3) evaluate if the given argument is valid. See Figure 5 in the next section (Data Analysis) for Question 9 as an example of questions in Part 2 of the logic instrument.

**Data Analysis**

The logic instrument described in the previous section was used in this study to measure students' logical thinking in terms of their knowledge of logical equivalence (KoLE), knowledge of mathematical validity (KoMV), and cognitive consistency (CC). We first generated the coding scheme in order to score students' mark-offs to the questions in the logic instrument. Different weights were applied to questions in Part 1 and questions in Part 2 as each examined different aspects of students' logical thinking. After coding student responses in terms of the scoring rubric, we finally generated KoLE, KoMV, and CC scores for each student.

**Scoring Rubric for Knowledge of Logical Equivalence (KoLE).** Student knowledge of logical equivalence between two statements was measured from student responses to the questions in Part 1 of the logic instrument**.** As each of the seven questions (Q1 ~ Q7) in Part 1 was scored between 0 and 2 as described in Table 3, total score of students' KoLE could be possible ranged from 0 to 14.

*Table 3 Scoring rubric for Knowledge of Logical Equivalence (KoLE)*

| Question | Scoring Rubric | | | Score Range |
|---|---|---|---|---|
| | Sub-question score | | Scoring Formula | Final score |
| | Correct / Incorrect | score | | |
| Q1, Q3, Q5~Q7 | Correct | 0 | S = max{2+∑(sub-question score), 0} | S |
| | Incorrect | −1 | | |
| | Correct / Incorrect | | score | Final score |
| Q2, Q4 | Correct | | 2 | 2 |
| | Incorrect | | 0 | 0 |

Questions 1, 3, 5, 6 and 7 in Part 1 of the logic instrument present a statement and a set of six to seven instances. For each of these questions, sub-question scores were first generated based on students' mark-off to the instances as follows: Students' mark-off of O or X to each instance was scored either 0 (for the correct response) or −1 (for the incorrect response). The final score for each of these questions was then formulated as the maximum value between 0 and 2+∑(sub-question score). Using this scoring rubric, the scores for Q1, Q3, Q5, Q6, and Q7 were ranged from 0 to 2. For instance, Q1 (Figure 1) consists of a statement (*) and six instances of statements, but only two instances (3) and (5) are statements equivalent to the statement (*). If a student marked off O for exactly these two instances (3)(5) and marked off X for the rest of the instances, 2 was given to the student response to Q1 since every sub-question was scored 0 and thus the maximum value between 2+∑(sub-question score) and 0 is 2. On the other hand, if a student marked off incorrectly for only one instance (e.g., marking off O for (1)(3)(5) or (5), and X for all other instances), then 1 was given to the student response to Q1 as one sub-question was scored −1 and all other sub-questions were scored 0; thus 2+∑(sub-question score) is 1. In this case, 1 was given to the student response to Q1. As another example, if a student marked off incorrectly two or more instances (e.g., marking off O for (1)(2)(3)(5)(6) or (1)(4)), then two or more sub-questions were scored $-1$ and all other sub-questions were scored 0; then 2+∑(sub-question score) is less than or equal to 0, and thus 0 was given to the student response to Q1.

On the other hand, Questions 2 and 4 present a pair of statements (i) and (ii) and a set of four instances (a) ~ (d) describing relationships between the pair of statements. For each of these questions, students' check of one of the four relationships was scored either 2 (for the correct response) or 0 (for the incorrect response). For instance, in Q4 (Figure 4), the statement (ii) implies the statement (i) but the statement (i) does not implies the statement (ii). Thus, if a student checked (c) as the most accurate description for the relationship between these statements, the student's response to Q4 was scored 2 whereas the other responses were scored 0.

**Scoring Rubric for Knowledge of Mathematical Validity (KoMV).** Student knowledge of mathematical validity was measured from student responses to the second and third sub-questions to each of the five question in Part 2 of the logic instrument. Each question (Q8 ~ Q12) in Part 2 of the logic instrument was scored between 0 and 2 as described in Table 4.

*Table 4 Scoring rubric for Knowledge of Mathematical Validity (KoMV)*

| Question | Scoring Rubric | | | | Score Range |
|---|---|---|---|---|---|
| | (2) Validity (Argument) | | (3) Validity (Argument) | | Final score |
| | Correct/Incorrect | score | Correct/Incorrect | score | |
| Q8 | Correct | 1 | Correct | 1 | 2 |
| | | | Incorrect | 0 | 1 |
| | Incorrect | 0 | Correct | 1 | 1 |
| | | | Incorrect | 0 | 0 |
| | (2) Prove/Disprove (Argument) | | (3) Validity (Argument) | | Final score |
| | Correct/Incorrect | score | Correct/Incorrect | score | |
| Q9~Q12 | Correct | 2 | Correct | 0 | 2 |
| | | | Incorrect | $-1$ | 1 |
| | Incorrect | 0 | - | - | 0 |

Q8. Consider the following statement (★):

(★) For any real numbers $x$ and $y$ with $y > 0$, there exists a positive integer $n$ such that $x < ny$.

The followings are Alan's and Bob's arguments about the statement (★):

*Alan's argument. The statement (★) is false because for $x = 4$, $y = 2$, and $n = 1$, $x > ny$.*

*Bob's argument. The statement (★) is true because for $x = 4$, $y = 2$, and $n = 5$, $x < ny$.*

(1) Check the most appropriate one about the statement (★):
  a. ______ The statement (★) is true.
  b. ______ The statement (★) is false.
  c. ______ We cannot determine if the statement (★) is true or false.

(2) Check the most appropriate one to describe if Alan's argument is valid.
  a. ______ Alan's argument is valid as a proof of the statement (★).
  b. ______ Alan's argument is invalid as a proof of the statement (★).
  c. ______ We cannot determine if Alan's argument is valid or invalid.

(3) Check the most appropriate one to describe if Bob's argument is valid.
  a. ______ Bob's argument is valid as a proof of the statement (★).
  b. ______ Bob's argument is invalid as a proof of the statement (★).
  c. ______ We cannot determine if Bob's argument is valid or invalid.

*Figure 4. Q4 in the logic instrument*

For Q8 (Figure 4), we scored student responses to the two sub-questions, the evaluation of the validity of the given arguments: 1 was given for the correct response to the validity of the given argument; otherwise 0 was given. For Q9 ~ Q12, we first reviewed student responses to the second sub-question asking to determine if the given argument is an attempt to prove or an attempt to disprove the statement: 2 was given to the correct mark-off to the second sub-question; otherwise, 0 was given. Next, we scored student responses to the third sub-question asking to evaluate the validity of the given argument. Among those who marked-off correctly to the second sub-question (proof or disproof), if the student also responded correctly to the third sub-question (valid or invalid), we scored 0 for the response to the third sub-question; otherwise, $-1$ was given. On the other hand, if the student response to the second sub-question (proof/disproof) was incorrect, we scored 0 to any response to the third sub-question regardless of its correctness.

For KoMV, we scored student responses to the second sub-question first, and then student responses to the third sub-question. However, we did not use student responses to the first sub-question (evaluation of the truth value of the given statement) when examining students' KoMV. Indeed, regardless of knowing whether a statement is true or false, students would be able to evaluate if someone else' argument about the statement is valid. On the other hand, we examined student responses to the second sub-question before examining their responses to the third sub-question because students' evaluation of the validity of an argument (the third sub-question) would be affected by their identification of the type of attempts for the argument (the second sub-question). For instance, if a student fails to identify correctly whether the given argument is an attempt to prove or to disprove a statement, the student' validation of the given argument would not be correct.

Q9. An integer $a$ is said to be odd if and only if there exists $n \in \mathbb{Z}$ such that $a = 2n + 1$. Tim was asked to prove or disprove:

(♣) For any positive integers $x$ and $y$, if $x$ and $y$ are odd, then $xy$ is odd.

The following is Tim's argument.

$$x = 2n + 1, n \in \mathbb{Z}$$
$$y = 2n + 1, n \in \mathbb{Z}$$
Therefore, $xy = (2n + 1)(2n + 1) = 4n^2 + 4n + 1 = 2(2n^2 + 2n) + 1$ is odd.

(1) Check the most appropriate one about the statement (♣).

a. _______ The statement (♣) is true.

b. _______ The statement (♣) is false.

c. _______ We cannot determine if the statement (♣) is true or false.

(2) Check the most appropriate one to describe what Tim attempted to prove.

a. _______ Tim attempted to prove the statement (♣) is true.

b. _______ Tim attempted to prove statement (♣) is false.

c. _______ We cannot determine if Tim attempted to prove the statement (♣) is true or he attempted to prove the statement (♣) is false.

(3) Check the most appropriate one to describe if Tim's argument is valid.

a. _______ Tim's argument is valid as a proof of the statement (♣).

b. _______ Tim's argument is invalid as a proof of the statement (♣).

c. _______ We cannot determine if Tim's argument is valid or invalid.

*Figure 5. Q5 in the logic instrument*

**Scoring Rubric for Cognitive Consistency (CC).** Cognitive consistency was measured from student responses to the questions in Part 2 of the logic instrument. We first identified cognitive inconsistencies only when student responses to sub-questions of a question imply any logical contradiction. For instance, in the case of Q9 (Figure 5), if a student were to mark off that (1) the statement (♣) is true, (2) Tim's argument is an attempt to prove the statement (♣) is false, and (3) Tim's argument is valid, then the student's responses contain a logical contradiction since an attempt to prove that a true statement is false cannot be valid. Similarly, if a student responds to Q9 that (1) the statement (♣) is false, and (2) Tim's argument is an attempt to prove the statement (♣) is true, and (3) Tim's argument is valid, then the student also appears to have cognitive inconsistency. Table 5 describes all instances evidently determined to have cognitive inconsistency from student responses.

We measured students' cognitive consistency by assigning either $-1$ or 0 to each of the questions (Q8~Q12) in Part 2 of the logic instrument. Specifically, we scored $-1$ whenever there is evidence of cognitive inconsistency, i.e., a logical contradiction from student responses to its sub-questions. On the other hand, we scored 0 in all other cases but the instances described in Table 5 since there is no evidence of logical contradictions from the cases. As there were five questions in Part 2, the total score on cognitive consistency could be possibly ranged from $-5$ to 0.

*Table 5 All instances of cognitive inconsistency*

| Question | Sub-Questions | | | |
|---|---|---|---|---|
| Q8 | | (1) True/False (Statement) | (2) Validity (Argument) | (3) Validity (Argument) |
| | Cognitive Inconsistency | (a) True or (c) Cannot determine | (a) Valid as a proof for false | - |
| | | (b) False or (c) Cannot determine | - | (a) Valid as a proof for true |
| Q9~Q12 | | (1) True/False (Statement) | (2) Prove/Disprove (Argument) | (3) Validity (Argument) |
| | Cognitive Inconsistency | (a) True or (c) Cannot determine | (b) Prove False | (a) Valid |
| | | (b) False or (c) Cannot determine | (c) Prove True | (a) Valid |

Obviously, if a student marks off correctly to all sub-questions to a question in Part 2, the student does not appear to have a cognitive inconsistency in his response to the question. On the other hand, although the student responses to some sub-questions are not correct, the student's cognitive consistency score to the question could still be 0 in the case when there is no evidence of logical contradiction within the student's responses.

## Results

Figure 6 summarizes the distributions of student scores in terms of KoLE score, KoMV score, and CC score. KoLE scores were ranged from 0 to 14 while the median of the KoLE scores was 5 (out of 14 points) and 50% of student KoLE scores were between 2 and 9. KoMV scores were ranged from 0 to 10 with the median 5 (out of 10 points) while 50 % of KoMV scores were distributed between 3 and 8. Finally, scores were ranged from $-2$ to 0, and about

21% of the participants showed at least once cognitive inconsistencies in their responses to the logic instrument.

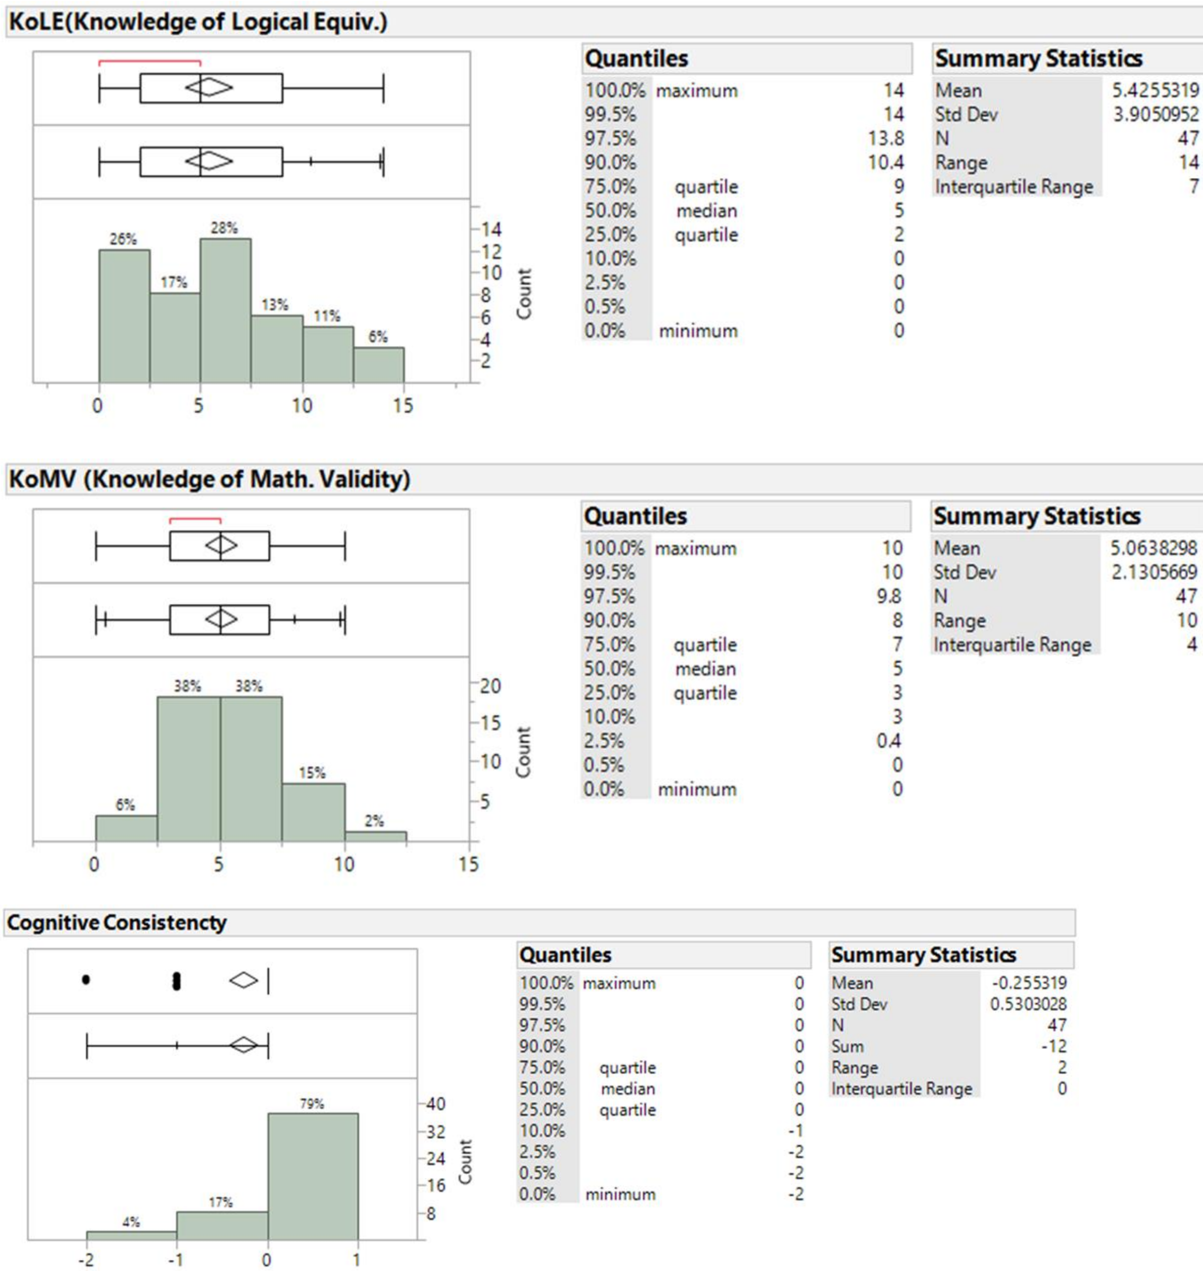

*Figure 6. Distributions of three parts of the overall logical thinking scores*

The scatter-density plot in Figure 7 further shows that students' knowledge of logical equivalence (KoLE) and students' knowledge of mathematical validity (KoMV) were somewhat related to one another.

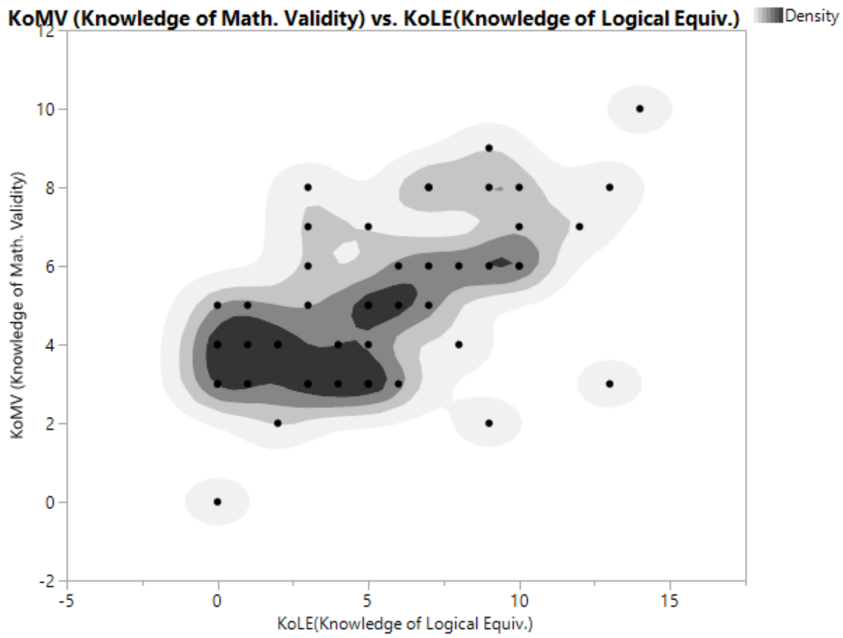

*Figure 7. Scatter-Density plot: KoMV vs. KoLE*

On the other hand, cognitive consistency (CC) was *not* closely related to either knowledge of logical equivalence or knowledge of mathematical validity. According to the scatter-density plots in Figure 8 students scored the cognitive consistency score $-2$ did not have higher scores than the median of each KoLE and KoMV scores.

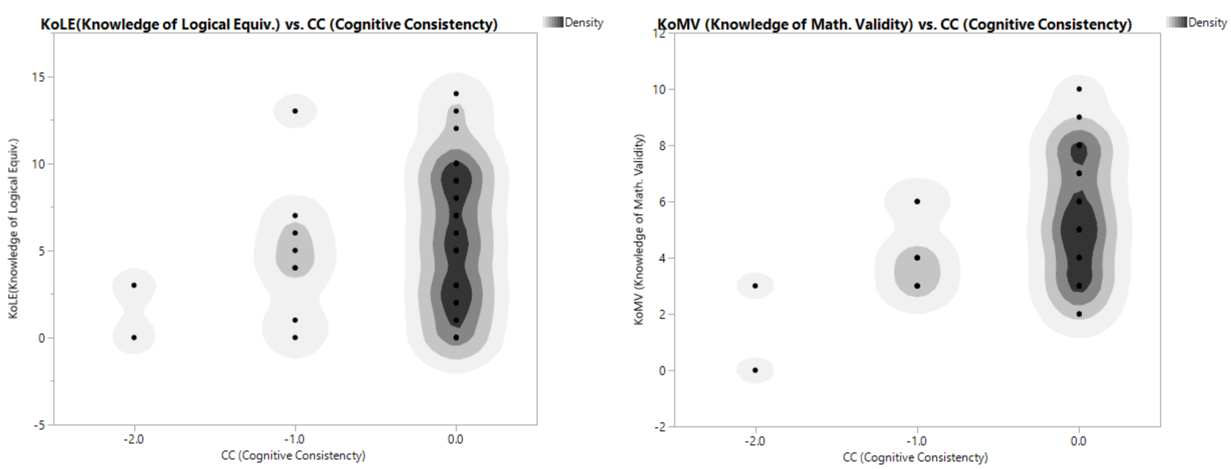

*Figure 8. Scatter-Density plots: KoLE vs. CC (left), KoMV vs. CC (right)*

On the other hand, in the case that the cognitive consistency score was $-1$, students' KoLE scores or KoMV scores were distributed with relatively wide range containing higher scores than the median (see the shaded cells in Table 6 and Table 7). There was one student who received a very high score on KoLE (13 out of 14) but scored $-1$ on the cognitive consistency (see Table 6). These findings indicate that students might have cognitive inconsistencies even though they attained high scores on knowledge of logical equivalence and knowledge of mathematical validity, respectively.

*Table 6 Contingency Table: Cognitive Consistency Score by KoLE Score (Median = 5)*

| | KoLE (Knowledge of Logical Equivalence) | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 12 | 13 | 14 | Total |
| Cognitive Consistency | | | | | | | | | | | | | | | |
| −2 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| −1 | 1 | 1 | 0 | 0 | 2 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 8 |

| Total | 1 | 0 | 2 | 10 | 8 | 7 | 7 | 4 | 6 | 1 | 1 | 47 |

## Conclusion & Discussion

In this study, we explored undergraduate students' cognitive consistency and its relation to their knowledge of logical equivalence and mathematical validity. The findings of this study indicate that students' cognitive consistency was not closely related to either their knowledge of logical equivalence or their knowledge of mathematical validity. Indeed, some students who received high scores on knowledge of logical equivalence or on knowledge of mathematical validity still had cognitive inconsistencies. Furthermore, these students already took a course for logic and mathematical proofs for about at least fifteen weeks. Thus, it might be an unreasonable expectation that students with more knowledge on logical equivalence and mathematical validity would not have cognitive inconsistencies.

The findings of this study also suggest some significant implications for the teaching and learning of logic and mathematical proofs. In particular, although undergraduate students received formal instruction for logic from a logic and mathematical proof course, they could still have cognitive inconsistencies. Furthermore, this implication of the results of this study is critical in the sense that having a cognitive inconsistency means that the student does not recognize a logical contradiction in his or her argument. Thus, we contend that cognitive consistency must be treated as a crucial component of logical thinking. Designing special tasks or instructional interventions would be needed to reveal students' cognitive inconsistencies and to help students recognize logical contradiction in their arguments if they have any. The structure of sub-questions in Part 2 of the logic instrument in this study could be an example of reference to reveal students' cognitive inconsistency what might have been.

# Figurative Thought and a Student's Reasoning About "Amounts" of Change

Biyao Liang
University of Georgia

Kevin C. Moore
University of Georgia

*This paper discusses a student coordinating changes in covarying quantities. We adopt Piaget's constructs of figurative and operative thought to describe her partitioning activity (i.e., mental and physical actions associated with constructing incremental changes) in terms of the extent that it is constrained to carrying out particular sensorimotor actions on perceptually available material, and we relate such descriptions to her thinking about quantitative amounts of change. We conclude the paper by discussing how characterizing these nuances in her partitioning activity contributes to current literature on covariational reasoning and concept construction.*

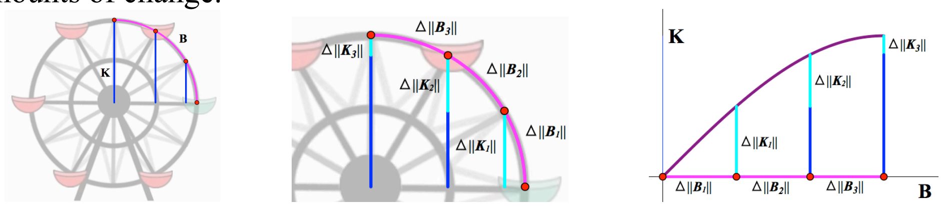
*Keywords:* Cognition, Piaget, Covariational Reasoning, Amount of Change

Researchers have shown that students' *quantitative* and *covariational reasoning*—the mental actions involved in conceiving measurable attributes changing in tandem (Carlson, Jacobs, Coe, & Hsu, 2002; Thompson, 2011)—are critical for their learning of function and rate of change (Ellis, 2011; Johnson, 2015; Thompson & Carlson, 2017). Stemming from the complexities of students' thinking, these researchers have called for investigations that identify nuances in students' covariational reasoning. We answer these researchers' call by using Piaget's (1976, 2001) notions of *figurative* and *operative* thought to explain the extent a student's reasoning of amounts of change of covarying quantities is constrained to sensorimotor actions and the produced results of those actions. Drawing on these distinctions, we discuss the importance of our findings with respect to students' concept construction.

## Quantitative Reasoning, Covariational Reasoning, and Partitioning Activity

Thompson (2011) described that the mental construction of a *quantity* involves "conceptualizing an object and an attribute of it so that the attribute has a unit of measure" (p. 37). Although Thompson used the term "measure," he emphasized that reasoning quantitatively does not require reasoning about a specified quantity's value; sophisticated conceptions of quantity entail reasoning about a quantity's magnitude (i.e., amount-ness) while anticipating that it has an infinite number of measure-unit pairs (Thompson, Carlson, Byerley, & Hatfield, 2014). A distinction between a quantity's magnitude and its measure enables us to account for reasoning about covarying quantities that is not constrained to the availability of values; importantly, our focus on a quantity's magnitude affords characterizing mental activity in terms of perceptual material associated with a quantity's amount-ness (e.g., a perceived segment and its length).

An individual imagining variations in a quantity's magnitude (and hence value) is positioned to reason covariationally. When reasoning covariationlly, "a person holds in mind a sustained image of two quantities' values (or magnitudes) simultaneously…one tracks either quantity's value with the immediate, explicit, and persistent realization that, at every moment, the other quantity also has a value" (Saldanha & Thompson, 1998, p. 299). Building on Saldanha and Thompson's (1998) covariation, Carlson et al. (2002) specified mental actions involved in coordinating quantities, among which students' coordination of amounts of change of one quantity with respect to changes in another (Mental Action 3 in their framework) is central to our work here. An individual coordinating amounts of change imagines quantities' magnitudes accumulating in successive states (and possibly anticipates continuous covariation between these states; see Thompson and Carlson (2017)). To illustrate, a student reasoning about covarying quantities B and K can envision the magnitude ||B|| accumulating in equal accruals, construct the magnitude ||K|| accumulating in terms of corresponding accruals, and coordinate those accruals in ||K|| to conceive ||K|| increasing by decreasing amounts with respect to ||B|| (see Figure 1a-c for an illustration with respect to the Taking a Ride task in Figure 3a). Because coordinating amounts of change involves an activity of constructing a magnitude's accumulation in terms of accruals, we use *partitioning activity* to refer to students' mental and sensorimotor actions associated with their constructing and reasoning about these incremental changes that may represent amounts of change.



(a) (b) (c)

*Figure 1. As ||B||(denoted in pink) increases by equal amounts, ||K|| increases (denoted in (a) dark blue and in (b)-(c) light blue plus dark blue) by decreasing amounts (denoted in light blue), which can be represented in (c) a Cartesian coordinate system.*

In addition to research on covariation, we draw on research into students' partitioning activity (i.e., "the process of dividing a unit into equal-sized parts, either solely mentally or also materially"; see Hackenberg and Tillema (2009, p. 2)) primarily in the area of whole number, fraction, multiplication and unit coordination (Izsák, Tillema, & Tunç-Pekkan, 2008; Steffe, 2003; Steffe & Olive, 2010). These studies have illustrated that although many students are capable of carrying out partitioning actions, their understandings of fractions and number lines are not necessarily productive with respect to such activity. As it relates to the current study, we are interested in characterizing the extent that students' meanings of quantities are constrained to particular partitioning actions for envisioning or visualizing amounts of change magnitudes across different representations.

## Figurative and Operative Partitioning Activity

### Figurative and Operative Thought

We have found the theoretical distinction between *figurative* and *operative* thought (Piaget, 1976, 2001; Steffe, 1991; Thompson, 1985) useful in developing models of students' partitioning activity. Piaget (1976, 2001) characterized figurative thought as based in and constrained to sensorimotor actions and perception, and he described operative thought as the coordination of mental operations so that these coordinations dominate figurative material (i.e., sensorimotor and perceptual entailments). We emphasize that characterizing a student's thinking as operative does not imply her thinking does not entail fragments of figurative material. Likewise, characterizing a student's thinking as figurative does not imply that her thinking does not entail operative schemes. A researcher's sensitivity to these distinctions is an issue of "figure to ground" (Thompson, 1985, p. 195). When a student's thinking foregrounds carrying out repeatable (mental or sensorimotor) actions and the results of those actions, it is figurative; when a student's thinking foregrounds the coordination of actions and transformations of those actions and their results, it is operative. As we illustrate at the end of this section, the issue of foregrounding is important for describing students' partitioning activity because such activity necessarily entails figurative aspects and material (e.g., drawing graphs and partitions) and likely entails operative schemes (e.g., understanding a coordinate system in terms of directed distances).

### Anticipation and Re-presentation

Regarding students' capacity to imagine or repeat previously carried out partitioning activity, we find von Glasersfeld's (1998) notions of *anticipation* and *re-presentation* useful. Von Glasersfeld (1998) elaborated on the construct of *anticipation* to operationalize how humans make predictions through reflecting on past experience and abstracting regularities from it. A critical and advanced form of anticipation of a desired event, situation, or goal involves an individual recognizing a situation (i.e., perceiving a situation in experience via assimilating it to existing cognitive structures), expecting specific results to occur regarding that situation, and attempting to attain those results by generating their cause (e.g., carrying out associated activity). For example, if a student has experienced partitioning activity to represent decreasing amounts of change in height on a Ferris wheel (see Figure 1b), when she conceives a circle in another occasion she may recognize it as similar to the Ferris wheel, and she may attempt to carry out similar partitioning activity to reconstruct partitions on the circle expecting to obtain decreasing changes in height.

What is critical to this form of anticipation is the individual's ability to generate the cause of expected results; namely, the individual needs to "mentally run through the actions she might take in order to produce a particular result of goal, and in this process [she] adapts or refines her planned actions in relation to the effects she imagines they will generate" (Hackenberg, 2010, pp. 387-388). This requirement aligns with von Glasersfeld's (1995) notion of *re-presentation* as re-playing or reconstructing something that *was* present in a subject's experiential world *at some other time*. Importantly, it's "a mental act that brings a prior experience to an individual's consciousness" (von Glasersfeld, 1995, p. 95). Re-presentation and recognition are similar in a sense that they both require memory; there must be something experienced previously that has remained in a person's mind so that she can re-present or recognize it in another occasion (von Glasersfeld, 1991). However, recognition is less effortful than re-representation. Recognition requires the sensory material to be available (e.g., recognize an English word when hearing or reading it), while re-presentation is wholly self-generated (e.g., re-present an English word when writing or speaking it) (von Glasersfeld, 1991). As von Glasersfeld (1995) stated, re-presentation is "the recollection of the figurative material that constituted the experience" (p. 95), which requires the subject to mentally generate some substitute for the sensory material that was present in prior experience. In the current study, since we attempt to gain insights into students' ability to re-represent, we choose to use re-presentation in a general sense in that we partially supply students figurative material (e.g., circles, segments, coordinate systems with defined axes, etc.) for them to reconstruct their partitioning activity. In this case, re-presentation of previously constructed partitioning activity necessarily requires recognition of the supplied figurative material to be relevant or similar to a prior situation, and thus it is not strictly self-generated.

### Figurative and Operative Partitioning Activity

Combining these constructs to characterize students' partitioning activity, we make the distinctions of figurative and operative partitioning activity in Table 1. *Figurative partitioning activity* refers to an individual's re-presentation of partitioning activity being constrained to having available some perceptual material permitting the same sensorimotor actions of partitioning and, thus, repeating the same sensorimotor actions (i.e., in-complete re-presentation; see von Glasersfeld (1995)). Consequently, when the perceptual material constitutes a prior situation is unavailable in a new situation, she may not perceive the new situation to be relevant or similar to the prior (i.e., not recognize the current situation), or she may not be able to carry out associated partitioning activity due to the absence of available perceptual material. She thus does not anticipate re-presenting the activity (see an illustration in the first theme under the Results section). In another case, when an individual does recognize the current situation due to perceiving perceptually similar elements, she may re-present her partitioning activity by repeating the same sensorimotor actions in order to produce similar perceptual results regardless of the differences in those two situations (see an illustration in the second theme under the Results section). In contrast, *operative partitioning activity* refers to an individual's re-presentation of partitioning activity being based in coordinated mental structures and transformation of those structures. When she conceives a new situation to be relevant, she can anticipate re-presenting a relationship constituting another situation by transforming her mental activity to account for the new situation (see Figure 1b and 1c, where a student traces an arc on the circle and transforms this action to trace a horizontal increment on the horizontal axis; also see an illustration in the third theme under the Results section). She can also wholly self-construct her partitioning activity without any perceptual material given (i.e., complete re-presentation).

*Table 1. Figurative and Operative Partitioning Activity*

| Partitioning Activity | Foregrounded Actions of Partitioning Activity |
|---|---|
| *Figurative Partitioning Activity* | Repeating sensorimotor actions of partitioning tied to particular perceptual material and results;<br>Potentially constrained to re-presenting partitioning activity on available perceptual material permitting the same sensorimotor actions;<br>Conceived invariance among situations is with respect to sensorimotor actions and their perceptual results. |
| *Operative Partitioning Activity* | Sensorimotor actions subordinate to mental actions (e.g., quantitative and covariational reasoning);<br>Potentially can re-present partitioning activity on unavailable or novel perceptual material;<br>Conceived invariance among situations is with respect to coordinated mental actions and their transformations. |

To illustrate these distinctions, consider a student determining if the graphs in Figure 2a and Figure 2b represent the linear relationship $y = 3x$. With respect to Figure 2a, a student who engages in figurative partitioning activity could imagine the graph in terms of successive movements of one axes mark to the right (denoted in blue) and then three axes marks up (denoted in red), and associate such movements with a positive slope of 3 (Paoletti, Stevens, & Moore, 2017). With respect to Figure 2b (a rotated graph of Figure 2a), the student could conceive movements up the graph (denoted in blue) as corresponding to movements to the left along the graph (denoted in red), and associate such movements with a negative slope of $-\frac{1}{3}$. In each case, the student's thought is dominated by carrying out particular sensorimotor actions to the extent that associations (e.g., a line falling left-to-right necessarily has a negative slope) are tied to that activity and its perceptual results. Hence, the student concludes that the two graphs are different.

In comparison, a student who engages in operative partitioning activity could conceive that both graphs are such that any directed change in $x$ corresponds to a directed change in $y$ three times as large as that in $x$. The student's partitioning activity is operative because she can coordinate and transform activity specific to each graph to conceive an underlying invariance that dominates figurative differences in activity. The student might also anticipate re-presenting invariant partitioning activity in other coordinate systems (e.g., polar coordinates, Figure 2c) or contexts (Figure 2d), as well. Figure 2d illustrates four bar pairs (two are orthogonally-oriented, two are parallel), with each bar being able to be manipulated in length. Each pair provides different perceptual material than that of Figure 2a, 2b, and 2c, and none of the pairs provide a perceptually available trace or graph. But, a student might anticipate re-presenting the same relationship associated with Figure 2a, 2b, and 2c on these bar pairs by manipulating the end-points of those bars so that each successive increment in red is always three times as large as a corresponding blue increment. The anticipation of re-presenting partitioning activity aligns with Moore and Silverman's (2015) *abstracted quantitative structure*: a structure of related quantities a student has internalized as if it is independent of specific figurative material (i.e., representation free) so that they can re-present this structure to accommodate novel contexts or situations permitting the associated quantitative operations.

## Methodology

We take the epistemological stance of radical constructivism (von Glasersfeld, 1995) to approach the current study. We consider knowledge as actively constructed through interaction with environment and in ways idiosyncratic to a knower. Knowledge is not a true representation of an objective ontological "reality"; rather, it is adaptive so that it functions and organizes viably at the moment in the course of an individual's experience. This implies that as researchers or mathematics educators, we should respect our students' mathematical knowledge and consider their mathematics as "legitimate mathematics to the extent that we can find relational grounds for what students say and do" (Steffe & Thompson, 2000, p. 269). Also, because we have no access to students' knowledge, we can only attempt to construct hypothetical models of their knowledge that viably explain our observations of their observable behaviors (Steffe & Thompson, 2000).

Under these theoretical assumptions, we conducted a semester-long teaching experiment (Steffe & Thompson, 2000) with prospective secondary mathematics teachers (Lydia, Emma, and Brian) to develop viable models of their thinking. They were in their first semester of a four-semester secondary mathematics education program at a large university in the southeast United States. Each student had completed at least one course past an undergraduate calculus sequence at the time of the study, and we chose them on a voluntary basis from a secondary mathematics content course. We conducted 10-11 teaching sessions (1 to 2 hours each) with each student. The project principal investigator (the second author) served as the teacher-researcher (TR) at every teaching session. At least one other research team member was present as the observer(s). Each session was videotaped and digitized for analysis. In both ongoing and retrospective analyses efforts, we conducted conceptual analysis (Thompson, 2008) to develop models of students' mathematics. Specifically, our iterative analyses efforts involved constructing hypothetical mental actions that viably explained the students' observable and audible behaviors. We continually searched the data for instances that the models could not account for, and we modified our models or we attempted to explain developmental shifts in a student's meanings. In this paper, we focus on the case of Lydia because of particular aspects of her partitioning activity that were consistent throughout the teaching experiment. We consider it important to characterize her ways of thinking in order to add nuances to our prior conceptualizations of students' quantitative and covariational reasoning.

## Task Design

We describe Lydia's activity on four related tasks: (1) Taking a Ride, (2) Which One, (3) Circle, and (4) Blue-Red-Green. The Taking a Ride task included an animation of a Ferris wheel (Desmos, 2016) (see Figure 3a). We designed this task to focus students on constructing the covariational relationship between the *height* of the green rider above the horizontal diameter of the wheel and its *arc length* traveled (the sine relationship; Moore (2014)). We then presented the Which One task (Figure 3b) after students' first attempt on the Taking a Ride task. It included a simplified version of a Ferris wheel (left) with the position of a rider indicated by a dynamic point. The topmost line segment (shown in blue, right) represented the arc length the rider had traveled counterclockwise from the 3 o'clock position. Students could vary the topmost segment length by dragging its endpoint or by clicking the "Vary" button, with the dynamic point on the circle (i.e., the rider) moving correspondingly. We asked students to determine which of the six red segments, if any, could accurately represent the rider's height above the horizontal diameter as the rider's arc length varied. Segment 1 is a normative solution and segments 2-6 vary with either different directional variation or rates. In students' initial attempt on these two tasks, we did not prompt them to construct a graph in order to gain insights into their reasoning with displayed magnitudes while minimizing the influence of their graphing meanings. For the Circle task (Figure 3c), we asked students to graph the relationship between the *horizontal distance* and the *arc length* associated with a dynamic point (i.e., the cosine relationship).

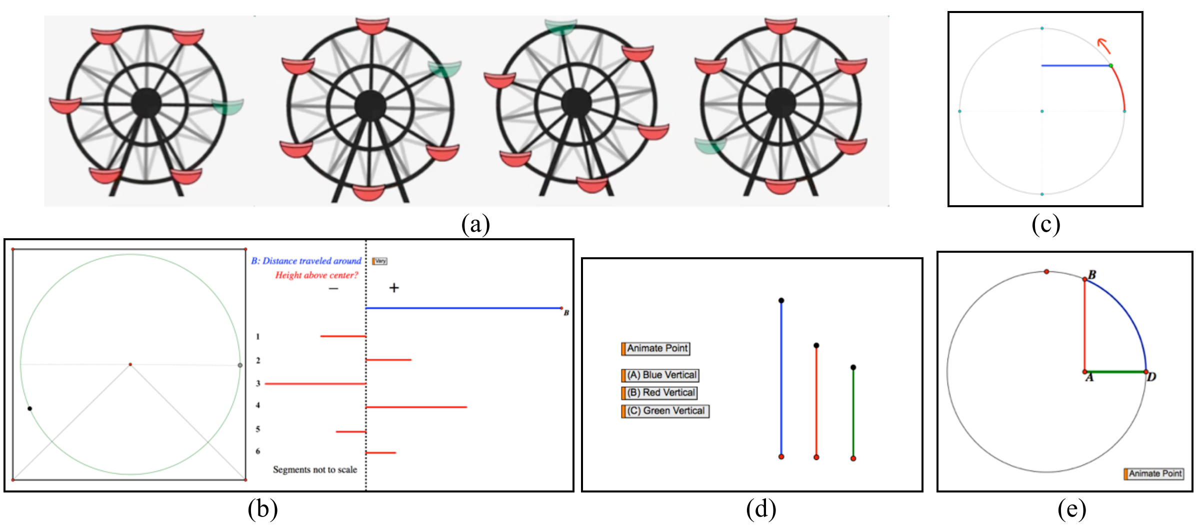

*Figure 3. (a) Animation snapshots of Taking a Ride, (b) Which One (numbering of segments is labeled for readers), (c) Circle, (d) Blue-Red-Green, and (4) the quantitative meanings of the three bars in the Red-Blue-Green task.*

The Blue-Red-Green task (Figure 3d) included an animation in which three vertically-oriented bars (shown in blue, red, and green) simultaneously varied. These three bars entailed the same variations and relationships as the three segments shown in Figure 3e, with their colors matching each other. Namely, with respect to the blue bar (arc) increasing (Point B is draggable along the circle), the red bar (sine) increased at a decreasing rate while the green bar (versine) increased at an increasing rate. We then asked students to describe how any of the two bars varied in tandem and to construct graphs to represent paired relationships. We intentionally chose the red and green quantities on the circle in an attempt to engage our participants in reasoning with quantities' magnitudes that entailed the same directional change (i.e., both increased or decreased) but different rates of change with respect to the blue bar. In students' initial attempt to this task, we presented the interface shown in Figure 3d but not Figure 3e. We were interested in understanding how reasoning with quantities' magnitudes independent on the circle context affected students' covariational reasoning and graphing activity.

We draw attention to a few common task design principles that underscore the focus of this paper, with additional design decisions reported elsewhere (Stevens, Paoletti, Moore, Liang, & Hardison, 2017). First, we designed the tasks to entail (what we perceive to be) figurative material representing the quantities' magnitudes that we asked the students to conceive, coordinate, and act upon; each task involves (varying) segments because a student can conceive a varying segment as figurative material associated with a distance magnitude (i.e., lengthiness). We consider it important to engage students in reasoning with quantities' magnitudes independent of numerical values (unless introduced by students) because written numbers are inscriptions that do not (naturally) permit quantitative activity. Second, we designed the series of tasks to provide different contexts and representations, but similar or identical covariational relationships, in order to tease apart differences in students' re-presentation and recognition activity including the extent it was dominated by figurative or operative thought. By supplying different figurative material (e.g., a circular Ferris wheel, circles, arcs, parallel bars, horizontal and vertical segments) and asking students to construct coordinate graphs, we attempted to determine if a student's partitioning activity reflects an abstracted quantitative structure that students can re-present and recognize across different figurative material (i.e., operative partitioning activity) or if their activity is constrained to re-presenting particular sensorimotor actions on available or similar perceptual material (i.e., figurative partitioning activity). For instance, we were interested in how (and if) the students would attempt to re-present the relationship they constructed during Taking a Ride when choosing a segment on Which One. Third, although we focused a majority of the tasks on the sine relationship, we included several tasks that involved other (but similar) relationships (e.g., cosine in the Circle task and versine in the Blue-Red-Green task) for the purpose of comparing students' partitioning activity across different covariational relationships.

## Results

In this section, we illustrate Lydia's partitioning activity with a focus on her attempts to re-present her partitioning activity, particularly as she considered a variety of representations.

### Partitioning Activity Constrained to Available Perceptual Material

In the first teaching session, we worked with Lydia on Taking a Ride (Figure 3a). She initially described, "the arc length has increased to this [*drawing an arc on the first quarter of the circumference of the wheel*] while the distance from the center has increased to that [*drawing a vertical segment from the top position to the center of the wheel*]." Eventually, with much effort, Lydia made use of the spokes of the Ferris wheel to partition traveled distance equally and construct what we perceive to be successive amounts of change of height for successive, equal changes in arc length (see her construction in Figure 4a-c). Noticing that the blue segments (in Figure 4c) decreased in magnitude, Lydia concluded that, "[A]s the arc length is increasing... [the] vertical distance from the center is increasing ... but the value that we're increasing by is decreasing." Suggesting she was excited that she had identified this relationship, she explained with enthusiasm, "I just discovered this by myself." This revealed that her activity of drawing partitions and identifying amounts of change was novel to her at the time.

(a) (b) (c)

*Figure 4. Lydia (a) used the four spokes to partition distance traveled into three equal increments, (b) identified height of the green rider in each successive state, and (c) identified amounts of change in height.*

Immediately following this task, we presented the Which One task (Figure 3b). After some exploration, Lydia claimed that she desired to choose a red segment that is moving at a constant rate. She eliminated four of the six segments and then had difficulty deciding which of the other two segments was moving constantly (see the top two red segments in Figure 5a). She then decided to orient one of the segments (the normatively correct solution) vertically, and placed it inside the circle (Figure 5b). She confirmed that the length of that segment matched the height of the dynamic point for different states (Figure 5c). When asked if that segment entailed the amounts of change relationship constructed in the initial Taking a Ride task, she responded:

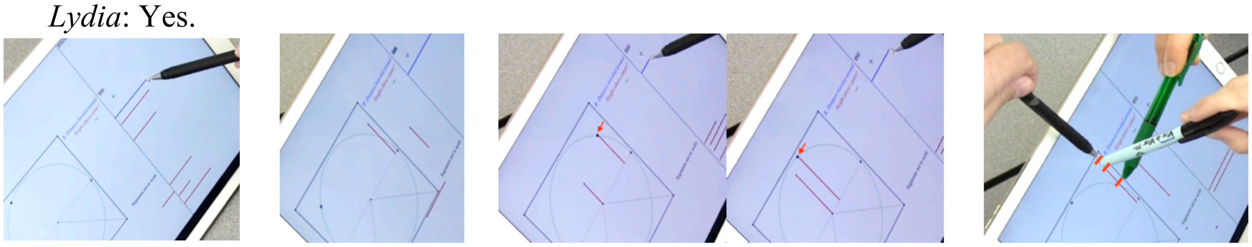
*Lydia*: Not really…Um, I don't know. [*laughs*] Because that was just like something that I had seen for the first time, so I don't know if that will like show in every other case…Well, for a theory to hold true, it like – it needs to be true in other occasions, um, unless defined to one occasion.

*TR*: So is what we're looking at right now different than what we were looking at with the Ferris wheel?

*Lydia*: No. It's – No…Because I saw what I saw, and I saw that difference in the Ferris wheel, but I don't see it here, and so –

*TR*: And by you "don't see it here," you mean you don't see it in that red segment?

*Lydia*: Yes.



(a) (b) (c) (d)

*Figure 5. (a) Lydia was limiting her solutions to two red segments, (b) checking a red segment point-wisely, and (c) we were assisting Lydia to identify amounts of change in height on a red segment.*

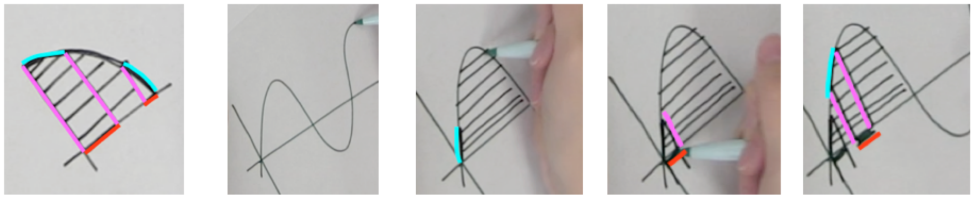
We find it noteworthy that Lydia described height increasing by decreasing amounts as a "theory" to be tested in this new situation despite her having identified that the red segment worked point-wise with respect to traversed arc length; her knowing that the red segment worked for each state did not imply by necessity that the red and blue segments existed in a covariational relationship consistent with that between height and arc in Taking a Ride. Furthermore, Lydia was unable to re-present her previous partitioning activity with respect to the red and blue segments in the Which One task ("I saw that difference in the Ferris wheel, but I don't see it here"). It was only after this exchange, and when the researchers intervened to create perceptually available material using pens to denote amounts of change of the red segment (Figure 5d), that Lydia responded (in surprise) that her "theory" held true.

We characterize Lydia's partitioning activity as figurative due to her difficulty re-presenting such activity from one context to another. Although she identified successive accruals in height on the Ferris wheel (Figure 4c), her understandings of amounts of change (or her "theory") were rooted in carrying out particular activity of partitioning and creating perceptually available increments for comparison in that specific context. When moved to a context in which there were several bars changing continuously and the spokes of the Ferris wheel were not perceptually available, she did not anticipate re-presenting her partitioning activity. As she considered successive red segment states in Which One (Figure 5c), she was unable to hold in mind the red segment associated with a prior state to compare it to a current state and thus was unable to mentally construct and re-present those incremental changes in height. In addition, she was engaged in a different sensorimotor action (e.g., point-wise checking of each red segment) and such action did not result in her producing similar perceptual results (i.e., incremental curves or vertical segments) to those on the Ferris wheel. Due to her conceived invariance of partitioning activity being limited to particular sensorimotor actions and their perceptual results in the Taking a Ride context (as opposed to abstracted quantitative structures), she had difficulty with conceiving the invariant relationship of the Ferris wheel in the Which One context and anticipating transforming her partitioning activity.

**Repeating Sensorimotor Actions of Partitioning Activity**

After the first teaching session, Lydia worked with two other students on the Taking a Ride task (Figure 3a) and the Circle task (Figure 3c). During these two group sessions, the students constructed graphs to re-present relationships they constructed during these tasks (i.e., sine and cosine), and Lydia primarily observed the other students. The TR began the fourth session by asking Lydia what she recalled from the previous sessions. She first drew a quarter of a circle (Figure 6a) and discussed the relationship between arc length and horizontal distance:

> "So we kind of said as the arc length is increasing in the first quadrant that our X distance is decreasing [*drawing the horizontal segments within the circle from bottom to top in Figure 6a*], and then…distance will decrease more in the same amount of space. So like from here to here [*highlighting the bottom blue arc*], then we'll say these are the same arc length [*highlighting the top blue arc*]…so we're going to take this point here [*marking a point at the top of the far-right pink segment*] and then drag it down [*drawing the far-right pink segment*], we've only lost this much [*highlighting the shorter red segment*]. And then from here [*drawing the middle pink segment*] to here [*tracing the far-left pink segment*] we lost this distance [*highlighting the longer red segment*], but we're saying those are the same arc length [*pointing to the two blue arcs*], so it's a lot more distance."



(a) (b) (c) (d) (e)

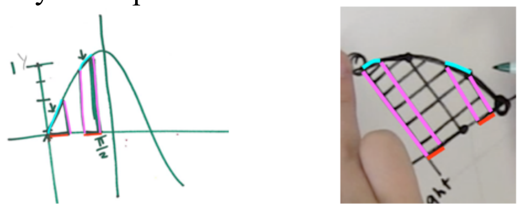
*Figure 6. (a) Lydia's drawing of the circle situation, (b) Lydia's graph, and (c)-(e) her partitioning activity.*

Lydia's re-presented partitioning activity appeared compatible with that from previous sessions, and thus the TR asked Lydia how such activity related to graphing the relevant relationship. The TR did not provide a graph in order to allow Lydia to re-present the activity (as she perceived it) from the previous sessions. Lydia drew a graph (Figure 6b; what we perceive to be a sine graph) and explained how the graph related to her partitioning activity in Figure 6a:

> "As we go up in arc length [*highlighting the blue curve in Figure 6c*]…that distance is decreasing [*drawing the horizontal segments from bottom to top in Figure 6c*], and so we see that here [*drawing the pink segment in Figure 6d*] is like this [*highlighting the red segment in Figure 6d*], and then [*highlighting the blue curve and drawing the pink segments in Figure 6e*] ... here is this [*drawing the red segment in Figure 6e*]. So that's the same conclusion we had gotten from the circle, so then we can say that this circle relates to this graph."

Lydia's partitioning activity across the situation and graph included: (a) drawing horizontal segments emanating from the circle and curve (see Figure 6a and 6c), (b) tracing arcs from lower end points to higher end points on the circle (denoted in blue, see Figure 6a) and tracing the curve in the same manner (denoted in blue, see Figure 6c and 6e), (c) drawing vertical segments from the end points produced by the arcs or curves to a horizontal segment or line (denoted in pink, see Figure 6a, 6d and 6e), and (d) drawing horizontal segments between two pink segments and comparing their lengths (denoted in red, see Figure 6a, 6d, and 6e). Although we infer that Lydia's activity did entail some operative schemes (e.g., making quantitative comparisons between lengths, denoted in red), we characterize her partitioning activity as figurative due to it foregrounding repeated sensorimotor actions that produce similar perceptual results (e.g., partitioning along something curved, drawing vertical segments, and drawing and comparing horizontal segments). We specifically note that her constructing partitions along the curve of her graph and not maintaining a fixed reference point for her horizontal segments are contradictions that her partitioning activity was operative (Lee, Moore, & Tasova, submitted).

Providing additional evidence that Lydia's partitioning activity was figurative, later in the teaching session, Lydia drew a similar graph (Figure 7a) in order to discuss the relationship between "height" and "arc length". Her activity included tracing from left to right two equal horizontal segments (denoted in red, Figure 7a), drawing vertical segments from end points of the horizontal segments up to the curve (denoted in pink, Figure 7a), and tracing two corresponding curves (denoted in blue, Figure 7a). She compared the lengths of these curves and concluded that the increases in height decreased for equal changes in arc length. Similarly, on a circle, she traced two horizontal segments (denoted in red, Figure 7b), drew vertical segments (denoted in pink, Figure 7b), and traced and compared two arcs on the circle (denoted with blue, Figure 7b). Again, Lydia's figurative partitioning activity involved her carrying out same sequence of sensorimotor actions on her curve and circle (e.g., the sequence of drawing horizontal and vertical segments, and curves), the elements of which entailed similar perceptual results. We draw attention to her constructing partitions along the horizontal diameter of the circle and constructing and comparing lengths of curves and arcs to refer to changes in height; these are contradictions that she constructed abstracted quantitative structures of the situation and graph or her partitioning activity was operative.



(a) (b)

*Figure 7. Lydia's (a) new graph and (b) circle with drawn partitions.*

**Re-presenting and Transforming Partitioning Activity**

As the teaching experiment proceeded, we provided Lydia with additional opportunities to engage in partitioning activity. During the tenth teaching session we presented Lydia with the Red-Blue-Green task. Differing from previous, her activity suggested her re-presenting partitioning activity operatively across multiple representations.

After watching the animation (Figure 3d), Lydia claimed that as the blue bar was increasing at a constant rate, the red bar was increasing at a decreasing rate. Here, she was making claims about each bar's "rate" based on fastness of its movement experientially. She then constructed a graph, carried out partitioning activity on her graph, and concluded from her orange highlighted segments that, "because that amount of change [in red] is getting smaller and smaller, it's increasing at a decreasing rate" (Figure 8). Here, we interpret that she was making claims about "rate" by parameterizing amounts of change in red with respect to implicit time.

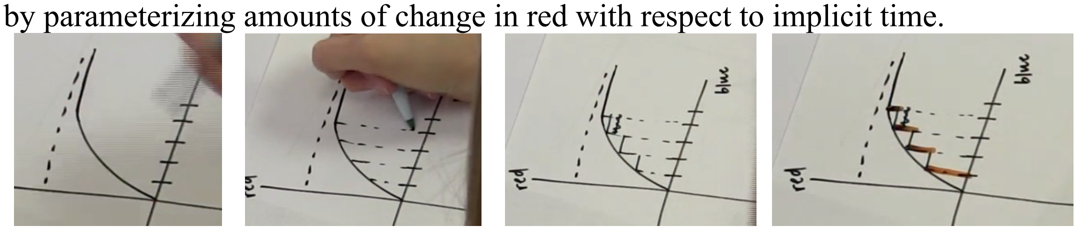


*Figure 8. Lydia's construction process of partitioning activity on her graph.*

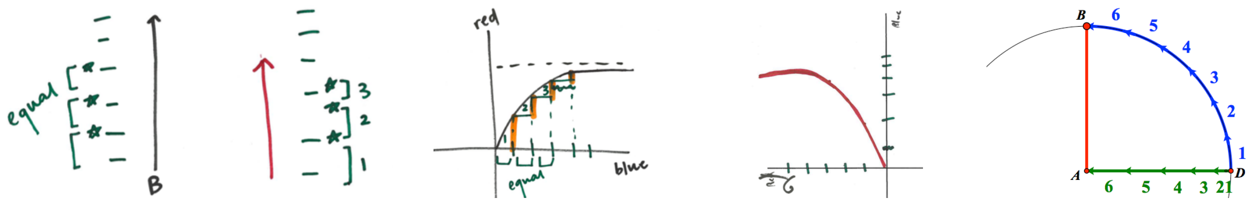
The TR then asked Lydia to draw a picture of the situation with dynamic bars and show how she would manipulate the bars in ways that are consistent with those partitions on her graph. Lydia first drew two vertical lines and a collection of little horizontal segments to indicate landmarks of equal increments (Figure 9a). She then simulated how she imagined each bar first increasing to the respective bottom star symbol, then to the middle, then to the top correspondingly. She explained that she intentionally drew the three stars respective to the left segment at equal partitions but not the red segment on the right. She explained, "the red is already like started to slow down, so then it hasn't reached the next partition, so then we can see they're not traveling at equal paces… it's not reaching the next partition when the black is." The TR then asked her to return to her graph and talk about how her two drawings were related to each other. She wrote down labels of "equal," "1", "2," and "3" on both drawings to indicate how each increment was corresponding to each other (see Figure 9a and 9b). In contrast to her work on the Which One task, Lydia was able to mentally envision these two continuously varying bars as varying by successive increments and to re-present her partitioning activity on novel figurative material. Her representational activity also involved her transforming her partitioning activity between the graphical representation and the bar situation such that they both entailed the same quantitative structure.



(a) (b) (c) (d)

*Figure 9. (a) Lydia was re-presenting her partitioning activity on two bars, (b) her final graph of red versus blue, (c) her graph of blue versus green, and (d) annotated recreation of Lydia's partitioning activity on the circle as she dragged Point B from the 3 o'clock position to the 12 o'clock position.*

After the discussion on the blue and red bars, the TR drew her attention to the relationship between the blue and green in Figure 3d. Observing from Lydia's prior activity that she was able to re-present her partitioning activity on two bars, the TR decided to provide her another version of the sketch in which the same three bars were presented but were not growing and shrinking continuously; rather, the endpoint of each bar was movable and she could drag the endpoint to manipulate the length of each bar. By manipulating the blue bar to increase by equal increments, Lydia claimed that there was "hardly a change in green" for an initial increment in blue and there was a "decent jump in the value of green" for a subsequent equal increment in the blue. She then concluded that the green bar was increasing at an increasing rate with respect to the blue bar.

Turning to a graphical representation, TR decided to ask her to create a graph on a coordinate system with the horizontal axis labeled as green and the vertical axis labeled as blue (defined left and up as positive; see Figure 9c) in order to see whether she could re-present her partitioning activity in a non-conventional Cartesian coordinate system. Lydia then claimed she could transform her prior statement of the relationship between green and blue to a statement of "blue is increasing at a decreasing rate as the green increasing at a constant rate." She then created a drawing shown in Figure 9c where she drew equally-spaced partitions on the horizontal axis, drew partitions with decreasing amounts of space on the vertical axis (starting from the origin), and drew a graph that represented the uniting of corresponding partitions. She explained later that this graph could also represent the green bar increasing at an increasing rate with respect to the blue while she motioned her hand as if she was drawing equal partitions along the blue (vertical) axis and anticipating the space between successive green (horizontal) partitions increasing in size. We claim this activity indicated operative partitioning activity because she was able to mentally anticipate and re-present partitioning activity without physically carrying out specific sensorimotor actions to make their results perceptually available. Also, the novel coordinate system did not constrain her re-presenting invariant covariational relationship; rather, she transformed her partitioning activity on the two parallel blue and green bars to accommodate the given Cartesian coordinate system with novel axes orientations.

As further evidence of operative partitioning activity, approaching the end of the teaching session, we presented Lydia with the circle animation shown in Figure 3e and asked her to determine if the variation of the green segment on the circle corresponded to that of the green bar she discussed. She anticipated that, in order for the circle segments to have the same relationship as the bars, "the change in the arc length is like, when it changes 1 unit, then like the change in green is very small, but then as the green value increases, the change is also increasing." She then confirmed this relationship by dragging Point B for six successive equal increments along the circle circumference and envisioning the green segment increasing by increasing amounts (see her activity in Figure 9d).

## Discussion

Characterizing a student's thinking of amounts of change in terms of figurative or operative partitioning activity is significant in that it allows us to describe nuances in Carlson et al. (2002)'s covariation framework and, more generally, mental actions involved in quantitative reasoning (Thompson, 2011). A student's amounts of change meanings can differ in the extent that her partitioning activity is restricted to particular sensorimotor actions and the perceptual results of these actions. In this paper, we illustrated that a student's partitioning activity was initially figurative because it involved her seeking to repeat sensorimotor actions in a particular order across various situations. Furthermore, her partitioning activity was constrained to having perceptually available material. Consequently, when confronted with a novel situation in which these figurative elements were absent or carrying out the same sensorimotor actions failed (e.g., Which One), she had difficulty re-presenting partitioning activity.

We infer that Lydia's later success in anticipating and re-presenting partitioning activity in various contexts (e.g., circles, bars, and graphs) was partially due to her repeated experience of partitioning in previous teaching sessions. Throughout the teaching experiment, we intentionally prompted her to switch back and forth among various representational systems to re-present her partitioning activity, which included circle situations (e.g., Taking a Ride, Which One, and Circle), dynamic bars (e.g., Which One and Blue-Red-Green), and graphs with different axes orientations (e.g., Figure 9b and 9c). Towards the end, we interpret that her partitioning activity was not constrained to carrying our particular sensorimotor actions to produce similar perceptual results in a particular context as before; rather, she was able to sustain quantitative meanings of quantities across different representations and re-present and transform her partitioning activity to perceive invariant relationship among these representations.

von Glaserseld (1982) defined *concept* as "any structure that has been abstracted from the process of experiential construction as recurrently usable…must be stable enough to be re-presented in the absence of perceptual "input" (p. 194). Characterizing partitioning activity as we have enables us to extend and apply this definition in the context of students' reasoning about relationships between covarying quantities. When a student abstracts her partitioning activity so that it is not tied to particular figurative material, thus mentally anticipating transformations of such (e.g., changing orientations or representations), she has constructed a *concept* related to this relationship (e.g., the concept of sine or rate of change). The case of Lydia implies that researchers should be more careful about making claims about students' covariational reasoning and meanings before gaining insights into their activities among a variety of contexts. Students' mathematical meanings that involve carrying out particular actions in one specific context does not necessarily imply that their meanings are operative or they construct a concept related to those meanings. Moving forward, we call for continued explorations into how students reflect upon their sensorimotor actions related to some mathematical ideas (e.g., partitioning actions) and abstract quantitative relationships and structures (e.g., rate of change).

Moreover, we conjecture that engaging students in reasoning with varying bars that represent quantities' magnitudes can support their construction of graphs (Moore & Thompson, 2015). A potential explanation for Lydia's success in the Blue-Red-Green task is that she started with reasoning about continuous variations in the two parallel bars, and then imagined the two bars (including their partitions and variations) being oriented orthogonally to construct a graph, and finally *embedded* the bars back to the circle to construct their quantitative meanings. In contrast, in the Which One task, she had much difficulty with *disembedding* the height and arc segments from the Ferris wheel and anticipating variations of two corresponding bars independent of that.

The complex figurative features of the Ferris wheel situation might have constrained her from re-presenting her activity in another context.

Geometric and Algebraic Reasoning in Adults on the Autism Spectrum: Excerpts from Case Studies

Jeffrey Truman
Virginia Tech

*In this report, I examine the unusually precise geometric reasoning of a student on the autism spectrum in linear algebra given the beginning of the Magic Carpet sequence outside of their normal curriculum, as well as strong tendencies toward geometric interpretation of other problems and its effects. I contrast this with a similarly strong tendency toward algebraic reasoning in two other adults on the autism spectrum. Analysis of possible reasons for taking these approaches and implications for teaching are presented.*

*Keywords:* autism, linear algebra, geometric reasoning

My research attends to mathematical problem solving by adults on the autism spectrum (with a formal diagnosis), particularly those with a relatively strong background in mathematics. In this report, I focus particularly on the case of one student's work on one of the Magic Carpet problems of Wawro, Rasmussen, Zandieh, Sweeney, & Larson (2012).

There is a wide range of conceptions of what being on the autism spectrum means, including various academic and clinical definitions. The Autistic Self Advocacy Network (2014), the leading autism advocacy group run by people who are themselves autistic (and identify as such) states that autism is a neurological difference with certain characteristics, each of which is not necessarily present in any given individual on the autism spectrum. These include differences in sensory sensitivity and experience, atypical movement, a need for particular routines, and difficulties in typical language use and social interaction. They also list "different ways of learning" and particular focused interests (often referred to as 'special interests'), which are especially relevant for research in education. Of those characteristics, it is primarily the existence of special interests and the differences in language use and social interaction that are used as diagnostic criteria by the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5).

Much of the research currently done on mathematics learning in people on the autism spectrum is focused on young children (e.g. Klin, Danovitch, Mers & Volkmar, 2010; Simpson, Gaus, Biggs & Williams, 2010; Iuculano et al., 2014) or looks at mostly arithmetic. There is also a notable strain of work done on the population of research mathematicians (e.g. James, 2003; Baron-Cohen, Wheelwright, Burtenshaw & Hobson, 2007), but very little attention is paid to groups in the middle (mainly high school and college students, or adults other than career mathematicians). This is a gap which I have sought to help fill with my own research, including the particular selection which I present here.

## Theoretical Framework

The theoretical framework that guides my research starts with the work of Vygotsky. In Vygotsky's writing, there is some work that directly addresses the study of "defectology". At the time, this was used to refer to studies involving children with certain disabilities (of a narrower scope than we might consider today) (Gindis, 2003). One of the main characteristics of Vygotsky's (1929/1993) conception of 'defectology' was the idea of overcompensation. Vygotsky explained this initially in a framework of physical overcompensation, such as a kidney or lung necessarily strengthening when the other one is missing or by analogy to vaccination. He argued that overcompensation also occurred in psychological development, both in its general course and in particular in the presence of various disabilities (concentrating primarily on those who were blind or deaf, as with most related efforts at the time). Based on this, he criticized the education of children with disabilities of the time as inappropriately focusing on only the weaknesses, not the strengths, of their students. Thus, Vygotsky's emphasis on the social reasons for psychological differences among people with disabilities also has much in common with modern social constructionist views of disability and the perspective of neurodiversity. Jones (1996) contrasts the social construction model (crediting its introduction to a paper by Asch in 1984) with "functional limitations" and "minority group" conceptions. Vygotsky (1929/1993) directly stated that "a handicapped condition is only a social concept" (p. 83), and Asch's (1984) criticisms of social attitudes toward people with disabilities are remarkably similar to statements by Vygotsky (1993) such as "the task is not so much the education of blind children as it is the reeducation of the sighted" (p. 86). In terms for specific to autism, the Autistic Self Advocacy Network and others work from a perspective in support of neurodiversity, a term coined by Judy Singer in the 1990s, and generally referring to a positive and inclusive perspective on not only autism, but also other neurological differences (Silberman, 2015). It is these more positive perspectives that I work from in my research and analysis.

While the diagnosis of autism did not exist when Vygotsky wrote, he viewed impacts on communication as a particularly important aspect of the effects of disability (with the issue coming up primarily in comparison between the blind and the deaf). Since differences in communication based on language are a major component of autism, it would be expected to have a strong impact on the shape of individual development in the Vygotskian framework. However, it should also be noted that all of the criteria for the autism diagnosis in the DSM-5 are entirely in the deficit-focused model which Vygotsky criticized. Additionally, since Vygotsky's perspective has a social-first model of child development (as opposed to the individual-first model of Piaget and others), the developmental differences linked to autism should be expected to be more significant and far-reaching in a Vygotskian model than in other models.

## Methodology

Given my interest in focusing in-depth on interviews with a small number of people, a method of case studies was a natural fit for my work. Case study focuses on in-depth understanding of the case in question, and only secondarily on generalizations from that understanding. Additionally, while generalization is possible, it is not of the same nature as generalization in other types of research (Stake, 1995). These are sometimes divided between embedded and holistic case studies, where an embedded case study is interpreted as examining a particular feature or subset of the case in question, while a holistic case study does not use such subdivisions (Yin, 2009). In this case, my decision for a holistic case study naturally follows from my neurodiversity-informed view that the nature of being autistic is not a discrete part of the person that can be separated, and thus an embedded design does not apply.

While my views are informed by the Vygotskian framework, there are some issues with using it directly. Some parts that are particularly relevant in autistic people, such as the ideas about atypical development and concept formation, particularly concern things that have already must have occurred far before starting university coursework, and thus cannot be observed in my interview subjects. The examination of inner speech also has difficulties; Vygotsky himself used children whose inner speech had not yet fully developed in his clinical experimentation on the subject. Thus, while those ideas from Vygotsky inform my views, additional constructs were required for the data analysis, and are elaborated upon below.

## Participants, Tasks, and Data Collection

Joshua (a pseudonym) was recruited from my university's center for students with disabilities. He received an Autism Spectrum Disorder diagnosis at age 18 (changed from a previous diagnosis of Obsessive-Compulsive Disorder), and was in his early twenties at the time of interview. He reported a strong interest in chemistry (which he was majoring in) as well as a particularly low level of interest in subjects unrelated to the sciences and a strong inclination to work alone. He was taking integral calculus and linear algebra courses during the time he participated in interviews.

Cyrus was recruited in the community outside of the university, received an ASD diagnosis at the age of 13, and was in his thirties at the time of interview. His mathematical background included a bachelor's degree in mathematics, and he was working in computer programming at the time of interview. In contrast to Joshua, none of his special interests were strongly apparent in the interviews (although mathematics or computing in general may be an exception).

Mark was also recruited in the broader community, received a diagnosis of Asperger syndrome at age 21 (this occurred before the release of the DSM-V), and was in his mid-twenties at the time of interview. Like Cyrus, no strong special interests appeared in Mark's interviews. His mathematical background included a bachelor's and master's degree in mathematics.

The data for my study comes from a series of clinical interviews with each of these participants that I conducted, focusing on a variety of problems (with most given to at least two participants as appropriate). The interviews were audio recorded on a password-protected device. In this report, I focus on results from three tasks. The first of these is the first of several Magic Carpet tasks, introduced by Wawro, Rasmussen, Zandieh, Sweeney, & Larson (2012). The task used is formulated as follows.

| |
|---|
| You have two modes of transportation: a hoverboard and a magic carpet. The hoverboard moves along the vector (3,1) and the magic carpet moves along the vector (1,2). Can you get to a cabin at (107, 64) using these modes of transportation? If so, how? If not, why is that the case? |

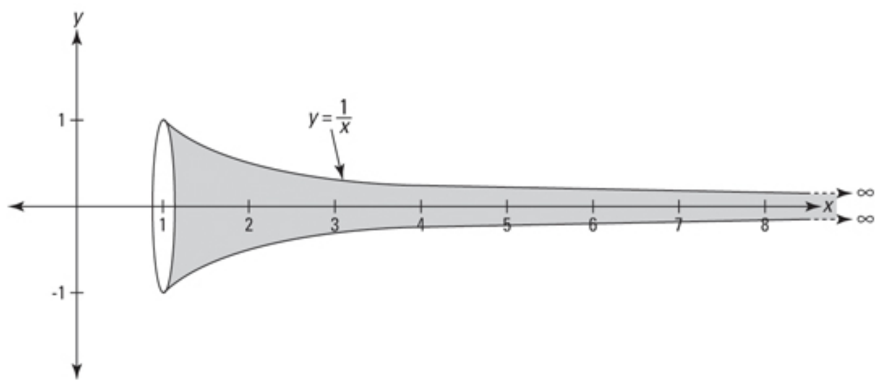
*Figure 1. Magic Carpet Problem Formulation*

For this problem, a possible (and expected) solution in the context of a course in linear algebra is to find values $a$ and $b$ such that $a\begin{bmatrix}3\\1\end{bmatrix} + b\begin{bmatrix}1\\2\end{bmatrix} = \begin{bmatrix}107\\64\end{bmatrix}$; in this case, those are $a = 30, b = 17$.

The Magic Carpet tasks as a whole were designed for and used with students in a linear algebra course, who had completed at least two semesters of calculus. Since they were used at the beginning of their course, the students had not been previously exposed to the standard linear algebra solution above, although all had been introduced to the idea of a vector in some capacity. Instructionally, the intent of the problem in the context of a linear algebra context was primarily to introduce the idea of linear combinations, and to lead into other problems in the setting which introduce span and linear independence of vectors. For additional context, the second Magic Carpet task asks if there are any points that one cannot reach with a combination of the magic carpet and hoverboard from the first problem. This demonstrates part of the overall intent, to guide students toward ideas of linear independence and span as they find that there is no such point and justify their answer.

The second task I consider in this report is the classic Gabriel's Horn or Painter's Paradox.

Gabriel's Horn is the object created by rotating the graph of the function 1/x around the x-axis (starting from x=1), as shown below.



Its surface area and volume can be calculated as follows:

$$A = \lim_{b\to\infty} 2\pi \int_1^b \frac{1}{x}\sqrt{1+\left(\frac{-1}{x^2}\right)^2}\,dx \geq \lim_{b\to\infty} 2\pi \int_1^b \frac{1}{x}\,dx = \lim_{b\to\infty} 2\pi \ln b = \infty$$

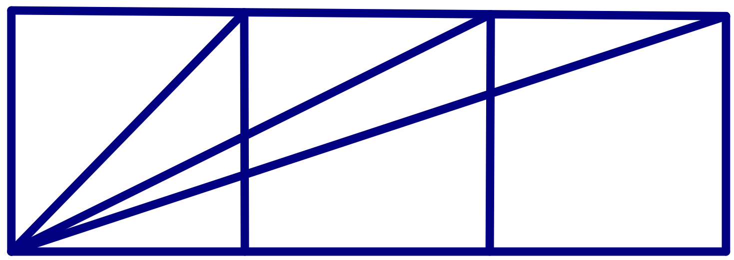
$$V = \lim_{b\to\infty} \pi \int_1^b \left(\frac{1}{x}\right)^2 dx = \lim_{b\to\infty} \pi\left(\frac{-1}{b}+1\right) = \pi$$

Since the surface area is infinite, it should require an infinite amount of paint to cover the surface. However, since the volume is finite, the horn could be painted by filling it with that amount of paint. Is this possible? How can this be resolved?

*Figure 2. Gabriel's Horn Problem Formulation*

This result was discovered by Torricelli in 1641, and regarded as paradoxical by its discoverer and many later mathematicians, who used the result in discussions about the philosophical status of mathematics (Wijeratne and Zazkis, 2015). Wijeratne and Zazkis gave the problem to twelve undergraduates in a calculus course who had been presented with the relevant integration techniques in their course, and conducted interviews about the task afterward. One of the more common responses, reported from a majority of participants, was something with regard to the physical or contextual considerations of the problem (such as paint 'getting stuck' at an atomic level once the horn is small enough); because of this, this problem is another case in which I saw possibilities in considering geometric approaches against the more standard approach, with added complications in the paradox with infinity and the related opposition of the geometric intuition and standard solution.

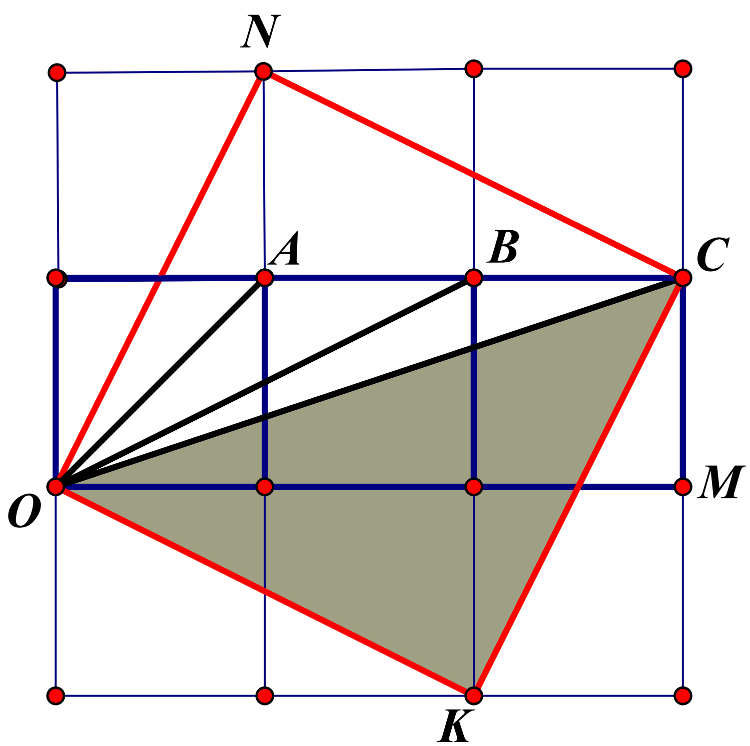
The third task is a more geometrically-focused one, starting with the figure below.



What is the sum of the three angles formed between the bottom line of the figure and the hypotenuses of the three right triangles in the figure?

*Figure 3. Squares and Triangles Problem Diagram*

The intended solution to this task is geometric, and can be seen from this second figure:



Here, it is easy to show that the angle ∠BOM is equal to the angle ∠MOK (for example, by considering congruent triangles), and that the sum of the measures of angles ∠COM and ∠MOK is 45 degrees (as this sum is ∠COK and OC is a diagonal in the square OKCN). Since ∠AOM is clearly also a 45 degree angle, the sum of the measures of the three angles is 90 degrees.

*Figure 3. Squares and Triangles Solution Diagram*

The inclusion of this problem was guided by the desire to introduce a counterpart to the first problem, one where the geometric interpretation is ultimately the intended solution. This occurred after some findings with Joshua related to geometric tendencies, and allowed a broader range of testing possibilities for or against such geometric tendencies.

### Interviews with Joshua

When presented with the Magic Carpet problem, Joshua's first response focused on drawing a sketch:

*Joshua*: Here's how I would do it. Draw a sketch. [drawing] So, I don't know if this has to be explicitly done mathematically or whether it can be done by drawing a sketch but in physics I know that we always drew sketches. That way, the person knows what is going on in our heads.

*Interviewer*: Okay, well, that's what I want to know, so that's good.

*Joshua*: Okay, so here's what's going on in my head. [more drawing]

*Joshua*: So now we've got the vector that we wanted to, which... look like so... 1, 2 we could scale up to 10, 20, so that's what I did here, and we have the vector 3, 1, which we could scale up to 30, 10. Oh, that's right, and so now, how we could approach this is we could follow this vector here, ...we could follow the vector, this is the vector 30, 10, and this is the vector 10, 20, I just scaled it by 10,

*Joshua*: Each vector scaled by 10, then from this point here, what we could do, is we could slide this vector up, slide it up all the way up to here and then, so what we could do, is from this point here, we could draw, so if we have 64, 107, we could- go down 20, 20 units, and 10 units to the left, like so, and then, we have the same vector, we just literally transformed the vector. I guess not [transformed], we moved the vector, the point is that it's the same thing, 10, 20, and then, this point of intersection, is where we would change what instrument we were using, so you want to look at that.

*Interviewer*: Okay. Interesting.

*Joshua*: So that's how I would do it. I'd approach it literally geometrically. Yeah, there you go.

*Joshua*: And so we've got two lines there, and that little point of intersection is where, and you can find that quite easily, on the x-axis, and that point of intersection is where you would switch your instruments, ...and again, we have the vector 1, 2, we can find the slope of that vector, and then we can move it over to the point 107, 64, and then, you know, it wouldn't really be that hard to find that point of intersection but that's how I'd do it, literally just play around with those vectors.

Joshua starts off by drawing the destination point, using a ruler to measure precisely where the point should be to get a drawing that is properly scaled. For the first step in the sketch, he draws the given vectors for the magic carpet and the hoverboard, scaled up by a factor of 10 (given the rest of the scaling, they would be barely visible otherwise). After doing this, he moves the vector (20,10) so that its tip touches the destination point, and then extends the two vectors so that they intersect, concluding that the intersection point is where you should change from one mode to the other. The end result sketch is shown in Figure 2 below.

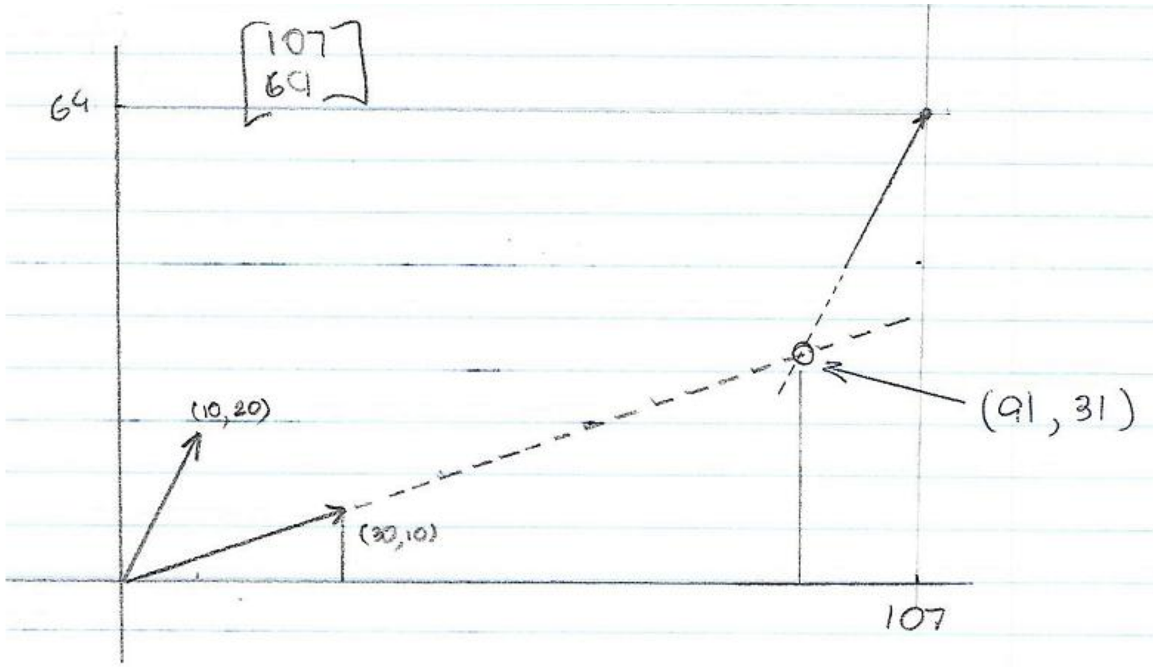


*Figure 2. Joshua's Magic Carpet Solution*

This solution is unlike those of any of the students observed by Wawro et al. (2012) in their use of this task. The drawings used by Joshua were produced using a ruler and were very precise, enough to give a correct solution (note that this was done on lined paper, not a square grid). However, it is notable that Joshua terms this a "sketch" (possibly ignoring some of that word's connotations) and seems to not regard this solution as "mathematical". The drawings were measured after they were produced, and the point of intersection found by the drawings was the correct point (though the coordinates written above are very slightly off). The interpretation as the location where the person in the problem changes from one mode to the other is also correct. Thus, this solution accomplishes the stated goal of the problem (to find a way to get to the cabin) perfectly well, although by approaching the problem this way, Joshua avoids the intent to push the student toward a standard linear algebra solution. Joshua's solution is less directly related to linear combinations of vectors, though a geometric version of the idea can be brought out from the drawing used for the solution. In particular, vector scaling is used to arrive at the solution, as well as vector addition (which is geometrically accomplished by placing the start of one vector at the end of another).

As Joshua acknowledges, he had been presented with the linear algebra material that one could use to solve it in the intended linear algebra way. Thus, it is particularly noteworthy that not only did he gravitate toward the geometric solution in Figure 1 first, but that even when asked for an algebraic solution, he adapted his geometric solution to its algebraic counterpart rather than produce a more standard solution:

*Joshua*: Well, like I said, I'd probably find the slope of the vector 1, 2, make that, once I have the slope, make a line with slope 1, 2, so literally it would be y is equal to m x plus b, so, our y and our x values would have been 64 and 107, we have 64, 107 with some slope, you find the b, you find the y-intercept, you'd have an equation y equals m x plus some y-intercept, you'd know the slope, you'd find the other slope, you'd find the other equation, and that point of intersection is where the x and the y values are the same. Do you know what I mean?

*Joshua*: You find two equations for both lines, so I found two lines there, find equations for both lines and then find the common solution for both lines.

*Interviewer*: So you're finding an equation that's sloped on one of the vectors and hits this point, and the other equation that's sloped on the other vector hits the origin.

*Joshua*: Yeah. Exactly. And then find a common solution to those. And that's where you would switch your implements [indicating the modes of transportation].

This version of the algebraic solution suggests that Joshua is connecting his extensions of the given vectors to ideas about lines, but not the algebraic presentation of vectors which he had learned. After Joshua presents his algebraic solution, he does ask if there is an easier way to do the problem. After being shown the standard algebraic solution, he responds:

*Joshua*: Oh, that's a lot easier. See, I didn't think of that application. It's easier for me to just literally draw it out. Yeah no, that didn't even come to mind. Goes to show you what I'm getting out of this class, [laugh]. Which I'm not saying is his fault, it's just the way it is.

For comparison, Wawro et al. (2012) state in their research that the student solution attempts they observed fell into three categories of "guess and check", "system of equations first", and "vector equation first". The third category fits most closely with the standard linear algebra solution, and its presence for the original study's students highlights the differences in Joshua's approach (which fits into none of the three): some students with no prior linear algebra instruction presented an algebraically vector-based solution, while Joshua did not, despite linear algebra instruction from the course he was taking at the time which included a discussion of linear combinations similar to what this problem is building toward.

When Joshua was presented with the Gabriel's Horn paradox and the mathematical solutions for the integrals (which he unfortunately did not arrive at himself), this was his response:

*Joshua*: Well, it does seem kind of strange, because, like I said [?] the integral test, we learned that if the volume underneath the series is divergent, then the series itself is divergent, but here you've clearly shown that, you know, we've got a convergent volume, but the series itself must be divergent, because you need an infinite amount of paint to paint the trumpet, the horn, whatever you want to call it. So, that's how I would think about it. Is there something that you would add?

*Interviewer*: Well, I'm just curious as to whether you feel this is a conflict or not.

*Joshua*: I do actually feel like it's a conflict. Because we've, again, when I work this out in my head, it would seem kind of weird that the volume is smaller than the surface area, and the surface area, if we take surface area to be in $\mathbb{R}^2$, should be smaller than the volume, which we take as being in $\mathbb{R}^3$, so yes, it does seem kind of conflicting. Do you know what I mean?

*Interviewer*: Okay.

*Joshua*: How can a volume be smaller than an area? For the same- and, I, you know, now I'm thinking about that orange paint thing, and it seems kind of bizarre. So yeah, I see what you're saying.

Unlike the first and other interviews, there was not as much of a geometric tendency shown (possibly due to Joshua being unable to produce his own solution), but the main objection above is one considering dimensions. In a subsequent interview, Joshua was pushed further, and ultimately asked which of the two interpretations he viewed as being in conflict was more correct. This was his response:

*Joshua*: The volume being defined. Um, it feels more correct because when... okay, I visualize a horn in real life, and I visualize literally filling the horn, tipping the horn vertically and filling it with paint, and, to me, um, if I filled the horn, which went all the way, you know, the little thing got- the tip went all the way to infinity, to me, you know, in real life that's not possible, and so the horn has to end somewhere, and so, to me, the volume having some defined volume makes more sense than, you know, the surface area being infinite. So I'm literally going with a real-life interpretation of this. Literally, you can't fill the horn with more paint than when the tip of the horn reaches the diameter of the paint molecule. You know, once the tip of the horn moves further out to space than the diameter of a paint molecule, you can't fit any more. You can't fit any more paint, and so it's got to have some defined volume.

*Interviewer*: Okay. What if we were to simply consider the abstract mathematical volume without putting any paint in it?

*Joshua*: I wouldn't really say that any of them are correct or incorrect, because mathematically they're, you know, that's... the law, I don't know if you want to call it the law, but the equations show what they show, and if they show what they show, you know, if they show that the surface area is infinite but the volume is defined, and not infinite, then that's what they show, you know, there's nothing we can really do about it, I mean, I'm sorry. So, graphically speaking, you know, neither of them seem really, you know, it's just like one over infinity. You know, infinity isn't a number, it's a concept, so how do you take the inverse of infinity? Or, how do you take the inverse of a concept? Well, it would seem kind of not correct to me, but I think it's perfectly fine to do that, and so I accept one over infinity as being zero, considering that if I plug in a really big number into my calculator, and take the inverse, it spits out some really tiny number that I more or less could consider zero. So I can't say that either [?] correct or not correct.

Overall, Joshua demonstrates a particularly high level of trust in mathematics. He also shows a lower level of trust in intuition, although it is unclear whether this is from having less of a sense of intuition or simply less trust or value put on it. The results here are quite different from those of Wijeratne and Zazkis (2015); most of the students in their research did not readily separate physical or 'real-life' considerations (typically expressed geometrically) from the mathematics. Here, while Joshua does produce some contextual geometric analogies as expected, he does not resist separating them from the abstract mathematical result, and again voices acceptance of its validity. This suggests that Joshua's strong preference for using geometric solutions does not translate into a belief in those geometric solutions as more true or more valid than more standard mathematical solutions.

## Interview with Cyrus

Cyrus was also presented with the Magic Carpet and Gabriel's Horn tasks. By contrast to Joshua, his approach to the first Magic Carpet problem was an entirely algebraic one, setting up and solving a system of equations using matrices. However, the solution he arrives at is not correct, having negative values for both coefficients. He recognizes that this is not reasonable, and suggests that this means reaching the point is not possible. When asked what kind of solution would indicate that reaching the point was possible, this is his response:

*Cyrus*: Okay, that's fine. Okay, so, yeah, that's pretty much what I make of this problem. If we were able to find- there would be two cases. If these had both been positive numbers and there was a unique solution, then definitely there is- this is- the problem was asking if you can- you can reach this point. Using either the carpet or the hover-thingy.

*Interviewer*: Not either-or. We can use part of one then part of the other.

*Cyrus*: But can we reach this as our destination and, if there was either one unique solution and it must be positive, or if there was infinitely many solutions, in either of those cases it would be possible to do this.

Here, we see that even approaching the problem from a hypothetical standpoint, the interpretations provided are still entirely algebraic. This approach fits with the majority of students in the study from Wawro et al. (2012), although those students likely did not have previous exposure to the method that Cyrus is recalling here. Cyrus' reaction to the negative solution he obtained, combined with his correct interpretation of the hypotheticals that he gives, shows that he is not approaching the algebraic problem in a way entirely detached from the original problem's context. However, he did not bring up the geometric interpretation of that context independently, so it is uncertain whether he is more inclined to translate the solution into terms of the geometric context, or to mentally translate the context into algebraic terms.

When Cyrus was presented with the Gabriel's Horn paradox, the interviewer presented each of the formulas present in the solution, similar to Joshua's case. Here, Cyrus is first given the description of painting the horn, and says (before seeing the calculation) that the surface area's amount should be sufficient to paint the horn, and the volume amount would be excessive but would also work. He is then presented with the solution and asked for his thoughts:

*Cyrus*: So, does it seem reasonable that this object would have a finite volume and an infinite surface area?

*Interviewer*: So, does it seem reasonable that this object would have a finite volume and an infinite surface area?

*Cyrus*: Does it seem reasonable, um,

*Interviewer*: Does it make sense?

*Cyrus*: Not at first. But it seems like it is mathematically sound, so, it does seem like the right answer. So I would say yes, it makes sense overall, when you find the limits. But it still kind of contradicts intuition.

*Interviewer*: Okay. So, that's an interesting thing you said there, ah, is contradicting intuition a particular problem? How do you feel about that?

*Cyrus*: It isn't a problem when you're dealing with mathematics. It happens, I don't want to say frequently, but often enough.

Given the results of the integrals, Cyrus does not show any signs of doubt, but instead immediately states that the volume is sufficient to paint the horn. While he recognizes it as a paradox, he doesn't seem to have any problem with this, and concludes that he would accept the mathematical answer. From the discussion of using volume or surface area, we saw that Cyrus started off with an intuitive idea that the volume should be larger than the surface area, an idea which Joshua also held. Compared to Joshua's case, however, Cyrus seems to be less attached to the idea that a volume should be larger than a surface area, referencing it only once and making no reference to physical impossibility.

Cyrus' responses when asked about the role of intuition suggest that he uses it to some extent, but considers the formal result more significant. In particular, he does not consider "contradict[ing] intuition" to be a barrier to "mak[ing] sense overall". He also suggests that this is particularly true in the area of mathematics; this belief may be simply stronger there, or may be restricted to certain fields only.

**Interview with Mark**

When Mark was presented with the sum of angles problem, his initial (rejected) thought was to consider it as a sum of arcsines.

*Mark*: I'd like to keep track of what I'm doing, so I'll call that theta one, theta two, theta three, and I want to find the sum, and okay, this is a square, so I'll just note that theta one is pi over four. Okay, so, there's probably a more elegant way to do this than oh, calculate all the angles and what they are, and these two aren't nice, anyway. Are they? Mm... no.

*Mark*: So, wait, what kind of thing am I supposed to be getting for the sum? I mean, I could say, arcsine of this plus arcsine of this plus arcsine of this but that seems to sort of go against the spirit of the problem. That seems to sort of 'not count', if you will.

After rejecting this first idea, Mark considers that in this context the sum should be a "nice number", and works on some ideas from there.

*Mark*: What is the ratio of these angles to... this. Let's see. I had this sort of intuitive idea that maybe this angle is half of this one, and I'm not sure if that's actually true. But, well, it would be pretty nice if it were true, and I could definitely use it. So, could I try and show if that were true in some way? Let's see. This is a slope of one, and this is a slope of one half, so this is halfway up. Uh, yeah, so this thing is, we've got one half, one, theta two, and, wait, no, if that were true, then sine would look like a bunch of jumping lines or something. Would it? Because sine is the ratio, of these. And this is staying the same, so yeah, that's probably not true. But I think this should come out to be something nice.

*Mark*: Wait, is this ratio something useful and I forgot? No. Hmm. Well, I could say that, these angles up here are also theta one, theta two, theta three and then, well, I'll just call these complementary angles phi one, phi two, phi three, and the sums of the theta plus phis are all ninety, or pi over two, hmm, does that help anything? I don't see how that's going to help anything.

*Mark*: Okay, I feel like I don't have anything else to say, but there's got to be something. I can do, do something like this, um, hmm. What useful facts about geometry could I use here? There's some trig identities about sums of angles, no, hmm. What if I think of this in a sort of polar coordinate radial thing? Like, what would these points be in polar coordinates and would that give me anything useful? Well, if I assume that the square side length is, one, might as well, then this is root 2, pi over 4 well, okay, this one is, this is, root 5, something, this is, root 10, something else, well, no, that doesn't seem to be a useful fact. Hmm. It must be one of those things that's simple when you see it. But I'm never quite sure what to do with those. Not some kind of, orderly procedure or sequence of building blocks of smaller facts or something. [Mark continues to make attempts at solving the problem for about 15 minutes, without success.]

After Mark's lack of success at solving the problem, the interviewer presents the solution detailed previously. After this explanation, Mark is asked if the solution is clear:

*Mark*: Yes and no, I mean, it's clear in that, I see that all of these things are true and they produce the result, but it's one of those, okay how am I supposed to think of doing this?

*Interviewer*: Okay. So you think that it's just a trick out of the pocket, or…

*Mark*: Well, there must be some sort of way that someone thinks of doing this, but it doesn't quite mesh with the sort of way I usually think about things.

Overall, we can see two characteristics demonstrated in Mark: an inclination toward algebraic solutions, and a tendency to think about the problem at least in part via considering the hypothetical problem designer's intent. In this particular case, the second leads to the quick dismissal of the first, though it is still mentioned again. The reoccurrence of mentioning the rejected solution suggests there may be some difficulty in switching away from the preferred method, even once it is recognized as necessary. This is somewhat demonstrated in the next few steps, as Mark puts some known facts about the problem into algebraic terms and searches for geometric facts with algebraic forms of expression. Outside of algebra specifically, there is also a desire to see things in a systematic way, or to fit them inside of an existing system. There is little to no mention of intuition in this consideration of the problem.

That this problem is ultimately not solved independently is a piece of evidence for the supposition that problems that are strongly skewed toward solution methods the participant disfavors can pose a particular challenge, which is most likely reinforced by that preference's leading to having had less prior practice in using those methods successfully. This could be particularly prominent in problems which require particular cognitive jumps, or have unusual solutions in a way that particularly draws on the problem solver's weak points.

Although Mark does not have confidence in understanding the rationale behind the solution's construction himself, for him this does not translate into a lack of confidence that such a rationale exists. This continues the trend shown with Joshua where trust and confidence in mathematics is generally high and not cast into doubt by individual problems with a task.

## Analysis

As mentioned above, while Vygotsky's ideas guided my design, additional theoretical constructs informed my analysis. In this report, I use two additional constructs: Fischbein's notion of intuition (1979, 1982) and Grandin's work on geometric reasoning and autism (1995).

In Fischbein's (1979) use of the idea, intuition is separated into different categories, particularly "primary intuition" (developed outside of a systematic instructional setting) as opposed to "secondary intuition" (developed in a systematic instructional setting). The division of categories here has similarities to Vygotsky's distinction between everyday and scientific concepts, and I find it reasonable to consider the primary and secondary intuition used by Fischbein as identifying intuitive reasoning related to everyday or scientific concepts, respectively. Further exploration of intuition by Fischbein (1982) uses a similar division between "affirmatory intuitions" and "anticipatory intuitions", focusing primarily on the former. In this division, affirmatory intuitions are those that are "self-evident [and] intrinsically meaningful", which again stands outside the systematic instructional context. In the context of other works, it is this definition that is closest to what is typically meant when 'intuition' is named but not explicitly defined, which is useful for situating other work which mentions intuition but does not focus on it.

The precision and completeness of Joshua's geometric solution suggests some possibility for a tendency toward thoroughness instead of skipping steps, which is consistent with other observations of more systematic and less intuitive reasoning. In particular, it may suggest that the geometric solution in his mind has more in common with a scientific concept and less in common with everyday concepts or primary intuitions than is generally expected from students using geometric/visual solutions (as seen in the geometric attempts of students observed by Wawro and colleagues). In fact, Joshua explicitly situates his geometric work in a classroom context (although one in physics rather than mathematics), also pointing to the realm of secondary rather than primary intuition. From Joshua's response to the Gabriel's Horn paradox, he demonstrates a valuing of results from systematic reasoning over results from intuition, further supporting this difference in his view. Cyrus' response to this paradox reflects similar values, and Mark also explicitly expressed a desire for more systematic forms of reasoning when thinking about the geometric problem he was given. For some students on the autism spectrum, a general problem with or mistrust of intuitive reasoning (particularly primary intuition) may lead to a kind of compensation where knowledge that is learned explicitly as a scientific concept, instead of formed as an everyday concept, is emphasized. Additionally, these results and Mark's confidence in a systematic reason for the construction in the solution presented for his problem (although he did not know it himself) support a trend of high trust and confidence in the structure of mathematics.

Joshua's tendency toward geometric thinking about the problem may result from an instance of overcompensation, as defined by Vygotsky (1929/1993). Joshua may have particular strengths in areas related to the geometric reasoning he uses here, which he is using to compensate for weaknesses in areas related to the algebraic reasoning that would be involved in the 'standard' solution to the problem. Cyrus and Mark's tendency toward algebraic thinking may be from a similarly structured instance of overcompensation based on different individual strengths and weaknesses. In their solutions, both Joshua's neglect of the standard linear algebra solution from his course and Mark's returns to the arcsine solution are examples of the strength of these tendencies even when working against them in different ways. However, since overcompensation is an idea defined in relation to individuals' development, the observations in interviews with adult students will most likely be of the end result of the compensation process that Vygotsky described (and not show the process itself). The more common tendency toward some more systematic form of reasoning may be an avenue for further investigation along these lines.

The use of a geometric/visual approach in Joshua also notably fits with what we see in other sources, such as a description of the thought process in Temple Grandin's work. Grandin (1995) describes her own memory as being based on remembering static or moving images, and being able to both understand others' information and express her own better in writing than verbally (which may suggest an issue with the interview process). She also describes thinking of abstract ideas in terms of images or sequences of images. However, the range of variation in autism as well as other interview experiences (as seen here) lead me to believe that the underlying principle for differences in problem-solving methods is more complex and does not always push toward a geometric approach; it may be more common, but it was not with the sample in my study. The adaptation of the geometric solution for an algebraic solution, staying rooted in the original geometric thinking, further highlights the strength of Joshua's inclinations toward geometric methods as well as suggesting a possibility for drawing connections. More broadly, while Mark's attempt at an algebraic solution was not successful in this instance, in my overall data there are examples of both success and failure with both participants' preferred approaches. In terms of the case study method, Joshua can be considered representative of the subgroup with geometric problem-solving tendencies, while Cyrus and Mark may be representative of algebraic or abstract problem-solving tendencies.

## Conclusions

One possible effect of the unusual tendency seen here is that it may pose a difficulty for an instructor's plan to confront students with a problem that would ordinarily necessitate a particular approach (the introduction of which is the goal of the activity), as happened with this problem. The intent seen in the problem design by Wawro et al. (2012) was to create a need for the use of a vector-based approach, which notably did not occur here. The purpose of this seen in the context of the full Magic Carpet sequence is to move toward an understanding of linear combinations and linear independence of vectors. By avoiding the use of vectors entirely, Joshua would not get the intended effect of a logical transition to the following topics without further input. The resignation in the expression of this by Joshua above suggests that this is something that has occurred in classes before.

Since mathematics coursework in a traditional academic setting uses scientific concepts explicitly, and the role of everyday concepts is often viewed as interference to be minimized, an inclination away from intuitive reasoning would most likely be helpful in the context of a standard mathematics classroom. By contrast, ideas for mathematics instruction involving the use of students' pre-existing real-world concepts or other ideas, such as the Magic Carpet problem used in this case study, may be less helpful for students on the autism spectrum without additional attention to their particular differences.

The concluding remarks by Joshua – "It's easier for me to just literally draw it out…that didn't even come to mind. Goes to show you what I'm getting out of this class" – not only point to a need for instructional attention in the linear algebra class, but also suggest that there could be a more general pattern across multiple courses of using unexpected approaches that may avoid (or appear to avoid) the general intent of the lesson. Although the other tasks are less explicitly instructional, a similar possibility can be observed with Mark's attempted solution. I suggest that while this can certainly be a problem if it goes unnoticed, with a well-tuned approach it could be turned to an advantage. This is much like Vygotsky's concept of compensation, although strictly speaking Vygotsky's original conception of compensation was for development of more general reasoning abilities as well as child development. While the strict conception would not apply to adults or to specific linear algebra skills, I think that the general idea of using strengths to reinforce weaknesses, possibly in ways that have a different form than the expected one, is useful here. The construction of connections between a student's unusual approach and the standard approach can lead to a deeper understanding, particularly if it allows the student to make use of their particular strengths. Additionally, taking advantage of the opportunity to demonstrate the connections between standard and unusual approaches in a classroom setting has the potential to enrich learning for the class as a whole.

These results as well as others in my line of research show that there is not necessarily a single approach that students on the autism spectrum can be expected to use, and that a variety of forms which may be considered unusual can produce successful results. This highlights the importance of being able to see validity in unusual student work and interacting with students without deficit-based preconceptions, something which holds particular importance across a variety of forms of disability-related education research.

## Math Help Centers: Factors that Impact Student Perceptions and Attendance

Christine Tinsley
University of Oklahoma

Beth Rawlins
University of Oklahoma

Deborah Moore-Russo
University of Oklahoma

Milos Savic
University of Oklahoma

*Mathematics help centers have become common fixtures in post-secondary education, where undergraduate students can go for more assistance on typically first and second-year courses. However, there is scant research on them. In this study, we report on existing literature concerning Math Centers. Then, we use data collected at one university in the southwestern United States from 1088 students over six academic semesters and grounded theory analysis techniques to study and draw initial conclusions. For example, of the 14% of students who did not attend, 45% stated that they did not feel they needed any help. Roughly half of the 67% of students that went to the math center more than once a month felt as if the tutors were responsive to their needs and willing to help. We claim that more work needs to be done, specifically inter-institutionally, on math centers in order to corroborate many of our results.*

*Keywords:* tutoring, university mathematics, support services, math center

Mathematics help centers, also known as mathematics learning centers, mathematics support centers, mathematics tutoring centers, or simply "math centers" (the term that will be used in this paper) typically aim to provide support to undergraduate students in their mathematics courses. Math centers often focus on the mathematics courses students take during their freshman and sophomore years of study. At most of these facilities, students typically receive tutoring services from peer tutors (Rickard & Mills, 2018) who are often advanced undergraduates or, in some cases, graduate students. This tutoring is usually provided on a drop-in basis.

Math centers have become common fixtures in postsecondary education. This is evidenced in a recent study of calculus conducted by the Mathematical Association of America, where over 70% of the course coordinators surveyed reported that their institutions had a math center (Johnson & Hanson, 2015). There has also been an increased focus on math centers as noted by a recent handbook for math center directors (Coulombe, O'Neill & Shuckers, 2016). The handbook, which had contributors from 31 institutions ranging from two-year community colleges to liberal arts institutions to large research universities, demonstrated that a variety of institutions have given math centers a permanent position in their academic-support service structure. The increase in math centers is not just a U.S. phenomenon; efforts to implement math centers are found in the United Kingdom as well (Gill, Mac an Bhaird, & Ní Fhloinn, 2010; Matthews, Croft, Lawson, & Waller, 2013).

With a rise in the numbers of math centers and increased attention on them, there has also been an increase in educational research related to math centers. This can be noted by the new working group in RUME (i.e., the *Research Opportunities for RUME Researchers in the Context of Mathematics Resource Centers* working group) dedicated to this line of research. We aim to add to this small, but growing, research on math centers.

## Research on Math Centers

While there is a sizable body of research on tutoring at the collegiate level across subject areas, Cooper (2010) has suggested that tutoring at math centers with drop-in attendance differs significantly from traditional tutoring and has called for more research on the impact of this kind of tutoring. Some educational researchers (e.g., Matthews, Croft, Lawson &Waller, 2013; Rickard & Mills, 2018) have answered this call. In the most recently published study related to this line of inquiry, Rickard and Mills (2018) reported that attending math center tutoring had more of an impact on lower-achieving students' grades than the grades of other students for their first calculus course, even when other variables were considered. Their model predicted that students' final course grades increase by one percent with every three visits to the math center.

Rickard and Mills' findings are in line with those of Cohen, Kulik and Kulik (1982). In their meta-analysis that considered tutoring for a variety of content areas, they found a positive correlation between students' attendance in tutoring programs and their course outcomes. For the more than 60 studies they considered, Cohen and colleagues reported that students who received tutoring consistently outperform students who did not. In addition, they reported that tutors also benefitted from the interactions with the students. Moreover, the noted benefit of attending tutoring centers was reported as being more pronounced with mathematics tutoring than other content areas.

While many of the math centers provide drop-in tutoring, it should be noted that math centers may also offer other services to students. Some services include access to print or digital resources, guidance on use of digital devices and platforms used in mathematics courses, and review sessions prior to mid-semester and final examinations (Coulombe, O'Neill & Shuckers, 2016). In one of the few studies that considered a mathematics support service other than tutoring, White, O'Connor, and Hamilton (2011) investigated the reasons students in a statistics class gave for attending peer-led review sessions. The authors reported that there was increased attendance when the students had positive attitudes of the review sessions. The results of this study also support the theory of planned behaviors, saying the intention to perform a behavior (e.g., attend a review session) is related to the rate of carrying out that behavior (e.g., actually attending the review session).

Many studies related to attendance often focus on data associated with sign-in information that many math centers collect. These data are often gathered from students' academic files or students' self-reports. Bannier (2007) used correlational analyses to examine which students attended math centers based on a variety of variables, such as the student's age, prior college experience, confidence level in mathematics, perceived importance of mathematics, current course enrollment, and enrollment history. She found that academic experience (i.e., years in college) and life experience (i.e., years since high school graduation) both positively correlated with math center attendance, while confidence in mathematics had a negative correlation with attendance. Bannier concluded that young, inexperienced students might be the least likely population to visit a math center. This finding is in line with Hodges and White's (2001) study with high-risk students in a university setting. Their design featured four groups of students, one control group and three treatment groups (one of which involved explicit encouragement for students to attend tutoring). None of treatments produced any increase in tutoring attendance. In a third study, Rogers (2010) came to a similar conclusion and reported that underprepared students were less likely to seek out tutoring than other students.

Mac an Bhaird, Morgan, and O'Shea (2009) and Halcrow and Iiams (2011) reached similar conclusions as the studies previously mentioned. Mac an Bhaird and colleagues (2009) reported that attending a math center had a positive effect on students' grades, and this was particularly beneficial for students whose mathematical backgrounds were weaker. Halcrow and Iiams (2011) found that lower ability students were less likely to attend a math center, and that there was a correlation between the time spent in a math center and course grades. They also reported that once students overcame their fears of interacting with tutors, they generally found them to be helpful. According to the authors, students felt that tutoring helped contribute to their mathematical success. These studies add on to the growing number of studies regarding math centers that have taken place in Ireland (Dowling & Nolan, 2006; Gill & O'Donoghue, 2007; Mac an Bhaird & O'Shea, 2009; Ní Fhloinn, 2010). Most of these studies have considered either the contributions of math centers or ways to evaluate the services offered by math centers.

## Research Questions

The benefits of attending a math center are somewhat documented, particularly that those who would benefit most from attending a math center are often the least likely to make use of it. However, little is known regarding students' perceptions of and reasons for attending a math center. For that reason, the following open research questions guided the current study: *What do students expect from a math center? What are their perceptions of a math center? What impacts students' attendance at a math center?*

## Context

This study was conducted at a large, public, research university in southwestern United States. The university has a math center that serves students in freshman- and sophomore-level mathematics classes. The math center primarily offers drop-in mathematics tutoring. Undergraduate tutors offer just over half of the tutoring, and mathematics graduate students working as graduate assistants for the mathematics department offer the rest. The math center also offers other support services, such as access to print resources, guidance on use of digital devices and platforms used in mathematics courses, and review sessions before exams.

Students who attend the math center are in a wide range of courses including a) the general mathematics course typically taken by arts and humanities majors; b) algebra through calculus courses typically taken by business, life science, and social science majors; and c) algebra through multivariable calculus courses typically taken by science, technology, engineering, and mathematics majors. Each fall semester approximately 5000 students are enrolled in courses that are served by the math center. Of all individual students eligible to attend the math center, well over 40% typically visit the center at least once during the fall semester.

The research team consisted of four individuals with a variety of backgrounds. They included the math center director, who has served in this position for five years; a mathematics professor with RUME interests, who helped create the survey; the first-year mathematics director with RUME interests, who started in her position in fall 2017; and a Ph.D. mathematics education graduate student, who has served as a tutor in the math center.

## Data Collection

A voluntary, online survey was used to collect data for this study. All instructors for courses served by the university's math center were asked to share the link for this survey with their students. For the last three semesters of data collection, the math center director also sent the survey link out directly to all students in courses served by the math center. In addition, signs were posted in and around the math center with information regarding the survey link.

Data from student responses are obviously self-reported. Students participating in the survey were not asked to share any identifying information to encourage honest participation from the students. A total of 1,088 students participated in the survey. Of the participants, 63% were freshman; 24% were sophomores; 8% were juniors; and 5% were seniors, while the rest did not respond. The participants' attendance is given in Table 1 below.

*Table 1: Self-Reported Attendance of Participants to Math Center (Note: Sum is not 100% due to rounding.)*

| | Respondents | Percent of Respondents |
|---|---|---|
| Never | 154 | 14% |
| Once or Twice | 207 | 19% |
| Once a Month | 190 | 17% |
| Once a Week | 352 | 32% |
| More | 177 | 16% |
| No Response | 8 | 1% |

The survey consisted of multiple-choice, Likert-scale and free-response items. Individual items will be discussed in the findings section; however, we first outline the manner in which the coding system, which was used for the free response items, was created.

## Data Coding

Similar to grounded theory analysis, the research team used general inductive techniques and constant comparison to study and draw initial conclusions on students' perception of and reasons for attending the math center. According to this method, the researcher does not begin with a preconceived structure but allows categories to emerge from the data. The researcher utilizes these categories to make sense of observed activity or phenomena (Thomas, 2006).

Two members of the research team (the first and third authors) individually read through the data individually using theoretical memoing (Glaser, 1998) to record and classify ideas evident in the data set. They then discussed their findings together combing back through the data until categories emerged. As the two discussed the data, new categories were examined as they emerged to determine if they were unique or could be subsumed under, or merged, with other categories. Once it was determined that all coding categories had been developed, they went through and coded a subset (10%) of the data with over 90% agreement. They discussed discrepancies and decided that more clarification on some of the subcategories was needed. The following categories and subcategories, which are presented in Table 2, were used for coding. These were shared with the other two research team members to verify that they were reasonable. Note that responses not related to the math center, such as comments on issues related to courses or instructors (e.g., desire for a high grade, perception of instructor deficiencies) were not coded.

Two members of the research team, the first and second authors, coded all of the responses using a single response to a free-response item as the unit of analysis. When there was a discrepancy, they discussed this between themselves and with the third author, until there was a resolution. For each coding category, the research team recorded the comment as being either positive (i.e., agreement that the math center under study was doing well in this area) or as being negative (i.e., comment related that the math center under study needed improvement in this area). For the current study, the number of positive and negative responses are not addressed; instead, both positive and negative responses were calculated in a total sum since either type of response indicated that the issue was of sufficient importance for the student to make the comment.

*Table 2: Categories Used for Coding*

| Category | Subcategory | Code |
|---|---|---|
| *Facilities* (should have) | Sufficient space, tables, chairs | F1 |
| | Good environment/atmosphere for studying | F2 |
| | Outlets for digital devices | F3 |
| | Food in or nearby area | F4 |
| | Quiet areas, no noise distractions | F5 |
| *Tutors* (should be) | Attentive, "on point", not caught up in their own work, not distracted | T1 |
| | Knowledgeable, know material, not sharing incorrect methods | T2 |
| | Able to teach or explain, able to show different ways to do problems | T3 |
| | Able to help with digital devices and platforms (e.g., WebWork) | T4 |
| | Supportive, encouraging, not condescending | T5 |
| | Patient | T6 |
| | Friendly, pleasant, kind, approachable, not rude | T7 |
| | Responsive to needs, willing to help/helpful | T8 |
| | Proactive in seeing if students need help | T9 |
| | Able to communicate in understandable English | T10 |
| | Able to help students learn how to work independently; don't take over | T11 |
| | Good hygiene (e.g., cover mouth when coughing) | T12 |
| | Able to admit not knowing, willing to get help if needed from others | T13 |
| *Systems & Procedures* (should ensure) | Sufficient number of tutors available, scheduling enough tutors | S1 |
| | Ability to make appointments with tutors | S2 |
| | Access to tutor schedules (for specific tutors) | S3 |
| | Access to support materials, do more than tutoring (general) | S4 |
| | Math center is staffed with course instructors rather than tutors | S5 |
| | Students from a variety of academic majors serve as tutors | S6 |
| | Tutors are easily identifiable | S7 |
| | System is in place to efficiently get a tutor's attention | S8 |
| | Organization of students by class at same table | S9 |
| *Access* (to the following should be provided) | Solutions from the textbook, with photographing options | A1 |
| | Solutions to homework problems, specifically related to the digital platform being used | A2 |
| | Additional practice problems, not assigned as homework | A3 |
| | Exam review sessions | A4 |
| | Exam answer keys | A5 |
| | Tutoring for all math courses, not just those in the first two years | A6 |
| | Books to check out | A7 |
| | Online tutoring | A8 |
| Hours | Extended evening hours (i.e., stay open late) | H1 |

| | | |
|---|---|---|
| (should include) | Extended morning hours (i.e., open early) | H2 |
| | Extended weekend hours | H3 |
| Location (should be) | Specific cite (e.g., central, in dorms, close to math classes) | L1 |
| | Be more than one place; have multiple locations | L2 |

## Findings

In the first non-demographic item, 82% of students responded that they felt like they were encouraged to attend the math center by their instructors. Students were then asked about their math center attendance, which was reported in Table 1 above. Students who never attended the math center (n=154) were given a multiple-choice item that asked why they did not attend and allowed more than one response to this item. The results are in Figure 1: Reasons students did not attend the math center below.

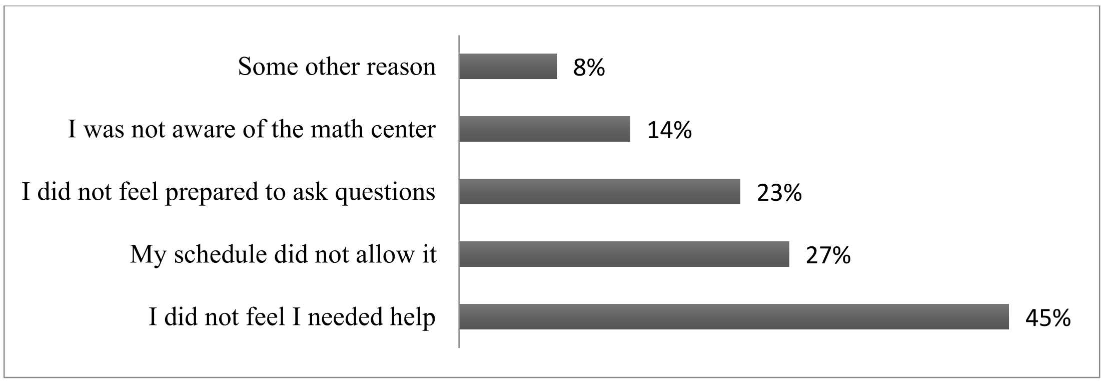

*Figure 1: Reasons students did not attend the math center*

*Students who attended the math center once a month or more (n=530) were given a multiple-choice item that asked why they did attend and allowed more than one response to this item. The results are in*

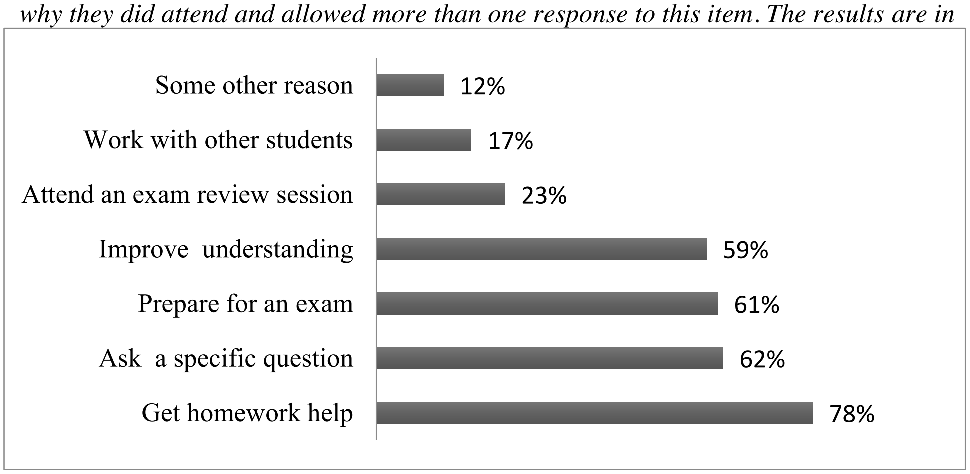

Figure 2: Reasons students did attend the math center below. Note that this population was intentionally used to eliminate those students who only attend the math center immediately before (often the same day of) an exam.

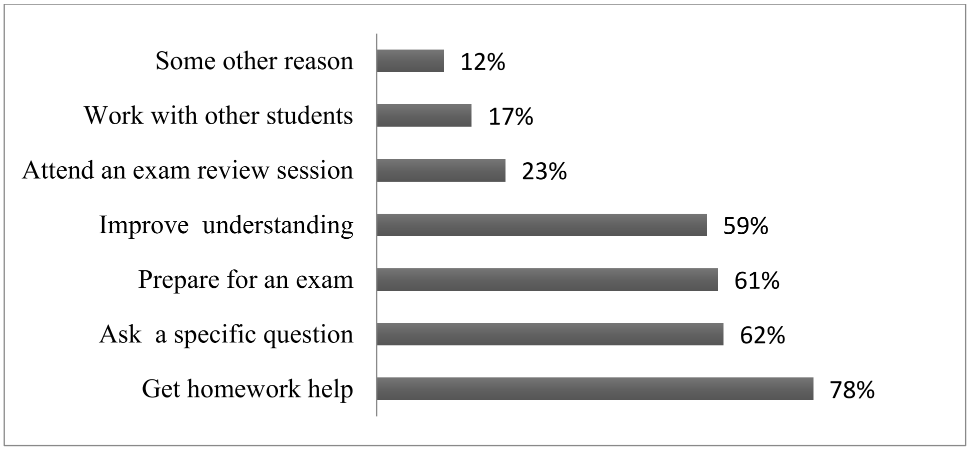

*Figure 2: Reasons students did attend the math center*

Students who had attended the math center at least once a month were then given four different Likert Scale items related to their impressions of the math center. The results are reported in Table 3.

*Table 3: Responses to Likert-Scale Items Related to the Math Center*

| The math center... | Agree to Strongly Agree | Neutral | Disagree to Strongly Disagree | No Response |
|---|---|---|---|---|
| Was helpful to me | 83% | 7% | 7% | 3% |
| Was dedicated to my success | 82% | 6% | 2% | 10% |
| Improved my math performance | 77% | 9% | 10% | 3% |
| Created a positive learning atmosphere | 75% | 11% | 9% | 10% |

These same students also responded to four different Likert Scale items related to their impressions of the math center tutors. The results are reported below in Table 4.

*Table 4: Responses to Likert-Scale Items Related to Math Center Tutors*

| The math center tutors... | Agree to Strongly Agree | Neutral | Disagree to Strongly Disagree | No Response |
|---|---|---|---|---|
| Were responsive and patient | 78% | 8% | 6% | 9% |
| Helped me feel at ease | 73% | 12% | 6% | 9% |
| Were knowledgeable | 75% | 11% | 5% | 9% |
| Explain in ways that I understood | 72% | 13% | 6% | 9% |
| Encouraged me to work independently | 65% | 22% | 5% | 9% |

Those students who had never attended the math center, or only once or twice a semester, were given two opportunities to respond to free-response items that asked for comments on and recommendations to improve the math center. Students who had attended the math center at least once a month were given the same two items as well as a third item that asked for comments on the math center tutors. Responses from both groups to these free-response items were coded with the subcategories listed in Table 1.

Even though most (52%) of the responses to free-response items were coded as pertaining to the *Tutor* category, there are two other categories that merit mention. The most noted subcategory of the *Systems & Procedures* category was “sufficient number of tutors available, scheduling enough tutors” with 82.6% of the responses recorded in this category mentioning how important this was to them. A number of students commented this was an issue especially right before examinations. The *Facilities* category’s most noted subcategory was with regard to providing “sufficient space, tables, chairs” (71.1% of the responses recorded). The responses coded in the *Tutor* category, for subcategories noted in 20 or more responses, are in Table 5.

*Table 5: Responses to Related to Tutors Coding Category (n=719)*

| Tutors are... | Number of Responses Coded |
|---|---|
| Responsive to needs, willing to help/helpful | 346 |
| Knowledgeable, know material, not sharing incorrect methods | 147 |
| Able to teach or explain, able to show different approaches to do problems | 124 |
| Friendly, pleasant, kind, approachable, not rude | 103 |
| Patient, supportive, encouraging, not condescending | 84 |
| Able to help students learn how to work independently; don’t take over | 23 |
| Attentive, “on point”, not caught up in their own work, not distracted | 22 |
| Able to admit not knowing, willing to get help if needed from others | 20 |

## Discussion and Future Work

We will now consider each of the research questions and attempt to answer them using the most apparent findings. The first research question was, “*What do students expect from a math center?”* When looking at the responses across the survey items, the results suggest that respondents focused on the tutoring provided by the math center and the capabilities of the tutors. Students expect the math center to serve as a place where they can: ask specific questions, receive help with homework, and prepare for upcoming exams. Moreover, students had a number of certain expectations of math center tutors. Primarily, students expect the tutors to be responsive to their needs and willing to help them. Students also expected tutors to be both knowledgeable and approachable with an ability to explain concepts, sometimes using multiple approaches. Finally, students want tutors who will be both patient and encouraging when they are helping them. Some of the findings of this study correspond with those reported by Johnson (2014); however, more studies are needed to determine how student-tutor interactions in math centers play a role in students’ perceptions of math centers and their attendance in math centers.

The second research question asked, “*What are students’ perceptions of a math center?”* Those respondents who attended a math center regularly (once per month or more) tended to find the math center helpful, feeling it was dedicated to their mathematical success. They also felt it helped improve their performance in mathematics and provided a positive learning environment. All of the items received at least 75% ratings of “agree” or “strongly agree.” This might be, however, an artifact of those students who received this question. The online survey directed students to different questions based on their responses. The intention of the original survey design was to provide feedback from those students who attended the math center for more than exam preparation. Yet, this might artificially inflate the agreement ratings. For this reason, work is currently underway on this corpus of data to consider all of the student responses, be they positive or negative, to the free-response items to consider student perceptions from all students regardless of the number of times they attended the math center.

Finally, we consider the third research question, "*What impacts students' attendance at a math center?*" While 82% of the respondents felt like they were encouraged to attend the math center, 14% of the respondents never attended. The data shows that out of that 14%, only 45% did not attend because they did not feel they needed help. The results of this study suggest that future research is needed that focuses on the students who are not coming to the math center and the reasons for their lack of attendance. An interesting follow-up study would focus on those who did feel they needed help but still didn't attend, especially since 23% of those who never attended said the reason for this was because they did not feel prepared to ask questions.

## Limitations and Contributions

There are definite limitations to this study. The most obvious is the poor response rate (which was about 1%). This is not surprising considering it was an optional, anonymous, online survey. Another limitation is that the survey data was primarily collected to benefit the institution and department, and the participants came from a single institution. However, there are still elements of this study that might be beneficial to others studying math centers. The data provides insight as to what students want and expect from a math center, especially related to the tutoring provided there. It also provides information as to why students might not attend the math center.

As the body of research literature on math centers expands, we hope to see three different, yet potentially overlapping, types of studies related to math centers. First, we would like to see more statistically rigorous studies, such as those recently published by Mills and Rickard (2018) and Byerly, Campbell, and Rickard (2018). There is also room to do qualitative studies to explore a number of math center issues, including some of those that have been raised above regarding future work.

Finally, a third line of research that would be assist the field of mathematics education would be more inter-institutional studies. One of the contributions this study provides is the coding system for students' math center expectations which was developed for the free-response items. Others studying math centers might want to use, revise, or expand on the categories and subcategories used in this system to study data that has been collected. In this manner, there would be a mechanism to compare the student expectations of math centers across institutions.

# Generalizing in Combinatorics Through Categorization

Zackery Reed Elise Lockwood
Oregon State University

*Basic counting formulas, such as the combination $\binom{n}{k}$ and permutation $n!/(n-k)!$, constitute students' initial exposure to the structure of combinatorial processes. Understanding the structure and nuance of these counting formulas is important, as more complicated processes rely on the foundation these formulas set. In this paper we describe a study in which we used a categorization task to have students focus on salient aspects of counting processes, ses of outcomes, and formulas/expressions. We describe their generalizing activity and present an instructional theory for the production of four basic counting formulas.*

Key words: Generalization, Combinatorics, Design Experiment, Instructional Design

## Introduction

The activity of generalization is integral to mathematical thinking and affects all levels of education (Amit & Klass-Tsirulnikov, 2005; Lannin, 2005). While there is a growing body of literature on student generalization, we still have much to learn about fostering productive generalizing activity in various contexts. Through a multi-phase study, we sought to better understand students' generalizing activity in a combinatorial setting. Combinatorics provides a natural setting for generalization, as counting problems are often accessible yet challenging (Kapur, 1970; Tucker, 2002), and these accessible problems provide a natural structure from which students may generalize. In this report, we discuss the results of student engagement with a categorization task designed to facilitate reflection on prior activity in which they solved various counting problems. The students collectively produced sophisticated generalizations while individually maintaining unique combinatorial understandings. We discuss the various nuances of their understandings as well as some affordances of attending to certain combinatorial structures.

We will discuss the students' generalizing activity in accordance with Lockwood's (2013) model of combinatorial thinking. This framing provides insight into the potential source material for students' generalizations in combinatorics. Leveraging generalization as a guiding mechanism for learning, we conducted two iterations of a design experiment in which students reinvented the basic counting formulas $\binom{n}{k}$, $n!/(n-k)!$, $n!$, and $n^k$. One goal of these experiments was to investigate how students might develop sophisticated understandings of these formulas, including the underlying counting processes and sets of outcomes associated with these problem types. To facilitate reflection on prior activity, we prompted students to solve multiple counting problems of each type and then later categorize the problems they solved. Using data from these experiments, we present an initial *domain-specific instructional theory* (Cobb and Gravemeijer, 2008) for the learning of these four basic counting formulas. We will discuss students' generalizing activity (in the sense of Ellis, Lockwood, Tillema & Moore, 2017) as well as the combinatorial nature of students' generalizations (according to Lockwood's 2013 model) as theoretical underpinnings of the instructional theory. We seek to answer the following research questions: *What do students attend to combinatorially as they generalize? How can generalizing activity be leveraged to help students understand key combinatorial ideas?*

## Literature Review

### Generalization

Generalization has been recognized as a key aspect of mathematical activity by both researchers (Amit & Klass-Tsirulnikov, 2005; Ellis, 2007b) and policymakers (Council of Chief state School Officers, 2010). While much of the literature on student generalization focuses on algebraic contexts (Amit & Neria, 2008; Carpenter, Franke & Levi, 2003; Ellis, 2007a/2007b; Radford, 2008; Rivera, 2010; Rivera & Becker, 2007/2008), there has been some history of examining generalization at the undergraduate level (e.g., Dubinsky, 1991), and more recently studies have looked at undergraduate student generalizations in calculus (Fisher, 2007; Jones and Dorko, 2015; Kabael, 2011) and combinatorics (Lockwood & Reed, 2016). Combinatorics provides a natural setting to investigate student generalization, as problems are often both accessible and challenging (Kapur, 1970) and have regular structure that can be naturally generalized. This report contributes an account of student generalization as the foundation for an initial *combinatorics-specific instructional theory*.

### Student Reasoning about Basic Counting Formulas

Though combinatorics provides accessible and deep tasks (Kapur, 1970; Tucker, 2002), students struggle with reasoning combinatorially (Batanero, Navarro-Pelayo, & Godino, 1997; Eizenberg & Zaslavsky, 2004). Our hope is that through investigating how students reason combinatorially, we may discover ways to foster productive thinking in combinatorics. One such productive way of thinking that emerged from research is a set-oriented perspective (Lockwood, 2014), where students consider the set of outcomes as integral to the solving of counting problems. Our study contributes to this literature base by leveraging generalization as a means to develop deep understanding of basic counting phenomena. By analyzing students' combinatorial understandings as they generalize, we learn more about the nature of students' combinatorial thinking about fundamental combinatorial ideas.

Previously, reinvention studies (e.g., Lockwood, Swinyard, & Caughman, 2015) have revealed ways in which students come to discover basic counting formulas. For instance, Lockwood, et al. (2015) conducted a teaching experiment in which two students numerically generated four basic counting formulas. This experiment is particularly noteworthy because the students constructed the counting formulas by attending to numerical regularity rather than attention to combinatorial structure. While these results provide an instance of students coming to know the basic counting formulas, the students did not attend to the combinatorial processes at play. There is a need for more work that tries to help students focus on processes and structure and not just on numerical results. Our current report builds off of this previous study by examining students' reinvention of the basic counting formulas while engaging with the combinatorial processes the formulas count. Further, research has identified ways in which students might confuse basic counting formulas, such as the combination and permutation, by appealing to a problem's wording as a means of differentiation (Batanero, Navarro-Pelayo, & Godino, 1997; Lockwood, 2013; 2014). This report contributes to the literature by exploring how generalization might facilitate alternative ways in which students might differentiate basic counting problems.

## Theoretical Perspectives

### Generalization

For purposes of describing students' activity as they generalize, we adopt Ellis, Lockwood, Tillema and Moore's (2017) *Relating-Forming-Extending* (R-F-E) framework of generalizing activity. Ellis et al. draw from Ellis' (2007) taxonomy of generalizing activity to describe ways in which students across mathematical disciplines generalize their knowledge. We use the term *generalizing* to refer to the activities in which students engage, and *generalization* refers to the product of their activity. Each category in the framework represents a different manifestation of generalizing activity in student work. *Relating* occurs when students establish "relations of similarity across problems or contexts" (p. 680). This form of generalizing involves the construction of meaningful relationships across mathematical contexts. *Forming* involves student attention to regularity within the context of a particular mathematical task. In particular, while forming, students "[search] for and [identify] similar elements, patterns, and relationships" within a single task (p. 680). Finally, *Extending* involves the application of established patterns and regularities to new cases (p. 680).

We will primarily see students *relating situations*, which involves creating "a relation of similarity across contexts, problems, or situations" (p. 680). Note that careful analysis does attend to the students' consideration of context in their activity. Our instructional theory leverages *relating* to establish relationships between similar counting problems that students have already solved. Moreover, the relationships formed can then be *extended* to constructs such as general formulas or general problem statements. Specific *extending* activities relevant to the task used in this study include *continuing*, *transforming*, and *removing particulars*. *Continuing* involves application of a regularity, pattern or activity to a new case (p 682). *Transforming* occurs when students "[extend] a generalization and, in doing so, changing the generalization that is being extended". (p 682). Finally, *removing particulars* involves extending "a specific relationship, pattern, or regularity by removing particular details to express the relationship more generally" (p 682). Student engagement in *extending* will result general statements of the counting problems.

**Combinatorial Reasoning**

To frame students' combinatorial reasoning, we use Lockwood's (2013) model for the different kinds of reasoning in combinatorics. Lockwood describes three components of students' combinatorial reasoning: formulas/expressions, counting processes, and sets of outcomes. *Formulas/expressions* refer to the expressions (involving numbers, variables, and/or operations) that symbolically express the answer to the counting problem. For example, some ways to express the solution to a problem like *How many arrangements are there of the letters in the word MATH?* include $4 \cdot 3 \cdot 2 \cdot 1$ and $4!$. These expressions have underlying *counting processes*, which refer to the enumeration procedures or steps that someone engages in when they solve a counting problem. For example, $4 \cdot 3 \cdot 2 \cdot 1$ reflects a process of first choosing which of the four available letters can go in the first position, then which of the three remaining letters can go in the second position, then which of the two remaining can go in the third position, and then placing the last remaining choice in the last position. *Sets of outcomes* refer to the set of objects (concrete or not) being counted. The counting processes generates the set of outcomes and imposes a particular structure on the set of outcomes. In our example, the process we described would created a lexicographic list of the set of outcomes. Lockwood (2013) maintains that there are important relationships between these components, and students would do well to understand and reinvorce the relaitonship between counting processes and sets of outcomes especially. Lockwood (2014) further emphasized this point by introducing a *set-oriented perspective*, where the set of outcomes becomes a cornerstone of reasoning about any particular counting problem. Students reason in this way by viewing "atten[tion] to sets of outcomes as an intrinsic component of solving counting problems" (p.31). We refer to these components of the model as we describe and characterize students' combinatorial reasoning in this paper.

**Domain-Specific Instructional Theory**

We follow Cobb and Gravemeijer (2008) in viewing a *domain-specific instructional theory* as complementary to an instructional sequence of tasks designed to foster a particular form of learning. Cobb and Gravemeijer consider a *domain-specific instructional theory* to be "a substantiated learning process that culminates with the achievement of significant learning goals as well as the demonstrated means of supporting that learning process" (p. 77). Our *instructional theory* is specific to the domain of combinatorics, counting in particular. Cobb and Gravemeijer speak to the usefulness of *domain-specific instructional theories* as their justification "offers the possibility that other researchers will be able to adapt, test, and modify the activities and resources as they work in different settings" (p. 77). Thus, the "underlying rationale" of the *instructional theory* allows for further refinement of the instrucitonal sequence in research settings.

We leverage student generalizing in combinatorics as the rationale for the learning process supported by our instructional sequence. In particular, the Categorization Task leverages prior activity as a means of abstracting meaningful relationships between counting problems with similar combinatorial structure, resulting in the learning of the basic counting formulas. This instructional theory has three key elements: 1) facilitating student engagement with novel counting problems to establish meaningful activity to draw from, 2) facilitate explicit *relating* of solved counting problems so that combinatorial relationships can be established across various structually similar contexts, and 3) facilitate *extension* of the constructed relationships and reflections on activity to general counting formulas abstracted from previous activity. Applying the R-F-E framework, the initial categorization of their previously solved problems allows the students to construct meaningful relationships amid present cognitive material through *relating*. Our analysis using Lockwood's model to the students' combinatorial reasoning will reveal qualitatively different nuances of the combinatorial relationships being constructed during categorization. In particular, students will need to leverage all three components of the model to co-construct both the general counting formulas as well as the combinatorial problems that generate them. The relationships formed through categorizing then constitute abstractable cognitive material to be *extended*. *Removing particulars* plays a key role in facilitating the construction of the general counting formulas, as the combinatorial quantities are *extended* from specific problem solutions. Moreover, the activities of the students reveal combinatorial understandings (in the sense of Lockwood's model) that persist throughout the generalizing. The data will further demonstrate the ways in which the R-F-E framework and Lockwood's (2013) model for combinatorial understanding provide a rationale for the learning process facilitated by the instructional sequence.

**Mathematical Discussion**

We are specifically concerned with the combinatorial operations of arrangement with unlimited repetition, arrangement without repetition, permutation, and selection. We characterize these four problem types because they tend to be some of the four basic problems to which students are introduced (in courses or in textbooks, for example). Thus, we feel that, while this is not the only way to characterize basic counting problems, this is a useful distinction to make for students who are first learning counting problems.

One problem type that involves iterative multiplication is arrangement with unlimited repetition. This involves constructing an outcome by making $k$ choices repeatedly from the same set of $n$ objects, where repetition of an element is allowed. An example problem of this type is *How many length 5 ternary sequences exist?* An expression for a solution to this problem is $3^5$, which represents the process of considering three choices (0, 1, and 2) for each of 5 positions in the sequence. As each choice made is from $n$ distinct objects, the solution to these problems involves iterative multiplication of the number of choices for each selection by the number of choices for the next selection until all choices have been made. As the number of choices is constant in this case, the solution to these problems is $n^k$, as $k$ selections are being made.

Another problem type is permutation, which involves the ordering of $k$ distinct objects from a potentially larger collection of $n$ distinct objects, as seen in the example problem *10 horses run in a race. How many ways can a gold, silver and bronze medal winner?* We focus on two interpretations of the permutation operation. The first primarily considers the multiplication principle and warrants a solution method identical to that of arrangement (in fact, arrangement problems are permutations of $n$ objects from a set of $n$ objects). Specifically, the outcomes of a permutation process form $k$ ordered objects which can be selected from the set of $n$ objects one at a time. This construction warrants iterative multiplication resulting in the solution $n \cdot (n-1) \cdot ... \cdot (n-k+1) = n!/(n-k)!$. The final form of the answer warrants a different interpretation of the outcome structure which was leveraged in the design experiment. Specifically, the $n$ objects can first be arranged in $n!$ ways. As the first $k$ objects in each arrangement are desired, this method produces an extra $(n-k)!$ outcomes for each desired outcome of $k$ ordered objects. Thus, dividing $n!$ by $(n-k)!$ produces the desired arrangements of $k$ objects as the $(n-k)!$ further arrangements of each $k$-object arrangement are each reduced to a single outcome.

A special case of permutations occurs when we arrange all of the $n$ objects, which is arrangement without repetition. An example problem of this type is *How many words can be formed from the letters in MATH?*, which we briefly described in terms of Lockwood's (2013) model above. The expression of $4 \cdot 3 \cdot 2 \cdot 1$ represents a four-stage counting process.

Finally, selection problems (also sometimes called combination problems) make up the final problem type. These problems involve the selection of $k$ objects from $n$ distinct objects, an example problem being *How many ways are there to hand out three identical lollipops to eight children?* Here, we can select 3 of the 8 children to get lollipops, yielding an expression of $\binom{8}{3}$. The solution method achieved by both student groups builds off of the permutation process. Specifically, a permutation $n!/(n-k)!$of $k$ objects from $n$ objects results outcomes of $k$ ordered objects taken from a set of $n$ objects. A selection concerns only the collection of $k$ objects chosen from the set of $n$ objects. Orderings of those $k$ objects produces $k!$ outcomes for each of the desired selected outcome. Thus, division of the permutation by $k!$ results the solution as the $k!$ differently ordered selections are reduced to a single outcome, resulting in the solution $\binom{n}{k} = n!/[(n-k)!k!]$.

## Methods

The work in this paper draws on two iterative design experiments conducted as part of a larger study in which we investigated the nature of student generalization in combinatorial settings. We first conducted a paired teaching experiment (Steffe & Thompson, 2000) consisting of fifteen hour-long sessions followed by a small group design experiment consisting of nine ninety-minute sessions with four students. The students from both studies were recruited from vector calculus courses, and they were selected from an initial set of applicants based on a selection interview process. Each of the students in these studies had not taken a discrete or combinatorics course before so that their activity and generalizations were indeed based on their activity rather than trying to recall formulas or implement extant schemes.

This study reports on the first three sessions of each experiment, wherein the students reinvented the basic counting formulas $\binom{n}{k}$, $n!/(n-k)!$, $n!$ and $n^k$ (discussed above in the Mathematical Discussion section). The goal of these sessions was to facilitate reflection on activity with basic counting problems, culminating in the construction of the four general formulas as well as general statements of problems that yield those formulas. Below we describe the students in both experiments and present their activities in the teaching experiments and typical interventions implemented. We then conclude with a description of the sequence of activities in the Categorization Task that demonstrate our initial domain-specific instructional theory.

**Paired Teaching Experiment**

We recruited two vector calculus, Rose and Sanjeev (all names are pseudonyms), to participate in our study. As noted above, because of their activity during their selection interviews, we felt confident that Rose and Sanjeev were novice counters adept at communicating their thinking and working together. The fifteen hour-long sessions occurred over the course of six weeks and the students were monetarily compensated for their time. During each session the students primarily worked on a chalk board, solving counting problems either together or individually followed by discussion. The students had no exposure to any of the general counting formulas before the sessions so that their reinvention was a result of their generalizing activity rather than recollection of a previously encountered general formula. The students were given specific counting problems to work through together, and were often prompted to explain their thinking as they worked. The interviewer occasionally prompted students to further their thinking, explain their reasoning, or to reflect on a particular representation of the combinatorial setting. The sessions were each video taped, and a retrospective analysis (Steffe & Thompson, 2000) was performed on the video records. Transcripts of each session were made and then enhanced with notes and figures representing student activity. Episodes of student generalizing were cataloged and coded using the R-F-E generalization framework and students' combinatorial reasoning was coded using Lockwood's (2013) model for student combinatorial thought. Further, models of students' combinatorial reasoning were constructed (in the sense of Steffe & Thompson, 2000) so that productive ways of reasoning combinatorially could be identified and used to refine both the sequence of activities as well as our instructional theory. The data analysis then informed the sequence of tasks and interventions implemented in the small group design experiment conducted the following year.

**Small Group Design Experiment**

The purpose of the design experiment was to observe student generalization in a small group setting that more realistically represents the classroom environment. Much like the paired teaching experiment, the small group design experiment consisted of students recruited from vector calculus courses that also engaged in selection interviews. Our selection criteria was slightly different for the design experiment, as we sought a group of four that demonstrated a more realistic collection of students in a classroom small group. Specifically, while we still pursued novice counters who were willing to engage with the material and communicate their ideas willingly, we sought to have students that demonstrated different levels of adeptness with counting. Specifically, we sought to balance students who demonstrated productive counting strategies in the selection interview with students who might perhaps struggle with more complicated counting processes and arguments. Our small group thus consisted of a student who performed well in the selection interview, two students who performed moderately and one student who still engaged with the material but struggled at times to reason combinatorially. This experiment consisted of nine ninety-minute sessions in which the students again solved problems of the same type as solved in the teaching experiment. The sessions and activities largely imitated those of the paired-teaching experiment, with a few added interventions aimed at facilitating productive student thinking as identified in the teaching experiment. For instance, one such intervention involved prompting reflection on the relationship between division and the structure of the set of outcomes. Also during the design experiment, the researcher more freely communicated summative ideas to the students. For instance, a frequently discussed topic in the initial interview was the generation of outcomes as reflected in multiplication. Once the students had a few discussions of generating a set of outcomes to reflect multiplication, and the students had some exposure to reasoning about outcomes based on the positioning of elements within the outcome, the researcher gave a brief summative discussion of the ways in which outcomes might be generated specifically through iterative multiplication. Two video cameras were used to record these sessions. During individual group work, the cameras each focused on two separate students to capture their activity. During group discussions, one camera would focus on referenced written work and the other camera would capture the social interaction between students. The videos were then spliced together so that both records could be viewed at once during data analysis. Data analysis was then conducted in a similar manner as that of the teaching experiment, allowing us to again refine the instructional theory for production of the basic counting formulas.

**Categorization Task**

We now present the instructional sequence from the experiments that culminated in the reinvention of the basic counting formulas $\binom{n}{k}$, $n!/(n-k)!$, $n!$ and $n^k$. Throughout the first two sessions, we gave students the problems in Figure 1. Their activity with these problems constitutes the first component of our instructional theory, namely that the students meaningfully engage in novel counting to establish patterns of activity to later be leveraged through *relating* and *extending*.

| **Arrangement Problems** |
| --- |
| *The Recess Problem*: How many ways are there for 27 kids to line up for recess? |
| *The Projects Problem*: How many ways are there to assign 8 projects to 8 different students? |
| *The FAMILY Problem*: How many ways can you arrange the letters in the word FAMILY? |
| *The MATH Problem*: How many ways can you arrange the letters in the word MATH? |
| **Permutation Problems** |
| *The Restaurant Problem*: Corvallis has 25 restaurants. How many ways are there to pick your 5 favorite Corvallis restaurants? |
| *The Collar Problem*: You have a red, blue, yellow and purple collar. How many ways can |

| |
|---|
| you distribute the collars among 7 cats so that each cat will wear only 1 collar? |
| *The Race Problem*: 10 horses run a race. How many ways can the horses finish in 1st, 2nd and 3rd place? |
| **Selection Problems** |
| *The Subset Problem*: How many 4-element subsets are there of the set $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$? |

Figure 1: The Counting Problems of the Categorization Task

After solving various problems of each type, we gave the students the following broad prompt to engage them in a categorization activity: *You have previously solved these fourteen problems, we want you to do now is as a group is categorize them in some way*. The goal was to facilitate generalization between the problems through reflection on their prior activity, resulting in the production of the basic counting formulas. Our broad stating of the task was so that the students created categories that were meaningful to them rather than by their interpretations of categories meaningful to the researchers. This constitutes the second component of our instructional theory wherein students engage in *relating* to construct meaningful relationships between each of the four problem types based on their previous activity with the problems. Once the students agreed on the categories for the problems, they were asked to describe a general formulation of each category, and then to construct a general formula for the solution to each problem type. This culiminated in the production of the four counting formulas described above, as well as general statements of problems and conditions in which they might be applied. This step also concludes our instructional theory by facilitating student *extending* the relationships constructed through the *relating* activity. In particular, combinatorial strategies, activities and structures are abstracted from the established relationships to form general counting processes and formulas, thus marking the completion of the instructional sequence.

## Results and Discussion

We present episodes of student activity from both the paired teaching experiment and small group design experiment as examples of the ways in which students learn the basic counting formulas according to our domain-specific instructional theory. For the purposes of this report we will focus primarily on the Categorization activity itself and demonstrate the ways in which students can create the general relationships that then abstract to general versions of the basic counting formulas. We will first present an episode of student novel combinatorial activity within the first two sessions to represent the first component of the instructional theory and to demonstrate the kinds of activities that then later generalize to the students' constructs of the basic counting formulas. We then present data from the Categorization activity itself to represent the second component of our instructional theory and to demonstrate the combinatorial nuances of the students' generalizations as well as the formation of some productive understandings as influenced by their generalizing. This then culminates in the records of the students' generalizations of the basic counting formulas from both experiments as representations of the final component of our instructional theory. Specifically, in these results we use data as examples of the three key elements of our domain-specific instructional theory described in our theoretical framework.

**Initial Activity with Selection Problems**

This first section gives a brief episode from the small group design experiment when the students first engaged in a selection problem (The Lollipop Problem). When first solving selection problems, the students engaged in *set-oriented* reasoning, which they would then later generalize as the primary distinction between permutations and combinations. We see the students' *set-oriented perspective* as a productive way to understand the distinction between permutations and combinations. We will later highlight the students' generalizing activity that facilitated the *continuing* of this *set-oriented* thinking, thus demonstrating the ways in which their generalizing facilitated productive understandings in this instructional sequence. The students initially produced the solution $8 \cdot 7 \cdot 6$ to The Lollipop Problem. The researcher then intervened and asked the students to discuss the distinction between identical lollipops and distinct lollipops. As The Lollipop Problem involves counting identical lollipops, exploration of the same problem set up but with distinct lollipops was meant to facilitate reflection on the ordering implied by their initial solution, thus prompting a new solution accounting for the uniformity of the lollipop. Responding to this prompt, Josh and Carson had a nice discussion about how they would solve this problem. Josh first realized that they needed to account for identical possibilities by incorporating the $3!$ arrangements of unique lollipops. This then prompted the following solution from Carson:

*Carson*: That makes sense, yeah. So, for any given three kids, the lollipops can be arranged - So, if this solution [their $8 \cdot 7 \cdot 6$] is treating the lollipops as distinct from one another and we're just trying to find distinct groups of three kids that could be given a lollipop, then we need to find the number of ways that any number of lollipops can be distributed to any number of kids. So, I think that we need to divide again [the first division being for a permutation] because - rather than subtract, we need to divide because this [$3!$] is our distinct number of outcomes and then we need to divide it by . . . Because that's going to happen for all the different groups of kids rather than just one group of kids. Right? So, this makes sense but you need to divide rather than subtract. I'm having a hard time putting into words why, but it's because this is all the possible arrangements - all the possible combinations of three kids - are included, not just one possible arrangement of three kids. Yeah, so it should be $8!/(5! \cdot 3!)$ which just comes out to 8 times 7.

This discussion demonstrates that Carson was focused on *outcomes*, which would later be *continued* for other selection problems and then referenced during the categorization. In particular, note that Carson's justification for division considers that a given outcome of three kids has $3!$ orderings, and this ordering happens for each different outcome. His reasoning specifically attends to the entire set of outcomes and the multiplicative effect of ordering each outcome. This focus on *outcomes* reasoning provides an example of the kinds of activities the students engaged in while solving counting problems. This also provides an example of the combinatorial relationships that were later generalized through categorization. To summarize this section, this episode provides an example of the kind of thinking, activity, and conversation in which the students engaged in this initial activity. Such activity with novel counting situations provides meaningful and nuanced cognitive material to then be generalized through categorization. Thus, this activity is a representative how the first component of our instructional theory might unfold.

**Categorization Task**

We now detail the generalizing activity of the students during the Categorization Task. We will discuss various moments of generalization during the categorization, including the *continuing* of their focus on *outcomes* discussed on the Lollipops problem. This will then culminate with the students' final generalized statements of the counting formulas.

Throughout the categorization of their prior solved problems, we saw students engage in *relating* by creating meaningful relationships between the problems they categorized. Much of the combinatorial meaning can be characterized in terms of Lockwood's (2013) model.

For instance, Carson provided the following description of two arrangement with unlimited repetition problems he grouped during the first few moments of the categorization task:

> *Carson:* This [The Quiz and Sequence Problems] is independent events. So, [The Quiz Problem] there are eight questions but the outcome of one doesn't affect the others. [Points to The Sequence Problem] There are six characters, but the outcome of one doesn't affect the others.

Here he was relating that each question described a combinatorial structure in which there was no dependence between selections. Indeed, while his language was in terms of outcomes, he described the outcomes not affecting other outcomes in the process. From this we infer Carson attended to the combinatorial *process*. Similarly, Josh then identified two more arrangement with unlimited repetition problems that had still not been categorized:

*Instructor*: . . . and why did those two go with those [the original collection Carson grouped together]?
*Josh*: Those two also deal with independent events and finding all the possibilities in those events depend on something raised to some power.
*Instructor*: Okay, okay, good.
*Josh*: Like the number of choices that you have raised to the number of choices that you make.

Again, we see Josh combinatorially *relating* different selection with repetition problems. Specifically, Josh identified his new problems as similar according to the formula for the answer. Thus, Josh attended to *formulas/expressions* while Carson is attended to *counting processes*. This variety in what aspects of the model students attended to was common during these discussions. Indeed, Josh and Anne-Marie often attended to the *formulas/expressions* of the problems as category indicators while Carson and Aaron indicated more frequent attention to the combinatorial *process* generated by the problems. We see this as a strength of the Categorization Task, as students often collaboratively generated the categories while appealing to individually different combinatorial details. The students be explored the problems through all components of Lockwood's model, which seemed to promote well-rounded combinatorial understandings.

There were similar instances in the teaching experiment. For example, while categorizing the same type of problem, the students in the teaching experiment had the following exchange:

*Sanjeev*: And then you want to paint 6 different houses on your block and there are 3 acceptable paint colors you can pick —
*Rose*: Would that one come down here? Because that would be —
*Sanjeev*: You have 6 houses and —
*Rose*: 3 to the power of 6?
*Sanjeev*: you have 3 different paint colors for each, yeah. So this [The Houses Problem] would be this one [referring to the collection of arrangement with unlimited repetition problems]?

Notice that Sanjeev and Rose were attending to different components of Lockwood's (2013) model during this exchange. Sanjeev attended to *processes* by focusing on the process of picking paint colors. Rose, in turn, attended to the *expression* involving exponentiation as a means of relating the houses problem to other arrangement with unlimited repetition problems she experienced. This further demonstrated the students' abilities to communicate and generalize across varying combinatorial language.

While there was, as noted, variety in the students' generalizations and combinatorial understandings throughout the task, we found a surprising uniformity of language pertaining to combination problems in particular (that is, selection problems). Indeed, all students demonstrated attention to the structure of the *sets of outcomes* when discussing combinations. The discussions about differentiating combinations from other combinatorial processes revolved around taking care not to count two similar outcomes as different. For instance, when separating the permutations and the combinations, Rose and Sanjeev said the following:

*Rose*: It's [referring to their collection of permutations]— it's how many — it's basically how many ways to put certain amount of items into fewer spots where 1, 2, 3 and 3, 2, 1 are different. And this [their collection of combinations] is how many ways you put a certain amount of things into fewer spots where 1, 2, 3 and 3, 2, 1 are the same.
*Sanjeev*: On these ones [permutation problems] you've got combinations [not referring to the combinatorial sense of the word]. So 1, 2, 3 - 3, 2, 1 would be different combinations. With this one [The Lollipop Problem], for example, if you have identical lollipops you can label them 1, 2, 3 or you can just label them 1, 1, 1. So 1, 2, 3 and 3, 2, 1 would be the exact same thing, because 1, 2 and 3 are all the same.

The students in the teaching experiment had also initially solved combination problems by considering sets of outcomes much in the same way as the students in the design experiment. The distinction of making $\{1, 2, 3\}$ and $\{3, 2, 1\}$ the same indeed explicitly involves attending to which *outcomes* should or should not be counted the same. We find attention to outcomes in this way as productive, as it allows for careful consideration of what is being counted. Indeed, this form of differentiation meaningfully examines the permutation/combination distinction as opposed to other means of differentiation present in the literature such as attending to montras and phrases in problems. Further, this highlights that differentiation between combinatorial objects is also a means of students engaging in *relating*. Indeed, understanding of the permutation and combination is occurring through the creation of similarity-based relationships and also differentiations between combinatorial structures.

As another example, we saw similar discussions of combinations emerge from the design experiment. Initially, when describing the difference between combinations and permutations, Ann-Marie remarked:

*Anne-Marie*: Yeah, so in those two problems [a pair of combination problems] you divide by two factorials to cancel out the duplicate answers whereas in the other ones you don't have to do that.

Notice that her response also included a focus on a *formula/expression*. Indeed, Ann-Marie confessed that she primarily thought of the formula representation when thinking of the problem types. Ann-Marie made the distinction of "two factorials" in this case to contrast division by "one factorial" in the group of permutation problems. What we see here is that within her formula driven remarks, she also used outcome-based language to describe the need for the extra division by a factorial. Also, later when explaining why the formula for $\binom{n}{k}$ includes an addiitonala division by $k!$, Aaron explained:

*Aaron*: Well, because you're trying to get rid of all the combinations that you're not looking for that you can make out of those three slots because they're all the same. So, that just accounts for it.

Indeed, most descriptions of combinations involved *outcome* - based language so that they could be differentiated from permutations. Often, the design experiment students described "dividing by redundancies" when performing combinations. It is interesting that among the students we worked with, combinations were uniformly a source of *outcome* - based language. Returning to the teaching experiment, we see Rose also using *outcome* - based language when describing why a subset selection problem is grouped with other combinations. After negotiating the particulars of the problem involving finding subsets of a set of numbers, Rose said the following:

*Rose*: and if that was the case then we'd want to put it over into this group [the collection of combination problems].

*Int*: Okay. And how come?

*Rose*: Because now you don't want — you just want unique combinations. And if you're getting rid of all the — the repeated subsets, then you're just finding the unique combinations.

Here, we see Rose clarified that the desired outcomes were indeed "unique combinations". The uniqueness was generated by getting rid of repeated subsets, which indeed would emerge from a standard permutation. Thus, we see that Rose diverged from her typical focus on *formula/expressions* to attend to unique outcomes.

The above examples illustrate the kinds of generalizing that is facilitated through categorization. Indeed, these excerpts represent the second component of our instructional theory.

**Generalizaing the Basic Counting Formulas**

While much of the above discussions centered around the activity of *relating*, the overal Categorization Activity culminated with the students *extending* the relationships they had formed to produce general counting formulas and statements. To facilitate this, we gave the students the prompt to characterize what each group of problems was counting (and each set of students also produced a general formula). Our goal was to have them engage in generalizing and to focus on the various aspects of the model. To give examples of possible final generalizations, we present the students' general of each category and formula. The design experiment students gave the following characterizations of the arrangement and permutation problem types: *1) Limited slots and limited objects. Unique arrangements of unique objects: $x$ objects $\rightarrow x!$ 2) Selection from* *arrangement - order matters:* $a!/(a-b)!$*,* $a$ *=total amount of objects,* $b$ *=how many objects you choose*. For the third group (combinations), the students *continued* their earlier activity of first permuting the combinatorial objects and then accounting for repeated outcomes. Indeed, while categorizing Carson described the combination problem as"an arrangement one as well just with the caveat that there are only four of them". Carson is referring to a permutation problem when he talked about arrangement. In this dialogue, he described this combination problem as a permutation problem with an extra condition. Indeed, this type of language was common when the students would describe combinations. Often when describing the different categories, the students would reference combinations as permutations with added conditions. While writing the general statement of the combination category, the students had the following exchange:

*Carson*: So, the same as above [their general permutation statement], with another caveat that some of the elements are —

*Josh*: Arrangement doesn't matter.

*Carson*: Right, that arrangement doesn't matter.

*Aaron*: I believe for this one [the combination category], you'd be dividing by three factorial in addition to the same process here [their permutation category].

*Ann-Marie*: Mm — hmm.

*Josh*: Yeah, I think that you're also going to — it's basically this [a permutation] except you're also dividing by the number of things that you're picking from because order doesn't matter. So, it would be I guess —

*Aaron*: B factorial on the side [as in $a!/[(a-b)! \cdot b!]$?

*Josh*: Yeah.

Through this discussion the students thus *extended* their understanding of combinations by *transforming* their generalization of a permutation via division by $b!$. This indeed is the same activity they initially engaged in when solving the lollipop problem and thus constitutes *continuing* of their activity to a general setting. Moreover, we consider division by $b!$ as *transforming* because they specifically reference that the division operation is an intentional alteration of the permutation $a!/(a-b)!$ to *extend* to this new case by accounting for the ordering of the outcomes. Thus, *extending* in this way was the mechanism that produced their third category: *3) Arrangement does not matter. Divide out duplicates, similar to 2):* $a!/[(a-b)! \cdot b!]$. Their final category took the form *4) Independent events with given number of elements:* $a^b$*,* $a$ *=possibilities of each choice,* $b$ *= total number of choices you make*. Note that the students indeed produced the four distinct counting formulas as a result of their generalizing activity from prior work.

The teaching experiment students wrote out the following general statements of the problem types accompanied by the general counting formulas: *1) How many ways to arrange a given number of elements w/o reusing:* $n!$*. 2) How many ways to arrange a given number of elements into a given number of spots without reusing any elements:* $n_e!/(n_e - n_s!)$*. 3)* $\uparrow \ldots$ *and divide by the factorial of the given spots to delete repeated sequences:* $n_e!/(n_e - n_s)!/n_s!$*. 4) How many ways to put a certain amount of things into a certain amount of places assuming you can put the same thing into more than one place:* $n_c^{n_e}$. Note that the general statements of the problems reflect various components of Lockwood's model, and that again the combination is stated in term of a *transformation* of the permutation group. Indeed, these generalizations represent the final product of the instructional sequence and the culmination of the students' *extending* in the final component of our instructional theory.

## Conclusions and Future Directions

We see that the categorization task allowed the students to generalize their prior work on individual counting problems into more general contexts in which different combinatorial structures could be illuminated. In particular, the students productively engaged in *relating* and *extending*, both activities underpinned by the nuances of the combinatorial settings, as described by Lockwood's (2013) model. This constitutes a *domain-specific, instructional theory* to accompany the instructional sequence of activities provided by the Categorization Task. In particular, the Categorization task provides an instructional approach to introducing the counting formulas that relies on student generalizing to generate the formulas from meaningful activity. This provides evidence of student reinvention of the basic counting formulas from combinatorial understandings rather than the numerically-based reinvention as seen in Lockwood, Swinyard and Caughman's (2015b) study. Further, the students' distinctions between permutations and combinations demonstrated productive understandings of the combinatorial objects through a *set-oriented perspective*. In particular, this type of reasoning provides productive understandings of the combinatorial objects rather than previously documented problematic strategies such as attending to the wording of problems or appealing to "montras" such as "and means multiply" (Batanero, Navarro-Pelayo, & Godino, 1997; Lockwood, 2013; 2014). The Categorization Task thus constitutes an instructional sequence supported by a *domain-specific, instructional theory*. Future research will see further refinements of our *instrucitonal theory* moving towards classroom implementation.

# Examining the Effectiveness of a Support Model for Introductory Statistics

Seth Chart Melike Kara Felice Shore Sandy Spitzer
Towson University

*This paper describes a pilot program, aimed at improving outcomes in Introductory Statistics, in which undergraduate peer coaches led teams of students in activities designed to address common misconceptions about statistics during weekly sessions. Preliminary analysis suggests that introducing these sessions may reduce the percentage of students that finish Introductory Statistics with a grade of D, F or W, although the small number of students in the pilot program did not provide sufficient power to detect statistical significance. We also observe that the population of students who attend most of the optional sessions seems to be a mixture of high performing students and lower performing students. Participants in the program reported mainly positive perceptions of the program's usefulness. We intend to continue investigating these observations in future iterations of the program where we hope to improve participation and refine the session activities.*

*Keywords:* Introductory Statistics, Peer-Led Team Learning, Collaborative Learning, Statistics

An ongoing concern in undergraduate mathematics education is students' struggle in "gateway" mathematics courses, such as College Algebra or Basic Statistics. Research suggests that student success in these gateway courses strongly correlates with retention and degree completion (Adelman, 2006). Thus, these courses offer a significant opportunity to boost overall retention. In this paper, we describe one attempt to increase course success in such a gateway course: Introductory Statistics. The choice of Introductory Statistics was motivated by several factors. First, increasing numbers of students are taking an introductory Statistics course to satisfy either a major or general education requirement (Blair, Kirkman, & Maxwell, 2013). This increasing enrollment is in response to calls to increase access to college level courses (e.g. Treisman, 2015), and boosted by evidence that success in a first Statistics course does not require algebra-intensive preparation (Charles A. Dana Center, 2015). However, Introductory Statistics can only fulfill the vision of improving access to college mathematics if students master course material and successfully complete the course. At our own institution, historical failure rates (including students earning D, F, and W) range between 0-65% by section, with a mean failure rate of 24%. Because we offer a large number of sections (~ 20 per semester), reducing this failure rate (even by a modest amount) could meaningfully improve overall retention.

With the goal of improving student success in this course, we implemented a Peer-Led Team Learning (PLTL) model, in which students attend collaborative sessions to improve their prerequisite skills and conceptual understanding. Chemistry programs have used this model extensively (see, e.g., Grosser et al., 2008), and a recent meta-analysis indicated significant evidence that this model is effective across the STEM disciplines (Wilson & Varma-Nelson, 2016). Indeed, PLTL programs have demonstrated success in improving mathematics students' understanding of content (Merkel et al., 2015), course passing rates (Hooker, 2011), retention (Quitadamo et al., 2009), and attitudes toward mathematics (Curran, Carlson, & Celotta, 2013).

In this paper, we aim to describe our methodology, including a detailed description of program structure, in order that other institutions might learn from our successes and challenges. We also present data on the effectiveness of the program, focusing on three central questions:

A) Who attended the PLTL sessions?

B) What effect did the PLTL sessions have on course outcomes?
C) How did participants perceive the PLTL sessions?

In our presentation, we aim to begin a conversation, soliciting ideas from others about how the PLTL program might be improved, as well as how such complex interventions can be studied and replicated.

## Methodology

The implementation and study of our PLTL program was informed in part by descriptions of similar programs that reported some success (e.g. Carlson et al., 2016). In order to test the effectiveness of the program, both in terms of course outcomes and participants' perceptions of the program, we used a quasi-experimental, control group design with matched pairs of course sections.

### Participants and Measures

Study participants consisted of students enrolled in ten sections of introductory statistics, chosen among a total of 20 sections offered at a large, comprehensive, regional public university in the Mid-Atlantic. We selected five pairs of sections, such that a common instructor taught each pair of sections. From each pair of sections, we randomly selected a treatment section. Thus, each of the five treatment sections had a corresponding control section taught by the same instructor. Total enrollment was 134 students in the treatment sections and 136 students in the control section. To investigate the effectiveness of the program, we examined students' final course grades, as well as performance data (e.g. exam scores) provided to us by the course instructors.

In order to gauge students' thoughts about the recitation sessions (and answer Research Question C), we created an online survey and invited all treatment group students to participate in the survey. The survey was administered after the end of semester. The participation was voluntary and anonymous. Students were able to leave any question blank. The survey consisted of both open-ended and multiple-choice items students' perception of the sessions in terms of content, instructional techniques, and schedule. Students were also asked to give feedback for further improvements of the program. Further details about the survey are shared alongside the results.

### Program Structure and Content

Students from the five treatment sections (each of which enrolled approximately 28 students) of Introductory Statistics were invited to attend weekly 2-hour collaborative problem-solving sessions, facilitated by paid peer coaches. A total of 72 students could be accommodated each week, choosing from among six different sessions, each with a different coach and at a different day and time. PLTL sessions began about one week prior to the halfway point of the semester and one or two weeks after students' first midterm exam was returned. The hope was for struggling students to attend voluntarily, encouraged by a modest grade incentive.

Coaches were undergraduate students who had received an "A" in the same course two semesters prior and who were hired based on an interview to ascertain their relatability and confidence to lead sessions. Coaches attended Friday training meetings at which they went through and provided feedback on the following week's session activities. Two of the authors, one a mathematician and one a mathematics educator, both faculty in the Department of Mathematics, devised the weekly session activities and ran the training meetings. The goal was to prepare the coaches to facilitate the students' work through the activities and especially to stimulate discussion of the focal ideas. Thus, besides becoming familiar with the specific activities, coaches were given lesson plans that included discussion-generating questions to help focus attention on the most crucial concepts.

The intent of the program was to deepen students' conceptual understanding of key ideas in statistical thinking outlined in the GAISE College Report (2016). Additionally, although the sessions were constructed so as not to feel like another "lecture class," our hope was for students to engage with those ideas through activities recommended by the report as much as possible. Finally, we wanted weekly topics to be timely relative to recently covered class material. That was accomplished to the extent possible, given that individual instructors have some flexibility in the sequence and timing of topics on the course outline. Ultimately, a schedule of 8 sessions was constructed to best meet the aforementioned goals. Brief descriptions of the content of each session follow.

**Session 1: Histograms, standard deviations, and normality**. Students created and examined histograms for six different large sample data sets, matching each to its respective population description based on shape. Students revisited standard deviation calculation, then determined the percentage of data falling within one, two, and three standard deviations of the mean.

**Session 2: Normal distribution and the empirical rule.** Students examined a uniform distribution as a comparison to the normal. They used the "empirical rule" on a contextualized normal distribution to identify scores associated with different relative frequencies and vice versa, and to compare normal curves on same axes, given means and standard deviations.

**Session 3: Meaning of z-scores and associated probability statements for a random score from a normal population.** Students developed meaning of a z-score and reasoned out the formula based on its meaning. They standardized scores from a contextualized distribution, locating them along the x-axis using the empirical rule as a reference. They determined probabilities associated with population values falling in various intervals and vice versa.

**Session 4: Sampling distributions 1 – sample proportions**. Students physically tossed coins to first predict, then examine the distribution of proportions of heads from samples of size five and then 10, comparing results. Next, they observed computer simulations for proportions of heads for samples of size 10, then 30, then 100, where dot plots for 1000 samples were generated. Discussion focused on effect of sample size on variability.

**Session 5: Sampling distributions 2 – sample means**. Students physically rolled dice to first predict, then examine the distribution of mean rolls from samples of size one (uniform distribution) and size three (more normal). Key features of the distributions were discussed. Next, they observed computer simulations for mean dice rolls for samples of size 10, then 30, then 100, where dot plots for 1000 samples were generated. Students reviewed z-scores in light of CLT and answered questions, relating questions and answers to confidence intervals.

**Session 6: Confidence intervals and hypothesis tests on real data**. Students gathered data on Hershey's Easter candy to check the reasonableness of company claims found on product packaging using confidence intervals and hypothesis tests on means and proportions.

**Session 7: Connecting concepts and representations**. Students played matching games and completed sorting tasks that had them reviewing big ideas of the course, particularly those central to the inferential techniques learned thus far.

**Session 8: Correlation and linear regression**. Students played matching games and used computer applets to combine their intuition and knowledge to answer questions about how two numerical variables were linearly related.

## Results

Our results indicate that the PLTL intervention had somewhat complicated and mixed results; overall, the small number of participants limits our ability to detect statistically significant relationships. We present our results in terms of each of our initial research questions.

### Research Question A: Who attended the PLTL Sessions?

We invited all 134 students enrolled in treatment sections to participate in the eight PLTL sessions. The number of students who chose to participate is presented in Table 1. Out of the 134 students enrolled in a treatment section, 40 (29.9%) participated in at least one session, 27 (20.1%) participated in three or more sessions, and 15 (11.2%) participated in six or more sessions. The percentage of students participating in one or more sessions ranged from 18.5% to 42.3% in treatment sections. Similarly, the percentage of students participating in three or more sessions ranged from 10.7% to 34.6%. Although Table 1 indicates that many students chose to participate in the PLTL sessions, we plan to make attempts in future semesters to both recruit students to attend a session and retain those students to additional sessions.

*Table 1. Number of students participating in one or more and six or more sessions organized by instructor.*

| Instructor | Enrollment: Control Section | Enrollment: Treatment Section | Students attending one or more sessions | Students attending three or more sessions |
|---|---|---|---|---|
| 1 | 24 | 28 | 6 (21.4%) | 3 (10.7%) |
| 2 | 29 | 26 | 9 (34.6%) | 8 (30.8%) |
| 3 | 27 | 27 | 9 (33.3%) | 3 (11.1%) |
| 4 | 28 | 27 | 5 (18.5%) | 4 (14.8%) |
| 5 | 28 | 26 | 11 (42.3%) | 9 (34.6%) |
| Totals | 136 | 134 | 40 (29.9%) | 27 (20.1%) |

We were also interested in the achievement levels of the students who chose to participate in the PLTL sessions. We recorded the overall GPA (for all collegiate courses that students had completed at the end of the semester they enrolled in Introductory Statistics) for students in the control group, and for those attending different number of PLTL sessions. These results are presented in Figure 1. Examining this figure, we can observe from the first graph that the entire treatment group and control group had similar distributions of GPA. In the second graph, we notice that the distribution of GPA for students attending three or more sessions is slightly bimodal, with higher frequencies of both students with overall grades in the A and C range. This bimodal tendency is even stronger for students attending six or more sessions.

We are encouraged by the fact that a mix of students of different overall achievement levels chose to participate in the PLTL sessions. In future semesters, our goal is to maintain a diversity of achievement levels. However, given our goal of reducing course failure (DFW) rates, it might be prudent to target recruitment toward students performing at the overall level of "C" or lower, and/or scoring below average on the first course exam.

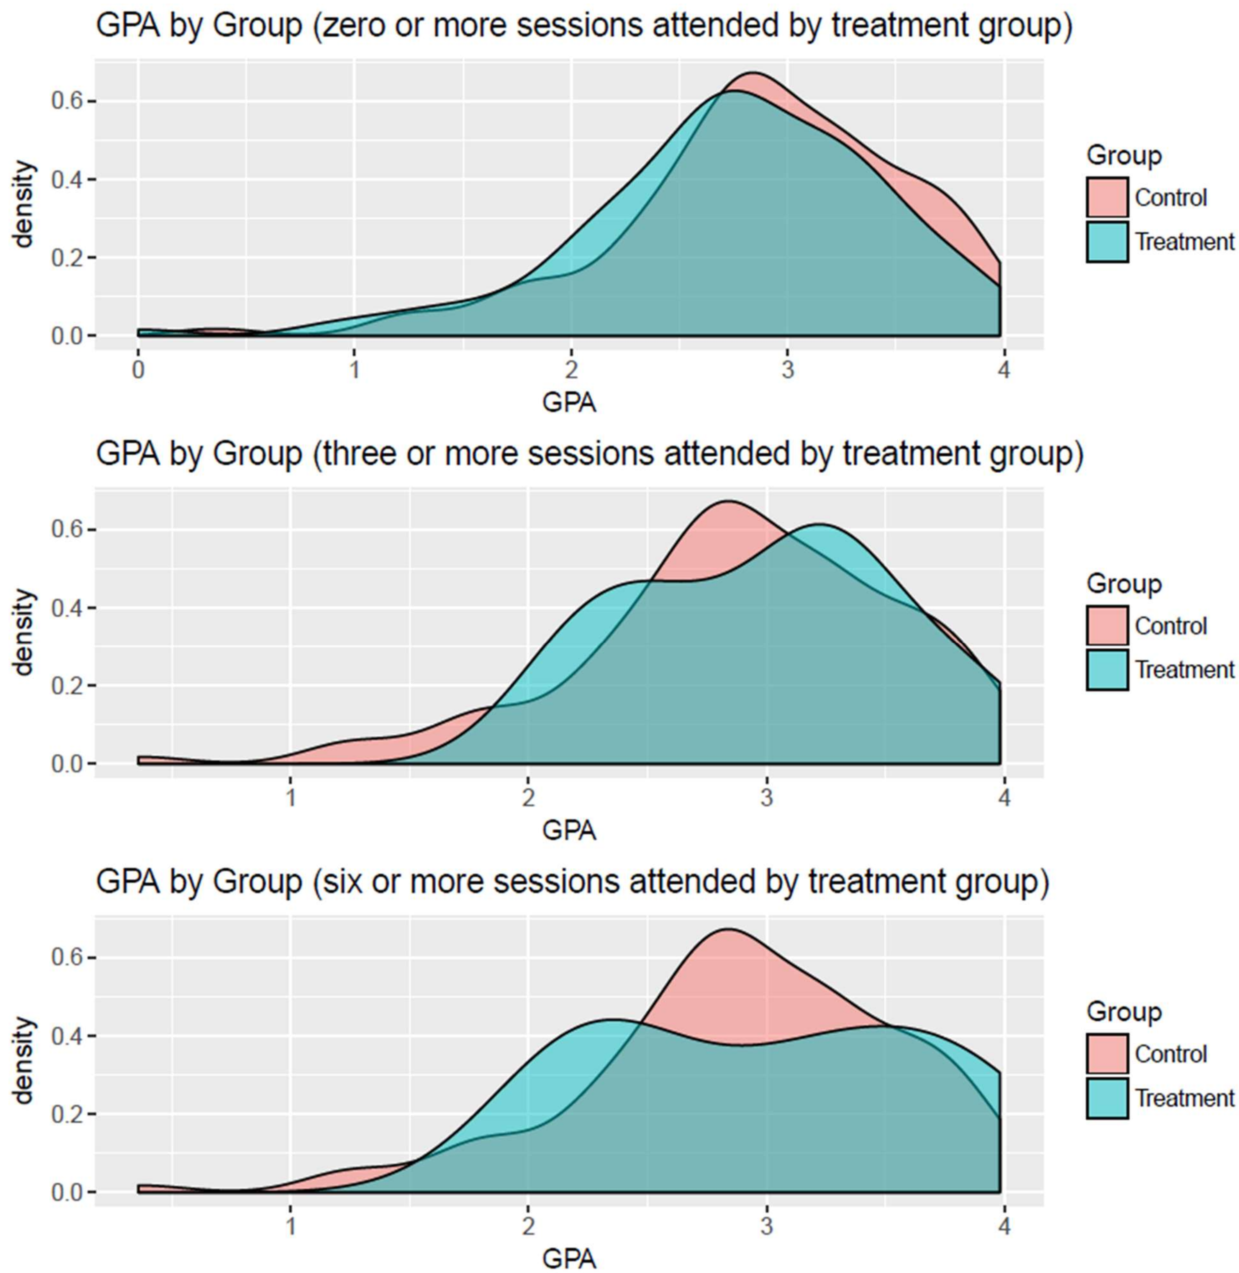

*Figure 1. Density plots of overall college GPA for students in the control group and attending PLTL sessions.*

**Research Question B: What effect did the PLTL sessions have on course outcomes?**

Because our primary goal in instituting the program was to increase student success rates, we began by analyzing its effects on students' course passage. We recorded the number of students obtaining a grade of D, F or W (that is, students not completing the course successfully) and compared the percentage of DFW's in the control group to students who participated in three or more sessions, and to students who participated in six or more sessions. The students who participated in three or more sessions were well matched to students in the control group based on first exam performance (Hedge's g=0.007). This indicates that, on average, students who chose to participate in three or more sessions and students in the control group did not perform differently on the first exam, which occurred before sessions began. We observe that the percentages of DFWs in the participating groups (32.5% and 33.3%) are approximately 5% lower than the percentage of DFWs in the control group (37.5%), but this difference is not statistically significant ($p = 0.347$ for students who attended one or more sessions, and $p = 0.49$ for students who participated in six or more sessions).

We also examined the effects of the intervention on course grade. Figure 2 presents a histogram displaying the course grades for the control group (in order to provide a comparison) and students who attended three or more PLTL sessions. The mean course grade (with A=4, B=3, etc, and W grades removed) was 2.20 (SD = 1.30) for the control group and 2.11 (SD = 1.16) for students attending three or more sessions; this difference was not significant. This finding, along with the data in Figure 2, demonstrates that attending three or more sessions did not appear to have a strong influence on students' success in the course.

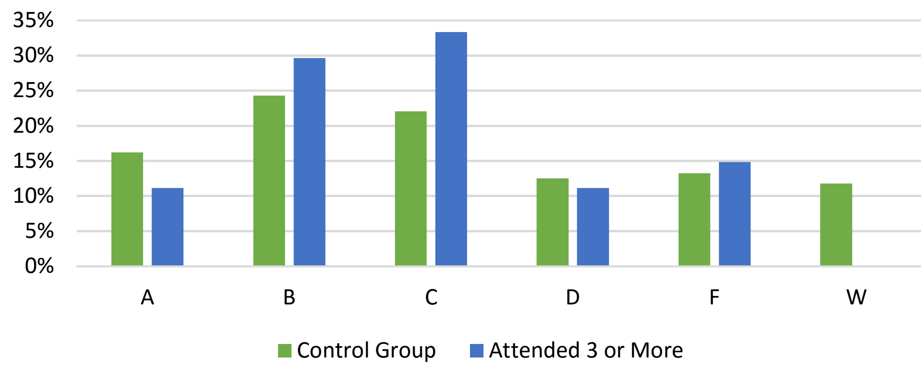

*Figure 2. Course grades for control group and students attending three or more sessions.*

While the observed data does not allow us to draw any firm conclusions about the effectiveness of the PLTL at lowering the DFW rate and increasing course success in introductory statistics, we plan to collect data during the Fall 2017 and Spring 2017 semesters. Program improvements might enhance the effects on student achievement, while increased participation may allow us additional power to observe such effects.

**Research Question C: How did participants perceive the PLTL sessions?**

All students who attended one or more PLTL sessions (N=40) were invited to complete a survey about their perception of the PLTL intervention; 20 students responded (a response rate of 50%). Table 2 shows the number of sessions attended by each of the 20 respondents. We asked why participants attended sessions and how useful they found the sessions to be. We further asked about the most helpful characteristics of the sessions and which topics they found most valuable. Finally, we asked a variety of questions to ascertain participants' perceptions of the coaches, including their helpfulness, preparedness, and enthusiasm.

*Table 2. Number of sessions each of the 20 survey respondents attended*

| Number of sessions attended | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|---|---|---|---|---|---|---|---|---|
| Number of students responding | 1 | 1 | 2 | 3 | 2 | 2 | 2 | 7 |

The most common reasons for attendance were "to earn the incentive" (nine students) and "to hopefully do better in the course by learning the content better" (nine students). When asked "If you didn't come to the sessions regularly or if you stopped coming, what was the reason?", six out of nine students chose “Session content did not match up with my class,” and three students stated that “Two hours for sessions was too long.”

For the most helpful and valuable characteristics of the sessions, common responses included “The sessions reviewed ideas and gave me practice on material I needed” (nine students) and “The sessions taught me something I hadn't understood before” (five students). According to the responses, coaches were viewed positively overall. On a 5-point scale that included “neutral,” 80% or more of the responding attendees agreed or strongly agreed that coaches explained concepts clearly, seemed knowledgeable, and were helpful, organized, enthusiastic, and encouraged discussion.

For each specific topic we covered (see Program Structure, above), we asked students: “How much did the session improve your understanding on the following topics?” 60% or more respondents considered sessions on the following topics at least somewhat helpful: standard deviation, z-score, probabilities associated with the normal curve, hypothesis testing, and meaning of distribution shapes. Eleven students (58%) found half or more of the sessions to be useful. Moreover, the majority of the students stated that going to the sessions was a positive experience and they would recommend these sessions to other students.

Responding attendees made several suggestions for improving the program. More than one student expressed the wish: 1) that sessions started earlier in the semester; 2) for more problems from the textbook and 3) for more hands-on activities. An unsolicited email came to us after the semester in which the student expressed that whereas the tutoring center was not a helpful support service for the course, these “extra classes” were. The student elaborated, “[Coach’s name] ran the classes I went to, and I got a good bit from them. I really got the Empirical Rule, and could estimate some answers just based on my understanding of it. Based on my experience and talking to the other students in [Coach’s name]'s group, I recommend the program.”

## Discussion

In this pilot project, we were unable to document statistically significant changes to students’ success in Introductory Statistics. However, some data, such as the positive perception that students had of the program and the anecdotal finding that shows a small drop in DFW rates, motivate us to offer this program again. Looking forward, we aim to conduct further research on Peer-Led Team Learning structures by conducting a second iteration of this program in a future semester. We plan to make some important adjustments, including starting earlier in the semester and redesigning activities to make them more engaging. Our goal is to increase the program’s impact on student learning and course success. In addition, we aim to offer the intervention to more course sections and increase recruitment efforts. Additional participants will allow a more robust statistical analysis of the effect of sessions on student outcomes.

Implications for undergraduate mathematics education point to the importance and difficulty of creating scalable extra-curricular programs that can support student success in “gateway” mathematics courses. Using knowledgeable peers (as we did in our PLTL program) requires less faculty involvement, but introduces the possibility of misconceptions being passed from coaches to students. We also experienced tensions between our goal of deepening students’ conceptual understanding and students’ goals of improving procedural fluency in answering homework and exam questions, as well as difficulty in providing content that was applicable to students across different sections and instructors. Addressing these challenges will take collaboration and conversation across Mathematics Departments nationally; we aim to add to that conversation through our presentation and this paper.

Students' Strategies for Setting up Differential Equations in Engineering Contexts

Omar A. Naranjo Steven R. Jones
Brigham Young University

*Ordinary differential equations (ODEs) comprise an important tool for mathematical modelling in science and engineering. This study focuses on how students in an engineering system dynamics course organized the act of setting up ODEs for complex engineering contexts. Through the lens of ODEs as a "coordination class" concept, we examined the strategies that seemed to guide the students' interpretations of problem tasks and their activation of knowledge elements during the tasks, as the students worked to produce ODEs for those tasks. This led to our uncovering of three main strategies guiding the students' work, and the finding that being able to flexibly draw on all of these strategies may be beneficial for student success.*

*Keywords:* differential equations, mathematics in engineering, system dynamics

Ordinary differential equations (ODEs) comprise a branch of mathematics that is extremely useful for mathematical modelling in a range of STEM (science, technology, engineering, and mathematics) fields. For example, it can be used in biology to model population dynamics, in engineering to model the evolution of mechanical system, and in physics to model changing quantities. A growing body of research has been examining how students understand, solve, and interpret ODEs in mathematics. Most of this work has focused on how students understand solution processes and the solutions themselves (Arslan, 2010; Camacho-Machín, Perdomo-Díaz, & Santos-Trigo, 2012; Habre, 2000; Rasmussen, 2001; Rasmussen & Blumenfeld, 2007). From this we know that students may struggle with the idea of a *function* being a solution (Rasmussen, 2001), that students may be hesitant about using graphical solution procedures (Camacho-Machín et al., 2012; Habre, 2000), and that equilibrium solutions are not well understood by students (Rasmussen, 2001; Zandieh & McDonald, 1999).

There is much less we know about how students organize their work for *setting up* ODEs for given contexts. Rowland and Jovanoski (2004) and Camacho-Machín and Guerrero-Ortiz (2015) each examined the setting-up process and interpretation of simple ODEs and found that students struggled to use "rate of change" thinking when doing so. They often thought of constants in ODEs as representing *constant amounts* rather than *constant rates of change*. While these studies provide useful results, the contexts used in the tasks were fairly simple and all the needed information was provided in the task. By contrast, in engineering, students encounter quite complex situations for which not all of the information is directly presented. This type of situation implies more challenges for the students as they attempt to organize their work to produce an ODE. We believe it important to extend the research on ODEs by examining how students go about the process of setting up differential equations for tasks that involve complicated systems. In summary, this report is meant to investigate the research question: What strategies do students use when setting up ODEs for complex engineering tasks?

## Coordination Class Concepts

For this study, we used the lens of coordination classes from the knowledge-in-pieces paradigm (diSessa & Sherin, 1998). Coordination classes are useful for describing concepts whose purpose is "getting information" (p. 1171). In the context of system dynamics, the information regarding the system is obtained through an ODE. A coordination class concept involves readout strategies and causal nets. *Readout strategies* are the "means of seeing things that relate to the target information" (diSessa, 2004, p. 141). For our purposes, we see readout strategies in terms of how one interprets external stimuli. The *causal net* is "the set of all possible inferences that lead to determining the relevant information" (diSessa, 2004, p. 141). That is, once a person has interpreted external things, those interpretations can then be linked with other pieces of knowledge so as to progress toward the desired information. Causal net elements might consist of known relationships, formulas, informal ideas, beliefs, and so on.

Next, diSessa and Wagner (2005) define a *concept projection* as the collection of knowledge elements related to that concept, as well as the guiding strategies, that a person uses in a particular context. The strategy used to obtain the information impacts the readouts and causal net elements that are activated. For example, suppose one wants to find the volume of a three-dimensional object (the desired information). One might first use a readout strategy to identify whether the object's shape is a typical geometric shape, or not. If it is, such as a box, the person might activate the causal net knowledge element $V=lwh$. Using this geometric formula, they could obtain the object's volume. We could call this a "geometric strategy," because the person used the geometric regularity of the object to determine how to find the information. On the other hand, if the object is an irregular shape, the person might instead activate a causal net knowledge element of Archimedes principle, which states that the volume displaced by water is equal to the volume of the submerged object. The person could then use that inference to determine the object's volume. We could call this a "experiment strategy," because the person would enact an experiment based on a known principle to determine the information.

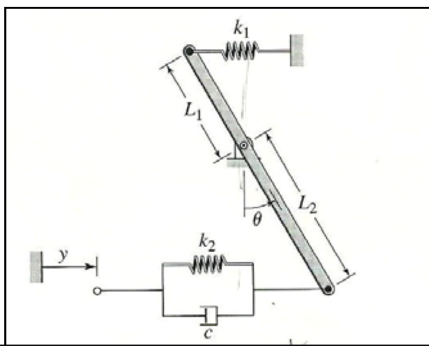
## Data Collection and Analysis

In order to provide insight into the strategies students use to set up ODEs for complex tasks, we recruited students for interviews who were taking an engineering "system dynamics" course. We chose a system dynamics course because (1) taking an ODE course is a prerequisite for the system dynamics course, meaning all the students had experience with ODEs; and (2) the system dynamics course is designed entirely around the idea of setting up and solving ODEs for different engineering systems. Thus, the students were in the process of learning to set up ODEs for complex contexts, though the instructor mostly just lectured on how to set up ODEs. To recruit students from the system dynamics class, we first administered a survey to the entire class to obtain background information on how the students interpreted a generic ODE. The survey displayed the equation $ay''+by'+cy = 0$ and asked the students to describe what this equation meant and what the various symbols in it represented. We chose two students who provided strong responses regarding the equation (Rebecca and Zane), two students who provided moderate responses about the equation (Harry and Josh), and one student who showed some weaknesses in their understanding of the equation (Kira). These five students participated in two interview sessions where they were asked to set up an ODE for a total of three different tasks.

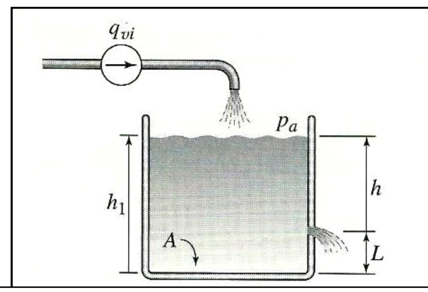
We designed the interviews to focus on contexts that matched those seen in the students' system dynamics course. The three tasks consisted of a mechanical context, an electrical context, and a fluid context. For the purposes of this abbreviated conference report, we focus on the mechanical task (task 1) and the fluid task (task 3), shown in Figure 1, as they suffice for describing the main strategies the students used for organizing their work of setting up an ODE. For the interview, the students worked out the tasks, explaining their thinking aloud, and the interviewer asked follow-up and clarifying questions while the student worked.

The interview data were analyzed in two separate phases. In the first phase, which was essentially a preliminary phase in terms of this paper's research question, we identified readouts and causal net elements the students used while working on the tasks. Operationally, readouts were defined as any place in the data where a student appeared to make a direct interpretation of any part of the given interview task, whether symbols, words, or parts of the figure. The apparent interpretation was recorded as the "readout." Causal net elements were operationally defined as any time a student mentioned, wrote, or suggested an idea that was not a direct interpretation of a part of the task. The substance of the causal net element, as well as what other piece(s) of information may have triggered its activation, was recorded as a "causal net link."

In the second phase, which allowed a more direct answer to this paper's research question, we used the resulting readouts and causal net links recorded in phase one to examine the overall flow of the students' work. This allowed us to infer strategies the students appeared to be using to set up the ODE. We did not have pre-set notions of what the strategies would consist of, but rather let the nature of the strategies emerge from the student's documented process. This led to the identification of three main strategies, described in the next section. Lastly, we determined whether the strategies were productive for the students, by observing (1) whether a particular strategy helped the students produce a solution, (2) whether that solution was correct, and (3) whether the student had to revise their solution because the approach led to a "dead end."



Task 1: Assuming that $\theta$ is small, derive the equation of motion of the pendulum shown in the figure. The input is $y(t)$ and the output is $\theta$. The equilibrium corresponds to $y = \theta = 0$.



Task 3: The cylindrical tank shown in the figure has a circular bottom of area $A$. The volume inflow rate from the flow source is $q_{vi}(t)$, a given function of time. The orifice in the side wall has an area $A_0$ and discharges to atmospheric pressure $p_a$. Develop a model of the liquid height $h$.

*Figure 1. The mechanical and fluid tasks from the interviews (taken from Palm, 2005, p. 244 and 397).*

## Results

In this section, we describe, one by one, the three main strategies used by these five students to guide their work setting up ODEs for the tasks. We do this by providing a single illustrative case from the data for each of the three main strategies. We then provide a summary about which students used each strategy, and end by discussing possible benefits of the three strategies.

### Strategy #1: Diagram-based Approach

To illustrate the first strategy, we describe the case of Zane working on task 1. While his complete work is too lengthy to describe here in its entirety, we highlight enough of his work to hopefully demonstrate his main guiding strategy. An important early readout in Zane's work was to view the bar in the figure as the main object about which to reason. This led Zane to draw what, in engineering, is called a free-body diagram. His diagram consisted of the bar, by itself, which he continually annotated and revisited throughout his work (see Figure 2). The diagram helped him focus on two other readouts, namely the top of the bar and the bottom of the bar (arrows at the top and bottom of his diagram). He then inferred that forces and horizontal displacement were both relevant attributes of the top and bottom of the bar. The top arrow was linked to a single force from the upper spring, while the bottom arrow was linked to two forces from the lower spring and the damper. His diagram also helped him visualize the implicit presence of two right triangles each having $\theta$ as an angle (added to Figure 2). He used the triangles, together with Hooke's Law ($F=k\cdot\Delta x$) and the fact that $\sin(\theta) \approx \theta$ (inferred from the "small angle"), to describe the three forces in terms of $L_1$, $L_2$, and $\theta$ (seen in Figure 2 as $k_1L_1\theta$ and $k_2L_2\theta$ for the springs, and $cL_2\dot{\theta}$ for the damper). Causal net links between *velocity* and *first derivative* and *rotational acceleration* and *second derivative* allowed him to invoke the $\dot{y}$, $\dot{\theta}$, and $\ddot{\theta}$ seen around the "cloud" in Figure 2. Zane used the standard engineering "dot" notation for time-derivatives, as did the other students. While there are additional science-based knowledge elements Zane used along the way, such as a "moment" being force times the distance from the center of rotation, and $\sum moments = I\ddot{\theta}$, we can see that most of his readouts and causal net links were scaffolded by his free-body diagram. Putting all of these elements together, Zane was successful at producing a correctly set up ODE for this task, shown in Figure 3.

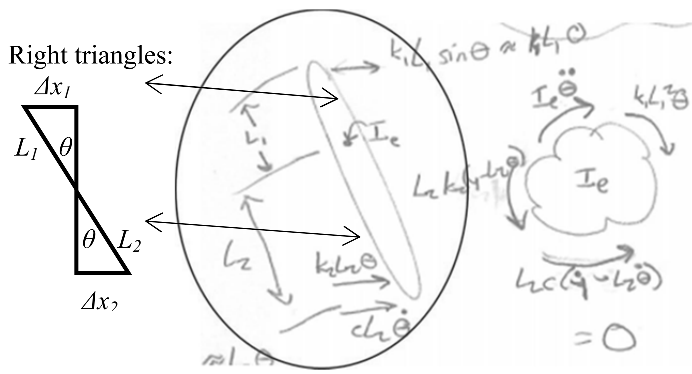


*Figure 2. Zane's initial free-body diagram (circled) and his work based off the diagram*

$$I_e\ddot{\theta} + k_1L_1^2\theta - L_2c(\dot{y} - L_2\dot{\theta}) - L_2k_2(y - L_2\theta) = 0$$

*Figure 3. Zane's correctly set up ODE for task 1.*

Having briefly recapped Zane's work, we can see that his overall strategy consisted of using a single diagram to organize most of his readouts and causal net links. Thus, we call Zane's strategy the "diagram-based" approach. In general, we can think of the diagram approach as a *general-to-specific* method that initially focuses on the entire system. Then, within that system, the student can attend to individual parts that have relevance to the system. The diagram approach is not limited to mechanical free-body diagrams, but can also be seen in "schematics" for electrical contexts and "control volumes" for fluid contexts. In fact, the simple existence of names for these types of diagrams in various engineering contexts suggests its generalizable usefulness as a strategy for setting up equations, which apparently extends to ODEs as well.

**Strategy #2: Components-based Approach**

The second strategy we describe contrasts with the diagram-based approach in that it could be considered a *specific-to-general* strategy. To illustrate it, we describe the case of Rebecca also working on task 1. Unlike Zane, who first "read" the bar in isolation, Rebecca's initial readouts were to scan the task to locate and identify various individual elements and to begin to keep track of them. She immediately identified three elements, $k_1$, $k_2$, and $c$, each as representing forces. This is different from Zane, who initially began with only two elements, namely the top and bottom of the bar. Thus, we can see a distinction in what these strategies might focus on. She then made the causal net link that each force multiplied to its distance from the center of rotation gives the moment at that point. Using these individual components, and the fact that the sum of moments equals $I\ddot{\theta}$, she wrote an early version of the ODE, shown in Figure 4.

$$F_{k_1}L_1 + F_{k_2}L_2 + F_c L_2 + I\ddot{\theta} = 0$$

*Figure 4. Rebecca's initial equation, focused on compiling individual elements of the system.*

Rebecca then returned to each individual element in order to flesh each one out, which resembled Zane's work at this point. She similarly inferred $\sin(\theta) \approx \theta$ from the "small angle" in order to elaborate on $F_{k1}$, $F_{k2}$, and $F_c$. This approach is visible in her work shown in Figure 5, where she used a string of causal net links to establish how each element was related to $y$, $\dot{y}$, $\theta$, $\dot{\theta}$, and $\ddot{\theta}$. After finding each element in Figure 4 in terms of these variables, she combined them into a correctly set up ODE, shown in Figure 6.

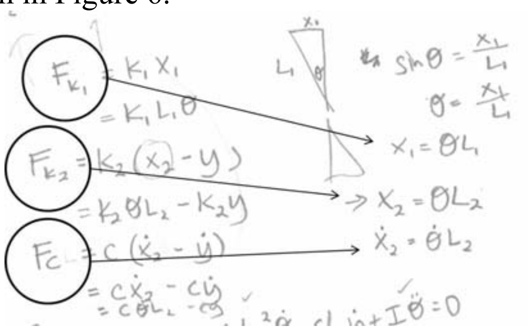

*Figure 5. Rebecca's work of focusing on each element and how it could be represented in terms of θ.*

$$I\ddot{\theta} + cL_2^2\dot{\theta} + k_1L_1^2\theta + k_2L_2^2\theta = cL_2\dot{y} + k_2L_2y$$

*Figure 6. Rebecca's correctly set up ODE for task 1.*

In Rebecca's work, rather than beginning with a diagram, we can see the strategy of reading out specific elements *first* and *then* subsequently trying to piece them together. Of course, there were many overlapping readouts and causal net inferences with Zane's work, once she performed her initial organization of the task. Also, it is certainly true that Rebecca *did* employ holistic thinking in her work, evidenced by when she put the various components together, like in Figure 4. However, what is different and noteworthy is that her guiding initial strategy was "reading" the task through the identification of each individual element and then figuring out how to compile them. For Rebecca, the individual elements seem to have come first, and then knowledge pieces were used to organize the elements into a coherent whole. We can see that, for Rebecca, this strategy was just as successful as Zane's diagram approach, since it provided a direct path toward creating a correct ODE for this context.

**Strategy #3: Equation-based Approach**

For the third strategy, we again describe Rebecca's work, but this time with task 3. An important initial readout for Rebecca in task 3 was simply to attend to the general *fluid flow* context of the problem, as opposed to any individual element within it. Her recognition of this type of context seemed to immediately activate a causal net link that an adaptation of Bernoulli's equation governs these types of fluid contexts. This link allowed Rebecca to immediately invoke an entire equation as a single knowledge resource, $q_{in} - q_{out} = \rho\dot{V} + \dot{\rho}V$ (where $q$ is a flow rate, $\rho$ is the fluid's density, and $V$ is the fluid's volume in the container). That is, rather than *piecing together* an equation, as Zane and Rebecca (and other students) did for task 1, in this case an entire equation was *recalled* from memory because of its relevance to the context. The remaining work for Rebecca in this task was then to manipulate this equation by making substitutions or cancelations that would produce the desired ODE.

To do so, Rebecca first used the readout of "water" to infer incompressibility, meaning that the density would not change and $\dot{\rho} = 0$ (see Figure 7, and note the scribbled out "$\dot{\rho}V$" above the last term). Next, she used the facts that $V = Ah$, and that the cross-sectional area was constant, to substitute $\rho A\dot{h}$ in place of $\rho\dot{V}$. Lastly, she used Toricelli's Law, $q_{out} = c\sqrt{2gh}$, to make a substitution for $q_{out}$ (where $h$ is the distance between the fluid surface and the outflow). Notice that in her final equation (Figure 8), she could not recall exactly what was supposed to be "inside" the square root, and so her expression diverges a little from a "correct" solution. However, had she had access to a book or sheet of equations, she could have easily corrected this and thus we still consider her final ODE to essentially be "correct." Also, for clarification, her "sgn" term is the "sign function" for whether the argument is positive or negative.

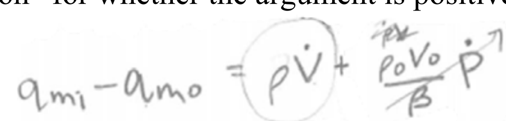

*Figure 7. Rebecca's direct invocation of an entire equation governing fluid flow.*

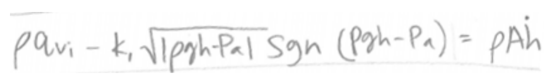

*Figure 8. Rebecca's essentially "correct" final ODE for task 3.*

In general, Rebecca's equation approach seemed to rely on the fact that there was a single main equation governing that particular class of systems. From that equation, Rebecca centered all her efforts to obtain the ODE by manipulating the equation through substitutions or cancellations. Thus, the use of this strategy would first require the perception (i.e. causal net link) that there is, in fact, such an equation that can be used for a given system. This strategy was also successful in that it provided Rebecca a clear path toward an essentially correct ODE.

**Approaches Used by All of the Students**

We now provide a brief summary of all five students in terms of which strategies they used (diagram, component, or equation) and whether they were successful, partially successful, or unsuccessful at setting up an ODE (see Table 1). We note that we allowed "successful" set ups to include equations where there was a simple recall mistake, like Rebecca's in task 3. We considered "partially successful" set ups to be those that had one or two significant flaws (beyond simple recall) but that still contained many correct elements in the equation. An "unsuccessful" set-up was one where the student never produced a final equation, or one in which the equation had multiple major flaws.

We see in Table 1 that not all students confined themselves to a single strategy for a given task. Harry, Josh, and Kira each used multiple strategies for at least one task in order to help them progress in their work. In some ways, because these students struggled more than Zane and Rebecca, who each only used one strategy per task, one might conclude that using more strategies is a sign of weakness. However, we do note that using different strategies actually allowed Harry, Josh, and Kira to each make more progress than they would have otherwise made with a single strategy alone. That is, once they were stuck, switching modes to a different strategy often seemed to unlock additional causal net links that may have been hidden from them while using the other strategy, even if they did not fully reach a completed ODE.

*Table 1. Strategies used and whether the student was successful (S), partially successful (PS), or unsuccessful (UN)*

| | Rebecca | Zane | Harry | Josh | Kira |
|---|---|---|---|---|---|
| Task 1 | Component (S) | Diagram (S) | Component (PS) | Diag/Comp (PS) | Diag/Comp/Eq (UN) |
| Task 3 | Equation (S) | Equation (S) | Diag/Eq (S) | Diag/Eq (PS) | Diag/Eq (S) |

**Discussion of the Three Strategies**

We believe the empirical documentation of these three strategies provides some insight into how students might identify and use information relevant to ODEs in complex contexts through readouts and causal nets. While experts might see the strategies as equivalent, we believe there are nuances to each, and this report may be seen as an "unpacking" of possible ways to reason about ODEs for complex engineering tasks. In fact, our study suggests these strategies could be important in *developing* expertise. All three approaches were used by students to correctly set up ODEs for these complex tasks, or at least to construct partially correct ODEs, as seen in Table 1.

We can see that there is not necessarily "one correct strategy" for a given problem. Rebecca and Harry both used the component approach to productive ends for task 1, but Zane and Josh both used the diagram approach instead to make progress on that task. While all of the students used the equation approach on task 3, Harry, Josh, and Kira also used the diagram approach (in the form of a "control volume") to help further their work. Yet, while there may not be one correct strategy, we observe that the trends in Table 1 suggest some strategies being more easily invoked for some tasks than others. The equation approach was hardly used at all for task 1, but was used extensively for task 3. This gives evidence that some problems may lend themselves better to bringing in an overarching governing equation. For example, task 1 could be considered to have the governing equation $\sum moments = I\ddot{\theta}$, but this is not where these students tended to start. Rather, this equation emerged as a causal net link further down the line, once the students were ready to organize the elements into a whole. By contrast, the fluid flow equation seemed readily available as an immediate starting place for task 3. Thus, developing expertise in setting up ODEs in these types of contexts may have something to do with being able to recognize when it may be best to start with a diagram, start with individual components, or start with an equation.

Since using multiple strategies helped the weaker students in this study make more progress than they otherwise would have with only a single strategy, evolving expertise could also partially deal with being able to switch strategy modes if a roadblock is reached within a task. Perhaps it is true that greater expertise may lead to better identification of a single productive approach, as with Rebecca and Zane. However, as students mature *toward* that point, becoming aware of which of the three strategies they are using may help them see the value in switching between strategies for a given task. This may help them develop better flexibility in which strategies they use, and to begin to see connections between certain problem types and certain strategies that are useful for that type. We see this exploratory study as a useful step, in that it could be expanded into a teaching experiment to confirm, refute, or nuance these results.

Student Status in Peer Conferences

Daniel L. Reinholz
San Diego State University

*This paper provides an analysis of students' peer assessment conversations in introductory college calculus. In particular, it explores gender differences in the types of feedback and word choices used by students. Using computer-aided textual analysis, it draws connections between the types of words that students use and their relative status in the class. Surprisingly, the use of pronouns based on gender did not follow what one would predict based on prior studies. Possible explanations and implications for future research are discussed.*

*Keywords:* peer assessment; status; feedback; equity.

## Introduction

Imagine one hundred calculus students trading papers amongst themselves and providing constructive feedback. You overhear the following in a peer conference:

> It said in the beginning of the problem that each statement below is true sometimes, and it says give an example of a function when it's true and when it's not true. For yours you only put when it's true, but when it's not true you didn't really put anything there.

As you continue walking, you overhear another student:

> I think the main thing is that for part A, I think there should be just one equation dV/dt and you would incorporate both dh/dt and dr/dt. I think just somewhere in your differentiation you didn't do something…I'm not sure what. I think there should just be one equation for dV/dt.

What could you learn about these students and this classroom based on the words you overheard? In the first excerpt, the student gives process-focused feedback, telling their peer what is required to answer this type of question, but does not give the answer itself. In contrast, the second excerpt is product-focused, describing the correctness of an equation. While both of these types of feedback can promote learning, process-focused feedback tends to promote better learning (Hattie & Timperley, 2007; Reinholz, 2015a).

What else could you infer? In the first excerpt, few first-person pronouns are used. Rather than saying what they *think* about their peer's solution, the student simply makes statements about what their solution *should be*. In contrast, the second excerpt features a large number of "I" statements. The feedback is clearly coming from the perspective of *that student*. This difference in pronoun usage is often indicative of status hierarchies (Pennebaker, 2011). The first student, who uses many more second-person pronouns, is likely of higher status than the student who uses primarily first-person pronouns. Thus, simply by looking at the types of pronouns students use in the conversations, it may be possible to uncover subtle status hierarchies in the classroom.

This paper responds to recent calls to focus on issues of equity in undergraduate mathematics (Adiredja & Andrews-Larson, 2017). By studying the language use of students in calculus, it provides insight into status hierarchies, which are of consequence for understanding how students may have access to differential opportunities to learn (e.g., Cohen & Lotan, 1997). This article focuses on the following research questions: *How does participation differ for individual students, or groups of students (e.g., by race, gender)?* In light of this question, the implications of using peer assessment as a tool to create more equitable learning opportunities are discussed.

## Theoretical Framing

A large body of literature connects classroom discourse and learning (Bransford, Brown, & Cocking, 2000; Lampert, 1990; Sfard, 2008). This literature emphasizes opportunities to participate in meaningful discourse constitute opportunities to learn (Hufferd-Ackles, Fuson, & Sherin, 2004; Michaels, O'Connor, Hall, & Resnick, 2010). Simply speaking during class, for instance, in low-level, Initiate-Response-Evaluate (IRE) sequences (cf. Cazden, 2001; Mehan, 1979), is insufficient to promote deep learning. Rather, students need opportunities to engage with mathematics in cognitively demanding ways that push them to engage in mathematical sense making (cf. Stein, Grover, & Henningsen, 1996).

Simultaneously, a growing literature has examined issues of equity in classroom discourse (Esmonde & Langer-Osuna, 2013; e.g., Herbel-Eisenmann, Choppin, Wagner, & Pimm, 2012). This literature highlights how subtle inequities can emerge, particularly in terms of gender, race, and other social markers. For instance, some groups tend to receive lower-level participation opportunities, based on their gender (Sadker, Sadker, & Zittleman, 2009), race (McAfee, 2014), and immigration status (Planas & Gorgorió, 2004). While these patterns of marginalization often emerge unintentionally, they are nonetheless problematic and require attention.

For the purposes of this paper, equality is taken as a necessary but insufficient baseline for equity (Secada, 1989). While it may be impossible to decide exactly what instruction is required to provide *equitable* opportunities for all students, it is clear that if students from historically-marginalized groups receive proportionally less opportunities to participate than their historically-dominant peers (which literature shows is often the case), it is highly problematic. In other words, if all students receive at least *equal* opportunities to participate, it is a positive (yet insufficient) step in the right direction.

Accompanying the wealth of literature describing inequity in discourse, there are also valiant efforts to reduce such inequity. One well-known example is the set of techniques associated with Complex Instruction. These instructional moves (e.g., the multiple ability treatment, assigning status) help mitigate status hierarchies in heterogeneous classrooms, leading to more equitable outcomes for all students (Cohen & Lotan, 1997; Nasir, Cabana, Shreve, Woodbury, & Louie, 2014). In other words, power imbalances (e.g., who is perceived as an authority) lead to less equitable outcomes (Engle, Langer-Osuna, & Royston, 2014; Langer-Osuna, 2016), but when these imbalances can be addressed, learning becomes more equitable (Cohen & Lotan, 1997).

The above literature highlights how issues of inequity arise across a variety of mathematics classroom settings. This paper focuses particularly on calculus, which is known to significantly decrease student confidence, enjoyment, and interest in mathematics (Bressoud, Carlson, Mesa, & Rasmussen, 2013). While these effects impact all students, they differentially impact non-dominant students. For instance, women with the same grades as men are 1.5 times as likely to leave the calculus sequence (Ellis, Fosdick, & Rasmussen, 2016). Moreover, there are salient societal narratives about who can and cannot do mathematics, which can have a negative impact on students (e.g., Nasir & Shah, 2011; Stinson, 2008). In other words, the status quo for calculus is severe inequity. A classroom that were to achieve *equality* would be a considerable step in the right direction.

From this backdrop, the present study focuses on issues of equity and status in peer conferences. Peer conferences are an important feature of peer assessment (cf. Falchikov & Goldfinch, 2000; Topping, 2009), and offer unique opportunities for addressing issues of inequity in discourse. In particular, peer conferences generally involve only two students, so the complexities of promoting participation from all students in a small group or a whole class are reduced. Moreover, peer conferences position students as competent authorities, because they must critically judge the work of their peers, which provides them with space in the classroom to act as experts (cf. Engle & Conant, 2002; Reinholz, 2015b).

## Method

### Context

The present study took place in calculus I at a relatively large (over 30,000 students), racially diverse (e.g., ~65% students of color) research-extensive university in the US. The course consisted of a combination of large lectures (100-200 students) taught by full-time instructors and smaller breakout recitation sections (30-40 students) taught by Graduate Teaching Assistants. This paper focuses on a single large-lecture section (N=124), which met three times weekly for 50 minutes at a time. In addition, students in the lecture met twice weekly for 50 minutes for their recitation sessions, but those sessions are not a focus of this paper.

### Design

Each week students engaged in a peer assessment learning activity called Peer-Assisted Reflection, or PAR (Reinholz, 2015b; Reinholz & Dounas-Frazer, 2016). The goal of PAR is for students to develop self-assessment skills as they assess the work of their peers (Black, Harrison, & Lee, 2003; Reinholz, 2015c). Specifically, PAR consists of a four-part cycle through which students: (1) complete a draft solution to a conceptual mathematics problem for homework, (2) reflect on their solution by identifying which aspects of their solution they would like to receive feedback on, (3) trade papers with a peer in class and exchange peer feedback, and (4) revise their work before turning in their solution. Students receive homework credit both for the correctness of their solution and for completing the PAR process, which encourages students to revise their work (in practice nearly all students do so). Prior studies show that PAR has a significant impact on student learning (Reinholz, 2015b, 2016), but the learning impact of PAR is not the focus of the present study.

This implementation of PAR differed from prior iterations (in nearly 20 courses), because it took place a large-lecture course, which imposed different logistical constraints. In terms of the actual PAR process, students were able to engage productively during their large lecture sessions: they simply turned to a peer, traded papers, and conferenced about their work. Yet, prior research suggested that PAR was most effective when students chose their partners randomly, as this allowed them to get a variety of perspectives and it changed the dynamics of peer relationships (Reinholz, 2015b). While students were encouraged to choose new partners each week, in practice, this was difficult to enforce because of the large-lecture environment. Moreover, the large number of students enrolled in the course (N = 124) meant that students received little feedback from the instructor on the quality of their PAR solutions and the feedback that they provided to their peers, in contrast to prior implementations of PAR. Because students received less feedback about the quality of their feedback, it was assumed that the learning impact of PAR would be lessened somewhat.

During the feedback exchange component of PAR (step 3), students read each other's work silently for five minutes and write comments, and then have five minutes to discuss their feedback. Forcing students to engage silently with each other's work before the discussion helps ensure that students actually talk about their peers' solutions, not just the problem. Moreover, PAR positions both students as competent, as they *both* provide feedback to one another, rather than creating an asymmetric relationship in which only one student provides feedback to the other. This was a feature designed to promote student authority (cf. Engle & Conant, 2002). In the context of a large-lecture course, this was intended to provide *all* students with opportunities to engage in meaningful talk around mathematics, which can otherwise be difficult to facilitate in whole-class conversations.

### Participants and Data

A total of 84 students participated in the study (in a class of N=124). Demographic information was collected from the university's office of Institutional Research (see Table 1).

*Table 1. Participant demographics (N = 84).*

| | Women | Men | **Total** |
|---|---|---|---|
| African American | 0 | 3 | **3** |
| Asian/Pacific Islander | 4 | 11 | **15** |
| Hispanic | 8 | 16 | **24** |
| International | 0 | 1 | **1** |
| Multiple Ethnicities | 1 | 4 | **5** |
| White | 9 | 19 | **28** |
| Unknown | 4 | 4 | **8** |
| **Total** | **26** | **58** | **84** |

The primary data source for this article was students' peer conversations. During their PAR conferences students recorded their conversations (the second part of their feedback exchange) using audio recorders on their cellular phones. A total of 172 conversations were recorded in this way. While the majority of conversations consisted of student dyads, some of the conversations involved three students at a time. To account for a variable number of students in certain conversations, a unit of 'participant-conversations' was used for analysis, which represents how many times some student from a particular group participated in some conversation. This paper focuses on gender of students. There were 116 participant-conversations for women, and 254 for men.

### Analytic Methods

To support data analysis, all conversations were transcribed and linked to student names. This allowed for demographic information to be attached to each individual student contribution. Cleaning of the dataset and data analysis was completed in R statistics, using a variety of text processing packages (e.g., stringi, lsr, lexicon). Student conferences were analyzed for the type of feedback provided using a prior coding scheme that focused on process, product, and person feedback (Reinholz, 2015a). Student conferences were also analyzed for their pronoun usage. In particular, when students have higher status, they tend to use fewer first-person singular pronouns, more first-person plural pronouns, and more second-person pronouns (Pennebaker, 2011). Thus, by looking at the relative use of pronouns in these three categories, it was possible to explore issues of authority in peer conferences. One would expect that historically dominant students (e.g., White/Asian men) would speak as though they had more status.

All analyses must be interpreted with some caution. For instance, a wealth of literature highlights differences in word usage based on gender (Argamon, Koppel, Fine, & Shimoni, 2006), task characteristics (Newman, Groom, Handelman, & Pennebaker, 2008), topic (Bamman, Eisenstein, & Schnoebelen, 2014), and age (Huffaker & Calvert, 2005). Despite this level of nuance, some commonalities exist across settings. For instance, women tend to use first-person singular, cognitive, and social words more, while men use more articles, and there are no meaningful differences for first-person plural or positive emotion words (Pennebaker, 2011).

In sum, one can expect that there will be differences in word usage by different groups of students in the peer assessment process, simply by virtue of their membership in particular gender, racial, or other demographic groups. Simultaneously, it will be difficult to predict in advance what these differences may be. Nevertheless, as others continue to look at such patterns of word usage in other educational contexts, this paper will provide a baseline to compare to.

Finally, it is recognized that reducing socially-constructed identities (e.g., based on gender, race) can be potentially problematic, as it obscures that positioning individuals is a power-laden process (Davies & Harré, 1990). While it can potentially be problematic to essentialize such characteristics, it can also be 'strategic,' as a tool to highlight or address inequities (Gutierrez, 2002). In other words, this strategic essentialism makes it possible to illuminate subtle patterns of inequity (e.g., men speaking more than women), which are problematic and need to be addressed. As such, essentialism can be used as step towards greater equity, while acknowledging the need for complementary approaches that treat social markers more fluidly (e.g., Nasir, McLaughlin, & Jones, 2009).

**Results**

Table 3 summarizes students' word usage. To contextualize these results, they are compared to two prior iterations of PAR (Reinholz, 2015a). The table shows that in the present study each student contributed an average of 149.09 words to each conversation. These conversations were shorter than those in prior iterations. Also, at an absolute level, the Phase II conversations contained more feedback in these three categories than during the current study. Yet, when looking at density of feedback, the amount of feedback based on how many words were spoken is highest for the current study. In other words, it seems that students were saying more with fewer words, and likely there was less off-topic talk. Given differences in the implementation of PAR and student populations, it is difficult to identify exactly the source of these differences.

*Table 3. Average word usage (by participant conversation)*

| | Present (N=370) | Phase I (N=116) | Phase II (N=184) |
|---|---|---|---|
| Total Words | 149.09 | 163.17 | 295.19 |
| Process Words | 6.04 | 4.86 | 9.00 |
| Product Words | 1.32 | 0.70 | 1.07 |
| Person Words | 3.54 | 2.43 | 2.48 |

Figure 1 shows feedback types by gender. The data are expressed as an "equity ratio" (Reinholz & Shah, in press). This ratio describes the actual participation by students (in number of words), divided by what one would expect based on demographics alone. Thus, a ratio greater than one means that students contributed more than expected, a ratio of one is what would be expected, and a ratio less than one means that they contributed less than expected. Here we see that men contributed more than one would expect for total words $\chi^2(1, N = 55284) = 102.67$, p = $3.9 * 10^{-24}$, Cramer's V = 0.53 (large effect size). Women used more person-focused feedback (i.e. praise), $\chi^2(1, N = 1387) = 39.18$, p = $3.85 * 10^{-10}$, Cramer's V = 0.33 (medium effect size). Men used more product feedback (i.e. describing right or wrong), $\chi^2(1, N = 484) = 19.2$, p = $1.2 * 10^{-5}$, Cramer's V = 0.22. There were no significant differences for process words.

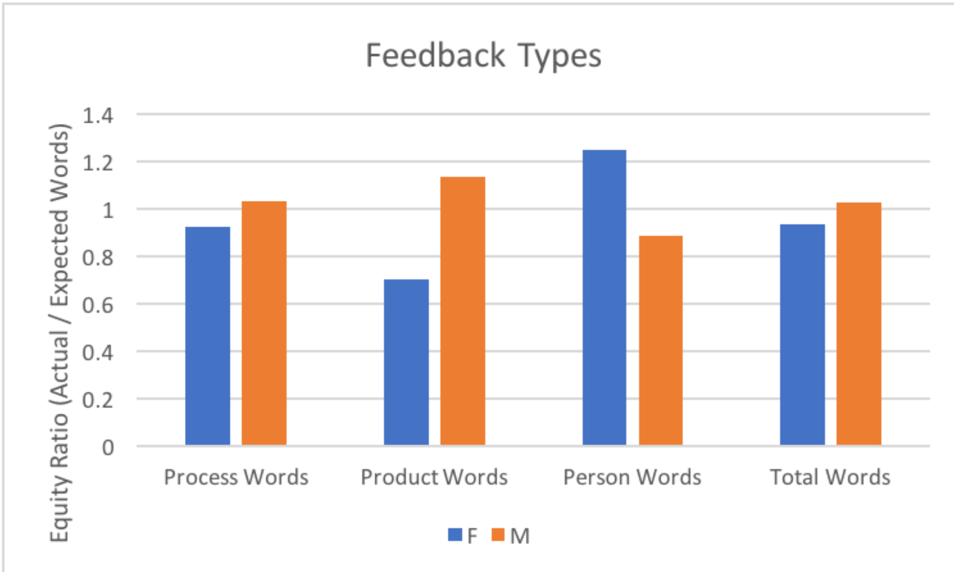

*Figure 1. Feedback types by gender*

What can be inferred from these results? Figure 1 indicates that men and women behaved the same when it came to giving process-focused feedback, which is the most valuable type for learning. Yet, there were also stylistic differences with men focusing more on correctness of the solution and women offering more praise. This provides contrast to some other settings, where women tended to use more positive emotion words (Pennebaker, 2011). On the whole, men did talk more, but the equity ratio for total words was near one. Thus, this statistically significant difference may have less practical significance.

Figure 2 shows pronoun usage by gender. Men used significantly more first-person singular pronouns $\chi^2(1, N = 3751) = 71.34$, p = $3 * 10^{-17}$, Cramer's V = 0.44 (medium-large effect size), and more second-person pronouns, $\chi^2(1, N = 5121) = 24.25$, p = $8.4 * 10^{-7}$, Cramer's V = 0.26 (medium effect size). There were no significant differences for first-person plural pronouns.

These results related to pronoun usage add a second layer of understanding. Across prior studies, women tended to use more first-person singular pronouns (Pennebaker, 2011), but the opposite was true here. This would generally indicate that the women were of higher status in these conversations, which is possible, but would contradict one would expect based on prior studies. Men used more second-person pronouns, which does provide some indication of higher status, but these equity ratios were much closer to one than for first-person singular.

To interpret such results, I considered the pairings of students based on gender. Of the conversations that included women, 42 of them were entirely women groups, and 29 of them were mixed gender. This indicates that women were mostly talking with their women peers, which may have had an impact on status differences. Moreover, in the cases where there were mixed-gender groups, these were chosen by the students, and they were typically friends in the class. This may have also had an impact. Finally, one must also consider that peer conferences themselves could have been effective in mitigating some power differentials in the classroom, because they are highly-structured and generally take place between two students.

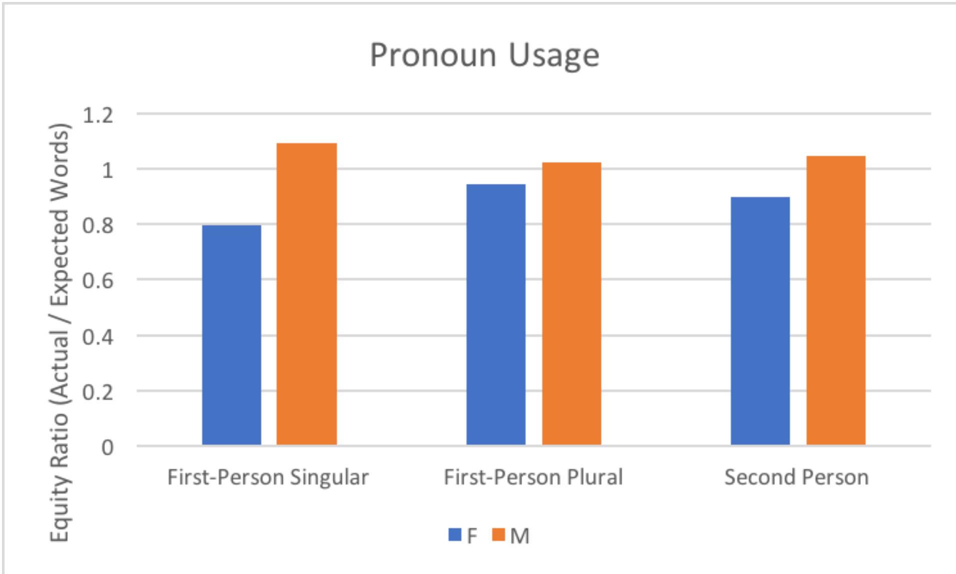

*Figure 2. Pronoun usage by gender*

**Discussion**

Promoting equity in classroom interactions is a challenge and an ongoing concern (e.g., Adiredja & Andrews-Larson, 2017). This paper offers a new method for studying such issues: analyzing pronoun usage in a peer discussion to study status differences. In future studies, this methodology could be used in conjunction with qualitative analyses to provide a deeper picture of such equity issues.

The paper also contributes a baseline understanding for gender differences in talk in undergraduate mathematics. The results are somewhat surprising, suggesting that the women in the class were actually of higher status in the peer conversations. Of course, further study is required, but this result suggests that peer conferences could be a powerful tool for promoting equity in the classroom space. They have a number of affordances that support more equitable interactions: they position students as competent, they are generally between two students, and they are highly structured. This structured nature of the activity makes it more likely that students from different groups will have an equal opportunity to contribute, rather than allowing historically dominant students to dominate. These are all issues for further study.

Extending Prospective Secondary Teachers' Example Spaces for Functions

Rina Zazkis
Simon Fraser University

*The focus of this study is on secondary school teachers' example spaces for the concept of a function. This is examined via participants' responses to a scripting task – a task in which participants are presented with the beginning of a dialogue between a teacher and students, and are asked to write a script in which this dialogue is extended. The examples for a function under certain constraints provide a lens for examining participants' concept images of a function, as well as what they perceive to be concept images of their students. These scripts are then used as a springboard for extending participants' example spaces.*

*Keywords:* function, script writing, example space

A function is a fundamental concept in mathematics. A large amount of literature in mathematics education has attended to this concept over the past 50 years (e.g., Dubinsky & Wilson, 2013). Researchers have identified conceptual difficulties associated with the concept, such as recognizing what a function is (or is not) (e.g., Breidenbach, et al., 1992, Clement, 2001) or recognizing a function in its various representations (e.g., Thompson, 1994). This study is focused on the examples of functions generated by a group of prospective secondary school teachers in an imagined instructional situation.

## Example Spaces and their Features – Theoretical Underpinning

Watson and Mason (2005) introduced the notion of example spaces, which are collections of examples that fulfill a specific function. They argued that learner generated examples (LGEs) are valuable pedagogical tools. Zazkis and Leikin (2007) extended this argument, noting that LGEs are also a valuable research tool, because the examples individuals generate provide researchers with a lens into their cognitive structures.

Watson and Mason (2005) distinguished between personal example spaces, which are triggered by a task, and collective and situated example spaces, which are local to a classroom or other group at a particular time. In a follow up study, Sinclair, Watson, Zazkis and Mason (2011) described features of personal example spaces:

> *Population*: refers to the scarcity or density of available examples.
> *Generativity*: refers to the possibility of generating new examples within the space using given examples and their associated construction tools.
> *Connectedness*: refers to whether examples are disconnected, loosely connected, or well-connected.
> *Generality*: refers to the extent to which the given example is specific or whether it is representative of a class of related examples. (pp. 301-302).

This study stems from the assumption that examples generated by the participants illustrate their concept images (Vinner, 1983) as well as features of their personal example spaces.

## The Study

Twenty prospective secondary school teachers participated in the study. They held degrees in mathematics or science, with extended coursework in mathematics (usually a minor) required for teaching certification. At the time of data collection they were in the final term of their teacher education program, enrolled in a course titled "Investigations in Mathematics". Extending teaches' knowledge of school mathematics while drawing explicit connections to disciplinary mathematics was an explicit goal of the course.

During the course the participants completed a series of scripting tasks (e.g., Zazkis & Kontorovich, 2016). In each scripting task participants are presented with a prompt, which is the beginning of a dialogue between a teacher and students. They are asked to continue the dialogue in a way that reflects how they imagine the instructional interaction may progress. In addition to writing a script (Part-A), they are asked to explain their choice of instructional approach (Part-B) and to note if their personal understanding of the mathematics involved in the task differs from what they chose to include in a conversation with students (Part-C).

Participants' responses to the 'Table of Values' scripting task comprise the data corpus for this study. The associated prompt is presented in Figure 1.

Teacher: Consider the following table of values. What function can this describe?
Alex: y = 3x
Teacher: And why do you say so?
Alex: Because you see numbers on the right are 3 times numbers on the left
Jamie: I agree with Alex, but is this the only way?
Teacher: …

| x | y |
|---|---|
| 1 | 3 |
| 2 | 6 |
| 3 | 9 |
| 4 | 12 |
| 5 | |
| 6 | |

*Figure 1: A prompt for the Table of Values scripting task*

The scripts developed by participants were analyzed with a focus on the particular examples of functions considered in the dialogues. The following research question guided the analysis: What are the participating teachers' example spaces for a function that contains the four given points? Part-C of the task is of major importance as it helped distinguish between instructional choices, in which examples can be purposefully limited, and the participants' personal example spaces triggered by the task.

## Results and Analysis

The analysis is presented by the main themes that were identified in the scripts. In designing the prompt, Jamie's question, "is this the only way" was intended to direct the script-writers to consider alternative functions. However, in several scripts the question led to alternative ways of describing the identified relationship, either by giving alternative algebraic expressions or by considering the relationship recursively. In what follows, after presenting "the other ways" to describe y=3x, we highlight several repeated features in the script-writers' example spaces.

### Different Ways of Describing y= 3x

In four scripts, exemplified in the excerpt by Charlie below, the examples of a different way to represent the y=3x function included various expressions that can be simplified to get 3x. The example spaces of these script-writers appears limited by the suggested linear relationship concluded from the table of values.

*Teacher*: Do you have another way Jamie?
*Jamie*: When I did it I came up with an equation $= x^2 + (3 - x)x$ .
*Alex*: No, the relationship is clearly linear you can't be right.

*Teacher*: Well Alex and Jamie, why don't you two find some board space with the rest of your classmates and investigate the different approaches together. First just try to confirm if substituting the values gives you what you expect.

*Alex*: I can't believe it, and I really don't understand how Jamie's equation can be right because it looks so wrong, but when we substitute the values for y we get the expected values for x.

*Teacher*: Well this is the beauty of mathematics; things can be represented different ways. I challenge you two to come up with a way to show the two equations will or will not always yield the same response.

**[…]**

*Alex*: I think I see the teachers point. Although it may be the same equation, we can represent it differently. Watch… $y = 3x$ … $x = \frac{y}{3}$

*Jamie*: Then I guess we could also just say… $0 = 3\mathrm{x} - \mathrm{y}$

*Alex*: Ohhh right I didn't even consider that!

Teacher: This is excellent work; Jamie, do you have any idea what the equation you just came up with is called?

The dialogue in Charlie's script continued to consider how to determine whether the presented relationship is linear. The commentary that Charlie provided (in Parts B and C of the task) did not mention alternative functions, rather, it focused on the value of different representations, reconfirming the teacher-character's claim that "things can be represented different ways". This leads to the conclusion that the population feature of Charlie's personal example space triggered by the prompt was limited to different representations of 3x, rather than resulted in the consideration of different functions.

**Identifying the Relationship Recursively**

In a search for an additional way to describe y=3x, three script-writers focused on describing the identified pattern recursively. An excerpt from Angel's script exemplifies this approach:

*Teacher*: What was the pattern we were seeing?

*Alex*: We just add 3 to get the next value.

*Teacher*: Perfect, so we can rewrite our y values so they show that relationship. $y_2 = y_1 + 3$ and $y_3 = y_2 + 3$. What would $y_4$ be?

*Jamie*: It should be $y_3 + 3$ right?

*Teacher*: Exactly right. And what would $y_{10}$ be?

*Alex*: $y_9 + 3$

*Teacher*: And what about $y_n$ ?

*Jamie*: $y_{n-1} + 3$ ?

In this excerpt, the identified linear relationship is explicitly linked to its recursive description, pointing to the connectedness of (this part of) Angel's example space.

**Focusing on Domains**

Eight scripts included an example of the function y=3x, in which the domain was restricted to integers or to natural numbers. In five scripts out of these eight the issue of domain was explicitly mentioned (as is demonstrated in the excerpt from Jill's script), where in others it was implied graphically, by plotting the dots, but not connecting them.

*Teacher*: You plotted the points in the table of values, totally correct. Then you connected the dots using a straight line, what is the assumption here?

*Alex*: Assumption? ……
*Teacher*: The table of values only gives you the natural numbers, 1, 2, 3, and so on.
*Alex*: Oh, I guess I assumed that all the points in between follow the same pattern.
*Jamie*: Well, I guess so too. But now that the teacher mentioned it, maybe the points in between don't have to follow the same pattern?
*Alex*: I guess so… because they are not in the table of values anyways.
*Teacher*: That's right! So what other functions can you have?
*[Alex and Jamie look at the graph and think.]*
*Alex*: Can we just have those points in the table of values?
*Jamie*: Like this?
*Alex*: Yah. It looks a little wired. But it is still a function, right?
*Jamie*: Right, because it passes the vertical test. It is a function. How do we write the equations then?
[*Alex and Jamie feel stuck here.]*
*Teacher*: What is the difference between graph 1[line] and graph 2 [only discrete points]?
*Jamie*: Graph 1 has all the x values, and graph 2 only has natural numbers.
*Teacher*: Can you describe this difference in more mathematical terms?
*Alex*: They have different domains?
*Teacher*: Right, now, can you write the domains for both functions?
*Alex*: The first one is all real numbers.
*Jamie*: The second one is all natural numbers.
*Teacher*: Exactly, when you write the equations, you need to specify domains. By restricting the domains, you have different functions.

In this excerpt we note connectedness of Jill's examples, highlighting their different attributes. We further note that student-characters consider "vertical line test" as the main identifying criterion for a function, which points to Jill's awareness of this tendency.

**Connecting the points and "covering" the real numbers**

While in the above excerpt from Jill's script the teacher confronts students' tendency to connect the points, in other scripts "connecting the points" appears to be the convention that is either supported or invited by the teacher. Taylor exemplifies this tendency:

*Teacher*: Excellent question Jamie [.… ] Why don't we start by plotting these points. And by we I mean you. [Student plots the points]
*Teacher*: Good, so how would it look if we used Alex's function?
*Jamie*: It would have a straight line through all the points.
*Teacher*: Yes, but how else can we connect these points?
*Jamie*: I suppose we could do a zig zag line.
*Teacher*: Sure, that would work. But we want this to be a function, so what rule do we need to follow?
*Jamie*: The vertical line test.
*Teacher*: Which is the easy way of remembering what?
*Jamie*: Each output can only have 1 input.
*Teacher*: Correct, so how can we connect these points then?
*Jamie*: Any way we want as long as we don't break the vertical line test.

In this excerpt "how else can we connect these points" is the teacher's question, which leads students to explore various connections, in addition to the straight line, implicitly restricting the domain to all real numbers. While connecting the points limits the population feature of example spaces, various ways of connecting the points "anyway we want" indicate generativity, as well as the generality, of Taylor's example space.

**Acknowledging a Polynomial**

A possibility of a polynomial function that can be generated from the given table of values was mentioned by three participants. It is exemplified by Logan below:

*Teacher*: Well in all of these cases we have assumed something subtle. If we filled the table of values what would we get for the remaining y entries?

*Alex*: 15 and 18

*Teacher*: Does it have to be those values? What if I put 16 and 23?

*Jamie*: … Can you do that?

*Teacher*: Why not? The points could be modeling anything! There is nothing there that says it has to be a line.

*Jamie*: Can we find an equation for that though?

*Teacher*: Certainly, but I need to talk about degrees of freedom. In our table of values we could make up 6 values of y and therefore we have 6 degrees of freedom. Simple enough?

*Jamie*: Mhmm.

*Teacher*: So we need to find a polynomial with at least 6 degrees of freedom to describe it, that is a polynomial with at least 6 terms.

*Alex*: So a $5^{th}$ order polynomial?

*Teacher*: Exactly Alex, we could find a polynomial of the form $y=ax^5+bx^4+cx^3+dx^2+ex+f$ that fits the table of values.

*Jamie*: But how can we ever assume that any patterns we see in a table of values continues?

*Teacher*: An excellent question, short answer is we don't. When we make these equations we are assuming that the trend we observe will continue. When making this assumption we need to look for reasons to explain the trend and then ask if we expect those factors to stay the same. Maybe the data was showing the population of a species but at x=5 more food is introduced or a predator is removed and the species can grow at a faster rate.

While general solutions are often considered in mathematics as more valuable than specific ones, Zazkis and Leikin (2008) noted that often general examples point to an individual's inability to generate a specific one. In this case, the possibility of a polynomial function can be seen as a generality of Logan's personal example space, while it may also point to inability to generate a specific polynomial function.

While Logan noted the existence of a polynomial function, Corey provided such a function "out of the blue" and left it for students to verify that it is consistent with the entries on the table of values.

*Jamie*: It's kind of obvious that it's y = 3x. What are we learning here?

*Alex*: I guess it's making us think outside the box a little, but yeah, our other answers are kind of lousy. […]

*Teacher*: Then let me give you an extension. Check out this function

$$y = x^4 - 10x^3 + 35x^2 - 47x + 24.$$

*Alex*: Where did you get that from?

[…]

*Alex*: But it's not a line!

*Jamie*: Who cares? It's a function. And I guess it takes going to the power of four to hit all four points.

*Teacher*: I'll leave you to it. Figure out how to derive that equation! I didn't just pull it out of thin air.

In his commentary in Part-C, Corey added that the polynomial was generated by a computer program, using matrices to solve systems of equations. He felt, however, that this material was inappropriate for his students. Corey wrote: "The level of math needed to determine the final function is beyond what I consider high school level math. After being given the function the answer can be easily revealed, but it still is not easy."

**"Shield"**

A *shield* is the term used by Koichu and Zazkis (2013) to describe a situation in which a script writer elaborates on related concepts or pedagogical strategies to avoid dealing with the mathematical core of the task. In the Table of Values task, the intended mathematical core involved responding to a student's question, "is this the only way", and in exemplifying a variety of alternative functions that result in values consistent with the table provided in the task.

However, in three scripts the student question was not addressed and no additional example for a function that fits the table of values was provided. Instead, the dialogues focused on either revisiting the notions of slope and intercept (review as a shield) or creating additional tables of values from which a unique formula was to be determined (extension as a shield). From the commentary that accompanied these scripts we conclude that these participants have not considered any examples of functions that satisfy the given table of values, beyond y=3x.

**Features of the Examples**

The scripts provided a lens on what instructional examples teachers plan to use and how they imagine students' ideas about functions. Since most of the script writers did not provide additional examples in Part-C of the task (how their self-explanation differs from what they chose to discuss with students) the examples mentioned in the scripts, either by student-characters or by the teacher-characters, reflect participants' personal example spaces. While the population feature of participants' example spaces was not extensive, generativity was a feature in scripts that involved multiple examples.

In addition, the examples clearly address the expected students' belief that a function should be described by a single formula (e.g., Vinner and Dreyfus, 1989). Script-writers either relied on their experience with students or their personal former confusion, and addressed this expected student belief via creating student characters, who believe that "other points follow the same pattern" (see excerpts from Angel, Logan and Jill above). Moreover, students' reliance on the "vertical number test" (see Wilson, 1994) was clearly present in scripts as an identifying feature for a function (see excerpts from Taylor and Jill above).

The chosen examples of participants reported herein also point to teachers' concept image of a function that was not elaborated upon in prior research: that the domain of a function is infinite and unbound. Focusing on the domain, Bubp (2016) noted that in an attempt to prove mathematical statements students often used "implicit, unwarranted assumption that the domain of the function $f$ was $\mathbb{R}$ "(p. 592) and that "a function cannot have a restricted domain" (p.593). While such assumptions were not apparent in our data, even in the examples where the domain was restricted to integers, it still included infinitely many points. No example of a finite domain or of a function on a bound interval was provided. In addition, there was a repeated tendency to consider continuous functions.

## Follow up Discussion

The scripts provide not only a valuable lens for a researcher for investigating participants' understanding of a concept, they also provide valuable information for a teacher educator for orchestrating a follow up discussion. The examples provided in the scripts constitute the collective example space of the participants. Once the scope of the collective example space is understood, there is an opportunity to extend the participants' example spaces via presenting alternative prompts or in class discussion.

An alternative prompt, in which there was no "easily determined" polynomial function, was presented to the participants (see Figure 2) after the original Table of Values task. This served as a scaffold for ideas and led to the consideration of "split domain" and multiple examples of functions defined piecewise – a family of examples that was not explicitly featured in the responses to the original prompt.

| | |
|---|---|
| Teacher: | Consider the following table of values. What function can this describe? |
| Alex: | It doesn't fit a function. |
| Teacher | And why do you say so? |
| Alex: | For 1, 2 and 3 you clearly see that this is x-squared. But for 4 it isn't. |
| Teacher: | And what about other values? |
| Janie: | I see that there is another pattern. 11= 4×3-1; 14=5×3-1, so 3x-1, same for 6. |
| T: | Interesting… |

| x | y |
|---|---|
| 1 | 1 |
| 2 | 4 |
| 3 | 9 |
| 4 | 11 |
| 5 | 14 |
| 6 | 17 |

*Figure 2: A prompt for the New Table of Values scripting task*

The ensuing in-class conversation focused on considering potential student misconceptions related to the concept of a function as well as on further extending teachers' personal example space. For example, consistent with Clement (2001), most teachers' expressed the belief that a table of values or set of ordered pairs do not identify a function, but are derived from a function.

Furthermore, the in-class discussion focused on how to identify a polynomial non-linear function consistent with the given table of values. While teachers easily generated a function that has zeros in 1,2,3 and 4 [$f(x) = (x-1)(x-2)(x-3)(x-4)$], it was a conceptual leap to combine it with the $g(x) = 3x$ (suggested by the table of values in Fig. 1) to generate a family of polynomial functions $h(x) = kf(x) + g(x)$. Of note, for $k = 1$, $h(x)$ is simplified to $x^4 - 10x^3 + 35x^2 - 47x + 24$, which is the function that a computer program generated for Corey.

## Conclusion

It was noted in prior research that scripts generated by teachers provide a lens – for researchers and teacher educators – for examining teachers' mathematical knowledge and their instructional choices (e.g., Zazkis, Sinclair & Liljedahl, 2013). Extending this observation, the presented study demonstrates that scripts provide a lens for studying participants' personal example spaces, as well as the perceived limited example spaces of their imagined students. Most scripts attempted to confront a student idea that a function should be represented by a single formula. In addition, the chosen examples pointed to specific identifying features of teachers' example spaces of functions: unbound domain and continuity. Further research will investigate whether these features point to ideas broadly held, or were specific to the given task.

**Katlyn's Inverse Dilemma: School Mathematics Versus Quantitative Reasoning**

Teo Paoletti
Montclair State University
paolettit@mail.montclair.edu

*In this report, I examine the interplay between Katlyn's (an undergraduate student's) inverse relation (and function) meanings developed through her continued school experiences and her reasoning about relationships between quantities. I first summarize the literature on students' inverse function meanings and then provide my theoretical perspective, including a description of a quantitative approach to inverse relations (and functions). I then present Katlyn's activities in a teaching experiment designed to support her in reasoning about a relation and its inverse relation as representing an invariant relationship. Although she engaged in such reasoning, her continued school mathematics experiences constrained her in reorganizing her inverse function meanings. I conclude with a discussion and areas for future research.*

Keywords: Inverse Function, Inverse Relations, Preservice Teacher Education

Researchers examining students' quantitative reasoning (Thompson, 2011) have found that students can develop foundational meanings for various concepts such as linear (Johnson, 2012) and exponential functions (Ellis, Ozgur, Kulow, Williams, & Amidon, 2012) by reasoning about relationships between quantities *before* developing more formal mathematical understandings. In contrast, examinations of students' inverse function understandings have found students often maintain disconnected inverse function meanings after they have received instruction (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Vidakovic, 1996). I conjectured quantitative reasoning could potentially support undergraduate students relating and connecting their inverse function meanings developed through their school experiences. Working with a pre-service teacher, Katlyn, who had K-14 school experiences with inverse function, I investigated how she could potentially re-construct her inverse function meanings via her reasoning quantitatively. In this report, I present Katlyn's progress in a semester-long teaching experiment intended to investigate the question: How does a student's quantitative reasoning interplay with her inverse function meanings developed through her continued school mathematics experiences?

## Research on Inverse Function

Vidakovic (1996) proposed that students develop inverse function schemas in the following order: (a) function, (b) composition of functions, then (c) inverse function through a coordination of (a) and (b). Whether implicitly or explicitly, many researchers (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Vidakovic, 1996) examining students' inverse function meanings have emphasized composition of functions and the formal mathematical definition (i.e. $f$ and $f^{-1}$ are inverse functions if $f(f^{-1}(x)) = f^{-1}(f(x)) = x$) as paramount to students developing productive inverse function meanings. However, these and other researchers have found students often maintain disconnected (from the researcher's perspective) inverse function meanings, often related to executing certain activity in analytic rule or graphing representations (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Paoletti, Stevens, Hobson, LaForest, & Moore, 2015). For instance, students often use a "switching-and-solving" technique when determining the inverse function of a given function represented by an analytic rule (i.e., given $y = x - 2$ they switch the variables and solve for $y$ to obtain $y = x + 2$) but are experience difficulties interpreting the results of this activity for a contextualized analytic rule. The extent to which students relate their switching-and-solving technique or their other activities to function composition is an open question. The current body of research indicates that current approaches to teaching inverse function have been ineffective in supporting students in developing interrelated inverse function meanings. In this report, along with Paoletti (2015), which I elaborate on below, I begin to address the evident need to re-conceptualize ways to support students developing sophisticated inverse function and inverse relation meanings.

## Theoretical Framing

I examined the possibility of supporting students developing inverse relation (and function) meanings via their reasoning about relationships between quantities. A *quantity* is a conceptual entity an individual constructs as a measurable attribute of an object or phenomena (Thompson, 1994, 2011). An individual constructs *quantitative relationships* as she associates two varying (or non-varying) quantities (Johnson, 2012; Thompson, 1994). As an individual constructs and analyzes these relationships, she engages in *quantitative reasoning* (Thompson, 1994).

Specific to inverse relations, I conjectured if a student constructed a (non-causal) quantitative relationship between two quantities (e.g., quantities A and B), then she could decide to consider one quantity as the input of a relation (e.g. B input, A output) whilst anticipating the other quantity would be the input of the inverse relation (e.g., A input, B output). By focusing on the underlying quantitative relationship, the 'function-ness' of a relation and its inverse falls to the background; a student can describe and represent a relation and its inverse without (necessarily) being concerned if either represents a function. Further, the student maintains an understanding that choosing input-output quantities does not influence the underlying relationship that the associated relations or functions describe.

I conjectured a student maintaining such understandings can interpret a single analytic rule or graph as simultaneously representing a relation and its inverse relation. With respect to graphing, the student anticipates that either axis can represent the input quantity of a relation. Although this reasoning may seem insignificant, Moore, Silverman, Paoletti, & LaForest (2014) illustrated that students' graphing meanings are often restricted to reasoning about the input quantity exclusively represented on the horizontal axis.

In Paoletti (2015), I demonstrated the feasibility of this way of thinking by presenting one undergraduate student's (Arya's) activities as she reorganized her inverse function meanings compatible with this description. When addressing inverse function tasks in a pre-interview Arya relied on switching techniques (e.g., switching-and-solving) and understood a function and its inverse represented different relationships. Throughout the teaching experiment Arya experienced several prolonged perturbations. Resolving these perturbations supported her in reorganizing her inverse function meanings as well as her meanings for variables and graphs. Specifically, at the conclusion of the study, Arya understood that a relation and its inverse relation, regardless of 'function-ness', represented an invariant relationship. Keeping this invariant relationship in mind, Arya understood a single graph could be interpreted as either a relation or its inverse by choosing either quantity represented on either axis as a relations input. In context, she made sense of the switching-and-solving procedure by changing the quantitative referent of each variable when switching variables (i.e. if $V$ represented volume and $s$ represented side length in the original analytic rule then $V$ represented side length and $s$ represented volume in the inverse analytic rule). Arya's meanings at the conclusion of the study demonstrate both the viability of the ways of thinking described above and one way students can relate their quantitative reasoning to the switching-and-solving procedure.

## Methods and Task Design

I conducted a semester-long teaching experiment (Steffe & Thompson, 2000) with Katlyn and Arya (pseudonyms), two undergraduate students enrolled in a secondary mathematics teacher education program. The students were juniors who had successfully completed at least two courses beyond a calculus sequence. I engaged the students in three individual semi-structured clinical interviews (Clement, 2000) and 15 paired teaching episodes. Clinical interviews and teaching episodes provided flexibility to create and adapt tasks to explore how students might develop meanings compatible with those I described. Specifically, I used clinical interviews as one pre and two post interviews to develop models of Katlyn's mathematics (Steffe & Thompson, 2000), including her quantitative reasoning and her inverse function meanings, without intending to create shifts in her meanings. I used teaching episodes to examine the viability of my hypothesized models and to pose tasks I conjectured might create perturbations for Katlyn, possibly leading her to make accommodations to her meanings.

I analyzed the data using open (generative) and axial (convergent) approaches (Strauss & Corbin, 1998) in combination with conceptual analysis (Thompson, 2008). I developed and refined models of Katlyn's mathematics by initially analyzing the videos identifying episodes of Katlyn's activity that provided insights into her meanings. These instances supported my generating tentative models of her mathematics that I tested by searching for corroborating or refuting activity. When Katlyn exhibited novel activity, I adjusted my models to explain this activity including the possibility that this activity indicated fundamental shifts in her meanings. Through this iterative process of creating and adjusting hypotheses of Katlyn's mathematics, I was able both to characterize her thinking at a specific time and to explain shifts in Katlyn's meanings throughout the teaching experiment.

I first raised the notion of inverse function in the *Graphing Sine/Arcsine Task* (Figure 1). The research team designed this task to support students in developing inverse relation meanings compatible with those described above. The first two prompts ask students to create graphs of the sine (Graph 1) and arcsine, or inverse sine, (Graph 2) functions. The third prompt asks the students to consider how they could interpret Graph 1 as representing the arcsine function. This prompt also asks the students to consider if Graphs 1 and 2 represent "the same relationship." I conjectured asking the students to foreground the "relationship" represented by the graphs might support them in conceiving either quantity, on either axis, could represent the input of a relation in order to conceive Graph 1 as representing both the sine and arcsine functions or relations.

| | |
|---|---|
| Graph 1: | Create a graph of the sine function with a domain of all real numbers. What is the range? |
| Graph 2: | Using **covariation talk**, create and justify a graph of the arcsine (or inverse sine) function. |
| Prompt 3: | Can you alter (**do not draw a new graph**) Graph 1 such that it represents the graph of the arcsine function? Does this graph convey the same relationship as the second graph? How so or how not? |

*Figure 1*. The Graphing Sine/Arcsine Task.

## Results

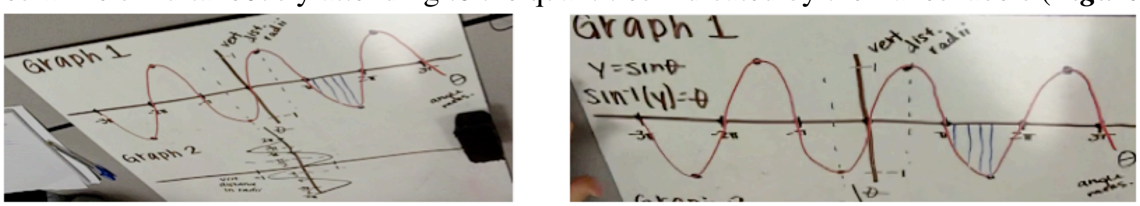
I first present analysis from the initial clinical interview that provides insights into Katlyn's inverse function meanings relevant to this report. I then present her activity addressing the prompts in the Graphing Sine/Arcsine Task. I conclude with Katlyn's activity in the final clinical interview, highlighting the interplay between her quantitative reasoning and her inverse function understandings developed through her continued school mathematics experiences.

### Results from the Initial Clinical Interview

During the initial interview Katlyn's predominate meaning for inverse functions involved "switching." For example, given the equation $C(F) = (5/9)(F - 32)$ defining the relationship between degrees Celsius and degrees Fahrenheit, Katlyn switched $C$ and $F$ and solved for $C$ determining the inverse rule $C^{-1}(F) = (9/5)F + 32$. Given a line representing the relationship between temperature measures, Katlyn estimated values of several coordinate points then switched abscissa and ordinate values to determine points on a line she drew to represent the inverse function. In both cases, Katlyn was uncertain how to interpret the results of her activity in relation to temperature measures indicating she did not attend to the underlying quantities when engaging in these techniques. For example, Katlyn identified that the point (10, 50) on the given line represented that 10 degrees Fahrenheit corresponds to 50 degrees Celsius but when interpreting the point (50, 10) on her constructed line Katlyn said, "My whole reasoning in this entire process… is switching $x$ and $y$, is switching $C$ and $F$ which is how I came up with this graph. So I don't necessarily know what... the new graph would stand for." Katlyn did not assign any meaning in relation to temperature measures to the point (50, 10) on her constructed graph representing the inverse function.

**Reasoning about the Sine and Arcsine Relationships**

In the first four teaching episodes the students represented the relationship between angle measure and vertical distance above the horizontal diameter in a circular motion context and understood this relationship was defined by the sine function, compatible with the descriptions of Moore (2014). After these episodes, I prompted the students with the Graphing Sine/Arcsine Task. They carefully attended to the quantitative relationship between angle measure and vertical distance as they created Graph 1, then constructed Graph 2 by switching abscissa and ordinate values while simultaneously attending to the quantities indicated by their axes labels (***Figure 2***a).



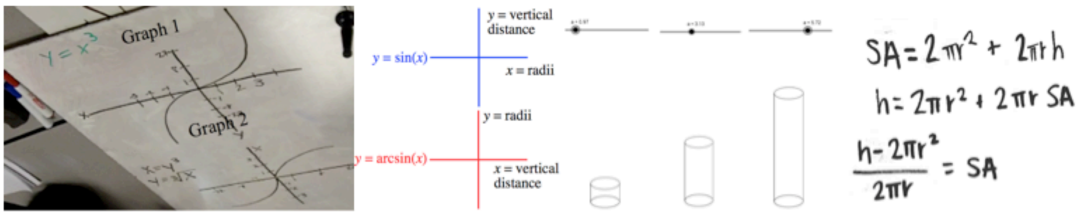
(a) (b)

*Figure 2*. The pair's (a) Graph 1 and Graph 2 and (b) Graph 1 with added equations.

Having drawn both graphs, the pair set out to address Prompt 3. Katlyn wrote $y = \sin(\theta)$ next to Graph 1, indicating this was the equation they initially represented with Graph 1. She then added $\sin^{-1}(y) = \theta$ below $y = \sin(\theta)$ (see added labels in ***Figure 2***b). Katlyn anticipated considering vertical distance as her input, represented on Graph 1's vertical axis, stating, "We're looking at the $y$ [*pointing to y in* $\sin^{-1}(y) = \theta$], so we go to one [*motioning to 1 on the vertical axis*] and then we're like okay well… which angle's sine is one?" Katlyn motioned horizontally to the three points on Graph 1 with a vertical distance value of one. Continuing to explain her reasoning, Katlyn said, "If we're switching the input and output… So we want theta to be our answer, 'cause then originally theta was our input but now we want it to be our output." As in the initial clinical interview, Katlyn referred to "switching" but in this episode she maintained her focus on the invariant relationship between vertical distance and angle measure as she considered how to interpret Graph 1 as representing a relation with vertical distance as the input quantity. Katlyn reasoned quantitatively to consider a relation and its inverse relation as representing an invariant relationship but with different chosen input and output quantities.

**Considering a Decontextualized then Contextualized Relationship**

Because the students never referenced switching-and-solving when working with the sine and arcsine relations, two teaching episodes later, I asked the pair to address the prompts in Figure 1 for a decontextualized function ($y = x^3$) to investigate if, and if so how, their activity would be different for a decontextualized function. The students drew Graphs 1 and 2 (see Figure 3a) by maintaining the relationship between $x$ and $y$ (e.g., they described that for $x > 0$ with $x$ represented on the horizontal and vertical axis in Graph 1 and Graph 2, respectively, $y$ increased at an increasing rate with respect to $x$). However, the students experienced a perturbation as this graph, which they understood was defined by $x = y^{1/3}$, was not defined by the analytic rule, $y = x^{1/3}$, they had determined by switching-and-solving. This perturbation led the students to question their prior activity with the sine and arcsine relations in which they did not switch-and-solve.



(a) (b) (c) (d)

*Figure 3*. (a) The pairs decontextualized graphs, (b) the color-coded axes with Katlyn's added labels, (c) the cylinder animation, and (d) Katlyn's work.

Intending to maintain the students' focus on quantitative relationships, I contextualized this function as representing the volume and side length of a cube ($V = s^3$) as I conjectured they would not switch the variables to represent the inverse rule in a context. I asked the pair what the inverse rule would be and Katlyn immediately responded "cube root of $V$ equals $s$." I repeated, "cube root of $V$ equals $s$," to which Katlyn refuted, "No, but that's not right." Katlyn experienced a perturbation as she oscillated between her switching technique and maintaining the relationship between volume and side length while maintaining the quantitative referent of each variable.

I asked Katlyn if she knew why she switched variables and she responded, "No, I just remember doing that, that's just our definition… you like switched $x$ and $y$ and solved for $y$ again because in standard position $y$ is [on the vertical axis] and $x$ is [on the horizontal axis]." I considered her argument of "standard position" of $x$ and $y$ as a way to support Katlyn in relating her switching technique and maintaining the underlying quantitative relationship. Drawing attention to the possibility of using variables to arbitrarily represent quantities values, I wrote $y = \sin(x)$ in blue and $y = \arcsin(x)$ in red along with Cartesian coordinate axes next to each (Figure 3b). For each graph, I asked Katlyn to identify the variable and quantity each axis would represent if she were going to graph each rule. Responding to this, Katlyn used the variables $x$ and $y$ arbitrarily to define angle measure and vertical distance to represent the input with the variable $x$ on the horizontal axis in each graph (see black labels in Figure 3b).

After this Katlyn described her reasoning about the inverse function in the side length-volume context, arguing, "We've just been saying like we need to switch them in the equation [*pointing to* $y = x^{1/3}$] but like, we're like switching them in real life." Katlyn then reasoned she had to reassign the quantitative referents of the variables when switching-and-solving (i.e. $s$ represented volume and $V$ represented side length in $V = s^{1/3}$). In the moment, Katlyn understood that in a contextualized situation (e.g., sine and arcsine, volume and side length) a relation and its inverse represented the same quantitative relationship but with different input quantities; she reassigned the quantitative referents of each variable when switching in order to maintain this relationship.

**Results from the Final Clinical Interview**

Based on the described teaching sessions, which spanned two weeks, I conjectured Katlyn potentially reorganized her meanings such that she understood a relation and its inverse represented an invariant relationship with the difference being which quantity she chose to represent the input. I intended to test this conjecture in an interview two months after the last teaching episode addressing inverse relations. I showed Katlyn an applet displaying a cylinder with varying height and a constant radius (Figure 3c) and asked her to determine a relationship between the cylinder's surface area and height. Reasoning quantitatively, Katlyn described imagining the net of the cylinder composed of two circles with constant area and a rectangle with varying area (i.e. $h$ varies and $r$ is constant) and determined the analytic rule $SA = 2\pi r^2 + 2\pi rh$. She drew a linear graph and described the relationship stating, "As like the height is increasing, surface area is also increasing." Conjecturing Katlyn was capable of considering surface area as the input, I asked, "Is there another way to read [the graph]?" Katlyn responded, "As surface area increases, height increases.... whatever happens to one is like happening to the other one." Although Katlyn chose to consider height first, she anticipated this was only one of the options; from my perspective Katlyn reasoned about a relation and its inverse relation as she anticipated coordinating either quantity varying first.

I asked Katlyn to determine the inverse analytic rule conjecturing she would maintain the relationship she had described. However, Katlyn switched-and-solved (Figure 3d). I asked Katlyn to "talk me through what you did there", and she responded:

*Katlyn:* It's funny that you say that 'cause I'm tutoring two girls and we were doing inverses yesterday. And I don't, and I still can't explain why we do this. I was trying to think of a way to explain it to them, and I didn't know the answer. Um [*pause*]. Because that's what I've been told to do for six years…

*TP:* Okay. So you said you were just tutoring someone on this?

*Katlyn:* Yeah, and… they were just like, 'well how do I do it?' And so I told them, like you have to make sure the… function is one-to-one so like for every… input there's only one output and for every output there is only one input. All that nonsense that doesn't, I don't really know why we do that. But that's what has to happen before you can switch your input and output and then solve. So, why do we do this? I don't know. But I know this is what the answer is and I. Yeah, I don't know.

*TP:* Okay and so this is the answer [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]?

*Katlyn:* Yes. Yeah, yeah.

*TP:* But, you're sort of also acting like there's something you're not comfortable with about it.

*Katlyn:* I just don't know what it means, like I don't, why do I care about this [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]?

*TP:* So say a little bit more what do you mean you don't know what this [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$] means?

*Katlyn:* I don't know what it means. I know [$SA = (h - 2\pi r^2)/(2\pi r)$] is the inverse, for surface area of a cylinder. That is all I know. Why is it the surface area? What does it, what does the inverse for surface area mean? I guess I'm thinking like. [*pause*] Okay, it reminds me of that time that we were doing like volume of a cube being like side-squared and then we switched the two and then I was like, okay so now, $s$ means volume and $V$ means side[length]. So now does here, [*pause*] surface area mean height and height mean surface area? Or did we just not finish the problem in class to conclude about what, I don't, I don't remember. I have no idea why we do this.

*TP:* So, you're starting to say here [*pointing to* $SA = (h - 2\pi r^2)/(2\pi r)$]. If, if $SA$… represented height, and $h$ represented surface area?

*Katlyn:* Well, it wouldn't make any sense. Because then it would just be the same. Like if you multiplied [$SA = (h - 2\pi r^2)/(2\pi r)$] all back out you would get [$SA = 2\pi r^2 + 2\pi rh$], I guess. And so like I'm attributing [$SA = (h - 2\pi r^2)/(2\pi r)$] to be the same thing where this is now height [*pointing to SA in* $SA = (h - 2\pi r^2)/(2\pi r)$] and this is now surface area [*pointing to h in* $SA = (h - 2\pi r^2)/(2\pi r)$]. That doesn't make any sense. We might as well have kept it that way [*indicating* $SA = 2\pi r^2 + 2\pi rh$]. [*pause*] That's probably not right then cause it has to mean, it has to mean something different.

From my perspective Katlyn described the relation and its inverse prior to the term "inverse" being raised but reverted to switching-and-solving when asked about the "inverse". She engaged in this technique, which she learned as a student and was reinforced as a tutor, despite her being reflectively aware that she did not know *why* she engaged in this activity (e.g., "So, why do we do this? I don't know") or *how to interpret* the activity's results (e.g., "*I just don't know what it means*… why do I care about this"). Katlyn recalled the volume-side length situation from months earlier and considered switching the quantitative referent of each variable. However, she rejected this as the inverse rule would represent the same relationship as the original rule leading her to conclude a function and its inverse function must represent different relationships (e.g., "That doesn't make any sense. We might as well have kept it that way").

## Discussion and Concluding Remarks

Katlyn's story exhibits difficulties students may encounter when attempting to reason about relationships between quantities by leveraging their non-quantitative mathematical meanings. Compatible with Arya (Paoletti, 2015), Katlyn reorganized several of her meanings during the teaching experiment (i.e., using variables arbitrarily to represent quantities). However, these reorganized meanings did not lead to shifts in her inverse function meanings. One possible explanation is that Katlyn engaged in in-the-moment activity (potentially both in the study and in her tutoring) to assuage a perturbation without reflecting on if her activity was related to other contexts or situations.

Despite not reorganizing her meanings, Katlyn's inverse function meanings at the end of the study were not significantly different than other students' meanings researchers have characterized (Brown & Reynolds, 2007; Kimani & Masingila, 2006; Paoletti, Stevens, Hobson, LaForest, & Moore, 2015; Vidakovic, 1996). Thompson, Phillip, Thompson & Boyd (1994) distinguished between teachers maintaining calculational and conceptual orientations, noting the latter "focus students' attention away from thoughtless application of procedures and toward a rich conception of situations, ideas and relationships among ideas" (p. 86). If a teacher maintains inverse function meanings similar to Katlyn's, she will be unable to support her students in developing a rich conception of relationships among ideas and instead will have to focus on a thoughtless application of the switching-and-solving technique (i.e. "I was trying to think of a way to explain it to them, and I didn't know the answer…"). Hence, future researchers should continue to address calls (Thompson, Phillip, Thompson & Boyd, 1994; Thompson, 2008) for increased focus on ways of reasoning that support future teachers development of rich conceptions of ideas and relationships among ideas that they can call on in their teaching.

# Planning to Succeed in a Computer-Centered Mathematics Classroom

Geillan Aly
Hillyer College, University of Hartford

*Most developmental mathematics students in community colleges, particularly those of color, are unsuccessful and fail to reap the benefits of higher education. In-class computer-centered (ICCC) classes are a possible solution to this issue because students work independently at computers during class time while instructors facilitate learning by answering students' questions. This case study focuses on one student's ICCC classroom experience by focusing on how the student's plan to pass the course were validated by the classroom environment. Ultimately, that plan was insufficient to address the needs of the student.*

*Keywords:* Developmental mathematics, computer-centered learning, student agency

Many high school graduates who want a postsecondary education turn to community colleges to further their academic development or acquire credentials and job training leading to hitherto inaccessible opportunities. Yet their mathematical background obstructs this path when they place into developmental, not college-level, mathematics courses. Mathematics departments have introduced in-class computer-centered (ICCC) classes to support these students, providing a flexible environment to help struggling students proceed at their own pace, meeting their academic and personal needs. Whether or how students use this flexibility is not yet clear.

Research examining the ICCC class compares achievement outcomes and result vary. What has not yet been fully explored is the set of actions students take to learn mathematics in this setting. Plans and actions are key to student learning – and in a computer environment in which students have significant independence – it is important to consider the role of agency in students' engagement in the course. In this study, I focus on the plans students make to achieve their goals, how the course structure validates a plan, and what interferes with a plan's execution. Ultimately, this study sheds light on how a classroom setting designed to be flexible around the needs of as-yet-unsuccessful students supports or hinders their mathematics learning.

## Addressing Remediation in the Community College

Many students do not complete postsecondary degrees because they are not successful in required developmental courses. Of students who entered a public two-year postsecondary institution in 2003 – 2004, 68% took at least one developmental course, with mathematics being the most common (Chen, 2016). Furthermore, passing rates in developmental classes are low and generally disfavor students of color (Bahr, 2008, 2010). Students who need support in such courses are not an anomaly; those who succeed in them are. Furthermore, forty percent of students enrolled in postsecondary institutions and who required remediation did not complete a Certificate, Associates, or Bachelor's within six years (Green & Radwin, 2012). Enrolling in developmental courses reduces the likelihood that a student will achieve their academic goal.

Computer-centered instruction has grown in the United States and is being utilized in many postsecondary institutions to help students improve their mathematics proficiency (Allen & Seaman, 2011). These courses combine student individualization and flexibility with instructor support. In ICCC classes, at least 80% of the content is delivered via stand-alone software during scheduled class time using prerecorded video lectures. Students work online answering questions to test their learning, advancing at their own pace. They can also work outside scheduled class times. Instructors monitor student progress, offering assistance by answering questions. The individualization and autonomy offered by these courses gives students opportunities for agency.

Overall few studies on ICCC mathematics classes focus on the student experience (Webel, Krupa, & McManus, 2016). However, there is no shortage of quantitative studies on computer-centered classes which compare student achievement in a computerized class with another format, usually lecture-based, instructor-centered classes. Results vary as to whether ICCC mathematics classes have higher achievement rates than traditional lecture courses (Bishop, 2010; Carrejo & Robertson, 2011; Herron, Gandy, Ningjun, & Syed, 2012). Many of these evaluative studies do not provide a pedagogical rationale for incorporating technology into the classroom or consider the pedagogical differences between computerized learning and traditional courses (Tallent-Runnels et al., 2006). Such studies for example do not differentiate the role the computer plays over that of a traditional instructor.

One way to theorize the relationship between technology and learning is to consider the student experience rather than achievement since these courses provide options like the flexibility to work at convenient hours and the ability to rewatch lectures, options heretofore nonexistent in traditional classes. This research is needed since this course structure harkens to Earlwanger's (1973) Benny (Webel, Krupa, & McManus, 2015). Recent research in this area showed that computer-centered courses better serve students who do not require significant remediation and improves students' ability to answer familiar problem sets (Webel et al., 2016). Short, focused computerized interventions have also been successful (Li & Ma, 2010; Wladis, Offenholley, & George, 2014) Students in ICCC classes also felt that course requirements necessitated a significant time commitment (Ariovich & Walker, 2014), supporting other findings that time on task related to successful completion (Fay, 2017). Overall, more research is needed to better understand the student experience in this realm.

## Student Agency and ICCC

In ICCC courses, students can choose from a variety of learning activities. This freedom provides students with extensive agency, defined as the set of actions students take to achieve their goal. For example, students have the flexibility to work at their own pace in and out of class (Aichele, Francisco, Utley, & Wescoatt, 2011; McClendon & McArdle, 2002; Vassiliou, 2012; Xu, Meyer, & Morgan, 2009). For example, a single parent can make up for days missed or can work ahead or at home to account for unexpected absences to care for their child.

The agency available in the ICCC classroom is not infinite. The software's didactic approach limits mathematical agency, the ability to develop mathematical conjectures or explore mathematical concepts, by only accepting specific answers or methods. Thus, while students have significant student agency by being able to study when, where, and as much as they want, WHAT they must do to succeed and HOW they demonstrate knowledge is narrowly defined. This paradox of limited mathematical agency, and unlimited student agency provides a tension likely to yield findings on student actions.

In this study, I sought to understand a part of student agency in an ICCC mathematics classroom. More specifically, this study focuses on the intention a student sets, a future goal, action or purposeful outcome, and the basic plan for achieving said goal (Bandura, 2001, 2006, 2008). Without intention to establish purpose, a person's actions could not be considered agentive since they cannot be distinguished from unintended outcomes. Intention is one of four characteristics of agency which Bandura places in the realm of Social Cognitive Theory (Bandura, 1986). According to Bandura, a person's agentive acts are a part of his or her behavior and both affects and is affected by environmental and personal factors.

## Methods

The data presented here come from a larger body of work researching four cases of student agency in an ICCC developmental mathematics classroom. This study reports on only one case, Eduardo, a 24-year-old Hispanic student entering college for the first time. Three research questions were considered: (1) What are the student's intentions in an ICCC developmental mathematics class, (2) what portions of the course structure validate this plan, and (3) what challenges does the student encounter when attempting to fulfill his intention? These questions consider Eduardo's intention while taking into account social-cognitive factors that may contribute to success. The site of this study was a developmental-level mathematics class in a community college in the Southwestern United States, a designated Hispanic Serving Institution where at least 25% of the student body is of Hispanic origin. In the ICCC course, students move from developmental coursework to college-level content using Pearson's MyMathLab software to complete modules, similar to a chapter in a mathematics textbook. Students demonstrate mastery of a module by answering questions on assignments and exams. They are expected to complete twelve modules per semester, completing the course in approximately three semesters.

Over the course of one academic semester, I collected four main sources of data. The first was Eduardo's classroom activity to understand his actions with respect to his intentions. This included over eleven hours (nine classes) of video recordings covering what Eduardo did in class, corresponding recordings of his computer screen, interactions with his instructor, photographs of his written work, and supplemental field notes. Two interviews with Eduardo comprised the second and third sources. They addressed Eduardo's mathematics background, his study habits, his intentions in the class, and clarifying questions to understand his actions. Interviews with the instructor, Shaun, was the fourth source of data and asked about his philosophy when teaching this course and discussed Eduardo's progress.

Eduardo's intentions were identified and coded using template analysis (Ray, 2009). Actions were intentive if a second datum (action or utterance) supported such. In other words, a second source of data must support the determination that a given act had intention. Actions and utterances were also coded based on Bandura's remaining characteristics of agency, forethought, reflection, and reaction. Codes were sorted and counted and explored for code co-occurrences. A second round of descriptive open coding allowed other themes to emerge.

I wrote analytic memos to make sense of the data as they were coded. Analytic memos clarified my reflections on the coding, overall inquiry process, and emergent patterns and themes (Saldaña, 2009). These analytic memos asked and addressed questions of the data. An example of such a question is "What did the participant do after answering a question incorrectly?" Answering these questions helped sort through the data so themes could emerge. These memos were shared with peers to check analysis and findings.

Since multiple types of data were recorded, findings and interpretations were triangulated. Data were collected in multiple class sessions giving long-term and repeated observations that allowed for the development of accurate findings.

## Findings

In ICCC classes, the plans students develop to achieve a specific goal may be validated by the classroom environment. However, these assumptions may have fundamental flaws which could adversely affect whether the goal, passing the class, is achieved. Eduardo is an example of such a case. Eduardo's plan for success centered around working outside of class and relying on the computer, rather than his instructor, to learn mathematics. This plan was based on assumptions that were insufficient because of Eduardo's weak mathematical skills.

**Eduardo's Intentions**

Mathematics courses were required for Eduardo to receive a degree in Business Administration and Management. Results of his placement exam placed him in developmental mathematics, MAT075. Eduardo had a specific goal for massing MAT075. "I'll get my 12 modules done in 5 months" (20:170). Eduardo planned to achieve this goal by working extensively on the course material outside of class and watching videos repeatedly. When Eduardo was asked, "What's your game plan for getting through your 12 modules?" He replied, "Definitely doing 'Homework'. As far as doing that outside of the classroom. Definitely doing that." (20:175). Eduardo intended to and was certain that he could get an A in the course by working outside of class. "I think I'm gonna be doing this more out of class because you get better in math if you practice and practice and practice and I don't think like an hour and a half is much time you know to finally get it" (22:1). Eduardo recognized how important it was to work on mathematics class outside of his class. He also had a computer and high-speed internet at home giving him the ability to work at home at his discretion. The other main component of Eduardo's plan was his decision to extensively use video lectures, which he favored over conventional class lectures. This was demonstrated several times, where Eduardo would replay videos or assert his intention to rewatch videos.

> I'm gonna go over this [video] again at home and then I'll do the concept check. . . . then I'll do it again [watch the video] like probably two more times until [I] master this small piece and then move on to the next one. (5:1)

Eduardo began his next class reviewing his previous work. "I started with the first page [of the corresponding text] so I could refresh my memory on it because I wanted to do that. I want to learn it" (20:75). By reviewing, Eduardo reaffirmed the importance of repetition.

**Factors supporting Eduardo's plan**

Eduardo's plan to pass MATH075 was validated through the design of the software and course structure. These factors supported Eduardo's plan to spend adequate time working through the course and consistently review the content.

The course encouraged students to work as often as possible, placing a stronger emphasis on seat time rather than conceptual understanding. The classroom was available for over 40 hours per week, and was designed so that computers were available to students who were not scheduled to attend, so students could feel free to come in when their schedule allowed. The online nature of the course also allowed students to work outside of class whenever they wanted. Students were also able to work ahead one module, encouraging them to keep working.

Shaun, Eduardo's instructor, expressed how critical it was to maximize seat time and reinforced the importance of working as often as possible. If they were not discussing procedural questions related to the course structure, Shaun and Eduardo's interactions were centered around the idea that spending time outside of class was essential to passing the course.

> [You] might think about what your time is like and can you be in here outside of class. Is there time between classes? Is there time after classes where you don't have to be somewhere right away or before? Can you come in early, you know? You think about your own personal circumstances and see if there's more time that you can squeeze. Any time you can be here, you're welcome here, right. (23:20)

Shaun attempted to help Eduardo with his time-management skills and help Eduardo see multiple opportunities during the day where Eduardo could work on the class.

Eduardo reflected on how the course structure allowed repetition and on the importance of replaying videos and to help him learn.

> I love the structure of it. I think this works out better for me because I could keep - go back and back and back, you know. Reread the video or replay the video over and over again. And sometimes, like, well, the way I learn, you have to, like, tell me a lot of times for me to, like, learn something new until I really get it. So I love it. (5:4)

The feature of the MyMathLab software that he used most often, the videos, was a feature that aligned with his belief in how he learned best. With the course being on computer, Eduardo had complete control over his learning the material, answering questions, and his ability to rewatch videos so he could advance at a comfortable pace.

Eduardo also believed the software was fully contained, in that all answers to his questions could be found in the video lectures or another part of the software. When I asked what he would do if he had a question about the content, Eduardo was very direct. "The way he [the narrator] explains it there is no questions; well at least for me. You just have to read it. I mean he explains everything. If I did [have a question], maybe I missed it when he was talking (30:3)". Eduardo believed that the computer was the source to be trusted and if he was unclear about a specific concept, it was his fault. This assumption supported his belief that by spending more time engaged in the software and by reviewing material, he could pass a module.

The assumption that MyMathLab was designed to be a fully contained program was supported by the software. The program had no surprises in that questions presented to students on exams are of the exact form given in "Homework" assignments. There are no advanced, conceptual questions or questions in forms students have not seen before. This allowed Eduardo to work through challenges and answer questions on his own.

Shaun, throughout his discussions with Eduardo, supported Eduardo's belief that seat time was essential for success in MATH075. The course structure and environment also emphasized seat time over understanding. Thus, there was no indication that Eduardo's plan was not reasonable. However, relying exclusively on the computer's features to review and answer his questions and focusing on the time spent in front of a computer did not meet his academic needs.

**Intention Thwarted: Eduardo's Plan Did Not Work**

Eduardo's plan to pass the course did not work. Before the middle of the semester, Eduardo had stopped attending the course and ultimately failed the class. Eduardo's plan assumed that his arithmetic skills were sufficient to succeed and that he only needed the software to be successful.

Like all students new to MATH075, Eduardo began with Module one, which introduced whole numbers, rounding, the arithmetic operations, and orders of operations with whole numbers. Shaun strongly encouraged all new students to pretest this module, taking the Module 1 test without working through the content, saving the time of working through "Homework" problems that students could presumably do. Eduardo chose to work through the module.

Shaun's attempts to have Eduardo finish this module demonstrated the extent to which Shaun considered this material rudimentary. Shaun tried to encourage Eduardo to come into class ready to test Module one. "Do you think you can do the topics, finish the 'Homework', over the weekend, and test on Monday?" (33:6). In this interaction, Eduardo was expected to complete units 1.7 – 1.11 so he could test. Shaun's tone with Eduardo was more imperative than curious, attempting to motivate Eduardo rather than inquire if doing that much work was possible. This statement implied that Eduardo could complete these modules if he put in the time to work through the questions. There was no consideration as to the academic challenges these units may have posed for Eduardo. Unfortunately, Eduardo had significant difficulty with these units.

In an example of how weak his arithmetic skills were, Eduardo was asked to solve the division problem $7\overline{)469}$. Eduardo relied heavily on the calculator and the video lectures to help him answer this question. He did not know the mechanics of dividing a three-digit number by a single-digit number until he watched the video. Eduardo relied heavily on his calculator to assist him through the intermediate steps. When the computer indicated that he had the wrong answer, Eduardo replayed the video on division and followed his extensive notes on how to perform long division. This single problem, including re-watching the video, took over thirty-five minutes to complete. The time and effort demonstrated here stand as a testament of Eduardo's dedication and resiliency, and as an indication of the extent of his mathematical deficiencies and the amount of effort necessary to overcome them. It was also an indication as to how challenging this course could be for someone with Eduardo's level of content knowledge when they relied exclusively on the computer software to advance.

Eduardo's progress through this division problem shows the extent to which he had difficulty with and needed mathematical support. His assumptions that the program was self-contained was demonstrated when Eduardo did not seek Shaun's help on solving the problem, even when Shaun interrupted Eduardo to discuss his progress while Eduardo was working on said problem. Furthermore, Shaun's classroom statements that the first module should be skipped along with his focus on how little time Eduardo was spending working at home may have prevented Shaun from recognizing Eduardo's challenges and intervening to help him.

The idea that the software was self-contained, that all questions could be answered in some way using MyMathLab, was incomplete. Although all questions could be answered based on definitions, examples, or lectures in the software, students were expected to have a certain amount of prerequisite knowledge, namely a command of addition, subtraction, multiplication, and division facts up to thirteen. This basic knowledge could have helped Eduardo with the aforementioned division problem and other problems in this module. In addition, without this basic knowledge, Eduardo could not pass the exam which did not allow use of a calculator.

MyMathLab was able to support Eduardo in working through the problem by allowing him to watch online videos as often as necessary to understand concepts. However, it did not address that he did not understand how division is a grouping operation or recognize that he did not know his basic multiplication / division facts. Eduardo may have successfully completed one problem, but this did not ensure he could do similar problems without the same extensive support from the computer and calculator. Although the features in MyMathLab helped Eduardo work independently through confusing questions, because of Eduardo's weak arithmetic skills, the amount of time it would have taken him to work through the course would have been prohibitive.

Eduardo and Shaun's focus on overall time spent working may have deflected attention in the wrong direction. Shaun was consistently focused on whether Eduardo worked outside of class and did not realize the extent to which Eduardo was having difficulty with the content. Whenever Shaun initiated a conversation with Eduardo, it was always about Eduardo's pace or progress and Eduardo would indicate he was not working outside of class. It would then be reasonable for Shaun focus on Eduardo's pacing, rather than focus on any challenges with content since Eduardo spent minimal time working and not asking for help. Shaun assumed Eduardo's lack of progress was due to his sparse seat-time and directed his energy towards this area of need.

At no time did Eduardo's reflections on his progress in the course focus on factors other than whether he was spending enough time with the software. He in fact was not working outside of class, and was not implementing that portion of his plan due to transportation difficulties and other external factors. Yet it cannot be denied that Eduardo also had to overcome multiple hurdles due to his extensive arithmetic weaknesses. However, he did not look for help beyond the computer. Instead, he leveraged multiple electronic avenues to work through the immediate question such as using a calculator and replaying a video to further understand the mathematical procedures. However, these avenues did not address his underlying arithmetic weaknesses, which were necessary for him to advance.

## Discussion

In the MATH075 classroom Eduardo did not achieve his goals. He did not ask for help with difficult problems or concepts because the software was designed to be fully contained, in that no outside help was needed to work through the material. In addition, Eduardo had extensive deficiencies in his arithmetic which made the likelihood of success remote. Focusing on Eduardo's seat time became a distracting influence, preventing both Eduardo and Shaun from recognizing and addressing Eduardo's actual challenges with mathematics. Shaun never asked Eduardo whether he was having difficulty with the content and Eduardo did not reflect on his mathematical skills and how that may affect the assumption that seat time was sufficient for him to succeed. His plan also did not consider or account for the conceptual challenges he had with foundational topics in mathematics.

This case demonstrates how assumptions can be insufficient for a plan to successfully achieve a goal, consequently leading to intentions not being fulfilled. In this case, Eduardo established his plan, which was validated through the course structure. This plan turned out to be problematic and insufficient for student success. Eduardo's assumptions, that the computer alone was a reliable instructor, ultimately doomed his success in MATH075. Furthermore, no part of his plan accounted for how much help Eduardo needed to understand and work through basic arithmetic concepts. Eduardo's focus on the computer being the ultimate authority on learning did not take into account that the computer did not give more nuanced feedback to him. At no point did the computer indicate that he needed to, for example, learn his multiplication facts. Eduardo may have trusted the computer, but the computer was not providing him with the support he needed to succeed. Furthermore, both Eduardo and the instructor were preoccupied with seat-time rather than challenges with content.

Overall, Eduardo was not made conscious of his mathematical challenges. Furthermore, Eduardo believed strongly that MyMathLab was sufficient for him to learn, but MyMathLab did not provide the type of feedback that his instructor could. Likewise, Shaun did not recognize that Eduardo was held back mathematically. MyMathLab consequently created a wedge, preventing the instructor from diagnosing the student's challenges and discouraging the student from looking to the instructor for support. As each trusted in the software, the expertise in the course instructor was marginalized to the detriment of the student.

Students' failed plans may have devastating consequences. In Eduardo's case, as a student on financial aid, if he cannot succeed in his courses, he will be left with student loan payments, taking on a new financial burden without the added economic benefits of a college degree. Community colleges, and postsecondary institutions in general, must address students' assumptions about learning, the knowledge base they bring, and how success is achieved.

*Research-based assessments (RBAs), such as the Calculus Concept Inventory, have played central roles in many course transformations from traditional lecture-based instruction to research-based teaching methods. In order to support instructors in assessing their courses, the online Learning About STEM Student Outcomes (LASSO) platform simplifies administering, scoring, and interpreting RBAs. Reducing barriers to using RBAs will support more instructors assessing the efficacy of their courses and transforming their courses to improve student outcomes. The purpose of this study was to investigate the extent to which RBAs administered online and outside of class with the LASSO platform provided equivalent quantity and quality of data to traditional paper and pencil tests administered in class for both student performance and participation. We used an experimental design to investigate the differences between these two test modes. Results indicated that the LASSO platform can provide equivalent quantity and quality of data to paper and pencil tests.*

*Keywords:* Assessment, quantitative methods, technology

## Introduction

Research-Based Assessments (RBAs), such as the Calculus Concept Inventory (Epstein, 2007), are often used to both develop and disseminate research-based teaching methods that improve student outcomes. Subsequently, RBAs are the focus of many influential publications in physics education research, such as Hake's (1998) comparison of traditional and interactive-engagement courses. The large increase in the number of RBAs in physics education research coincided with a dramatic increase in the collaboration in the PER community (Sayre et al., 2017). Because of these successes, many educators are interested in using RBAs. Madsen et al. (2016), however, found that many instructors want support in choosing appropriate assessments, administering and scoring the assessments, and interpreting the results of their assessments. To address these needs the Learning Assistant Alliance developed the LASSO platform to host and administer RBAs online (LA Alliance, 2017). Hosting the RBAs online meets instructors' needs by allowing for the tests to be administered outside of class, to be promptly and automatically scored, and for instructors to be provided with a summary report to help interpret the results.

Extensive research has investigated the differences between computer based tests (CBTs) and pencil and paper tests (PPTs). Meta-analysis of the literature has revealed that there is no systematic difference in scores between these two modes of administering tests (Wang et al., 2007). However, the studies in these meta analyses were conducted using high-stakes standardized tests at the K-12 level, and most had the CBT being administered in class. Because the LASSO platform is designed to administer RBAs outside of class in order to free up class time, the results of this earlier work may not apply to the LASSO platform.

In a similar study to this one, Bonham (2008) conducted research in college astronomy courses and administered assessments online outside of class. Bonham and colleagues had students complete both a locally-made concept inventory and a research-based attitude survey.

The students were randomly assigned to two conditions with either the concept inventory done in class and the attitude survey done outside of class via an online system or the reverse. A matched sample was then drawn from the students who completed the surveys. They concluded that there was no significant difference between CBT and PPT data collection. In contrast to their findings, a close analysis of their results revealed that there was a small but meaningful difference in the data and that the study did not have a sufficient sample size to rule out any meaningful differences; their study was underpowered. Their results indicated that the online concept inventory scores were 6% higher than the in class scores, which was an effect size of approximately 0.30. While this is a small difference, lecture-based courses often have raw gains below 20% and a 6% difference would skew comparisons between data collected with CBT and PPT modes. Therefore, it is not clear from the prior literature that low-stakes tests provide similar data when collected in class with PPTs compared to outside of class with CBTs.

## Research Questions

The purpose of the present study was to inform if data collected with LASSO is consistently different than data collected with paper tests. In pursuit of this purpose we asked:

(1) To what extent does the online administration of RBAs outside of class using the LASSO platform provide comparable data to the in-class administration of RBAs using PPTs? (2) How do instructor administration practices impact participation rates for low-stakes RBAs, if at all? (3) How are student course grades related to participation rates for low-stakes RBAs, if at all?

If the LASSO platform provided equivalent data to paper based administration, then the LASSO platform represents a much simpler entry point for instructors to begin assessing and transforming their own courses because it addresses many of the instructors' needs that Madsen et al. (2016) identified. A second major benefit of the widespread use of the LASSO system is that it automatically aggregates all of the data and makes this data available for research. The size and variety of this data allows for investigations that would have been underpowered if conducted at only a few institutions or lacking generalizability if only conducted in a few courses at a single institution.

## Methods

The data was collected at a large regional Hispanic-serving university across two semesters in three different introductory physics courses: algebra-based mechanics, calculus-based mechanics, and calculus-based electricity and magnetism (E&M).

The study used a between-groups experimental design (Figure 1). Stratified random sampling created two groups within each section with similar representations across student gender, race, and honors status. One group completed a concept inventory (either the Force Concept Inventory [FCI] or Conceptual Survey of Electricity and Magnetism [CSEM]) online outside of class using the LASSO platform and an attitudinal survey (the Colorado Learning Attitudes about Science Survey [CLASS]) in class using paper and pencil. The other group completed the concept inventory in class and the attitude survey online outside of class. Both conditions were repeated at the beginning and end of the semester. Paper and pencil assessments were collected by the instructors, scanned using automated equipment, and uploaded to the LASSO platform. Student assessment data was downloaded from the LASSO platform and combined with student grades and demographic data provided by the university. The data analysis did not include students who joined the class late, dropped, or withdrew, leaving a total sample of 1,310 students in 25 course sections.

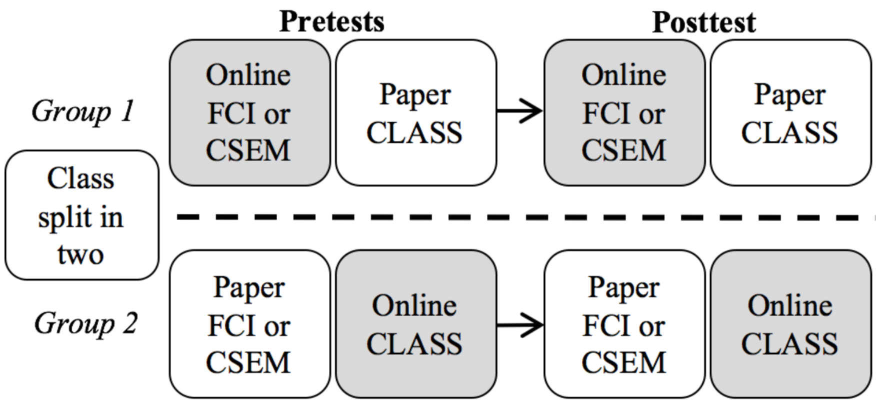

*Figure 1. Design of the research conditions.*

At the end of each semester of data collection participating faculty were interviewed to identify how the faculty motivated their students to complete the CBT. Four different practices were identified that we will refer to as *recommended practices*: 1) email reminders, 2) in class announcements, 3) participation credit for the pretest, and 4) participation credit for the posttest.

We used the HLM 7 software package to create multi-level models to analyze the performance and participation data. We analyzed the performance data for the concept inventories using 2-level Hierarchical Linear Models: test conditions (level 1) were nested within course types (level 2), no covariates were used. We analyzed the participation data using 3-level Hierarchical Generalized Linear Models: assessments (Level 1) were nested within students (level 2) nested within either course sections (level 3), the number of recommended practices and students grades in the courses were used as covariates.

The final models for performance and participation consisted of posttest score or participation as the outcome variables. The models were built in 3 or 4 steps: (1) no predictors, (2) add level 1 predictors, (3) add level 2 predictors, (4) add level 3 predictors (if applicable). This four-step process informed how much additional information was being explained by the addition of the new predictors in each step as indicated by a reduction in the variance for that variable.

Completion rates for the PPT condition were 94% for the pretest and 74% for the posttest and for the CBT were 68% for the pretest and 54% for the posttest. For the performance analysis, missing concept inventory data (i.e. students who did not take either the pre or posttest) was replaced using Hierarchical Multiple Imputation (HMI) with the MICE package in R. HMI is a form of multiple imputation (MI) that takes into account the fact that students were nested in different courses and that their performance may have been related to the course they were in. MI addresses missing data by (1) imputing the missing data m times to create m complete data sets, (2) analyze each data set independently, and (3) combine the m results using standardized methods (Dong & Peng, 2013). Our MI produced m=10 complete data sets. Multiple imputation is preferable to list-wise deletion because it maximizes the statistical power of the study and has the same basic assumptions.

## Findings

### Performance

The model of student performance on concept inventories showed very little differences in either pretest or posttest performance across test conditions. The largest predicted effect of test condition on student performance was on posttest for E&M students (Figure 2). This predicted effect bordered on being large enough to be meaningful because it indicated a 2.2 points higher posttest score for students doing the CBT and the overall predicted gain for the E&M students was only 11.6 points. However, the pre- and posttest across the three courses created six total measurements of the predicted effect for test condition; in three of those measurements the effect was nearly zero, in one it was positive, and in two it was negative. In addition to these inconsistencies in all six comparisons across condition there was large overlap in the 95% confidence intervals, indicating that the differences were not statistically reliable. Examination of the model variances showed that the inclusion of test conditions led to larger variances, indicating that conditions were not a reliable predictor of student performance.

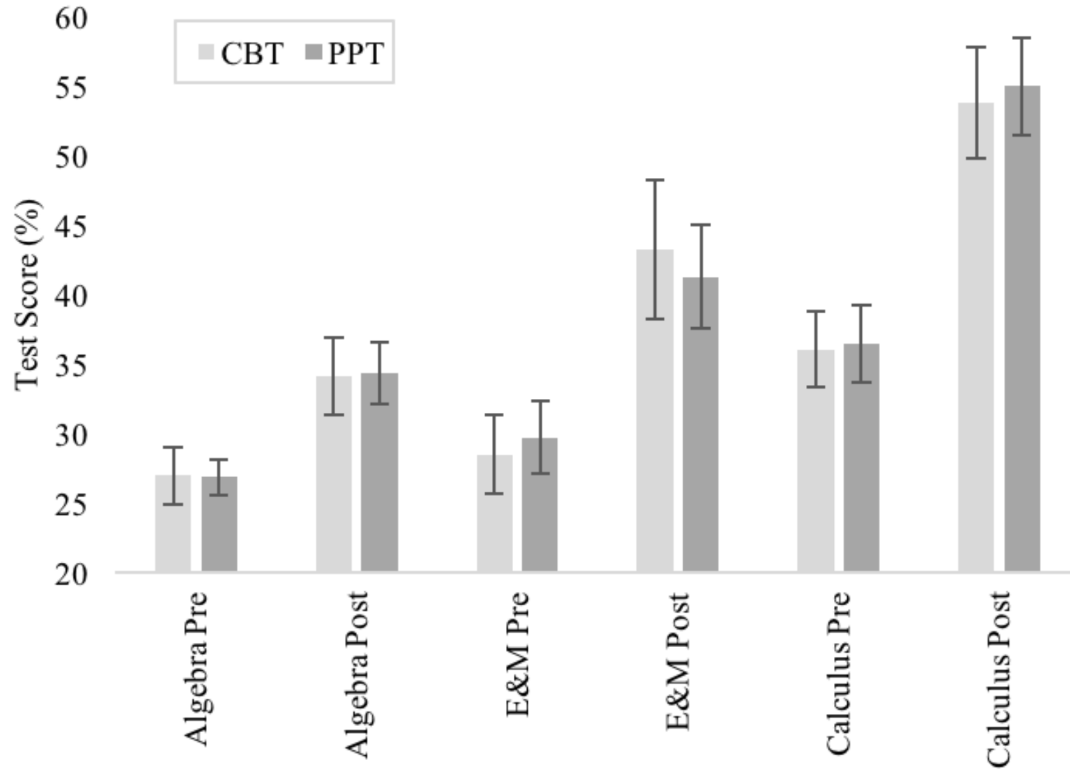

*Figure 2. Predicted Mean Scores with 95% CIs.*

**Participation**

The results of our HGLM model of the student data, indicate that the more recommended practices instructors used, the higher the participation rates were for their CBT assessments. Student course grades were also a statistically reliable predictor of student participation.

Figure 3 illustrates the predicted student participation rate based on student course grades and the number of recommended practices that instructors used. In terms of data collection, the posttests represented the limiting case as predicted participation rates on the posttests for both the PPT and CBT were lower than on the pretests. With the exception of the PPT pretest there was a large difference in predicted participation based on course grades. The number of recommended practices that instructors used dramatically increased predicted participation rates such that when instructors implemented all four recommended practices the participation rates of the CBT and PPT posttest were very similar. The impact of recommended instructor practices on predicted participation rates occurred for all students, but was largest for high achieving students. Relationships between student participation, grades, and instructor practices on the CBT pretest were similar to those on the CBT posttest. These results indicated that similar participation rates to those on PPT can be achieved via CBT when instructors use all four recommended practices.

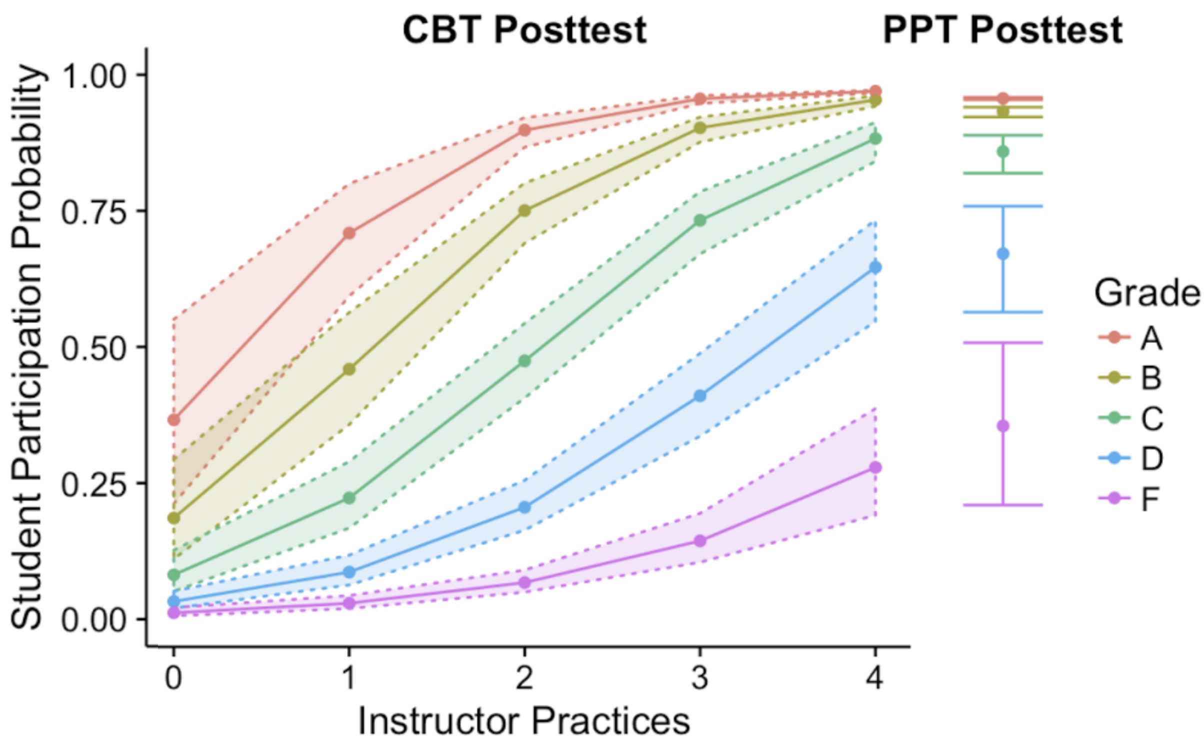

*Figure 3. Predicted student participation rates with 95% CIs. Only posttest predictions are shown as it is the test with the lower participation rates and is the primary limiter for data collection.*

## Conclusion and Implications

Our study shows that CBT and PPT administrations of low-stakes assessments can lead to similar student performance and participation. This similarity indicates that when our recommended practices are implemented instructors and researchers can use online systems, such as the LASSO platform, to collect valuable information about the impacts of their courses that is comparable to prior research that was collected with paper and pencil tests. Collecting data with the LASSO system can also greatly reduce the barriers to instructor's use of RBAs since instructors do not need to dedicate class time to collect the data or their own time to sort, scan, and analyze the data. It is important to note, however, that instructors do need to make some effort to motivate their students to complete the online assessments. We have found that by making announcements in class, sending out email reminders, and giving credit to students who complete the RBAs instructors can achieve similar participation rates on CBT assessments as on PPT assessments. Our hope is that reducing the barriers to using RBAs use will lead more instructors to assess the efficacy of their courses and, subsequently, to adopt research-based teaching practices that support student success.

In addition to promoting the use of RBA's developed by the DBDR community, the LASSO platform anonymizes, aggregates, and makes its database available to researchers with appropriate IRB protocols. The LASSO database has already provided multi-level large-scale data to examine questions of equity in student outcomes (Van Dusen & Nissen, in press), effects of near-peer mentors on student outcomes (White et al., 2016), and effects of instructor experience on their effectiveness (Caravez, in press). As the LASSO dataset grows, it will allow the DBER community the ability to quickly access a dataset designed to support the investigation of student outcomes from across the country.

While these findings are generally encouraging, there are several unexamined factors that could strengthen the conclusions and generalizability of the work. Useful areas for future research includes: (1) examining the associations between student demographics and student participation and performance in CBT and PPT conditions, (2) comparing student performance at the item-level (rather than total score) on CBT and PPT conditions, and (3) replicating the study in diverse institutional settings.

# An Activity Theory Approach to Mediating the Development of Metacognitive Norms During Problem Solving

Emilie Hancock
University of Northern Colorado

*Metacognition has long been identified as an essential component of the problem-solving process. Research on metacognition and metacognitive training has historically adopted an acquisitionist view. This study takes a participaionist lens by considering metacognition as a habit of mind or dispositional tendency. Problem-solving habits of mind can be viewed as normative ways of thinking to which students become attuned by participating in authentic problem-solving situations. This study explored one such situation, in which portfolio problem-solving sessions and write-ups were used to mediate metacognitive thinking. Periodically, students worked together on non-routine problems and submitted individual write-ups documenting their judgement and decision-making processes. Analysis utilized Activity Theory, which operationalizes the participation structure of a classroom, to document the nonlinear development of classroom metacognitive norms during problem solving. Micro-analysis revealed a shift from product- to process-oriented metacognitive norms. Macro-analysis situated these results, highlighting social mediators of activity and contradictions as catalysts for change.*

*Keywords:* Metacognition, Problem Solving, Norm Development, Activity Theory

## Introduction and Motivation

The importance of problem-solving practices has been emphasized and studied extensively (NCTM, 2010). Although literature has identified metacognition as a key component of the problem-solving process (e.g. Schoenfeld, 1985), metacognition remains undertheorized and under-studied in its application to classroom communities (Carroll, 2008). While the importance of prolonged metacognitive instruction embedded in content matter has been emphasized (Lester, Garofalo, & Kroll, 1989; Veenman, Van Houte-Wolters, & Afflerbach, 2006), most metacognitive research has overlooked the crucial impact of sociocultural contexts and learning environments in its development (Larkin, 2015). Further, metacognitive research, with foundations in cognitive information processing theory, has taken an almost exclusively acquisitionist (Sfard, 1998) approach to metacognition, where metacognitive skills are decontextualizable commodities (products) to be transmitted to students. As such, research concerning the teaching and learning of metacognition has been limited in its practical classroom application by overlooking the process characteristics of metacognitive thinking. There is a difference between "*knowing-about*" and "*knowing-to act in the moment*" (Mason & Spence, 1999). Becoming a skillful problem solver means coming to know the nuanced ways of *doing* or acting (as opposed to *having*) in authentic mathematical problem-solving situations.

Rather than viewing metacognitive knowledge and skills as objects to be transmitted, this research study took a complementary approach by appealing to metacognition as a habit of mind (Costa & Kallick, 2000), a disposition toward certain ways of acting during the problem-solving process. Taking a participationist (Sfard, 1998) view of the teaching and learning of metacognition, a skilled problem solver must both "communicate in the language of the community and act according to its particular norms" (p. 6). Problem-solving habits of mind, such as metacognition, can be viewed as normative ways of thinking or acting within the "skilled problem solver" community of practice. Through legitimate peripheral participation (Lave & Wenger, 1991), students become attuned to these normative, habitual tendencies or dispositions, eventually transforming their own habits of mind as they become full participants (i.e., skilled problem solvers) in this community. This theoretical approach requires understanding the process of student participation in metacognitive thinking, with attention to the contexts that afford or constrain such dispositional transformations toward full participation.

Accordingly, the purpose of this study was to investigate the use of portfolio problems (defined below) as a mediator of participation in metacognitive thinking during problem solving, delivering a prolonged intervention embedded in mathematics content called for by Lester, Garofalo, and Kroll (1989). Students worked on six portfolio problems throughout the semester, each of which consisted of two main parts: small group problem-solving sessions in class and individual write-ups. Except for the first problem which only involved one session, groups worked on a given problem over two in-class sessions, with each session lasting roughly one-third of a class period. These non-routine problems were chosen to align with the NCTM's (2010) "worthwhile-problem criteria," and to increase the likelihood that a solution path was not immediately known to students. Further, problems were selected with key mathematical ideas directly related to the content unit in which the problem was presented. The instructional team encouraged students to record their work and observations or questions on scratch work. Students wrote in different colored pens to identify individual contributions. This scratch work was emailed to each group after class, and students were expected to continue working on the problem outside of class. Students then submitted individual write-ups documenting a revised solution that included mathematical justification and reasoning, as well as their judgement and decision-making processes during the entire problem-solving attempt, from initial thoughts to final result. For example, students might include questions they asked themselves, or a discussion of why they employed or abandoned a particular representation or problem-solving strategy.

## Theoretical Framing

In studying students' attunement to normative ways of thinking, one must consider that the natural, purposeful activity within a classroom creates a microculture of negotiated activities and interactions among students and the teacher (Lave & Wenger, 1991). Over time, normative behavior emerges, but the interpretation and function of these norms change through iterations of negotiation. Consequently, metacognitive norms may develop in a way so that the resulting activity is not necessarily identical to that intended by the teacher. Thus, the focus of investigation turns to the development of a classroom community's normative metacognitive activity during problem solving. This necessitates an appropriate framework to document the nonlinear development of classroom problem-solving norms.

Third-generation Activity Theory (Engeström, 1987), which is conducive to a participation metaphor for learning (Barab, Evans, & Baek, 2004), was used in the present study as an analytic framework for systematic investigation. Activity Theory accounts for the complex interaction between the individual and community by expanding Vygotsky's (1978, 1986) notion of mediated activity to include additional social mediators (Engeström, 1987) (Figure 1). Individuals or groups of individuals form a motivated, object-oriented activity system, where the entire activity system forms the unit of analysis. An activity system dynamically transforms, expanding or changing qualitatively over (relatively long periods of) time through adaptation to contradictions or tensions (Engeström, 1987). In the context of this study, students in a first-year mathematics content course for pre-service elementary teachers formed one activity system, while an instructional team, consisting of myself and the instructor of record, created a "culturally more advanced" (Engeström, 1987) activity system that interacted with the student activity system.

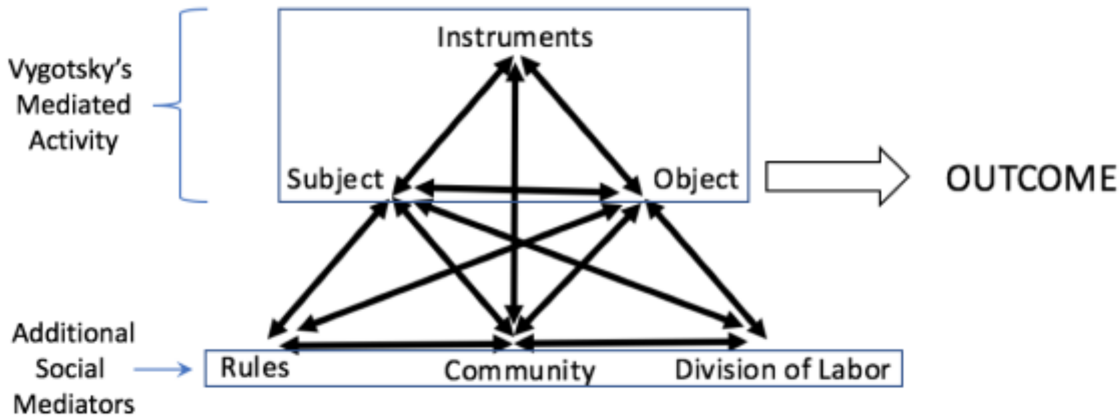

*Figure 1. Vygotsky's mediated activity embedded within the expanded activity triangle.*

In the context of documenting the process of classroom norm development, (Third-generation) Activity Theory is particularly advantageous. Specifically, Activity Theory provides:

1) *Operationalization*: Activity Theory operationalizes the participation structure of a classroom community for detailed, systematic investigation (described in the following Methods section).
2) *Attention to Reflexivity*. The classroom collective and individual students influence each other in a cycle of negotiation and influence (see Ernest, 2010). By framing students and the teacher as interacting activity systems, Activity Theory provides explicit language with which to document this nuanced, reflexive interaction over time.
3) *Expansion, and Horizontal Expansion.* Classroom norms are not pre-established, unchanging concepts, and their development can be influenced by students. Further, students' learning and development is not necessarily vertical, from "lower" to "higher" levels of competence. Activity Theory accounts for student growth and potentially non-vertical, or horizontal growth, through the process of expansive transformation, which occurs "when the object and motive of the activity are reconceptualized to embrace a radically wider horizon of possibilities than in the previous mode of the activity" (Engeström, 2001, p. 137).
4) *Process-Focused Interaction of Social Activity and Individual Actions*. Activity Theory focuses on the process of interaction over time, allowing for documentation of the transformational process of reflexive interaction between covert social activity affecting participation and individual actions of participation.
5) *Contradictions as Catalysts for Change*. Characterizing system dynamics through contradictions and tensions is a powerful means for interventionist-motivated design research. This study capitalized on portfolio problems as a mediating instrument to create a purposeful contradiction between the object/motive pair of the student activity system and the object/motive pair of a culturally more advanced form (the teacher activity system).

## Methods

This qualitative research study, grounded in the aforementioned theoretical perspective, was guided by the research question: What is the role of portfolio problems as a mediating instrument in the development of normative metacognitive activity during problem solving, within an undergraduate mathematics classroom community of pre-service elementary education majors? To address this question, sub-questions were posed: (a) What metacognitive actions during problem-solving become normative activity? (b) What contradictions or tensions exist within the classroom community that catalyze the development of such normative metacognitive activity during problem solving? and (c) What actions of the teacher influence, positively or negatively, the development of such normative metacognitive activity during problem solving?

Six qualitative data sources were collected in the 15-week semester: (1) video- and audio-recorded classroom sessions, (2) three videotaped, semi-structured individual interviews with 13 of the 23 students at the beginning, middle, and end of the course, (3) two audio-recorded interviews with the instructor of record, (4) students' written artifacts (assignments, exams, and portfolio-problem submissions and scratch work) collected before grading, (5) recorded planning sessions of the instructional team, and (6) journal reflections written by each member of the instructional team after each class session. The first data source, recorded classroom sessions, was utilized for micro-analysis, while all data sources were used for macro-analysis.

The first and second student interviews (data source (2)) had three parts. First, students were asked questions targeting their beliefs about mathematics, mathematical problem solving, and perceptions of the course. Students then worked, thinking aloud, on non-routine problems related to course content. This portion of the interview provided a reference point for students to discuss their problem-solving activity more generally. Finally, students compared their problem-solving attempts during the interview with their "typical" problem-solving activity in the course, as well as the problem-solving activity of course instructors, other students in the course, and other courses. The third interview did not include problem solving, but was a series of questions asking students to reflect on their experiences in the course.

Two levels of analysis were employed: a micro-analysis of language-mediated discourse [the upper boxed portion of the activity triangle in Figure 1], followed by macro-analysis using Engeström's expanded activity triangle to highlight tensions within the activity system (Jaworski & Potari, 2009). Micro-analysis served to address research sub-question (a) by identifying metacognitive actions (adapted from Carlson & Bloom, 2005) present during each of the in-class portfolio problem-solving sessions (Table 1). Recalling that a participation metaphor for learning was adopted in this study, the focus was on students' real-time *actions*. Thus, while written artifacts of students' judgement and decision-making processes were collected as part of the portfolio problems, only those actions demonstrated in situ were documented to evidence normative metacognitive activity.

*Table 1. Metacognitive actions identified during portfolio problem-solving sessions*

| | |
|---|---|
| MA 1. | Mathematical concepts, knowledge, tools, and facts are assessed and considered |
| MA 2. | Various solution approaches or strategies are assessed and considered |
| MA 3. | Validity/reasonableness of solution process is assessed/considered/tested |
| MA 4. | Results are assessed/tested/considered for their reasonableness/validity |
| MA 5. | Reflects on the efficiency and effectiveness of cognitive activities |
| MA 6. | Manages emotional responses to problem-solving situation |

Macro-analysis situated micro-analysis results, using a six-step method (Jonassen & Rohrer-Murphy, 1999) to describe various components of the student activity systems (Table 2). The student activity system was analyzed at multiple points throughout the semester to document potential change over time. Contradictions and tensions within the student activity system, as well as between the student and instructional team activity systems, were detected in the final step of macro-analysis, addressing research sub-question (b). As an additional part of both micro- and macro-analyses, actions taken and decisions made by the instructional team potentially impacting the development of metacognitive norms were identified, addressing research sub-question (c).

*Table 2. Six Steps for Analyzing an Activity System (Jonassen and Rohrer-Murphy (1999))*

| Step 1. | *Clarify the purpose of the activity system.*<br>Describe the motives and conscious goals of the activity system. |
| Step 2. | *Analyze the activity system.*<br>Define the subject, object, community, division of labor, and rules. |
| Step 3. | *Analyze the activity structure.*<br>Delineate the hierarchy of activity, concrete actions, and automatized operations. |
| Step 4. | *Analyze tools and mediators.*<br>Describe the tools, rules, and roles of participants that mediate activity within the system. |
| Step 5. | *Analyze the context.*<br>Characterize the internal, subject-driven and external, community driven contextual bounds. |
| Step 6. | *Analyze activity system dynamics.*<br>Step back from the delineated activity system to describe and assess how components affect each other. |

## Results and Discussion

Micro-analysis results, addressing research sub-question (a), indicated a shift in function of metacognitive thinking during problem solving. Over the course of the semester, the normative metacognitive activity employed during portfolio problem-solving sessions transformed from a retroactive focus on checking answers (*products*), to a proactive focus on the evaluation of the problem-solving *process*, especially the consideration of various solution approaches, tools, and strategies. Figure 2 broadly illustrates this change, where Metacognitive Action 4 (MA4) was prevalent at the beginning of the semester, but dissipated in use over time, with process-focused actions becoming dominant (e.g., MA2, MA3). By the end of the semester, students recognized this transition away from reflecting *only* at the end of a problem-solving attempt, as highlighted in the following student quote taken from the final interview:

> I've just been able to be actively engaged in the problem, realizing what I'm doing. Rather than just like, 'Well, this is the first step and second step,' and then afterwards I'm like, 'Oh, that was wrong, and that was wrong.'

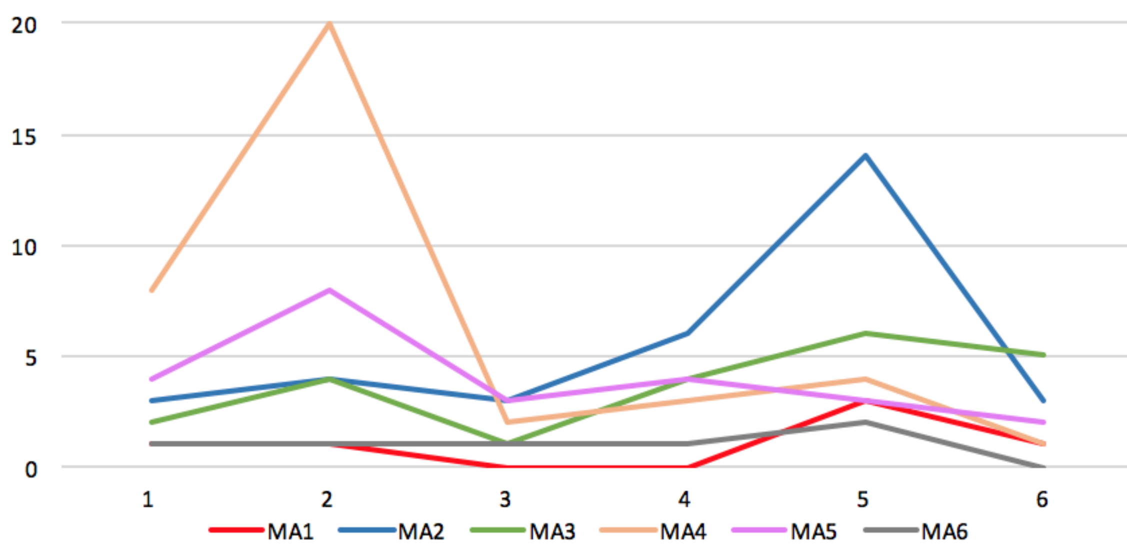

*Figure 2. Total occurrences of Metacognitive Actions during the six in-class portfolio problem-solving sessions.*

Macro-analysis situated these results, revealing contradictions that shaped the development of the normative metacognitive activity from micro-analysis, directly addressing research sub-question (b). Notably, the introduction of portfolio problems as a mediating instrument for problem solving constituted a significant catalyst for change. Students identified all aspects of the portfolio problems (in-class problem-solving sessions, scratch work, and submitted write-ups) as contributing to the awareness of their thinking during the process of problem solving. The portfolio problems also contradicted many students' motives and expectations for the course. While students anticipated learning to teach mathematics, the focus of the course was for students to improve as mathematical thinkers themselves. The non-routine, open nature of the portfolio problems brought this tension to the fore, encouraging students to adjust their course goals and embrace opportunities for personal development.

Additionally, instructor actions contributing to the development of metacognitive norms were identified during both micro- and macro-analyses, directly addressing research sub-question (c). The instructional team encouraged students to focus on process over product, generalize their problem-solving solutions and methods, and look for commonalities across problem contexts. Further, the team attempted to make overt the typically invisible mediators of mathematical problem solving. While this motive of the instructional team was consistent throughout the course, portfolio problems provided a rich setting within which to have these conversations, amplifying the influence of teacher actions. For example, the instructional team noticed students' increased frustration that they were not finding solutions to the portfolio problems. The team used this as an opportunity to discuss perseverance in the problem-solving process, using a video describing Andrew Wiles' lengthy process for generating a proof of Fermat's Last Theorem to aid in facilitating this discussion. This discussion allowed the class to both focus on the process of problem solving, and see that perseverance is an important aspect of this process.

In this study, portfolio problems contributed to students' shift in focus from reflection on the answers or outcomes (*products*) of a problem-solving attempt, to metacognitive thinking during the entire *process* of problem solving. While an inquiry-oriented course design and complementary teacher actions facilitated this shift, the portfolio problems accelerated the effects of these actions by creating contradictions or tensions as catalysts for student transformation. The intervention design in this study, with portfolio problems directly related to course content and used throughout the entirety of the course, supports the claim that metacognitive instruction must be embedded as part of the classroom culture. Additionally, Activity Theory proved useful as a framework for analysis, as it explicated the role of portfolio problems as facilitators of change through the creation of contradictions or tensions. This characterization is a powerful tool for intervention-based design research intended to create *purposeful* contradictions that can lead to productive beliefs (NCTM, 2014) about the teaching and learning of mathematics.

Collective Argumentation Regarding Integration of Complex Functions Within Three Worlds of Mathematics

Brent Hancock
University of Northern Colorado

*Although undergraduate complex variables courses often do not emphasize formal proofs, many widely-used integration theorems contain nuanced hypotheses. Accordingly, students invoking such theorems must verify and attend to these hypotheses via a blend of symbolic, embodied, and formal reasoning. This report explicates a study exploring student pairs' collective argumentation about integration of complex functions, with emphasis placed on students' attention to hypotheses of integration theorems. Data consisted of task-based, semistructured interviews with pairs of undergraduates, as well as classroom observations. Findings indicate that participants' explicit qualifiers and challenges to each other's assertions catalyzed new arguments allowing students to reach consensus or verify conjectures. Although participants occasionally conflated certain formal hypotheses, their arguments married traditional integral symbolism with dynamic gestures and clever embodied diagrams. Participants also took care to avoid invoking attributes of real numbers that no longer apply to the complex setting. Teaching and research implications are discussed as well.*

*Keywords:* Collective Argumentation, Complex Variables, Integration, Reasoning

## Introduction and Literature Review

Although the discipline of mathematics often rests on generalizing results from one domain to another, at times "mathematical thinking may involve a particular manner of working that is supportive in one context but becomes problematic in another" (Tall, 2013, p. xv). Such considerations can arise when studying the teaching and learning of complex analysis. For example, Danenhower (2000) discovered a theme of "thinking real, doing complex" (p. 101) wherein participants invoked attributes of real numbers that do not necessarily apply in the complex context. Troup (2015) additionally evidenced this phenomenon when undergraduates reasoned about complex differentiation. Within the setting of real-valued functions, the literature abounds with examples of students' struggles with integration (Grundmeier, Hansen, & Sousa, 2006; Judson & Nishimori, 2005; Mahir, 2009; Orton, 1983; Palmiter, 1991; Rasslan & Tall, 2002). However, most of these studies showcased the *product* of students' deficiencies and misconceptions rather than the *process* of students' reasoning. Accordingly, although students might sometimes draw incorrect conclusions regarding integration, their process of reasoning may healthily appeal to intuition or past experiences. When cultivated properly, such connections between experientially-based intuition and formal mathematics could benefit students' reasoning in courses such as complex variables (Soto-Johnson, Hancock, & Oehrtman, 2016).

Furthermore, according to Wawro (2015), by researching students' successful reasoning about undergraduate mathematics topics, we can document "what deep understanding and complex justifications are possible for students as they engage in mathematics" (p. 355). The subject of complex variables is particularly amenable to such an investigation, as the content in this course often lies between symbolic calculation and formal proof. Specifically, students that integrate complex functions tend to apply powerful theorems that rely on idiosyncratic hypotheses and draw on notions from real analysis and/or topology. Though formal proof is typically not emphasized in undergraduate courses in complex variables (Committee on the

Undergraduate Program in Mathematics, 2015), the application of such theorems requires that students at least recognize when these hypotheses apply. As such, students may invoke a blend of intuition, visualization, symbolic manipulation, and formal deduction when integrating complex functions. Accordingly, integration of complex functions lends itself to eliciting the rich student justifications called for by Wawro. Complex integration also has numerous practical applications for students, such as computing flux, potential, or certain real-valued integrals.

Despite these practical and theoretical assets, no existing educational research examines undergraduates' reasoning about integration of complex functions. In particular, researchers have not yet documented how students reason algebraically, geometrically, and formally when integrating such functions. This study served to ameliorate this gap in the literature and to inform the teaching and learning of complex variables by analyzing undergraduates' multifaceted argumentation about integration of complex functions. Using Tall's (2013) Three Worlds of Mathematics framework, my research sought to answer the following guiding questions:

1. How do pairs of undergraduate students attend to the idiosyncratic assumptions present in integration theorems, when evaluating specific integrals?
2. How do pairs of undergraduate students invoke the embodied, symbolic, and formal worlds during collective argumentation regarding integration of complex functions?

In this study, argumentation is defined according to Toulmin's (2003) model consisting of six components: data, warrant, backing, qualifier, rebuttal, and claim. Given that my study considers how pairs of students reason about integration tasks, it is additionally important that I consider how each individual contributes to an argument. Accordingly, I adopt Krummheuer's (1995) notion of *collective argumentation* in which multiple participants construct arguments through emergent social interaction. These interactions involve four speaker roles (author, relayer, ghostee, and spokesman), classified according to how syntactically and/or semantically responsible an individual is for the content of his or her statement. Readers unfamiliar with these speaker roles may consult Krummheuer (1995) or Levinson (1988) for more information.

The existing mathematics education literature implementing Toulmin's model manifests itself in several contexts. In the in-class setting, some researchers (Krummheuer, 1995; Krummheuer, 2007; Rasmussen et al., 2004; Stephan & Rasmussen, 2002) used a reduced Toulmin model omitting the qualifier and rebuttal, and rarely evidenced explicit backing. However, when more formal arguments such as proofs were concerned, researchers (Alcock & Weber, 2005; Inglis, Mejia-Ramos, & Simpson, 2007; Simpson, 2015) argued for the use of the full Toulmin model. These researchers also highlighted that simply reading the finished product of a purported proof is inherently difficult because backing and warrants are often implicit and cannot be elicited through real-time discourse with the proof author. Thus, my investigation into undergraduates' nuanced argumentation about integration of complex functions incorporated the full Toulmin model as well as opportunities for clarification in an interview setting.

## Theoretical Perspective

This work is theoretically oriented by Tall's (2013) Three Worlds of Mathematics as a lens through which to analyze undergraduates' reasoning pertaining to integration of complex functions. Tall's perspective situates mathematical knowledge within three distinct but interrelated forms of thought: *conceptual-embodied*, *operational-symbolic,* and *axiomatic-formal.* Conceptual embodiment begins with the study of objects and their properties, and can incorporate mental visualization. Operational symbolism grows out of actions on objects and can be symbolized flexibly as *procepts*, symbols operating dually as process and concept (Tall, 2008). The world of *axiomatic formalism* attends to “formal knowledge in axiomatic systems specified by set-theoretic definition, whose properties are deduced by mathematical proof” (p. 17). These three worlds can also combine to form, for example, *embodied-symbolic* or *formal-embodied* reasoning. As mentioned earlier, our prior experiences with mathematics can either support or clash with new and abstracted mathematical notions. Tall refers to the mental schemas predicated on these prior experiences as *met-befores*. He also argues that mathematical growth is afforded by three innate *set-befores* of recognition, repetition, and language. These set-befores foster categorization, encapsulation, and definition in order to compress knowledge into *crystalline* structures, which house various equivalent formulations of a mathematical object and can be unpacked in various worlds.

Moreover, “each world develops its own ‘warrants for truth’” (Tall, 2004, p. 287). In the embodied and symbolic worlds (respectively), truth derives from what is *seen* to be true by the learner visually, and from calculation. Yet in the formal world, a statement is either assumed as an axiom, or can be proven from axioms. Hence, Tall’s three-world perspective can complement the Toulmin analysis of a mathematical argument by adding specificity with regard to the types of backing and warrants used. As such, I classify participants’ Toulmin components as embodied, symbolic, formal, or various mixtures of these, as viewed through Tall’s three-world lens. Consequently, I define *reasoning* as mathematical argumentation within one or more of the three worlds. I also garner specificity by adopting Simpson’s (2015) three classifications of backing. Specifically, *backing for the warrant’s validity* explains why a warrant applies to a given argument. A second type serves to “highlight the logical field in which the warrants are acceptable,” which Simpson characterized as *backing for the warrant’s field* (p. 12). The third type, *backing for the warrant’s correctness*, demonstrates that a given warrant is actually correct.

## Methods

In order to rigorously address my research questions, I enlisted the help of two pairs of undergraduate students to partake in a videotaped, semistructured (Merriam, 2009), task-based interview comprised of two 90-minute portions and 13 tasks. Participants were selected from undergraduate students at a military academy in the United States, enrolled in a complex variables course during the spring 2015 semester. My first pair of participants consisted of Sean and Riley. Sean was a fourth-year physics and mathematics major and Riley was a second-year applied mathematics major with a cyberwarfare concentration. The second pair consisted of Dan, a third-year mathematics major, and Frank, a second-year applied mathematics major with an aero concentration. All participants’ names listed here are pseudonyms. A sample analysis of interview data is detailed in the next section.

To obtain a rich understanding of the context in which these participants learned about integration of complex functions, I also observed and videotaped six class sessions at participants’ undergraduate institution. These observations and ensuing field notes allowed me to document what mathematical content was introduced and emphasized during the integration unit in the complex variables course. They also allowed me to discern the nature of mathematical argumentation that was deemed appropriate for the complex variables course. For the sake of brevity, I restrict the presentation of results here to my interview findings. I also note here that I read tasks aloud verbally during the interviews so as not to overtly suggest any particular representation or world to participants.

## Results and Discussion

Due to my definition of reasoning in the context of this study as collective argumentation within one or more of Tall's (2013) three worlds, I format my results within each task according to argument. Included in my account of each collective argument are: pertinent excerpts of the participants' interview transcript; a Toulmin (2003) diagram summarizing the argument; and figures illustrating participants' gestures or inscriptions, often for the purpose of documenting embodied reasoning. Because of page constraints, this report showcases select results from Riley and Sean's interview. In particular, I present analysis of Riley and Sean's response to one task, in which participants evaluated the integral $\int_L \frac{1}{z} dz$, where $L$ denotes the unit circle $|z| = 1$ traversed counterclockwise. Afterwards, I allude to general findings from both pairs' interviews, and discuss various implications of my work.

### Sample Task Analysis

In illuminating Riley and Sean's reasoning about the task, I reference line numbers from their transcript excerpts and refer to various components of the Toulmin diagrams I constructed based on my interpretation of their responses. I also convey individual participants' speaker roles germane to each Toulmin component in the collective argument. Throughout the transcript pieces and Toulmin diagrams presented in this section, 'Int.' signals statements that I said aloud as the interviewer, while 'R' and 'S' stand for Riley and Sean, respectively. Bracketed phrases represent non-verbal events such as gestures or written inscriptions produced by the participants. In the Toulmin diagrams, italicized statements represent participants' exact verbiage from the transcript, while non-italicized statements more succinctly summarize participants' reasoning or deduce implicit Toulmin components based on their verbiage, gestures, and inscriptions, or lack thereof. Horizontal and vertical lines show how argumentation components are linked within a collective argument or subargument. Following the format of Wawro (2015), I represent shifts in the Toulmin categorization from one type of component to another (such as claim to data) in the figures by a diagonal line.

As I read the task aloud, Sean symbolically relayed the data comprised of the integral $\int_L \frac{1}{z} dz$ and the path $|z|= 1$ (line 4). He also authored an embodied datum by drawing the circular path on an Argand plane (see Fig. 1). As spokesman, Sean then symbolically rewrote $L$ as $C_1^+(0)$, and I acknowledged this alternate symbolism from their class (lines 4-5). Riley agreed, but Sean made sure to document that this was the professor's notation, as if indicating that he did not hold any agency when using it (lines 6-8).

Sean proceeded as spokesman, indicating that they could apply an antiderivative, as in the last task (lines 9-10). He also qualified this suggestion with the phrase, "I think I'm pretty sure that…" (line 9). However, Riley challenged Sean as she authored a warrant: "There's no branch we can choose […] so that [the integrand] is going to be analytic over the entire path" (lines 11-12). Invoking embodied reasoning, Riley also revised Sean's initial diagram of the circular path to include a positive orientation (see Fig. 1).

*Int:* Ok so more integration stuff. And I think given what we just discussed, I think this one shouldn't be too bad for you. So how would you find the integral of $\frac{1}{z}\,dz$, and this is over the path $L$, if $L$ represents the unit circle $|z| = 1$, traversed counter-clockwise?
*S:* [Writes $\int_L \frac{1}{z} dz$, |z|= 1, and draws the path on an Argand plane. Changes notation of $L$ to $C_1^+(0)$]
*Int:* Yeah, and I realize you guys have your own notation for that too, so—
*R:* Yeah.
*S:* Dr. X's notation. I'll document that [laughs].
*Int:* Right [laughs].
*S:* Ok so kind of like we did last time, I think I'm pretty sure that— I normally call it using the antiderivative, but—
*R:* [Draws in orientation on path] There's no branch we can choose, right, so that it's going to be analytic over the entire path?
*S:* Yeah, so I'd just say, $z = e^{i\theta}$ [writes this]. Therefore $z'(\theta) = ie^{i\theta}$ [writes this]. So we say the integral from 0 to $2\pi$, because theta is of course from these values [writes $0 \leq \theta \leq 2\pi$ ], 1 over $e^{i\theta}$, times $ie^{i\theta}\,d\theta$ [writes $\int_0^{2\pi} \frac{1}{e^{i\theta}} ie^{i\theta}\,d\theta$]. Which then you're going to get $i\int_0^{2\pi} d\theta$ [writes this], $2\pi i$ [writes $= 2\pi i$], which gives the well-known result of integral of 1 over $z$ minus a pole [points to $\int_L \frac{1}{z} dz$ inscription], a circle centered around it [points to diagram of path], gives you $2\pi i$ [points to $2\pi i$ inscription].

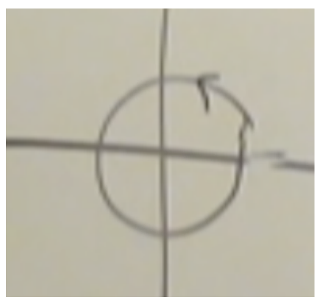

*Figure 1. Sean's diagram for the path L and Riley's counterclockwise orientation in Task 6.*

Sean conceded, and used their warrant to author an alternate approach implementing parametrization. Specifically, he first used embodied-symbolic reasoning to conclude that $z = e^{i\theta}$ is a parametrization of their path (line 13). Using this now as a datum, he further concluded that $z'(\theta) = ie^{i\theta}$, evidencing symbolic reasoning (line 13). As spokesman, Sean implemented embodied-symbolic reasoning to re-write the original integral, incorporating this new parametrization. The embodied aspect of this rewriting came from the decision to allow theta to vary from 0 to $2\pi$, a decision qualified by the phrase, "theta is of course from these values" (lines 13-15). Sean symbolically simplified this integral to obtain $i\int_0^{2\pi} d\theta$, and claimed that they obtained the "well-known result" of $2\pi i$ (lines 16-18). This sole argument for Task 6 is summarized in Figure 2.

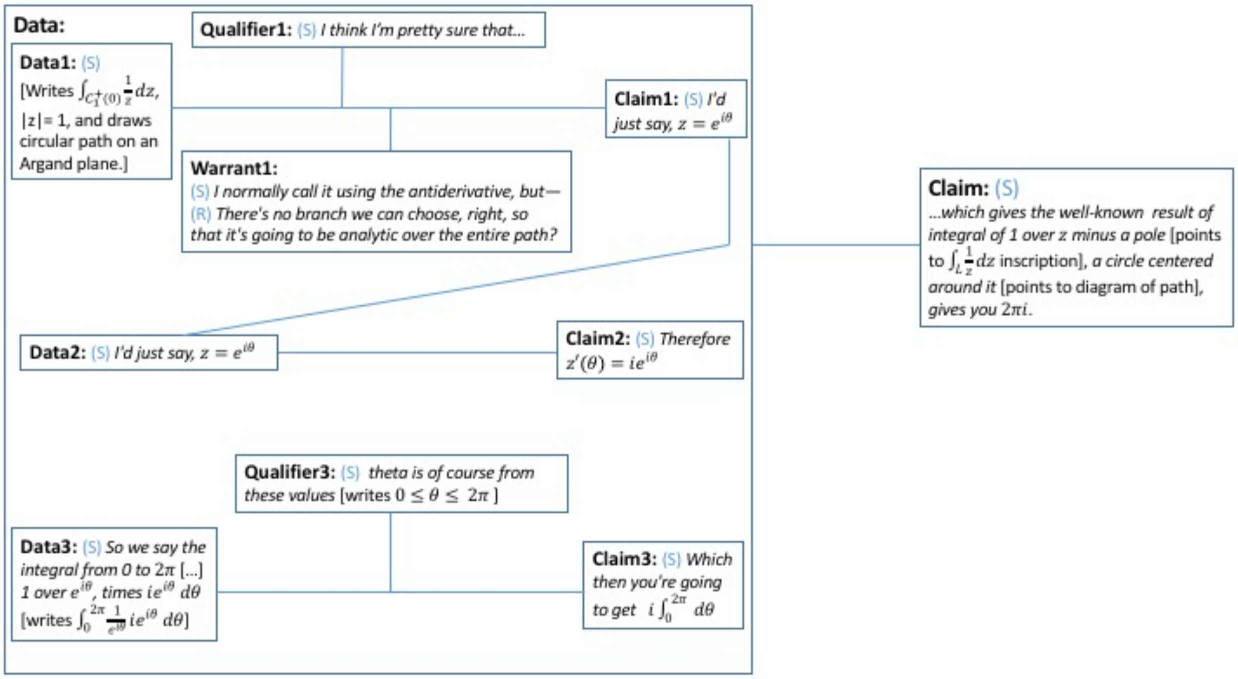

*Figure 2. Toulmin diagram for Riley and Sean, Task 6.*

## General Findings and Implications

With the above sample analysis in mind, I now elucidate some general findings that address my aforementioned research questions. I also discuss teaching and research implications associated with these results. Recall that my first research question regarded how undergraduate student pairs attended to the assumptions pertaining to integration theorems. In the present study, neither pair of participants appeared confident nor certain about the assumptions needed for employing certain tools, approaches, or theorems. For instance, Riley and Sean repeatedly questioned themselves in a previous task about whether the integrand function needs to be differentiable in order to employ parametrization. By explicitly qualifying such arguments, and in conjunction with my follow-up questioning, they eventually reached a consensus that the function only needs to be continuous. However, because they did not spend significant time in their course carefully justifying continuity arguments, the students exhibited substantial difficulty justifying why given functions, such as $\bar{z}$, are continuous or not. In particular, they pursued limit calculations to try to show this function was not continuous, but muddled their symbolic limit inscriptions.

Although Dan and Frank exhibited more confidence and decisiveness when deciding a function's continuity, they faltered a bit when justifying their application of Cauchy's Integral Formula in the above task. In particular, when Dan claimed they could produce a simply-connected domain containing the path $L$, Frank questioned the existence of such a domain, and his attempt at drawing one resulted in a domain that was not simply-connected. However, as with the above example, Dan and Frank's eventual consensus resulted from an explicit modal qualifier. The importance of such explicit qualifiers across the interviews was that they often led to follow-up arguments wherein the participants discussed assumptions in greater detail, including their applicability to the integral at hand. As such, my findings corroborate previous researchers' contention that one should consider the full Toulmin (2003) model when analyzing undergraduate level mathematical arguments.

My second research question inquired about the nature of students' invocation of Tall's (2013) three worlds during collective argumentation about complex integration. Quite unsurprisingly, my participants' formal reasoning dealt primarily with Cauchy's Integral Formula, the Cauchy-Goursat Theorem, the Cauchy-Riemann equations, and related results when evaluating specific integrals. However, more illuminating were the ways in which participants instantiated formal-symbolic, formal-embodied, or embodied-symbolic reasoning to justify the implementation of such theorems. For instance, Riley (and eventually Sean) explicitly instantiated embodied-symbolic reasoning by drawing arrows on the whiteboard between symbolic inscriptions and embodied paths of integration which were drawn on the board. Participants also expressed a symbolic answer next to a particular embodied path of integration by writing "= 0" next to a diagram of a closed path containing no singularities, for example. When discussing limits and path-independence, all four participants produced symbolic limit inscriptions, but also conveyed corresponding dynamic gestures embodying their chosen paths of approach. In one task, Riley and Sean demonstrated a purely embodied method for integrating the conjugate $\bar{z}$. The pair plotted tangent vectors along the circular path of integration and conjugates resulting from reflection transformations, and Riley and Sean also enacted visual vector addition.

Accordingly, the manners in which students intertwined embodied reasoning with symbolic and formal reasoning highlight the importance of visualization and geometry in the study of complex integration. Although complex variables courses tend to focus on symbolic computations and applications involving integration, the above examples point to an important consideration for teaching such a course. Specifically, they suggest that instructors might want to more explicitly highlight how the symbolism that abounds during the integration unit of a complex variables course can intertwine with the embodied and formal worlds. For instance, after providing a formal definition for a simply-connected domain or a simple curve, students could benefit from drawing numerous examples and counterexamples with one another. At times, my participants conflated some of these formal requirements, suggesting that additional care should be taken to produce examples that satisfy one requirement but not another. Despite participants' occasional struggles with formal hypotheses, both pairs were cognizant of the *thinking real, doing complex* (Danenhower, 2000) phenomenon, and avoided inappropriate applications of it. For instance, all participants voiced concerns such as "I'm tempted to think of this in terms of real numbers, but I know the analogy doesn't work" at various times during the interviews.

Finally, my study complements and extends the mathematics education literature regarding students' mathematical argumentation, particularly regarding how Toulmin's (2003) model is adopted to the context of *collective* argumentation. Specifically, not only did my participants' explicit qualifiers catalyze new arguments, but follow-up arguments also ensued when individuals challenged each other's assertions. According to Krummheuer (2007), individuals participate in collective argumentation in two ways: (1) the production of statements categorized according to Toulmin's model, and (2) an individual's speaker role (author, relayer, etc.). Notice that both of these forms of participation primarily serve to either introduce new ideas or support/re-voice existing ideas. However, they do not account for disagreement between parties or changing one's own mind following internal reflection. Accordingly, I contend that a third type of participation can drive collective argumentation, namely *challenging*.

## Students' Usage of Visual Imagery to Reason about the Divergence, Integral, Direct Comparison, Limit Comparison, Ratio, and Root Convergence Tests

Steven R. Jones J. Mitchell Probst
Brigham Young University

*This study was motivated by practical issues we have encountered as second-semester calculus instructors, where students struggle to make sense of the various series convergence tests, including the divergence, integral, direct comparison, limit comparison, ratio, and root tests. To begin an exploration of how students might reason about these tests, we examined the visual imagery used by students when asked to describe what these tests are and why they provide the conclusions they do. It appeared that each test had certain types of visual imagery associated with it, which were at times productive and at times a hindrance. We describe how the visual imagery used by students seemed to impact their reasoning about the convergence tests.*

*Key words:* calculus, sequences, series, convergence tests, visual reasoning

This study was motivated by practical issues we have encountered as second-semester calculus instructors, where students work with the concepts of sequences ($a_n$), series ($\sum_{n=1}^{\infty} a_n$), and the notion of convergence. Students are typically supposed to learn several convergence tests that can be used to determine whether a given series will converge or diverge. Students struggle with these, both in terms of calculation and in terms of reasoning about why these convergence tests work (i.e. why the results are valid). In appealing to the research literature for insight into this topic, we found that while studies have examined student understanding and reasoning about sequences and series (e.g., Alcock & Simpson, 2004; Mamona-Downs, 2001; Martinez-Planell & Gonzales, 2012; McDonald, Mathews, & Strobel, 2000; Tall, 1992; Tall & Vinner, 1981), there is very little work done about how students reason about *convergence tests* specifically.

González-Martín, Nardi, and Biza (2011) noted that visual representations of convergence were mostly limited to depictions of the integral test. Earls and Demeke (2016) have found that students made many types of mistakes or errors when testing convergence, such as using an inappropriate convergence test or failing to check whether a series meets the criteria for a given convergence test. Earls (2017) also found that students may confuse sequence convergence with series convergence while performing these tests, sometimes imagining them as interchangeable. While these few studies have provided an initial foray into the topic of convergence tests, we feel there is much work to be done in this area. This study is meant to contribute by investigating the question: How do students reason about the convergence tests presented in second-semester calculus? Additional specificity about "reasoning" is given in the "Framework" section.

### Recap of the Convergence Tests

In our study, we examined the divergence, integral, direct comparison, limit comparison, ratio, and root tests. For our purposes, the "p-test" is considered a special case of the integral test and what we call "direct comparison" is often simply called the "comparison" test. The divergence test states that if $\lim_{n\to\infty} a_n \neq 0$, or does not exist, then $\sum_{n=1}^{\infty} a_n$ diverges. The integral test states that if $f(x)$ is continuous, positive, and decreasing on $[1,\infty)$, and $a_n = f(n)$, then the series converges if and only if $\int_1^{\infty} f(x)dx$ converges. The direct comparison test begins with the assumption that $0 \leq a_n \leq b_n$ for all $n$. Then, if $\sum_{n=1}^{\infty} b_n$ is convergent, so is $\sum_{n=1}^{\infty} a_n$. If $\sum_{n=1}^{\infty} a_n$ is divergent, then so is $\sum_{n=1}^{\infty} b_n$. The limit comparison states that for positive sequences

$a_n$ and $b_n$, if $\lim_{n\to\infty}(a_n/b_n) = c$ where $0 < c < \infty$, then $\sum_{n=1}^{\infty} a_n$ and $\sum_{n=1}^{\infty} b_n$ either both converge or both diverge. The ratio test begins with the assumption that $\lim_{n\to\infty}|a_{n+1}/a_n| = L$. If $L < 1$, then $\sum_{n=1}^{\infty} a_n$ is convergent. If $L > 1$, then $\sum_{n=1}^{\infty} a_n$ is divergent. If $L = 1$, the test is inconclusive. The root test begins with the assumption that $\lim_{n\to\infty} \sqrt[n]{|a_n|} = L$. If $L < 1$, then $\sum_{n=1}^{\infty} a_n$ is convergent. If $L > 1$, then $\sum_{n=1}^{\infty} a_n$ is divergent. If $L = 1$, the test is inconclusive.

## Framework: Visual Imagery

For this study, we narrowed our scope on reasoning by focusing on reasoning based on *visual* imagery. We chose a visual imagery perspective because it has been well-studied and advocated for in mathematics education research. Also, it has been applied specifically to sequences and series (Alcock & Simpson, 2004), and there is a small amount of information known about how textbooks use visual imagery for the integral test (Martinez-Planell & Gonzales, 2012). For our framework, we began with Presmeg's (1986, 2006) five visual imagery categories, shown in the first five lines of Table 1. During analysis, we also remained open to the possibility of additional visual imagery types being added to this framework. In fact, we identified two useful additional categories (the last two lines in Table 1). First, many students used the *visual appearance* of the symbols and expressions in reasoning. Second, students often used their hands to *spatially locate* conceptual objects, like a sequence or a series, in the physical space in front of them, similar to the use of a "signer's box" in sign language. These two categories were added to our framework.

*Table 1. Definitions and operationalization of the visual imagery categories we used in our study.*

| Imagery | Definition | Operationalization: The student… |
|---|---|---|
| Concrete | Static image or picture in the mind | …produces a non-moving/changing image, whether with pencil/pen/fingers or verbally described. |
| Pattern | Imagined relationship stripped of concrete details | … quickly recites a specific structure or pattern pertaining to a convergence test. |
| Memory of Formula | Image recall of a literal formula or expression | …writes, gestures, or verbalizes a generic symbolic template associated with a convergence test. |
| Kinesthetic | Imagery inherently using physical movement | …uses bodily movement as an inherent part of the initial image (not just for communication purposes). |
| Dynamic | A static image that is then moved or transformed | …begins with a static image and then describes it as transforming (including if gestures are used). |
| Symbol Appearance | Visual look of a symbol or symbolic expression | …uses the way a symbol or expression looks to make a conclusion, comparison, or connection. |
| Spatial Location | Physically locating a conceptual object in space | …uses gestures to "place" an object in physical space around them, or to references those objects. |

## Methods

We used semi-structured interviews with nine second-semester calculus students (labelled A–I) who had recently learned about series convergence tests in their calculus course. The students came from the same "large-lecture" calculus course (~250 students), which was taught in a fairly traditional manner. However, the instructor did attempt to incorporate discussions about what series convergence meant, typically centered on sequences terms becoming small "fast enough" for the series to converge. The students were selected based on their performance to three series convergence questions, with four correct on all three questions and five correct on two questions.

In the interviews, the students were asked to discuss the six convergence tests. For each test, the students were asked (a) to describe what that test is, (b) to explain why that test works for assessing convergence, and (c) to explain why the conclusions of each test are justified. The first part gave us information on the student's knowledge of each test's contents, and the second and third parts allowed us to examine the visual imagery and visual reasoning used by the students.

The analysis consisted of four phases. In the first phase, we reviewed the interviews to look for additional possible visual imagery categories, which produced the two described previously. In the second phase, we applied our visual imagery framework (Table 1) to the data, coding every instance in each interview that fit within any of those categories. Our coding was then independently checked by a separate research assistant. Any changes made by that assistant were reviewed again by us, to make final decisions. For each student, counts were made for how many instances of each type of imagery occurred during their discussion of the individual convergence tests. Aggregate counts were also tabulated across all nine students. In the third phase, we noted trends of how each type of visual imagery was typically used across the students. This was done by grouping together all instances of one type of imagery and looking for commonalities. Then, in the fourth phase, we examined how the different types of imagery influenced how students reasoned about each type of convergence test. This was done by looking at whether certain types of imagery proved helpful, or not, for making sense of the each convergence test.

## Results

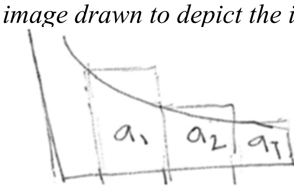
We organize the results as follows. First, we describe, generally, the trends we saw for how each type of visual imagery was used across the students. Then, we provide summary frequencies for each kind of visual imagery used for each convergence test. Last, we explain how these types of visual imagery affected how the students reasoned about each convergence test.

### How Students Generally Used Each Visual Imagery Type

To acquaint the reader with the overall trends in student imagery use, we start our results by first describing the common ways that each type of visual imagery was present in the data set.

**Concrete imagery.** Students frequently used concrete imagery. For the integral test, they drew the "typical" textbook image (Figure 1) of a continuous function passing through the "dots" representing the sequence, with rectangles having heights equal to the sequence values.

*Figure 1. Typical concrete image drawn to depict the integral test (from Student C).*



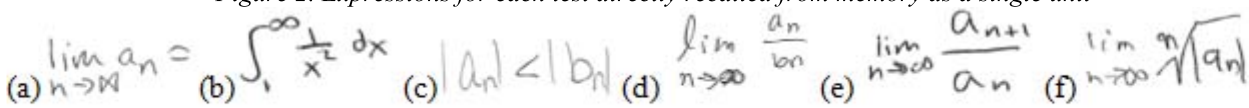
In fact, students drew many decreasing "functions," either on paper or in the air. Students also used concrete imagery to imagine sequences as an ordered list of numbers $a_1$, $a_2$, $a_3$,... . This was evidenced by gestures where students would "point" to the imagined successive numbers as they described a sequence. Concrete imagery was also frequently used by students to imagine "sizes" of numbers or sequence terms. For example, students used their index finger and thumb to make small or large "size" gestures, or they used the distance between their hands to show size.

**Pattern imagery.** Overall, there was less evidence for pattern imagery. The main instances of this imagery were students quickly reciting the pattern of a convergence test's results. For example, when describing the ratio or root test, many students quickly recited the $L > 1$, $L = 1$, and $L < 1$ cases. Students seemed to have this pattern laid out visually in their minds, as they would sometimes point "up" when referring to the $L > 1$ case and "down" when referring to the $L$

< 1 case. Pattern imagery was also used, but much less so, for limit comparison, in quickly stating that $0 < c < \infty$ implied one thing and that 0 or $\infty$ implied the opposite.

**Memory of formulae imagery.** Each convergence test had an expression type recalled from memory by the students directly in its symbolic form (see Figure 2). These expressions seemed invoked as a single visual unit when the students initially discussed a given test. Note that for the integral test, students typically *verbally* stated that the integrand was the function obtained by replacing "$n$" in the sequence with "$x$," but usually wrote an example rather than a generic $f(x)$. For some expressions, there were variations in how the students imagined it, such as the expression $a_{n+1}/a_n$ with no "$\lim_{n\to\infty}$" on it, or some expressions having absolute values or not.

*Figure 2. Expressions for each test directly recalled from memory as a single unit*



**Kinesthetic imagery.** This imagery was the most extensively used by the students, largely because of the kinesthetic nature of how the students seemed to think about convergence and divergence. This is likely related to the instructor's discussions of sequence terms becoming small "fast enough." Students frequently gestured off to the right when talking about these concepts, sometimes "downward" for convergence and "upward" for divergence (though not always). Another common place this type of imagery was used was when students thought of the series as summing up the terms of the sequence. The students sometimes made gestures like "collecting" terms together, or "grabbing" them one by one, implying *action* during summation.

**Dynamic imagery.** Dynamic imagery mostly showed up when students began with a *symbolic expression* and then imagined it transforming in some way. We highlight that this is different from symbolic manipulation, because it was the *imagery* associated with the expression itself that changed. For example, Student G, in describing how the root test is convenient for cancelling off $n$-th powers, stated, "If you look at just what's *inside* [student emphasis] the $n$-th power, you'll kind of have a better idea of what's going on." This statement was accompanied by a gesture where he put his rounded his hands next to each other and then shrunk the space between his hands as though "zooming." Instances like this one suggest that the students were implicitly imagining some transformation to the symbolic expression itself.

**Symbolic appearance imagery.** This type of imagery was less common, but was used across the tests. When discussing the integral test, the students generally used the appearance of the sequence to write the function for the integral. This was done by simply swapping any "$n$" in the sequence formula for an "$x$" in the integral. Next, several students discussed the comparison tests in terms of how related the symbolic expressions of the two sequences were. For example, Student A began explaining the direct comparison test by using the example of two series with sequences $1/(n^2 + 2)$ and $1/n^2$. She stated that she used these two because, "You're just comparing something that is similar." Also, the students frequently invoked sequences of the form $[]^n$ as examples for the root test, and sometimes used sequences with factorials for the ratio test. These suggest the usage of symbolic appearance to match some series with certain tests.

**Spatial location imagery.** Students frequently used a hand or finger to locate a number, a sequence, or a series in the space in front of them. While this type of visualization occurred throughout the interviews, it occurred more often when students discussed the comparability of sequences or series. For example, Student B described the limit comparison test by stating, "If it's not zero or infinity, you know they are related to each other enough that they're going to do the same thing." As she said this, she brought her fingers together at two locations on the table that were close to each other. Later, she stated, "If it goes to zero, if it goes to infinity, it gives you the same result, but you can't compare them because they're too different." In this case, she cupped her hands in two different locations that were much farther apart.

**Summaries of Visual Imagery Used**

We next provide summary counts for how often each type of imagery was used by the students while discussing each convergence test (Table 2). The percentages are out of the total number of instances coded for *that* particular convergence test. Each test had certain types of imagery used more frequently than other types, and we shaded in gray any having at least 20%. We note that within each test, there was a reasonable amount of consistency across the students in terms of which types of visual reasoning they employed for that convergence test. Thus, we consider it sufficient for this report to only show the aggregate data across all students.

*Table 2. Frequencies and percentages of each type of visual reasoning for each convergence test.*

| | Divergence ($n$ = 103) | Integral ($n$ = 97) | D. Comp ($n$ = 69) | L. Comp ($n$ = 79) | Ratio ($n$ = 160) | Root ($n$ = 86) |
|---|---|---|---|---|---|---|
| Concrete | 15 (15%) | 39 (40%) | 12 (17%) | 7 (9%) | 44 (28%) | 9 (10%) |
| Pattern | 0 (0%) | 0 (0%) | 2 (3%) | 4 (5%) | 13 (8%) | 7 (8%) |
| Formulae | 9 (9%) | 4 (4%) | 5 (7%) | 13 (16%) | 14 (9%) | 7 (8%) |
| Kinesthetic | 46 (45%) | 22 (23%) | 12 (17%) | 18 (23%) | 52 (33%) | 18 (21%) |
| Dynamic | 13 (13%) | 2 (2%) | 6 (9%) | 2 (3%) | 11 (7%) | 23 (27%) |
| Sym App | 3 (3%) | 14 (14%) | 9 (13%) | 10 (13%) | 7 (4%) | 18 (21%) |
| Spatial Loc | 17 (17%) | 16 (16%) | 23 (33%) | 25 (32%) | 19 (12%) | 4 (5%) |

**Using Visual Imagery to Reason about the Convergence Tests**

In this final results subsection, we now describe how these types of visual imagery appeared to influence the students' reasoning about each of the convergence tests.

**Divergence test.** Kinesthetic imagery seemed to help the students reason about the divergence test. Students B, C, E, F, and G visualized active summations of the sequence terms and gestured grabbing or gathering the terms into a total. Many also raised their hand up and to the right to talk about how adding up infinitely non-negligible terms would result in a total that diverged. However, the dichotomous nature of the "upward" divergence and "downward" convergence motions may have caused occasional confusion. Student I used this dichotomous visualization to conclude that *any* sequence with limit zero would have a convergent series. She stated that the purpose of all other tests was simply "making it easier to take the divergence test."

For this test, students also used the concrete imagery of a list of sequence terms. However, a problematic component of this imagery arose for Students D and I. These students envisioned sequences as having a "final term" that is the value of the limit (cf. Davis & Vinner, 1986). For example, Student D was discussing a sequence with limit "$e$," and said, "The last number that we're going to add is $e$. So, there is a possibility that all of the numbers before that might be small enough so that the whole thing doesn't go to infinity, or the series doesn't go to infinity."

**Integral test.** A significant portion of the students' imagery used for the integral test involved the type of concrete image shown in Figure 1. However, importantly, while all of the students were able to produce this type of image, most of them did not know how to reason about it. In fact, only Student C was able to describe how the areas of these rectangles could be used to show that $\sum_{n=2}^{\infty} a_n \leq \int_1^{\infty} f(x)dx \leq \sum_{n=1}^{\infty} a_n$. Several students' reasoning simply focused on the visual aspect of how the heights of the rectangle "followed" the graph. For example, Student C stated, "It's drawing a line through all your little points, and if that line converges to something, then that means that your series will converge." Thus, it was the simple visual similarity between the curve and rectangle tops that became the salient feature, rather than the comparison between the area under the curve and the area of the rectangles. Student H even compared the rectangles to "a kind of histogram-like thing," which likely elicited ideas about how statistical histograms can sometimes be seen as an approximation to a population distribution curve.

**Direct comparison test.** The students were generally successful in reasoning about this test, mostly through identifying "comparable" series and sequences. The students often spatially located two series near each other when describing compatibility, or far from each other when describing incompatibility. Symbolic appearance was a key reasoning tool in identifying comparable series. The students often described two series as comparable if the sequences had the same "leading term" symbol, such as $1/n$ and $1/(n–1)$, or $1/n^2$ and $1/(n^2+1)$. One issue with reasoning for this test was a failure to distinguish between comparing sequences, $a_n \leq b_n$, versus comparing series, $\sum_{n=1}^{\infty} a_n \leq \sum_{n=1}^{\infty} b_n$ (cf. Earls, 2017). For example, Student F stated, "So, when you compare to a series that you know diverges, if it's greater than that series, then you know that this one also diverges." Student F compared the series, rather than the sequences as stipulated by the test. Focusing on symbolic appearance may have led some students to overlook the differences between sequences and series, as well as which one the condition of this test uses.

**Limit comparison test.** For this test, as with direct comparison, the students also frequently reasoned about "comparability." Symbolic appearance imagery again helped the students know what comparisons to make, with Student H even suggesting that the point was to find a "prettier" version of the given sequence. However, the students had more difficulty reasoning about why the test actually works. Some knew that a finite, non-zero result meant that the two series would do the same thing, but they were unsure how to justify it. Only Students B and C gave possible reasons. They loosely argued, based on kinesthetic imagery, that as the sequences "went" to infinity, their terms became more similar to each other. The spatial location imagery was also at times helpful, but at other times not. For example, Student F justified the result "infinity means inconclusive" by saying, "If you compare them and they go to infinity [places one hand off to the right and the other off to the left], then it kind of seems like they're not similar at all." Infinity seemed to have induced a spatial arrangement that led Student F to correctly believe the two sequences under consideration were not "similar." However, he then struggled to use the same type of reasoning for the result "zero means inconclusive." He said, "But zero, I guess, they're also not similar [hesitantly placing hands apart]… I don't know." It appeared that the use of the word "zero" felt inconsistent with placing two objects far apart, which interfered with Student F's reasoning and led him to doubt his conclusion.

**Ratio test.** All of the students struggled to reason about the ratio test. Most struggled to do more than describe the computational process of using the test. Four students (B, E, F, and G) made incorrect connections to the limit comparison test, based on the similar symbolic appearance of $a_n/b_n$ and $a_{n+1}/a_n$. Problematically, this led Student E to claim that the ratio test results "should be the same as the limit comparison test." Based on the analogy to limit comparison, Students E and G used dynamic imagery to incorrectly imagine the term $a_{n+1}$ as representing some sort of graphical shift of the $a_n$ sequence. Student E imagined $a_{n+1}$ as an "upward" shift of $a_n$, and Student G described $a_{n+1}$ as, "If you add one, you shift the graph, basically, to the left." On the other hand, computationally, students tended to use factorial examples, suggesting that that symbolic appearance was at least beneficial in determining one type of series for which it is helpful to *use* this test. Lastly, two students (D and H) used a problematic concrete image of a graph with a horizontal line at $y = 1$ to reason about the ratio test results. They incorrectly imagined that if the sequence converged to anything below that line, the series converged, which seemed to conflate sequences and series convergence (cf. Earls, 2017).

**Root test.** The root test was also quite difficult for the students to reason about. Students B and C, however, made meaningful comparisons to the geometric series based on the symbolic similarity of the $[]^n$ format. This reasoning is used in one proof of the root test. Thus, in this case, symbolic appearance played a useful role in these students' reasoning. Other students attempted to use dynamic imagery to help provide some rationale for the test. The students saw the root test as getting rid of the exponent, *n*, allowing them to focus in on the "inside" of the sequence. They were not able to provide a rationale for why the test had the results that it did, though. Yet, Student D did use dynamic imagery in a different way, explaining that *n*-th roots of numbers less than one produce larger values. He described a sequence converging to zero and imagined a term for a very large *n*. "That would be a really small value. And then when we take the *n*-th root of that, that will increase the value [spreads hands apart]. If that increased value is between 0 and lesser than 1, that means that it went to 0 fast enough." Lastly, pattern imagery also played a useful role for most students by assisting in the quick recall of the appropriate test results.

## Discussion

In this study, we saw differences in the type of imagery students relied on to reason about each test, such as kinesthetic imagery for the divergence test, concrete imagery for the integral and ratio tests, and spatial location imagery for the two comparison tests. Further, we saw that some tests were easier to reason about, like the divergence and direct comparison tests, and others were more difficult to reason about, like the integral, ratio, and root tests. We identified particular aspects of visualization that helped or hindered the students' reasoning. For example, symbolic appearance helped students reason about the direct comparison and root tests, but then seemed problematic for reasoning about the ratio test. Dynamic imagery helped students focus their attention on the relevant parts of a symbolic expression. Concrete imagery was useful in imagining "sizes" or sequence terms, but was problematic when that imagery was not well understood, like incorrectly "completing" the image of a sequence by including a "last term." The common picture used for the integral test also turned out to be poorly understood by the students. This result has implications for how instructors may wish to use concrete imagery for convergence tests, such as using formative assessment to ensure that students understand what those images are meant to be representations of. Lastly, spatial location imagery may have been helpful for students in cognitively managing the various objects being referred to in a test. This lesser-studied type of visualization may need more attention in future work.

Our study has many connections to research on sequences, series, and convergence. The sequence list imagery is closely related to the SEQLIST conception described by McDonald et al. (2000). Martinez-Planell and Gonzales (2012) argued that a SEQLIST conception is less productive for understanding series convergence than if the sequence is understood to be a function from the natural numbers to the reals. Our results in some ways agrees with this claim, but in other ways disagrees, since this imagery was at times helpful for the students. However, it is true that the sequence image with a "last term" is certainly problematic (see Davis & Vinner, 1986). For this misconception, our results may actually indicate a possible *imagery*-based origin.

The concrete imagery of a continuous graph for the integral test also shows that students seemed to have internalized this common image (see González-Martín et al., 2011). However, the students' understanding of this image seemed far from the intention of the picture. Finally, we can see that series of the form $\sum_{n=1}^{\infty} 1/n^m$ for $m = 1, 2$, or 3 were commonly used and might indeed be "prototypical" examples of series, as mentioned by Alcock and Simpson (2002).

# A Study of Calculus Students' Solution Strategies when Solving Related Rates of Change Problems

Thembinkosi P. Mkhatshwa
Miami University

Steven R. Jones
Brigham Young University

*Contributing to the growing body of research on students' understanding of related rates of change problems, this study reports on the analysis of solution strategies used by five calculus students when solving three related rates of change problems where the underlying independent variable in each problem was time. Contrary to findings of previous research on students' understanding of related rates of change problems, all the students in this study were able to translate prose to algebraic symbols. All the students had a common benchmark to guide their overall work in one of the tasks but no benchmark to guide their overall work in the other two tasks. Three students exhibited weaker calculational knowledge of the product rule of differentiation. Directions for future research and implications for instruction are included.*

*Key words:* related rates, implicit differentiation, problem solving, calculus education

Related rates of change problems form an integral part of any first-year calculus course. However, there have been relatively few studies that have examined students' reasoning about related rates of change problems. Engelke (2007) argued that there is a dearth of research that examines how students understand and solve related rates of change problems in introductory calculus. Findings of a comprehensive review of literature on students' understanding of various topics in college calculus by Speer and Kung (2016) indicate that studies on related rates of change are scarce. Of the few studies involving related rates problems, Piccolo and Code (2013) found that students had computational difficulties when calculating derivatives involving more than one time-dependent variables. Engelke (2007) described several beneficial components for successful solutions, including drawing diagrams, determining functional relationships (algebraic equations), and checking the answer. She also added that proficiency with the chain rule helped the students make sense of the problem context and the components of the functional relationship. Other studies have focused more on how students read and interpret the problem statement (Martin, 2000; White & Mitchelmore, 1996). White and Mitchelmore found that students struggled to "symbolize," or mathematize, the related rates problems, often being unsure as to how to use all the given information in a related rate problem. Martin also found that students struggled to convert the written prompt into a mathematical structure on which the students could operate.

While these studies have provided beneficial information about how students set up and solve related rates of change problems, there is still much to be explored about the specific difficulties that limit students' success when solving such problems, which is the motivation for this study. Thus, to build on these studies, we intend to explicitly examine students' understanding of the key steps that are generally involved in the process of solving related rates of change problems where the underlying independent variable is time. In particular, our study was guided by the following research question: What do calculus students' solution strategies when solving related rates of change problems reveal about the difficulties that limit students' success when solving such problems?

## Related Literature

For a working definition, a mathematical task is said to be a related rates of change problem (abbreviated as "related rates problem") if it involves at least two rates of change that can be related by an equation, function, or formula. As noted earlier, research on students' understanding of related rates of change is sparse. Piccolo and Code (2013) analyzed Calculus I students' written responses to related rates problems at a large research university. This analysis revealed that the students were successful in performing the early steps of solving the problems (e.g., identifying the quantities involved in the problem and finding an equation that relates these quantities). However, using implicit differentiation was a major issue for the students' success in the problems. More specifically, Piccolo and Code reported that implicitly differentiating functions with several time-dependent variables, with respect to time, was problematic for a majority of the students. Consequently, most of the students were unsuccessful in solving the problems they were given. Piccolo and Code asserted that students' difficulties with solving related rates problems stems from a lack of facility with the process of differentiation, rather than a misunderstanding of the physical context of such problems.

Engelke (2007) used a teaching experiment, consisting of six teaching episodes, to examine how calculus students understand and solve related rates problems. Engelke argued that knowledge of the chain rule appeared to help the students in solving the problems they were given. This researcher reported that the students had difficulty imagining each variable in the problems as a function of time especially when time was not explicitly mentioned in the problem statement. Engelke further proposed a framework for analyzing students' work when solving related rates problems. Details of this framework are provided in the next section.

Martin (2000) analyzed students' responses in a problem-solving test containing several items assessing the students' ability to solve related rates problems in an introductory calculus class. Martin reported that overall performance was poor, and claimed that "the poorest performance was on steps linked to conceptual understanding, specifically steps involving the translation of prose to geometric and symbolic representations" (p. 74). White and Mitchelmore (1996), who studied the conceptual knowledge of 40 undergraduate mathematics majors when solving four application problems (including two related rates problems) at the level of introductory calculus, reported similar results. White and Mitchelmore also found that the students tended to replace unfamiliar variables with either $x$ or $y$, an idea that has come to be known as the "$x, y$ syndrome" (p. 89).

## Conceptual Framework for Related Rates

This study uses Engelke's (2007) framework, which characterizes the phases involved in solving related rates problems in calculus. The framework emerged from interviews, using a think-aloud protocol, with three mathematics professors who were solving three related rates problems similar to the tasks we used in this study. The framework lists five phases that one follows when solving related rates problems. These phases are: (1) draw and label a diagram, (2) determine a meaningful functional relationship, (3) relate the rates of change, (4) solve for the unknown rate of change, and (5) check the answer for reasonability. However, in our study, we realized the need to add an additional "orienting" phase, because the students often spent time simply acquainting themselves with the problem context. We label this the "zero-th" phase, (0) orienting to the problem. The following is a description of each of these phases.

The orienting phase consists of the solver carefully reading the problem (aloud or silently), with the goal of identifying what the solver considers to be important information. More specifically, the solver identifies given quantities and the required quantity (the unknown rate).

Then, in the diagram phase, the solver draws and labels a diagram illustrating the relationship of the quantities in the problem. In Task 1 (methods section), for example, the solver may draw a right triangle where the horizontal leg of the triangle represents the distance between the westbound plane and the airport, the vertical leg of the triangle represents the distance between the northbound plane and the airport, and the hypotenuse of the triangle represents the distance between the two planes.

In the functional relationship phase, the solver constructs a meaningful relationship (algebraic equation) between the quantities he/she identified while orienting himself/herself with the problem or while drawing a diagram. In the case of Task 1, the solver may use the Pythagorean Theorem, $x^2 + y^2 = z^2$, where $x$ is the distance of the westbound plane from the airport at any point in time, $y$ is the distance of the northbound plane from the airport at any point in time, and $z$ is the distance between the two planes at any point in time. During the relate the rates phase, the solver implicitly differentiates with respect to a time variable the algebraic equation he/she identified as relating the quantities in the problem. The process of implicit differentiation results in the creation of a new equation that shows a relationship of the rates of change involved in the problem. In Task 1, the process of implicit differentiation with respect to a time variable $t$, would result in the equation, $2xdx/dt + 2ydy/dt = 2zdz/dt$, where $dx/dt$ is the speed of the westbound plane at any point in time, $dy/dt$ is the speed of the northbound plane at any point in time, and $dz/dt$ is the rate at which the distance between the two planes reduces at any point in time.

In the solve for the unknown rate phase, the solver substitutes all the given quantities in the new equation and then solves for the required rate of change. In Task 1, this means solving for the value of $z$ at a particular point in time when the quantities of $x$ and $y$ are known, using this value of $z$ together with the known values of the quantities $x$, $y$, $dx/dt$, and $dy/dt$ to solve for the unknown quantity, $dz/dt$. Finally, during the check the answer phase, the solver uses certain goals or benchmarks to guide their overall work. The goals or benchmarks include: (a) having a sense of knowing if the answer the solver found (the unknown rate) is higher or lower than would be expected, (b) expecting the answer to have a particular sign (positive or negative), and (c) expecting the answer to have particular units (e.g., miles per hour instead of miles). Checking the answer for reasonability in Task 1 may, for instance, mean having an awareness that the units of $dz/dt$ should be in miles per hour since it is a rate and that the sign of the value of $dz/dt$ should be negative as the distance between the two planes decreases over time.

## Methods

This qualitative study used task-based interviews (Goldin, 2000) with five students. The interviews lasted about 45 minutes, on average, and contained three tasks:

**Task 1:** Two small planes approach an airport, one flying due west at a speed of 100 miles per hour and the other flying due north at a speed of 120 miles per hour. Assuming they fly at the same constant elevation, how fast is the distance between the planes changing when the westbound plane is 180 miles from the airport and the northbound plane is 200 miles from the airport?

**Task 2:** A leak from the sink is creating a puddle that can be approximated by a circle, which is increasing at a rate of 12 $cm^2$ per second. How fast is the radius growing at the instant when the radius of the puddle equals 8 $cm$?

**Task 3:** For the next problem, let me give you a little background on a formula that we will use. Suppose a gas is inside of a container. Many gases under normal conditions follow the "ideal gas law," $PV = kT$, where $P$ is the pressure the gas exerts on the container, $V$ is the volume of the container, $T$ is the temperature of the gas, and $k$ is a constant. $P$ is measured in "atmospheres," $V$ is measured in cubic meters, and $T$ is measured in Kelvins. Kelvins is a lot like Celsius, except that it is scaled so that 0 means absolute zero (lowest possible temperature), which makes water's freezing point to be $273\ °K$. Do you have any question(s) about this formula, or any of the quantities [like temperature in Kelvins] before we proceed?

In a laboratory, an experiment is being done on a gas inside a large, flexible rubber balloon. For the experiment, the temperature of the gas is being heated at a rate of 8 degrees per second. At one point, when the temperature of the gas is $300\ °K$, the pressure is 1.5 atmospheres, the volume of the gas is one cubic meter, and the volume of the gas is growing at a rate of 0.01 $m^3$ per second. At that moment, is the pressure in the balloon increasing or decreasing? What is the rate of that increase/decrease?

The students worked through these tasks while the interviewer asked clarifying questions about their work. After the student concluded their work for each problem, the interviewer asked the following questions about the task and the content of their solutions: (a) Have you seen a problem like this before? (b) What did you need to do to solve this task? (c) What does your answer tell you? (d) What does the sign of your answer tell you? (e) What are the units for the rate you found? (f) What does each quantity throughout your solution [including amount quantities and rate of change quantities] mean? (g) What does each computational step mean in terms of the quantities? (h) Will your answer for this problem be the same for all points in time for this context? Most of the students' time was spent on Task 1 while the least amount of time was spent on Task 3. We remark that Task 3 was not a routine task to the students in that the students' prior experiences with related rates problems in course lectures and in the course textbook was limited to problems similar to Task 1 and Task 2.

**Setting, Participants, and Data Collection**

The study participants were five undergraduate students (pseudonyms Ben, Bill, Jake, Nick, and Tim) at a research university who were enrolled in a traditional calculus I course in the summer of 2017. The course met twice a week (each meeting lasted for 2 hours and 45 minutes) for a duration of 12 weeks. The students were recruited via an official class roster obtained from their professor. The students were chosen based on their willingness to participate in the study. The students were familiar with the key ideas examined in the three tasks (instantaneous rate of change and the process of implicit differentiation) from course lectures and the course textbook. Three of the participants (Ben, Nick, and Tim) were Business/Economics majors while the other two students (Bill and Jake) were Engineering majors. Two students (Ben and Tim) had taken a high school calculus course prior to participating in this study. At the time of the study, three of the students were sophomores, one student was a junior, and the other student was a senior. The cumulative grade point averages (GPAs) of the five students had a mean of 2.02 on a 4.0 scale and a standard deviation of 0.71, suggesting that these were low performing students. As we would discuss in the concluding section of the paper, analysis of interviews conducted with this sample of students were both surprising and interesting at the same time. Data for the study consisted of transcriptions of audio-recordings of the task-based interviews and work written by the five students during each task-based interview session. When transcribing the audio recordings of the interviews, we used video recordings of the interviews to check what students were referring to when they pointed at something during the interviews in cases when such information could not be easily obtained from work written by the students during the interviews.

## Data Analysis

Data analysis was done in two stages. In the first stage, we used a priori codes, consisting of the five phases from Engelke's (2007) framework, plus the additional "orienting" phase we included. More specifically, we carefully read through each interview transcript and coded instances where each student reasoned about: (0) how they interpreted the problem, (1) drawing diagrams illustrating what is happening in each task, (2) constructing algebraic equations relating the quantities in each task, (3) differentiating the equations, (4) solving for the unknown rate, and (5) checking the answer (unknown rate) for reasonability. In the second stage of analysis, we looked for patterns in each of the codes identified in the first stage of the analysis. These patterns included trends in the students' understandings, or difficulties they had in connection with each of the phases of the related rates framework. The common understandings or difficulties in students' reasoning found in the second stage of our analysis provided answers to our research question.

# Results

Analysis of the data revealed that: (1) all the students were able to translate prose to algebraic symbols, (2) all the students had a common benchmark to guide their overall work in the first task, (3) students typically had no benchmark to guide their overall work in Tasks 2 and 3, and (4) three students exhibited difficulties with the product rule of differentiation.

## Translating Prose to Algebraic Symbols

All of the students successfully identified the appropriate algebraic equation that shows how the quantities in each of Task 1 and Task 2 are related (Task 3 already had a formula given to the students). That is, translating the text of each task into algebraic symbols, and relating these symbols using the appropriate equation, was not problematic for the students. As previously noted in the methods section, we argue that this may have been because the students had been shown how to solve problems similar to Task 1 and Task 2 through examples that were given during course lectures. Four of the students provided reasonable rationales for using the Pythagorean Theorem in Task 1. Bill is representative of this group of four students. When asked how he moved from the "right triangle," which he claimed was a "picture" of what is happening in Task 1, to the equation $x^2 + y^2 = z^2$, Bill stated that the two planes "are heading due west and due north, it's a right triangle, so use the Pythagorean Theorem [pointing at the equation $x^2 + y^2 = z^2$]." When probed on what the Pythagorean Theorem meant in terms of $x$, $y$, and $z$, Bill indicated that it "relates all of them together." We remark that Bill correctly interpreted $x$, $y$, and $z$ as distances that are measured in miles. More specifically, Bill interpreted $x$ as the distance of the westbound plane from the airport, $y$ as the distance of the northbound plane from the airport, and $z$ as the distance between the two planes. When asked to elaborate on what the Pythagorean Theorem meant, Bill stated, "this side [pointing at one side of the triangle which he labelled $x$] squared plus this side [pointing at another side of the triangle which he labeled $y$] squared, equals this side [pointing at the hypotenuse of the triangle which he labeled $z$] squared." We argue that Bill recognized that by virtue of the two planes flying west and north respectively, the distance between the two planes is given by the hypotenuse of a right triangle. This is rightfully so because the two planes are assumed to be constantly flying at the same elevation in the description of the task.

One student, Ben, knew that he had to use the Pythagorean Theorem to relate the quantities in Task 1, because it was used in a similar problem that was solved in class. Ben, however, did not provide a convincing rationale for using the Pythagorean Theorem in this task. When asked on why he used the Pythagorean theorem in this task, Ben said "I don't know, I just wrote it up here [pointing at the equation, $a^2 + b^2 = c^2$] because I figured that the problem might have something to do with it." Ben added, "I don't know, it's a habit I have had since I started learning calc, or geometry for a long time, and so I actually implemented it to the solution right here [pointing at the equation, $x^2 + y^2 = z^2$ which was part of his solution]." All the students provided reasonable rationales for using the formula for the area of a circle as an equation that relates the quantities in Task 2. Common among these rationales was that the puddle is circular, as described in the task description.

**Benchmarks used by Students to Guide their Overall Work**

None of the students used any goals or benchmarks to guide their overall work in Task 2 and Task 3. More specifically, they did not mention any specific way of having a sense about whether or not their answers to these tasks were correct. However, in Task 1, all the students had an expectation that the required unknown rate had to be negative regardless of whether or not their work leading to the answer is correct. The following excerpt, illustrates how Nick, for example, determined the benchmark for his solution to Task 1.

*Researcher:* I noticed that $c'$ came out as positive 160mph [Nick's Answer], what does that mean?

*Nick*: That it [$c'$] is increasing over time, like going up by increments by units so like if it's a hundred and sixty miles per hour now, over time it will go up to a hundred and seventy, a hundred and eighty, and it will get faster and faster. If it [$c'$] were negative, it would decrease. So in this case, I would assume it will be negative [changing 160mph to -160mph] because they [the two planes] are coming closer and closer [to each other], and they are getting near to the airport, so it [$c'$] will be decreasing.

We argue that Nick's claim that $c'$ should be negative may have been a result of two things. First, Nick may have correctly determined that $c'$ should be negative by reasoning about the context of the task, that is, the distance between the two planes is getting smaller as the planes approach the airport hence $c'$ should be negative. Second, Nick could simply be recalling a justification for $c'$ to be negative that was given by his calculus professor when he did a problem similar to Task 1 during course lectures.

**Difficulties with the Product Rule**

Three students (Tim, Bill, and Ben) incorrectly applied the product rule when differentiating the equation, $PV = kT$, in Task 3. Figure 1 shows how Tim used the product rule to differentiate $PV = kT$.

$$P\frac{dP}{ds}V + PV\frac{dV}{ds} = t\frac{dt}{ds}$$

*Figure 1. Tim's derivative of PV=kT.*

By incorrectly applying the product rule, Tim concluded that the derivative of $PV = kT$ with respect to a time variable $s$ (which he stated would be measured in seconds) would be

$PVdP/ds + PVdV/ds = TdT/ds$ instead of $PdV/ds + VdP/ds = kdT/ds$. Tim did not use the stated conditions in the task to determine the value of the constant $k$. Instead, he either discarded the constant $k$ or substituted a "1" for it when taking the derivative of $PV = kT$. Bill and Ben treated $k$ in a similar way when finding the derivative of $PV = kT$. Bill's work (Figure 2) is representative of how these two students differentiated the equation, $PV = kT$.

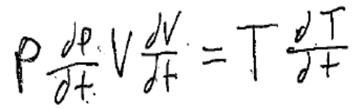

*Figure 2. Bill's derivative of PV=kT.*

Bill differentiated the equation, $PV = kT$, implicitly with respect to the time variable $t$ which he said would be measured in "seconds". As can be seen in the solution in Figure 2, Bill recognized that he had to use the product rule to find the derivative of $PV = kT$. He, however, incorrectly applied the product rule. More specifically, Bill's derivative of $PV$ is $PdP/dt * VdV/dt$ instead of $PdV/dt + VdP/dt$. His derivative of $kT$ is $TdT/dt$ instead of $kdT/dt$. The other two students (Nick and Jake) did not make any attempt of finding the derivative of $PV = kT$ or let alone mention that they have to find one. Instead, they systematically guessed the answer to the question of whether or not the pressure of the gas inside the balloon is increasing or decreasing.

## Discussion and Conclusions

Contrary to findings of previous research (Martin, 2000; White & Mitchelmore, 1996) on students' understanding of related rates problems, findings of this study indicate that translating prose to algebraic symbols was not the problematic part of the process for the students in this study. More specifically, the students in our study did not have any difficulty with symbolizing, algebraically, the quantities in each task in addition to finding an appropriate equation that relates the quantities mentioned in each task. This result is more striking given that the students in our sample were weaker overall, meaning that even these weaker students did not have issues with these parts of the process.

Interestingly, the students in this study expressed a common benchmark to guide their overall work in one of the tasks but did not express any benchmark to guide their overall work in the other two tasks. In particular, all the students indicated that the unknown rate they were trying to find in Task 1 (how fast the distance between the two planes is changing) had to be negative since the distance between the two planes decreased as the planes approach the airport. Future research might examine the role of problem context in students' use of benchmarks to guide their overall work when solving related rates problems. Finally, students' reasoning about the non-routine task (Task 3) revealed that most of the students in this study had difficulty using the product rule. As a recommendation, calculus instructors may need to help students develop greater facility with procedures such as the chain rule, product rule, and quotient rule prior to applying these rules when solving contextualized related rates problems (cf. Engelke, 2007). As a limitation of our study, we note that because the participants are five students from the same class, the results may not generalize.

Peer Mentoring Mathematics Graduate Student Instructors: Discussion Topics and Concerns

Kimberly Cervello Rogers
Bowling Green State University

Sean P. Yee
University of South Carolina

*We developed and implemented a peer-mentoring program at two US universities whereby nine experienced mathematics graduate student instructors (GSIs) each mentored three or four first- and second-year GSIs (novices). Mentors facilitated bi-weekly small group meetings with context-specific support to help novices use active-learning techniques and augment productive discourse (Smith & Stein, 2011). Meeting discussion topics were informed by novices' interests, concerns raised by both mentors and novices, and ideas from other small groups. We examined what topics from small-group peer-mentoring meetings novices valued and timing of the topics that mentors suggested for future cycles. We qualitatively coded meeting topics and analyzed novices' ratings of topics discussed. Results indicate specific topics novices valued and the importance of timing some topics appropriately, informing future professional development for GSIs. These results offer insight and synergy between educating GSIs and improving undergraduate mathematics teacher pedagogy.*

*Keywords:* Teaching Assistants (TAs), Professional Development, Peer-Mentoring

Mathematics graduate student instructors (GSIs)[1] teach hundreds of thousands of undergraduate mathematics students each semester, yet typically lack guidance and support to teach undergraduate students effectively (Rogers & Steele, 2016; Speer & Murphy, 2009). GSIs' initial teaching experiences represent a crossroad between how they teach in the short term in graduate school and in the long term as potential future faculty members (Lortie, 1975). Moreover, in this context, GSIs participate in professional development (PD) concurrent with their first couple semesters as instructors of record, responsible for the day-to-day interactions and content-delivery and assessments in undergraduate mathematics classrooms. That is, GSIs are uniquely positioned as a population of instructors who are simultaneously receiving and applying strategies and theories learned in PD seminars, courses, and other such opportunities. As researchers have documented (e.g., Belnap & Allred, 2009; Bressoud, Mesa, Rasmussen, 2015; Ellis, Deshler, & Speer 2016a; 2016b), PD opportunities and teaching assignments for GSIs vary significantly in mathematics departments and universities across the US, which makes it challenging to determine what and how PD for GSIs can be the most impactful and effective for improving student learning outcomes in undergraduate mathematics courses. In light of this challenge, we developed and implemented a peer-mentorship program to provide additional support for novice GSIs' learning to teach.[2] We saw this as a prime opportunity to study this undergraduate instructor population and find what pedagogical topics are perceived as valuable from GSIs' perspectives as novices discuss their teaching and concerns with one another and with peer-mentors in small-group meetings. Therefore, these topics, practically, inform the next iteration of the peer-mentorship program, but more broadly inform GSI education because it highlights topics of value and significance from the novices' perspective. We investigate the following two research questions:

---

[1] GSI was used instead of TA (Teaching Assistant) because GSI targets the specific set of graduate students who are instructors of record.
[2] Supported by a Collaborative IUSE NSF grant (Awards #1544342 & 1544346).

1. What value do novice mathematics GSIs place on pedagogical topics from peer-mentoring small group meetings?
2. What pedagogical topics, and in what order, do experienced, mentor GSIs suggest for future cycles of peer-mentoring small groups?

## Related Literature and Framework

### Secondary Teacher Education and GSI Teacher Education

To support mathematics GSIs' development as instructors, we draw upon and learn from the history of teacher education. Initially, in the U.S., novice secondary teachers were given a short three-to-five-day orientation and then thrown into the classroom with a sink-or-swim mentality (Portner, 2005). Educational policies (e.g., No Child Left Behind and emergency teacher certification) provide multiple avenues to teacher certification, limiting uniformity in teacher preparation programs (Ganser, 2005). Thus, secondary mathematics education researchers suggest that mentoring allows secondary schools to align teachers' prior experiences with their cultural and professional expectations increasing teacher support and retention (Portner, 2005).

Similarly, mathematics graduate students arrive at universities with diverse teaching backgrounds and teaching experience with many novices having no-prior-teaching experience and some may have extensive undergraduate teaching experience if they previously taught while completing a different graduate degree (Rogers & Yee, 2017). Morover, in a similar vein as noted in the secondary education setting, collegiate institutions vary regarding how they prepare and support novice undergraduate instructors, including brief orientations or seminars for PD or required PD courses. Although these forms of PD can be useful in helping novices recognize important issues within teaching, they do not provide one-on-one support that a mentor can to address each individual's needs (Yee & Rogers, 2017). In this research project, therefore, we incorporated mentoring with the intention being to help GSIs navigate the new teaching expectations at their new university and mathematics department.

When applying a pedagogical model (teacher mentoring) to a new audience (from primary and secondary preservice teachers to mathematics GSIs), it is critical to justify the framework through empirical research (e.g., Speer King, & Howell, 2015) to make sure one does not overgeneralize. Empirical research in GSI teaching practices is also needed due to the limited research of undergraduate mathematics education (Speer, Smith, & Horvath, 2010). Therefore, we look to teacher mentoring research to justify our framework and study design.

### Peer-Mentoring for GSIs Drawing from Teacher Education Research

Emerging trends in K-12 mentoring indicates that workshops, classroom visits, and meetings are vital to provide improvement and develop sustainability in leadership where novices eventually become mentors (Ganser, 2005). Overlapping these results with Boyle and Boice's (1998) empirical research on university teacher mentoring, further emphasizes the importance of systematic meetings among mentors and novices. Therefore, the mentoring structure used in our project includes these identified key components for teacher mentoring: systematic small group meetings, observations, and post-observation discussions (Ganser, 2005; Rogers & Yee, 2017).

We focus specifically on peer-mentoring (instead of faculty-mentoring) because faculty's relationships with doctoral GSIs can become ethically complicated since the faculty member can also take on different positions of power; i.e., advisors, qualifying exam evaluators, and course instructors (Johnson & Nelson, 1999). Furthermore, when a mentor is a peer, they are more likely to be genuinely aware of the individualized pedagogical decisions and needs associated with a novice's current experiences (Yee & Rogers, 2017). In this study, experienced GSIs who apply to be mentors are selected and serve as guides and resources for novice GSIs. Prior to mentoring, we provided a research- and practice-based PD seminar for mentors, where mentors met with the mentor facilitators (authors) for 1hr/wk for 15 weeks to learn the roles and expectations of mentors (Portner, 2005; Yee & Rogers, 2017).

Following Speer et al.'s (2010) call for increased research in undergraduate teaching practices, this peer-mentorship program provided a unique and credible lens for examining GSIs' pedagogical needs. As Speer et al. point out, undergraduate teaching practices for GSIs are still in their infancy and also lack significant empirical research about how and what to teach GSIs in PD courses. In our research study, mentor small-group meetings had topics chosen by the mentors and novices as critical and time-sensitive to their current work as new instructors of record. Thus, mentor and novice GSI topics of discussion could offer the field important insight into what teaching topics are critical for GSI development from their point of view.

## Method

### Peer-Mentoring Program Participants

Experienced GSIs at two universities applied and were selected to be mentors by the researchers based on their teaching experiences (aptitude for implementing student-centered techniques), their pedagogical accolades (teaching awards and student evaluations), and most importantly their desire to help novices to improve teaching at their university (essay responses were required). A total of nine mentors, who were mathematics and statistics doctoral candidates, were involved in this study across the two universities.

The number of participants was determined by the average size of each university's mathematics GSI program. Novices who were teaching an undergraduate mathematics course for the first time were required to have a peer mentor as an aspect of the mandatory PD seminar for new GSIs in both universities' mathematics departments. Novices who were teaching these courses for the second time or who already took the PD seminar but did not previously have a teaching assignment were invited to participate. The peer-mentoring program continues over an entire academic year, but we focus on the 32 novices who participated during a single semester because of the timing of when we collected survey data about their experiences.

### Pedagogical Topics Data Collection and Analysis

On a written survey that listed all topics discussed in small groups during the semester for each of the nine mentors, 23 novices. Novices to provided feedback on how valuable they found topics that were discussed in their peer-mentoring, small-group meetings in two ways:

a. From the list of topics from meetings this semester, they found their mentor's name and rated the topics listed on a scale from 1-10 (1=not valued, 10=highly valued).
b. They looked at the topics listed under the other mentors' names and circled those that they believed could have been valuable to discuss in small-group meetings.

To address RQ1, we analyzed the survey responses by considering frequencies of ratings novices provided for part (a) about how valuable they considered the topics they personally discussed with their mentor and small group. Using clustering analysis (Willig & Stainton-Rogers, 2007), we categorized the specific topics small groups discussed by grouping them by themes of participatory structure and educational context (Table 1). Additionally, since different mentors discussed different topics, we analyzed novices' responses to part (b) on the survey by tallying the number of topics circled and determined frequencies for each topic.

*Table 1. Topic Categories Discussed During Peer-Mentoring Small Group Meetings*

| **Categories** | **Examples** | **No. of Mentors** |
|---|---|---|
| (A) Facilitating Collaborative Learning | Strategies to enhance student interaction (e.g., pro and cons of group work, anonymizing questions, and giving students a voice and a choice) | 5 |
| (B) Facilitating Student Engagement | Encouraging student participation; Motivating students; Teaching students with varying levels of background knowledge | 3 |
| (C) Facilitating Reflection | Reflecting on the semester thus far; Things to try next time you teach; Video reflection | 5 |
| (D) Facilitating Constructive Criticism About Teaching | Mock lessons; Discussing strengths the mentor observed in novice's lessons | 6 |
| (E) Creating & Using Formative Assessment During Class | Using formative assessments (e.g., minute papers, polling); Incorporating assessments during class time; How to monitor student learning in class | 5 |
| (F) Creating & Using Effective Summative Assessments | Writing exams, quizzes, or homework assignments | 5 |
| (G) Grading Assessments | How to grade (incl., consistency, remaining objective, & group grading) | 6 |
| (H) Managing Students in Class | Addressing aggressive/overbearing students; Helping with submissive/quiet students; Addressing mathphobia | 3 |
| (I) Managing Students Outside Class | Communicating with students (via emails or in office hours). Communicating about grades | 5 |
| (J) Negotiating GSI Small Group Meeting Behavior | Determining expectations for small group meetings | 6 |
| (K) Managing Time Outside Class | Work-life-school balance | 2 |
| (L) Creating & Modifying Lesson Plans | Ways to save time lesson planning; Creating emergency lesson plans; Modifying lesson plans | 3 |
| (M) Brainstorming Course-Specific Advice | Advice about teaching MATH X; Difficulties about teaching MATH X in the first Y weeks | 2 |

To investigate RQ2, we solicited input from mentors after they completed their first year mentoring. We asked mentors to provide a likely timeline for the topics from Table 1 that they would most likely use in small group meetings if they mentored again. Since small-group meetings were typically bi-weekly, we broke a fifteen-week semester out into two-week blocks and listed the 15$^{th}$ week alone. Mentors specified at most two categories from Table 1 for each 2-week span. They could add additional topics or exclude any of the thirteen categories from their timeline, as they saw fit. Seven of the nine mentors suggested timelines in this way. From these data, we determined the frequencies and timing for each topic, focusing on topics that were suggested by multiple mentors for a similar time period of the semester.

## Results

We first present results relevant to RQ1, focused on what small-group meeting topics novices valued. Based on the mean across all topics by all novices was a 7.85 out of 10 with a standard deviation of 1.46, providing a viable striation of the data into thirds with the partitions of 1-5, 6-8, and 9-10. Thus, when recording responses to part (a) in the survey, we considered their perceived value of a given topic to be reported as: *High* with a 9 or 10 rating, *Medium* with a 6-8 rating, or *Low* with a 1-5 rating. Frequencies for how valuable novices rated each topic are displayed in Figure 1. Since novices only attended small-group meetings with their peer-mentor, they had the opportunity to rate how valuable they would find topics that other small groups discussed. The frequencies of circled topics are displayed in Figure 2, where the percentages are out of the total number of circled items.

We can see there are some topics, that were reported as highly valued (Figure 1) that were also rarely circled (Figure 2). For instance, *grading* (Topic G) was discussed in six mentor's small group meetings, and it was ranked highly valued, but it was only circled 1% of the time.

We interpret this to mean that for topics such as these, novices tended to perceive them as initially helpful, but they did not consider them as necessary to discuss multiple times or in a subsequent semester of peer-mentoring with the same group of novices.

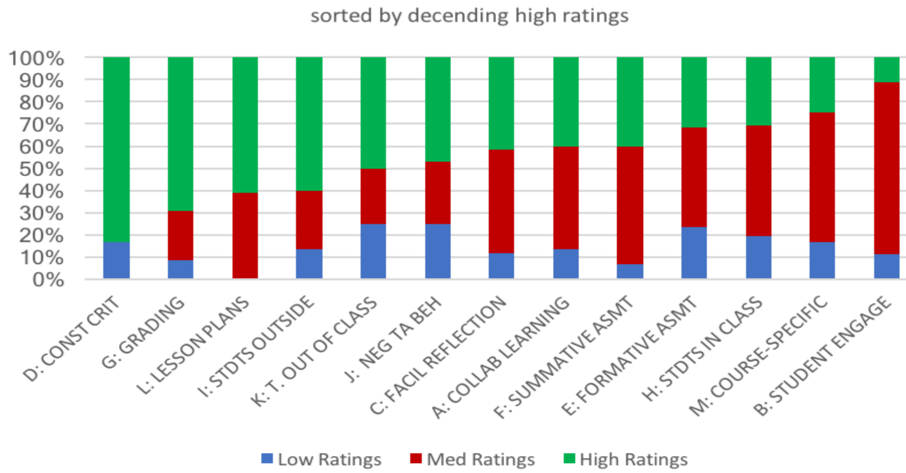

*Figure 1. Small-group meeting topics, sorted by novices' ratings for how they valued that topic.*

Other topics, however, were highly valued (Figure 1) and highly requested for future small-group meetings (Figure 2), even though they were addressed by many of the mentors. For instance, the most highly rated and most frequently circled topic *facilitating constructive criticism about teaching* (Topic D) was also discussed by six of the nine mentors (Table 1).

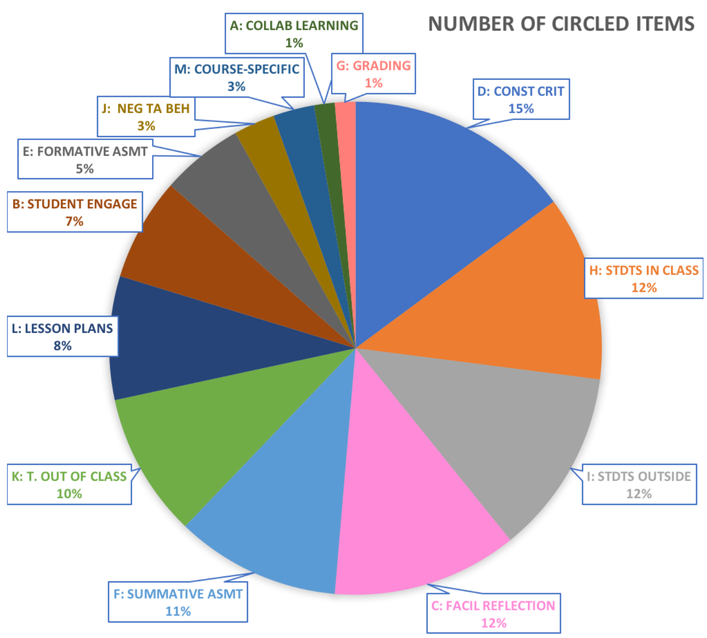

*Figure 2. Frequencies of topics novices circled in answering part (b) of the survey*

This topic often included opportunities for novices to participate in *mock lessons* during the small group meeting. This strategy was suggested when mentors were meeting with the peer-mentoring program facilitator (one author) and brainstorming ways to address one another's concerns. Specifically, one mentor was trying to figure out how to help a novice develop the ability to respond to students' questions with confidence and precise mathematical language during class. Another mentor suggested having the novice present a portion of a prepared lesson to the small group so the rest of the group, and the mentor, could pretend to be undergraduate students and then provide feedback and suggestions for the novice to improve. The rest of the mentors were excited about this strategy and decided to call it a "mock lesson." There was concern, however, that a novice might feel singled out if asked to present a mock lesson, so the mentors further brainstormed about ways to mitigate that possibility (e.g., having the mentor present a mock lesson first or soliciting volunteers from the small group initially then asking the remaining novices to select a week to do the same). This strategy was so well received at the university where it was first discussed that mentors at the other university involved on this project implemented this strategy a few weeks later. The survey results suggest, therefore, that there are topics that are popular among novices despite being addressed by many of the mentors, and should therefore continue to be incorporated into novices' small group meetings.

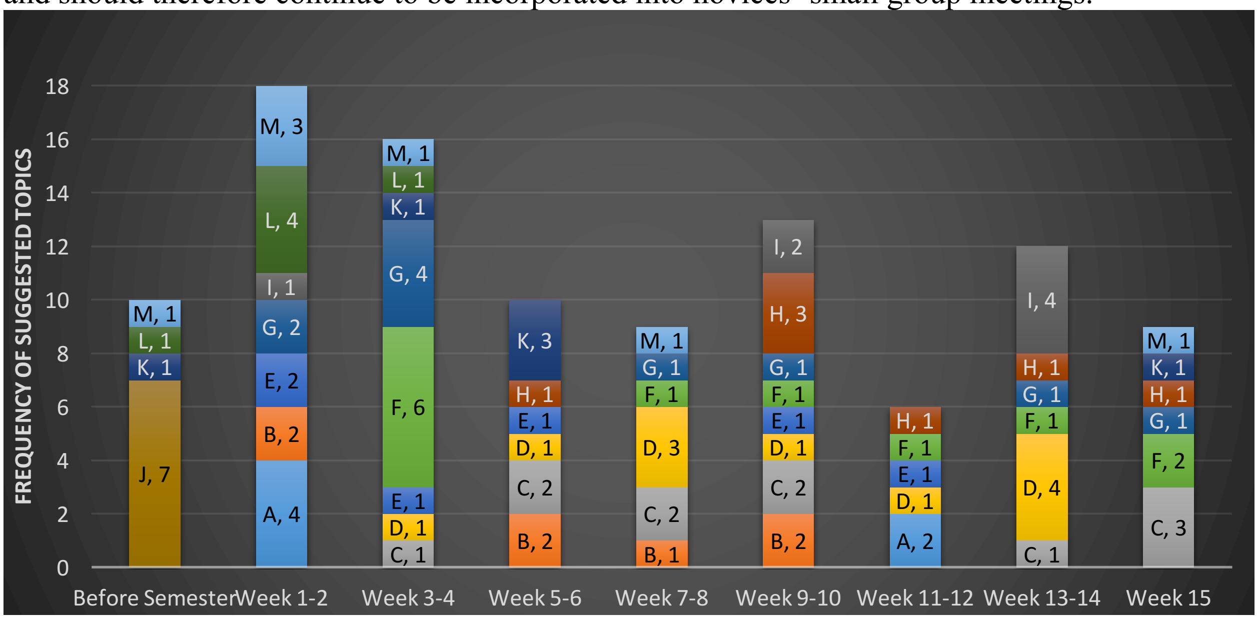

*Figure 3. Mentors suggested timeline of pedagogical topics relative to weeks of a 15-week semester*

Results relevant to RQ2 stem from seven suggested timelines that mentors created after mentoring for two semesters. The frequencies and timing for each topic, focusing on topics that were suggested by multiple mentors for a similar time period of the semester, are presented in Figure 3. The total number of suggested topics on the vertical axis could indicate that there were certain weeks of the semester that mentors considered more critical for sharing issues than others. That is, Weeks 1-2 (18) and Weeks 3-4 (16) had the greatest frequency of topic suggestions, which could suggest mentors saw these as crucial times to work with novices. Later in the semester, however, Weeks 11-12 received the fewest suggested topics.

Figure 3 also shows that before the semester began, all the mentors (7) preferred to discuss small-group meeting behavior (Topic J) rather than letting it unfold throughout the semester. During the first two weeks of the semester, mentors frequently suggested that collaborative learning (Topic A, 4), lesson plans (L, 4), and course-specific advice (M, 3) should be discussed while a majority of mentors suggested summative assessments (F, 6) and grading (G, 4) during Weeks 3-4. Moreover, nearing the end of the semester, mentors frequently suggested different topics: mock lessons (D, 4) and outside of class interactions (I, 4) during weeks 13-14 and reflection (C, 3) during the final week of the semester. By tallying each topic's frequency across the semester, we see that Topics C (11 total), D (11 total), F (12 total), and G (10 total) were the most popular throughout the entire semester with certain weeks where some topics may have been more frequently suggested (Figure 3). If we take the most frequented topic from each two-week timeframe, we see one possible timeline for the small-group meetings to be J, A & L, F & G, K, D, H, A, D & I, and C.

## Discussion

This study investigated what pedagogical topics novice GSIs perceived as valuable when participating in small group meetings during their first or second semester teaching collegiate mathematics and how experienced mentor GSIs suggested (re-)ordering these topics in a semester timeline. For RQ1, we found there were four meeting topics highly valued by at least 50% of novice: mock lessons, grading, interactions outside class, time management, and lesson plans (D, G, I, K, & L, Figure 1). Cross referencing these results with topic preferences novices circled (Figure 2) suggests that novices desired additional future group meetings to be centered around four of these five highly-valued topics (D, I, K and L). These results, coupled with the fact that the number of mentors who addressed these topics varied (6 mentors vs. 2 or 3 mentors; Table 1), suggests novices valued and desired more discussion of these critical topics. Considering the low-ratings (Figure 1), we note that time management (K) and small group behavior (J) had very similar ratings overall, but only two mentors discussed K while a majority discussed J. Cross referencing these results with Figure 2 suggests these topics are ones that novices would like to discuss further, but mentors may need additional, explicit support to facilitate effective discussions about them.

For RQ2, certain pedagogical topics were suggested at certain times with higher frequency than other topics (Figure 3). The most frequented topics throughout a semester were reflection, mock lessons, summative assessments, and grading (C, D, F, & G). Overlapping these results from RQ1, we see that only topic D, facilitating constructive criticism about teaching especially using mock lessons, is pervasive throughout the timeline for the mentors and a highly valued topic of the novices. This suggests that both the novices and mentors valued this topic for peer mentorship. This also supports the need for peer observations (see Yee & Rogers, 2017), another aspect of this peer-mentorship program, because themes from these observations contributed to mentors' use of mock lessons and these observations were designed to provide constructive criticism of novices' teaching.

Findings from this study provide empirical data that can inform undergraduate mathematics education. Our research design allowed us to capture some information about novices' perspectives of pedagogical topics discussed and mentors preferred timeline of those topics while novices were developing as instructors. Together, this data answered our research questions and provided empirical results, desperately needed by the field (Speer et al., 2015), on which pedagogical topics are specifically valued by novice and experienced GSIs of undergraduate mathematics education. Moreover, our work build's on Portner's (2005) work by expanding the field's understanding of teacher mentoring to GSIs of undergraduate mathematics courses.

The valued topics, and their suggested order, directly informed the next iteration of the peer-mentoring program; specifically, before the next mentoring cycle began mentors generated a draft of meeting topics informed by these results. More broadly, these findings can also provide structure for other universities designing teaching seminars, pedagogical courses, and teacher development. For example, an undergraduate teacher educator or course coordinator could use the results from Figure 3 to determine an ordering of certain course material relative to the timeline of struggles relevant to novice undergraduate instructors.

What are Conveyed Meanings from a Teacher to Students?

Author 1 Author 2

*In this paper we provide a new lens to explain conceptual connections between what a teacher knows, what a teacher does in the classrooms, and what his or her students learn. We observed three teachers' lessons and interviewed the three teachers and their students. By examining our data, we see that teachers' meanings and their assumptions about what students already understand have an impact on the ways they expressed their meanings during instruction. Then, students developed their meanings in trying to understand what the teacher said and did. Our analyses suggest that teachers need to think about how students might understand their instructional actions so that they can convey what they intend to their students.*

*Keywords:* Slope, Mathematical meanings, Conveyance of meaning

Teachers' mathematical meanings play a significant role in student learning. It is plausible that the more coherent mathematical understanding a teacher holds, students will have greater opportunities to construct robust understanding students have. In order to see how teachers' mathematical understanding influences student understanding researchers have investigated relationships between teacher understanding and student learning. They have tried to measure teachers' mathematical knowledge, the quality of instruction, and student performance. Studies have demonstrated that there is a positive relationship between teacher knowledge and student performance as well as teacher knowledge and their instructional quality (Baumert et al., 2010; Hill, Ball, Blunk, Goffney, & Rowan, 2007). However, researchers used different instruments to measure teachers' mathematical knowledge, the quality of instruction, and student performance: an assessment for teachers' performance, measure for teachers' performance in actual instruction, and a test for student achievement. Thus, what the researchers measured as teacher knowledge is not connected with what teachers did in instruction and what students understood because they used different frameworks for viewing them.

This study is designed to provide a new lens to explain conceptual connections between what teachers know, what teachers do in the classrooms, and what students learn. We studied these connections by using the constructs of *meaning* and *conveyance of meaning* to guide observations and analyses of classroom observations and interviews with teachers and students. We present a subset of our data by focusing on three teachers who taught the concept of slope and investigate teachers' understanding of slope, their instructional actions, and what students understood from the lessons. We seek to answer the following research question: *What relationships are there between teachers' mathematical meanings for slope, teachers' instructional actions, and meanings that their students construct regarding slope?*

## Literature Review

Deborah Ball and colleagues in Michigan and have developed assessments for mathematical knowledge for teaching (MKT) targeting elementary or middle school teachers in the U.S. (Charalambous & Hill, 2012; Schilling, Blunk, & Hill, 2007). COACTIV (Professional Competence of Teachers, **Co**gnitively **Activ**ating Instruction, and the Development of Students' Mathematical Literacy) also developed assessments for secondary mathematics teachers in Germany (Baumert et al., 2010; Kunter et al., 2007). The two research groups agreed that teacher knowledge influences students' mathematical achievement and the quality of instruction. Both the MKT group and the COACTIV group investigated two relationships: (1) the relationship between teachers' knowledge and students' performance, (2) the relationship between teachers' performance and the quality of their instruction. They used three different assessments to measure teacher knowledge, the quality of instruction, and student achievement.

The MKT group found that there is a positive relationship between teachers' knowledge and students' performance by showing that teachers' higher scores on the MKT assessment did predict gains in students' scores over the course of one year. They also demonstrated that teachers' higher scores on MKT assessment predict higher quality of instruction by reporting that teachers with lower scores showed more errors in their lesson whereas teachers with higher scores provided students with rich examples and representations (Hill et al., 2007). Similarly, the COACTIV group demonstrated that there is a positive relationship between teachers' higher scores on an assessment and students' higher scores on a single test (Baumert et al., 2010). They also found empirical evidence to confirm that there is a positive relationship between the quality of instruction and teachers' knowledge (Baumert et al., 2010; Kunter et al., 2007).

Both the MKT and COACTIV groups tried to find statistical relationships between what teachers know and what students performed as well as between what teachers know and what teachers teach. However, the groups focused on whether or not students solved mathematical problems correctly rather than focusing on the concepts students formed from teachers' instruction. Moreover, the two groups did not try to explain how teachers' knowledge influences student performance through their instruction because they did not ask what a student understands of what his or her teacher said. Thus, the MKT and COACTIV groups did not explain why what teachers know led them to do what they did in their instruction, nor how their instruction led students to learn what they learned. In the following, we present a new perspective to investigate what students learn from their teachers and the mechanisms of teacher influence.

## Theoretical Framework

Coherent mathematical meanings serve as a foundation for future learning, so it is important that students build useful and robust meanings. One way students develop meanings is by trying to make sense of what their teacher says and does in the classroom. Before discussing how meanings are conveyed from a teacher to students in the classroom, we explain what we mean by *meanings*. According to Piaget, to understand is to assimilate to a scheme (Thompson, 2013) and "assimilation is the source of schemes" (Piaget, 1977, p.70 cited in Thompson, 2013). A scheme is an organization of images, meanings and schemes. For example, a student can understand slope as a coefficient of $x$ because she learned "$m$" is slope in $y = mx + n$. This is her understanding of slope in the moment. Then, she could think about slope as "1" when first looking at $x = 1$ because 1 is the coefficient of $x$. This is an implication of her understanding in the moment. The students' meaning in the moment of understanding is the space of implications of that understanding. In this sense, what Thompson (2013) meant by *meaning* is the space of implications of an understanding.

Consider a teacher who teaches mathematical ideas to his students. A teacher has his meanings for the mathematical ideas. The teacher intends to convey the mathematical ideas to his students. In doing so, the teacher and his students are interacting and making an attempt to interpret others in class. Thompson (2013) proposed a theory to explain how two persons (person A and person B) attempt to have a conversation.

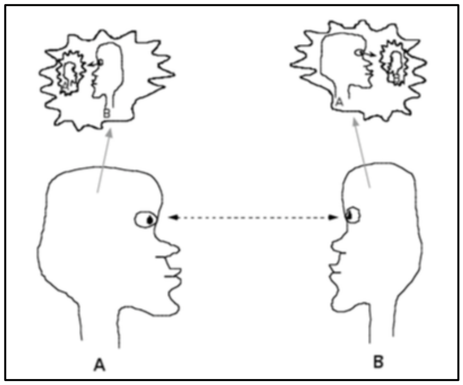

*Figure 1. Person A and B attempting to have a conversation (Thompson, 2013)*

According to Thompson (2013), person A in Figure 1 holds something in mind that he intends Person B to understand. Person A considers not only how to express what he intends to convey but also how person B might hear person A. In doing so, person A constructs his model of how he thinks person B might interpret him. Person B does the same thing in the conversation. Person B constructs her understanding of what person A said by thinking of what she would have meant if she were to say that. Thus, person B's understanding of what person A said comes from what she knows about person A's meanings, thereby person B's understanding of person A's utterance does not have to be the same as what person A meant.

Thompson's (2013) theory of conveyance of meaning is useful to explain what occurs in class. A teacher will express his meanings to his students by saying or doing something. Then, his students try to understand what the teacher says and does. Whatever meanings his students construct by attempting to understand what the teacher intends is the meaning that the teacher conveyed to the students. The conveyed meaning might or might not be the same as the teacher's meaning, and most likely is not.

Lew, Fukawa-Connelly, Mejía-Ramos, and Weber (2016) showed a discrepancy between what an instructor intended and what his students understood. The theory of conveyance of meaning explains why students might not understand what the teacher tried to convey. The conveyed meaning, whatever senses students made of, is rarely consistent with teachers' meaning or intended meaning.

## Methodology

Our research team developed the Mathematical Meanings for Teaching Secondary Mathematics (MMTsm), a diagnostic instrument designed to investigate mathematical meanings with which teachers operate. We administered the *MMTsm* to 513 U.S. and Korean high school teachers in 2013, 2014 and 2015. Eight Korean teachers agreed to classroom observations. Three high school teachers taught lessons on linear equations.

We used items in the *MMTsm* to see the three teachers' meanings for slope. One of items used is in Figure 2.

| |
|---|
| Mrs. Samber taught an introductory lesson on slope. In the lesson she divided 8.2 by 2.7 to calculate the slope of a line, getting 3.04.<br>Convey to Mrs. Samber's students what 3.04 means. |

*Figure 2. A slope item in the MMTsm © 2015 Arizona Board of Regents. Used with permission*

The first author asked each teacher to select two students who, in their judgment, have attended during lessons. For each classroom observation we conducted separate pre-lesson interviews and post-lesson interviews with the teacher and two students. The process of this study for one teacher is shown in Figure 3.

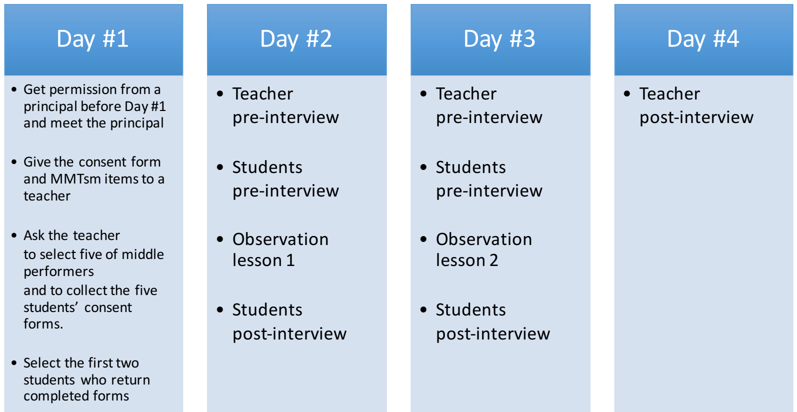

*Figure 3. The process of classroom observations for one teacher*

Before observing the first lesson, the first author conducted a pre-lesson interview with the teacher to investigate what the teacher intended students to learn. One of pre-lesson interview questions was, "Do you think your students might understand slope differently than what you intend?" We asked this to discern what the teachers think about student thinking before the lesson. After the pre-lesson interview with the teacher, the first author met the two students selected for interviews. The purpose of the pre-lesson interviews for students was to see their understanding of the topic covered in the upcoming lesson. We compared students' meanings demonstrated in pre-lesson interviews to their meanings demonstrated in post-lesson interviews to conclude what they understood from the lesson. After the lesson, the first author asked a student to describe what he learned from the lesson. The purpose of the post-lesson interviews for teachers was to give them the opportunity to reflect on their teaching and their meanings by showing excerpts from the two student interviews that reveal how they understood central ideas of the lesson.

We audio recorded pre-lesson interviews with teachers and students and post-lesson interviews with teachers. However, we video recorded the lessons and post-lesson interviews with students because we showed video clips of students' post-lesson interviews to their teachers.

## Results

Prior to pre-lesson interviews with the three teachers the first author reviewed their responses to the MMTsm item on meanings for slope. Table 1 summarizes three teachers' meanings for slope. The interviewer asked the three teachers in pre-lesson interviews to see their intentions for the lesson and what they think about student thinking.

*Table 1. Teachers' meanings in the slope item (see Figure 2)*

| | What the teacher wrote in the slope item |
|---|---|
| Jessica | Slope 3.04 means if $x$ increases by 2.7 (or 1), $y$ increases by 8.2 (or 3.04). |
| Katie | Rate of change in $y$ (8.2) when $x$ changes by 2.7 |

| | | |
|---|---|---|
| Liam | $\frac{\text{change in } y \text{ (rate of change)=8.2}}{\text{change in } x \text{ (rate of change)=2.7}} = 3.04$ |

The three teachers' meanings for slope focused on the relationship between a change in $x$ and the associated change in $y$. Additionally, teachers' thoughts on student thinking and their assumptions about what students already knew were similar. Each of the teachers seemed to be unaware that students might understand the concept of slope differently than they did. Although all of the teachers assumed students already knew the definition of slope before the lesson, their intentions for the lesson were different. Jessica and Liam wanted students to understand the idea of slope conceptually. In particular, Jessica said she would introduce advanced mathematical terms such as infinitesimal to help students understand slope conceptually. On the other hand, Katie wanted her students to understand slope as a part of formula. Katie wanted her students to use the slope formula algorithmically. The teachers taught the concept of slope differently, according to their intentions. What they said and did in class is in Table 2.

*Table 2. Teachers' lessons*

| Teacher | Lesson |
|---|---|
| Jessica | She said that slope is defined as "change in $y$/change in $x$" and "$\Delta y/\Delta x$". She drew $y=y_1$ graph, and said the slope is zero (without explanation). When teaching $x=x_1$ graph, she said the slope of $x=x_1$ is not defined because the denominator is zero in the slope formula that is $\Delta y/\Delta x$. She also said $\Delta y/0$ is not the same as neither infinite nor infinitesimal because infinite or infinitesimal is not a number but a process that is close to infinity or a very small number. |
| Katie | She said that when there are two points given, slope is $\frac{y_2-y_1}{x_2-x_1}$. Then, she said that the denominator of $\frac{y_2-y_1}{x_2-x_1}$ would be zero when $x_1=x_2$, so we cannot use $\frac{y_2-y_1}{x_2-x_1}$. She asked students to think about a case where slope is zero. Then, she kept saying $x_1=x_2$. One student asked "what is the slope of $y_1=y_2$?" She answered slope is zero by using $y=\frac{y_2-y_1}{x_2-x_1}(x-x_1)+y_1$. |
| Liam | He taught slope is tanθ and the coefficient $a$ of $x$ while pointing $y=ax+b$. Then, he compared $y=ax+b$ with $ax+by+c=0$. |

Jessica introduced infinite and infinitesimal to explain why the slope of $x=x_1$ is undefined. Katie emphasized the formula for slope during the lesson. During her lesson, Katie frequently said $x_1=x_2$ after discussion cases where the slooe was zero. Students in Katie's class might have understood Katie's claims to mean that the slope of $x_1=x_2$ is zero. In Liam's class, he said slope is tanθ because he assumed students already knew slope is $\Delta y/\Delta x$. He also mentioned slope is "$a$" while pointing at the equation $y=ax+b$.

After the lessons, the first author interviewed two students in each teacher's class to determine the conveyed meanings from the lesson, that is, to determine what the students understood. By comparing students' pre and post-lesson interviews we can witness meanings that students developed in the lesson. One student's meanings per each teacher in pre and post-lesson interviews are in Table 3.

*Table 3. Students' meanings in pre and post-lesson interviews*

| Teacher | Student | Meaning in pre-lesson interview | Meaning in post-lesson interview |
|---|---|---|---|
| Jessica | Justin | Slope is $\Delta y/\Delta x$ and slantiness. So, if $\lvert m \rvert$ (when $m$ is slope) is increasing, the line would be closer to $y$-axis. | Slope is $\frac{y_1 - y}{x_1 - x}$. He realized $\Delta y/\Delta x$ is connected to $\frac{y_1 - y}{x_1 - x}$. Regarding the slope of $x=x_1$ he said "the teacher said the denominator cannot be zero, but I cannot remember why she explained it." $x=x_1$ doesn't have slantiness, so the slope is zero. That means there is no slope of $x=x_1$. |
| Katie | Kim | Slope is slantiness and the length of hypotenuse (of a triangle), so she can measure slope by using Pythagorean Theorem. Slopes of $x$=2 and $y$=2 are all zero. | She still tried to use Pythagorean Theorem to find slope, then wrote $y - x_1 = \frac{x_1}{x_2}(x - x_1)$. Then, she found $\Delta y/\Delta x$ is different from $\frac{x_1}{x_2}$. After trying (3,4) and (2,6), she arrived at $\frac{y_2 - y_1}{x_2 - x_1}$. Slopes of $x$=3 and $y$=3 are zero. There is no slope of $y$=3. The slope of $y$=3 cannot be represented because it's parallel to $x$-axis. "No slope", "not being represented", and "zero slope" are same. |
| Liam | Lori | Slope is change in $y$ divided by change in $x$ and something related to an angle. Slope of $y$=2 is zero according to $\Delta y/\Delta x$. Additionally, Slope of $y$=2 is zero because the coefficient of $x$ is zero in $y=ax+b$. Slope of $x$=2 is 1 because the coefficient of $x$ is 1 in $y=ax+b$. | Slope is "$a$" in $y=ax+b$. Slope of $y$=2 is zero because the coefficient of $x$ is zero in $y=ax+b$. Slope of $x$=2 is 1 because the coefficient of $x$ is 1 in $y=ax+b$. |

Jessica's student, Justin, did not remember why she mentioned infinite and infinitesimal during the lesson. Justin thought the slope of $x=x_1$ is zero because $x=x_1$ does not have slantiness, which means no slope of $x=x_1$. Slantiness seemed to dominate Justin's meaning for slope even after the lesson. Kim's meanings for slope were changing during her post-lesson interview. Although she still made an attempt to use Pythagorean Theorem after the lesson, she came up with $\Delta y/\Delta x$. However, three statements, "the slope of $y$=3 cannot be represented," "the slope of $y$=3 is zero," and "there is no slope of $y$=3," were equivalent to Kim. In the case of Lori, her meanings for slope had not changed after the lesson. She kept saying that slope is the coefficient of $x$, so slope of $y$=2 is zero and slope of $x$=2 is 1. Lori's meaning for slope as the coefficient of $x$ was consistent with what Liam said and wrote in the lesson.

## Conclusion

The results show that teachers' meanings for slope and their assumptions about what students already understood influenced their instructional decisions. Three teachers assumed that students already learned the idea of slope, which led them to explain the basic concept of slope briefly. Jessica introduced difficult terms such as infinitesimal and Liam taught slope as tanθ and a coefficient of *x*.

The ways teachers expressed their meanings for slope in the lessons have an effect on meanings that students developed in the lessons. In Katie's lesson, she asked about a case where slope is zero and kept saying $x_1 = x_2$, which led her student to think slope of *x*=3 is zero. In the case of Liam, he said slope is a coefficient of *x* while pointing to the equation *y*=*ax*+*b*. What Liam said in class influenced his student's meaning as demonstrated in her claim that the slope of *x*=2 is 1 because the coefficient of *x* is 1 in *y*=*ax*+*b*.

In this study, we present a subset of our data as an illustration of the method for exploring teachers' meanings for the ideas they teach, the ways they express their meanings in instruction, and how students' meanings are affected by their attempts to understand what their teacher intends to convey. To do so, we created a method to explain how what teachers know led them to do what they did in the instruction, which affected what students learned. This study necessitates a conceptually coherent framework to investigate the relationships between what teachers know, what teachers do in the classrooms, and what their students learn. Suppose that we had scored what teachers wrote in the slope item and what students expressed during interviews in terms of correctness. Every teacher would have received a perfect score whereas every student would have received a low score because they expressed mathematically incorrect reasoning. Thus, we could not have demonstrated why students developed their meanings in the lessons. Additionally, if we had used different frameworks for teachers' meanings, their instructional actions, and meanings that their students developed we could not have explained what students understood from their teacher's instruction as well as why teachers made their instructional decisions.

Our results also suggest that teachers' high level of meaning does not guarantee that they convey their meanings to students in class. In post-lesson interviews, all three teachers said the conveyed meanings to their students were not what they intended to convey after watching students' video clips. This points to a breakdown in the conveyance of meaning from teacher to student when the teacher has no image of how students might understand his or her statements and actions. In this sense, this study indicates that teachers need to think about how students might understand their statements and actions when preparing for lessons in order to convey what they intend.

The Creation of a Humanistic Educational Framework for the Nature of Pure Mathematics

Jeffrey D. Pair
California State University Long Beach

*Within the field of mathematics education research, scholars have found that students often have naïve views about the nature of mathematics. Mathematics is seen as an impersonal and uncreative subject. What can educators do to challenge such views, and support students in developing richer understandings of the nature of mathematics? In this paper, I describe my dissertation study, the goal of which was to identify humanistic characteristics of pure mathematics which may be of benefit for undergraduate students in a transition-to-proof course to know and understand. Using the methodological framework of heuristic inquiry, which leverages the researcher as instrument in qualitative research, I identified humanistic characteristics of mathematics by reviewing relevant literature, collaborating with a professional mathematician, co-teaching an undergraduate transition-to-proof course, and being open to mathematics wherever it appeared in life. The main result is the IDEA Framework for the Nature of Pure Mathematics.*

*Keywords:* Nature of Mathematics, Identity, Dynamic Knowledge, Exploration, Argumentation

Students rarely have an opportunity to reflect on the nature of mathematics. Many have naïve views of mathematics, perhaps believing that mathematics is a static body of knowledge consisting of arbitrary rules and procedures (Beswick, 2012; Erlwanger, 1973; Muis, Trevors, Duffy, Ranellucci, & Foy, 2016; Presmeg, 2007; Solomon & Croft, 2016; Thompson, 1992). These naïve views may negatively affect the learning of mathematics (Erlwanger, 1973; Maciejewski, 2016). As Maciejewski (2016) claimed, "A deeper, connected view of the subject correlates to a deeper approach to study [...] Fragmented, superficial perspectives often result in less desirable outcomes" (p. 1). Many mathematics education scholars view and describe mathematical knowledge as a dynamic human product (Boaler, 2016), and emphasize the human aspects of mathematical work such as creativity (Burton, 1999) and fallibility (Ernest, 1991). These modern views are influenced by cultural approaches to mathematics (Bishop, 1988), theories of embodied cognition (Lakoff & Nuñez, 2000), humanistic philosophy of mathematics (Ernest, 1991), or perhaps scholars' own experiences doing mathematical work (e.g. Hersh, 1997). The gap between the views of mathematics held by students and the perspectives held by scholars needs to be addressed within mathematics education research.

## Purpose of the Study

While scholars in science education have done significant research aimed at understanding the teaching and learning of the nature of science (Lederman & Lederman, 2014), including undergraduate research (e.g. Abd-El-Khalick & Lederman, 2000; Schalk, 2012; Willoughby & Johnson, 2017), relatively little research has been done on this subject within mathematics education (Kean, 2012; Jankvist, 2015; White-Fredette, 2010). Research on the teaching and learning of the nature of science (NOS) is guided by frameworks or lists that explicitly outline goals for students' understanding of NOS (Lederman & Lederman, 2014). For instance, a goal is for students to understand that "Scientific knowledge is open to revision in light of new evidence" (NGSS, 2013, p. 4). These lists aid researchers in assessing whether instruction is effective in teaching students about the nature of science.

Researchers in mathematics education have not systematically studied the nature of mathematics to the extent that science education researchers have studied NOS (Kean, 2012). Our field has lists that outline important mathematical practices (e.g. CCSSI, 2010; NCTM, 2000) and mathematical habits of mind (e.g. Cuoco, Goldenberg, & Mark, 1996), but we do not have lists that outline goals for students' understanding of the nature of mathematics. Such a list would provide university instructors a guide for teaching the nature of mathematics to undergraduates mathematics students, including pre-service teachers. Alba Thompson (1992) noted, "Very few cases of teachers with an informed historical and philosophical perspective of mathematics have been documented in the literature" (p. 141). School teachers will not have informed views until the university, the place where teachers are educated, makes the nature of mathematics a subject of study for its students.

The purpose of this research project was to produce a humanistic framework for the nature of mathematics outlining characteristics of mathematics that may serve as goals for undergraduates' understandings. Two broad questions, "What is the nature of pure mathematics?" and "What should students understand about the nature of pure mathematics?" guided this study. Moreover, I focused on undergraduate students' understanding of the nature of pure mathematics within a transition-to-proof course. I sought to understand, "What should undergraduate students in a transition-to-proof course understand about the nature of pure mathematics?"

Felix Browder (1976) defined pure mathematics to be "that part of mathematical activity that is done without explicit or immediate consideration of direct application to other intellectual domains or domains of human practice" (p. 542). Undergraduate mathematics majors and minors experience pure mathematics in courses such as abstract algebra, topology, analysis, and transition-to-proof. Within transition-to-proof courses, students are expected to pick up the terminology of pure mathematics (e.g. theorem, conjecture, proof), learn to write proofs, and develop an understanding of selected pure mathematics content (e.g. set theory, functions and relations). To meet these learning goals, it may be necessary for instructors to discuss pure mathematics' particular nature, because what is valued in transition-to-proof may be different than what has been valued in students' prior mathematics courses.

## Methodology

### Theoretical and Methodological Frameworks

I sought to understand what is the nature of pure mathematics? But of course, pure mathematics is what mathematicians do. Courant and Robbins (1941) wrote, "For scholars and laymen alike it is not philosophy but active experience in mathematics itself that can alone answer the question: What is mathematics?" (p. xix). I reasoned that if I really wanted to understand the nature of mathematics, then I must have experience doing mathematics. I thus decided that a core feature of my study would be the documentation of and reflection on my collaboration with a research mathematician. Patton (2015) wrote that the core question of heuristic inquiry is "What is my experience of this phenomenon and the essential experience of others who also experience this phenomenon intensely?" (p. 118). In this light, heuristic inquiry seemed to be a perfect fit to study my experience doing pure mathematics for the purposes of developing a humanistic educational framework for the nature of mathematics. Heuristic inquiry is a self-study, and Douglass and Moustakas (1985) noted that, "It is the focus on the human person in experience and that person's reflective search, awareness, and discovery that constitutes the essential core of heuristic investigation" (p. 42). The ultimate end of heuristic inquiry is what Moustakas (1990) called the creative synthesis, in which

> The researcher creates an original integration of the material that reflects the researcher's intuition, imagination, and personal knowledge of meanings and essences of the experience. The creative synthesis may take the form of a lyric poem, a song, a narrative description, a story, or a metaphoric tale. In this way, the experience as a whole is presented, and, unlike most research studies, the individual persons remain intact. (p. 51)

Narratives play an important role in the mathematics education research (e.g. Ball, 1993; Erlwanger, 1973; Lampert, 1990), as stories can provide context for discussing and reflecting on ideas. In addition to a humanistic framework for the nature of mathematics (presented in the results of this paper), my dissertation also features ten stories that illuminate the characteristics of mathematics that comprise the framework. These are stories of my collaboration with a professional mathematician, events that took place in a transition-to-proof classroom I co-taught, or perhaps meaningful stories of my own family's interaction with mathematics. Each of these stories features direct quotations from the data that I collected.

The methodological framework of heuristic inquiry, which has roots in humanistic psychology, meshes well with the theoretical stance of humanism which I also take in this study in regards to the nature of mathematics. Humanistic philosophers of mathematics (e.g. Lakatos, 1976; Tymoczko, 1988) are frequently cited in mathematics education literature (e.g. Ball, 1988; Boaler, 2016; Komatsu, 2016; Lampert, 1990; Larsen & Zandieh, 2008; Weber, Inglis, Mejia-Ramos, 2014). Humanistic approaches are unique in that they take as foundational the notion that mathematical knowledge is a human product. As Hersh (1997) wrote, "To the humanist, mathematics is *ours*—our tool, our plaything" (p. 60). I sought to create a humanistic educational framework for the nature of mathematics that may guide the teaching and learning of the nature of mathematics and challenge naïve views. Humanistic philosophy of mathematics (e.g. Ernest, 1991; Hersh, 1997; Lakatos, 1976) and relevant mathematics education literature (e.g. Lampert, 1990, Thompson, 1992, White-Fredette, 2010) informed an initial review of the literature in which I identified several possible goals for student understanding of the nature of mathematics (Author, 2017). After the completion of this literature review, I continued my dissertation study using the methodological framework of heuristic inquiry.

**Data Sources**

In efforts to understand the nature of pure mathematics, I sought collaboration with a graph theorist, a full professor and active research mathematician, whom I refer to as Dr. Combinatorial. Dr. Combinatorial and I worked together in efforts to prove one of his unsolved conjectures related to the chromatic number of a graph. I recorded all of our conversations in which we discussed the conjecture, and kept hard copies or photos of all of our mathematical work. Throughout the process of working on the conjecture, I was not only doing mathematics, but I was constantly reflecting on my own experience and the nature of pure mathematics.

In order to reflect on what undergraduates should understand about the nature of pure mathematics, I also collected data in a transition-to-proof course required of undergraduate mathematics majors at a large Southeastern university. The course is called "Foundations of Higher Mathematics" and is meant to serve as a transition course as students proceed from lower-level to upper-level mathematics coursework. The transition represents a shift from the traditional procedurally-based school mathematics to the work that more closely resembles that of pure mathematicians. I co-taught this course with another mathematics education scholar, Dr. Amicable, who had designed the course and taught it for seven prior semesters. I fully took over teaching the last month of the semester as she took a planned leave of absence. The course was inquiry-based in nature, and students were constantly working together to draft arguments, critique arguments, and discuss and debate proof writing techniques. Twenty-three students from the course agreed to participate in the study. Dr. Amicable asked all of the students to choose a number type that best captured their own personalities. I have chosen these number types (e.g. Binary, Whole, Natural) to be their pseudonyms in this paper. I chose the number type Surreal as my own pseudonym. The data I gathered from this course included audio recordings of discussions I had with the co-instructor, audio of whole-class discussions, student homework, classwork, exit tickets, and all other class materials.

Another crucial piece of data for this self-study was a personal journal that I kept in order to write and reflect about my experiences doing and teaching mathematics. My writings were particularly focused on documenting and reflecting on my experiences relevant to the nature of mathematics (NOM) and its teaching and learning. Another source of data came from audio recordings of informal coffee-shop style interviews that I conducted with persons whom I was interested in speaking to about NOM (e.g. mathematicians). These interviews generally consisted of conversations about NOM and interviewees' opinions about what students should understand about NOM. Six people agreed to such interviews, and in some cases multiple interviews were conducted. Most notably among these were two mathematicians. Speaking to these mathematicians, I was able to get feedback on my ideas about possible goals for students' understanding of the nature of mathematics. See Table 1 for a list of all the data that was collected for this study.

*Table 1. Data Sources*

| |
|---|
| <u>Mathematics Collaboration Data</u> |
| Audio-recordings of discussions with mathematician |
| Hard copies of mathematical work (whiteboard photos and personal notebooks) |
| <u>Mathematics Course Data</u> |
| Class materials (e.g. handouts, PowerPoint slides) |
| Audio recordings of whole class discussions |
| Audio recordings of discussions with co-instructor |
| Student homework, classwork, and exit tickets |
| <u>Journal Data</u> |
| Journal in which the researcher reflected on his experiences doing mathematics, teaching mathematics, discussing NOM, and reading NOM literature |
| <u>Other Data</u> |
| Informal Interviews |
| Personal Audio / Other Photos / Documents / Notes |

**Data Analysis**

Moustakas (1990) wrote that heuristic analysis is on-going from the beginning to the end of an inquiry. Throughout the data collection process, I had in mind the inquiry questions, "What is the nature of pure mathematics?" and "What should students understand about the nature of pure mathematics (NOM)?" Whenever I had an idea for a possible NOM goal (for student understanding), I wrote it out and then saved it into a single word document. At the end of data collection I had a list of fifteen possible candidates for a NOM framework in addition to the initial characteristics identified in the literature review for a total of nineteen characteristics.

Often these characteristics were the topics of conversation during the informal interviews, as I asked mathematicians and others if they considered these characteristics to be worthy goals for student understanding of the nature of mathematics.

After the data was collected, I received feedback on preliminary results at research conferences and job presentations. I then transcribed all of the data (frequently making reflective notes pertaining to the nature of mathematics), and coded the entire set of data using the qualitative software Atlas-ti according to the potential NOM characteristics, which were used as deductive codes (Patton, 2015). Based on the collected data quotations associated with each code, I drafted stories of my experience to illuminate key features of the nature of mathematics. I sought to identify features of the nature of mathematics for which I could tell clear and compelling stories; characteristics that were not only grounded in the data, but also representative of my experience.

## Results

### The IDEA Framework for the Nature of Mathematics

The main result of this study is the IDEA Framework for the Nature of Pure Mathematics which consists of four characteristics: 1) Our mathematical ideas and practices are part of our ***i**dentity*; 2) Mathematical knowledge and practices are ***d**ynamic* and forever refined; 3) Pure mathematical inquiry is an emotional ***e**xploration* of ideas; and 4) Mathematical ideas and knowledge are socially vetted through ***a**rgumentation*. Note that IDEA corresponds to the key concepts of each of the four characteristics: I-Identity, D-Dynamic, E-Exploration, and A-Argumentation. I also tell ten stories to illuminate these characteristics of the nature of mathematics, but due to space limitations I will only present two abbreviated stories in this paper, *Tension* and *We are the Future*. In terms of the IDEA framework, these stories primarily illustrate the *E* and *D* characteristics of the framework. The first narrative, *Tension*, highlights the notion that pure mathematical inquiry is an Exploration of ideas. The second narrative, *We are the Future*, highlights the idea that mathematical practices (particularly standards of proof) are Dynamic, negotiated through Argumentation. The notion that our mathematical ideas are part of our Identity will be explored in-depth in another paper presented at the conference on RUME 2018. I tell the two stories now, followed by discussion and conclusions.

### Tension: Pure Mathematical Inquiry is an Emotional Exploration of Ideas

One of the first significant realizations I had during my inquiry into pure mathematics was that engaging with pure mathematics involves an emotional exploration of ideas. One night I began to work on Dr. Combinatorial's conjecture, and I wanted to summarize the important theorems I had just begun to understand. I wished to solidify them in my own mind so that I could make progress on finding a proof for the conjecture. I sat on my bed, writing theorems and proofs in my notebook. Upon writing a proof for a simple result, I noticed a tension. In at least one line, it is clear that I was writing the proof as I would write a proof in my graduate mathematics courses, as if I expected it to be read and graded. I labeled a 7-cycle as $u_1 - u_2 - u_3 - u_4 - u_5 - u_6 - u_7 - u_1$, but I did not use this symbolization elsewhere in the proof. Rather, I convinced myself of the truth of the conjecture through informal methods—drawing a diagram and counting possible chords. I could have written a formal argument, but it did not seem necessary. The tension is that on the one hand, I was working for personal understanding and on the other I was writing with the standards of rigor I believed to be expected in mathematical writing. The conflict is between a personal exploration and understanding of ideas versus the crafting of a communicative proof that satisfies perceived norms of rigor and symbolization.

After proving that theorem I moved onto another one, which involved a proof by induction. I wrote out minute details of the basis step for the n=0 and n=1 cases that were already clear in my own mind (but may not have been clear to a reader). I then wrote, "I find myself realizing this proof is more for me than another. I don't need to communicate all the details. The magic of mathematics is in the ideas one experiences when proving." Essentially I was giving myself permission, with those words, to drop any unnecessary symbolism and tedious explication, and just explore the mathematical ideas (and document that exploration). The very next thing I wrote was, "Out of curiosity, can I show [the n=2 case]?" I already knew a proof by induction could prove for all cases, but I decided to look at a specific case so I could better understand the general argument. I worked through this case myself, drawing several interesting figures. Then I wanted to keep going. I went on to prove the n=3 case. I was enjoying looking at the individual cases, and gaining insight through my work on them. I found the ideas involved in these types of proofs intellectually stimulating. As I began exploring the mathematical ideas related to this conjecture, I found deep satisfaction. Pure mathematics is an enjoyable exploration of ideas. The mathematics came alive through the proving process. Consider this journal entry:

> It is interesting how I see the problem forming. The proof of the problem is different in nature than the class of graphs the proof refers to. The proof has its own concept imagery in my mind—different mathematical processes and procedures disjoint from the class of graphs itself. … The mathematics is alive within the proof. When I imagine the truth of the conjecture, it is some sad lonely objective reality. But the proof is where the magic is. It is where my mind is. It is where the structure can be seen.

**We are the Future: Mathematics is Dynamic and Forever Changing**

One day near the end of a transition-to-proof class session, students were debating how much detail they needed to put into their proofs. If $k$ is an integer and $j$ is an integer, do you have to write "$k + j$ is an integer" if you use the fact within a proof? And do you have to justify this step by mentioning the closure property of the integers under addition? Some of the students say yes. Others say no. Others want to know if they will be "docked for points" if they do not.

Dr. Amicable says that the students should do whatever the classroom community agrees is best for communication. She asks me what I am thinking and I mention that in professional mathematics papers, there will often be gaps. I say, "It is assumed the mathematician audience knows these things. This sometimes makes the papers difficult for me to read—for someone like me who is not a super mathematician. So I would maybe appreciate some clarity sometimes."

Infinitely Repeating Decimal asks if he, or any other member of the class, were going to write up something for publication, "Would it be viewed in a negative light if it was too expository in areas in which it over explains?" I explain that it is a difference of opinion:

> Surreal: When I wrote my thesis, my professor said, "If we are going to publish this you will have to cut a bunch of stuff." But to me the papers are so hard to read. I would welcome someone coming into the mathematics community who was very explanatory. I just wish more mathematicians could really clearly convey their ideas. But it is just a difference of opinion. There is another mathematician I know who says, "that is the fun of it. You have to go check everything yourself and make sure you do all the side work."

That class laughs about this comment. Another student, Odd, recommends footnotes as a "happy medium" and Infinitely Repeating Decimal agrees. Then Dr. Amicable poses an interesting question taking the discussion to a different place: "You know who the next generation of mathematicians are, right?" There is silence until someone hesitantly says, "us."

Dr. Amicable: Yes! Right? So you are the community. And you will be able to determine those things. What counts as proof is really determined by who is in the community. So that's what's really neat. So if you all go out there and say I'm going to become a mathematician, and I'm going to change this. Just like Surreal. He is going to be right along with you. I want to change it so that it is a little bit easier to understand these arguments. Right?

Infinitely Repeating Decimal: We are going to change the world. I am going to change the entire mathematics community just for you.

## Conclusion and Discussion

The purpose of the IDEA framework is to be a list of goals for students' understanding of the nature of pure mathematics. I presented two stories: *Tension,* which touched upon my experience of pure mathematical inquiry as an exploration of ideas, and *We are the Future*, which focused upon a classroom discussion about the dynamic nature of mathematics in regard to standards of proof. Dr. Amicable and I tried to paint a dynamic picture of mathematics for our students. We told them they were the future of the discipline. We taught them that what counts as a proof is negotiated amongst mathematicians, and gave them the opportunity to debate what makes a good proof themselves. We encouraged them to see the value of mistakes in revising their knowledge.

Although students did have the opportunity to reflect on the dynamic nature of proof standards, I was unable to identify a time when students had the opportunity to experience pure mathematical inquiry as an exploration of ideas (as I did during my work on Dr. Combinatorial's conjecture). While Dr. Amicable and I encouraged students to make meaning of statements before proving, perhaps by constructing examples, what was ultimately deemed credit-worthy in the course was a valid deductive proof. I believe students frequently engaged in a syntactical proof production process like that defined by Weber and Alcock (2004):

> We define a syntactic proof production as one which is written solely by manipulating correctly stated definitions and other relevant facts in a logically permissible way. […] In the mathematics community, a syntactic proof production can be colloquially defined as a proof in which all one does is 'unwrap the definitions' and 'push symbols'. (p. 210)

In the transition-to-proof course, students' ability to write deductive proofs was prioritized over the ability to explore mathematical ideas. Perhaps it is a sign of the times, a result of the culture. According to Hersh (1997),

> Mathematics as an abstract deductive system is associated with our culture. But people created mathematical ideas long before there were abstract deductive systems. Perhaps mathematical ideas will be here after abstract deductive systems have had their day and passed on. (p. 232)

Are we satisfied to be part of a culture in which students spend less time exploring the ideas behind a theorem than on producing a valid deduction? We must put serious thought into how we structure pure mathematics courses so students develop healthy and productive conceptions of the nature of mathematics. To renew the culture of pure mathematics instruction will require a commitment from instructors and scholars to make choices that promote the values and vision expressed by humanistic philosophers of mathematics, ideas which are represented in the IDEA framework. To bring about changes in students' conceptions of mathematics they must be provided with opportunities to explicitly reflect on their own beliefs about mathematics while also being confronted with positions that challenge those beliefs.

# Sparky the Saguaro: A Teaching Experiment Examining a Student's Development of the Concept of Logarithms

Emily Kuper
Arizona State University

Marilyn P. Carlson
Arizona State University

*A number of studies have examined students' difficulties in understanding the idea of logarithm and the effectiveness of non-traditional interventions. However, few studies have examined the understandings students develop when completing conceptually oriented exponential and logarithmic lessons that build off prior research and understandings. This study explores one undergraduate precalculus student's understandings of concepts foundational to the idea of logarithm as she works through an exploratory lesson on exponential and logarithmic functions. Over the course of a few weeks, the student participated in a teaching experiment that focused on Sparky – a mystical saguaro that doubled in height every week. The lesson was centered on growth factors and tupling periods in an effort to support the student in developing the understandings necessary to discuss logarithms and logarithmic properties meaningfully. This paper discusses an essential component that students must conceptualize in order to hold a productive meaning for logarithms and logarithmic properties.*

*Key words:* Exponent, Growth factor, Tupling-period, Logarithm, Exponential

The idea of logarithms is useful both in mathematics (e.g., number theory – primes, statistics – regression, chaos theory – fractal dimension, calculus – differential equations) and in modeling real-world relationships (e.g., Richter scale, Decibel scale, population growth, radioactive decay). Therefore, a goal for mathematics educators should be to assist students in developing coherent meanings for the idea of logarithms. How does one achieve this goal? One hypothesis is to research the aspects of the idea of logarithm students have difficulties with. In particular, studies have shown that students have difficulty with logarithmic notation, logarithmic properties and logarithmic functions (Kenney, 2005; Strom, 2006; Weber, 2002; Gol Tabaghi, 2007). Another hypothesis is to develop and test the efficiency of interventions relative to standard curriculum (Weber, 2002; Panagiotou, 2010). Although these methods may shed light on epistemological obstacles students encounter or how successful a non-traditional approach was, neither examine the reasoning abilities needed to coherently understand and utilize the idea of logarithms. In fact, relatively few studies have examined what meanings students have for the idea of logarithms, and fewer have examined how students come to conceptualize the idea of logarithms.

This study investigated one undergraduate precalculus student's understandings of the idea of logarithm and concepts foundational to the idea of logarithm as she worked through an exploratory lesson on exponential and logarithmic functions. The research questions informing this study were:

1. What understandings are foundational to understanding the idea of logarithm?
2. What understandings of logarithmic functions do students develop during an exponential and logarithmic instructional sequence that emphasizes quantitative and covariational reasoning?

The findings of this study revealed an essential component that students must conceptualize in order to hold a productive meaning for the idea of logarithms. That is, in order to reason through tasks involving logarithmic expressions, logarithmic properties, and logarithmic functions in a way that both builds off prior meanings and is useful for more complex tasks, students must first conceptualize that multiplying by $A$ and then by $B$ is equivalent to multiplying by $AB$. In this study we modeled a student's thinking as she participated in an exponential and logarithmic instructional sequence that included cognitively scaffolded tasks designed to support students in constructing coherent meanings for the idea of logarithm.

## Literature Review

### Quantitative and Covariational Reasoning

Quantitative reasoning involves conceptualizing measureable attributes of objects and assigning these observations to a quantitative structure (Thompson, 1988, 1990, 1993, 1994, 2011). This way of thinking is critical for developing a coherent understanding of the idea of logarithm. For example, if one conceptualizes $\log_b(x)$ to represent the number of $b$-tupling periods necessary to $x$-tuple, then one could reason that $\log_b(b)$, the number of $b$-tupling periods necessary to $b$-tuple, should equal 1. The ability to conceptualize the expression $\log_b(b)$ in this way is foundational for their understanding the logarithmic properties and for using logarithms in applied settings. Smith and Thompson (2007) argue that students' ideas and reasoning (with quantities) must become sophisticated enough to warrant the use of algebraic notation and to reason productively with such tools. This investigation was designed to emphasize quantitative reasoning in the context of an exponential situation to motivate students to reason productively with the expressions, equations and functions they define.

The purpose of this study was to uncover the understandings of logarithmic functions students develop when working through an instructional sequence informed by the construct of covariational reasoning. Covariational reasoning is when a student conceptualizes two quantities' values varying in tandem while considering how they are varying together (Thompson & Carlson, 2017). Thompson and Carlson (2017) argue that being able to reason covariationally is crucial for students' mathematical development, especially when constructing meaningful expressions, formulas and graphs. Our lesson begins by attending to two varying quantities individually and then together to influence student thinking as they begin to construct exponential and logarithmic models. Students who are able to reason covariationally may find it easier to coordinate additive changes in one quantity with exponential changes in another quantity (Ellis et al., 2012).

### Research Literature on Students' Understandings of Exponents and Exponential Functions

Viewing exponentiation as repeated multiplication is a primitive, yet insufficient interpretation. While some researchers advocate a repeated multiplication approach (e.g. Goldin & Herscovics, 1991; Weber, 2002), others believe this approach limits students (e.g. Ellis, Ozgur, Kulow, Williams & Amidon, 2015; Davis, 2009; Confrey & Smith, 1995). In particular, Confrey and Smith (1995) argue that the standard way of teaching multiplication through repeated addition is inadequate for describing a variety of situations. Weber (2002) proposed that students first understand exponentiation as a process before viewing exponential and logarithmic expressions as results of applying the process. Once this is achieved, the student should be able to generalize the understanding to cases in which the exponent is a non-natural number. Specifically, Weber defined $b^x$ to represent "the number that is the product of $x$ many factors of $b$" and $\log_b(m)$ to be "the number of factors of $b$ there are in $m$." If a coherent understanding of exponential functions (and later logarithmic functions) is desired of our students, it is imperative that they have productive meanings for exponents.

Ellis et al. (2015) conducted a small-scale teaching experiment, informed by Smith and Confrey's (Smith, 2003; Smith & Confrey, 1994) covariation approach to functional thinking, with three middle school students that examined continuously covarying quantities. The students were asked to consider a scenario of a cactus named Jactus whose height doubled every week. The authors noticed three significant shifts in the students' thinking over the course of the study: (1) from repeated multiplication to coordinating $x$ and $y$, (2) from coordinating $x$ and $y$ to coordinated constant ratios, and (3) generalizing to non-natural exponents. The authors noted that a student's ability to coordinate the growth factor (or ratio of height values) with the changes in elapsed time contributed to the student successfully defining the relationship between the elapsed time and Jactus' height. This study leveraged findings from Ellis et al.'s study of Jactus the Cactus to promote more meaningful discussions on logarithms.

**Research Literature on Students' Understandings of Logarithms**

The topics of logarithmic notation and logarithmic functions often pose a variety of challenges to students (Kenney, 2005; Weber, 2002). Similar to the complexities present in function notation, logarithmic notation consists of multiple parts each with their own dual nature (Kenney, 2005). In the equation $\log_b(x) = y$, $b$, $x$, and $y$ take on a variety of meanings (i.e. parameters, variable). Kenney (2005) noted that because function names are often one letter, students do not naturally view log($x$) as representing an output to a function. In addition to these unavoidable complexities, Kenney's (2005) study discovered other difficulties students have with understanding logarithmic notation. The data revealed that students displayed mixed understandings of the bases in the expressions. For example, the students appeared to think that different bases always meant the logarithmic expressions were not equivalent (with the inputs being the same). However, when the expression involved the sum of logarithms, some students claimed equivalence because the bases would cancel out. Students also claimed that ln was equivalent to $\log_{10}$. The study also revealed that students would disregard or "cancel out" the word "log" when simplifying equations involving logarithms and solving for $x$. Despite the aforementioned difficulties, a few of the students were successful in arriving at the correct answer. However, Weber (2002) found that this was an unlikely result of traditionally taught students.

Weber (2002) conducted a pilot study that compared a traditional approach to teaching logarithmic functions with a more conceptual approach that introduced $\log_b(m)$ as the number of factors of $b$ there are in $m$. Weber's way of discussing the meaning of a logarithmic expression more clearly describes what the multiple parts of the notation represent - therefore addressing the issues Kenney observed in her study. In his study, Weber found that the students who received more conceptually based instruction were more likely to catch their mistakes when it came to identifying and justifying properties of logarithms and exponents. This data emphasizes the importance and need for more coherent and conceptually taught lessons for exponents, logarithmic expressions and logarithmic functions.

## Theoretical Perspective and Methodology

The theoretical framework of genetic epistemology (Piaget, 2001) and the theoretical perspective of radical constructivism (Glasersfeld, 1995) form the foundation of this study. A key assertion of radical constructivism is that knowledge is constructed in the mind of an individual and is not directly accessible to anyone else. Steffe and Thompson (2000) label the mathematical constructions made in the mind of a student as "student's mathematics." At best, researchers can develop models of student thinking based on the student's utterances, movements, written work, and essential mistakes. Such models of student's mathematics are referred to as "mathematics of students" (Steffe & Thompson, 2000). A model is considered reliable when the student acts in a way that remains consistent with the model. The process of developing the mathematics of students is one of scrutiny. Models are formed, tested, revised, and tested again until a viable model is developed. However, to say that a model is reliable is not the same as claiming the model directly represents the student's thinking – that is an impossible objective. Genetic epistemology focuses on both "what knowledge consists of [cognitive structures - schemes] and the ways in which knowledge develops [what those structures do]" (Piaget, 2001, p. 2). Piaget believed that knowledge is not static, but is always in a stage of development (1977). Therefore, for example, in order to discuss the ways in which students come to understand that $\log_b(m)$ represents the number of b-tupling periods needed to m-tuple, we must develop a model of students' cognitive structures and a roadmap of what happens to those cognitive structures as students' knowledge progresses from point A to point B. In this study, we attempt to model the participants' knowledge development of the ideas foundational to the idea of logarithm.

For this study, we conducted a teaching experiment (Steffe & Thompson, 2000) over the course of a three-week period in an effort to gain insight into student thinking and to develop the mathematics of students regarding logarithms and logarithmic functions. This study consisted of four 1.5-hour sessions with Lexi, a precalculus student, covering the topics of exponential and logarithmic functions in the context of a saguaro cactus that grows exponentially with respect to time (specifically doubling in height each week). Lexi, worked through a packet of questions while referring to a premade Geogebra applet to guide her thinking. As we conducted this teaching experiment, the lesson used was modified as needed during the stages of retrospective analysis. Lexi did not complete any additional assignments between teaching episodes.

## Results

This study's findings identified understandings foundational to the concept of logarithms. The section that follows reports findings that revealed foundational weakness that prevented Lexi from constructing targeted meanings in the lesson. Our findings are supported in our analysis of the discussions between Lexi and me as she completed the tasks.

### Foundational Understanding: Multiplying by *A* then multiplying by *B*, has the same effect as multiplying by *AB*

In this section, we present and discuss clips from the teaching episodes that suggest Lexi did not distinguish multiplying by *A,* then multiplying by *B* as having the same effect as multiplying by *AB*. This understanding, or lack thereof, reoccurred throughout the teaching experiment when discussing the meaning of percentages, growth factors and logarithmic ideas. We realized this crucial issue during the retrospective analysis of the third teaching episode and developed a task to allow Lexi an opportunity for reflective abstraction (Piaget, 2001; Thompson, 1985, pg. 196). We conclude this section by discussing the intervention and noting changes in Lexi's thinking.

The first two episodes focused mainly on percentages, percent change, growth factors and an exponential function. Throughout the first lesson, it became apparent that Lexi had two ways of acting on tasks involving percentages – one more dominant than the next. At first, Lexi associated percentages with a repositioning of the decimal place, but remained in a state of disequilibrium as she proposed a variety of values to represent the percent in decimal form. Lexi resorted to what ended up being her most dominant actions for percent problems. This action entailed Lexi first finding 1% of a value by dividing that value by 100 and then scaling this value to find the desired percent value. For example, to find 73% of $27, Lexi divided the $27 by 100 and took the result, $0.27, and multiplied it by 73 to get $19.71. When Lexi was presented with a percentage task involving multiples of 10%, she acted on the task in a different way. This action involved moving the decimal place of the value she was trying to find the percent of to the left one place (finding 10% of the value) and scaling up to find the multiple of 10. For example, the first author asked Lexi to determine 20% of $27, she moved the decimal place over one place to get $2.7 (10% of $27) and multiplied this value by 2 to get $5.40 (20% of $27).

Although Lexi's dominant action for percentages worked for her, her approach it is not the most productive way to approach tasks involving calculating a percent of a value. To address this observation in the second teaching session, we presented Lexi with the following two questions:

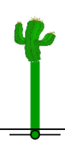
1. Suppose the division button on your calculator wasn't working. How would you determine 1% of $45.67?
2. Suppose the division button on your calculator wasn't working. How would you determine 73% of $45.67?

The purpose of this task was to help Lexi make the abstraction that to determine $n$% of a number, one can multiply by the decimal representation of $n/100$. She began by stating she could divide $45.67 by 100 to calculate 1% of $45.67. We then reminded her that she should assume the division button on the calculator was broken and that she needed to come up with a different way to calculate 1% of $45.67. Lexi's next response was to multiply $45.67 by 1/100. However, we noted that in order to enter 1/100 in the calculator, she would still need to utilize the division button. We followed that statement by asking her, "What is another way to represent 1/100?" and she responded, "0.2? 0.1? 0.01?" – eventually settling on 0.01. When attempting the second problem, Lexi stated, "Don't we just do the same thing?" and said she could determine 73% of $45.67 by multiplying $45.67 by 0.73. Lexi's attention to the results of her actions for the first problem suggests that she developed a new action in her scheme for percentages via a pseudo abstraction (Piaget, 2001). We asked Lexi how she might calculate the same value by using her answer in part (1). She explained that she would just have to multiply the 1% value by 73 to calculate 73% of $45.67. We attempted to draw Lexi's attention to the actions she performed in hopes that she would reflect on her work and abstract that multiplying by 0.73 has the same effect as multiplying by 0.01 and then by 73. That is, multiplying a value by 0.73 finds 73 1/100ths of that value, therefore calculating 73% of the value. Instead, Lexi claimed that the first method uses the 1% and the other (multiplying by 0.73) doesn't "necessarily need the 1% to find (the output)." Lexi's description of the two methods suggests that she viewed them as disjoint from one another. In other words, Lexi's actions suggest she viewed multiplying by 0.01 and then by 73 as being quantitatively different than multiplying by 0.73.

During the remaining portion of the second teaching episode, Lexi worked on a lesson that prompted her to determine different growth factors to represent Sparky the Saguaro's growth. In an attempt to determine the 3-week growth factor, Lexi began by noting Sparky's initial height of one foot at week zero and then claimed, "three time(s)– no, every week it's doubling, or times two for the height. So to get to week three, you'd say it's like, you wouldn't say 6 times as large – that wouldn't make sense. I feel like you would say 3 times as large – that doesn't make sense either." This quote suggests that Lexi first considered multiplying the 1-week growth factor (2) by the number of elapsed weeks (3) to calculate the 3-week growth factor. However, she quickly ruled out that option and looked to other values appearing in the situation. Lexi then appeared to observe the height of the cactus three weeks after its purchase and eventually concluded that the week 3 Sparky would be 8 times as large as the initial Sparky. However, there was no evidence to suggest that Lexi had reflected on the relationship between the 1-week growth factor (2) and the number of weeks that have elapsed (3) relative to the 3-week growth factor (8). In particular, although Lexi noted that Sparky was doubling in height every week, her responses and attention to the heights of the cacti suggest she had not yet abstracted that if Sparky doubles in height three weeks in a row, that will have the same effect as growing by a factor of $2^3$, or 8.

During the third lesson, we introduced the biconditional nature between statements involving growth factors and tupling periods. For example, we say the n-unit growth factor is b if and only if the b-tupling period is n-units. In the Sparky context, since the 1-week growth factor is 2, the 2-tupling period is 1 week. Lexi struggled with *n*-tupling periods when *n* was not a power of 2. For example, when we asked Lexi to approximate the 3-tupling period, she claimed it should be 1.5 weeks (so that the three foot Sparky would lie halfway between the 2 foot and 4 foot Sparky). Under the assumption that Sparky was three feet tall after 1.5 weeks, we asked Lexi to determine the number of weeks it would take Sparky to 9-tuple (or to determine the total amount of elapsed time if Sparky 3-tupled in height again). At this point in the teaching experiment, Lexi and the first author had already discussed and concluded that for equal changes in elapsed time, Sparky's height would grow by a constant factor. Therefore, if it took 1.5 weeks to triple, it should take 3 weeks to 9-tuple (but this is impossible since 3 weeks is the 8-tupling period). However, despite our conversations, Lexi's initial response to the 9-tupling question did not appear to rely on her statement that the 3-tupling period was 1.5 weeks. Instead, Lexi claimed the 9-tupling period would be 3.5 weeks and then modified her response to be 3.25 weeks (so that the 9 foot tall Sparky would lie closer to the 8 foot tall Sparky). Again, there was no evidence to suggest that Lexi had reflected on the relationship between the 9-tupling period and the 3-tupling period. In particular, Lexi's response suggests she did not have the understanding that in order to Sparky to 9-tuple in height, he must 3-tuple in height twice. For the remaining portion of the teaching session, Lexi continued to struggle with the idea that if Sparky first *m*-tupled and then *n*-tupled, we could describe his total growth as growing by a factor of *mn*.

After analyzing the third teaching episode and recognizing Lexi's main difficulty, we began the fourth teaching episode with an activity (Figure 1) to allow Lexi opportunities to engage in reflective abstraction on this topic before we introduced logarithmic notation.



| (A) At some point in time, Sparky was this tall. | (B) After some time, Sparky 2-tupled in height. Draw the resulting Sparky. | (C) After some more time, Sparky then 4-tupled in height. Draw the resulting Sparky. |
|---|---|---|

*Figure 1: Task to address foundational understanding*

Lexi drew Sparky (B) and Sparky (C) using a straightedge, documenting the initial height of the intervals and constructing a length that is 2 times as tall and 4 times as tall respectively. Lexi and the first author then had the following discussion:

INT: Sparky (C) is how many times as large as Sparky (A)?

Lexi: Um, wouldn't it be like 6 times as large?
INT: OK, can you verify that?
Lexi: Sure (reaching for straightedge)
INT: And as you are marking that off, can you explain how you concluded it should be 6?
Lexi: Um, well I figured that it would be 6 times as tall because right here this is two times so then that 2 plus that 4 would be 6. (Uses the straightedge to measure how many Sparky (A)'s fit into Sparky (C)) Oh so maybe I was wrong. OK, wait, so it's 8 because is it because it's 4 times 2? Would you multiply those instead of adding them?
INT: Mhmm
Lexi: OK
INT: But can you, can you think about, um, instead of just saying "We're going to multiply instead of add," can you think about why it is multiplication?
Lexi: Um, I guess that would make sense because right here, if you're like doubling it in height, you're multiplying it by two. And then if you're 4-tupling it I guess you are going to increase it by like another factor of 4. So instead of adding the factors you would need to multiply them.

Following this first activity, Lexi correctly completed and interpreted two similar tasks – one where Sparky tripled and then doubled in height, and another where Sparky tripled in height twice in a row. Lexi reasoned with the quantities and was able to conclude that if it took Sparky one week to 2-tuple and approximately 1.58 weeks to 3-tuple, then it should take 1+1.58=2.58 weeks to 6-tuple. In other words, the number of 2-tupling periods (weeks) needed to 2-tuple plus the number of 2-tupling periods (weeks) needed to 3-tuple is equal to the number of 2-tupling periods (weeks) needed to 6-tuple. Symbolically, $\log_2(2)+\log_2(3)=\log_2(6)$ - a specific case of a logarithmic property!

## Conclusion

Many studies have examined aspects of logarithms that present difficulties for students, while others have investigated the effectiveness of interventions. In this study, however, we examined the subject's thinking as she participated in a conceptually based lesson on exponential and logarithmic functions. Our findings revealed that the understanding that multiplying by $A$ and then multiplying by $B$ has the same effect as multiplying by $AB$ is crucial throughout a lesson on exponential and logarithmic functions. Types of problems that involve such reasoning include: calculating percentages of values (as witnessed in Lexi's interpretation of finding 73%), determining partial and $n$-unit growth factors (as witnessed in Lexi's struggle with determining the 9-tupling period), representing, interpreting and calculating logarithmic values (in this case, we measure one tupling period using another tupling period), and working with and explaining logarithmic properties (as witnessed with Lexi's interactions in the fourth episode). A student who does not hold this understanding can be successful in answering questions to determine percentages of values, as when Lexi first calculated 1% of a value and then scaled her answer to find a different percent. If our goal is for students to develop coherent understandings of exponential and logarithmic functions, then we must ensure that this foundational understanding is also developed. This finding will be used to improve the Sparky the Saguaro lesson for future research in an effort to provide students more opportunities to develop these foundational understandings at the beginning of the intervention. The Geogebra applet utilized in this study can be requested at egkuper@asu.edu.

An Initial Exploration of Students' Reasoning about Combinatorial Proof

Elise Lockwood
Oregon State University

Zackery Reed
Oregon State University

*Combinatorial proof involves proving relationships among expressions by arguing that the two expressions count sets with the same cardinality. It is an important topic because it is a kind of proof that has not been studied extensively, yet it represents an aspect of combinatorial reasoning that students should develop. In this paper, we report on data from two students who participated in a paired teaching experiment during which they solved tasks involving combinatorial proof. We highlight some productive aspects of their conceptions of combinatorial proof, and we also report on some pedagogical interventions that seemed to help students progress with successful combinatorial proving. We also argue that combinatorial proofs may naturally tend to be semantic rather than syntactic proof constructions (Weber & Alcock, 2004).*

*Keywords:* Combinatorics, Discrete mathematics, Combinatorial Proof, Proof, Student Thinking

## Introduction and Motivation

Binomial identities are equalities that describe relationships between binomial coefficients, such as $\binom{n}{k} = \binom{n}{k-1} + \binom{n-1}{k-1}$. These identities are important because they establish relationships that can be leveraged in a variety of combinatorial settings. While there are often multiple ways to prove such equalities (such as through algebraic equivalences or proofs by induction), a common way to establish binomial identities is through combinatorial proof. Through this technique, we prove that an equality holds by arguing that both sides of the equation count the same set of outcomes. Combinatorial proof tends to be introduced in discrete mathematics or combinatorics classes, and the mathematics community has established the fascinating and valuable nature of this method (e.g., Benjamin & Quinn, 2003). In addition to its use in combinatorial settings, combinatorial proof also provides an interesting setting for students to gain experience with proof and justification. Combinatorics is an accessible mathematical domain, and researchers have made the case that this makes it a useful context for mathematical exploration (Kapur, 1970). Similarly, combinatorial proof could provide an accessible context in which students can gain experience justifying and proving mathematical ideas. In particular, as we will argue, combinatorial proof may naturally provide students experience with semantic (rather than syntactic) proof productions (Weber & Alcock, 2004).

In light of the fact that combinatorial proof is useful for developing both students' combinatorial competency and their proving and justifying, we argue that it is a topic worth studying. However, to date, not much has been explored about this interesting topic. In this paper, we present results from an initial exploration into undergraduate students' reasoning about combinatorial proof. We seek to answer the following research question: *What are key elements of students' conceptions of combinatorial proof that facilitate success with combinatorial proof?*

## Literature Review

### Literature on Combinatorial Proof

A handful of studies have focused on students' reasoning and activity related to binomial coefficients. For instance, in their longitudinal study, Maher, Powell, and Uptegrove (2011) describe several instances in which students made meaningful connections between binomial coefficients, particular counting problems, and Pascal's Triangle. More specifically, Maher and Speiser (2002) documented student's reasoning about problems involving block towers, which can be solved using binomial coefficients. In a similar vein, Tarlow (2011) reported on eight 11th grade students who could make sense of a well-known binomial identity using both pizza and towers contexts. These studies provide examples of students reasoning about binomial coefficients and identities and show students forming (and in some cases justifying) relationships using combinatorial arguments.

There is another way to think about combinatorial proof, in which each side of an identity counts a different set, and the identity is proved by establishing a bijection between the sets (Mamona-Downs & Downs, 2004; Spira, 2008). The establishment of a bijection is not our emphasis in this study; rather we focus on proofs that count the same set in two different ways.

**A Model of Students' Combinatorial Thinking**

We draw on Lockwood's (2013) model of students' combinatorial thinking in order to frame our discussion of combinatorial proof; indeed, the model was an integral aspect of the design and analysis of the teaching experiment and design experiment. Lockwood (2013) describes three different components of her model: formulas/expressions, counting processes, and sets of outcomes. Formulas/expressions are the "mathematical expressions that yield some numerical value" (p. 252). Counting processes are "the enumeration process (or series of processes) in which a counter engages (either mentally or physically) as they solve a counting problem. These processes consist of the steps or procedures the counter does, or imagines doing, in order to complete a combinatorial task" (p. 253). Sets of outcomes are "the collection of objects being counted – those sets of elements that one can imagine being generated or enumerated by a counting process" (p. 253). The relationships between these components can help to articulate phenomena that occur when solving counting problems.

To see how this model applies to combinatorial proof, consider the binomial identity $\binom{n}{k}\binom{k}{m}=\binom{n}{m}\binom{n-m}{k-m}$, which we call Identity 1. We could establish this identity algebraically by using the definition of $\binom{n}{k}=\frac{n!}{(n-k)!k!}$. However, to prove this identity combinatorially the goal is to demonstrate that both sides of the equation are counting the same set of outcomes. We must first identify the counting process that is represented by each respective expression. Then, we argue that those two counting processes are counting the same set of outcomes. Since that set of outcomes has a certain cardinality, the two expressions will be equal.

For Identity 1, the expression on the left-hand side can be thought of a two-stage process of first selecting a $k$-person committee from $n$ people, and then selecting $m$ of those $k$ people to be on a subcommittee. Thus, the left counts all possible subcommittees of size $m$, which were chosen from committees of size $k$ (from a total group of size of $n$). Alternatively, the two-stage process that reflects the expression on the right-hand side can be thought of as first picking subcommittees of size $m$ from $n$ people, and then picking $k - m$ people from the remaining $n - m$ people to fill out the rest of the subcommittee. The right hand thus also counts the same set, and we can conclude that the identity holds.

In terms of the model, we view this combinatorial proof as being represented by the flow of arrows in Figure 1. Given a relationship between formulas/expressions, we identify two counting processes that reflect the respective formulas/expressions but count the same set of outcomes.

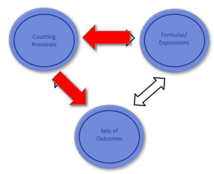

*Figure 1. Lockwood's (2013) model of students' combinatorial thinking*

We also note that while this direction (formulas/expressions → counting processes → sets of outcomes) reflects how proving combinatorial identities is typically introduced, there are other ways to potentially think about combinatorial proof in terms of the model. In particular, one way to introduce combinatorial identities is through leveraging the fact that there may be more than one way to solve a problem. So, following the example of Identity 1, we could consider trying to answer the question "How many ways can you choose committees of size *k* from *n* people, each of which has a subcommittee of size *m*?" If we tried to solve this problem in two different ways, two natural solutions would be first to pick the committees and then pick the subcommittees, or first to pick the subcommittees and then to pick the committees around them. In this way, we start with the set of outcomes, then we build up two counting processes, ultimately determining two respective formulas/expressions to reflect those processes.

## Theoretical Perspective

Harel and Sowder (1998) define *proving* as "the process employed by an individual to remove or create doubts about the truth of an observation" (p. 241). We adopt this definition of proving and consider a proof to be the product of the proving process. Broadly, we consider *combinatorial proving* to be this process of removing doubts about the truth of an observation about a combinatorial relationship, and a combinatorial proof is the product of that process. Specifically, *combinatorial proof* is the result of a certain process of counting the same set of outcomes in two different ways. Thus, to be a combinatorial proof the student must leverage some counting argument in order to establish the relationship. As we have documented above, this involves articulating counting processes that count the same set of outcomes (or, counting the same set of outcomes via two different processes that can be reflected in two expressions). In this paper, the observations that are being proven are always binomial identities.

Weber and Alcock (2004) identified two qualitatively different ways in which someone might produce a correct proof, and we use this distinction as a way of conceptualizing combinatorial proof. They define a *syntactic proof production* as "one which is written solely by manipulating correctly stated definitions and other relevant facts in a logically permissible way. In a syntactic proof production, the prover does not make use of diagrams or other intuitive and non-formal representations of mathematical concepts" (p. 210). In contrast, they define a *semantic proof production* to be "a proof of a statement in which the prover uses instantiation(s) of the mathematical object(s) to which the statement applies to suggest and guide the formal inferences that he or she draws" (p. 210). We interpret that semantic proof productions describe proof productions in which students meaningfully draw on some instantiation of a mathematical object or idea that may be external from the situation at hand. By emphasizing meaning, they highlight the importance of this instantiation providing some meaning that the symbolic proof normally would not. Although this distinction was introduced in terms of formal proofs (specifically in algebra and analysis context), we argue that these terms could still be a useful lens through which to think about combinatorial proof. We will argue that to prove a binomial identity, a combinatorial proof typically reflects a semantic proof production, whereas an algebraic or inductive proof might naturally be representative of a syntactic proof production.

## Methods

Our investigation of combinatorial proof is situated within a broader study investigating generalization in combinatorial contexts. For this paper, we present data from a paired teaching experiment, and we focus on those sessions in which we had students engage in tasks related to combinatorial proof. We conducted a teaching experiment (in the sense of Steffe & Thompson, 2000), during which we interviewed two students over 15 hour-long videotaped sessions. The sessions occurred over approximately 6 weeks during the school year, and the participants were monetarily compensated for their time. We sought students who satisfied three criteria. We wanted them a) to be novice counters, without having formal experience with counting in college, b) to demonstrate a disposition inclined toward problem solving, and c) to be able to articulate their thought process. With these criteria in mind, we chose students based on individual hour-long selection interviews during which they solved counting problems. Two students who fit the criteria (Rose and Sanjeev, pseudonyms) were engineering majors enrolled in a vector calculus class. During the interviews the two students worked together at a chalkboard, and they both regularly contributed to the conversation. The interviewer posed tasks and occasionally asked clarifying questions. We describe the tasks below.

In choosing tasks, we were motivated by the idea that it might be productive to have students first gain experience going from sets of outcomes to counting processes to formulas/expressions by essentially asking students to solve counting problems in two different ways. We also thought that students would benefit from considering a concrete problem (involving specific numerical values) instead of starting with a general statement involving variables. Binomial identities are typically stated as general statements (involving variables like $n$, $k$, and $r$), but we felt it would be useful for students to consider specific instances of those relationships. Due to space, we provide only a partial list of tasks in Table 1.

*Table 1. Tasks in the teaching experiment*

| **Activity** | **Task** |
|---|---|
| Starting with a specific problem, solving it in two different ways, then moving toward generalization<br><br>Formulas/expressions → Counting Processes → Sets of Outcomes | Task 1a: How many 15 person committees are there from 25 people? … Can you solve that in two different ways?<br>Task 1b: What about $n$ people and $k$ people committees? How would you count them in two different ways?<br>Task 2a: There are 10 people, and I want a committee of size six, there is one appointed chairperson. How many such committees are there, and can you solve it in two different ways?<br>Task 2b: Now what if there are $n$ people with committees of size $k$ and a chairperson? Can you solve it in two different ways? |
| Giving students the binomial identity and having them argue they count the same set of outcomes. | Task 3: $\binom{n}{k}\binom{k}{m}=\binom{n}{m}\binom{n-m}{k-m}$<br>Task 4: $\binom{n}{k}=\binom{n}{k-1}+\binom{n-1}{k-1}$ |

| | |
|---|---|
| Sets of Outcomes $\rightarrow$ Counting Processes $\rightarrow$ Formulas/Expressions | Task 5: $\sum_{k=0}^{r}\binom{m}{k}\binom{n}{r-k}=\binom{m+n}{r}$ |

The interview sessions were all transcribed. We created enhanced transcripts, which involved inserting relevant images and gesture descriptions into the transcript. We reviewed the enhanced transcripts of the teaching experiment first and wrote down interesting phenomena about students' reasoning about combinatorial proof. Once we had broad themes we then used the qualitative data analysis software MAXQDA to identify and code relevant data segments. We then synthesized and coordinated our themes into a coherent narrative. We also went through and identified proof productions that we determined to be syntactic or semantic. Due to space, we highlight only a couple of salient findings.

## Results – Students' Conceptions of Combinatorial Proof that Facilitate Success

### Students Should Understand What It Means to Prove a Relationship "Combinatorially"

Not surprisingly, it was not trivial for students to reason about what was entailed in a combinatorial proof, but we argue that it is important for them to develop this understanding. One noteworthy phenomenon is that the students had to reckon with what a proof is and why counting the same set might actually constitute a mathematical proof.

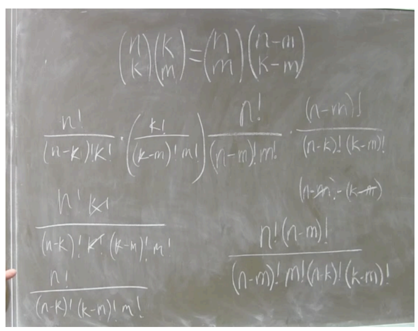

*Figure 2. The students establish an algebraic proof*

We asked Rose and Sanjeev to prove Task 3 (written at the top of Figure 2), and they asked if they could write it out in a different way. They then immediately started to write out the expressions and work toward an algebraic proof (Figure 2). Although the students were able to make combinatorial arguments, which they had demonstrated by correctly solving previous tasks combinatorially, their instinct was to use an algebraic justification. They subsequently went on to solve the problem combinatorially, but interestingly, even after providing combinatorial arguments, the students seemed more convinced by algebraic arguments.

*Interviewer*: You proved it algebraically, but suppose you hadn't. Would you be convinced then by your argument that that equation has to be true? Like, are you pretty convinced that that equation is true?

*Rose*: Uh-huh.

*Sanjeev*: If we didn't see algebra?

*Interviewer*: Yep.

*Sanjeev*: Probably not.

*Rose*: No.

On Task 4, the exact same phenomenon occurred, where the students immediately tried to prove it algebraically even after they had just combinatorially proved Task 3. This phenomenon is not necessarily surprising. It is important to note that these students were novice provers. As vector calculus students, they had not taken a course involving mathematical proving, and they likely had not been previously confronted with the question of what it means to prove a relationship (they may have seen 2-column geometry proofs in high school, but they had not taken a proof-based undergraduate mathematics course). Thus, it makes sense that perhaps the students' only way of understanding how to establish the equation would be to demonstrate equality through algebra. Nonetheless, even though these students were new provers, we do gain some insight from their work. In particular, their work suggests that when students are introduced to combinatorial proof and combinatorial identities, it may be worthwhile to have a discussion of what it might mean to prove an identity combinatorially.

This data suggests to us that developing a combinatorial proof is understandably nuanced. This implies that students may need to be explicitly taught what combinatorial proof is, both in terms of why it is a valid form of mathematical proof and what is entailed in making a combinatorial argument. Differences between combinatorial versus algebraic arguments might need to be addressed directly if we expect students to understand how to combinatorially prove an identity. Again, this is not surprising, but we have overwhelming evidence that even with very successful and consistent counters, this was a mysterious, new, and challenging idea for them.

**Students should develop a particular combinatorial context**

Our data also suggests an important aspect of combinatorial proof is for students to be able to reason within a particular context. This is how combinatorial proof tends to be taught, and we are not claiming to offer some new mathematical insight. However, what is noteworthy is that we see evidence of students establishing and leveraging particular contexts, which give them something concrete to count from which they can then generalize. For example, we gave students Task 1 and asked them to count it in two different ways, and their response is seen in the excerpt below (their work is seen in Figure 3).

*Interviewer*: So are those two things counting the same committees?

*Sanjeev:* Yeah.

*Rose*: Yeah.

*Sanjeev*: The remaining is the number of 15 people committees. In this case, you're making the committees, whereas in that case, you're making them not committees.

*Rose*: Making them leave.

*Interviewer*: Okay, but both are giving you the 15 people.

*Sanjeev*: I think so.

*Rose*: Yeah, because if you make these ten people leave, then you'll just be stuck with 15 people.

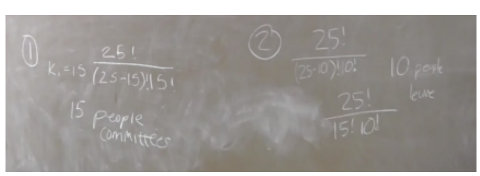

*Figure 3. Two different expressions for counting 15-person committees*

When we then asked them to generalize we could ask in terms of the same context, and students used the committees context to correctly establish the identity that in Task 1. We contend that being able to reason about and contextualize a problem is instrumental in supporting the combinatorial argument – without it, the formulas/expressions have no combinatorial meaning

## Discussion

### Combinatorial Proof as Semantic Proof Production

Combinatorial proof is a very specific kind of proof technique. However, although it is narrow, it can also be useful and important for a couple of different reasons. First, it is a specific combinatorial topic that reinforces other important combinatorial ideas like emphasizing sets of outcomes and the relationships between the components of Lockwood's (2013) model. Second, we also argue that it offers a different perspective on mathematical justification and proof. In particular, we propose that combinatorial proof naturally lends itself to semantic proof production. Weber and Alcock (2004) identify several aspects of knowledge required to produce semantic proofs, and we highlight a couple of them as being similar to aspects of knowledge required to produce combinatorial proofs. They emphasize instantiation and say that "One should be able to instantiate relevant mathematical objects. These instantiations should be rich enough that they suggest inferences that one can draw" (p. 229). They also note that "One should be able to connect the formal definition of the concept to the instantiations with which they reason" (p. 229). We interpret that the contextualized combinatorial arguments represent domain-specific instantiations that allow for meaningful proving and justifying. While it may be possible for a student to produce a combinatorial proof that does not involve knowledge that Weber and Alcock describe, we suggest that the kinds of context-based combinatorial justifications required for combinatorial proof are generally indicative of such knowledge.

## Conclusion and Implications

Combinatorial proof is a fascinating topic that is relevant both to the teaching and learning of combinatorics and to students' proving activity. In an initial exploration of students' engaging with combinatorial proof we have identified some key conceptions that may help students productively engage in combinatorial proof. We conclude with a couple of potential pedagogical implications of this work. First, students should focus on specific contexts and concrete problems. Then, teachers should give students opportunities to generalize from these particular cases. Our trajectory of concrete to general problems seemed productive in helping students gain familiarity with a context before generalizing using variables. Then, once students have established relationships in the concrete cases, they can attempt the more traditional combinatorial proofs of binomial identities. Overall, teachers should try to make sure students understand how their counting processes relate to the formulas/expressions and the set of outcomes, as discussed in Lockwood's (2013) model.

# Computing as a Mathematical Disciplinary Practice

Elise Lockwood
Oregon State University

Matthew Thomas
Ithaca College

Anna DeJarnette
University of Cincinnati

*The role of computation continues to be prominent in the STEM fields, and the activity of computing has become an important mathematical disciplinary practice. Given the importance of computational fluency in science and mathematics, we are curious about the nature of such activity in mathematics. To study this, we interviewed six mathematicians about the role of computation in their work, and we identified several aspects of computation that sheds light on the nature of computing as a mathematical disciplinary practice. In this paper, we present examples and applications of computation for these mathematicians, highlight types of computation, provide specific examples of computation in their work, and emphasize how computation relates to mathematics in particular.*

Keywords: Computation, Mathematical disciplinary practices, Mathematicians

## Introduction and Motivation

What is the role of computation for doing mathematics? What does computation mean, given the broad range of settings in which mathematics is applied? How could one justify the teaching and learning of computation, given the national focus on reasoning, problem solving, and abstract thinking at all levels of mathematics? Our research is driven by questions of this type, especially in light of the technological advancements that continually blur the lines that define what counts as doing mathematics among those in the profession. The content and practices of different levels of mathematics have traditionally been aligned to varying degrees with the discipline of mathematics (Moschkovich, 2007; Rasmussen, Wawro, & Zandieh, 2015). Thus, with current efforts to incorporate the use of technology, and to see mathematics as a setting to explore relationships with computer science (Grover & Pea, 2013), a natural question is how such work is conducted and perceived by professionals within the field of mathematics. Such perspectives can help to inform answers to questions about the meaning and purpose of computation at post-secondary levels.

With this study, we explore the relationship between activities that have come to be described as *computation* and *computational thinking* and the practice of doing mathematics. We used the lens of *disciplinary practices* (Rasmussen et al., 2015) to consider ways in which mathematicians view computation as an element of their professional work. To do this, we interviewed mathematicians about computation in their research and teaching, specifically, according to the following research question: *How do mathematicians characterize and use the disciplinary practice of computing in their work?* The results of our analysis indicate that members of the mathematical community value computing as a distinct practice, and that it may be beneficial to foster computational fluency among students. These findings give disciplinary support to efforts at incorporating computing and computer science into mathematics, and they begin to suggest some of the ways in which that integration may naturally surface.

## Background Literature

In computer science education research, there is a construct called *computational thinking* (CT) (Grover & Pea, 2013; Wing, 2006, 2008), which Wing initially described as "taking an approach to solving problems, designing systems and understanding human behaviour that draws on concepts fundamental to computer science" (2006, p. 33). Wing went on to characterize CT broadly and as encompassing many kinds of thinking and activity, such as "thinking recursively" (p. 33), "using abstraction and decomposition when attacking a large complex task or designing a large complex system" (p. 33), "using heuristic reasoning to discover a solution" (p. 34), and "making trade-offs between time and space and between processing power and storage capacity" (p. 34). Wing did not intend for computational thinking to be neatly defined, and indeed the broad characterization makes it difficult to pin down a precise definition. However, describing a notion of computational thinking provides a starting point for identifying common threads among computational activity. While we do not explicitly examine computational thinking in this paper, we acknowledge the role that this idea played in the design of our study.

In exploring the idea of defining computational thinking, Weintrop et al. (2016) developed a "taxonomy of practices focusing on the application of computational thinking to mathematics and science" (p. 128). For each of these practices, Weintrop et al. (2016) elaborated certain activities that the practice may entail. For example, they said that *Programming* "consists of understanding and modifying programs written by others, as well as composing new programs or scripts from scratch" (p. 139). For *Troubleshooting and Debugging*, they explained that there are "a number of strategies one can employ while troubleshooting a problem, including clearly identifying the issue, systematically testing the system to isolate the source of the error, and reproducing the problem so that potential solutions can be tested reliably" (p. 139).

In developing their taxonomy, Weintrop et al. (2016) started with activities that elicited computational activity and refined that framework through interviews with experts (including school teachers and scientists). Notably, though, while they interviewed scientists (biochemists, physicists, material engineers, astrophysicists, computer scientists, and biomedical engineers), they did not interview research mathematicians. Thus, even though our study bears similarities to this work – namely asking experts about the nature of computational activity – we highlight two key differences. First, rather than beginning with a set of computational activities, we begin with mathematicians' descriptions of their work, forming categories and types of computation based on their experiences and responses. Second, by interviewing research mathematicians, we focus specifically on the role of computation within discipline of mathematics and not on STEM more widely. This attention to research mathematicians is closely related and relevant to undergraduate mathematics education in ways that broader STEM and K-12 emphases are not.

## Theoretical Perspective

As we will see in the results, it is not trivial to define computation, and there are many ways in which computation can be characterized and framed. However, to clarify, in this paper we provide the following broad characterization as our working definition of computation: Computing is the practice of using mathematical calculations, processes, or algorithms, often to generate products that can be interpreted, investigated, or implemented in other contexts and problems. Computing often involves the aid of technology but can also be performed by hand.

Rasmussen, Wawro, and Zandieh (2015) defined disciplinary practices as "the ways in which mathematicians go about their profession" (p. 264), which they viewed as related to Moschkovich's (2007) notion of "professional discourse practices" (p. 264). These are the practices in which mathematicians engage in their professional spheres. Examples of disciplinary practices include algorithmatizing, theoremizing, defining, and symbolizing (Rasmussen et al., 2015). In this study, we are conceiving of computing as a disciplinary practice, something that mathematicians now do. Indeed, both Rasmussen et al. and Moschkovich argued that such practices are culturally and historically situated, and "socially, culturally, and historically produced practices that have become normative" (p. 25). We feel that this is an apt way to characterize computing, because computing seems like a particularly important disciplinary practice in our increasingly computerized society. That is, in light of increasing computational requirements for mathematics majors and computational methods in mathematical research (e.g., Bagley & Rabin, 2016), we feel that computing is becoming a relevant practice that is increasingly becoming an integral part of "being a mathematician." We thus consider computing to be a disciplinary practice and use this lens in framing our study. While the term computation could refer the product of the activity of computing, we use the terms interchangeably (as the participants used the term interchangeably during the interviews).

## Methods

To answer our research question, we interviewed six mathematicians in single 60-90 minute semi-structured interviews. The mathematicians were professors in mathematics departments, all holding PhDs in mathematics (see Table 1; all names are gender-preserving pseudonyms). It was a convenience sample (mathematicians to whom the authors had access and proximity), but we sought to maintain a balance of sub-disciplines of mathematics (especially pure versus applied).

*Table 1. Information about the Interviewees*

| Mathematician | Area of specialty | Years in field | Programming Language(s) |
|---|---|---|---|
| Michael | Mathematical Biology | 4 years | Mathematica, Matlab |
| Liliana | Applied Mathematics | 30 years | Matlab, Tecplot |
| Paul | Numerical Analysis | 12 years | Matlab, Comsol, Maple |
| Carter | Geometry | 35 years | Mathematica |
| Peter | Algebraic Combinatorics | 18 years | Maple |
| Andrea | Applied Mathematics | 7 years | Matlab, Python |

All interviews were audio-recorded. We began the interviews by asking the mathematicians to reflect upon various aspects of computation, including computation in their own work, the value of computing for themselves and for students, and how they might teach computing. For example, after asking some preliminary demographic questions, we asked the following: *Do you use computation in the work that you do? How so? How are you defining 'computation'?* and *What are some specific ways (or contexts) in which you use computation in your work? Could you provide an example or two?* This enabled us to get a sense of how they viewed and might use computation. We also asked whether (and why) they thought computation is important for students to learn. We concluded with discussions about whether and how they had taught computation before, and for them to weigh in on how students might learn computation.

We used a combined process of open and axial coding (Strauss & Corbin, 1998) to describe the concepts, perspectives, and processes that characterized the mathematicians' ideas about computation in mathematics. In the first phase, the first author studied the transcripts and coded them with descriptions of the core ideas or themes from the mathematicians' comments. Examples of codes that emerged through this round of analysis include "computation is related to proving," "computation is used for generating examples," and "computation requires the compartmentalization of steps."

In the second phase of analysis, the second and third authors applied the generated list of codes to the entire set of interviews. All three authors met regularly throughout this process, during which time we compared our coding of the transcripts to resolve any discrepancies, refined the meanings of the different codes, and began to articulate a set of themes according to which the codes could be organized. We returned to the interview transcripts during these meetings looking for evidence for and against the common perspectives we saw within each theme. The results of our analysis include a set of themes that can be used, broadly, to categorize our participants' comments about computation, as well as examples from the data to support the variety of viewpoints that surfaced within each of these themes.

## Results

We describe three main themes that characterize the mathematicians' comments about computation. First, we offer insights about how mathematicians characterized computation in their work, including similarities to and differences from programming. Second, we discuss practical applications of computation, including particular examples of how computation arises for these mathematicians. Third, we present mathematicians' views about the relationship between computing and mathematical problem solving. Through these results we seek to paint a more complete picture of how mathematicians think about and use computation in their work. Because of space we cannot highlight every point or make every part of it clear, but we can emphasize the main findings and provide evidence from a number of the mathematicians.

### Types of Computation

In order to get a sense of how mathematicians defined or exemplified computation, we asked all participants a variation of the question, "what is the computation involved in your work?" Their responses indicated that the definition of computation, even within the field of mathematics, is difficult to articulate and is context dependent. In particular, the mathematicians made a distinction between numerical computations, and what might be considered algebraic computation, as exemplified by Michael's comments below:

*Michael:* There's computation, for instance, like if you're proving some theorem and you need a technical lemma and you've got to work out this computation just to show that that lemma is true. So that's one way. The other way is sort of like numerical computation. Computations that you're not going to do by hand, so you get a computer to do it.

Michael gave as an example of the first type of computation the case of showing that a particular function is Lipschitz – which involves verifying a string of inequalities – in order to use that property toward proving a more involved theorem. Numerical computation itself, according to Michael, could be further broken down into two different types: a tedious calculation that might best be done by a computer (e.g., a binomial probability with a large number of events) or computations akin to mathematical modeling, for which a set of data needs to be analyzed with no predetermined algorithm or formula.

The types of computation that mathematicians saw as most relevant to their work corresponded to the specifics of different sub-disciplines of mathematics. Peter, an algebraic combinatorialist, described his use of computation primarily in terms of algebraic computation (e.g., factoring complex expressions) and numerical calculations (e.g., calculating the determinant of a matrix). Mathematicians in more applied fields described computation in terms of solving models (e.g., solving partial differential equations numerically) or using computation to analyze data or approximate solutions. It was clear from our interviews that there was no consensus on a single definition of computation, although computation can be characterized broadly by a few different types of activities.

To summarize, in response to the question of how mathematicians use computation in their work, we saw that what constitutes computation varies according to the types of problems that are relevant within different subfields of mathematics. Computation as a practice occurs at different scales, from performing symbolic manipulations and numerical calculations, to creating and implementing mathematical models.

### Examples and Practical Applications of Computation

The mathematicians articulated a number of ways in which they use computation in their work, and this provides insight into how and why computation can be so useful. Table 2 shows instances of what we coded as a practical application of computing, each with a supporting and exemplifying quote from a mathematician. This gives a set of concrete examples and evidence of the variety of ways in which mathematicians use computation in their everyday work.

*Table 2. Examples and quotes of practical applications of computation*

| Practical Application | Specific Example(s) and Supporting Quote(s) |
|---|---|
| Testing conjectures | *Peter*: I use software to enumerate combinatorial objects that satisfy certain constraints where I have, say a conjecture – a prediction of how many there should be or a predicted bound on how many there should be and I'll collect numerical data to test my results. |
| Visualizing | *Liliana*: And sometimes I use computers to illustrate, um, some salient features of a problem that are otherwise hard to just understand. You can formulate them using proper algebra, calculus, whatever. But, you know, how common is it for someone to understand a complicated feature of a problem, um, using just, um, a formal, a very formal statement that involves, I don't know, derivatives or something like this? We can do that, but people really—if you have a finite amount of time to describe a problem, um, visualization is an important component. Uh, I think of what it means to convey some ideas. It does take a lot of time, and it is frequently unappreciated as part of that, um, research. But I think it's a very important part. |
| Communicating | *Paul*: Yes, definitely. I mean, you wouldn't be able to do proofs if you couldn't do that and you wouldn't be able to do computation if you couldn't do that and you couldn't make clear arguments to convince people of other types of conclusions that you're trying to make if you didn't take your arguments through logical steps. So, if you're trying to convince anybody of something and you need to tell them that your solution or your idea does what you think it does and nothing else. And that's exactly what a code's supposed to do too.<br>*Interviewer*: Okay. Nice. And so, getting experience with that kind of coding could basically model that kind of experience of being able to give an argument and show that logical process of it.<br>*Paul*: Right. I'm saying that it not only helps with doing math, it also helps with communicating math. |

| | |
|---|---|
| Recovering from mistakes | *Liliana*: And so that's the other ability. That, and, well, of course, and there is the other ability of being able to recover from mistakes. Which, in computing, is fundamental. And not being too frustrated and just keep going back and forth. And trying to morph something that you know worked to something you know should work. |
| Using Computation in Teaching | *Carter*: I use the computer to check exam solutions when I teach calculus. I use the computer to draw graphics that I use both in my own textbooks and in my own teaching. |

Table 2 gives a sense of the variety of ways that mathematicians use computing in their work. Some of these applications (such as *using computation in teaching* or for *visualization* of ideas in research) help the mathematicians accomplish specific, practical goals. Other applications (such as *communicating* and *recovering from mistakes*) facilitate the development of other essential, broader practices and habits of mind. These examples inform why computation is a valuable and useful practice for mathematicians and suggest why it should be developed among students.

**Relationship between Computation and Mathematics**

The mathematicians also talked about the relationship between computation and additional mathematical practices. For example, some articulated that computation was related to proof, problem solving, and other aspects of mathematical thinking and research. In this section, we highlight some excerpts that raise some salient points of discussion about the role of computing in the field of mathematics specifically.

In the following exchange, Liliana describes the back and forth relationship between the mathematical and theoretical analysis she does and the computing in which she engages. We see that Liliana describes how she applies computational activity to mathematical analysis of a problem, which suggests that she is relating her computational activity back to the mathematical processes on which she is working.

*Liliana*: So, the other part, the theoretical part, is different. It can be supported by experimentation, so let's say you're not quite sure how the solution to this equation is going to behave. I don't know, nonlinear equation depending on the parameter, so you're not quite sure. You can do some analysis, and that can be tedious, but you can also explore it computationally. Which will suggest what tools you would use to analyze that. Or which would sort of verify some of the intuitions you had which you can later use here. Um, but generally—or you're deriving some kind of a theoretical result, which actually typically now we're, uh, research—you should verify, you should show some experiments that verify that indeed the convergence rates are this or that. If you can't get it to confirm, that's bad.

*Interviewer*: Mmhmm, because it suggests something is wrong your analysis.

*Liliana*: Something is either wrong with the implementation, or with the analysis.

*Interviewer*: Yeah.

*Liliana*: If you get a better result, then it's okay. I mean, if experimentally you're getting a higher rate than the one you did, then it means you didn't get sharp results. But if it was the other way, then you should go back to the drawing board because there was an unrealistic assumption you made or something like this.

Peter also emphasizes this relationship between the computation and the theoretical mathematical research he does. It is worth noting that Peter viewed computation as a way to generate examples and explore conjectures (as noted in the first row of Table 2 above). The following quote highlights that he views computational activity as providing necessary content that he can then use and apply in his mathematical research.

*Peter*: The act of doing the computations and the results that are obtained by computations are the content of mathematics. And so, the theorems and relationships we're describing are only good to the extent that they reflect something that either is calculated or that you're evaluating by not calculating directly or – you know, yeah. It's like if a poet has no life experience they can't write good poems. If a mathematician doesn't do computation or have the results of computations, they don't really have the subject that they're supposed to be reasoning about in writing their theorems?

Andrea also spoke to the important relationship between computational activity and theoretical mathematical work. In discussing teaching computing to students and what she wants them to learn through the practice of computing, she indicated that she would want them to be able to relate the programming they do to the mathematical ideas.

*Andrea*: Like, knowing a program, or knowing how to, say, code in Python is a skill. I think it's not really useful unless you can – like, by itself I don't think is useful. So, I would hope that the student also knows how to do mathematics on paper.

*Interviewer:* So, what else do they need besides just that ability to program in Python?

*Andrew:* I guess it's what I would say any mathematician or math student would need to have, and it's the ability to – I'm not going to say this right because this is not my area, but – to be mathematically skilled. But I don't really know what I would say that is. It's like, the ability to solve any type of problem. Maybe the ability to approach a math problem with some insight into which direction to go in.

In this section, we see that the mathematicians understand that computation in their work must be connected to the theoretical mathematics, and we gain insight into how this practice of computing can complement and enrich the mathematical work that they do.

## Conclusions and Avenues for Future Research

In this paper, we have reported on interviews in which we asked mathematicians about the role of computation in their work and in the field. We discussed their characterizations of computing, examples and practical applications of computing, and the relationship between computing and the theoretical mathematics they do in their research. Together these findings paint a picture of the varied ways that computation arises in mathematicians' work, and they highlight the important role that computation plays. In this way, we feel that our findings make a case for computing as a key mathematical disciplinary practice, helping us to justify the importance of developing this practice in undergraduate mathematics classrooms. Indeed, the fact that mathematicians use computation in a number of ways underscores that it is a practice that deserves more attention in mathematics education research.

In light of these findings, we have several ideas for further research. First, we feel that we should broaden our set of mathematicians, perhaps interviewing or surveying greater numbers of mathematicians and mathematicians in industry. Second, but we are interested in exploring the notion of computational thinking in mathematics. We contend that there may be certain ways of thinking that facilitate computation in mathematical contexts, and we want to investigate what such a way of thinking might entail. Third, we would like to investigate undergraduate students' characterizations and uses of computation in mathematics.

# Finite Mathematics Students' Use of Counting Techniques in Probability Applications

Kayla K. Blyman
United States Military Academy, West Point

Casey Monday
Northern Kentucky University

*In this study we seek to better understand how students are using counting techniques within the context of the probability application. To do so we investigate three semesters of finite mathematics students' use of enumeration, Venn diagrams, and counting formulas on probability free-response exam questions at a large public university in the mid-south. The study found that appropriate use of enumeration techniques and Venn diagrams both statistically significantly increased a student's likelihood of arriving at a correct answer, while there is statistically significant evidence that the use of counting formulas decreased a student's likelihood of arriving at a correct answer. We conclude with a discussion of the implications of this study for the practice.*

*Keywords:* Combinatorics Education, Probability, Enumeration, Venn Diagrams, Combinations

## Introduction and Motivation

The original finite mathematics course debuted in 1957 at Dartmouth College (Kemeny, Snell, & Thompson, 1957). While the course has changed some in the intervening span, it has remained relatively unaltered in the last forty years. This era of stability began when the business major became popular in the United States and business faculty recognized the importance of the finite mathematics course. This change also increased the popularity of the course. The Conference Board of Mathematical Sciences (CBMS) has not yet released their 2015 mathematics programs census reports, the 2010 report gives enough information to conservatively estimate that 120,000 students were enrolled in an introductory finite mathematics course in the United States per annum (Blair, Kirkman, & Maxwell, 2013). Despite having such a long, established history and substantial enrollment, the research literature regarding finite mathematics courses remains limited.

The counting and probability unit taught in Introduction to Finite Mathematics courses is full of versatile topics that matter to the population of students taking the course. This unit has been included in one form or another as a part of the finite mathematics from the courses' beginning in the late 1950s and are not likely to be excluded while business majors are still required to take the course. As Tucker (2013) states, "measuring and counting things [has] interested business-minded Americans from the republic's founding" (p. 692). Despite the interest in these topics and the importance put on them in the CCSSM, they remain largely unstudied at the undergraduate level. Yet, many people utilize counting and probability in their daily decision making without ever being conscious of it.

While it may be that finite mathematics courses and the way instructors teach counting and probability at the undergraduate level are maximally effective, educators cannot know for sure until the topic is fully explored. To date, Elise Lockwood has been the primary contributor to the field. Her studies have been qualitative in nature and have largely focused on students' association of counting with sets (Lockwood, 2011a, 2011b, 2012, 2013, 2014, 2015; Lockwood & Gibson, 2016; Lockwood, Reed, & Caughman, 2016). However, she has not yet addressed the application of counting techniques to probability. Counting and probability are interrelated topics and educators do not know if students are making the necessary connections. The current study allows educators to better understand how students are using counting techniques within the context of the probability application in a finite mathematics course.

As a part of a broader project (Blyman, 2017), this study seeks to address the following research question: *How successfully are students using the counting techniques of enumeration, Venn diagrams, and counting formulas when completing free response probability exam questions?* The results of this study provide insights to improve instruction in courses that include introductory counting and probability.

## Literature Review and Framework

All of Lockwood's work has contributed to a better understanding of students' thought processes which can be applied in the classroom. Lockwood (2011a, 2013) posited a model of students' combinatorial thinking where she explored connections students make between counting processes, formulas and expressions, and sets of outcomes. This model paired with mathematical theory relating probability to counting provides a framework for this study.

Lockwood has published various qualitative studies in undergraduate combinatorics education. Throughout her work, she primarily uses student interviews as a tool for gaining insight into the thought processes of students. Investigating counting techniques used by students has led to significant evidence that students struggle to solve counting problems (Lockwood, & Gibson, 2016). More specifically, students "struggle to detect common structures and identify models of underlying problems" (Lockwood, 2011b, p. 307) when solving counting problems. However, the roots of these struggles and ways to mitigate them have not yet been thoroughly studied (Lockwood, 2015).

Particularly relevant to this study are those studies which focus on listing sets of outcomes when working to solve counting problems (Lockwood, 2012, 2014; Lockwood & Gibson, 2016). These studies have resulted in evidence that students understand counting problems best when they enumerate sets of outcomes (Lockwood 2012, 2014; Lockwood & Gibson, 2016). Consequently, Lockwood (2012) encourages students and instructors alike not to be tempted to skip over the crucial step of listing outcomes when learning and teaching students to do counting problems. The multiplication principle connects counting processes with sets of outcomes and, consequently, deserves to be studied in and of itself (Lockwood, Reed, & Caughman, 2016). To begin studying it, Lockwood, Reed, and Caughman (2016) examined many finite mathematics textbooks' treatments of the multiplication principle in counting. They found there were many ways textbooks covered the multiplication principle and hypothesized this could have significant impacts on students' combinatorial thinking (Lockwood, Reed, & Caughman, 2016).

## Methodology

### Assumptions and Delimitations

This study assumes the course was taught identically by all lecturers and recitation instructors involved as collaboration and sharing of materials was common; however, they were not required to conduct lectures or recitations in the same manner. While informal conversations with lecturers and recitation leaders each semester have made it clear all classes look quite similar, lecturers and recitation leaders each bring their own style and varied experiences into the classroom, so some variance in instruction from section to section likely occurred.

Additionally, data were collected from students enrolled in an introductory finite mathematics course at a large public university in the mid-south for the Spring 2015, Fall 2015, and Spring 2016 semesters. Due to the structure of the course and homework, demographic information was not collected from participants. Consequently, demographics could not be used as covariates in the analyses of this study.

Finally, the format of the exams collected for qualitative data analysis changed between the Spring 2015 and Fall 2015 semesters. The Spring 2015 semester exams consisted of only free response problems while the Fall 2015 and Spring 2016 semester exams each only had 3 free response problems with the rest of the problems being multiple choice. As only the free response questions were considered in this study, the Spring 2015 exams provided much more data for each participant than did the Fall 2015 and Spring 2016 exams.

**Data Analysis**

To determine how successfully students are using counting techniques on free-response probability exam questions, a stratified random sample of the exams were coded and categorized using the provisional coding method (Saldaña, 2016). Provisional coding makes use of a list of *a priori* codes. For this study the list of codes was created by consulting answer keys to exams which were produced by instructors, considering mathematical connections, and by considering previous research in the field. Since the answer keys to exams from previous semesters are made available online to students as a study tool and the counting techniques which they were exposed to as a part of the course are rather limited, provisional coding using these *a priori* codes was an appropriate choice. While the textbook includes a section on the multiplication principle, the lecturers who wrote the answer keys chose to make use of combination notation over use of the multiplication principle. After scanning several exams and noting how much they resembled the answer keys from previous semester, it was clear that the set of *a priori* codes developed was sufficient to determine how successfully students were using enumeration, Venn diagrams, and counting formulas.

The strata for the sample were formed by recitation leader and the semester the data were collected in order to best form a truly representative sample. For each full-time recitation leader (leading *4* sections) *18* exams were selected and for each half-time recitation leader (leading *2* sections) *9* exams were selected. Sampling was used in order to make the data set more manageable. The numbers *18* and *9* were chosen because it resulted in over one quarter of the exams being coded. In total, *208* exams (*31.3%*) were coded. We scanned over the remaining exams to ensure the stratified random sample was a reasonable representation of all the exams collected. When coding exams, we considered any listing of elements of sets of outcomes to be enumeration, any attempt at using a Venn diagram to be using a Venn diagram, and any attempt at using a counting formula – even simply using combination notation – as making use of a counting formula. The exam answer keys provided examples of what each of the codes represented for reference throughout the coding process. Each part of each free response probability question was treated as an individual problem to be coded. During the coding process, neither coder found any student exams that warranted the addition of a new code.

Both authors coded the exams. Ten exams were coded together to establish consistency. To further guarantee consistency, both intra-rater and inter-rater reliability studies were conducted (Huck, 2012). Each grader reanalyzed a random sample of five exams to measure intra-rater reliability. Intra-rater reliabilities were *86.3%* and *91.5%*. We both analyzed a random sample of ten exams to establish inter-rater reliability. Inter-rater reliability was *86.8%*. In addition to categorizing techniques students were using, the study made use of frequency of codes in a quantitization process (Miles, Huberman, & Saldaña, 2014). Quantitization was used so that it could be determined how successfully students were using each of the counting techniques. Quantitizing the data allowed us to objectively determine if students were answering questions correctly more often or not when they appropriately used enumeration, Venn diagrams, or counting formulas. Using the quantitized data, three chi-square tests of association were conducted pairing each counting technique with correctness of the student's response. Based upon previous studies in the field and by recognizing Venn diagrams as a way of semi-enumerating a larger population by segmenting it, we hypothesized that enumeration and Venn diagrams would be positively associated with correctness on exam problems, while counting formulas would be negatively associated with correctness on exam problems.

## Results

Each of the chi-square tests was conducted with the null hypothesis that correctness is not associated with the use, or lack of use, of the given counting technique.

### Enumeration

The first of these tests examined the relationship between correctness and enumeration of possible outcomes. The questions included in this test were those on which the instructor chose to utilize enumeration on the published answer key for the exam and those questions which have an easily enumerated set of possible outcomes which the instructor chose not to list on the answer key. Namely, these were Spring 2015 (*n=81* coded exams) questions 1a-c and 7a-b; and Spring 2016 (*n=90* coded exams) questions 14b-c. This yielded a total of $5 \times 81 + 2 \times 90 = 585$ cases where enumeration was an appropriate technique for students to employ. The results of this chi-square test were $\chi^2(1{,}585) = 34.293, p < .001$. Therefore, this result is statistically significant with a small-medium effect size ($\varphi = .242$) since *.1* is considered a small effect and *.3* is considered a medium effect (Cohen, 1988). While students who chose not to enumerate the set of possible outcomes when solving the exam questions were split relatively evenly between those who got the question correct or not, students who used the enumeration strategy were more than twice as likely to get the question correct as incorrect (see Table 1). This result rejects the null hypothesis and confirms the hypothesis that enumeration is positively associated with correctness.

*Table 1. Chi-Square Test Results for Enumeration with Correctness.*

| | No Enumeration | Enumeration | Total |
|---|---|---|---|
| Incorrect | 154 | 78 | 232 |
| Correct | 147 | 206 | 353 |
| Total | 301 | 284 | 585 |

### Venn Diagrams

The second test examined the relationship between correctness and the usage of Venn diagrams. The questions included in this test were those on which the instructor chose to utilize a Venn diagram on the published answer key for the exam. Namely, these were Spring 2015 (*n=81* coded exams) question 5c; Fall 2015 (*n=27* coded exams) question 15a; and Spring 2016 (*n=90* coded exams) question 15a. This yielded a total of $81 + 27 + 90 = 198$ cases where using a Venn diagram was an appropriate technique for students to employ. The results of this chi-square test were $\chi^2(1{,}198) = 5.942, p < .05$. Therefore, this result is statistically significant with a small- medium effect size ($\varphi = .173$) since *.1* is considered a small effect and *.3* is considered a medium effect (Cohen, 1988). While students who chose not to use a Venn diagram when solving the exam questions were approximately two and a half times more likely to get the questions correct as incorrect, students who used Venn diagrams were almost six and a half times as likely to get the question correct as incorrect (see Table 2). This result rejects the null hypothesis and confirms the hypothesis that the use of Venn diagrams is positively associated with correctness.

Venn diagram problems were decidedly easier for students to correctly answer than their enumeration counterparts. Perhaps this is because Venn diagram problems require students to distinguish between at most three distinguishing traits and to classify portions of the population accordingly so there are at most eight numbers which the student is required to determine, while enumeration problems could require students to list as many as *36* possible outcomes to an experiment. On a timed test, students are more likely to not persist and not take the required time to make a list of *36* possible outcomes in such a way as to be able to successfully complete the exam problem.

*Table 2. Chi-Square Test Results for Venn Diagram with Correctness.*

| | No Venn Diagram | Venn Diagram | Total |
|---|---|---|---|
| Incorrect | 16 | 19 | 35 |
| Correct | 41 | 122 | 163 |
| Total | 57 | 141 | 198 |

**Counting Formulas**

The final test examined the relationship between correctness and the usage of counting formulas. The questions included in this test were those on which the instructor chose to utilize a counting formula on the published answer key for the exam. Namely, these were Spring 2015 (*n=81* coded exams) questions 1b, 2a-b, 3a-d, 7a-b, 8a-c, and 9a-b; Fall 2015 (*n=27* coded exams) questions 13a-c, and 14c; and Spring 2016 (*n=90* coded exams) questions 13a-c, and 14b-c. This yielded a total of $12 \times 81 + 4 \times 27 + 5 \times 90 = 1692$ cases where using counting formulas was an appropriate technique for students to employ. Students were counted as having used a counting formula if they made any use at all of a formula, even simply using combination notation in their answer. The results of this chi-square test were $\chi^2(1{,}1692) = 22.636, p < .001$. Therefore, this result is statistically significant with a small-medium effect size ($\varphi = .116$) since *.1* is considered a small effect and *.3* is considered a medium effect (Cohen, 1988). While students who chose to use a counting formula on exam questions were approximately equally likely to get the questions correct or incorrect, students who did not use counting formulas were approximately one and a half times as likely to get the question correct as incorrect (see Table 3). This result rejects the null hypothesis and confirms the hypothesis that counting formulas are negatively associated with correctness.

*Table 3. Chi-Square Test Results for Counting Formula with Correctness.*

| | No Counting Formula | Counting Formula | Total |
|---|---|---|---|
| Incorrect | 288 | 480 | 768 |
| Correct | 453 | 471 | 924 |
| Total | 741 | 951 | 1692 |

## Conclusion

The results of the chi-square tests show students were most successful solving probability problems when using enumeration and Venn diagrams. Students who enumerated sets of outcomes on problems where it was appropriate were more likely to correctly solve the problem than those who chose not to enumerate the set of outcomes on the same problems. Moreover, students who used Venn diagrams on the problems where Venn diagrams were used on the instructor-provided answer key, were much more likely to correctly solve the problem than those who chose not to use a Venn diagram on the same problems. However, students who used counting formulas on the problems where counting formulas were used on the instructor-provided answer key, were more likely to incorrectly solve the problem than those who chose not to use accounting formula on the same problems.

When attempting to solve probability problems set within the context of an inclusion-exclusion counting problem, Venn diagrams were highly effective as a problem-solving technique. A much higher percentage of students correctly responded to the Venn diagram questions than the enumeration or counting formula questions regardless of whether or not a Venn diagram was used. Therefore, students found the Venn diagram problems easier than their enumeration and counting formula counterparts. However, the likelihood of getting a probability question situated in an inclusion-exclusion setting correct increased quite dramatically when a Venn diagram was used.

These results confirm the hypotheses and Lockwood's findings that students understand counting problems best with enumeration (2012, 2014; Lockwood & Gibson, 2016). The chi-square test considering enumeration paired with Lockwood's work make it clear enumeration is an effective strategy for students to use when solving probability problems involving small sets of possible outcomes. Therefore, this study provided quantitative evidence for the findings of Lockwood's previous qualitative studies and extends those findings to the probability application of counting. Additionally, the study provided evidence that students using Venn diagrams have a relatively strong understanding of the problem and are equipped to take steps beyond the construction of their Venn diagram to answer a probability application question related to the Venn diagram that they have created.

Finally, the results of this study make it clear that counting formulas did not help students solve probability problems correctly. In fact, the study revealed students who use counting formulas have a diminished chance of correctly solving the probability problem. At the site of this study, students are offered the option of presenting their final answers as a quotient of two values written in combination notation rather than as the standard proper fraction, decimal, or percentage form of a probability. Through this policy and the presentation of solutions to past exam problems using combination notation, students are not only offered the chance to use this notation, they are strongly encouraged to use it rather than any other counting technique. While, the problems in which students are encouraged to use counting formulas are sometimes more difficult than the problems where they are encouraged to use other counting methods; however, not all the counting formula problems are more difficult. Whether the formula itself was the hindrance or there was some underlying factor at work, between their choice not to explicitly use a counting formula in their work and their misuse of said formula when they chose to use one, the majority of students made it clear they do not understand counting formulas.

**Implications for the Practice**

The implications of this study for undergraduate mathematics instructors are extensive. These implications stem from the struggles students are having using combination formulas to correctly solve probability problems. Instructors should be encouraging students to use those counting methods which best help them to understand the probability problem which they are attempting to solve. By allowing students to leave their answers in combination notation rather than requiring them to arrive at a proper presentation of a probability, instructors are allowing students to use a counting method without requiring the students know how to use it. Not only are they allowing this phenomenon to occur, they are actually encouraging it by providing students with answer keys to previous semesters' exams in which the solutions are only given in combination notation rather than as a decimal or fraction which the student could use to check an answer arrived at in a different way.

Additionally, since students are largely succeeding at enumeration and are struggling with properly applying the combination formula, it would be advantageous for instructors to give more attention to the multiplication principle – a known intermediary. In fact, given the nature of the counting and probability problems presented at the introduction to finite mathematics level, instructors should be reconsidering if the presentation of combination and permutation formulas is appropriate for the audience. With the limited time allotted for the counting and probability unit, perhaps students would be better served given a conceptual understanding of combinations and permutations while the methods for solving combination and permutation counting and probability problems are restricted to applications of the multiplication principle.

## Analyzing Narratives About Limits Involving Infinity in Calculus Textbooks

Andrijana Burazin
University of Toronto, Mississauga

Miroslav Lovric
McMaster University

*We analyze Calculus textbooks to determine to what extent narratives about limits at infinity and infinite limits align with research in mathematics education. As reasoning about limits falls within the domain of advanced mathematical thinking (AMT), we looked for evidence of appropriate treatment of, and support for, AMT: clear and precise narratives, deductive and rigorous reasoning, intuitive development that does not create or enhance students' misconceptions, opportunities for "personal reconstruction" (Tall, 1991), adequate representations, and the appropriate use of definitions. In conclusion, both high school and university Calculus textbook narratives do not place infinity in a precise, well-defined context, thus possibly creating or strengthening (novice) students' misconceptions. We identified very little evidence of the type of support for AMT that we were looking for. This paper concludes with several suggestions for possible modifications of narratives which involve infinity.*

*Keywords:* Narratives, Limits at Infinity, Infinite Limits, Advanced Mathematical Thinking, Mathematics Textbooks

This study reports on an analysis of presentations of the concept of infinity in textbooks. To be more specific—our aim is to determine if, or to what extent, and how, research in mathematics education has informed, and possibly affected, narratives about infinity in Calculus textbooks. We focus on infinity in the context of limits: limits at infinity (i.e., independent variable "approaches infinity") and infinite limits (i.e., dependent variable "approaches infinity"). This study falls within attempts at bringing research in mathematics education closer to teaching practice.

Discussing ways of improving the quality of mathematics instruction, Artigue (2001) writes: "existing research can greatly help us today, if we make its results accessible to a large audience and make the necessary efforts to better link research and practice" (p. 207). Burkhardt and Schoenfeld (2003) are not optimistic: "In general, education research does not have much credibility—even among its intended clients, teachers and administrators. When they have problems, they rarely turn to research" (p. 3).

In general, mathematics education research rests on well-developed theoretical foundations, and contains constructive information, suggestions and insights for teaching; however, these rarely go far enough and do not touch upon practical aspects of teaching—for instance, by providing content-specific teaching ideas, or by suggesting a rough lesson plan.

Case in point: numerous papers (including almost all cited throughout this paper) address challenges, problems and misconceptions related to teaching and learning infinity at secondary and/or tertiary levels —and yet none gives specific guidelines and suggestions which a textbook writer (or a course instructor) could readily learn from and use. Burkhardt and Schoenfeld (2003) echo this view:

> "The research-based development of tools and processes for use by practitioners, common in other applied fields, is largely missing in education. Such "engineering research" is essential to building strong linkages between research-based insights and improved practice. It will

> also result in a much higher incidence of robust evidence-based recommendations for practice." (p. 3)

There are exceptions. Kajander and Lovric (2009) examine the ways in which the concept of the line tangent to the graph of a function is presented in high school and university textbooks. Their analysis points at exact locations within the narratives that could be problematic (i.e., could lead to the development or strengthening of students' misconceptions), and concludes with specific alternative approaches.

We asked ourselves whether the views presented in Artigue (2001), Burkhardt and Schoenfeld (2003), and others—such as Ball (2000)—accurately portray textbook development of the concept of the limit, in particular when limits involve infinity. The fact that mathematics education researchers—almost as a rule—do not author mathematics textbooks, did not give us much hope that theoretical developments about teaching and learning of limits and infinity found their way into Calculus textbooks.

## Limits as Advanced Mathematical Thinking

Tall (1981), Davis and Vinner (1986), Tall (2001), Fischbein (2001), Jones (2015), as well as other researchers (some mentioned in this section, or later in this paper) agree that reasoning about limits falls within the domain of advanced mathematical thinking (AMT). Edwards, Dubinski, and McDonald (2005) write: "AMT is thinking that requires deductive and rigorous reasoning about mathematical notions" (p.17). AMT operates with abstract concepts which require serious mathematical treatment, usually reserved for advanced mathematics courses. Dynamic approaches to introducing the limit, usually discussed in introductory calculus courses, need to be rethought and modified to accommodate for AMT, as otherwise they lead to a variety of misconceptions (Nagle, 2013).

Plaza, Rico, and Ruiz-Hidalgo (2013) assert the importance of definitions as a characteristic that distinguishes elementary from advanced mathematics. Vinner (1991) argues that teaching and learning definitions is a serious problem, and states that a definition "represents, perhaps, more than anything else the conflict between the structure of mathematics, as conceived by professional mathematicians, and the cognitive processes of concept acquisition" (p.65). Edwards and Ward (2004) echo this view: "many students do not *use* definitions the way mathematicians do, *even when the students can correctly state and explain the definitions*" (p. 416).

In Tall (1991), we read: "Advanced mathematics, *by its very nature*, includes concepts which are subtly at variance with naïve experience. Such ideas require an immense personal reconstruction to build the cognitive apparatus to handle them effectively" (p. 252). Edwards, Dubinski, and McDonald (2005) concur, and state that

> "In dealing with limits, students often struggle with the human need to make sense of things by attempting to carry out a process that is impossible to see to the end. Students who view the concept of limit as a dynamic process (meaning a process of getting closer and closer to a limit, but not the object that is the limit) or an unreachable bound, for example, are demonstrating in this instance a failure to use AMT as they are not transcending the finite physical models available to them." (p. 21)

Some researchers identify "process and object components" (Cotrill et al., 1996; Jones, 2015) of the numeric, algorithmic, or theoretical calculation of a limit, with process being equivalent to the notion of "dynamic" in the quote above. For some, "dynamic reasoning" about limits includes both components (Jones, 2015).

Further challenges to creating narratives about limits lie in the language. It is well known that the differences between everyday language and the mathematics language contribute to students' difficulties in understanding (Cornu, 1991; Monaghan, 1991; Kim, Sfard, & Ferrini-Mundy, 2005). Using colloquial phrases such as "to reach," "to exceed," "to approach" in articulating understanding of limits negatively affects students' understanding (Plaza, Ruiz-Hidalgo, & Romero, 2012). Kajander and Lovric (2009) show that this colloquial, "reader-friendly" language leads to the development of misconceptions in textbook presentations of the concept of a tangent line.

Probing narratives can further profit from awareness of the distinction between "transparent" and "opaque" representations in the sense of Lesh, Post, and Behr (1987). As a way of summarizing, Zazkis (2005) writes: "A transparent representation has no more and no less meaning that the represented idea(s) or structure(s). An opaque representation emphasizes some aspects of the ideas or structures and de-emphasizes others" (p. 209).

In conclusion, in our analysis of textbooks, we look for evidence of appropriate treatment of, and support for, AMT: clear and precise narratives, deductive and rigorous reasoning, intuitive development that does not create or enhance students' misconceptions, opportunities for "personal reconstruction" (Tall, 1991), adequate (transparent or opaque) representations, and the appropriate use of definitions.

## Infinity in a High School Textbook

We examined one textbook (Dunkley, Carli, & Scoins, 2002), which has been used in grade 12 classrooms in Ontario, Canada. As it accurately reflects the expectations of Ontario high school grade 12 mathematics curriculum (Ontario Ministry of Education, 2007), we believe that this textbook is a likely representative of other textbooks in use.

High school students hear about infinity in a variety of contexts, including: (1) there are infinitely many real numbers; (2) an irrational number is an infinite decimal; (3) limits involving infinity and asymptotes; (4) notation for an infinite interval. (In (1), (2) and (4), we purposely used phrases found in textbooks, to hint at, and to illustrate potential problems.)

Ontario curriculum document (Ontario Ministry of Education, 2007) does not require a clear conceptualization of infinity, for instance by suggesting that infinity be discussed in a *precise, well-defined context.* For instance, the phrase "infinitely *many*" in (1) might suggest a counting approach (*potential infinity*) for a concept that is an instance of *actual infinity*. In (2), it is not clear what "infinite" means—an irrational number has an infinite non-repeating decimal interpretation (i.e., the number is not infinite, but its decimal representation does not terminate). In *Glossary* in Dunkley, Carli, & Scoins (2002), we read that the basis of natural logarithms *e* is a "non-repeating, infinite decimal" (p. 457). Not aware of the subtleties involved, some students think of irrational numbers as infinite (and yet having a finite value). In (4), it is not clear what is infinite about the "infinite interval" (we discuss this further later in this section).

Dunkley, Carli, & Scoins (2002) define infinity as "something that is not finite, that is countable or measurable" (p.459), without explaining what the terms "countable" or "measurable" mean (these two terms do not appear in *Glossary*, nor elsewhere in the text). Not only is this notion confusing, but there is no indication how it relates to the infinity in the context of infinite limits which are discussed in the textbook.

Often, infinity is qualified by what it is not. For example: "We say that the function values approach $+\infty$ (positive infinity) or $-\infty$ (negative infinity). These are not numbers" (Dunkley, Carli, & Scoins, 2002, p. 353). Stating that it is not a number does not clearly articulate what infinity is; the authors continue: "They are symbols that represent the value [plural needed] of a function that increases or decreases without limits" (p.353). Furthermore, the quoted sentences define an infinite limit using the word limit (which makes it a circular definition); or, they are just confusing, as they mix up different meanings of the term "limit" (Jones, 2015). As well, the phrase "without limits" suggests the meaning of the limit as something that bounds, which is a common misconception that students have about limits (Tall, 1991).

Routinely, the same symbol $\infty$ is used both in interval notation, such as $(1,\infty)$, and in the context of limits. In this case, an adequate narrative needs to resolve this conflict between static and dynamic interpretations of $\infty$. For instance, treating $\infty$ in $(1,\infty)$ as transparent (Lesh, Post, & Behr, 1987; Zazkis, 2005), a textbook author could say that the symbol $\infty$ in $(1,\infty)$ is there for convenience, and could be replaced by some other symbol; all it means ("no more, no less") is that the interval $(1,\infty)$ represents the set of all real numbers larger than 1. We did find such an explanation: Stewart, Davison, and Ferroni (1989) write: "This does not mean that $\infty$ is a real number. The notation $(a,\infty)$ stands for the set of all numbers that are greater than *a*" (p.162).

The use of the term "infinite interval" for intervals such as $(1,\infty)$ is ambiguous, as it is not clear what is infinite about it—the number of points it contains, or its infinite size, or something else? A correct term "unbounded interval," as in advanced calculus/ analysis books, should be used.

## Infinity in University Textbooks

Calculus textbooks published in North America since 1980s have been influenced by the so-called calculus reform, or reform-based learning. Besides precise definitions and statements of theorems we find metaphors and explanations which are supposed to help students develop deeper (often intuitive) understanding of concepts. We found out that, in the sections about limits involving infinity, it is these "aids" to building an understanding that are often, due to their authors' disregard for research in math education, worrisome, ineffective and sometimes make no sense. A possible reason for inclusion of narratives (in the case of limits) is an attempt to strike a balance between rigorous (theoretical) development of the limit concept (which is, however, rarely covered in year 1 calculus classrooms) and the need to provide some opportunities for students to deepen their understanding. As well, these narratives could support theoretical understandings, and thus enrich the classroom coverage, often heavily biased toward technical (algorithmic) aspects of limits. Liang (2016) writes: "Calculus teachers usually focus on the calculation of limit, sometimes on graphical illustration of limit, rarely on theoretical aspect (or definition) of limit" (p. 37).

We do not argue against using narratives to enhance understanding, but suggest that they be constructed with care, and with awareness of situations which could lead to the development of students' misconceptions (or complete misunderstandings). In this section we outline a small selection of common narratives that we found in Calculus textbooks. With *novice learners* in mind, we aim to alert instructors to potential issues that these students might face. Of course, certain narratives that we identify as problematic for novices have become an integral part of a language that experts, as well as senior mathematics students, use routinely, and with appropriate and accurate understandings.

All narratives that we discussed in the previous section are found in university textbooks as well. Of the many university Calculus textbooks available to us, we looked deeper into six only, realizing that many have almost identical narratives and identical features. (This important problem of an almost complete absence of variety in presentations, content, and design of Calculus textbooks will not be discussed here.)

Common phrases found in describing an infinite limit of a function "$f(x)$ *becomes* [emphasis added] infinitely large," and "*becomes* [emphasis added] a negative number of large magnitude" (Edwards & Penney, 2008, p. 281) suggest that infinity is "reachable" (an object) as the end of the process of calculating a limit. Instead, a dynamic (process) representation (Cotrill et al., 1996; Jones, 2015) such as "the values of $f(x)$ *surpass* any real number," or similar, should be used.

The phrase "$f(x)$ grows larger and larger" (Jones, 2015) is even more problematic: it suggests that a function has a *size*; however, $f(x)$ is a real number, and has a value, but not a size. The use of "size" as in this example should be avoided; we use "size" when we refer to the set of real numbers, and say that the set of real numbers is infinite (*actual infinity*). As well, "growing larger and larger" does not suffice to guarantee that the limit of a function is $\infty$.

Another notable feature of textbooks is the absence of a rigorous treatment of infinite limits that would parallel the development of limit laws in the case when all limits involved are real numbers. This absence is truly perplexing, as students are expected to routinely argue about, and use, formulas such as $\infty+1=\infty$, $3\cdot\infty=\infty$, and $\infty+\infty=\infty$. For instance, they need all three of these to compute the limit $\lim\limits_{x\to\infty}\left(3x+\ln x+1\right)$. Stretching their intuition further, students might (and do!) erroneously conclude that the indeterminate forms $\infty-\infty$ and $\infty\cdot 0$ are both equal to zero (Lovric, 2012).

More of an exception, we find *Limit Laws for Infinite Limits* explicitly stated in Adler and Lovric (2015, p. 218).

Textbooks often use narratives about infinite limits in the section on L'Hopital's rule. However, almost all that we found are inadequate, or do not contribute to understanding. In Anton, Bivens & Davis (2009), we read:

> "[…] a limit involving $+\infty$ and $-\infty$ is called an indeterminate form of type $\infty-\infty$. Such limits are indeterminate because the two terms exert conflicting influences on the expression; one pushes it in the positive direction and one pushes it in the negative direction." (p. 225)

It is unclear what students are supposed to make of "conflicting influences," i.e., why conflicting influences make an expression indeterminate. For example, in the expression $\lim\limits_{x\to 10}\left(100x-x^3\right)$ the two terms $100x$ and $x^3$ exert conflicting influences (in the sense of the quote above); however, this limit is not an indeterminate form.

In the same book, the authors discuss the indeterminate form $1^\infty$ coming from the expression $\lim\limits_{x\to 0^+}\left(1+x\right)^{1/x}$. They state that $1^\infty$ is indeterminate because "expressions $1+x$ and $1/x$ exert two conflicting influences: the first approaches 1, which drives the expression toward 1, and the second approaches $+\infty$, which drives the expression toward $+\infty$" (p. 225). Apart from other issues in this narrative, it is completely unclear why approaching 1 and approaching $+\infty$ are "conflicting influences." The two are certainly not conflicting, if we consider $\lim\limits_{x\to 0^+}\left(1+x\right)\cdot\frac{1}{x}$, i.e., in this case the limit is not an indeterminate form (we replaced exponentiation with multiplication).

Indeterminate forms have also been articulated as "competing forces." When describing $\infty/\infty$, Stewart (2016) uses a somewhat successful metaphor of a "struggle"

"There is a struggle between numerator and denominator. If the numerator wins, the limit will be $\infty$ […] if the denominator wins, the limit will be 0. Or, there might be some compromise, in which case the answer might be some finite positive number." (p. 305)

Later in the text, the author uses "contest" (p. 309). However, both metaphors break in the case of exponents, and the textbook offers no explanation as to why $1^{\infty}$ is indeterminate.

Hass, Weir, and Thomas (2016) call the indeterminate limit $0/0$ (equivalent to $\infty/\infty$) a "meaningless expression, which we cannot evaluate" (p. 242), without supplying any rationale as to what makes it "meaningless." Hass, Weir and Thomas (2007) use the term "ambiguous expression" (p. 285) when talking about other indeterminate forms; this phrase disappeared from Hass, Weir, and Thomas (2016).

Smith and Minton (2012) are a bit more explicit, when they state that "mathematically meaningless" means that "we'll need to dig deeper to find the value of the limit" (p. 223). However, there is no narrative explaining why these forms are indeterminate (is it just because we need to "dig deeper"?), or suggesting an approach that would help to understand them. Edwards and Penney (2008, p. 296) use inappropriate term "order of magnitude" in discussing the functions in the numerator and the denominator of the indeterminate form $\infty/\infty$ (one possible correct term is "leading behaviour").

Due to space limitations, we presented only a small sample of Calculus textbook narratives about infinity in the context of limits. However, we attempted to select narratives which are more common, and representative of issues and problems that could emerge when students try to read and understand them.

## Conclusion

Understanding of, and working with, the concept of the limit requires "an upgrade from intuitive concrete understanding to abstract recognition" (Merenluoto & Lehtinen, 2000). Such an upgrade requires an "immense personal reconstruction" (Tall 1991, p. 252), which includes "deductive and rigorous reasoning" (Edwards, Dubinski, & McDonald, 2005, p.17) and needs to be supported by adequate teaching and resources. Examining a sample of university Calculus textbooks for their treatment of infinite limits and limits at infinity, we have not identified much evidence of this, much needed, support.

Merenluoto & Lehtinen (2000) claim that before students learn about the (mathematical) concept of the limit, they already have experiences about limits. "Their understanding is mainly based on everyday experiences rather than mathematical understandings" (p. 37). As limits are "subtly at variance with naïve experience" (Tall, 1991, p. 252), it is important that textbooks address these experiences head-on to avoid creating or enforcing students' misconceptions about limits. Our examination shows that such narratives are missing from textbooks.

Although all textbooks we examined do cover theoretical aspects of the development of the concept of the limit, they do not dedicate sufficient attention to it. These "theoretical" sections *look* different compared to other sections in the textbooks: with dense presentations, terse language, abundance of symbols and a small number of examples, they seem to have been borrowed from advanced mathematical texts. They are organized in such a way that it is easy for an instructor to skip the material, or to assign it as optional reading. Perhaps we should not be too critical: these "theoretical" sections are an awkward compromise—textbook writers, under pressure from their editors, are forced to include "theory," although they know that many instructors will just skip it. This situation is in line with the general trend of moving theoretical material in Calculus textbooks from dominant to marginal locations (Bokhari & Yushau, 2006).

Nearing the end of this paper, in order to bring our analysis closer to teaching practice, we outline several suggestions, with textbook writers, as well as Calculus instructors, in mind.

Discussing clarity and transparence in teaching infinity, Lovric (2012) writes:

> "We need to make sure that the concepts are precisely *defined*. The necessity for, and a power of a mathematical definition now become obvious. Students will see how the precise and clear language of a definition eliminates multitudes of meanings, inappropriate metaphors and ambiguities in their understanding." (p. 141)

This demands that textbooks, as well as course instructors, bring certain theoretical considerations about limits back to their dominant position. For instance, a precise articulation (definition, together with appropriate illustrations) of the fact that $f(x) \to \infty$ should be accompanied by carefully crafted, transparent, narratives which alert the reader to possible misconceptions and misinterpretations (Monaghan, 1991; Jones, 2015).

All textbooks examined use the phrase "limit does not exist," but mostly do not clearly state that its precise (transparent, "nothing more, nothing less") meaning is "limit is not a real number." As illustration of a possible narrative that attempts to shed some light on this, but is not explicit enough, we quote Smith and Minton (2012): "It is important to note that while the limits […] *do not exist*, we say that they "equal" $\infty$ and $-\infty$, respectively, only to be specific as to *why* they do not exist" (p.97). Common misconception that "limit does not exist" means that the limit is $\infty$ or $-\infty$ leads students to conclude, confused, that "infinity does not exist." By the way—besides including infinite limits, "limit does not exist" refers to the case when left and right limits (which could be real numbers) are not equal.

Indeterminate forms should not be referred to as a "meaningless expressions" or "ambiguous expressions." For instance, they could be qualified in the following way: indeterminate forms are algebraic expressions which appear in the context of limits only; they include: division of zero by zero, the cases which are not covered by the limit laws for infinite limits, as well as certain exponential forms involving zero and $\infty$. (Next, the seven indeterminate forms are listed.) These expressions are called "indeterminate" because their values depend on the limits that generated them; in other words, just by looking at the limits of the form $\infty - \infty$, $\infty/\infty$, or $0 \cdot \infty$, we cannot tell what their values are. For instance, the following four expressions are all of the same indeterminate form $\infty/\infty$, yet the limits are 0, 1, 7, and $\infty$ respectively:

$$\lim_{x\to\infty} \frac{\ln x}{x}, \quad \lim_{x\to\infty} \frac{x+4}{x-1}, \quad \lim_{x\to\infty} \frac{7x+4}{x+3}, \quad \lim_{x\to\infty} \frac{x^2+1}{x}$$

An introduction to a discussion of infinite limits could start by stating that "'infinity' is really an extrapolation of our finite world, meaning that it is purely a mental construct that we do not encounter in our daily lives" (Tall, 1981, as quoted in Jones, 2015, p. 107). As this *mental construct* appears in various (sometimes incompatible) forms in different contexts, textbooks must be explicit about the context, and then keep their focus. A presentation about infinite limits and limits at infinity (*potential infinity*, *dynamic* nature of infinity) should avoid using terms and phrases such as "size," or "reaches infinity," or any narrative that would suggest objectification of infinity "as a sort of 'generalized large number'"(Tall, 1992, as quoted in Jones, 2015, p. 108).

In conclusion, these are initial, perhaps rough, findings of our analysis. As we probe deeper, we hope to come up with further insights into narratives related to limits involving infinity.

Cognitive Consistency and Its Relationships to
Knowledge of Logical Equivalence and Mathematical Validity

Kyeong Hah Roh
Arizona State University

Yong Hah Lee
Ewha Womans University

*The purpose of this study is to explore how cognitive consistency is related to knowledge of logic and mathematical proofs. We developed a logic instrument and administered it to forty-seven (47) undergraduate students who enrolled in various sections of a transition-to-proof course. The analysis of the students' scores on the logic instrument indicated that students' knowledge of logical equivalence and their knowledge of mathematical validity were somewhat related to one another. On the other hand, cognitive consistency was not closely related to either student knowledge of logic or knowledge of mathematical validity. Based on these findings, we address the importance of cognitive consistency in logical thinking and discuss implications for the teaching and learning of logic in mathematical contexts*.

*Keywords:* cognitive consistency, logical equivalence, mathematical validity, transition-to-proof

Our society expects people to have ability to make decisions in their workplaces more efficiently by deducing valid inferences from a tremendous amount of information and resources. In fact, a person's logical thinking plays a crucial role in generating valid arguments from the given information as well as in evaluating the validity of others' arguments. Hence, training our students as logical thinkers is a central component in education (NGAC & CCSSO, 2010; NRC, 2005). On the other hand, research in mathematics education reports that undergraduate students have weak knowledge on logic (e.g., Dubinsky, Elterman, & Gong, 1988; Epp, 2003; Inglis & Simpson, 2007). Such a deficiency of knowledge of logic would entail difficulties with using logic in deducing valid inferences to construct mathematical proofs (e.g., Moore, 1994), to comprehend mathematical proofs or interpret mathematical statements (e.g.,Mejia-Ramos et al., 2012; Selden & Selden, 1995), or to evaluate the validity and the soundness of someone's proofs (e.g., Selden & Selden, 2003).

With the importance of student knowledge of logic, we also consider *cognitive consistency* as an essential component in logical thinking. By cognitive consistency, we refer to "an intra-individual psychological pressure to self-organize one's beliefs and identities in a balanced fashion" (Cvencek, Meltzoff, & Kapur, 2014, p.73). Cognitive psychologists explain such a tendency as people behave in ways that maintain cognitive consistency or minimize cognitive dissonance among their interpersonal relations, intrapersonal cognitions, beliefs, feelings, or actions (Festinger, 1957; McGuire, 1966). For instance, a student might deduce two statements such as '$x$ is an integer' and '$x$ is not an integer' from given information as well as based on his own content knowledge of mathematics. Logically speaking, each of these statements contradicts one another, thus two statements cannot be accepted simultaneously. Since such a logical contradiction is a fatal flaw that makes the student's entire argument meaningless, it must be excluded from the argument. Once a student recognizes a logical contradiction in his argument, he would attempt to remove it from his argument. However, if the student does not recognize such a contradiction in his argument, he would be in cognitive inconsistency. One's recognition of cognitive inconsistency in his own reasoning or thinking will be the first step in self-regulating one's own cognition. However, if a student does not recognize cognitive inconsistency in his or her own knowledge structures, the student may not take any effort to change or modify his knowledge structure. Thus, it is very important to train students not only to gain more knowledge of logic but also to maintain cognitive consistency.

One might expect that the more knowledge of logic students has, they would unlikely deduce logical contradictions from given information or they would recognize logical contradictions if they happen to deduce them from given information. It might also be expected that students who do not recognize logical contradictions in their arguments would not be knowledgeable in logic. This study explores how students' cognitive consistency is related to their knowledge of logic and knowledge of mathematical validity, addressing the following research questions:

1. Do students with more knowledge of logical equivalence tend to have stronger cognitive consistency?
2. Do students with more knowledge of mathematical validity tend to have stronger cognitive consistency?

We developed the logic instrument to systematically measure three components of students' logical thinking: knowledge of logical equivalence between two statements, knowledge of mathematical validity of the arguments, and cognitive consistency. While we hope that this study provides new insights into the theories of cognitive consistency, our foci are distinct to previous ones from two aspects. First, in exploring the role of cognitive consistency, this study pays more attention to mathematical contexts such as logical equivalence of mathematical statements and mathematical validity, rather than focusing on personal or interpersonal attitudes and behaviors in social contexts (c.f., Cooper, 1998; Gawronski & Strack, 2004; Gawronski, Walther, & Blank, 2005; Stone & Cooper, 2001). Second, this study explores whether students recognize cognitive inconsistencies in their logical thinking rather than how students reconcile cognitive inconsistencies after recognizing them in their reasoning (c.f., Dawkins & Roh, 2016; Ely, 2010; Roh & Lee, 2011).

## Research Methodology

This study was conducted in the spring semester of 2014 at a large public university in the United States. Among 137 undergraduate students who enrolled in a transition-to-proof course various instructors, forty-seven (47) students voluntarily participated this study to complete the logic instrument. Due to the pre-requisite for the transition-to-proof course at the university, the participants had already completed at least the first semester calculus course. In addition, as the logic instrument was administered at the last week of the semester when the participants enrolled in the transition-to-proof course, the participants of this study had already been exposed to the terms used in the questions of the logic instrument, such as equivalent statements, logical connectives, quantifiers, negation, and valid arguments. Twenty-three participants (48%) were mathematics majors whereas twelve participants (26%) were mathematics education majors. The rest of the participants (twelve students, 26%) whose major areas of study were neither mathematics nor mathematics education were labeld as others.

### The Logic Instrument

The logic instrument we developed for this study consists of two parts with twelve questions in total. The first part (seven questions) was designed to test students' knowledge on logical equivalence between two statements. On the other hand, the second part of the logic instrument (five questions) was designed to test students' knowledge of mathematical validity.

**Part 1 of the logic instrument.** All questions in Part 1 present one or a pair of statements. We chose logical forms for these questions in Part 1 of the logic instrument among those that are frequently found in undergraduate mathematics textbooks from calculus and beyond. Several instances are also presented with the statement(s) in each question and students are asked to mark off all relevant ones among the given instances (See Table 1). All statements given in the questions in Part 1 of the logic instrument are *open* statements involving at least one free variable so that the truth-value of each statement cannot be determined. We purposely created and included such open statements to the questions in Part 1 in order to avoid the cases of students who answer to the questions based on their determination of the truth-value of a statement.

*Table 1 Summary of seven Questions in Part 1 of the logic instrument*

| | **Logical form of the given statements** | **Nature of the Questions** |
|---|---|---|
| Q1 & Q3 | $P(x) \to Q(x)$ | Mark off all logically equivalent instances to the given statement |
| Q2 & Q4 | A pair of statements in the forms of $\forall x \exists y P(x, y, z)$ & $\exists y \forall x P(x, y, z)$ | Mark off the best description about the logical relationship between the given statements |
| Q5, Q6, & Q7 | $\forall x, P(x, y) \to Q(x, y)$ | Mark off all logically equivalent instances to the negation of the given statements |

**Part 2 of the logic instrument.** All five questions in Part 2 are set up similarly in the sense that each question asks to (1) determine the truth-value of the given statement; (2) determine if the person whose argument is given in the question attempts to either prove or disprove the statement; and (3) evaluate if the person's argument is valid. See Figure 1 for Q9 as an example of questions in Part 2 of the logic instrument.

Q9. An integer *a* is said to be odd if and only if there exists $n \in \mathbb{Z}$ such that $a = 2n + 1$. Tim was asked to prove or disprove:

(♣) For any positive integers *x* and *y*, if *x* and *y* are odd, then $xy$ is odd.

The following is Tim's argument.

$$x = 2n + 1, n \in \mathbb{Z}$$
$$y = 2n + 1, n \in \mathbb{Z}$$

Therefore, $xy = (2n + 1)(2n + 1) = 4n^2 + 4n + 1 = 2(2n^2 + 2n) + 1$ is odd.

(1) Check the most appropriate one about the statement (♣).

a. _______ The statement (♣) is true.

b. _______ The statement (♣) is false.

c. _______ We cannot determine if the statement (♣) is true or false.

(2) Check the most appropriate one to describe what Tim attempted to prove.

a. _______ Tim attempted to prove the statement (♣) is true.

b. _______ Tim attempted to prove statement (♣) is false.

c. _______ We cannot determine if Tim attempted to prove the statement (♣) is true or he attempted to prove the statement (♣) is false.

(3) Check the most appropriate one to describe if Tim's argument is valid.

a. _______ Tim's argument is valid as a proof of the statement (♣).

b. _______ Tim's argument is invalid as a proof of the statement (♣).

c. _______ We cannot determine if Tim's argument is valid or invalid.

*Figure 1 Q9 in the logic instrument*

## Data Analysis

The logic instrument described in the previous section was used in this study to measure students' logical thinking in terms of *knowledge of logical equivalence* (KoLE), *knowledge of* *mathematical validity* (KoMV), and *cognitive consistency* (CC). We first generated the coding scheme to score students' mark-offs to the questions in the logic instrument. Different weights were applied to different questions as each question was used to examine different aspects of students' logical thinking. After coding student responses in terms of the scoring rubric, we also generated *the overall logical thinking* (OLT) scores as the sum of the three scores: KoLE, KoMV, and CC scores.

**Scoring rubric for knowledge of logical equivalence (KoLE).** Student knowledge of logical equivalence was measured from student responses to the questions in Part 1 of the logic instrument (see Table 2). Questions 1, 3, 5, 6 and 7 in Part 1 present a statement and a set of six to seven instances. For each of these questions, sub-question scores were first generated based on students' mark-off to the instances as follows: Students' mark-off to each instance was scored either 0 (for the correct response) or -1 (for the incorrect response). The final score for each of these questions was then formulated as the maximum value between 0 and 2+∑(sub-question score). Using this scoring rubric, the scores for Q1, Q3, Q5, Q6, and Q7 were ranged from 0 to 2. On the other hand, Questions 2 and 4 present a pair of statements (i) and (ii) and a set of four instances (a) ~ (d) describing relationships between the pair of statements. For each of these questions, students' check of one of the four relationships was scored either 2 (for the correct response) or 0 (for the incorrect response). KoLE score was then given as the sum of the scores on these seven questions in Part 1, which could be possible ranged from 0 to 14.

*Table 2 Scoring rubric for Part 1 of the logic instrument (Q1 ~ Q7)*

<table>
<tr><th>Question</th><th colspan="3">Scoring Rubric</th><th>Score Range</th></tr>
<tr><td rowspan="2"></td><td colspan="2">Sub-question score</td><td rowspan="2">Scoring Formula</td><td rowspan="2">Final score</td></tr>
<tr><td>Correct / Incorrect</td><td>score</td></tr>
<tr><td rowspan="2">Q1, Q3, Q5~Q7</td><td>Correct</td><td>0</td><td rowspan="2">S = max{2+∑(sub-question score), 0}</td><td rowspan="2">S</td></tr>
<tr><td>Incorrect</td><td>-1</td></tr>
<tr><td></td><td>Correct / Incorrect</td><td colspan="2">score</td><td>Final score</td></tr>
<tr><td rowspan="2">Q2, Q4</td><td>Correct</td><td colspan="2">2</td><td>2</td></tr>
<tr><td>Incorrect</td><td colspan="2">0</td><td>0</td></tr>
</table>

**Scoring rubric for knowledge of mathematical validity (KoMV).** Student knowledge of mathematical validity was measured from student responses to the second and third sub-questions to the questions in Part 2 of the logic instrument (see Table 3). First, we evaluated students' student responses to the second sub-question (asking to determine if the given argument is an attempt to prove or an attempt to disprove the statement); and then evaluated student responses to the third sub-question (asking to evaluate the validity of the given argument). To be more specific, for Q8, 1 was given for the correct response to the validity of each argument in the second and third sub-questions, respectively; otherwise 0 was given. For Q9 ~ Q12, 2 was given to the correct mark-off to the second sub-question; otherwise, 0 was given. Next, among those who marked-off correctly to the second sub-question (proof or disproof), if the student also responded correctly to the third sub-question (valid or invalid), we scored 0 for the response to the third sub-question; otherwise, $-\mathbf{1}$ was given. On the other hand, if the student response to the second sub-question (proof/disproof) was incorrect, we scored 0 to any response to the third sub-question regardless of its correctness. We then added the scores on its second and third sub-questions according to the scoring rubric described above. For instance, Q9 (Figure 1) presents an argument (2) attempting to prove the statement is true where (3) the argument is invalid. If a student were to mark off that (2) the given argument in Q9 is an attempt to prove that the statement is false (incorrect), and (3) the given argument is invalid (correct), then 0 was given to this response as the response to the second sub-question is incorrect. On the other hand, if a student were to mark off that (2) the given argument in Q9 is an attempt to prove that the statement is true (correct) and (3) Tim's argument is valid (incorrect), then 1 is given to the student response to Q9 as the correct response to the second sub-question is scored to 2 and an incorrect response to the third sub-question is scored to $-1$ while the correct response to the first sub-question is neglected due to the incorrect response to the third sub-question. The KoMV score was then given as the sum of the scores on these five questions in Part 2, which could be possibly ranged from 0 to 10.

*Table 3 Scoring Rubric for Part 2 of the Logic Instrument (Q8 ~ Q12)*

<table>

<tr><td>Incorrect</td><td>0</td><td>-</td><td>-</td><td>0</td></tr>
</table>

**Scoring rubric for cognitive consistency (CC).** For cognitive consistency scores, we first identified cognitive inconsistencies when student responses to sub-questions of a question imply any logical contradiction. For instance, suppose a student marks off to Q9 (Figure 1) as follows: (2) Tim's argument is an attempt to prove the statement (♣) is false, and (3) Tim's argument is valid. This student's responses contain a logical contradiction since an attempt to prove that a true statement is false cannot be valid. Similarly, if another student responds to Q9 that (2) Tim's argument is an attempt to prove the statement (♣) is true, and (3) Tim's argument is valid, then the student also appears to have cognitive inconsistency. Table 4 describes all instances of cognitive inconsistencies to be evidently found from student responses to the questions.

*Table 4 All instances of cognitive inconsistency*

<table>
<tr><th colspan="2">Question</th><th colspan="3">Sub-Questions</th></tr>
<tr><td rowspan="3">Q8</td><td rowspan="3">Cognitive Inconsistency</td><td>(1) True/False (Statement)</td><td>(2) Validity (Argument)</td><td>(3) Validity (Argument)</td></tr>
<tr><td>(a) True or<br>(c) Cannot determine</td><td>(a) Valid as a proof for false</td><td>-</td></tr>
<tr><td>(b) False or<br>(c) Cannot determine</td><td>-</td><td>(a) Valid as a proof for true</td></tr>
<tr><td rowspan="3">Q9~Q12</td><td rowspan="3">Cognitive Inconsistency</td><td>(1) True/False (Statement)</td><td>(2) Prove/Disprove (Argument)</td><td>(3) Validity (Argument)</td></tr>
<tr><td>(a) True or<br>(c) Cannot determine</td><td>(b) Prove False</td><td>(a) Valid</td></tr>
<tr><td>(b) False or<br>(c) Cannot determine</td><td>(c) Prove True</td><td>(a) Valid</td></tr>
</table>

Cognitive consistency *was* measured from student responses to all three sub-questions of the questions in Part 2 of the logic instrument. We measured students' cognitive consistency by assigning either $-1$ or 0 to each of the questions (Q8~Q12) as follows: $-1$ was assigned whenever there is evidence of cognitive inconsistency, i.e., a logical contradiction from student responses to its sub-questions. On the other hand, we scored 0 in all other cases but the instances in Table 4 since there is no evidence of logical contradictions from the cases. As there were five questions in Part 2, the total score on cognitive consistency could be possibly ranged from $-5$ to 0. Obviously, if a student marks off correctly to all sub-questions to a question in Part 2, the student does not appear to have a cognitive inconsistency in his response to the question. On the other hand, although the student responses to some sub-questions are not correct, the student's cognitive consistency score to the question could still be 0 in the case when there is no evidence of logical contradiction within the student's responses.

## Results

The overall logical thinking (OLT) scores were distributed between $-2$ and 24 with the interquartile range between 6 and 15. In addition, the mean of the OLT scores was about 10 and the highest OLT score was 24 which was the possible maximum for the OLT score with only one student receiving the highest score. On the other hand, there was one student who received $-2$ on the OLT scores due to negative values on the cognitive consistency score, which will be discussed later more in detail when analyzing the cognitive consistency scores. Furthermore, KoLE scores were ranged from 0 to 14 while the median was 5 (out of 14 points) and 50% of student KoLE scores were between 2 and 9. KoMV scores were ranged from 0 to 10 with the median 5 (out of 10 points) while 50 % of KoMV scores were distributed between 3 and 8. Finally, the CC scores were ranged from $-2$ to 0 and about 21% of the CC scores were negative.

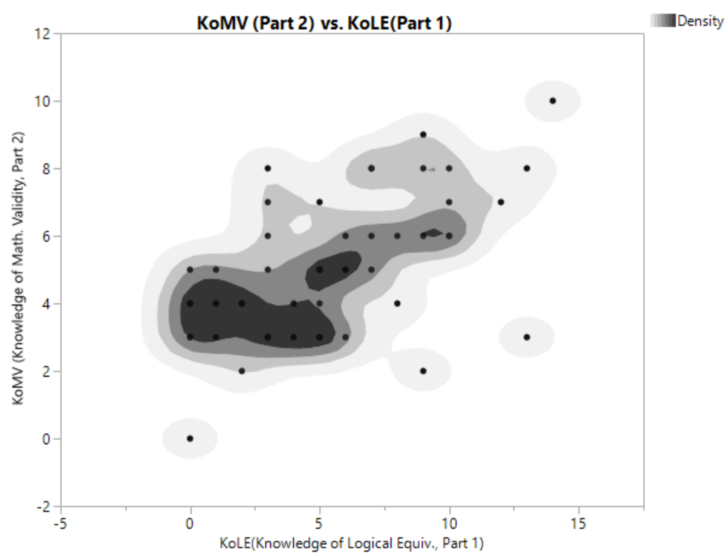

*Figure 2 Scatter-Density plot: KoMV vs. KoLE*

The scatter-density plot in Figure 2 further shows that students' knowledge of logical equivalence (KoLE) and students' knowledge of mathematical validity (KoMV) are somewhat related to one another. On the other hand, cognitive consistency (CC) was *not* closely related to either KoLE or KoMV. According to the scatter-density plots in Figure 3 and Figure 4, students whose cognitive consistency score was $-2$ did not have higher scores on KoLE and KoMV than the median of each score. However, in the case that the cognitive consistency score was $-1$, students’ KoLE scores or KoMV scores were distributed with relatively wide range containing higher scores than the median. There was one student who received a very high score on KoLE (13 out of 14) but scored $-1$ on the cognitive consistency. These findings indicate that students might have cognitive inconsistencies even though they attained high scores on knowledge of logical equivalence and knowledge of mathematical validity, respectively.

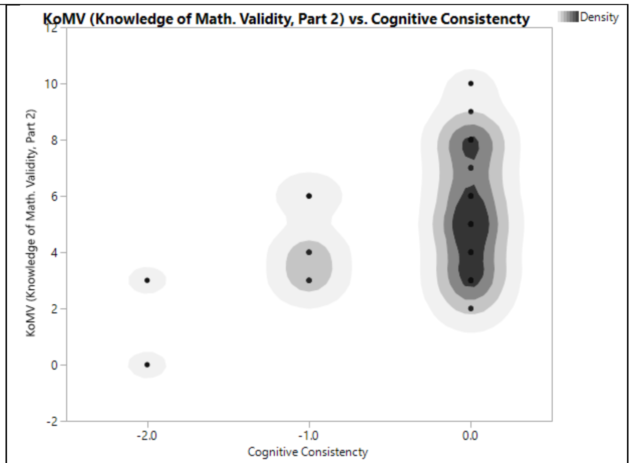

*Figure 4 Scatter-Density plots: KoMV vs. CC*

## Conclusion & Discussion

In this study, we explored undergraduate students’ cognitive consistency and its relation to their knowledge of logical equivalence and mathematical validity. The findings of this study indicate that students’ cognitive consistency was not closely related to either their knowledge of logical equivalence or their knowledge of mathematical validity. Indeed, some students who received high scores on knowledge of logical equivalence or on knowledge of mathematical validity still had cognitive inconsistencies. Furthermore, these students already took a course for logic and mathematical proofs for about at least fifteen weeks. Thus, it might be an unreasonable expectation that students with more knowledge on logical equivalence and mathematical validity would not have cognitive inconsistencies.

The findings of this study also suggest some significant implications for the teaching and learning of logic and mathematical proofs. Although undergraduate students received formal instruction for logic from a logic and mathematical proof course, they may not recognize a logical contradiction in his or her argument. Thus, we contend that cognitive consistency must be treated as a crucial component of logical thinking. Designing special tasks or instructional interventions would be needed to reveal students’ cognitive inconsistencies and to help students recognize logical contradiction in their arguments if they have any. The structure of sub-questions in Part 2 of the logic instrument in this study could be an example of reference to reveal students' cognitive inconsistency what might have been.

*Navigating the transition from computing to proof writing remains a key challenge for mathematics departments and undergraduate students. Numerous departments have developed courses to introduce students to the nature of proof and effective argument (David & Zazkis, 2017), but research assessing the impact of these courses has just begun. This paper reports the experience of four introduction to proof "graduates" after they completed a semester of real analysis. Each had participated in our prior study of students' experience in the introduction to proof course. Results indicate that students' success in real analysis was supported by their work in the introduction to proof course. Two students exploited the structure common to many proofs in real analysis; the other two relied on extensive practice with example problems. For both pairs, we see linkages between students' work in real analysis and their prior procedurally-oriented work in mathematics.*

*Keywords*: transition to proof, proof reasoning, students' experience, qualitative analysis

This paper extends our prior research that examined undergraduate students' experience in one introduction to proof course taught at a research-intensive university (Smith, Levin, Bae, Satyam, & Voogt, 2017). Most of the N = 14 participants in that study clearly indicated that they found the work to write proofs different from their prior work to compute numerical or symbolic "answers". Where the majority found proof writing challenging, most were relatively successful in the course, as judged by final grades and self-reports. But the success of courses designed to introduce students to proof and proof-writing cannot be judged "locally". As the warrant for such courses is to increase learning and achievement in upper-division mathematics, the "success" of these courses depends on how well students perform in subsequent proof-focused courses.

Here we report on the experience of four "graduates" of an introduction to proof course in their first semester of real analysis. All were successful in that course, as judged by both grades and self-reports. But their descriptions of their work in real analysis, offered in comparison to the introduction to proof course and prior work in mathematics through calculus, reveal a more complex pattern of similarities and differences in how students see and carry out mathematical work. For some students in real analysis, the differences between following procedures to compute answers and writing effective proofs may be less stark than we initially conjectured (and than they experienced in their introduction to proof course). If so, characterizing the transition to proof may need to embrace important continuities as well as discontinuities with prior mathematical work.

## The Transition to Proof and Proving

Understanding the challenges that undergraduate students face in learning to prove mathematical statements and designing courses and experiences that support their efforts to address those challenges have become major foci of research in undergraduate mathematics education. Recent work has focused on the nature and diversity of courses intended to introduce students to proof and proving (David & Zazkis, 2017; Selden, 2012), specific cognitive challenges in understanding and writing proofs (Sellers, Roh, David, & D'Amours, 2017), and following students' proving work and reasoning after an initial introduction to proof (Benkhalti, Selden, & Selden, 2017).

As one contribution to this growing literature, we interviewed N = 14 undergraduate students after they completed a one-semester introduction to proof course. Our analysis focused on four issues—how they saw the course as different from prior courses, the activities they undertook to learn the course content, how they characterized their thinking during work on proof (proof reasoning), and their sense of success in the course (Smith et al., 2017). None reported any significant prior work on proof. Most were clear that the course made new and different demands than prior courses, and in response, many initiated different patterns of work. Despite their reported struggle, most completed the task being and feeling relatively successful, leading us to conclude that the course had been successful in bringing students to and through the doorway to proof. In particular, the course had placed students into the work of solving mathematical problems and supported their adjustment to that work.

But the merit and impact of introduction to proof courses lies as much, if not more in how students perform after they complete such courses as it does in how well they perform in the courses. These courses typically survey the major domains of algebra, analysis, and number theory without exploring the content area in any depth (David & Zazkis, 2017). The main task of repeatedly addressing proof tasks in one content area for an extended period and thereby coming to understand more about that mathematics via proof lies ahead of them. If the gap between carrying out known procedures to compute single answers and proving statements is wide and deep (Selden & Selden, 2013), the transition to proof and proving will not be accomplished in a single semester. So it makes sense to ask about successful "graduates" of introduction to proof courses: Where does reasonable success in that course lead? How do they experience their first proof-based course situated in a particular content area? How do they compare their experience in that course to their "preparation" in the introduction to proof course and to their prior mathematical experience? Is it possible, at a reasonable level of precision, to chart students' experience and work from computing to proving?

## Conceptual Framework

Our analysis was informed by the main concepts that had oriented our prior work (Smith et al., 2017). Oriented by work to understand pre-college and college students' experience of work in "reform" and "traditional" courses (e.g., Smith & Star, 2007), we see the shift from computing single answers to proving statements to set the stage for major transitions in students' experience of mathematics, where their understanding of the nature of their work, how they feel about their experience and their abilities, and what they do to carry out that work change in quite substantial ways. Where mathematical transitions are not determined by the learning environment, some "external" structures make them more likely (e.g., fundamental changes in curriculum and pedagogy and new courses focused on proof). Our prior study conceptualized students' experiences in terms of (a) the differences they saw between the work in their introduction to proof course and their prior mathematics, (b) their sense of the task of writing proofs, (c) their learning activity, in and outside of class, and (d) their subjective "sense of success" in the course. As specified in these four foci, our task was to understand the participants' perspectives and judgments in their own terms.

In the present study, we focused on students' experience in real analysis in relation to their work in the introduction to proof class a year earlier. The above four foci again informed the development of our interview questions and the direction of our analysis. For the first focus (differences with prior courses), we were particularly interested in how students compared the introduction to proof course to real analysis. Our overarching theoretical stance remains constructivist: Students bring forward mathematical "resources" (knowledge, skills, learning practices) developed in prior courses and attempt to use them to address the tasks of their present courses. New challenges, at any scale, mean that some resources will work well, some must be adapted, and some are developed, more or less *de novo*, in the new setting. The view of the student as an agent in her own learning is also central to our perspective, especially with respect to learning activities outside of class.

## The Program, Courses, and Participants

In the university where our research is situated, students—both mathematics majors and minors—complete a calculus sequence, the introduction to proof course, a linear algebra course, and a number of proof-focused content courses. After linear algebra, the first semester of real analysis and the first semester of abstract algebra are the two most common sites where students experience proof-intensive work in a specific content area. Both courses are required for majors and minors, and both first require completion of the introduction to proof course. Majors are required to complete additional proof-based courses, including the second semesters of both real analysis and abstract algebra, as well as other courses. In the semester of our study, two sections of real analysis were taught by different instructors, but both used the same textbook (Ross, *Elementary analysis: The theory of calculus*, 2013). They differed somewhat in in-class activities, homework, and assessments. In this department, real analysis is widely seen by students, instructors, and support staff as among the most, if not the most challenging undergraduate course.

In Spring 2017, six of the 14 students from our previous study responded to our invitation to participate in a follow-up study. All the six were mathematics majors or minors and had taken real analysis and/or abstract algebra in 2016-17. The other eight initial participants either did not respond or indicated they had not taken either course, had changed majors, or left the university. Two respondents took both real analysis and abstract algebra; the other four took only one. For those who had taken both courses, our interview focused on the most recent course to reduce concerns about constructed memory. With four participants, the interview focused on real analysis; with the other two, it focused on abstract algebra. In this presentation, we will focus on the former group, who are described in Table 1 below.

*Table 1. Overview of participants*

| Student | Gender | Standing | Home | Major | Career Obj. | Other proof-based courses |
|---|---|---|---|---|---|---|
| S1 | Female | 3 | US | Mathematics | Teaching | Higher geometry (F16) |
| S2 | Female | 3 | US | Mathematics | Actuary | None |
| S3 | Female | 3 | US | Mathematics | Uncertain | None |
| S4 | Male | 4 | Int. | Mathematics | Grad school | Abstract algebra I (F16)<br>Abstract algebra II (Sp17) |

All four participants took the course in the same semester (Spring 2017), and we interviewed them just after they completed it. S1, S2, and S3 had the same instructor; S4 was taught by the other instructor. Though we did not directly observe either instructor's teaching as we had in the previous study, S1, S2, and S3 provided consistent descriptions of the course, their instructor's teaching, the assigned homework, the use of the text, and the course assessments.

The interviews were semi-structured around focal questions, about an hour in duration, and conducted either face-to-face or via video conference. In two cases (S1 and S3), follow-up interviews were used to clarify their responses from the first interview. Our central goal was to understand students' experience in real analysis relative to their experience in the introduction to proof course—with particular attention to the task of writing effective proofs. After checking basic information (e.g., major/minor, standing, career plan, other math courses), we asked about their sense of how well the introduction to proof course prepared them for the real analysis course (and any other proof-based courses they had taken). Making no assumptions about how participants saw the mathematics courses they took that year (e.g., linear algebra), we asked how they viewed each relative to its focus on proof (very little, somewhat, strongly). All four participants indicated that real analysis was strongly proof-based. For the course(s) characterized as somewhat or strongly proof-based, we asked participants to compare the difficulty of that course(s) to the introduction to proof course. Then we explored their experience in each course, but with greater attention to real analysis, including assignments and instruction, learning activities in and outside of class, and their view of proof tasks and work to produce acceptable proofs. The interviews also provided opportunities to return to participants' experience in the introduction to proof course, affording us the chance to check for consistency in their characterizations. Toward the end, we asked them to draw a Confidence Graph to represent the dynamics of their confidence across the semester (Smith et al., 2017). As before, these helped us understand the challenges participants faced at different points in the semester and how they addressed the challenges.

Figure 1 below represents the comparisons between the different mathematical experience that were supported in the two studies, the present (Phase 2) and the previous (Phase 1). The interviews from the present study supported comparisons between real analysis and the introduction to proof course, but also with participants' experience prior to any focus on proof.

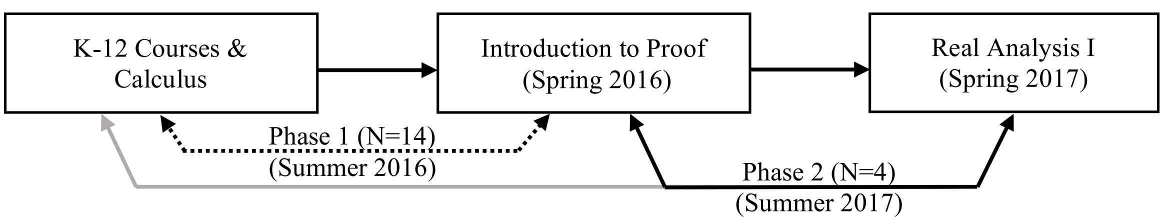

*Figure 1. The previous study and the present study across the sequence of the courses*

## Results

All four students reported success in real analysis, with both final grades (all received 4.0) and sense of mastery of the content. As indicated in Table 2 below, all four appreciated and valued the preparation for real analysis they received in the introduction to proof course, citing (a) "getting their feet wet" with proof, (b) learning specific proof methods (e.g., mathematical induction), and (c) gaining some introduction to real analysis content. However, S1 and S3 made a stronger case for their preparation in the introduction to proof course, where S2 and S4 indicated they did not learn some things that would have been useful in real analysis. S2 stated that she was not required and taught how to build up the structure of a proof; S4 mentioned that some methods (e.g., epsilon-delta proofs) were not taught in detail enough in the introduction to proof course. All four participants noted that the introduction to proof course moved frequently between content areas (making the course more difficult in the process), where real analysis focused on one set of related ideas. S1, S2, and S3 each indicated that they appreciated learning in real analysis why theorems and rules they learned in calculus were justified.

*Table 2. Summary of students' sense of preparation of the introduction to proof course for Real Analysis I*

| Student | Preparation | Relative Difficulty |
|---|---|---|
| S1 | Very well | Introduction to proof > Real analysis |
| S2 | Good | Real analysis > Introduction to proof |
| S3 | Very well | Introduction to proof > Real analysis |
| S4 | Good | Real analysis > Introduction to proof |

S1 and S3 found the introduction to proof course more difficult than real analysis, despite the fact that prior reports led both to expect that the latter would be very challenging. In contrast, S2 and S4 indicated that real analysis was more difficult than the introduction to proof but cited different reasons for their judgments. S4 indicated that the absence of sufficient example problems in his real analysis contributed significantly to its difficulty, where S2 found the concepts as well as proof construction more challenging in real analysis. Beyond these top-level judgments about "preparation," we found the two pairs of the participants (S1 & S3 and S2 & S4) provided two quite different narratives about the challenges of the course and how they had worked to address the challenges.

**S1 and S3: Work Together, and Exploit Similarity Across Tasks**

In explaining their success in real analysis, S1 and S3 both emphasized the quality of their instructor's teaching, citing four main similarities to instruction in their introduction to proof course: (a) group work in class, (b) regularly assigned and graded homework, (c) weekly quizzes, and (d) instructor encouragement. But this shared experience with instruction was coupled with changes in their learning activity. Where both S1 and S3 attended the Math Learning Center (MLC) at the university for the first time during their introduction to proof course and benefited from the activities and relationships supported there, neither attended in the MLC during real analysis. Instead, they worked remotely outside of class with the other members of their classroom small group that they maintained for the entire semester. When they got stuck on homework problems, they messaged with each other, sent pictures of the status of their solution attempts, and asked each other for suggestions. Both also reported they could reasonably predict the general nature of exam questions. They completed their homework each week, whose content predicted the weekly quizzes, which in turn predicted the content of exams. Their instructor also gave a practice final exam, described to resemble the actual final. S1 came to see a common structure among real analysis proofs (i.e., a standard way to develop and write epsilon-delta and epsilon-N arguments), whereas she could find no commonality among the proofs in her proof-based geometry course. When asked, S1 agreed that this common structure bore some similarity to her prior mathematics work, before the introduction to proof, of identifying known procedures and executing them on familiar tasks. S3 did not explicitly indicate an awareness of structural similarities among real analysis proofs but did strongly endorse the importance of collaboration with her peers, as complement to her own problem solving work on homework.

**S2 and S4: Work Independently on Lots of Examples**

In contrast, S2 and S4 emphasized the importance of repeated practice on numerous example problems for each course topic, as practice increased the likelihood of mastery and success on course assessments. In addition, both carried out this practice-focused work on their own. S4 expressed frustration that his instructor (different from S1-S3's) did not provide a sufficient number of examples comparable to his experience in his introduction to proof course. So he actively searched the internet for them, explaining that he looked for problems that were related to those worked in class and had complete solutions (proofs). S4 would then work the problem and compare his proof to the one provided. If he was unsure how to start, he reviewed the provided proof and then attempted to complete it on his own—comparing his proof to the one provided when he finished. S4 never went to the MLC during real analysis (in part because he did not think that Center personnel were prepared to help with that content), though he had done so regularly during his introduction to proof course. Also, he stated that he did not need to get help from MLC or office hours to complete the homework problems in real analysis, which are pretty much similar to what his instructor showed in class, whereas he was not able to even start some of the homework problems in the introduction to proof so he had to go to the MLC. S2 did not complain about the supply of example problems; she found the combination of problems worked in class, homework problems, and problems in the text not assigned for homework sufficient. Though she was part of the in-class group that S1 and S3 cited as important, S2 seldom contacted her group and solved most course problems on her own. She described her method of study for exams to involve "just doing lots of problems." Like her peers, S2 did not attend the MLC during real analysis, though she had done so repeatedly and productively during her introduction to proof course. She was also able to complete almost all the homework problems just from what her instructor showed her in class, whereas she reported that there were significant gaps between worked problems in class and homework, and between homework and exam problems in the introduction to proof.

**Common Structure Among Real Analysis Proofs**

One common thread in these results is the importance of noticing and abstracting a structure common to many real analysis proofs (what Selden & Selden [2013] have called a "proof framework"). Where S1 and S2 took different approaches to their work in real analysis, principally in how they engaged their peers, both spoke to the common structure they saw among the proofs their instructor produced and they produced in real analysis. S4 spoke to this issue in different terms, and S3 did so only obliquely and without emphasis. S1 saw the common structure among epsilon methods with some variation (e.g., epsilon-delta, epsilon-N) depending on the concepts involved in the statements (e.g., functions, sequence, and series). She was taught to always start with specific sentences in the structured way of proving the statements using the epsilon methods. She liked her instructor's practice of assigning similar problems using same approach/structure in homework and claimed her instructor's proof writing in class emphasized this pattern. Her perception of common structure contributed substantially her confidence going into major course assessments. S2 stated that the real analysis proofs were a lot more structured than the those in her introduction to proof course. She asserted this pattern ("the proof was basically the same for every type of like, every type of problem") and indicated that real analysis proofs had an "introduction" that stated an arbitrary epsilon, the body of the proof, and a "conclusion" that related the particular case to the definition. In contrast, S4 described the process of completing a real analysis proof after setting up its structure as "computation." He used that term to indicate the repeated process of determining appropriate values for delta or N in epsilon arguments. In his view, real analysis was 50% proof writing and 50% computation, where his abstract algebra experience was 80% of proof writing. Though he used different terms than S1 and S2, we interpret his assertion as similar to theirs: All three are citing structural regularities across many different real analysis proofs. This abstraction of common structure across many different proofs is significant for many reasons, not the least of which is that it narrows considerably the "problem solving space" students found themselves in during course assessments. None of the participants spoke to specific challenges in "filling in the blanks" of the common structure proof—Selden and Selden's (2013) "problem-centered part" of proof writing.

## Discussion

This study produced three main results; all concern "outcomes" from one introduction to proof course. First, the introduction to proof course prepared all four participants relatively well for proof-based work in real analysis, one major content area of advanced mathematics. If the goal of such courses is to increase students' achievement in upper-level coursework, this course succeeded, at least for some students. Note that the introduction to proof course covered the basics of proof and proving and situated students' work in three different content areas. As such it fell into David and Zazkis's (2017) category of "Standard + Sampler" introduction to proof courses. Only five of the 176 courses they reviewed across the R1/R2 institutions in the U.S. were of this type. Second, even in our small sample, we have examples of students pursuing and achieving success in real analysis in different ways, even after "the same" introduction to proof. In particular, these four students took up group-work from their introduction to proof course in quite different ways—from substantially to not at all. Third, returning to our opening metaphor, mathematical work on the other side of the "proof door" can be similar in important ways to the computationally focus of their prior work. Three of the four participants reported regularities across real analysis proofs that resemble in some ways the mathematical work that preceded the focus on proof—recognize problems and apply the appropriate procedure to produce answers without significant feature of problem-solving. Though their introduction to proof course regularly asked these students to solve real problems, the tasks in real analysis significantly reduced the problematic nature of their mathematical work, as noted by S1, S2, and S4.

One major limitation of this study is our small and "correlated" sample. Three of the four participants experienced real analysis with the same instructor and engaged each other in the same small group—though they indicated no knowledge of their joint participation in the study. Our two different approaches to mastery (engage one's peers vs. repeated individual practice) are likely not the only narratives of mastering real analysis. Variation among students (e.g., in prior mastery experiences) and among instructors both likely contribute to the diversity of students' experience in real analysis. A second limitation leads to our next steps in this research: Most of the "graduates" of the introduction to proof course in this study have thus far had only modest experience in proof-based courses. Their journey will continue into new content areas and under the direction of different instructors. In the next phases of the research, we intend to track their experience in these new contexts (e.g., abstract algebra, real analysis II) and extend the reflective comparison of present and past experiences that we initiated in this study. We also hope to increase our sample size as more participants in our previous study enroll in proof-based content courses.

# The use(s) of ‘is’ in mathematics

Paul Dawkins — Northern Illinois University
Matthew Inglis — Loughborough University
Nicholas Wasserman — Teachers College, Columbia University

*This paper analyzes some of the ambiguities that arise among statements with the copular verb* is *in the mathematical language of textbooks as compared to day-to-day English language. We identify patterns in the construction and meaning of* is *statements using randomly selected sample statements from corpora representing the two linguistic registers. In particular, for the grammatical form "[subject] is [noun]," we compare the relative frequencies of the subcategories of semantic relations conveyed by that construction. Specifically, we find that this construction – in different situations – conveys a symmetric relation, an asymmetric relation, or an existential relation. The intended logical relation can only sometimes be inferred from the grammar of the statement itself. We discuss the pedagogical significance of these patterns in mathematical language and consider some strategies for helping students interpret the intended meaning of the mathematical text they hear or read.*

*Keywords:* mathematical language, corpus analysis, copular verbs

What does ‘is’ mean in mathematics? This is an important question because ‘is’ is used much more often in mathematical English than it is in day-to-day English. In both British and American English "is" represents around 1.01% of words (Davies, 2017), however in mathematics research papers the figure is 2.66% (Alcock, Inglis, Lew, Mejia-Ramos, Rago & Sangwin, 2017). The relative frequency of ‘is’ in mathematics can perhaps be explained by its ability to encode logical relationships. Linguists categorize ‘is’ as a copular verb, meaning it is used to join an adjective or noun to a subject. While copular verbs are known to be confusing in all languages – they can mean both predication (an asymmetric relation) and identity (a symmetric relation) (e.g., Geist, 2008; Russell, 1919) – they can be especially problematic in mathematics teaching and learning because of potential logical misinterpretations (e.g., Moschkovich, 1999; Schleppegrell, 2007).

Inspection of some ready examples suggests that ‘is’ can have at least three distinct logical meanings, as biconditional (↔), conditional (→), and existence (∃):

i. In "a square *is* a regular quadrilateral," *is* is intended to represent a biconditional (↔) relationship: an object is a square if and only if it is a regular quadrilateral;
ii. In "a square *is* a rectangle," *is* is intended to only represent a conditional (→) relationship: if an object is a square then it is a rectangle;
iii. In "there *is* a rectangle that's a square" *is* is intended to assert existence (∃): there exists a rectangle that is also a square.

The potential confusion between the biconditional (i) and conditional (ii) interpretations is especially challenging. From our experience, high school geometry students often object to the statement "a square is a rectangle"; however, it is unclear if they do so because they do not recognize the entire set of objects that fulfill the definition of a rectangle (i.e., their concept image of rectangle is at odds with the given definition), or because they interpret this statement as a biconditional, rendering it false. In other words, correctly interpreting a mathematical statement, at times, requires knowing the conveyed relationship prior to reading the statement.

Consider another example. The statement "an isosceles trapezoid *is* a quadrilateral with congruent diagonals" intends to assert a conditional relation and not a biconditional relation. We know this despite the fact that this sentence structure looks nearly identical to the biconditional in (i) above. Even though in many cases one communicates a biconditional by providing a narrowing clarification (e.g., a square is not just a quadrilateral but a *regular* quadrilateral), in this example, the narrowing of quadrilaterals to only those with congruent diagonals is still not narrow enough to be defining.

The major point is that *is* can be logically ambiguous, which means there may be important issues that arise in the teaching and learning of mathematics around use of this word that are worth further consideration. In this paper, we investigate the various uses of and grammatical constructions with the word 'is' in mathematics (in comparison with common English), as a means to reflect on communication in the teaching and learning of mathematics.

## A corpus approach

Corpus linguists study language by analyzing large collections of texts – corpora – intended to be representative samples of particular types of language. Our goal here was to compare the usage of *is* in day-to-day English and in mathematical English in pedagogical contexts. To this end we randomly sampled occurrences of *is* from two corpora. We used the Brown and LOB corpora (Kucera & Francis, 1967; Johansson, Leech, & Goodluck, 1978) to represent day-to-day written English and a corpus of mathematics textbooks compiled by Alcock et al. (2017).

Kucera & Francis (1967) compiled the Brown corpus in the 1960s. It contains 500 samples of American English text, totaling around 1 million words, from a balance of sources (e.g., newspaper articles, biographies, government documents and so on). Johansson, Leech and Goodluck (1978) compiled a British English version of the Brown corpus using texts taken from a similar range of sources, and in similar proportions. It too contains around 1 million words. We combined these two corpora to form a supercorpus of day-to-day English.

To study pedagogical language in mathematics, we used the textbook corpus constructed by Alcock et al. (2017). This consists of processed versions of language taken from undergraduate-level textbooks (Alcock et al. describe the process required to convert LaTeX source files into analyzable plain text). All the textbooks were taken from the Open Textbook Library, the College Open Textbooks site, or the American Institute of Mathematics Approved Textbook list. Topics included abstract algebra, analysis, linear algebra, complex analysis, and transition to proof. In total, 21 complete undergraduate textbooks are included in the pedagogical corpus, comprising of 1.5 million words. In order to conduct the analysis reported below, we randomly selected 250 instances of the word *is* from each corpus, together with the surrounding context.

## Analytic strategy

The rationale for our analysis strategy was the belief that the comparison of *is* in day-to-day language and pedagogical mathematical language would lead to insights about the kinds of mathematical statements likely to be difficult for students to interpret appropriately. Motivated by our examples of ambiguity described in the introduction, we initially began by coding the randomly selected sample of *is* statements as expressing *symmetric relations* (if and only if), *asymmetric relations* (if, then), or *existential relations* (there is). It became clear that we needed to distinguish an additional fourth category of *verb phrases* such as "is graphed" or "is rolling" since *is* operated as part of the conjugation of another verb rather than as a simple linking verb. Doing so, however, led to the realization that there was great variation among such structures.

One of the most problematic issues with this coding related to the role of verbs in past participle form. For example, in mathematics we use phrases like "is graphed" or "is connected" that consist of *is* followed by a past participle verb. However, the former is a verb phrase expressing the result of past action and the latter is a property attribution where *connected* acts as an adjective. Because mathematicians are careful to define terms like *connected*, this distinction can be made with some certainty. In the Brown and LOB corpora (representing American and British English respectively), we found more challenging statements like "Mrs. Lavaughn Huntley is accused of driving the getaway car used in a robbery of the Woodyard Bros. Grocery." In this case, *accused* could be an adjective describing Mrs. Huntley or a verb phrase describing ongoing action. This distinction appeared much more challenging to apprehend.

The fact that we had to rely on our understanding of mathematical content to recognize that *connected* acted as an adjective led us to develop a two-stage coding process that distinguished words' grammatical form from their operative role in the statements. Doing so helped us differentiate what information the grammatical form of a statement makes available from what information the reader's knowledge of semantic relations must provide. Using the TagAnt software package (Anthony, 2015) – which identifies parts of speech in a corpus – the first stage in our coding process involved determining the subject and object of each of the 500 *is* statements. While both the subject and object often constituted phrases, we identified one representative word as the object of *is* and then categorized each statement by the object word's part of speech (which we shall call the *grammatical category*). The object words were coded as: 1) nouns; 2) adjectives; 3) verb phrase, in gerund or infinitive form; 4) verb phrase, in past participle form; and 5) prepositions. Then, the second stage in our coding process involved analyzing the sentences within each grammatical category by determining the semantic role that the object word played in each *is* sentence (which we shall call the *semantic subcategory*). The semantic subcategory thus identifies the type of relation *is* is intended to convey.

In what follows, we elaborate on the first grammatical category, [Subject] *is* [noun], and its semantic subcategories. We deemed this category to be of particular interest because it involved both a broad range of *semantic variation*, as well as apparent differences between its uses in day-to-day and mathematical language – what we refer to as *register variation*. In other words, we were interested in *is* constructions in which students would have to use semantic cues to infer the logical relations conveyed in the statement because the grammatical cues are ambiguous. This seems more likely to be difficult if there are a variety of possible semantic subcategories and the frequencies of these subcategories differ between day-to-day and mathematical usage.

## [Subject] *is* [noun]

In this and the following sections we shall present our analysis of the statements coded in each grammatical category along with the frequency of each category in our sample. We shall begin our discussion with example *is* statements taken from the corpora.

- Example 1 (Ped): "Inlinemath *is* the standard basis for inlinemath."[1]
- Example 2 (Ped): "The definite integral of a constant times inlinemath *is* the constant times the definite integral of inlinemath."
- Example 3 (Ped): "A rational number *is* a fraction built out of integers."
- Example 4 (Ped): "This map *is* an isomorphism because it has an inverse."
- Example 5 (B/LOB): "a distinction must, however, be drawn between that which is traditional and enduring and that which *is* the result of current political necessity."
- Example 6 (Ped): "Show that there *is* one dimensionless product."

[1] The mathematical corpora replaced all mathematical symbols and expressions with "inlinemath" to facilitate search functions and word counts without having to account for the complexity of LaTeX code for mathematical notation (Alcock et al., 2017).

- Example 7 (B/LOB): "And there *is* enough truth in that to set you thinking."

We identified three semantic subcategories of statements of the form "[subject] *is* [noun]" that correspond closely to our original categories: symmetric relation (1-3), asymmetric relation (4-5), and existential statements (6-7).

**Symmetric relation**

When *is* conveys a symmetric relation, it indicates "is the same as." We present three cases of the symmetric relations because we observe there are subtle variations among them. In Example 1, the subject and object noun phrase both refer to the same mathematical object, so the two are being identified as the same. Here both are understood as singular, though if either involved variables the entire claim may be understood as implicitly quantified. Example 2 similarly conveys that both the subject and object phrases refer to the same object, though in this case that object is a number. In both of these cases, the article *the* before the object noun provides an explicit cue that *is* conveys a symmetric relation. This was common among our sample of statements in the symmetric relation subcategory, as displayed in Table 1. Example 3 portrays how statements conveying symmetric relations can nevertheless use *a* or *an* before the object word. Because the object phrase "a fraction built out of integers" can be taken to define the subject "rational number," the relation is symmetric.

*Table 1. Article choice within the symmetric and asymmetric relation subcategories.*

| Corpus | Ped | B/LOB | | Ped | B/LOB |
|---|---|---|---|---|---|
| Total symmetric statements with articles (SYM) | 31 | 19 | Total asymmetric statements with articles (ASM) | 59 | 32 |
| - SYM with *a/an* before object | 2 (7%) | 2 (11%) | - ASM with *a/an* before object | 53 (90%) | 25 (78%) |
| - SYM with *the* before object | 27 (87%) | 17 (89%) | - ASM with *the* before object | 0 (0%) | 3 (3%) |

**Asymmetric relation**

When *is* conveys an asymmetric relation, it signifies "is one of" or "is an element of the set of." Example 4 is a prototypical example of this form because the object noun is preceded by *a* or *an* (see Table 1), which cues that the subject noun is an example of the class specified by the object noun (and not *the* class itself). Example 5 portrays how statements in this subcategory can still use the article *the* before the object word. It uses *is* to say "that" is an example "result of political necessity," meaning *is* conveys an asymmetric relation. Thus, the article on the object noun usually provides a grammatical cue for whether *is* conveys a symmetric or asymmetric relation, but there are both symmetric and asymmetric constructions that use the alternative articles.

**Existential relation**

Though questions of existence may differ between day-to-day and mathematical contexts, we did not observe semantic ambiguity in statements of this form in either corpus. The phrase "there is" seems to clearly distinguish statements in this subcategory. However, we observed an interesting trend in the frequency of this semantic subcategory, as presented in the next subsection.

**Frequencies of this grammatical category and semantic subcategories**

Figure 1 presents the frequencies of "[subject] *is* [noun]" statements in our two samples and the relative frequency of each subcategory. This grammatical category was much more common in our sample of mathematical statements, which may reflect mathematicians' tendency to use nominalizations for concepts or processes (Morgan, 1996). There was a significant difference in the balance of subcategories found in each corpus (Fisher's exact test, $p$ = .001), symmetric relations occurred with about equal frequencies while mathematics text conveyed asymmetric relations more often and day-to-day text conveyed existence relations more often. The latter fact seems surprising, though we expect this is because mathematicians more often use the more formal "there exists" (instead of "there *is*"), or the symbol ∃, since existential claims are by no means scarce in mathematics text.

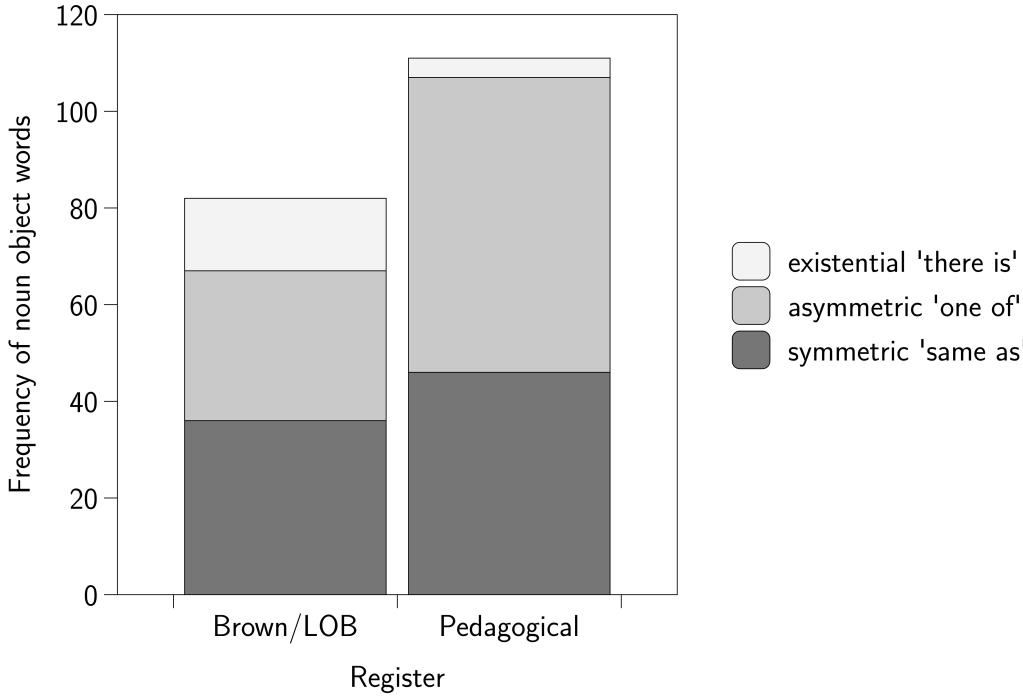

*Figure 1: Frequencies of noun object words and subcategories thereof.*

**Quantification in "A [Subject] is a [noun]" constructions**

The construction that began our investigation of *is* statements occurs when *is* links two nouns each with articles *a* or *an*. In this section, we explore further ambiguities that arise in this construction, particularly as they pertain to quantification and generalization, including a few more examples from the pedagogical corpus for discussion:

- Example 8 (Ped): "If inlinemath *is* a complete binary tree of height inlinemath, then…"
- Example 9 (Ped): "If inlinemath *is* a family of sets which covers inlinemath and inlinemath *is* a subfamily of inlinemath which also…"
- Example 10 (Ped): "The Cartesian product of two sets inlinemath and inlinemath, written inlinemath, *is* the set of all ordered pairs inlinemath, where inlinemath and inlinemath."
- Example 11 (Ped): "It can be shown that the best strategy is to pass over the first inlinemath candidates where inlinemath *is* the smallest integer for which inlinemath."
- Example 12 (Ped): "If inlinemath *is* a type 1 integer and inlinemath is a type 2 integer, then inlinemath is a type 2 integer."
- Example 13 (Ped): "If inlinemath, we say that inlinemath *is* a compact subset of inlinemath if, regarded as a subspace of inlinemath, it is a compact metric space."

As noted above, these *is* statements generally convey either a symmetric relation ("same as") or an asymmetric relation ("one of"). In most all cases the nouns on either side of *is* are singular with singular articles (*the, a, an*). However, given the value placed upon generalization in mathematics, these singulars are understood to represent entire classes through arbitrary selection (Durand-Guerrier, 2008). It is this implicit generalization that introduces so much of the ambiguity into statements of this grammatical form.

For instance, Example 1 seems to identify two singular objects. The subject of the sentence is the same as "the standard basis" for some other object. However, if this sentence is introducing a general notation for standard bases, it means to convey a universal relationship. Without recognizing whether *inlinemath* in that sentence represents a generic placeholder or some representation of a singular mathematical object (or a placeholder for some more specialized class), one cannot discern what relation *is* conveys. Example 2 conveys a general law of integrals, not merely a naming convention (despite being structurally similar to the definition in Example 10). However, one cannot tell from the grammatical form of the statement whether this sentence is stating the law in general or applying it to a particular case (Example 12 is similar in this regard). In Example 2, the article *the* is misleading. *The* marks the singularity of indefinite integrals, but the function being integrated should likely be understood as a placeholder representing any function. In other words there is one indefinite integral per function, but the statement almost certainly applies to a range of functions. Example 3 quite clearly means to convey a universal (defining) relationship, despite the singular article on both sides of *is*. The key point is that one cannot discern this merely grammatically – familiarity with the mathematical concepts is essential. In contrast, the grammatical cues in Example 4 convey more accurately that *is* relates a particular object ("this map") to a general class ("an isomorphism").

Our examples reveal other common grammatical cues that mathematicians use to convey the implicit generality behind nouns and noun phrases with singular articles. For instance, the *if*s at the beginning of Examples 8 and 9 are there to convey universal quantification of the subject of the *is* claim[2]. Example 13 presents an odd case where *if* is used in two slightly different ways in the same definition. The first *if* calls out an arbitrary metric space (a context assumption) while the second presents the defining condition for being a compact subset. In cases where *is* could relate an entire class represented by an arbitrary placeholder or a particular case, deciding whether the variable or name given to an object has appeared before or not (i.e. is already *bound*, Epp, 2009) provides a subtle cue. For instance, this would resolve some ambiguity in Examples 2 and 12. If the variable is not bound then the claim is likely universal; otherwise it may be an application of a warrant to a particular case or an introduction of cases within an argument. The mere grammar of the construction "If [subject] is a [noun]" does not distinguish between these uses. Furthermore, Example 11 shows how mathematicians sometimes compress the process of binding and using a variable by referring to a quantity before defining it in an appended clause.

What we gather from these examples is that the "[subject] is [noun]" grammatical structure entails semantic ambiguity that is only partially resolved by other grammatical cues (articles and conjunctions). In other words, one cannot infer the relationship between the subject and object nouns merely by the statement's construction. Mathematicians tend to state the general using arbitrary particulars, usually using placeholder variables or names with singular articles. This construction is not unique to mathematics (e.g. "The redeemed soul is a debtor to mercy alone"),

---

[2] Indeed one of our philosopher colleagues argues that such claims are not really conditional at all, but rather universal (L. Clapp, personal communication, December, 2016; c.f. Durand-Guerrier, 1996).

but it appears from our samples to be much more common. This means students will likely need to be trained to properly interpret such common constructions in the mathematical register.

## Reflections

The goal of our grammatical analysis was to 1) identify differences between *is* usage in day-to-day and mathematical language and 2) to identify the semantically ambiguous *is* constructions in mathematical language. Due to space limitations, we have only presented our analysis of "[subject] is [noun]" constructions.

We proffer two tentative points from preceding analysis regarding the nature of the issue and what can be done to address it. First, we do not mean to belittle or demonize semantic ambiguity in mathematical discourse. We view it as inevitable, despite mathematicians' pursuit of precision and explicitness. However, we observe there is a tradeoff between simple statements that entail semantic ambiguity and complex statements that are grammatically hard to parse (c.f. Schleppegrell, 2004). Pedagogically speaking, we must create ways for students to be apprenticed into mathematical knowledge and language, requiring that we make it easier to parse and interpret. Simplifying language often incurs a cost in precision. In many cases, we judge that this price must be paid. However, problems arise when mathematics instructors treat dense constructions like "A square is a rectangle" or "A rational number is a fraction built out of integers" as completely unambiguous, without recognizing the role their expertise plays in rendering these claims interpretable.

Second, we comment on what might be done to maintain efficiency in pedagogical language while increasing the fidelity of communication. We recognize that empirical study must ultimately determine this, but we offer two ideas for consideration. One, it may help to alternate the grammatical cues we use to convey similar relationships. For instance, one could state and restate one of our first examples – "A square is a rectangle" – in multiple ways:

- "Each square has all the properties of a rectangle."
- "All squares are also rectangles."
- "Each square is also in the class of rectangles."

Similarly, statements conveying symmetric relations – "A square is a regular quadrilateral." – can be restated:

- "A regular quadrilateral is known as a square."
- "A square is the only kind of regular quadrilateral."

Alternating *a* and *an* with *any* and *each* or clearly designating defining actions with phrases such as *is called* and *is known as* can help cue students to the relations that *is* statements convey. We do not think any one of these is uniquely best. A longer statement is more explicit while "A square is a rectangle" is easy to recall. We recommend that instructors practice parallel articulations conveying the same relations to scaffold mathematical parlance. Some of our other work in mathematical logic demonstrates the importance of students associating mathematical properties with the sets of objects exhibiting the properties (what Dawkins, 2017, calls *reasoning with predicates*). Helping students to manage some ambiguities tied to implicit quantification aligns closely with developing a set-oriented way of thinking about mathematical claims. Two, we perceive that interpreting these mathematical statements is directly tied to understanding mathematical practices such as defining, representing, equating, stating general claims, and applying general warrants to particular cases. Future research on linguistic interpretation may benefit from integrating analysis of students' emergent interpretations of mathematical practices.

*Although pervasive in school mathematics, few researchers have paid explicit attention to the impact graphing conventions have on teachers' meanings for function and rate of change. We examine the role conventions play in in-service teachers' (ISTs') meanings and ways to promote their developing more sophisticated meanings. We provided pre and post surveys to ISTs enrolled in an on-line graduate course specifically designed to promote their development of more sophisticated meanings for function and rate of change via reasoning quantitatively. We prompted them to consider hypothetical student responses about these ideas in unconventional representations. In this report, we characterize ISTs' meanings in relation to conventions commonly maintained in school mathematics and examine shifts in the ISTs' meanings.*

Keywords: Function; Rate of change; On-line education; In-service teachers

Whereas certain conventions (i.e., order of operations) impact the underlying mathematics at hand, other conventions are strictly representational choices (i.e., the input of a function is represented on the horizontal axis of a Cartesian coordinate system). Both types of conventions play an important role in mathematics but in this report we focus on the latter type of convention; although such conventions are pervasive in school mathematics (e.g., Hewitt, 1999), few researchers have examined the consequences for individuals' understandings of various ideas when particular conventions are strictly maintained. We are particularly interested in the extent to which teachers understand conventions as representational choices versus understanding these "conventions" as necessary features of particular mathematical ideas.

Thompson (1992) differentiated between a person using a "convention" unthinkingly and therefore being unaware of the "convention" as a convention versus understanding a convention as a particular choice that is customary (and often useful) while being aware that other choices may be equally correct or appropriate. Researchers have posited that students and teachers are hindered in making the latter distinction when they only have experiences in which particular conventions are maintained (e.g., Mamolo & Zazkis, 2012; Zazkis, 2008). Other researchers have noted that providing students opportunities to reason about relationships between quantities in non-canonical situations has the potential to support students in developing more sophisticated understandings that rely less on representational conventions and more on core mathematical ideas and understandings (e.g., Moore, Silverman, Paoletti, & LaForest, 2014).

In this report, we examine in-service teachers' (ISTs') function and rate of change understandings in relation to graphing conventions before and after an on-line course that was designed to support them in developing more sophisticated understandings of these ideas via reasoning about relationships between quantities (Thompson & Carlson, 2017). We address the questions: (a) To what extent do ISTs understand certain graphing conventions as choices or as mathematical rules that must be strictly maintained? (b) What impact does taking a graduate course focused on quantitative reasoning have on ISTs' meanings (and use of conventions)? As the intervention was on-line, we also seek to provide an existence proof that the impacts documented can be supported through carefully designed on-line professional development.

## Theoretical Perspective

The on-line course in which this study is situated was designed to leverage ISTs' quantitative and covariational reasoning to support their developing more sophisticated mathematical meanings. Quantitative reasoning consists of an individual conceiving of a situation, constructing quantities as measurable attributes of objects, and reasoning about relationships between quantities (Smith III & Thompson, 2008; Thompson, 2011, 2013). When an individual conceives and coordinates two quantities together, they engage in covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Saldanha & Thompson, 1998). An increasing number of researchers have highlighted how students can leverage quantitative and covariational reasoning to develop understandings of various topical areas including function classes, rate of change, and the fundamental theorem of calculus (e.g., Confrey & Smith, 1995; Ellis, Ozgur, Kulow, Williams, & Amidon, 2015; Johnson, 2012; Thompson, 1994a, 1994b) and to enact important mental processes such as generalizing and modeling (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Carlson, Larsen, & Lesh, 2003; Ellis, 2007).

Of relevance to this report, Moore et al. (2014) highlighted the extent to which engaging students in reasoning about relationships between quantities can support students in developing mathematical understandings that are not constrained by conventions commonly maintained in school mathematics (i.e., representing the input of a graphically represented function on the horizontal axis with the variable $x$). The researchers outlined several principles teacher educators can use to support pre-service teachers (PSTs) and ISTs developing more sophisticated meanings including (a) using tasks that intentionally break from conventional representational systems, (b) routinely using quantitatively rich situations (i.e., situations in which an individual can construct and reason about a variety of quantities in order to solve a problem), and (c) maintaining an explicit focus on quantities and their relationships in classroom discourse.

## Relevant Literature

### Students' and Teachers' Convention Understandings

Several researchers have noted that students and teachers can develop insufficient mathematical understandings if certain conventions are strictly maintained in school mathematics (Mamolo & Zazkis, 2012; Thompson 1992; Zazkis, 2008). For example, researchers who have investigated students' meanings for function and rate of change (e.g., Akkoc & Tall, 2005; Montiel, Vidakovic, & Kabael, 2008; Moore et al., 2014; Oehrtman, Carlson, & Thompson, 2008) have found that students often maintain meanings that require certain representational conventions to be followed. With respect to students' function meanings, Montiel, Vidakovic, and Kabael (2008) identified students applying the vertical line test, a common procedure included in U.S. curricula, to determine if a graph defined by $r = 4$ represented in the polar coordinate system represented a function. Breidenbach, Dubinsky, Hawks, and Nichols (1992) illustrated that only 11 of 59 undergraduate students in their study understood a graph we interpret as representing the function $x = f(y) = \sin(y)$ for $-4 < y < 4$ with $x$ and $y$ represented on the horizontal and vertical axis respectively as representing a function (i.e., $x$ as a function of $y$). In these examples, the researchers posed graphs they intended to represent functions but the students' meanings did not afford such interpretations; one possible explanation for this observation is that the students understood representational choices (e.g., graphs are unquestionably represented in the Cartesian coordinate system with the independent quantity represented by $x$ on the horizontal axis) as mathematical rules that must be followed.

Moore et al. (2013, in preparation) highlighted the extent to which PSTs in their study understood function and rate of change in relation to graphing conventions. The researchers noted less than 36% of PSTs interpreted hypothetical student work as unquestionably correct when these responses used unconventional, but mathematically viable graphs. Many PSTs indicated the hypothetical student would be correct if a certain feature of the graph was changed to maintain conventions but concluded that in the given orientation the hypothetical student was incorrect. We extend Moore and colleagues (2013, 2014, in preparation) work by examining a different population's, ISTs', function and rate of change understandings in relation to graphing conventions. We also examine the extent to which an on-line course focusing on reasoning quantitatively has the potential to promote shifts in ISTs' meanings.

**Teaching and learning mathematics on-line.** Online courses at the university level continue to grow as there is a belief that such courses can reduce expenditure and increase enrollment (Allen, Seaman, Poulin, & Straut, 2016). In this study, we employed an instructional environment grounded in design-based research that is referred to as Online Asynchronous Collaboration (OAC) in Mathematics Teacher Education (Silverman & Clay, 2010). At its core, the OAC model is grounded in the belief that replicating traditional teaching practices is not sufficient for online learning environments (Reeves, Herrington, & Oliver, 2004). The implementation of the OAC we report here consists of iterative cycles of three to four day "private" problem solving in an on-line discussion board (viewable only by the individual student and instructor), then three to four days of "public" discussion in which all students are given the opportunities to read, comment on and ask questions about each other's solutions. The last few days of each unit are designed to support students' synthesis and reflection on the ways of reasoning each problem set was designed to highlight. Researchers (Silverman, 2011; Silverman & Clay, 2010) have shown that this OAC model has the potential to support ISTs' development of pedagogical content knowledge and mathematics knowledge for teaching; we extend these results by examining how this model has the potential to support teachers' developing more sophisticated understandings in relation to graphing conventions.

## Methods and Analysis

### Participants and Settings

The ISTs who participated in the study were enrolled in a fully online graduate mathematics program designed specifically for ISTs. The ISTs were geographically distributed across the U.S. and each was, at the time of the study, a 6-12 grade mathematics teacher who was certified to teach mathematics in his/her home state. All of the ISTs had completed a minimum of three mathematics courses beyond Calculus III and had an undergraduate GPA of 3.0 or better. In total 34 ISTs took both the pre and post survey.

The on-line course was designed with the intention of leveraging the teachers' quantitative and covariational reasoning to develop more sophisticated understandings and followed the recommendations put forth by Moore et al. (2014) outlined above. The initial unit asked the ISTs to track and describe the behavior of various contextualized relationships (i.e., a car driving back and forth along a road as described by Saldanha and Thompson (1998)). There was a particular focus on supporting ISTs in identifying quantities from a given context, using variables to represent varying quantities, and analyzing relationships between relevant quantities verbally, numerically, and graphically. The remainder of the term asked ISTs to leverage these skills with a focus on exploring a variety of functional relationships (e.g., polynomial functions, trigonometry, related rates problems, modeling, and ideas from calculus) from a quantitative perspective. Table 1 presents an overview of the 10-week course.

*Table 1. 10-week Course Overview*

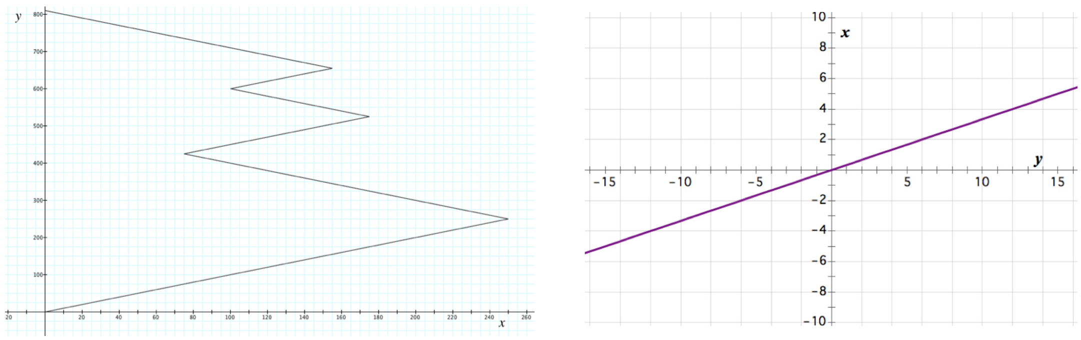
| Week | Focus |
|---|---|
| 1 | Covariation of Quantities |
| 2 | Trigonometry |
| 3 | Periodicity and Covariation: Trigonometric Functions |
| 4 | Functions as Relationships in Context |
| 5 | More Functions as Relationships/Functions as Actions and Processes |
| 6 | Families of Functions |
| 7 | Average Rate of Change |
| 8 | Rate of Change and Rate of Change Functions |
| 9/10 | Covariation in the Classroom |

## Analysis

We coded the ISTs' responses using open and axial approaches (Strauss & Corbin, 1998) and thematic analysis (Braun & Clarke, 2006). Throughout the coding process, the researchers did not know which IST's response they were coding or if the IST's response was part of the pre or post survey. A member of the research team read a subset of IST responses and we met to discuss our observations, identify commonalities across responses, and adapt or create new codes to capture more responses. We iterated this process four times as we refined our codes to accurately capture all responses; as the resulting codes are both methods and results, we present the codes themselves in the results. After we agreed on a final set of codes, a second researcher recoded approximately 65% of the data. We calculated inter-rater reliability by comparing the number of times both coders agreed on a code, achieving a high level of agreement on each problem (Sideways Mountain Task, Kappa = 0.78 and $y = 3x$ Task, Kappa= 0.85).

**Task design.** We adapted tasks used by Moore et al. (2013, submitted) to make inferences about PSTs' understanding of function and rate of change in relation to graphing conventions into items ISTs responded to in pre and post-course on-line surveys. Each task was designed with the intention of examining ISTs' understanding of mathematical ideas in relation to graphing conventions. In order to ensure the ISTs noticed the unconventional nature of the graphs, the tasks included hypothetical student responses that deviate from a particular convention but are mathematically viable (from the researchers' perspective). For example, the Sideways Mountain Task prompts an IST to respond to a student who stated for the graph in Figure 1a that "Sure, it can be a function… $x$ is a function of $y$." Whereas from the researchers' perspective the students' statement is mathematically correct, the graph, in its given orientation does not pass the vertical line test, which as described above, is often critical to students' and teachers' meanings for function in a graphing context. Hence, the tasks allow us to examine the extent to which an IST's function understandings are related to particular graphing conventions (i.e., a function's input must be represented by the variable $x$ or on the horizontal axis, or both).

Like the Sideways Mountain Task, the $y = 3x$ Task supports our examining ISTs' rate of change understandings in relation to graphing conventions. The task prompts ISTs to consider a student who graphed the relationship $y = 3x$ as shown in Figure 1b. Although the graph does represent the relationship defined by $y = 3x$, the hypothetical student's work deviates from the convention of representing $x$ and $y$ on the horizontal and vertical axes, respectively. Hence, the task provides insights into the extent to which ISTs' meanings for graphs and rate of change rely on representing particular variable quantities on particular axes versus accurately representing relationships between two quantities.



(a) (b)

*Figure 1.* (a) Sideways Mountain Task: Is $x$ a function of $y$? (b) The $y = 3x$ Task: A hypothetical student's work.

## Results

In this section we first describe the codes we created to capture the ISTs' responses. We then compare the ISTs' pre and post survey results for each of the two tasks described above. For both tasks, our final coding scheme categorized the extent to which the ISTs interpreted the hypothetical students' mathematical statement as viable. This analysis provides insights into the extent to which the ISTs' meanings for graphs, function, and rate of change are rooted in reasoning about relationships between quantities versus requiring graphing conventions to be maintained. Demonstrating a focus on understanding statements concerning rate of change and function to be statements about relationships between quantities, the first code was for responses that indicated the student's mathematical statement is correct notwithstanding the student breaking from conventions. Indicating a tension between reasoning about relationships between quantities and graphing conventions, the second category was for responses that specified the student's statement was mathematically true but, despite this, the student's solution was wrong because he or she did not follow conventions. Signifying the ISTs' meanings required certain conventions to be maintained, the final category was for responses that either indicated the student's mathematical statement was incorrect or did not address the student's statement.

Table 2 presents the code description, an example response to the Sideways Mountain Task and the counts for the pre and post survey. We first highlight that prior to the course, a majority of the ISTs interpreted the hypothetical student's solution as incorrect, despite the student's statement being mathematically viable from our perspective. Second, we note the trend of a positive shift in ISTs' responses towards interpreting the student's mathematical statement as correct despite the student breaking from conventions after taking the on-line course. We take this to indicate that the course supported many of the ISTs in developing more sophisticated meanings in regards to functions and their graphs. Finally, we note that despite this trend, nine ISTs still interpreted the student's mathematical statement as *incorrect* or did not address the students' mathematical statement in the post-survey. We return to this observation in the implications.

*Table 2. Code descriptions, sample responses, and counts for the pre and post survey for the Sideways Mountain Task.*

| Code description (value) | Example Responses to the Sideways Mountain Task | Pre | Post |
|---|---|---|---|
| The student's mathematical statement is correct despite breaking from conventions. (1) | That's great! I am so glad you were able to apply the "vertical line test" in a horizontal orientation and realize that you would have a function. You are correct in saying that $x$ is a function of $y$. | 11 | 19 |
| The student's mathematical statement is true but the student is incorrect because he/she broke from conventions. (2) | I think the student is understanding that $x$ can be a function of $y$ but they are not displaying it correctly through the graph. | 5 | 6 |
| The student's mathematical statement is incorrect or the IST did not address the student's mathematical statement. (3) | It was not a good explanation and $x$ is not a function of $y$, $y$ is a function of $x$. The value of $y$ depends on $x$. They also did not describe what would make it a function. | 18 | 9 |

Table 3 presents the code description, an example response to the $y = 3x$ Task and the counts for the pre and post survey. We again highlight that there is a general trend towards more ISTs' responses indicating that the hypothetical student's response is correct despite breaking from conventions. In contrast to the responses to the Sideways Mountain Task, we note that a majority of ISTs' pre-survey responses indicated that the student's statement was correct before the intervention. We take this finding to indicate that the ISTs' meanings for rate of change may be less reliant on certain conventions being maintained prior to taking the on-line course as compared to their function meanings.

Table 3. Code descriptions, sample responses, and counts for the pre and post survey to the $y = 3x$ Task.

| Code description (value) | Example Responses to the $y = 3x$ Task | Pre | Post |
|---|---|---|---|
| The student's mathematical statement is correct despite breaking from conventions. (1) | In this case, the student has graphed the relationship correctly given their choice of axis. Technically there is absolutely nothing wrong with this graph. | 20 | 24 |
| The student's mathematical statement is true but the student is incorrect because he/she broke from conventions. (2) | The student cannot receive full credit, as the graph is wrong, however it can easily be fixed by discussing the $y$ as the vertical axis and the $x$ as the horizontal axis. Once this discussion has ensued, I would ask the student to graph again but prompt them that they were correct in their understanding of $y$ being equal to 3 times the given $x$ value. | 6 | 8 |
| The student's mathematical statement is incorrect or the IST did not address the student's mathematical statement. (3) | The student did not graph the slope correctly, instead of a positive 3 they graphed a negative 3. They did label their $x$ and $y$-axis. Therefore, they are showing some correlation as to how the values of $x$ and $y$ vary and covary with each other. | 8 | 2 |

**Comparing surveys.** To further examine shifts in the ISTs' meanings from the pre to post survey, we assigned numerical values to each of the categories (shown in parentheses in the code description column). Table 4 presents the pre and post averages for each task; a score closer to 1 indicates that on average, the ISTs were attending more to the underlying quantitative relationships than to the student's response adhering to graphing conventions. In order to examine if there were statistically significant differences between the ISTs' responses pre and post course, we conducted one-tailed Wilcoxon Signed-Rank tests to examine if the mean scores differed significantly. We conducted one-tailed test because we expected the ISTs would exhibit a positive shift in their meanings based on the intervention and we conducted Wilcoxon Signed-Rank tests rather than *t*-tests as we cannot say if the population is normally distributed. Table 4 presents the *p*-values for each test. We note that there was a statistically significant result for the Sideways Mountain Task but not for the $y = 3x$ Task. We conjecture the latter observation may be due to the fact that the ISTs' initial responses indicate a tendency to evaluate the student's statement in the $y = 3x$ Task as correct prior to the on-line course.

Table 4. Average scores of pre and post survey for ISTs and *p*-values from a Wilcoxon Signed-Rank test.

| | Sideways Mountain Task | $y = 3x$ Task |
|---|---|---|
| Pre | 2.21 | 1.65 |
| Post | 1.71 | 1.35 |
| *p*-value | 0.0037* | 0.0618 |

## Discussion and Implications

In this report, we make several contributions to the research examining ISTs' understandings of mathematical ideas and ways to support ISTs' quantitative reasoning. We demonstrated many ISTs' initial meanings for function required certain graphing conventions to be maintained which is largely compatible with the PSTs reported by Moore and colleagues (2013, submitted). This finding underscores the importance of addressing such meanings in professional development and in PST training programs as teaching experience is not enough to support teachers in developing these meanings. We also highlight, and compatible with the PSTs reported by Moore and colleagues, the ISTs' responses to the $y = 3x$ Task differed from their responses to the Sideways Mountain Task. This finding highlights the extent to which an individual is constrained by a particular convention (i.e., a function's input is represented on the horizontal axis by the variable $x$) may be idiosyncratic to the particular mathematical idea at hand. Some may interpret this finding to indicate ISTs' and PSTs' meanings for rate of change are more focused on the underlying relationship between quantities (i.e., reason quantitatively) rather than maintaining particular conventions. Before we make such an argument, we believe there needs to be more research investigating teachers' understandings of rate of change in other non-canonical situations (i.e., polar coordinates).

Researchers (e.g., Mamolo & Zazkis, 2012; Moore et al., 2014; Paoletti, Stevens, & Moore, 2016; Thompson, 1992) have indicated that educators should provide students, PSTs, and ISTs with repeated opportunities to address unconventional situations in order to support them in expanding their meanings for various mathematical ideas such that they understand what aspects are conventional and what are required mathematically. Our data provides an existence proof that an on-line course can provide such opportunities for ISTs. This finding is especially important as on-line interventions have the potential to be scalable in ways that face-to-face courses typically are not. Future researchers may be interested in implementing and studying such scaling efforts to improve teachers' mathematical meanings.

A Case of Community, Investment, and Doing in an Active-Learning Business Calculus Course

Abigail Higgins
California State University Maritime Academy

*Presented here is a case study of Christina and her goals in an active-learning business calculus course. The larger project, from which this report emanates, involved an instructional redesign of a business calculus course intended to address two main student concerns: (seemingly) irrelevant content and a lack of opportunities to be active in class. Class size mediated Christina's access to community, which she perceived to be a necessary condition for her learning. Additionally, Christina drew a distinction between authentically situated mathematics and pseudo-situated problems that fail to invest her in the problem-solving process. She valued opportunities to do mathematics during class and receive feedback from her instructor and peers. This project has implications for the mathematics education of business students, active-learning in post-secondary mathematics, and situated mathematics problems.*

*Keywords:* business calculus, non-STEM, active-learning, situated mathematics, student goals

Student engagement is undoubtedly an important factor in the learning of post-secondary mathematics. As business calculus instructor, I especially struggled to develop and foster student engagement. Furthermore, students in this course considered the content to be irrelevant to their lives and futures. Business has long been the most popular post-secondary bachelor degree awarded in the United States (National Center for Education Statistics, 2015). Given the large student population associated with business calculus and the value of mathematics proficiency in society, addressing issues of student engagement and perceived irrelevant content in this course is critical. Aptitude in mathematics is a powerful societal tool regardless of students' trajectories. This project aims to contribute to existing research in the area of teaching business mathematics and hopes to emphasize the importance and value of the mathematics education of non-STEM students.

## Research Questions

The case presented in this report was part of a larger study which examined student agency in a business calculus course. A more detailed description of that study, its context, and methods is described elsewhere (Higgins, 2017). In the larger study, an operationalized understanding of an individual's achievement of agency was the resistive or supportive moves one makes in response to structure. Structure was defined as the set of forces that constrain or enable an individual's goal. Thus, to examine a student's achievement of agency in the context of this course, it was necessary to first determine that student's goals in this environment. This report focuses on the identification of a particular student's goals in this course. The goals of students in a mathematics course influence their engagement with mathematics and their behavior in the classroom. An instructional design informed by the intentions and ambitions of students in a mathematics course can leverage this information to better align the goals of students and instructors.

My instructional redesign of this course that was intended to address student concerns of passivity and irrelevant mathematics in this course. Given the time and curriculum constraints of this course at this institution, how could an instructional design address these student concerns?

1. What can an active-learning business calculus course designed to address student perceptions of irrelevant content and passivity look like?
2. What are the goals of a student in an active-learning business calculus course?
3. What elements of an active-learning instructional design facilitate or constrain these goals?

The results from this study inform the practice of teachers who value student goals in this context and have research implications for the mathematics education of students majoring in non-STEM fields.

## Theoretical Perspective and Implications for This Study

My theoretical perspective is rooted in sociocultural theory and draws on Lave and Wenger's (1991) model of situated learning. From this perspective, learning is conceived of as a process of apprenticeship. Experts model practices for novices and gradually include novices in increasingly legitimate participation in the community. Novices learn through both modeling and doing. Within a business calculus course, I am positioned as an expert in mathematics, however these students are explicitly not apprenticing into a mathematics community. In the larger and perhaps more relevant context of their academic majors, these students need to be apprenticing into a community of schooled businesspersons. This influenced my instructional design and motivated me to include more real-world problems and contexts that students might encounter in a business career.

## Literature Review

### Business Calculus

There is currently a striking gap in mathematics education literature regarding calculus courses for business students (Mills, 2015). Considering that business is the most popular undergraduate bachelor degree awarded in the United States (National Center for Education Statistics, 2015) and that many institutions require business majors to take courses through mathematics departments, this paucity of research is alarming. Due to the motivations and career goals of business students, there are many issues specific to this population that are not shared by students in a traditional calculus course. An intention of this project is to contribute to this area of research and highlight the importance of this student population and their mathematics education. In 2000, the Curriculum Renewal Across The First Two Years (CRAFTY) subcommittee of the MAA released a report that included recommendations for addressing needs unique to business students enrolled in mathematics courses (Lamoureux, 2000). Given the situated nature of businesspersons' actual use of mathematics, problems and associated decisions encountered in the real world are naturally coupled with significant ambiguity. This team recommended that this ambiguity be reflected in the problems included in mathematics courses for business students. Pedagogically, this report suggested including opportunities for student discussion of problems during class, invitations for students to present solutions and justifications to the rest of the class, and emphasized the importance of making relevant mathematics explicit. Given that these students are apprenticing into the world of business, a social industry, group work can help develop important social skills that are valued by employers. In this vein, student assignments should reflect the same material and scope that they might submit to a superior in the workplace. This report noted that mathematicians typically lack the resources to create valid and appropriate business-contextualized problems. Increased communication between mathematics and business faculty regarding mathematics courses for business majors would work toward solving this issue.

### Active-Learning Strategies

The literature on active-learning strategies is consistent and indisputable. Research indicates that these practices are linked to significant positive learning outcomes in students. Freeman and colleagues (2014) conducted a meta-analysis of research on active-learning and its effects on students in STEM courses and their learning. They found that for students who were in courses with at least some active-learning, student performance increased by nearly half a standard deviation when compared to student outcomes from a traditional lecture course. Additionally, students in lecture-style courses were more likely to fail than students taking courses that incorporated active-learning. Freeman and colleagues concluded that active-learning positively affects student performance in STEM courses at the post-secondary level. In 2016 the Conference Board of the Mathematical Sciences published a statement calling for an increase in active-learning strategies in the teaching of post-secondary mathematics (Braun et al., 2016). This statement advocates for the inclusion of active-learning techniques to provide students with meaningful mathematical experiences and as an avenue for modernizing the instruction of mathematics at the post-secondary level.

## Methodology

As stated previously, this report was part of a much larger project that involved a significant amount of pilot work including interviews with both business and mathematics faculty, interviews with students currently enrolled in the business calculus course at this institution, and a pilot version of my course re-design during Summer 2016, accompanied by interviews with students in this course. My course redesign included four intentional elements: daily reviews, in-class group activities, readings, and punctuated lecture style. Daily reviews were ungraded problem sets distributed at the beginning of each class that reviewed the content from the previous class and typically included a conceptual question and a few procedural problems. Student were encouraged to work on these problems with their peers. I circulated through the classroom answering both group and individual questions. After 10-15 minutes, we went over the solution as a class. Six in-class group activities coincided with application sections and foundational sections in the curriculum. Students split themselves into groups and worked through the problems during the class period. Each activity was also accompanied by a reading outside of class. These readings included motivation for the topic covered in the activity, an explanation of the concepts underlying the mathematics, the mathematics used to solve the problem, and a fully worked-out example problem. Students were required to digitally annotate each reading prior to the corresponding activity day. In order to allow for more time for students to be active, I was interested in eliminating lecture-style instruction as much as possible. The curriculum in this course covered a tremendous amount of content, which created challenging time constraints. Rather than resorting to direct instruction, I adopted a punctuated lecture style that encouraged students to participate routinely. I regularly asked students questions during instruction and included frequent opportunities for students to try problems on their own, work on problems with their classmates, or discuss questions with their classmates. These times generated ways for students to be actively engaged during instruction.

## Main Study

**Student make-up.** My business calculus course during Fall 2016 began with 51 students and ended with 50 students (one student withdrew from the course after approximately ten weeks). This was a reduced class size that required permission from the department chair. This course typically enrolls approximately 90 students in each section. There were 20 female students (19 after one student dropped) and 31 male students. There were nine freshman students, 20 sophomores, 18 juniors, three seniors, and one post-baccalaureate student. There were 43 students majoring within the college of business, four students majoring in economics, and four students whose majors were listed as either "exploring" or "undecided".

**Selection of participants.** This report focuses on one of my participants, Christina. She was initially selected to be part of the larger study because she appeared to be an exemplar of a very actively engaged student. Given her high level of engagement in the course, I was surprised to learn that Christina was retaking this course. She had previously taken business calculus in Fall 2015 and earned a D. Ultimately, Christina earned a B in my course. I was particularly interested in learning what her goals were in this course and the elements of my instructional design that facilitated or constrained these goals.

**Data Collection.** All class sessions were video and audio-recorded, save a few due to user error. The six videos of the in-class activities were completely transcribed (the first and second activity transcriptions contained less information due to missing recordings). In addition to the video and audio-recorded class sessions, a minimal amount of student work was collected for the larger study.

After the course ended, Christina participated in three interviews. The first interview involved her history with mathematics at the university level. This interview also helped me initially determine what her goals in this course were and what aspects of the design of our Fall 2016 business calculus course influenced those goals. The second interview was intended to validate things that I had inferred from the first interview. This involved confirming Christina's goals and the factors that influenced these goals. By our third interview, I had written a description of her goals in the course. This interview was meant to answer any remaining questions I had about her goals as a student in this course.

**Analysis.** To identify Christina's goals in this course, I began by writing a description of her experiences with post-secondary mathematics, primarily based on our first and second interviews. After the initial, general description of Christina and post-secondary mathematics, I composed a detailed summary of Christina as a student in our business calculus course, again mostly from our first and second interviews. These characterizations enabled me to both explicitly determine Christina's goals and identify characteristics of my instructional design that Christina perceived to be constraining or enabling. From these influential forces, I backward-inducted the goals that these affected. Once I had identified Christina's goals associated with this course, I coded all three of her interview transcriptions for these goals. These codes were used to perform a second coding pass, where I identified instances in our interviews when Christina referred to structural elements in our course. These codes were used to verify and justify claims made in her case. From the sets of goals and associated structural elements that I had identified, I described what Christina was a case of, her goals in the course, elements of our course that facilitated or constrained those goals, and the actions she took towards the progress of those goals.

## Christina: A Case of a Student Valuing Community, Investment, and Doing

### Classroom Community

Size of class was an important factor for Christina[1]. The first business calculus course in which she was enrolled consisted of approximately 80 students. During our first interview, she discussed her struggle to form working relationships with her classmates and connect with the instructor in that course. Christina uses her relationships with her classmates to secure feedback about her understanding of topics and to establish her belonging in a course: "It's just so not personal and I can't learn the same way. I feel like I'd be terrible in online classes because I need that interaction. And so, in some classes I am very involved, but other classes not." She explained in our interviews that she would have been much less likely to ask questions in our course if she had not formed a friendship with the student who sat next to her, Andy. Not only did she use this relationship to solicit feedback from Andy, she also explained that establishing a friendship in the class made her more comfortable asking questions and being honest about her misunderstanding. A sense of community is an important factor in the ways in which Christina advocates for her own learning. She is much more likely to act in ways that serve her other course goals if she has established relationships with other classmates and the instructor. Christina observed that the size of class affected her access to community, which is a mediating factor for advocating for her own learning. Regardless of instructor ability or effectiveness, in a large class, she perceives her learning to be inhibited. In this way, class size affects her ability to find community in a mathematics course, and a sense of community affects her successful achievement of agency.

### Contextualized Mathematics versus Pseudo-Situated Mathematics

Contextualized mathematics problems help invest Christina in the problem-solving process and connect mathematics to real-life issues, which motivates her to work to understand the solution process. When I asked her about the readings in our course, Christina drew a distinction between problems contextualized in real-life scenarios and problems that are pseudo-situated:

> Yeah, I think a lot of them had actual stories, like things that would actually happen in real life. And that's really helpful. Because a lot of math is a lot of numbers, so when you put words in there – I always hate math word problems. But if they're actually relevant and you're like, 'Ok, I'm understanding. Ok, this would happen in real life,' or like, 'This is something that does happen,' versus, I don't know, like apples and whatever. You know what I mean?

Being able to identify with a problem and recognize it as a valid real-life predicament invested Christina in the solution process and motivated her to focus and value the problem-solving process. Relevant problems motivated her to learn the material because she saw a potential future benefit for her in her career and she identified this connection between school mathematics and real life as a helpful force in her understanding of the material.

---

[1] The quotes and claims in this section come from transcriptions of interviews conducted with Christina.

### Opportunities to do mathematics in class

Christina noted that our course offered frequent opportunities to do mathematics during class. She especially valued this so that she could self-assess her knowledge and receive appropriate feedback. In her words:

> So when we're in class and you're making us do what we would be doing for homework and then you're there to ask – to help us if we need questions, that was really helpful for me, because sometimes I don't know what I don't know until I'm already home. And then I can't – it's harder to email about a question than it is to just ask in person.

She observed that this characteristic of our course was unique in comparison to her previous post-secondary mathematics courses. Prior to our course, she had mostly spent class time watching mathematics happen, rather than doing mathematics herself. Working through problems during class gave Christina an opportunity to address misunderstandings during class time and with the instructor or her peers. Opportunities to try problems, discuss with her classmates, and receive feedback from her instructor were greatly valued and noticeably used by Christina to aid in her learning.

## Discussion and Implications

### Real-Life Versus Pseudo-Situations

By the time students in this course reach higher education in the United States, they have a somewhat defined career path. To only include problems that are inherently procedural in nature, such as the pseudo-situated problems to which Christina referred, is a failure to serve our students. Problems situated within a business context should be an inherent characteristic of a business calculus course. Rather than trying to find how business situations can fit into the calculus curriculum, instructors should be focused on how calculus can fit into business contexts.

### Business Education

As referenced in the MAA CRAFTY (Lamoureux, 2000) recommendations, business solutions in the real world are often messy, ambiguous, and fail to adhere to procedures prescribed by school mathematics. Given this phenomenon, instructional practice in a business calculus course should reflect this same ambiguity. The mathematics education for these students should model, in some regard, the situations they will encounter in their career. Mathematics instructors are not typically experts in real life business situations. In order to effectively incorporate these kinds of problems and data sets, mathematics instructors need to collaborate with business faculty and with businesspersons working in industries.

### Research and Teaching Implications

**Business calculus instruction and course design.** Christina's experiences in this course suggest that opportunities to be active in class are valued by students. Student populations are dynamic and it is the onus of instructors to evolve our practices to best meet their needs. Opportunities for interaction with other classmates and with the instructor were conspicuous in this course. Past post-secondary mathematics courses in which Christina was enrolled allowed for little student activity. Christina considered interaction with other people to be a necessary condition for her learning. This finding is consistent with current research on active-learning in post-secondary mathematics courses.

**Real-life business problems and data sets.** The case of Christina illustrates that students in this course value problems that are contextualized in real-life situations and that students develop a stronger investment in solution processes when problems are situated in relatable contexts. The students in a business calculus course are not typically STEM students and most do not enter this course with an intrinsic interest in mathematics. They are majoring in a social field and are aware that their careers will likely involve working with other businesspersons. This finding is consistent with the recommendations from the MAA CRAFTY subcommittee.

**Non-STEM post-secondary mathematics education.** Recently, mathematics education has included a strong focus on the mathematics education of STEM majors. Like Mills (2015) reported, there is a striking lack of literature on calculus for non-STEM majors. This project examined student experiences in a non-STEM post-secondary mathematics course and contributes to the existing literature on calculus as a client discipline, mathematics education for business majors, and post-secondary mathematics education for students majoring in non-STEM disciplines. Mathematics courses for students in non-STEM disciplines encompass issues of motivation, relevancy, and confidence. While mathematics education for STEM students is clearly a significant issue, the lack of literature on calculus for non-STEM majors might suggest that these are not important issues. Despite this dearth of literature, I imagine mathematics educators and researchers would all agree that these student groups and their mathematics education are as valuable as any other student group. However, it is indisputable that non-STEM students are underrepresented in post-secondary mathematics education research. This underrepresentation is especially troubling considering that business is the most prevalent bachelor degree awarded in the United States. While this project hopes to contribute to the existing literature, there is a desperate need for more research in this area.

Individual and Situational Factors Related to Lecturing in Abstract Algebra

*Estrella Johnson* *Virginia Tech*
*Rachel Keller* *Virginia Tech*
*Valerie Peterson* *University of Portland*
*Tim Fukawa-Connelly* *Temple University*

*In this study, we report the results of a national survey of 219 abstract algebra instructors concerning their instructional practices and pedagogical decision-making. Organizing our respondents into groups (Alternative, Mixed, Traditional) based on proportion of class time lecturing, we investigated differences in the prevalence of specific pedagogical practices and the individual/situational factors influential therein. We used the reported teaching practices to generate profiles of the salient features of each instructional type and attempted to explain these differences through a combination of individual/situational factors. Results indicate that while significant differences in teaching practices exist, these are primarily explained by individual factors such as personal beliefs, level of experience, and interest in various scholarly activities. Situational characteristics, apart from institution type as identified by terminal degree, such as perceived departmental support and situation of abstract algebra in the broader mathematics curriculum did not appear to be related to instructional differences.*

*Keywords: pedagogy, abstract algebra, instructor decision-making*

In STEM higher education, and specifically in mathematics, lecture-based pedagogy is the norm. The most current report (2014) from the Higher Education Research Institute found that "more than two-thirds of faculty across STEM sub-fields utilize[d] extensive lecturing in all or most of their courses" (Eagan, 2016). This is despite the growing volume of literature, both from the learning sciences and professional organizations, urging teachers to adopt student-centered practices. Indeed, with the mounting body of evidence (see Freeman, et al., 2014 for a meta-analysis), the question is no longer "should we still be lecturing?" but is instead "why are we?"

Literature on instructional decision-making has long focused on individual characteristics, such as beliefs about teaching and learning (e.g., Calderhead, 1996), knowledge of research-based instructional practices (e.g., Henderson and Dancy, 2009), and professional development (e.g., Belnap, 2005; Speer, Gutman, & Murphy, 2005). While we do not discount the enormous influence of individual characteristics, we also acknowledge that a bevy of other external circumstances factor considerably. Research in science and mathematics education had identified a number of external influences, including expectations of content coverage, time expectations, promotion and tenure requirements, and class size (e.g., Henderson & Dancy, 2007; Hora & Ferrare, 2013; Hayward, Kogan, & Laursen, 2016; Johnson et al., 2013; Turpen, Dancy, & Henderson, 2016).

In this paper, our goal is to better understand the teaching practices of mathematicians and to begin to tease apart how both individual and situational characteristics relate to instructional decision-making. We conducted a national survey informed by findings from small-scale interview studies (e.g., Johnson et al., 2013; Roth McDuffe & Graeber, 2003) and from national surveys of undergraduate science educators (e.g., Henderson & Dancy, 2007). Our analysis of the responses provides a nuanced characterization of instruction, while also identifying individual/situational characteristics that are (not) associated with different instructional profiles.

## Literature Review and Theoretical Perspective

Case studies of mathematics instructors have uncovered multifaceted beliefs and goals that inform instructional practices (e.g. Johnson et al., 2013; Lew et al, 2016; Weber, 2004). As to be expected, beliefs about teaching and learning appear to be quiet varied. For instance, some are convinced of the benefit of non-lecture instruction as were the interview participants in a 2003 study who reported a desire to teach with “constructivist activities where the depth of knowledge is really greater” (Roth McDuffe & Graeber, p.336). On the other hand, there are those that are convinced of the strength of lecture, stating, “I believe students benefit from seeing education embodied in a master learner who teaches what she learned” (Burgan, 2006, p. 32). These beliefs do not exist in a vacuum and are likely informed by personal experiences – both as a student and a teacher – and influenced by activities such as attending workshops and conferences.

Regardless of how they developed, beliefs about teaching and learning alone do not appear to be deterministic of teaching style. For instance, in a previous report, we found that 64% of the respondents at research-focused institutions who think lecture is *not* the best way to teach lecture anyway (Johnson, Keller, Fukawa-Connelly, 2017). A common reason provided to explain the incongruity between how instructors want to teach and how they actually teach is a concern about content coverage (e.g., Johnson et al., 2013; Roth McDuffe & Graeber, 2003). Content concerns represent an interesting intersection of internal and external pressures. As discussed by Turpen, Dancy, and Henderson (2016), coverage concerns are influenced by personal beliefs about what should be included in the course, expectations from others in the department to cover a set curriculum, and more subtle indicators such as textbooks, their experiences as a student, and emotional attachments to topics. In this way, coverage concerns are to some extent self-imposed, yet attributed to external factors such as a common syllabus or need to prepare students for success in future courses. Such responsibilities to the discipline and the department illustrate that, while university instructors do control their own courses, “the influence of various external factors diminishes their perceived control over their teaching” (Lea & Callaghan, 2008, p.174). Similarly, time constraints are often cited as a strong factor influencing instructional practice. Turpen et al. (2016) noted interviewees discussing both “a broad sense of feeling overwhelmed with the responsibilities and demands on their time” and “specific aspects of their job description or institutional situation that led to them being stretched too thin” (p. 7).

This literature highlights the importance of instructors’ beliefs and experiences and institutional and departmental context on instructional decision-making – both of which are central to Henderson and Dancy’s (2007) model for predicting instructional behavior (Figure 1). This model provides a framework for considering instructional practices in light of the characteristics of both the instructor and his/her department. However, as acknowledged by Henderson and Dancy (2007), this is a “toy model” –

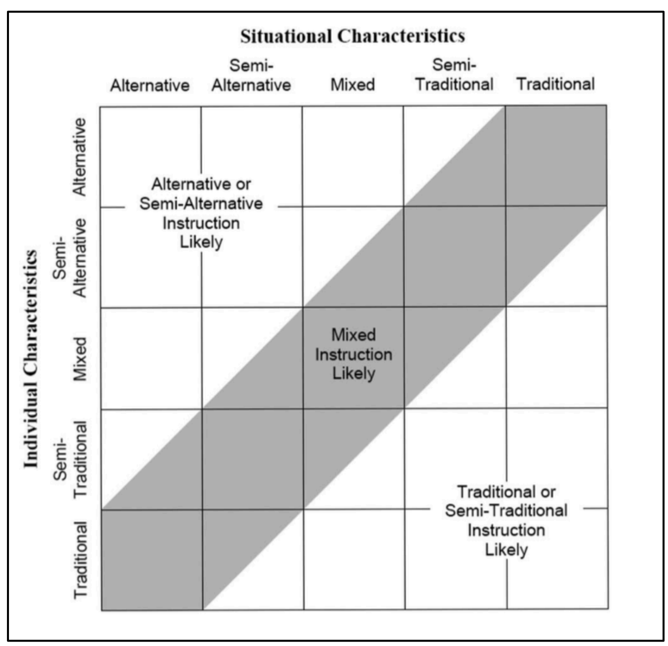

Figure 1. Toy Model

one that simplifies complex systems by highlighting dominant features, without detail about what is important within those domains. Better understanding the complex relationship between instructor characteristics (e.g., background, beliefs, knowledge, goals) and situational context (e.g., departmental norms, departmental supports, institution type) is the focus of this research. In this report we draw on data collected through a national survey of abstract algebra instructors in order to first characterize instruction and then to identify individual and situational factors that are associated with different teaching profiles. Specifically, we investigate three research questions: 1) What is the range and distribution of reported instructional practices in an upper division mathematics course (in this case, abstract algebra), as interpreted as traditional, mixed, and alternative instruction? 2) What individual characteristics (background, beliefs, knowledge and goals) are associated with instructors characterized as traditional, mixed, and alternative? 3) What situational characteristics are associated with instructors characterized as traditional, mixed, and alternative?

## Study Context, Data, and Methods

### Study Context

We focus on abstract algebra for the following three reasons. First, the major professional organizations have released a joint course-guide for abstract algebra calling for increased activity on the part of the students during the course meetings. Second, the research base in abstract algebra, including curricular innovations, is significant (at least in comparison to other proof-based courses). Finally, the course is often a small class taught by tenure-stream faculty. We have argued that these factors position abstract algebra, of all the required courses in the undergraduate mathematics plan of study, as the course best positioned to be taught with significant non-standard pedagogy.

For this report, we are drawing on two rounds of data collection, both of which used the same survey. In the first round of data collection the target population was instructors at universities that offer a graduate degree in mathematics. In the second round of data collection, we chose to target instructors at institutions not offering graduate degrees in mathematics. This decision was made upon considering the extant literature on teaching practices and observing that this research is primarily conducted by faculty at research-intensive universities about faculty teaching at such universities. Thus, even though the literature includes claims like: “lecture is overwhelmingly the dominant pedagogical technique both in terms of percentage of instructors claiming to use it and percentage of class time they report devoting to its use” (Fukawa-Connelly, Johnson, & Keller, 2016), it is possible that the lack of substantial representation of faculty at teaching-focused institutions may be a problem in terms of understanding the collected instructional practices of mathematicians in proof-based courses. For instance, the types of individuals who seek employment at research universities may have different beliefs about teaching and learning than their counterparts at teaching colleges. This, coupled with the disparate demands on time use, might influence the instructors’ willingness to adopt non-traditional pedagogies in different ways.

### Survey Design

The survey was designed to solicit information about the teaching practices, beliefs, and situational context of abstract algebra instructors. This survey was informed in part by both Henderson and Dancy’s physics-education survey (Henderson & Dancy, 2009) and the Characteristics of Successful Programs in College Calculus surveys. Our survey had sections to address: basic demographics and course context, teaching practices, beliefs and influences (including perceived supports and constraints), and knowledge of/openness to non-lecture practices. In the second round of data collection, the target population changed, but the information we were soliciting did not. For that reason, it was methodologically important that the items under investigation remain largely unmodified. While a few supplemental questions were added, the majority of the items were a subset from the previous survey with formatting intact. For the purposes of this paper, only those items unchanged by version were considered for analysis.

**Participants and Data**

The present data set is the result of two independent sampling attempts. The first data collection period was conducted in 2015. Survey requests were sent to departmental administrators at approximately 200 institutions. We received 126 responses, 91% of which represented instructors teaching abstract algebra at an institution offering at least a Master's degree in Mathematics. The second data collection period took place in summer 2016. In this follow-up, a random sample of 400 institutions was drawn from the IPEDS list, targeting specifically Bachelor's-granting schools. This sample yielded 112 responses, 91 of which were complete. For the purposes of this paper, all responses on applicable items have been combined into a single data set and disaggregated by instructional type for all future analysis. In total, 219 respondents were retained: 96 from Bachelor's-granting institutions, 44 from Master's-granting institutions, and 79 from PhD-granting institutions.

**Methods**

The purpose of this study was to describe the range and distribution of instructional practices as reported by abstract algebra instructors interpreted to be implementing a traditional, mixed, or alternative approach; and, furthermore, to investigate similarities/differences in the individual and situational factors influencing those practices. The characterization of instructional type was made using the prompt, *Please indicate the approximate percentage of class time that you are lecturing*, for which we coded the respondents as "Alternative" for responding *Never* or *0-25%*, "Mixed" for responding *25-50%* or *50-75%*, and "Traditional" for responding *75-100%*. This classification resulted in the following distribution of respondents: 17% Alternative (38/219), 57% Mixed (125/219), and 26% Traditional (56/219).

To address the first research question – the range and distribution of instructional practices - three survey items were analyzed. In each instance, the prompt instructed respondents to indicate the prevalence (instances per term / instances per class meeting / percentage of class time) of specific classroom activities/pedagogical practices utilized in their classrooms. To address the second research question – the specific individual factors characteristic of each instructional type – five survey items were analyzed. The first two items gathered demographic information on the teaching experience of the respondents and the latter three items polled respondents as to their beliefs about students, beliefs about teaching, and interest in professional activities as measured by a 4-point Likert scale. To address the third research question – situational factors characteristic of each instructional type – eight survey items, divided into two sets, were analyzed. The first were those that situated abstract algebra within the broader mathematics curriculum and the second subset were those intended to capture respondents' perceptions of departmental support for, and institutional constraints on, innovative teaching.

Group mean scores for each sub-item were computed by instructional type and compared using inference testing procedures such as ANOVA, Chi-square, or the Kruskal-Wallis test, as applicable to the data, with post-hoc testing for pairwise comparisons therein; within each item, the Holm-Bonferroni correction was applied to control for the family-wise error rate affiliated with multiple comparisons when appropriate.

## Results

### Research Question #1 – How can we conceptualize "traditional", "mixed", and "alternative" instruction in upper division mathematics courses?

In order to conceptualize the classroom experience of each instructional approach, the mean reported prevalence of a variety of pedagogical practices was computed and used as a means of comparison. Sorting respondents based on proportion of time spent lecturing highlighted 14 instructional practices that varied significantly between at least two of the three categories, with 8 practices being significantly different (family-wise error rate < .05) on all three pairwise comparisons. Considering reported teaching practices altogether generated these profiles:

- **Alternative** instruction is characterized by spare lecture, with class time split class time (fairly evenly) between showing students how to write proofs, having students work in small groups, having students give presentations, having students work individually, lecturing, holding whole class discussions, and having students explain their thinking. For alternative instruction, when compared to the other instruction profiles, it is less likely for instructors to pause and ask questions, use visual representations, diagrams, and informal explanations. Students in these classes are frequently asked to make presentations to the class and develop their own conjectures and proofs and are sometimes asked to develop their own definitions.
- **Mixed** instruction is characterized by moderate use of lecture lecturing, with significant class time devoted to showing students how to write specific proofs, pausing to ask students questions, and using diagrams, visual representations, and informal explanations to help students with formal ideas. Additionally, there is some class time devoted to students working alone and in small groups, giving presentations, and explaining their thinking. Students in these classes are pretty frequently asked to develop their own proofs, and are sometimes asked to present their work to the class and develop their own conjectures.
- **Traditional** instruction is characterized by heavy use of lecture. During lectures instructors report they are showing students how to write specific proofs and pausing to ask students questions. These lectures often include diagrams to illustrate ideas and informal explanations of formal statements, but are the least likely to discuss why material is useful and/or interesting amongst the three categories. Students in these courses are sometimes asked to develop their own conjectures or proofs.

We do not claim it is surprising that, with less time devoted to lecturing, Mixed and Alternative instructors are spending more time engaging students in mathematical activity (e.g., developing proofs) and in peer-to-peer activity (e.g., working in small groups and giving presentations). Rather, we offer these results to justify using the amount of time spent lecturing as a viable means for differentiating instructors as Traditional, Mixed, and Alternative.

### Research Question #2 - What individual characteristics are associated with instructors that report traditional, mixed, and alternative instruction?

Keeping in mind the goal of elaborating on the "toy model" presented in Figure 1, our investigation of research question #2 has yielded information that draws distinctions on individual characteristics between types of instructors. In particular, at least one significant pairwise comparison existed for 12 of the 17 items under consideration: teaching experience

(2/2), beliefs about teaching and learning (7/10), and interest in various types of scholarly activities (3/5). Traditional instructors (i.e., those reporting lecturing more than 75% of class time) are the most experienced group, hold the strongest beliefs in favor of the appropriateness or necessity of lecture and the most pessimistic views on their students' abilities, and have a stronger interest in mathematical research than educational research. Conversely, alternative instructors (i.e., those reporting lecturing less than 25% of class time) tend to be the least experienced, hold the strongest beliefs in favor of non-lecture activities and the most optimistic views on their students' abilities, and prefer research in teaching and learning to that of abstract algebra. For all items, the Traditional and Alternative groups always occupied the extreme positions on the continuum with the Mixed group in between. This provides further evidence to suggest that separating instructors based on a single characteristic (i.e. proportion of class time lecturing) does result in meaningful categorizations.

**Research Question #3 - What situational characteristics are associated with instructors that report traditional, mixed, and alternative instruction?**

Our investigation of research question #3 failed to provide distinctions on situational characteristics between types of instructors, at least as we have defined them. At least one significant pairwise comparison existed for only 2 of the 8 items under consideration: institution type and time pressure. When considering the distribution of institution type by instructional approach, we found that Traditional instructors are significantly more likely to reside at a PhD-granting institution than either the Mixed ($p < .001$) or Alternative ($p = .001$) groups. Nearly 60% of Traditional instructors are at PhD-granting institutions, whereas only 18% of Alternative instructors are. Furthermore, while we can see that the modal class for all institution types is Mixed instruction, we do see a gradual rise in incidence of Traditional instruction as the terminal degree escalates from Bachelor's (12.5%) to Master's (25%) to Doctorate (41.77%). Collectively, these results indicate a dependency between institution type and instructional approach.

When considering abstract algebra in the broader mathematics curriculum, we found little to suggest that the instructors in the various groups experienced different departmental circumstances. The distribution of responses on both the prerequisite course and follow-up course items revealed some interesting trends, but the lack of statistical significance indicated that these items are likely independent of instructional approach. Alternative instructors tend to be the most likely to work in a department to require a proof-based prerequisite (79%) and the least likely to work in one that offers a subsequent algebra course (58%). Additionally, we observed that the requirement of a proof-writing prerequisite seems to be inversely related to the proportion of time spent lecturing (Alternative > Mixed > Traditional) and that the existence of a follow-up algebra course appears to be directly related (Alternative < Mixed < Traditional); however, there were no significant pairwise comparisons in either case.

The second sub-set of items analyzed included those questions intended to capture respondents' perceptions of departmental support for, and institutional constraints on, innovative teaching. These items focused on departmental expectations and content pressure, the availability of time for teaching and course redesign, travel support for professional development, and freedom to make changes to their abstract algebra course. We found that, not only were there no statistically significant differences for many of these items, the distributions were nearly identical. The lone exception being the question: *Do you feel like your job requirements allow you to spend as much time as you would like on teaching…?* Here we see that about 70% of

Alternative and Traditional instructors responded in the affirmative, whereas slightly less than half of the Mixed instructors felt that way.

## Discussion

The goal of this research study was to investigate the range and distribution of reported instructional practices in abstract algebra instruction and how different individual and situational characteristics are associated with instructors who report different types of instructional practices (see Figure 2). This analysis has allowed us to provide further insight into the “toy model” that Henderson and Dancy (2007) developed. In particular, while prior research suggested the importance of a variety of individual and situational characteristics, our work suggests that a relatively small collection of individual characteristics may be actually be the most important for teaching practices, at least in terms of the broad-strokes characterization of instruction we use here.

*Researching affective issues can be difficult in education; methods like interviews and surveys can place artificial categories on participants' experience and exert biased influence. This lack of tools to study affect calls for better methods. We explore graphing as a potential tool with affordances for studying affect, by reporting results of three separate studies at different timescales where undergraduates graphed affective phenomena like confidence or emotion: two in an introduction to proof course and one in a pre-service teacher content course. By systematically describing each study and looking across the three, we argue that graphing can be a useful technique for representing experience. Its utility lies in aligning research goals with the structure imposed by the temporal axis. More structure along the temporal axis allows researchers access to what a student experiences at predetermined temporal points and less structure allows access to what students themselves find to be salient events.*

*Keywords:* Methodology, Affect, Introduction to Proof, Preservice Teachers

Research is beginning to appreciate the deep importance of affect in the experience of learning mathematics (Ainley, 2006; McLeod, 1992). However, despite this increased recognition of the importance of affect, the field lacks methodological tools to investigate students' non-cognitive, affective, emotional experience during cognitive activity. This methodological paper reports on the approach of affect graphing during learning experiences (building upon the work of McLeod, Craviotto, & Ortega, 1990; Smith & Star, 2007; and Smith, Levin, Bae, Satyam, & Voogt, 2017). We explore the use of affect graphing across three recent studies within undergraduate mathematics education (two studies situated in the context of an introduction to proof course and one study situated in the context of a number and operations content course for pre-service elementary teachers). Particularly notable is how different time scales were engaged in each context: the scale of reflection on work on a single problem, a single class discussion, and finally the scale of reflection was an entire course.

Interviews remain a commonly used method that takes as its object of inquiry the experience of the individual. However, studying affect on the sole basis of verbal protocols is problematic. For example, while interviewers can prompt a subject to report how they are feeling in the moment, one needs to be aware that is an intervention in the experience and may change or shape the perception of the experience. Asking subjects to report their experience in a completely open way can lead to subjects focusing in on very particular moments and not supporting reflection across an entire time interval of interest to the researcher. Lastly, interviews are dependent on interviewees being able to articulate their emotions and feelings in words. Depending on the amount of direction given, participants may need to interpret and respond to categories given to them as opposed to describing their own experience and its ebb and flow in their own terms.

A second potential contrasting approach to studying affect involves surveying participants about their affective experience. Positive implications of such an approach include the ability to generate a larger volume of data with prompts that serve as proxies for experience, beliefs, and participant feelings during problem solving. However, such methods are less responsive to participants' own categories of experience, forcing subjects to again fit their experience into the pre-conceived categories of the researcher. Surveys are also conducted in a way that does not allow for the temporal, moment-by-moment recording of an experience.

While the above discussion of contrast methods is not meant to suggest that adaptations of such methods cannot ameliorate some of the constraints of those methods of data collection, it is meant to point out that other methods (such as the graphical approaches we discuss here) may have advantages in addressing such questions. The field needs better tools for studying affect.

## Framework

This paper differs from the typical empirical report in that we explore the affordances of an innovative methodology. The goal of our paper then is to analyze the ways in which graphing was productive. We therefore present a framework for how we describe each context and compare them to each other. For each context, we provide (1) a *description* of the overall study, (2) the *purpose* of graphing as a tool in this context, (3) what the graph *measured*, (4) *features* of the graph such as timescale, axes, labels, (5) *results* from analyses and suggestion for potential analyses that could be done, and finally (6), a prototypical *example*.

## The Three Contexts

We describe three separate studies in which the approach of graphing was used. Two of the contexts were research projects and one was from a course, as seen in Table 1.

*Table 1. Features of the Three Studies Using Graphing as a Methodological Tool.*

| Course | Population | Axes | Graph Measures |
|---|---|---|---|
| Intro to Proof | Math majors and minors | 1st quadrant | Students' confidence |
| Numbers & Ops | Pre-service elementary teachers | 1st quadrant | Students' confidence |
| Intro to Proof | Math majors and minors | 1st & 4th quadrant | Students' emotion |

The first was a study of undergraduates' confidence reflecting on a completed intro to proof course. The second project examined elementary pre-service teachers' confidence levels in reaction to a class discussion in a numbers and operations course. The third context was also in the intro to proof course but focusing on students' emotions while working on a proof. Each of these studies was conducted by different subsets of the authors of this paper.

We have chosen to order contexts by timescale, from broadest to shortest. We do this to make salient the variations in how the graph was used when the time scale shrinks. In addition, the first and second contexts use graphing to measure the same construct (confidence), while the last context measures emotion; emotion may include confidence but can be multi-dimensional.

### Context 1: Introduction to Proof Undergraduates Graphing Confidence over a Semester

The focus of the first study in which we explore the use of graphing was understanding undergraduates' experience in an introduction to proof course. The population ($N = 14$) consisted of math majors and minors who had just completed the introduction to proof course. In a prior study, Smith et al., (2017) interviewed them about their view of the nature of the course in contrast to past math courses, their sense of success, and how their view of and work on proof tasks may have changed over the course.

The researchers also wanted to tap into the affective dimension of experience – how they felt at different points – so they asked students to graph their confidence in the course across the semester. Interviewers left the room while students drew their graph and when they returned, asked students to talk through their graph. The x-axis measured time, from before the semester started (to account for expectations of the class prior to its start) to right after the final exam. There were otherwise no fixed tick marks along the x-axis, because of the interest in not only how students' confidence changed but *what* influenced shifts in confidence. The y-axis measured confidence. Tick marks on the y-axis were given, corresponding to low, medium, and high confidence. The majority of students drew continuous graphs. The task was kept relatively open to allow students to represent their experience however they chose to, away from our judgment of what may be important milestones in the course.

One analysis is to categorize the *shape* of the graph, to identify common patterns of confidence over the semester. We found five categories of shapes, with two graphs as outliers to categorization. The most common ($n = 4$) shape for confidence was a "W" shape: initial high confidence in the course with a quick drop early in the semester, then an increase over time, followed by a decrease and then a final increase to the end of the course (see Figure 1).

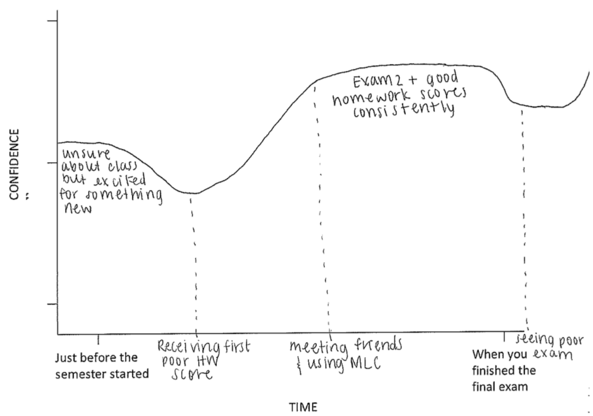

*Figure 1.* Example of the "W" shape, the most common pattern for confidence over time. This figure also shows the kinds of x-axis markers students included as places where their confidence shifted.

The other four shapes in our set of 14 graphs were: (a) continuous increase, (b) concave up parabolic shaped graph, (c) initial increase followed by a sinusoidal wave for the rest of the semester, (d) initial increase followed by decrease, with a final confidence level that was lower than their initial level. The W pattern as the most frequent makes sense given the different nature of a proof-based work and the introduction to advanced mathematics (analysis, linear algebra, number theory) after the half-way point of the course.

Graphing was insightful here in that it gave students a vehicle through which to reflect across an entire semester (half a year). The act of drawing the graph served as a way of recalling and organizing how they felt, in a way that localized interview questions did not capture. In addition, the openness of the x-axis meant students could tell us what events corresponded with rises and falls in their confidence, as opposed to our assumptions that it would revolve around exams for example. With this, we could identify the events that stood out as pivotal moments, relative to the entire experience.

**Context 2: Pre-service Teachers Graphing Confidence over a Class Period**

The second context that used graphing involved a study of pre-service teachers' response to an orchestrated classroom discussion. Two of us have been involved in developing and revising a one-semester course on number and operations for pre-service teachers with an emphasis on justification, specifically on developing our prospective elementary teachers' (PTs') abilities to analyze and critique the work of others. These goals are not easily achieved, as there are issues that arise in orchestrating such class discussions, particularly those that capitalize on incorrect patterns of reasoning that PTs themselves may generate (e.g., Chamberlin, 2005; Silver, Ghousseini, Gosen, Charalambous, Strawhun, 2005). Toward this end we have been developing a strategy for orchestrating discussions for enabling PTs to consider and analyze divergent thinking on mathematical tasks.

The strategy has 4 main stages: (1) Engagement: PTs generate their own ideas for a solution; (2) Interruption, juxtaposition, and re-focusing: The teacher posts two different answers and asks PTs to determine a solution path that would lead to each answer; (3) Articulating the reasoning of another: PTs present ideas for the chain of thinking that led to an answer. This discussion focuses on understanding the reasoning (without bias), along with establishing common ground; (4) Validity: PTs consider how to determine the validity of one approach (and thus why the other approach is not valid). The goal of this orchestration was to destabilize PTs' thinking. Prior analysis of class videotapes indicated this approach's efficacy, but we wanted tools for tracking individual PT thinking at key stages of the orchestration strategy, along with evidence of their understanding at the conclusion of the activity. Graphing was used for this purpose.

Immediately following the activity, PTs were asked to rate their confidence level in their own thinking at each stage on a 5-point scale from low to high, thus creating a "confidence graph" for the activity. At the end of the activity, students were asked to explain the valid strategy in a way that would help someone with the invalid strategy understand why it was invalid. Our data suggest that the orchestration strategy used in this case was successful, both in establishing cognitive dissonance, and also, importantly, in allowing students to come to resolution.

The main patterns in student confidence graphs were the same across two different classrooms with different instructors: the lowest confidence level was at Stage 2b (2.7 out of 5, or 54%) and the highest confidence level was at the end of the activity (4.7 out of 5, or 95%). With respect to the overall shape of PTs confidence graphs, the majority of the students (83%) had at least one point in the activity at which their confidence took a downward turn (indicating some degree of destabilization in their thinking). Analysis of the written student work that accompanied the generation of the confidence graphs, in conjunction with students' professed levels of confidence at the end of the activity, indicated that students came away from the activity with a heightened understanding of the mathematical content of the activity.

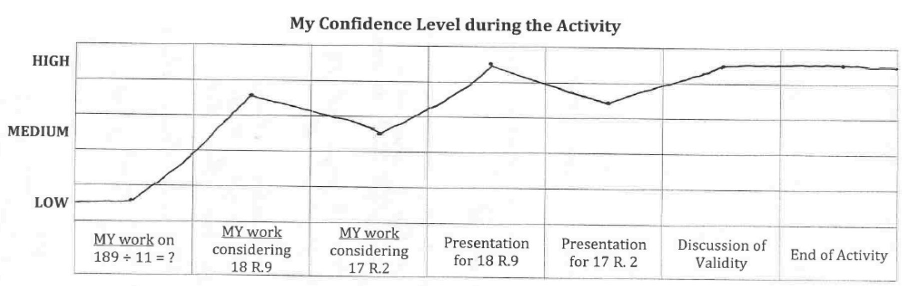

*Figure 2.* Sample confidence graph produced by a student reflecting on their confidence over the course of the class discussion of 189 divided by 11.

Collecting PT's reflections on their affect across the discussion allowed us to capture data that would be difficult to get from other methods like class observation and videotape. Though video reveals an "impression" that at least some of the PTs were deeply engaged in discussions, the confidence graph activity gives researchers (and teachers) a tool for measuring where the entire class is in their understanding and how this shifts over the course of the discussion.

**Context 3: Introduction to Proof Undergrads Graphing Emotion over a Single Problem**

The third study we discuss tracked students' emotions while working on a proof construction task. N = 11 undergraduate students (some math majors, some not) were interviewed four times across the semester, while taking an intro to proof course. In each interview, they were given two proofs to work on for a maximum of 15 minutes each, which were picked intentionally to be challenging, hence problems. Students were encouraged to "think-aloud" while working. After each task, students were asked to describe their process, choose from a given set of emotion words to describe what they felt and then draw a graph of their emotions during that problem.

Graphing as a technique was chosen (a) as a talking aid, to help students articulate their emotions, which in general can be difficult and (b) to succinctly compare patterns of emotion across participants on the same problem and that of a single participant within a problem. The level of intensity in how they felt at various points could be better seen and compared visually.

The graph measured emotion, signed (positive or negative) intensity without specifying the exact emotion. The x-axis was time, from when the student started working on the problem to when they stopped. The y-axis represented emotion, with a tick mark above the x-axis denoting positive emotions (e. g. satisfaction or excitement), a tick mark below the x-axis denoting negative emotions (e. g. frustration or panic), and the axis itself being neutral with no particular emotion, i.e. one's "resting state." All students drew continuous graphs, a line graph across the page. They also marked on the graph reason(s) why emotions shifted.

In sorting the graphs, the analysis revealed 6 general profiles of graphs: (1) overall positive, (2) overall negative, (3) flat, (4) concave down, (5) concave up, and (6) other. Of the 88 graphs, 40% were concave up, 18% were overall positive, 13% were overall negative, 10% were flat, 8% were concave down, and 11% fell into the other category. Concave up graphs suggested that the student overcame struggle(s), whereas overall positive graphs had no issues impacting emotion. Flat graphs showed experiences with little variation in emotion, whether completely flat and above the x-axis because the problem was easy, or right at the x-axis because the student stayed unsure the entire time. Concave down graphs were experiences that started well but where the student got stuck and could not resolve it.

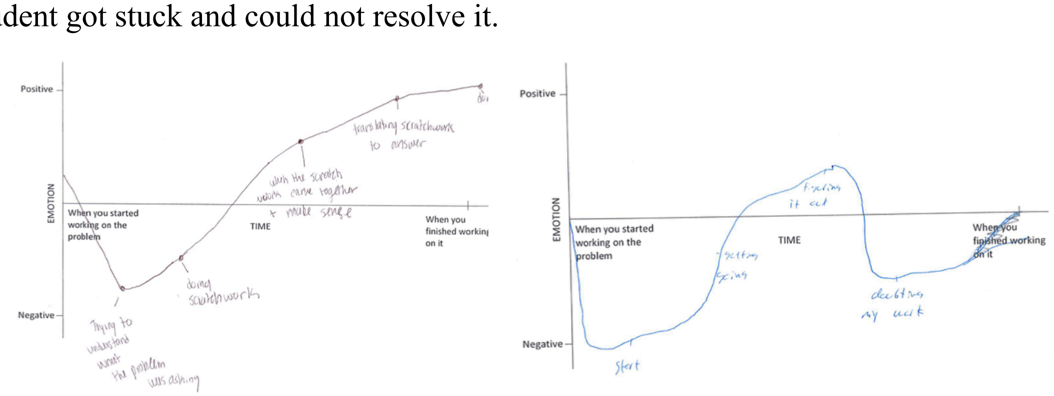

*Figure 3. (Left)* Prototypical example of concave up, the most common graph type. *(Right)* An example of a graph in the Other category, showing rises and falls in emotion.

The other category consisted of graphs with many changes in emotion (such as a “W” shape), large rises and falls, and states of confusion. This other category is a collection of volatile problem solving experiences, due to the size and number of rises and falls in emotion.
The results showed that there were a number of experiences where students successfully worked past a struggle. The graphs were useful in quickly and visually identifying whether students engaged in problem solving behavior - the existence of a struggle.

The choice to collect graphs at multiple timestamps for each student allows for temporal analyses as well. For example, one could look at how students’ emotions while problem solving change over time, as seen in Figure 4.

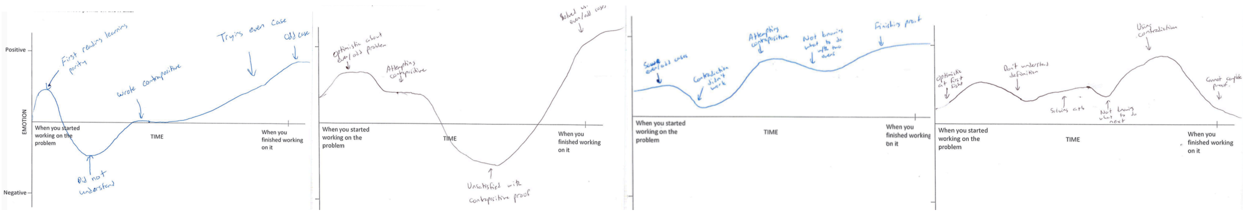

*Figure 4*. Graphs of emotions for one participant over 4 points in time.

Overall, graphing was most useful as a way for students to communicate their problem solving experience in a temporal fashion. Like in the first context, keeping the x-axis unstructured meant students talked about (and annotated on the graph) the events that caused their emotions to shift. The identification of these events and how students interpreted them, and how this changed over multiple points in time especially, was valuable.

## Discussion

We now turn to comparing the use of this new analytic tool across the three contexts and point to directions for future use of the tool. We focus our discussion on the affordances of this tool across the three contexts.

In all three contexts, graphing an aspect of affective experience during learning and problem solving (e.g., confidence, emotion) was used to glean information that would have been challenging to gather using traditional methods such as verbal interview, video of problem solving or class discussion, or survey methods. In all cases, we considered the affective variable over time and assumed that the experience (problem solving, taking part in a class discussion, engagement in a course) influenced the graph that was produced. All three contexts ask participants to reflect on their experience and represent it graphically. As discussed earlier, the produced graphs tap into the utility of this approach for understanding participants’ experience of events of differing time scales: work on a single problem, engagement in a class discussion over an entire period, participation in a course over a semester.

The presentation of the studies and results where this tool was used demonstrates the wide applicability of this methodological tool. While we used the tool with both undergraduate mathematics majors and with pre-service elementary teachers, we can envision that this tool would be possible to use with an even broader range of participants. Mathematics majors were more familiar with graphing and more able to interpret and adapt the tool (e.g., including their own points of salience along the x axis). For the pre-service teacher study, we included more structure along the x axis and grid lines to allow participants to either create a continuous graph or to simply mark whether they had high, medium, or low affect at each of the pre-specified points within the discussion. Many students chose this way of interacting with the given template, creating a bar graph as opposed to a line graph. From a theoretical standpoint, we see that the act of drawing the graph serves as a form of *rendering* for the student, i.e. making sense of an experience. It locates but also provides temporal structuring, allowing students to organize their experience temporally, which helps them communicate their experience to us.

At a general level, there are several affordances to this approach. The method is easy to administer. Participants have a range of agency in terms of what they draw and how (completely open in the case of undergraduate math majors; more structured in case of PSTs). A methodologically attractive feature of the graphs produced is that they capture the students' reflection on their affect over the entirety of the experience as opposed to the interviewee focusing in on one particular part of the experience that was more salient to them. For this reason, giving participants the opportunity to explain their written graphs can allow researchers to elicit data on the relationships between participants' affect at different points in time over the entire experience and also what parts of the experience were most salient. The graphing activity encouraged a negotiation in the representation of particular focal experiences/feelings and a global sense of the experience. Having participants discuss their graph also gave insight into participants' views of the driving forces or reasons behind shifts in confidence or affect. The shared artifact to talk over seemed to help participants craft a narrative not only of how their experience shifted but what was behind those shifts.

While there are numerous affordances of the method, the approach, like any qualitative approach focuses on self-report. However, because our interest is in participants' models of their own experience, it is less critical for us to judge whether or not participants' confidence or emotions actually did increase or decrease in the ways they reported. The important data for us is participants' perception of their own experience, captured very well by the graph. One constraint with capturing data on participants' perception of their experience is that the most vivid data about participants' perceptions comes as close as possible to the experience itself. In the study of problem solving and the study of students' experience of the classroom discussion, the reflections took place immediately after the experience. We felt this was the "best possible" timing so that participants would not be simultaneously reflecting on their experience while also engaging in the focal task. The post-hoc interviews of confidence over the experience of the course were more challenging in this respect because, necessarily, more time had passed between the experience and the participants' reflection on it.

Graphing as a tool has implications for other purposes besides research too. While we focus here on the use of graphing as a research tool, it also works as an in-class tool, as a form of formative assessment. It can function as a support for student reflection or for teachers to check-in with students, as was done in the pre-service teacher context here. We believe graphing is useful for other populations of students also. We focused on the use of this tool with college populations and admittedly, there is reason to believe it is especially useful there because they undergraduates are familiar with graphing as an activity. However, a more structured approach like in the PST context could translate well to less mathematically sophisticated populations.

Conceptual Blending: The Case of the Sierpinski Triangle Area and Perimeter

Naneh Apkarian[1], Chris Rasmussen[1], Michal Tabach[2], & Tommy Dreyfus[2]
San Diego State University[1], Tel Aviv University[2]

*In this report, we present an analysis of 10 individual interviews with graduate mathematics education students about the area and perimeter of the Sierpinski triangle (ST). We use conceptual blending as a theoretical and methodological tool for analyzing students' reasoning to investigate how students encounter and cope with the ST having zero area and infinite perimeter. Our analysis documents the diverse ways in which the students reasoned about the situation. Results suggest that conceptualizing an infinite perimeter is more accessible to these students than is zero area, that encountering the paradox is dependent on how blends are composed, and that resolution of the paradox comes through completion and elaboration. The analysis furthers the theoretical/methodological framing of conceptual blending as a useful tool for revealing the structure and process of student reasoning.*

*Keywords*: Conceptual blending, Infinite processes, Fractal, Paradox, Student thinking

*It's still hard for me to wrap my mind around the Sierpinski triangle, and that there's infinite perimeter and no area. It makes sense to me individually, but both together at once, I'm still, it's still mind-boggling. – Carmen, graduate mathematics education student*

Straightforward notions of the area and perimeter of geometric shapes are first learned in elementary school, and are revisited and leveraged throughout middle and high school. When dealing with fractals, however, some counter-intuitive situations involving these ideas arise. One such situation, a region with zero area and an infinitely long perimeter, was encountered by a class of mathematics education master's degree students in a chaos and fractals course when investigating the Sierpinski Triangle (ST) shown in Figure 1. As seen in Carmen's introductory quote, this was a non-trivial exercise and caused some students serious consternation.

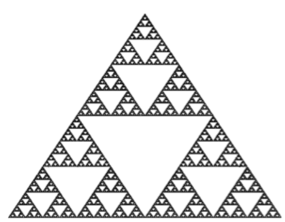

*Figure 1. The sixth step in creating the Sierpinski Triangle.*

To investigate student reasoning about the ST we conducted individual interviews about three weeks after its in-class investigation. Based on the interview data, and using the ideas of conceptual blending, we address the following two related research questions: (1) How do students make sense of (a) area and (b) perimeter of the ST? (2) How do students coordinate the area and perimeter of the ST and cope with the resulting paradoxical situation?

## Theoretical Background

We use conceptual blending theory (Fauconnier & Turner, 2002; Núñez, 2005) as a theoretical and methodological tool for analyzing students' coordination of two infinite processes, one increasing (perimeter) and one decreasing (area). Blending is based on the notion of mental spaces, which are "small conceptual packets constructed as we think and talk, for the purposes of local understanding and action" (p. 40). According to the theory, these mental spaces "organize the processes that take place behind the scenes as we think and talk" (p. 51). Conceptual blending is defined as the conceptual integration of two or more mental spaces to produce a new, *blended,* mental space. An important feature of this new blended space is that it develops an emergent structure that is not explicit in either of the input mental spaces. This emergent structure is generated by three processes: composition, completion, and elaboration.

*Composition* is the selective projection of elements from input spaces into a common space. During composition, distinct elements may be projected on top of each other or *fused,* and common elements may be projected separately. The composition process develops a new space, with the potential for structure not available in either input space. *Completion* is the process of recruiting familiar frames to the blended space, along with their entailments. That is, an individual recognizes certain aspects of a blended space as parts of a familiar frame and brings in additional knowledge, scripts, assumptions, etc., to complete the frame and prescribe structure for the blended space. These frames can serve as tools for *elaboration*, which is sometimes called *running the blend*. Elaboration is the process that leads to the emergence of something new within the blended space, using the tools of the completion process and the elements that compose the blend. These processes, composition, completion, and elaboration, do not necessarily take place sequentially (Fauconnier & Turner, 2002).

Underlying our analyses is our knowledge of previous research related to conceptual blending in other contexts (e.g., Lakoff & Núñez, 2000; Yoon, Thomas, & Dreyfus, 2011; Zandieh, Roh, Knapp, 2011), infinity (e.g., Ely, 2011; Fischbein, Tirosh, & Hess, 1979; Núñez, 2005), paradox (e.g., Dubinsky, Weller, McDonald, & Brown, 2005ab; Sacristán, 2001; Wijeratne & Zazkis, 2015). A review of these works is beyond the scope of this report, but we acknowledge the impact of this prior work for our own and note that our work is some of the first to bring together all these ideas.

## Methods

The study took place in a graduate level mathematics course of 11 mathematics education students (10 of whom agreed to participate in individual interviews). The course was taught by one of the research team members. Students sat in four groups and daily worked on tasks in their small groups and engaged in whole-class discussions of these same tasks. Data was collected as part of a larger study and included video-recordings of each class session, individual task-based interviews conducted at the middle and end of the semester, and copies of all student work.

The focus of the analysis in this paper are students' responses to the following question from the mid-semester interview: *In class, we discussed the Sierpinski Triangle. How do you think about what happens to the perimeter and the area of the ST as the number of iterations tends to infinity?* This question was accompanied by a printout of the ST (as seen in Figure 1), with a follow-up prompt to tell us what they thought about the following claim of a fictitious student, Fred: "The computation shows that the perimeter goes to infinity because the perimeter is given by $3(3/2)^n$ which increases to infinity as n tends to infinity. But, the perimeter can't really be infinitely long, because there is nothing left to draw a perimeter around, since the area goes to zero." This interview task was designed based on the classroom discussion of the ST, which took place two weeks before we began interviewing students. At that time, students seemed to agree that the area went to zero but were unsure of what happened to the perimeter. They publicly considered the possibilities that it went to infinity, converged to some value, or did not exist because there was nothing left for a perimeter to go around. The interview was structured so that we would first gain insight into the students' reasoning about the area and perimeter of the ST, followed by an opportunity for them to respond to Fred's claim.

To identify a student's input space for area (similarly for perimeter), we first marked which of their utterances were about the area. Next, we categorized these utterances into sets of ideas about the area of the ST - including the process by which it is created and the resulting product. In the spirit of grounded theory (Strauss & Corbin, 1998), these ideas were coded and compared iteratively until a coherent set of idea codes emerged. The interviews were divided into two groups and analyzed by different members of the research team. These analyses were then swapped, compared, and vetted.

We investigated students' blending by identifying each of the three processes: composition, elaboration, and completion. To see how a student's blend was composed, we identified which elements of the student's input spaces were brought up as they considered the coordination of area and perimeter (prompted by Fred's paradox). We identified the ways students elaborated their blended spaces by identifying ideas which were not in the input spaces, but emerged as they worked to make sense of the task. Interpretation of completion and elaboration was done first as a group, with all four authors debating each point, then a more detailed pass was made by two members of the team in close comparison with the transcripts, and these analyses were then discussed again among the four authors until agreement was reached.

## Sample Results

During the in-class discussions about the ST there was widespread agreement that the area would go to zero but less agreement that the perimeter would diverge to infinity. We were therefore surprised to find that only six of the ten students concluded that the area of the ST goes to zero but all ten students concluded that the perimeter tends to infinity.

### Area and Perimeter (Research Question 1)

Among students' justifications for their conclusions, we identified seven qualitatively different mental space elements for area and seven qualitatively different mental space elements for perimeter. As a sample we display three of the most prominent different mental space elements side-by-side, with descriptions of the elements and illustrative quotes.

| **Area** | **Perimeter** |
| --- | --- |
| <u>Infinite decreasing process</u><br>Common among all 10 students was the element that area is the result of an infinite, decreasing process. For example:<br><br>Carmen: *So, ok eventually the area gets to zero, but that's if you could do it infinitely many times. And if you actually* | <u>Infinite increasing process</u><br>All 10 students conceived of the perimeter of the ST as the result of an infinite increasing process. Elise's reasoning is typical of this thinking:<br><br>Elise: *You're just like forever adding length to your perimeter, so I feel like your perimeter is forever increasing.* |

| | |
|---|---|
| *conceptualize doing infinitely many times you're never gonna stop.* | |
| Area removed at each step<br>All students except Curtis there was explicit use of the justification that area is removed at each step. Two students computed the first few steps during their interviews.<br><br>Kay: *We're always taking out the middle triangle of each equilateral triangles and we're doing that infinitely so it's like we're taking away area with each iteration.* | Perimeter is added at each step<br>All students except Curtis also pointed to the fact that perimeter is added at each step. Four students accompanied this with computation for the first few iterations.<br><br>Joy: *I think it goes towards infinity because each iteration you're creating more triangles and so you're creating, you're adding to the perimeter.* |
| Change in the rate of change<br>Shani and Kay, who were in the same group, were the only two students who concluded that the area tended to something non-zero. They were also the only two who shared what we refer to as the change in the rate of change for area element, as exemplified in this excerpt.<br><br>Shani: *As we keep taking off little pieces and more become white, it's getting smaller and smaller. Or the amount that it's increasing is getting smaller and smaller and smaller.* | Change in the rate of change<br>Two other students, Elise and Carmen, gave some consideration to the rate at which the perimeter increases and to changes in this rate. For example, Elise argued that<br><br>Elise: *Every time after the first iteration I'm adding more perimeter than I added before. So if I keep adding more then I think it's going to keep going to infinity because I'm just going to keep adding bigger and bigger.* |

**Discussion**. Other reasoning about area and perimeter included reasoning multiplicatively, reasoning about congruent figures, reasoning with geometric series and associated convergence or divergence criteria, and thinking of the ST being composed of leftover or removed pieces. Students primarily made sense of the area and perimeter of the ST as infinite iterative processes. This is not surprising given the construction process students were introduced to in class. What *did* surprise is the fact that, except for Curtis, students used informal additive reasoning to reach their conclusions. The few students who did some computations did so only for the first few iterations and did not generalize the adding of perimeter or removal of area into algebraic expressions from which to take limits. While some students used limit language or referred to convergence criteria, it was not done concretely, despite their mathematics experience.

Given students' informal ways of reasoning, the parallelism between area and perimeter ideas is noteworthy. Each element of reasoning about area had a corresponding element of reasoning about perimeter. While some of these ideas were common (infinite processes, adding area, removing perimeter), others were not. In several cases students' idiosyncratic ways of thinking were consistent within students across area and perimeter. Despite the idiosyncrasies, there was quite a lot of consistency in ways of reasoning across students, both with respect to area and with respect to perimeter.

**Blending Area and Perimeter (Research Question 2)**

One element appears in every student's blended space which did not appear in the area/perimeter section: *infinite creation process*. This element is a result of fusion, wherein two input space elements (here, infinite increasing and infinite decreasing) are projected onto one element. As students were introduced to the ST as something created through an iterative, recursive process affecting both area and perimeter, in a sense the students are re-fusing elements which they originally separated. To organize these ideas, a three-part diagram is used: rectangles represent mental spaces, with the upper rectangles representing the input mental spaces and the lower rectangle representing the blended mental space, and the lines show mappings between the spaces. Due to space constraints, we present only four students and two blending diagrams.

**Joy.** We gained access to Joy's blending process primarily through her response to Fred's argument. Her blended space was composed of the infinite process of creating the Sierpinski Triangle, the area tending to zero, and perimeter tending to infinity. Completion brought into the blended space a metaphor of *perimeter as fence*, along with several entailments. One such entailment is that fences should remain, even if the space they enclose is no longer there. Part of Joy's elaboration based on this frame, as she worked to resolve Fred's paradox, was to say that "we don't count their space, but there is still a perimeter associated with it." Another entailment of the fence framing is that not only do fences have length, but they also take up space. This contributed to another element of Joy's elaboration, that the perimeter will fill in the Sierpinski Triangle, "so eventually in a sense it's all fence." Some parts of Joy's elaboration are grounded in a physical metaphor, and she recognizes this when responding to Fred. She adds to her elaboration that the Sierpinski Triangle is "not a real object," and identifies the juxtaposition of an infinite mathematical process with the physical world as "where the disconnect is."

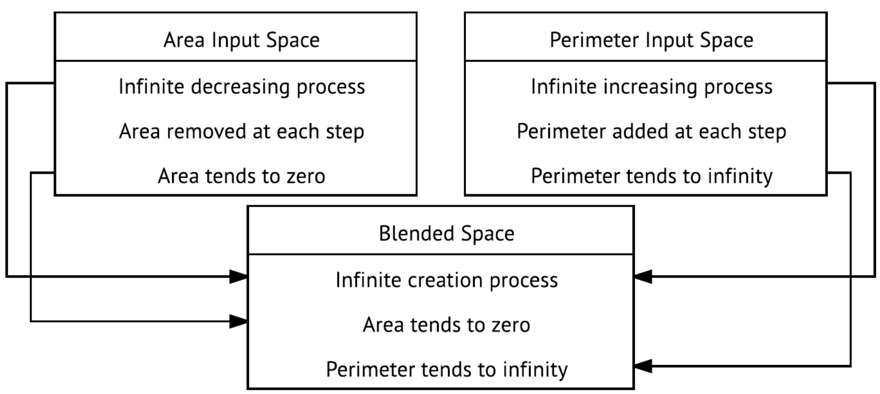

*Figure 2. Blending diagram for Joy's reasoning*

**Elise.** Like Joy, Elise's blended space is composed of the infinite process of creation for the ST, perimeter tending to infinity, and area tending to zero. However, the framing metaphor that completes Elise's space is one of a skeleton, not a fence. She elaborated her blend, saying, "I'm thinking of our perimeter as like, like I guess I think at the end of this I have this skeleton, so I have no area, nothing is left inside" This skeleton metaphor brings with it entailments of bones remaining when flesh has gone, clearly mapping perimeter to bones and area to flesh. In addition, we note that Elise mentions "at the end" in her elaboration, perhaps hinting that she sees the ST as an abstract object at the end of a generating process.

**Curtis.** As with Elise and Joy, Curtis's blended space is composed of an infinite creation process, perimeter tending to infinity, and area tending to zero. Unique to his blended space, however, is his formal, multiplicative formulation of area and perimeter as the limits of infinite sequences. The completion process brings in a zooming frame, saying, "we could say you could zoom in for infinitely, as much as you want, and you could get like these as tiny and tiny as you want, there's still more perimeter to draw" when prompted with Fred's paradox. The second frame we see Curtis leverage is one related to mathematics classes (e.g., Calculus, Analysis) where symbolic manipulations are sufficient. Evidence of this comes from the fact that Curtis did not encounter a paradox when considering an object with zero area and an infinite perimeter on his own, something he elaborated by saying "this isn't like, not physically drawing something like a perimeter, it's kind of just a concept."

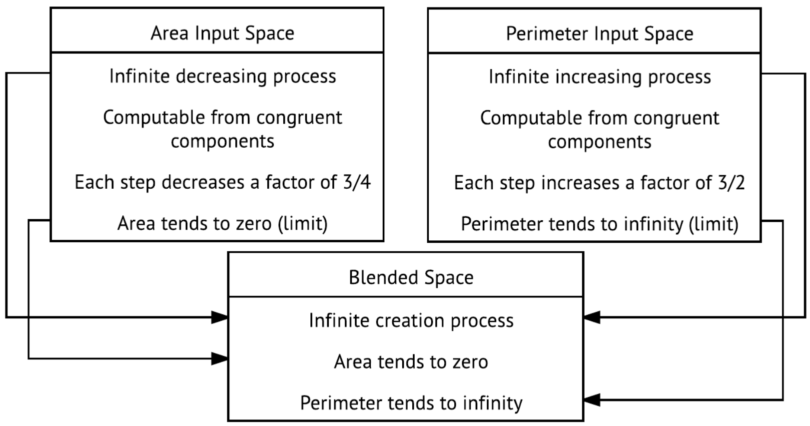

*Figure 3. Blending diagram for Curtis's reasoning*

**Carmen.** Carmen's blended space is, like several others', composed of an infinite process of creation, area tending to zero, and perimeter tending to infinity. The completion of her blend, however, is particularly distinct. She brings in a calculus frame and identifies "analogies to calculus or real analysis," including Riemann sums, that she sees as similar to Fred's paradox. The "calculus arguments" that she references seem to imply, to Carmen, that Fred's paradox is like other paradoxical situations that she has seen in previous mathematics courses. Upon reading Fred's arguments during the interview, Carmen stops to query whether "the perimeter can't really be infinitely long" implies zero perimeter or some non-zero finite length (for Fred). She proceeds to resolve the dilemma by eliminating each, leaving only the possibility that the perimeter is indeed infinite and Fred is wrong. During this episode, two more frames appear. Like Joy, she brings in a fence metaphor for the perimeter and the entailment that fencing should remain, but does not use the idea that fences take up space. Her elaboration using the fence frame, "you have sort of your old triangle fences that you had before [...] we still have this fence around, that big triangle and the center, and we still have those other ones we made before," is how she argues that the perimeter of the ST cannot be zero. Finally, she brings the frame of self-similarity, with the entailment that "we can keep zooming in." The elaboration using this frame is that the perimeter cannot be a finite value, which she explains using a contradiction. Carmen says "I think if we could [stop] then you could say ok it's this number," but the zooming goes on forever, "so that's kind of why it can't be a number."

**Discussion**. Our analysis of students' blending processes, especially as provoked by encountering Fred's argument, revealed how students deal with the paradox of coordinating infinite perimeter and zero area associated with the ST, and how they cope with, or resolve, the cognitive dissonance it provokes. It was sometimes challenging to unpack and distinguish the completion and elaboration processes. We attribute this difficulty in part to the fact that this was the second opportunity in which the students were prompted by Fred's paradox.

All students *composed* a blended space from their area and perimeter input spaces following Fred's prompt, and most of them also *completed* their blended space with additional frames, which then supported *elaboration* of the blend - leading to new implications. In two students' interviews we saw evidence of completion but not elaboration; only for one student we do not have evidence of completion. We saw one commonality across all students' composition processes: the fusion of *infinite (increasing) process* and *infinite (decreasing) process* into a unified *infinite creation process* for the stepwise creation of the ST. This is not to say that there was a shared conception of exactly what happens at each step, only that the process is infinite.

For all but one student, we have evidence of 1-3 distinct frames being used to complete their blended spaces. In all the cases, one of the frames has to do with the nature of mathematics – e.g., the nature of infinite processes. However, four students also used physical frames (fence, skeleton, zooming-in) and their entailments to coordinate area and perimeter and to make sense of that coordination.

## Conclusion

As the 10 students we interviewed were in the same graduate program, part of the same class, had worked together and discussed the Sierpinski Triangle (and, essentially, Fred's argument), we expected to see a certain level of consistency in their responses. However, this was not entirely the case, as seen at every stage of our analysis. To be sure, some ideas about the nature of the infinite iterative process were present in all interviews. But while in class students seemed comfortable with the idea that the area of the ST goes to zero, and concerned about what happens to the perimeter, *all* students' input spaces for perimeter included that it was infinite, and only six of the ten spaces included area going to zero. There were other idiosyncratic elements present in students' input spaces such as Curtis's multiplicative reasoning. There were also idiosyncrasies in terms of the composition of blended spaces. Some students completed their blends with ideas from calculus or analysis, fractal dimension, and metaphors. These frames resulted in varied elaborations. Some related to the nature of the ST, such as "it's not a real object", its non-integer dimension, or that is only the remaining outline; others framed the nature of the paradox itself.

More generally, our analysis methods allow us to point to some of the precise points of departure, from initial ideas to completing frames and final elaborations, one of the methodological implications of our work for future researchers. Along with Zandieh et al. (2014), our articulation of the component process of conceptual blending in a mathematical context allow for nuanced analysis of students' reasoning – though they looked at group blends and types of blends, while we look at more individualistic reasoning. This is particularly relevant for situations where students must bring together multiple ideas. Identifying all three processes - composition, completion, and elaboration - allows us to examine not only the main ideas students mention, but how they are used and enacted, or what leverage they give students in thinking about mathematical objects. This is in contrast to other lenses which make claims about the level of students' understanding, the extent to which their ideas are normative, or the conceptual structures that they might "possess." We are particularly impressed with the analytic power of the completion process, allowing us to articulate the tools by which students elaborate their blends. Thus, our analyses lie fully within the domain of enacting ideas.

Themes in Undergraduate Students' Conceptions of Central Angle and Inscribed Angle

Biyao Liang
University of Georgia

Carlos Castillo-Garsow
Eastern Washington University

*Researchers have investigated students' multifaceted conceptions of angle and their difficulties with connecting angle measure to arcs or circles. In this study, we investigated three undergraduate students' thinking about angles in the context of circle geometry, specifically their conceptions of central and inscribed angle. Conceptual analysis of the data revealed that students involved in the tasks and interviews had various conceptions of these angles that either supported or constrained their ability to complete the tasks. Particularly, conceiving the dynamic transformation of both central and inscribed angles, or identifying their common subtended arc was productive, while considering angle as area or ray pair constrained their thinking.*

*Keywords:* Student Thinking, Angle Conception, Geometry, Preservice Secondary Teachers

The Common Core State Standards for Mathematics (CCSSI, 2010) covers angle content in Grade 2 through High School, starting from identification of angles in planar shapes to angles in trigonometry. These topics highlight the complexity and variety of angle meanings in school mathematics, including angles as "geometric shapes that are formed wherever two rays share a common endpoint," angle measure with reference to a fraction of a circle, angle measure as a turn, and the relationships between central, inscribed, and circumscribed angle (ibid).

Despite the efforts studying students' understandings of angle (Keiser, Klee, & Fitch, 2003; Mitchelmore & White, 1998; Moore, 2013), little attention in mathematics educational research has been given to students' conceptions of angle involved in circle geometry. In the present study, we attempt to gain insights into students' understandings of angle by exploring three undergraduate students' ways of reasoning as they are asked to identify a central angle corresponding to a given inscribed angle in a circle. We illustrate the students' multiple conceptions of angle and how their different ways of thinking affect their ability to identify a corresponding central angle. We conclude by discussing what approaches potentially promote students' understandings of the relationship between central and inscribed angle and instructional implications.

## Background and Motivation

Researchers have discussed how mathematicians in history (Keiser, 2004; Matos, 1990, 1991) and students and teachers (Clements & Battista, 1989; Keiser et al., 2003; Krainer, 1993; Mitchelmore & White, 1998) conceptualized angle concept. There are three viewpoints of angle that occur repeatedly in this literature: (1) angle as ray pair, (2) angle as region, and (3) angle as turn.

Students who conceive angle as ray pair construct an image of angle formed by two rays meeting at a common vertex. Mitchelmore and White (1998) indicated nearly forty-five percent Grade 4 children's responses of their angle definitions reflected they conceptualized angle in a way similar to this. Some third-grade and sixth-grade students' definitions of angle included: "an angle is where two vertices meet and make a point," or "[i]t's when two lines meet each other and they come from two different ways" (Clements & Battista, 1989; Keiser et al., 2003). Students who conceive angle as region consider an angle as a space bounded a ray pair. In this construction, a ray pair will contain two angles (large and small) instead of being one angle itself

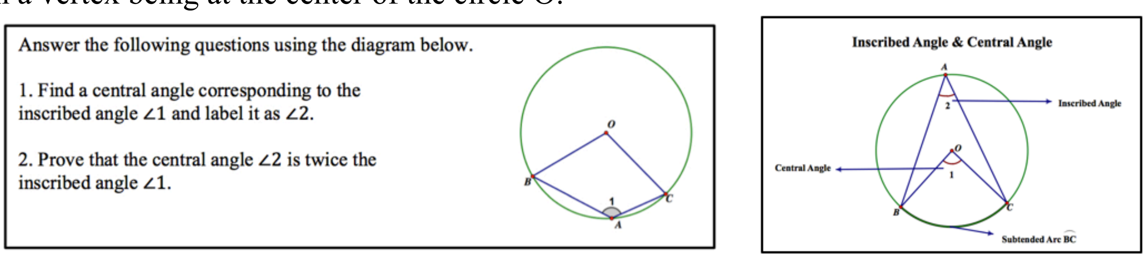
(Krainer, 1993). Fifteen percent of the four-graders' in Mitchelmore and White's (1998) study defined angle as an area. Students who conceptualize angle as turn or opening consider an angle as being formed by a dynamic rotation of one ray from another or angle as describing such rotation. Mitchelmore and White (1998) indicated only 4 out of 36 elementary students interviewed defined angle as turning. Clements and Battista (1989) suggested third graders who had Logo experience were more likely to define angle as a certain amount of rotation. Some children in this study defined angle as "something that turns, different ways to turn," or "when you turn some degrees" (Clements & Battista, 1989).

Noticing that researchers of most of these studies have focused on elementary students' *concept definitions* (i.e., words used to specify a concept) of angle, we consider it necessary to draw attention to their *concept images* (i.e., the total cognitive structure that is associated with a concept, which includes all the developing mental pictures and associated properties (Tall & Vinner, 1981; Vinner, 1991)). The focus of our study is to identify these concept images of angle. Specifically, given the paucity of research on undergraduate and/or teachers' conceptions of angle, our study aims at answering two research questions:

1. What are undergraduate pre-service teachers' concept images of central and inscribed angle in the context of circle geometry?
2. In what ways do these conceptions support and/or constrain their ability to solve circle geometry tasks?

## Methods

We investigated the mathematical thinking of nine undergraduate students majoring in secondary math education from a large public university in the United States. The study consisted of three tasks: a pre-test, a reading task, and a post-test followed by a short interview. Each student completed the series of tasks individually. In the pre-/post-test, students were asked to complete a proof (Figure 1a) with the help of a handout that included a graphical definition of central and inscribed angle (Figure 1b). The normative solution of Question 1 is the reflex angle with a vertex being at the center of the circle O.



(a) (b)

*Figure 1. (a) Pre-/post-test problem, (b) Inscribed and central angle definition handout.*

After finishing the pre-test, they worked on the reading task set up on a computer. We designed two sets of presentations for this task (i.e., Static and Dynamic), and randomly assigned students to them. The Static presentation demonstrated the proof of the Inscribed Angle Theorem in three different cases and the supporting diagram of each case is static (see Figure 2a-c). The Dynamic presentation contained a dynamic diagram with a slider (see Figure 2a-d) The slider allowed students to move the Point C along the circle so that infinite cases could be seen. Meanwhile, the proofs would appear to the right of the figure depending on which static case the current state of the diagram belonged to. The fourth static case: to be tested in the post-test, was omitted from the static presentation and left blank in the dynamic presentation (Figure 2d).

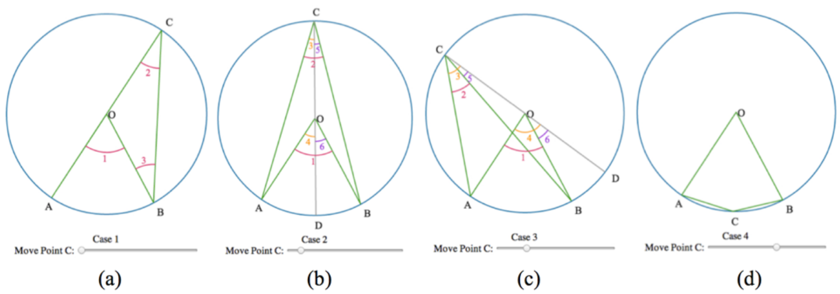


*Figure 2. Snapshots for the four cases in the Dynamic presentation. The Static presentation included Case 1-3 without the slider.*

After the post-test, each student participated in a clinical interview (Clement, 2000) to reflect on their thinking of the three tasks. We audiotaped all interviews and digitized students' written work. The process of how students drew the diagrams and thought aloud was also recorded with a Smart Pen throughout the study. Upon completion of data collection, we transcribed the interviews and incorporated figures and annotations.

In data analysis, we conducted conceptual analysis of an individual (Thompson, 2008) in order to develop models of a student's mathematical thinking. As researchers, although we cannot have access to students' minds, it is possible for us to make inferences about their mathematical thinking in ways that are consistent with our interpretations of their talking and observable actions. Both ongoing and retrospective analysis involved constructing conceptual models of pre-service teachers' meanings of central and inscribed angle. Using the observed conclusions about central and inscribed angle the students reached, we constructed hypothetical mental operations that would viably justify those conclusions that comprised these models.

Due to space constraints, we only report the reasoning of three of the nine students: Joanna (Static group), Hayley (Static group), and Jack (Dynamic group). We choose these three students because their stories establish the existence of highly varied understandings of angle among undergraduate pre-service teachers and the mathematical consequences of those understandings.

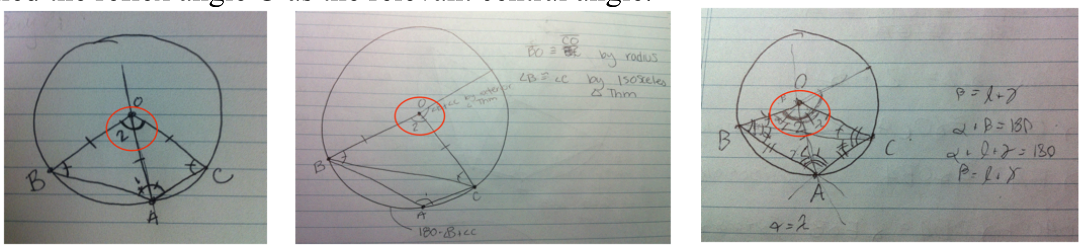
## Results

We organize the three students' conceptions of central and inscribed angle into five themes (Table 1) and describe how these conceptions influence their ability to identify a central angle.

*Table 1. Themes in students' conceptions of central and inscribed angle.*

| Theme | Theme Description | Students |
|---|---|---|
| Outside-Inside | A student considers an inscribed angle as being inside an area bounded by a quadrilateral (within a circle) while a central angle as being outside the same quadrilateral. | Joanna |
| Angle Size as Area | A student considers the openness (as area) of a central angle should be bigger than that of an inscribed angle. | Joanna |
| Angle as Ray Pair | A student considers a central angle as the minor angle constructed by two radii meeting at the center of a circle. | Hayley |
| Shared Arc | A student considers an inscribed angle and a central angle should share a subtended arc. | Hayley |
| Oriented Angle Rotation | A student considers the orientation of an angle as starting from one ray and ending on the other; the orientation of central and inscribed angle should be consistent. | Jack |

In the pre-test, all the three students identified the smaller (obtuse) measure of angle O as the angle measure relevant to Question 1 (see "∠2" in Figure 3a-c). In this section, we will report our analysis of the post-test and interviews, where the three students changed their minds and identified the reflex angle O as the relevant central angle.



(a) (b) (c)

*Figure 3. Diagrams produced by (a) Joanna, (b) Hayley, and (c) Jack during the pre-test.*

**Outside-Inside: Joanna**

When working on the post-test problem, Joanna first realized that the central angle she labeled in the pre-test might be incorrect:

*Joanna*: …But that ["∠2" in Figure 3a] was not the central angle so then I didn't know what to do. So then I got a little bit confused.

*Int*: So you have discovered that this is not the central angle?

*Joanna*: Yeah, I figured it out, because…well because one has to be outside, one has to be inside. And they are both inside, so then I figured out that can't be right…

Joanna claimed that, for the central angle and the inscribed angle, "one has to be outside, one has to be inside." By comparing her own drawing (Figure 3a) and the figure in the handout (Figure 1b), Joanna realized that the central angle she labeled was incorrect, since she thought the area bounded by the correct central angle should not be also "inside" the quadrilateral ABOC. Joanna's "outside-inside" conception can be thought of as relative to the area of the quadrilateral in the circle (see the quadrilateral shaded in orange in Figure 4), with the central angle being outside and inscribed angle inside. We infer that she was conceiving angle as area and the relative positions of the angle-areas of central and inscribed angle. Eventually, Joanna changed her solution and labeled the reflex angle as the central angle.

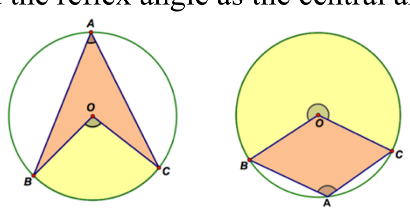


*Figure 4. Interpretation of Joanna's "outside-inside"conception of central and instribed angle.*

**Angle Size as Area: Joanna**

Although Joanna correctly (from our perspective) chose a central angle, she was uncertain about whether the angle was correct, saying "I figured it out but I don't know whether that was right, because I don't think it is." She thought the angle she labeled could not be right because "it was like the way too big to be a central angle, I don't think that's a central angle". Joanna had difficulty with conceiving an angle that is greater than 180°. As Joanna was conceiving angle-areas, here we inferred, Joanna's "too big" (the size of angle) probably referred to the measure of the openness of angles as the areas enclosed by the angles. The reflex nature of the angle might have made it appear to Joanna that the angle was enclosed by the area, rather than the reverse.

Later, she provided an explanation of what confirmed her choice of that central angle. She claimed that the openness of a central angle should "be like…really big" and that it "might be even bigger" than the given obtuse inscribed angle. This idea – a consequence of the theorem she was trying to prove – gave her enough confidence with her selection of central angle to finish the task.

Collectively, Joanna was reasoning with the position (i.e., her "outside-inside" approach) and the size of the angle-areas (i.e. "might be even bigger"). We consider her conception of angle as area in general as the fundamental reasons for her uncertainty about the correctness of her central angle. She continued to use hedge-words in the interview, and despite her success of providing a proof of the Inscribed Angle Theorem, she was not convinced that she had found a correct central angle.

**Angle as Ray Pair: Hayley**

In the interview, we started with asking Hayley about her reasoning in the pre-test:

*Int:* How do you think about this problem? Where did you get stuck?

*Hayley*: Umm…the arc part, like finding the first angle…this was the central angle ["∠2" in Figure 3b], right?

*Int*: What do you think is a central angle?

*Hayley*: The central angle would be in the middle of the circle [moving her hands along the two rays towards the center] cause this is the center, so that's why I put that this "O" is the central angle.

Hayley was describing a central angle as an angle constructed by two radii meeting at the center of a circle. She only conceived of the two radii BO and CO as constructing a single minor angle. Hence, she could only build a correspondence from this singular angle to the subtended minor arc BC and considered angle "O" to have exactly one measure.

Hayley also had a difficulty building a correspondence between central and inscribed angles, instead looking at each angle individually:

*Int*: Do you think going through these three cases would help you identify the central angle?

*Hayley*: I don't know because it is in the same spot. In all those and they are always the same angle in all them ["∠1" in Figure 2a-c]…because they are the same angle, so…yeah, I don't think that will be helpful.

Her awareness of the invariance of the angle location (i.e., "in the same spot") across cases suggested that she was considering the location of a central angle was absolute rather than relative to the inscribed angle. Due to the central angles of the first three cases being less than 180 degrees and thus fitting into her minor angle conception, the presentation was not helpful for Haley to change her previously identified central angle to the reflex angle, and thus she went with the same central angle as a solution for the post-test.

**Shared Arc: Hayley**

Haley's difficulty stemmed from her approach of first identifying a central angle and identifying the arc corresponding to that angle. In the subsequent interview, the interviewer instructed her to instead identify the subtended arc of an inscribed angle first, and then to find the corresponding central angle of that arc. The interviewer and Hayley went through all the three cases using this approach to identify corresponding central angles with given inscribed angles. When Hayley looked at the post-test problem again, she identified the correct central angle for the first time by making use of the shared subtended arc of the central and inscribed angle.

## Oriented Angle Rotation: Jack

In the interview, Jack talked about how he identified the correct central angle by interacting with the dynamic diagrams in the reading task. When looking at the presentation, Jack carefully tracked the angles as the point C moved along the circle and paid particular attention to the transition between Case 3 (Figure 2c) and Case 4 (Figure 2d). He interpreted this process as "take[ing] a limit," by which he meant he was trying to exhaust all the details in between Case 3 and Case 4 to carefully observe how the angles changed and how they were "opened up" differently in this process. He later explained what changed between Case 3 and Case 4 in terms of the angles that made him refined his original choice of the central angle:

> "… you like keep track of the angles as they move because you can see here [Figure 2c], you know these angles stay the same, the same, but they just flipped over [Figure 2d], so you can just sort of generalize it."

Jack was interpreting when Point C went through Point A (from Case 3 to Case 4), the inscribed angle changed its orientation ("flipped over"; Figure 5). Jack may have imagined one ray to be the starting ray (AC), and the other ray to be the ending ray (BC). So as the orientation of the angle flipped (Figure 5; left to right), the direction of rotation also changed (counter clockwise to clockwise). Therefore, the original central angle AOB constructed by AO as the starting ray and BO as the ending ray should also change to the reflex angle AOB constructed by the same starting and ending rays but rotating from a clockwise orientation instead. Another interpretation of Jack's "flipped over" is that before C passes A, the inscribed angle ACB is constructed by AC on the angle's left and BC on the right (facing into angle C from the bottom of circle). After C passes A, the angle is constructed by BC on the angle's left and AC on the right (facing into angle C from the top of circle). So an inscribed angle and its "flipped" angle were orientationally different, and thus the original central angle AOB should also "flip" to its reflex angle with BO on the left and AO on the right (viewing angle C from the top of circle). Both interpretations lead to the same mathematical conclusion, so we consider them equivalent.

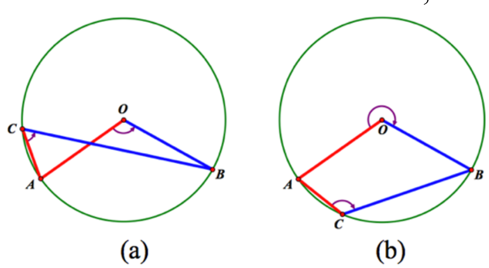

*Figure 5. Interpretation of "Jack"'s "flipped over" as the orientation of an angle changing from (a) counter clockwise to (b) clockwise rotation of one ray from another.*

## Conclusions

The results of our study indicate that, regardless of angle contexts or grade levels, students' understandings of angle as ray pair (i.e., Hayley), angle as rotation (i.e., Jack), and angle as area (i.e., Joanna) persist from elementary students (Clements & Battista, 1989; Foxman & Ruddock, 1984; Keiser et al., 2003; Mitchelmore & White, 1998) to late undergraduates. That these undergraduates' conceptions of angle are similar to the definitions elementary students learn in school should not be surprising. What should be considered significant, however, is the impoverished nature of these images. These advanced undergraduates, many of whom will become mathematics teachers, do not have understandings of angle that have advanced very far beyond ray-pair, rotation, and area. Consequently, all the students struggle to track a changing inscribed angle and thus have difficulties in finding its corresponding central angle.

Although there is a very large body of work on identifying student definitions of angle (e.g., Keiser et al., 2003; Mitchelmore & White, 1998), there has been little work done on identifying students' concept images of angle *and* the mathematical consequences of these images. We have not merely identified Joanna as having an area-meaning, Haley as having a ray-pair-meaning, and Jack as having an orientation-meaning (possibly a rotation-meaning) of angle. We have also shown that these meanings directly cause the students' struggles and successes. Joanna, who conceived angle measure as area had difficulties with conceiving angles greater than 180° since these angles are "too big" to enclose an area. Additionally, her "outside-inside" approach is too specific to the particular situation to be a generalizable understanding of angle. It will easily fail in the situations where no reference objects or shapes (i.e., the closed figure: the quadrilateral) can be identified, or where it is necessary to conceive of a single angle that changes between "inside" and "outside" among cases. The case of Hayley suggested that students who had a ray-pair conception may not inherently or easily conceive of the structure of two segments as having two measures, and therefore constructing two angles. Only perceiving the minor angle constructed by two segments potentially results in students' difficulties with conceiving angles of 0°, 180°, 360°, and larger than 360° (Keiser, 2004). Fortunately, Haley's conception of angle measure as arc provided her a foundation to perceive the shared subtended arc, which was critical in her success. Finally, Jack's image of an angle as having an orientation (or a rotation) supported him to correctly keep track of the inscribed angle in the dynamic situation.

Contributing to the previous work on classification of students' angle conceptions (Clements & Battista, 1989; Keiser et al., 2003; Krainer, 1993), these three students' profiles indicate how the multiple meanings of individual students can interact. Their concept images of angle may not simply be "angles are areas" or "angles are arcs." For instance, Haley's difficulty with perceiving the major arc is generated by the complex combination of angle as a ray pair and angle as arc (i.e., one ray pair only corresponds to one angle measured by one arc).

Lastly, our findings highlight the need for supporting student understandings of angle in the context of circle and arc. The presence of the circle context of the tasks did not inherently lead the students to incorporate circles and arcs into their identification of central angle. Ultimately making use of the circle context was critical to the success of both Hayley (who found a common subtended arc) and Jack (who imagined the angle orientation changing as the vertex moved around the circle). Despite our attempt to assist Joanna to identify the subtended arc shared by an inscribed and central angle, she did not consider this approach as useful since she did not imagine the arc of a circle as having a role in angle measure. We hypothesize that if these students had an image of angle measure as arc (Moore, 2013), they would be more comfortable with relating central and inscribed angles using their shared arcs.

In order for teachers and researchers to be better able to recognize, explain, and respond to student thinking, and identify ways to assist them, we need to further explore their various conceptions of angle and angle measure, attend to the nuances of student thinking and its mathematical consequences, and be sensitive to the students' awareness (or lack of awareness) of the relationships between ray-pair, area, angle measure, circle, and arc.

*Acknowledgements*: The research reported in this paper was supported by Q-Center at Kansas State University. Our deepest gratitude first goes to Dr. Andrew Bennett for his unwavering support and considerable guidance and help throughout the study. We would like to thank all the Q-Center members who were involved in the preparation, discussion, and suggestion for this study. We would also like to thank the students whose participation made this study possible.

# Developing Proof Comprehension and Proof by Contradiction Through Logical Outlines

Darryl Chamberlain Jr.
University of Florida

Draga Vidakovic
Georgia State University

*Proof is central to the curriculum for undergraduate mathematics majors. Despite transition-to-proof courses designed to facilitate the shift from computation-based mathematics to proof-based mathematics, students continue to struggle with mathematical proof. In particular, there are few tasks beyond writing proofs that are specifically designed to develop students' understanding of the proofs they read and the proof methods they utilize. The purpose of this paper is to introduce and discuss the merits of two such tasks: constructing and comparing logical outlines of presented proofs. Grounded in APOS Theory, this paper will illustrate a case study that suggests students can improve their understanding of the proofs they read as well as a particular proof method - proof by contradiction – through these two tasks.*

*Key words:* Proof Comprehension, Proof by Contradiction, Transition-to-proof course, APOS Theory

Proof is central to the curriculum for undergraduate mathematics majors. Despite transition-to-proof courses designed to facilitate the shift from computation-based mathematics to proof-based mathematics, students continue to struggle with mathematical proof (Samkoff & Weber, 2015). Instructors of these courses have stressed that students' ability to understand the proofs they read (*proof comprehension*) is of utmost importance and yet, there are few tasks beyond writing a complete or partial proof of some statement that are designed to improve students' proof comprehension. In short, writing proofs have been the primary tasks used to assess students' understanding of the proofs they read. Noting this, Mejía-Ramos et al. (2012) developed a proof comprehension assessment model that split students' understanding of the proofs they read into two categories: local and holistic. *Local* types of assessment focused on one, or a small number, of statements within a proof whereas *holistic* types of assessment focused on students' understanding of a proof as a whole. Utilizing this assessment model, two groups of researchers developed teaching experiments aimed at improving students' proof comprehension. A brief description of their design and results follows.

Samkoff and Weber (2015) developed a teaching experiment to assess whether certain proof-reading strategies, identified in Weber and Samkoff (2011) and aligned with the previously mentioned proof comprehension assessment model, would aid student understanding. They found that: (1) specific prescriptive guidance helped students implement the strategies more effectively, (2) these strategies were beneficial to students, and (3) that there were impediments to proof comprehension that could not be addressed by these strategies (Samkoff & Weber, 2015). These results suggest that while the proof comprehension model by Mejía-Ramos et al. (2012) may assess student understanding of proof, it cannot, alone, be used as a pedagogical tool to develop instruction for a transition-to-proof course.

Hodds, Alcock, and Inglis (2014) developed a booklet containing self-explanation training focused on the logical relationships within a mathematical proof. Through a series of three experiments, they found that: (1) students who received the self-explanation training scored higher on a comprehension test, (2) self-explanation training increased cognitive engagement with a proof, and (3) a short self-explanation training session within a lecture improved students' proof comprehension and that this comprehension persisted over time (Hodds et al., 2014). These results suggest that focusing on the logical relationships within a mathematical proof can improve students' proof comprehension.

To contribute to the paucity of tasks designed to improve proof comprehension, the authors of this study first utilized APOS Theory to model how students may come to understand the proofs they read and, by extension, how they come to understand a particular proof method: proof by contradiction. These models were then used as a guide to address the following research question:

> *Can outlining given proofs and comparing these outlines enhance students' proof comprehension and overall conception of proof by contradiction?*

The following section briefly describes APOS Theory and the preliminary cognitive model we developed for proof by contradiction to address this research question.

## APOS Theory

APOS Theory is a cognitive framework that considers mathematical concepts to be composed of mental Actions, Processes, and Objects that are organized into Schemas. An *Action* is a transformation of Objects by the individual requiring memorized or external, step-by-step instructions on how to perform the operation. As an individual reflects on an Action, he/she can think of these Actions in his/her head without the need to actually perform them based on some memorized facts or external guide; this is referred to as a *Process*. As an individual reflects on a Process, they may think of the Process as a totality and can now perform transformations on the Process; this totality is referred to as an *Object*. Finally, a *Schema* is an individual's collection of Actions, Processes, Objects, and other Schemas that are linked by some general principles to form a coherent framework in the individual's mind (Dubinsky & McDonald, 2001). Utilizing the mental constructs of Actions, Processes, Objects, and Schemas, an outline of the hypothetical constructions students may need to make in order to understand a concept can be developed, referred to as a *genetic decomposition* (Arnon et al., 2014). This genetic decomposition is then used as a foundation to develop instructional materials. A preliminary genetic decomposition for proof by contradiction is provided below.

### Preliminary Genetic Decomposition for Proof by Contradiction

1. Action conception of propositional or predicate logic statements as specific step-by-step instructions to construct proofs by contradiction for the following types of statements: (I) implication, (II) non-existence, and (III) uniqueness.
2. Interiorization of each Action in Step 1 individually as general steps to writing a proof by contradiction for statements of the form (I), (II), and (III).
3. Coordination of the Processes from Step 2 into developing a single Process of a proof by contradiction.
4. Encapsulate the Process in Step 3 as an Object by utilizing the law of excluded middle to show proof by contradiction is a valid proof method. Alternatively, encapsulate the Process in Step 3 as an Object by comparing the contradiction proof method to other proof methods.
5. De-encapsulate the Object in Step 4 into a Process similar to Step 3 that then coordinates with a Process conception of other proof methods to prove statements that require two or more proof methods.

In particular for APOS Theory, there is a focus on repeatable transformations that can be reflected on and subsequently generalized by the individual. For proof by contradiction, the repeatable transformation is logically outlining presented proofs (described in Step 1). That is, as students continue to read and reflect on the logical structure of presented proofs (and thus develop their proof comprehension), they can generalize their understanding of these example proofs to develop an internal conception for proof by contradiction based on the structure of the statement proved (described in Step 2). As students encounter different logical structures of proof by contradiction based on the structure of the statement to be proved, they can compare these specific logical structures to develop an internal, general conception for any type of proof by contradiction (described in Step 3). This report will focus on a single student's experience in dealing with tasks designed to induce the mental constructions described by Steps 1, 2, and 3 in the preliminary genetic decomposition. The following section will give an overview of the study's design and a description of the particular tasks this paper will focus on.

## Methodology

This report is situated in a larger research project on how students develop an understanding of proof by contradiction within a transition-to-proof course, *Bridge to Higher Mathematics*, at a public R1 university in the southeastern United States. To test the validity of the preliminary genetic decomposition, a five-session teaching experiment was developed and implemented in Fall 2016. These sessions were conducted primarily out-of-class and so the number of sessions a student participated in varied. Of the initial 27 participants, only two completed all five sessions.

This report will focus on two particular tasks developed as part of this teaching experiment: Outlining and Comparing. *Outlining* tasks asked students to logically outline a presented proof by contradiction. These tasks were included to prompt students to identify the logical argument within a presented proof by contradiction. *Comparing* tasks asked students to compare two or more logical outlines of presented proofs. These tasks were used as a reflection tool for students to consider the necessary logical lines of a general proof by contradiction and how these lines logically relate.

Data for this report consists of Yara's responses to these two tasks during the teaching experiment. Yara was a senior Mathematics major with a minor in Educational Psychology. Beyond the required prerequisite courses for *Bridge to Higher Mathematics,* she had already taken *Mathematical Statistics*, *Methods of Regression and Analysis of Variance*, *Foundations of Numbers and Operations*, and *Applied Combinatorics*. However, none of these courses required proof writing and thus *Bridge to Higher Mathematics* was her first experience with formal proofs. She completed all five sessions of the teaching episode. This report focuses on Yara as she was the most elaborative in her responses and provided the most data through which to analyze and support how her understanding of the proofs she read as well as her understanding of proof by contradiction evolved throughout the teaching experiment. The following section will describe how we analyzed her responses.

## Data Analysis and Results

All five of Yara's teaching episode sessions were video recorded and then transcribed. Transcripts of these five sessions with Yara were organized and subsequently analyzed using MAXQDA, a qualitative data analysis software. First, sections of the transcripts were grouped by task. Then, Yara's level of understanding proof by contradiction, according to APOS Theory, was analyzed per task. This analysis provided a tool to identify which task or tasks aided her in developing an understanding of the proof method. Due to space constraints, the rest of this section will provide examples from a subset of these sessions on how two tasks, *Outlining* and *Comparing*, aided Yara in developing both a deeper understanding of the proofs she read as well as a more robust understanding of proof by contradiction in general.

**Outlining Task**

As mentioned previously, *Outlining* tasks asked students to logically outline a presented proof by contradiction. For Outlining task 1, students were given propositional representation for the statement and the majority of lines in the proof. For Outlining task 2, students were given predicate representation for the statement only. Finally, for Outlining tasks 3, 4, and 5, students were not given any logical representation. During these tasks, students were encouraged to use either propositional or predicate symbols to outline the logical structure of the proof. Due to space limitations, this report will focus on Outlining task 3.

The presented proof (Figure 1) and Yara's response to Outlining task 3 (Figure 2) are presented below.

**Statement:** The equation $5x - 4 = 1$ has a unique solution.
**Proof:** Assume the equation $5x - 4 = 1$ does not have a unique solution. Then either there is no solution to the equation $5x - 4 = 1$ or there are at least two distinct solutions to the equation $5x - 4 = 1$. Note $x = 1$ is a solution of $5x - 4 = 1$. Thus there are at least two distinct solutions to the equation $5x - 4 = 1$, call them $y$ and $z$. As both $y$ and $z$ are solutions of the equation $5x - 4 = 1$, $5y - 4 = 1$ and $5z - 4 = 1$. Then $5y - 4 = 5z - 4$ and so $y = z$. Therefore it is not true that there are at least two distinct solutions to the equation $5x - 4 = 1$. This is a contradiction, as we assumed that either there is no solution to the equation $5x - 4 = 1$ or there are at least two distinct solutions to the equation $5x - 4 = 1$. Therefore it is not true that the equation $5x - 4 = 1$ does not have a unique solution. In other words, the equation $5x - 4 = 1$ does have a unique solution.

*Figure 1: Presented proof for Outlining task 3.*

| **Statement:** $\exists!\, x$ s.t. $P(x)$ |
|---|
| 1. Assume $\sim(\exists!\, x$ s.t. $P(x))$ |
| 2. $R \vee Q$ |
| 3. $\sim R$ |
| 4. $Q$ |
| 5. $5y - 4 = 1 \wedge 5z - 4 = 1$ (Algebra) |
| 6. More algebra ($y = z$) |
| 7. $\sim Q$ |
| 8. $\sim(R \vee Q)$ |
| 9. $\sim(\sim(\exists!\, x$ s.t. $P(x)))$ |
| 10. $\exists!\, x$ s.t. $P(x)$ |

*Figure 2: Yara's logical outline of the presented proof for Outlining task 3.*

Yara provided a desired representation of the statement as $(\exists!\, x)\big(P(x)\big)$ and first line of the outline as $\sim(\exists!\, x)(P(x))$. Then, she switched to propositional logic and initially represented the statement "then either there is no solution to the equation $5x - 4 = 1$ or there are at least two distinct solutions to the equation $5x - 4 = 1$" as $P \vee Q$. An excerpt of her thought process behind this representation is provided below.

*Yara*: And then *[long pause]* and then either there is no solution to the equation or there is at least 2 disinked, I mean, 2 distinct solutions to the equation $5x - 4 = 1$. *[pause]* So it would be the or? Like $P$ or $Q$?

*Teacher*: Alright. *[pause for writing]* $P$ or $Q$. So do these have any relation to the original one?

*Yara*: No?

*Teacher*: So if this one doesn't have a relation, then maybe we should call it something else. Like $R$ or $Q$.

*Yara*: Oh! To separate that $P$ from that $P(x)$.

Note that she saw the 'or' in the statement and immediately suggested the representation $P \lor Q$. After reflection, she clarified that this $P$ should be changed to separate it from $P(x)$. This suggests the cue word 'or' prompted the representation $P \lor Q$ as a standard representation for an 'or' statement. After teacher's prompting and suggestion to use a different notation, she realized that $P$ should be separate from the initial statement $P(x)$. This suggests that in her initial thinking, Yara automatically used $P \lor Q$, a standard notation for an 'or' statement, without considering the relationship of that statement to the previous statement. In terms of APOS Theory, this excerpt illustrates a possible Action conception of proof by contradiction in relationship to this particular task. However, analyzing further her proof outline, it appears that she is at a higher level of understanding. We illustrate this below.

Overall, her outline contained the two key steps of a proof by contradiction: assuming the negation of the statement is true (line 1) and arriving at a contradiction (line 8). In addition, she verbally described the logical argument of the proof and how lines in the proof related. For example, when she reached the contradiction line in the presented proof, she stated:

> Then... this is a contradiction as we assumed that there is either no solution to the equation $5x - 4 = 1$ or there are at least two distinct solutions to the equation $5x - 4 = 1$. So it would be $Q$ and not $Q$? Or would we not have to put that because we have it [$R \lor Q$]... It's already labeled out. [...] Okay, so then not... I was just trying to make sure I had it in my head right like, that [$R \lor Q$] would go into not $R$ and not $Q$.

Her first sentence quoted the line from the presented proof. She then immediately considered the representation $Q \land \sim Q$ - the standard representation of a contradiction. Representing a statement by focusing on cue words (i.e., contradiction means $Q \land \sim Q$) is indicative of an Action conception of proof by contradiction and suggests, as in the previous paragraph, that Yara did not attend to the logical relation between lines in the proof. However, she then recognized that she would not represent this particular contradiction with $Q \land \sim Q$ as she already represented part of this contradiction with $R \lor Q$. Indeed, her final comment "I was just trying to make sure I had it in my head right like, that [$\sim (R \lor Q)$] would go into not $R$ and not $Q$" suggests that she recognized the logical equivalence $\sim (R \lor Q) \equiv \sim R \land \sim Q$ and thus recognized that the contradiction $\sim (R \lor Q) \land (R \lor Q)$ was reached. That is, she recognized and verbally described the logical reasoning behind how a contradiction was reached in this particular proof, which is indicative of a Process conception of proof by contradiction. In addition, she generalized lines 5 and 6 in her outline as "algebra" and thus described the purpose of the algebraic manipulations in the overall argument. In other words, Yara was able to use the logical outline to describe the purpose of specific lines in the proof and thus exhibited local comprehension of the presented proof.

## Comparing Task

As mentioned previously, *Comparing* tasks asked students to compare two or more logical outlines of presented proofs. These logical outlines were provided by the teacher based on the Outlining tasks. For example, Table 1 illustrates the side-by-side logical outlines from Outlining tasks 1, 2, and 3 that were presented to students for Comparing task 2.

*Table 1: Side-by-side logical outlines from Outlining tasks 1, 2, and 3.*

| Outlining Task 1<br>**Statement:** $P \to Q$ | Outlining Task 2<br>**Statement:** $(\nexists x)(P(x))$ | Outlining Task 3<br>**Statement:** $(\exists!\, x)(P(x))$ |
|---|---|---|
| 1. Assume $\sim (P \to Q)$<br>2. $P \wedge \sim Q$<br>3. $\sim Q_k$<br>4. $(\sim Q_k \wedge P) \to Q_k$<br>5. $Q_k$<br>6. $Q_k \wedge \sim Q_k$<br>7. $\sim (\sim (P \to Q))$<br>8. $P \to Q$ | 1. Assume $\sim (\nexists x)(P(x))$<br>2. $(\exists x)(P(x))$<br>3. $P(n)$<br>4. Using $P(n)$, get to a contradiction.<br>5. $\sim (\sim (\nexists x)(P(x)))$<br>6. $(\nexists x)(P(x))$ | 1. Assume $\sim (\exists!\, x)(P(x))$<br>2. $\sim (\exists x)(P(x)) \vee (\exists x, y)(P(x) \wedge P(y) \wedge x \neq y)$<br>3. Show $P(n)$ for some $n$.<br>4. $(\exists x, y)(P(x) \wedge P(y) \wedge x \neq y)$<br>5. $P(x) \wedge P(y) \to x = y$<br>6. $(\nexists x, y)(P(x) \wedge P(y) \wedge x \neq y)$<br>7. $\to\leftarrow$ (lines 2, 3, and 6)<br>8. $\sim (\sim (\exists!\, x)(P(x)))$<br>9. $(\exists!\, x)(P(x))$ |

When prompted to compare the outlines in Table 1, Yara grouped lines together and described a general purpose for each group of lines (see Table 2).

*Table 2: Yara's general approach for Comparing tasks 1 and 2.*

| Comparing Task 1 | Comparing Task 2 |
|---|---|
| 1. Assume $\sim P$<br>2. Rewrite $\sim P$<br>3. Look at specific value of step 2.<br>4. Work (Algebra)<br>5. Get Contradiction<br>6. $\sim$ Assumption<br>7. $P$ | 1. Assume $\sim P$<br>2. Negate $P$ (Rewrite $\sim P$)<br>3. Use math skills to get to a contradiction.<br>4. $\sim$ Assumption<br>5. $P$ |

Yara's approach for proof by contradiction contained both the key steps of a proof by contradiction and descriptions of how these key steps are logically related (e.g., that lines 3 and 7 logically implied line 8). Comparing her general approach between Comparing tasks 1 and 2, we see the she condensed steps 3, 4, and 5 in task 1 into the single step “Use math skills to get to a contradiction.” Consider the following exchange as Yara compared the logical outlines from Outlining tasks 1 and 2.

*Yara*: So I guess it just, maybe it like, depends on the proof, and what you are trying to prove. Whether you do algebra or... umm...
*Teacher*: So what do we do in that one [*outline during Outlining task 2*]?
*Yara*: In this one, it says to use $P(x)$, get a contradiction. So we did algebra, right?
*Teacher*: Yeah, we did algebra that time as well.
*Yara*: So this one you do... which math skills do you use? Because math skills could mean plenty of things. It could be, like, one of them induction whatever…

From the above excerpt, it is clear that Yara's expression ‘math skills’ stands for ‘mathematical knowledge’ since it includes algebraic skills as well as other proof methods such as induction. Yara stated that the steps in the proof depend “... on the proof, and what you are trying to prove." Sometimes, these steps might mean performing some algebra while in the other situation it may mean using a different proof technique. We interpret this to mean that Yara has generalized the notion of a proof by contradiction and exhibited an Object conception of proof by contradiction. She obviously was able to think of these two proof outlines as two entities that could be compared, de-encapsulated each one of them into the processes they came from, and compared separate lines in each outline to distinguish their similarities and differences.

## Discussion

Both the Outlining and Comparing tasks enhanced Yara’s understanding of the presented proofs in addition to enhancing her understanding of proof by contradiction, as suggested by the preliminary genetic decomposition. These results suggest that the two tasks may be useful in developing transition-to-proof students’ proof comprehension as well as their understanding of particular proof methods as they provide a repeatable transformation (outlining the logical structure) that can be reflected on and subsequently generalized by the individual (through comparing logical outlines). While a robust implementation of tasks to transition-to-proof students at a variety of universities would be necessary to validate these tasks, we find these initial results to be encouraging.

## Implications for Teaching Practices

This report presented two non-traditional tasks that aided students in developing proof comprehension as well as a robust understanding of proof by contradiction. That is, outlining the logical argument of presented proofs by contradiction (Outlining tasks) and comparing these outlines in order to develop general steps for the proof method (Comparing tasks) differ from the traditional proof writing tasks of “definition-theorem-proof” format transition-to-proof courses (Weber, 2004). This is not to say instructors should abandon proof-writing tasks. Rather, we suggest that Outlining and Comparing tasks should be used in conjunction with traditional proof writing tasks to improve and assess a different aspect of proof: comprehension. The tasks introduced in this report join the tasks based on proof reading strategies by Samkoff and Weber (2015) and the self-explanation training tasks by Hodds et al. (2014) as some of the first tasks designed to improve students' proof comprehension.

Moreover, Outlining and Comparing are the first tasks designed to improve students’ comprehension of a particular proof method: proof by contradiction. This is critical as research suggests this method is difficult for students to construct and comprehend (Antonini & Mariotti, 2008; Brown, 2017). These tasks may also provide students a fundamental understanding of the proof method so that other validation tasks, such as critiquing sample proofs and proof editing, may be utilized to further improve on their conception of proof by contradiction.

Finally, these tasks are compatible with other Constructivist frameworks (e.g., Vygotsky’s Social Constructivism) and can be used to develop other proof methods (e.g., mathematical induction). Therefore, these two tasks can be used in any transition-to-proof course to develop students’ proof comprehension as well as their understanding of particular proof methods.

*In this article we discuss the Inquiry Oriented Instructional Measure (IOIM). The development of the IOIM was a multi-phase, iterative process that required analyzing current research literature and videos of classroom instruction and piloting the measure with both experts and novices. The process resulted in identifying multiple instructional practices that support the successful implementation of Inquiry-Oriented Instruction (IOI) at the undergraduate level, and creating a rubric for evaluating the degree to which one's classroom instruction is reflective of these practices. Our goals with this paper are to share the development process and elaborate on the rubric so as to contribute to the knowledge base regarding the implementation of IOI.*

*Keywords:* Inquiry-oriented instruction, Instructional measure, Teaching

Student-centered forms of instruction have been shown to have many positive outcomes for undergraduate mathematics students. Empirical studies demonstrate that Inquiry Based Learning (IBL) is a more equitable form of instruction and leads to greater affective and cognitive gains when compared to non-IBL teaching methods (Laursen, Hassi, Kogan & Weston, 2014; Kogan & Laursen, 2014). These outcomes directly align with the goals of recent calls for improving undergraduate STEM education. Ferreni-Mundy and Gucler (2009) noted all of the calls for reform in STEM education surrounded increasing student understanding of concepts, providing equitable access to students, and transitioning away from traditional teaching approaches to those that are student-centered and involve strategies that encourage active learning. With the push to increase the quality of STEM education, implementing such forms of instruction is important.

Instructional measures are one tool that can be used by various groups within the community to support the successful reform of undergraduate education. Researchers can utilize measures to assess the effects of instructional interventions, and practitioners can use measures to improve their instruction. In addition, measures can provide a vernacular and specific descriptions of instructional practices that promote instructional change. In this paper we begin with a brief discussion of a National Science Foundation funded project, *Teaching Inquiry-oriented Instruction: Establishing Supports* (TIMES). We outline the general design and provide a detailed account of the development of the inquiry-oriented instructional measure (IOIM), a measure for evaluating the degree to which a lesson consists of practices that reflect inquiry-oriented instruction (IOI).

## Background

This work stems from the TIMES project, the goal of which was to scale up inquiry-oriented curricular materials (including developing instructor materials) for Abstract Algebra (Larsen, Johnson, & Weber, 2013), Differential Equations (Rasmussen, 2007), and Linear Algebra (Wawro, Rasmussen, Zandieh & Andrews-Larson, 2015). These curricula are research based and have been continually refined over the past two decades to scaffold student reinvention of mathematical concepts. The grant led to widespread dissemination and implementation of the curricula by recruiting mathematics instructors from across the United States. These instructors participated in activities intended to support them in implementing instruction that aligned with the four underlying instructional principles of IOI (Kuster, Johnson, Keene & Andrews-Larsen, 2017). The IOIM was developed as part of this project to help evaluate the efficacy of the support activities.

Generally, evaluation tools used for research and practice serve specific purposes; purposes that align with the goals of the research being performed. Common observation protocols and instructional measures include the instructional quality assessment (IQA), the mathematics quality of instruction (MQI), and the reformed teaching observation protocol (RTOP). The IQA was developed with a focus on "opportunities for students to engage in cognitively challenging mathematical work and thinking" (Boston, Bostic, Lesseig & Sherman, 2015, p. 160) and revolves around assessment of cognitive demand (Boston, 2014). The MQI was developed to aid in drawing connections between teacher knowledge and classroom instruction (Hill et al., 2008) and focuses on evaluating the quality of the mathematics available to students during instruction. The main goal of the RTOP was to serve as a tool for pedagogical development aimed at improving instruction. The RTOP is designed to measure the degree to which classroom instruction is *reform-oriented* (Sawada et al., 2002). With regard to the TIMES project, we found that these tools and others like them did not fit the specific needs of the project, in that they failed to attend to the nature of IOI to the degree we needed. Our goal was to focus on the instructional practices in which the teacher engaged while in the classroom.

## Overview of the Inquiry-Oriented Instructional Measure

The IOIM is a rubric designed to provide quantitative and descriptive data concerning the enactment of the four main instructional principles of IOI: *generating student ways of reasoning, building on student contributions, developing a shared understanding, and connecting to standard mathematical language and notation* (Kuster et al., 2017). Broadly speaking these principles reflect three characteristics of the role of an IOI teacher: 1) inquiring into student mathematics, both in terms of individual students and in terms of the learning trajectory (Rasmussen & Kwon, 2007; Johnson & Larsen, 2012); 2) being an active participant with the developing mathematics, both in terms of the mathematics of the moment and in terms of the mathematical trajectory intended by the curricular materials (Johnson, 2013; Johnson & Larsen, 2013); and 3) bridging the gap between where the students are and the mathematical goals of the lesson (Wagner, Speer & Rossa, 2007; Speer & Wagner, 2009). The IOIM consists of a set of practices that support the enactment of each of the principles, and a rubric (shown at the end of this report) that measures the degree to which a lesson is inquiry-oriented by examining the quality of the enactment of these practices.

Each of the practices is scored on a 5 point likert-scale from low to high. Generally, within each of the practices, the quality of the mathematical activity promoted by the teacher is what distinguishes a low (1) from a high (5). Take for example Practice 2: teachers elicit student thinking and reasoning. If a teacher evokes solely procedural contributions from students, they score significantly lower (medium-low) than if they routinely have students share their thinking, reasoning and justifications (high).

## Development of the Inquiry-Oriented Instructional Measure

The measure was developed in five phases using data consisting of research literature, videos of classroom instruction from both expert and novice IOI instructors, expert validity checks, and notes from pilot training-sessions. The overall process began with codes and categories that were developed from the data and iteratively refined in the process of creating a descriptive framework of IOI. In addition, new data was sought to specifically address questions and hypotheses as they arose, and subsequently led to the refinement of the framework. Other research methods were incorporated into the phases such as Lesh and Lehrer's (2000) iterative video analysis. In the following sections we outline the work completed in each phase.

### Phase 1: Defining the Task - What is IOI and how do we measure it?

This phase resulted in a general understanding and vocabulary for characterizing IOI and information on how to measure teaching in general. In this phase, we searched through research literature for defining characteristics of IOI and determined that a distinguishing feature was that the teacher, students, and tasks each have a critical and active role in developing the mathematics. After returning to the literature and coding for "teacher", "students", and "tasks", we generated a starter list of instructional practices of IOI and supported these practices with justifications and examples from the literature. After our working definition of IOI was complete, we examined existing instructional measures (e.g., RTOP, IQA, MQI) to determine if they adequately captured our characterization of IOI. Though it was ultimately determined the other measures were not applicable, they did influence the refinement of practices and provided useful descriptions for what some practices looked like when enacted.

### Phase 2: Examining Data - Verifying practices and identifying measure limitations

Although the research literature led to the identification of numerous practices of IOI, the utilization of a measure required being able to *observe* these practices. In this phase, we cycled between analyzing videos and existing literature to verify that the practices identified from the literature were also evident in classroom instruction. In the first pass through the video data, we watched two expert instructors (IO curriculum developers) and three novices. The variation in experience level was purposeful; we intended it to highlight key aspects of instruction. While watching these videos, we documented the classroom events with content logs, coded for critical components, and wrote narratives for each of the practices based on what was observable in the videos. This process resulted in refining the list of practices and their characterizations. Thus, the characterizations of the practices were created in terms of supporting literature and video data.

Once the practices were defined and descriptions of their enactment were created, we delineated across the various levels (i.e., high, medium and low) at which instructors performed each of the critical components. Using the video data, we created a rubric for scoring the quality of the implementation of each component by ranking the various instructors in terms of how well their instructional practices aligned with the tenets of IOI. We then identified themes within the various levels of quality by comparing across the components within each of the scores. The process of ranking the instructors also raised important questions regarding issues such as how these practices connected to each other and how they fit within the four instructional principles.

**Phase 3: Refinement using outside sources**

In this stage, we began seeking resources from beyond IOI research literature and feedback from researchers not directly involved in the development of the measure. First, we asked a researcher not familiar with IOI to code two videos with the drafted rubric. After discussing areas of confusion and working out discrepancies between scores, we began searching through K-12 research literature looking for aspects of K-12 instruction that were commensurate with the practices we identified in IOI. These steps led to refining the practices and led to a better understanding of the principles and the supporting practices. Specifically, the K-12 literature was able to provide descriptions for what we noticed from the IOI video data and language for delineating among the various levels of implementation.

**Phase 4: Sharing to clarify**

In this phase our intent was to pilot the rubric with experts and novices to both clarify connections between the principles and practices and work toward a common interpretation of them. We first asked researchers familiar with IOI but not with the measure to use the rubric to score the same lesson. While this step had multiple benefits, there were two important outcomes. Most importantly, despite no training, the scores across all six researchers (including two rubric developers) were all within one point. Thus, while some reorganization was needed, the descriptions in the rubric were generally meaningful to researchers familiar with IOI.

We then engaged in a pilot training process where we trained three graduate students having no background in IOI on how to use the rubric. During this process we asked the coders to take careful notes of issues that arose for them as they utilized the rubric. We also recorded the meetings when we met to discuss the scores they assigned. From this we concluded that two practices were capturing the same aspects of instruction and removed one of them. We also created resources for coders, including guiding questions, “evidenced by” descriptions, and boldfacing certain words in the rubric.

**Phase 5: Sharing to use**

In this phase, we implemented the full scale training of six graduate students from various mathematics education backgrounds. Training started with having the coders watch video clips exemplifying the different levels of IOI for each of the practices. As training progressed, coders were given more opportunities to watch longer segments of classroom video with a partner or on their own each evening and to justify their own scores using the rubric. In group meetings, coders would then engage in facilitated debates of their scores, which allowed misunderstandings of terms and weaknesses in justifications to be resolved. The coders were also encouraged to articulate in their own words what each practice would look like at high, medium, and low levels as another check of their understanding.

At the end of a week of training, coders were given a test video to determine their readiness to code independently. All coders gave scores within 1 level of the trainer's scores, which allowed them to be released to code videos gathered from TIMES instructors. Five of the six coders then went on to each score eight to twenty-one other videos. (The sixth did not score any videos after training.) In order to insure reliability, the trainer had a meeting with each coder after every fifth video to make sure all scores remained within 1 of the trainer's scores. In seven of the ten meetings, the scores were all within 1 of the trainer. In cases where the coder was off by two levels, they were asked to rewatch and rescore the video in light of the discussion with the trainer before being allowed to continue scoring videos.

## Discussion

In this paper, we outlined our development of a rubric for IOI. Creating a measure for IOI at the undergraduate level presented non-trivial and unique challenges. First, it was necessary for the IOIM to have the flexibility to be utilized across an array of undergraduate mathematics courses. Though, not only does the content differ across introductory courses such as differential equations, linear algebra, and abstract algebra, most notably, the mathematical goals are often vastly different. For instance, an introductory differential equations course is often intended to develop an understanding of solution methods, whereas introductory abstract algebra is often utilized to develop notions of formal mathematical proof. Instead of being overlooked this difference in goals needed to be flexibly built into the measure.

Second, the IOIM needed to incorporate a wide variety of instructional strategies. From a theoretical standpoint, in IOI the teacher navigates along the continuum of pure telling and pure student exploration (Rasmussen & Marrongelle, 2006). From a practical standpoint, flexibility across instructional types was necessary because of the nature of the TIMES project: supporting instructional change. That is, the measure needed to provide information regarding how the participating instructors were incorporating aspects of IOI into their instruction and to what degree they were doing so. These challenges and others greatly influenced the resulting structure of the measure. With this we hope to contribute to a broad community, one consisting of mathematics education researchers as well as practitioners.

# Inquiry-Oriented Instructional Measure

| Practice | Component | Description | 5 | 4 | 3 | 2 | 1 |
|---|---|---|---|---|---|---|---|
| | | | High | Medium High | Medium | Medium Low | Low |
| 1. Teachers facilitate student engagement in meaningful tasks and mathematical activity related to an important mathematical point. | Generate | This practice is characterized by student engagement in mathematical activity related to an important mathematical point. This activity is likely to be supported with meaningful, cognitively demanding tasks. (Jackson et. al, 2013; Hiebert, 1997; Speer & Wagner, 2009). However, we are not evaluating the tasks, rather the quality of the mathematical activity.<br><br>Stein's "doing mathematics" includes conjecturing, argumentation ... all of the things we call engaging in authentic mathematical activity. (Stein, et al., 2008)<br><br>This activity is likely to be supported by providing the students with meaningful, cognitively demanding tasks and supporting their engagement in these tasks through questions that promote the identification and investigation of the mathematical concepts. | Students were engaged in generalizing their thinking to mathematical claims that they then tested/supported with arguments, examples, and counterexamples. The teacher tried to connect the task to the students' prior experiences with guidance that helped facilitate continued engagement in the task. The students were "doing mathematics."<br><br>**"Doing Mathematics"** | While the students were provided opportunities to "do mathematics" the majority of the mathematics during the discussion was performed by the teacher. The teacher used the tasks to engage the students in the conceptual ideas.<br><br>**"Procedures with connections"** | The teacher engaged students in the tasks, focusing on the correct answer or the procedures as opposed to the mathematical ideas underlying those procedures.<br><br>**"Procedures without connections"** | The students engaged in few mathematical practices. The majority of the "learning time" consisted of watching the instructor provide the correct answer. The teacher did not utilize the tasks to support the development of the mathematics. The teacher engaged students in tasks that largely focus on memorization of important mathematical ideas.<br><br>**"Memorization"** | The teacher lectured the material (i.e. there are no mathematical tasks for the students to engage in). The majority of the mathematical activity was carried out by the teacher, with little to no time for students to do anything but watch.<br><br>**No space for student mathematics** |
| 2. Teachers elicit student reasoning and contributions | Generate | Teachers prompt students to explain their reasoning and justify their solution strategies, with the focus on the reasoning the students utilized during the task as opposed to solely focusing on the procedures used. Research on instructional quality indicates that the type of contributions teachers elicit is directly related to the students' opportunities to learn. Thus it is important that teachers elicit thinking and reasoning that "uncover the mathematical thinking behind the answers" (Hufferd-Ackles, Fuson & Sherin, 2004, p.92). | The teacher explicitly asked students to share their approaches to the tasks and their reasoning. The focus was not on what answer they got, but more on how they arrived at that answer, how they were thinking about the problem, the method they took, and a justification for choosing that method. Students may be sharing **thinking/reasoning** and questions without prompting from the teacher.<br><br>Teacher questions and student contributions are about student reasoning, methods, and justifications, with students providing full and meaningful contributions. | The teacher routinely and explicitly asked the students to share contributions pertaining to their thinking and reasoning such as, "Why do you think the examples you generated are working that way?" "How did you do it?" and "What does this mean?" The teacher, however seemed to **interpret and revoice these contributions** for the students without allowing the students to fully explain them or respond to them, which took ownership of the ideas away from the students. Although the student's line of reasoning on the solution path is given, why the student chose that solution path is not. | The teacher typically elicited descriptions about how students solved a task, but not about how they were thinking about and/or approaching the task; **solutions and descriptions of how those solutions were obtained are the focus**. Additionally the instructor often talked about the students' contributions as opposed to allowing them to explain their thinking. The instructor elicited solutions but not reasoning. This includes well-worded questions that are asked in such rapid succession that they lose their ability to elicit students' reasoning. Alternatively, the focus of questions was still more on the correctness of procedures or answers, and not on students' understanding. | The instructor made an effort to elicit student contributions (e.g., reasoning, methods, and justifications) but often these attempts yielded **procedural statements**.<br><br>Questions are segues into lecture. | The teacher asked fill in the blank questions. There were **little to no opportunities for students** to make deep and meaningful contributions. The Instructor does not ask students to share their thinking. |
| | Build | Leatham et al. [22] note that foundational to building on student thinking is the presence of student mathematical thinking that "is likely to advance students' development of important mathematical ideas—whether the student thinking is mathematically significant" (p. 92). Thus, in order to build on student thinking, rich contributions must be elicited. | | | | | |
| 3. Teachers actively inquire into student thinking. | Generate | This practice means that instructors purposely and intently inquire into student thinking for the purposes of determining if and how student generated ideas can be utilized to promote a more sophisticated understanding of the mathematics. The questions asked by teachers not only direct student investigations and provide the teacher with insight into student thinking, they also help students refine and reflect on their own thought process (Borko, 2004; Hiebert & Wearne, 1993; Rasmussen & Kwon, 2007). By asking them questions about how they are thinking - you are supporting them in further engaging in their thinking. | The teacher engaged in conversations with the students about their thinking. These conversations indicate that the teacher was assessing their own understanding of students' thinking. There are instances of probing, rephrasing of student contributions, and representations. (Davis description of interpretive listening and Rasmussen, Kwon, Marrongelle's IO-DM, and Henningsen, Stein 1997))<br><br>It seems as though the teacher is trying to figure out, "How are my students thinking about this?" They are trying to **"build a model of students' understanding."** | The teacher appeared to **actively figure out** the student's mathematical **contributions** (e.g., reasoning, methods, and justifications) - were their conjectures valid, were the students contributions useful in developing the mathematical agenda?<br><br>The teacher appeared to try to answer the question, "Are this student's mathematical **contributions useful?**", as opposed to "What sort of thinking led to this contribution?"<br><br>*This is good pedagogical reasoning on the part of the teacher and very useful for responsiveness and connecting and all sorts of things - but it is not the main point of this practice. | The teacher attempted to figure out how the students solved a problem or task with attention to the concepts underlying that solution method.<br><br>Their focus was on why **something worked**, not how the student was thinking about the mathematics. (E.g., "because of the associative property I can regroup these elements" provides a valid mathematical justification for how to do something but does not provide information about how the student was thinking about the task/mathematics.)<br><br>**Thinking – procedures with connections** | The teacher appeared to be trying to figure out how the students solved a problem with attention to the **validity** of the student's solution **strategies**. That is the focus was on the correctness of the procedures, not on why those procedures worked.<br><br>**Trying to figure out "Can they do it correctly?"** | The instructor's response to student contributions was limited to determining if the contribution (often just "the answer") matched a predetermined and expected answer. In this sense the teacher inquiry served an evaluative role, determining the **correctness of student responses**.<br><br>There is no evidence that the teacher was trying to figure out how the students are thinking, just if their "answer" appears to be correct.<br><br>Trying to figure out "do they have the right answer" |
| | Build | Teacher inquiry serves many functions and roles throughout a lesson (see Hufferd-Ackles, Fuson, & Sherin, 2004; Johnson, 2013; Rasmussen & Kwon, 2007). With regard to building on student contributions, teacher inquiry allows teachers to form models of student thinking and understanding, reconsider important mathematical ideas in light of those models, and formulate questions and tasks which enable the students to build on those ideas (Rasmussen & Kwon, 2007). | | | | | |
| 4. Teachers are responsive to student contributions, using student contributions to inform the lesson | Build | Rasmussen and Marrongelle (2006) state that, "an important part of mathematics teaching is responding to student activity, listening to student activity, notating student activity, learning from student activity, and so on" (p. 414). By doing so, the teacher can generate instructional space where "the nature of student mathematical thinking might compel one to take a particular path because of the opportunity it provides at that moment to build on that thinking to further student mathematical understanding" (Leatham et al., 2015, p. 118). Rasmussen: IO informs questions and tasks that enable students to build important math ideas. | The instructor listened to students' contributions (e.g., reasoning, methods, and justifications) and, when appropriate, used these ideas as a springboard for follow up questions and further exploration by the students. Questions about student contributions were asked to the class. The teacher used intermediate student progress to re-direct and focus small group work towards the important mathematical ideas. The instructor often took advantage of student thinking that they felt promoted the mathematical agenda by shifting focus to a student generated justification.<br><br>Willingness and space to follow/explore unexpected contributions - where the students are doing the exploration.<br><br>**Lots of instructional space: students build on each other's contributions/questions/suggestions** | Student ideas guiding the teacher's exploration - The teacher was willing to follow/explore unexpected contributions (e.g., reasoning, methods, and justifications), and provided space to do so. However the teacher was doing the exploration, not the students.<br><br>**Some instructional space: teacher builds on students' contributions/questions/suggestions** | Student contributions (often answers evaluated for correctness) were used by the teacher as a way to support a predetermined path. Little attention or instructional space is devoted to unexpected contributions (or to eliciting unexpected contributions).<br><br>Additionally, the contributions were often utilized as a way for the instructor to lecture about the topic/idea at hand or lead the students to replying in a predetermined manner.<br><br>**Predetermined contributions to support the predetermined path.**<br><br>*One possible way of getting a score of 3 in this practice, is if a "lecturer" explains a procedure, students practice procedure, and the teacher uses their answers to indicate it is time to teach the next procedure, to do more practice problems, or to do an additional lecture based on how the students did on the procedure. | The teacher rarely considered students' contributions with regard to the mathematical agenda. The use of student contributions was limited to "fill in the blank" responses that indicate is it time to move forward. For example, the teacher lectures for awhile, then the students practice a procedure, and then the instructor explains the correct answer before repeating the process. If necessary, the teacher might lecture further if there were common misconceptions.<br><br>**Limited instructional space** | The teacher was adhering to a pre-determined lesson plan. There was little to no instructional space for exploring student ideas or questions. The teacher's instruction did not make reference to student contributions (apart from answering clarification questions). Essentially the teacher lectured for the whole period.<br><br>**Little to no instructional space** |
| | Shared | When teachers are responsive to student contributions they can create new instructional space (Johnson and Larsen, 2012). In regards to this component, the instructional space is created for the purpose of developing a shared understanding within the classroom community. | | | | | |

| Practice | Component | Description | 5 | 4 | 3 | 2 | 1 |
|---|---|---|---|---|---|---|---|
| | | | High | Medium High | Medium | Medium Low | Low |
| 5. The teacher engages students in one another's thinking (reasoning?) | Shared | Stein and colleagues (2008) provide several examples of how teachers can support students in making mathematical connections between differing student contributions and important mathematical ideas. Some of these examples include asking students to reflect on the contributions of other students, assisting students in drawing connections between the mathematics present in solution strategies and the various representations that may be utilized, and facilitating mathematical discussions about different student approaches for solving a particular problem. Doing so can prompt students to reflect on other students' ideas while evaluating and revising their own (Bransford & Fryklholm, 2000; Engle & Conant, 2002).<br><br>By engaging with one another's thinking, students are able to deepen their thinking, generate new ideas, and make mathematical connections. As discussed by Jackson et al. (2013), "the teacher plays a crucial role in mediating the communication between students to help them understand each other's explanations" (p. 648). | During whole class discussions, the teacher makes instructional space for **students to reflect on the contributions of other students** - e.g., "How are you guys making sense of what they are starting to think about here?" The teacher encouraged students to ask each other questions about alternate approaches and ways of thinking. Additionally the instructor often pointed out ideas other students had while working on the task as a way to support the students' progress. The **teacher and students share responsibility for the mathematical ideas**. Essentially, students interact with each other's ideas without the teacher acting as much of a filter. | During whole class discussion, student ideas were made public and students were asked questions such as "Did anyone think of it a different way?" Most of the interactions left the students with **access to each other's approach but not to each other's thinking/reasoning or justifications**. In general, it did feel like the **student contributions were leading to meaningful class discussion**, as mediated or filtered through the teacher. While the students are responsible for the mathematics, the **teacher is the mathematical authority** in the room.<br><br>Teacher rephrases/revoices student ideas for the purpose of having other students react/interact with it. This is done in a way that does not preserve the student's contribution - or alters/adds/"smooths" in a significant way. The students are interacting with the teacher's version of the student's ideas - as opposed to interacting directly with the other student's ideas. | Students contributed to whole class discussions, during which students were asked questions such as "Did people get the same/different answer?" However, students were not prompted to reflect/compare/assess other students' contributions or ideas or students' responses may not have included much reasoning. **Overall, there was not an explicit attempt to have students make sense of each other's contributions though they did have access to them. The teacher is still the mathematical authority.** | There were opportunities for students to engage in one another's thinking (e.g., small group work).<br><br>However, **during whole class discussion and/or lecture, students did not have access to one another's thinking**. The whole class discussions seemed more like a space to contribute possible correct ideas for feedback from the instructor, as opposed to a space for students to engage in argumentation, explanation, and/or justification.<br><br>For instance, if the only thinking elicited (Practice 2) is a med-low (i.e. procedural statements and answers are shared) then students cannot engage in one another's reasoning. | There is **no student reasoning** shared (in small group or whole group discussion) for the students to engage in. |
| 6. Teachers guide and manage the development of the mathematical agenda | Build | Teachers need to actively guide and manage the mathematical agenda and can do so by: identifying and sequencing student solutions to "ensure that the discussion advances his or her instructional agenda" (Jackson et al., 2013, p. 648); utilizing Pedagogical Content Tools "to connect to student thinking while moving the mathematical agenda forward" (Rasmussen & Marrongelle, 2006, p. 389); or by refocusing the class towards the use of certain student generated ideas, marking important student contributions, and assigning tasks meant to clarify and build on students' ideas/questions. In these ways, teachers can guide and manage the development of the lesson while building on student contributions, developing mathematical ideas in directions commensurate with the mathematical agenda, and maintaining the student ownership of the mathematics. | The teacher monitored small group work, and both recorded and used student contributions during whole class discussions as a way to promote the development of the intended mathematical ideas. The teacher **guided student explorations towards the mathematical goals** of the day. This could include asking students questions to allow them to find a solution in their own way. The teacher's questions and interactions appeared to be directed towards a clear mathematical goal. Additionally the instructor managed both the small group work and the whole class discussions. | There was a **well defined structure within the class**, and the instructor focused the students on the important mathematical ideas. The instructor utilized strong guidance to direct the lesson consisting mostly of student contributions. Specifically the **instructor was responsible for exploring the mathematics, and the students were responsible for responding to that exploration**. This could include asking questions that lead students along the teacher's line of reasoning. | There was certainly a **well defined goal and structure** within the class. The instructor focused the students on the important mathematical ideas. The instructor however did **not** seem to be **utilizing student ideas to progress the mathematical agenda**. | Though there was a goal in mind, the **structure of the class was not well defined**. Additionally, the teacher did not facilitate the progression of the mathematical agenda. | The teacher did **not** appear to have a **clear mathematical goal** in mind. The students are left to explore the mathematics at their leisure. |
| 7. Teachers support formalizing of student ideas/contributions and introduce language and notation after a need/understanding has been established. | Connecting | In inquiry-oriented instruction, as the students reinvent the mathematics, their reinventions build to be commensurate with formal mathematical ideas. The instructor must be able to promote the students' ability to connect their mathematical ideas to more formal mathematics. "The teacher plays a crucial role … in supporting students to link student-generated solution methods to disciplinary methods and important mathematical ideas" (Jackson et al., 2013, p. 648).<br><br>Formal notation is introduced after the students have generated an understanding of what is being notated and a need for it has been established. "In contrast to more traditional teaching in which formal or conventional terminology is often the starting place for students' mathematical work, this teacher [one implementing an inquiry-oriented curriculum] chose to introduce the formal mathematical language only after the underlying idea had essentially been reinvented by the students" (Rasmussen, Zandieh, Wawro, 2009, p. 203). | The students **formalized their own ideas and contributions, doing all of the formalizing except being told that the concept is a standard one with a standard name**. The students were provided with opportunities to make connections between their work and the more formal mathematical notation (e.g., students are asked to translate and/or interpret formal mathematical nomenclature utilizing their own generated ideas). When appropriate, the teacher notated student contributions with formal mathematical language and notation. This was done after the students had a chance to informally develop the mathematical concepts, and when it was likely that the students could make sense of the formal mathematics by connecting it to their previous work.<br><br>There is instructional space for students to formalize their own ideas - where formalizing can mean connecting to standard language and notation. This formalizing draws heavily on the students' work and contributions. There was instructional space for students to translate their contributions and prior reasoning into the newly introduced language and notation. | Teacher does the formalizing of ideas that originated with the students - where formalizing can mean connecting to standard language and notation. This formalizing draws heavily on the students' work and contributions. **The teacher used notation as a way to capture, notate and translate student ideas and contributions. The translation however was done by the teacher, not by the students.**<br><br>The teacher formalized the students' mathematics and made the connections (i.e., there was not an opportunity for students to translate or formalize their own ideas - this was done by the teacher)<br><br>The difference between this and high: with medium-high the teacher records student thinking with notation, but then the teacher does all the translating into the notation. With "high" the teacher introduces notation and then asks the students to do the translation. | Students were given an opportunity to work toward formalizing their own arguments and ideas. However, there is a **significant disconnect between what the teacher introduces and the students' work.** This can happen in a number of different ways. For instance:<br>– The teacher does not draw on the students' ideas/work. Instead, the instructor follows up students' work with a summary that does not directly reference the students' ideas or makes no explicit connections between the students' ideas and the language and notation introduced by the teacher. In effect, the **teacher ignored the formalization students had done.**<br>– The teacher does not attend to the ways in which the students are using formal language and notation, causing **a disconnect in the meaning of words used by the teacher and the students** (e.g., a student uses the term "inverse" or "one-to-one" and the teacher assumes a shared formal meaning).<br>– There are **not enough student ideas** present for formalizing. | **The students were given a brief opportunity to formalize ideas, but they were not successful in formalizing.** This lack of success could be due to insufficient time to complete the task, a poorly framed task, or students not understanding well enough to approach the task. One example of this may be if the students were asked to complete a sequence of tasks, and at the end were asked to come up with a conjecture/generalization about a pattern common to task sequence. Their contributions were ill-formed or not utilized by the instructor.<br><br>Additionally, there were little to no connections between the students' ideas that did arise and the language and notation introduced by the teacher. | **Formal mathematical language and notation were introduced prior to student engagement with a task.** The language and notation were introduced before a need had been established for it. (e.g., Definition/Theorem/Proof)<br><br>**Alternatively, standard mathematical language and notation are not introduced to the students at any point in the lesson.** |
| | Shared | Mathematical language and notation does not only serve as a way to mark important mathematical ideas. In an inquiry-oriented classroom, the introduction of language and notation also serves as a way for teachers to support the use of a common way of thinking about a mathematical idea, which then serves as a launching point for the construction of more formal mathematics. Rasmussen and Marrongelle (2006) indicate that inquiry-oriented instructors often notate student thinking in ways that allow the class to then solve new problems. | | | | | |

# Professor Goals and Student Experiences in an IBL Real Analysis Course: A Case Study

Paul Christian Dawkins
Northern Illinois University

Michael Oehrtman
Oklahoma State University

Ted Mahavier
Lamar University

*Through an in-depth case study of one real analysis course taught by a very experienced instructor, we gain insight about two goals expressed by advocates of Inquiry Based Learning (IBL) instruction: developing students' persistence in mathematical study and their identity as mathematics learners. The research study was guided by collaborative workshopping research priorities and questions with of a group of experienced IBL instructors. We provide an in-depth characterization of this highly-experienced instructor's conceptualization of his teaching practice in undergraduate Real Analysis; specifically, we identify how his deviation from conventional proof-oriented instruction served to uphold his key goals that students* create proofs *and* overcome challenges*. We then use this characterization of his practice to report on students' experiences learning in the course, especially as related to the professor's two goals.*

*Keywords:* Inquiry-based learning, identity, persistence, instructor goals, motivation

## Motivation for the Study and Research Questions

There currently exist multiple broad movements in undergraduate mathematics education toward various forms of inquiry-oriented instruction (e.g. Dawkins, 2014; Kogan & Laursen, 2014; Kuster, Johnson, Keene, & Andrews-Larson, 2017; Rasmussen & Kwon, 2007). In this context, the term *inquiry* covers a range of particular notions and functions. Kogan and Laursen's (2014) study distinguished Inquiry Based Learning (IBL) courses that spent more than 60% of class time on student-centered activities from non-IBL courses in which instructor speech occupied more than 85% of class time. We rather focus on particular values and goals endorsed by practitioners of inquiry-oriented instruction. This project was initiated by the authors' participation in a collaborative workshop hosted by the American Institute of Mathematics (http://aimath.org/pastworkshops/iblanalysisrep.pdf). The workshop brought together IBL real analysis instructors and mathematics education researchers focused on real analysis to foster professional partnerships and to outline some agendas for research on IBL real analysis instruction. One such research agenda focused on how IBL instruction influenced students' persistence in mathematical study and their identity as mathematics learners. In response, we formulated the current study of the teaching practice of one highly experienced IBL instructor (Professor X) and his students' experiences. We pursued the following questions:

1. What goals for student development does the IBL instructor articulate throughout teaching the course and reflecting on student progress?
2. How does the professor structure the course and his interactions with students to achieve his articulated goals and provide all students with appropriate opportunities to overcome the challenge of creating proof?
3. How do student interact with the course structure and instructor to navigate through the course and how do these trajectories achieve or challenge the instructor's learning goals?

## Theoretical Perspectives on Inquiry in Mathematics Instruction

Rasmussen and Kwon (2007) provide an influential definition of inquiry for undergraduate mathematics instruction. In their view, classroom inquiry includes both 1) student inquiry into mathematical tasks that are meaningful and accessible to them and 2) the instructor's inquiry into students' mathematical reasoning. The first type of inquiry helps students see mathematics as a human activity in which they participate. The latter allows the professor to build instruction on student thinking. As we shall argue later, Professor X's practice was compatible with both criteria, though student inquiry was more prominent and Professor X built on student thinking in more indirect ways. Since it is rooted in Realistic Mathematics Education (Freudenthal, 1973; Gravemeijer, 1994) this tradition of inquiry emphasizes a range of mathematical activities such as defining, conjecturing, theoremizing, and proving. Professor X instead almost exclusively invited students to prove mathematical claims. He provided the vast majority of definitions and statements to be proven in the course script (though students were not always told whether the given statements were true or false). Kuster et al. (2017) describe four principles of this tradition of inquiry oriented instruction: generating student ways of reasoning, building on student contributions, developing a shared understanding, and connecting to standard mathematical language and notation. Of these, Professor X only focused on the first because he wanted to maintain the independence of student contributions in overcoming challenges.

Professor X is more directly aligned with the tradition of inquiry studied by Kogan and Laursen (2014). Professor X does not allow any collaboration among students in his course, which was a key component of the positive experiences Kogan and Laursen reported. Still, those authors go on to explain, "Public sharing and critique of student work may serve as vicarious experiences that enhance self-efficacy and link effort, rather than innate talent, to mathematical success" (p. 197). This explanation of how peer presentations may influence students' mathematical mindset (Good, Rattan, & Dweck, 2012) suggests affective mechanisms that would still be present in Professor X's class, though students worked independently.

## Literature Review

Numerous studies attest to the significant challenges students face in learning the definitions and logic native to real analysis. Conceptual difficulties abound with limits (Oehrtman, Swinyard, & Martin, 2014; Pinto & Tall, 2002), monotonicity (e.g. Alcock & Simpson, 2017; Bardelle & Ferrari, 2011), cardinality (Shipman, 2012), completeness (Durand-Guerrier, 2017), and compactness (Dubinsky & Lewin, 1986). Definitions in analysis frequently include multiple quantifiers that evoke non-normative interpretations among students (Dubinsky & Yiparaki, 2000). Real analysis also includes proof methods students need to learn (Weber, 2001) such as universal generalization (Durand-Guerrier, 2008), absolute value inequalities, and constructing functional relationships between quantified terms. Students' must also reason fruitfully about examples and visual representations to coordinate their concept image with the concept definition (e.g. Alcock & Simpson, 2004; Tall & Vinner, 1981). As mentioned above, Professor X did not present on these definitions, but rather provided students with tasks to prove or disprove and expected students to learn about these concepts relatively independently. As we shall report, Professor X reorganized these concepts to facilitate student learning, though it is beyond the scope of this report to fully explore this conceptual reorganization.

## Methods

The bulk of the research data gathered consisted of Professor X's reflections on the class meetings and student learning as facilitated by the two researchers. Two weeks into the class, after Professor X had time to get to know the students and allow them to settle into the routine of the course, we created an *Initial Summary Document* including summaries of the students based on Professor X's observations and past experience. Using categories created by the expert participants at the AIM workshop, we prompted Professor X to classify students' early proving capabilities, from Novice to Master. We then established two online collaborative documents, an *Interactive Diary* and a *Student Summaries*. In the interactive diary, Professor X recorded interesting and noteworthy episodes from the class as well as general comments about the course notes or classroom culture. Professor X also created notes on the work and progress of individual students in the Student Summaries file, based on student presentations, office hour visits, and homework. The researchers provided comments and questions in each document. We used different colors and date stamps for each entry to make it easy to track the dialogue among speakers and to notice what still required response. We also conducted monthly phone interviews to discuss the interactive diary and student summaries entries, adding to each as possible.

At the end of the semester, the researchers requested interviews from 15 students, five from each of three ranges of success at the end of the semester as perceived by Professor X. Three students from the lower success range (faux initials CR, TJ, and BT), four students from the middle range (LN, KC, SQ, and RU), and three students from the higher range (TC, OI, and OO) agreed to be interviewed. We crafted questions to elicit their perceptions of: 1) the course, 2) the IBL instructional methods, 3) professor and peer interactions in the class, 4) how they progressed in the class, 5) how they benefitted from the class, 6) what they struggled with, 7) what they were most proud of, and 8) what helped them most throughout the course. We conducted a 60-90 interview with each of the 10 participants with online videoconference software so that we could share images of their work and record the session. We centered large portions of the interview on artifacts of the students' work to ground the conversation in the class activity. The researchers then conducted one final interview with Professor X to discuss the work and interview responses of each of the 10 interviewees and his overall assessment of the course.

After all data was collected, the researchers reviewed the student and professor interviews, presentations, homework, and notes files, first to document any insights relative to Research Questions 1 and 2 on Professor X's goals for the course and his enacted strategies to achieve those goals throughout the course. We then made subsequent passes through the data focusing on Research Question 3 for one of the 10 interviewees at a time. We then wrote a narrative detailing each of the 10 student's experience in the course using code words for the 35 emergent categories from the initial analyses when possible. We refined categories and clustered students by similar experience, resulting in 6 subgroups of the 10 students. Rereading the narratives within each cluster, we identified broad characteristics that separated the students into subgroups, resulting in an emergent hypothesis about the effects of student buy-in, goal orientation, and achievement in the course defining their overall experience. We detail the various categorizations with case studies in the results section.

## Results

The following articulates our model of Professor X's conceptualization of his own teaching practice relative to the primary goals of *creating proofs* and *overcoming challenges*. The emergent categories from our model appear in italics. They are organized to portray how they all coherently operated in service of Professor X's two primary goals. We then present three accounts of student experience representing variations within the IBL learning environment.

### Creating Proofs

For Professor X, creating proof is the heart of mathematical practice and students should not complete a course of study in mathematics without learning how to prove independently. To push students to create proof is to engage them in *real mathematics*. Professor X also believes it gives students *deeper understanding and ownership* over what they learn.

**Proof competencies.** To successfully apprentice students in creating proofs, Professor X attended to their growth in terms of three requisite skills for proving: *writing/logic*, *ideas*, and *details.* This view of proof writing competence was embedded in his *assessment structure* on homework assignments in which the grades corresponded closely to the proving competencies he wanted to foster. Students could *rewrite* a proof if they earned below a B. Professor X focused the first four weeks of the course on developing writing and logic by allowing students to turn in proofs that other students presented for homework. After that point students could only submit a problem before it was proven in class.

**Means of learning to prove.** Students were required to *turn in proofs as homework* once per week and *present completed proofs* at intervals throughout the semester. Professor X was readily available for *office hours* and had many students discuss their proofs with him before presenting to the class. In this context he provided *differentiated feedback* targeted at the competence he perceived that the student needed to develop. Students were expected to learn from observing *peer presentations*, which allowed them to see proof approaches that were more accessible to them and help them see proving as an activity in which they could engage.

**Reformulated content**. To help students independently create proofs in the complex context of Real Analysis, Professor X *reformulated some of the mathematical content*. For instance, the definition of supremum was divided into Right Most Point (RMP) and First Point to Right (FPR), which respectively apply when the supremum is in the set or is not. Neighborhoods were described by order relations rather than absolute value inequalities. Because he valued proof creation, Professor X consistently *ignored elegance and efficiency* in student proving. He generally avoided *demonstrating standard methods*, but rather *legitimized student proofs* so long as they were valid and covered all cases

**Differentiated feedback.** Many students praised Professor X's feedback. This feedback consisted of *praising and validating student work* and *providing minimal prompts* to move them forward. Professor X articulated gaps in student proofs as lemmas, an instance of *mathematizing student contributions*. Professor X consistently tried to provide minimal feedback so that students retained *ownership* over their created proofs. Providing counterexamples to student proofs was also a way that Professor X *expanded students' concept image* over time.

**Creating mathematicians.** A final aspect of Professor X's practice related to creating proof was his overarching goal of training new mathematicians. Professor X persistently *invited appropriate students to further study in mathematics*. This invitation had an affective influence, since it represented an expert's high assessment of students' mathematical ability.

**Overcoming Challenges**

The other overarching aspect of Professor X's view of the value of inquiry-based instruction was pushing students to attempt and complete challenging proof tasks. Stronger students benefitted because they often had never faced challenge in mathematics courses before. Weaker students gained *confidence* by independently writing proofs and presenting them to their peers.

**Task difficulty.** One key means by which Professor X encouraged students to attempt and overcome challenges was including tasks in his notes that varied markedly in difficulty. Students could not always assess a task's difficulty, leading them to try hard tasks inadvertently. Stronger students who could identify easier tasks turned in proofs for *simple* and *complex tasks* to maintain good grades while spending more time working on *challenge tasks*. Finally, some of the students that Professor X identified (and who self-identified) as mathematically weaker reported attempting problems later in the notes so they had more time to work on them before others presented them in class. Professor X at times withheld *feedback* or guidance from students he perceived as mathematically strong because he wanted to maintain the challenge of the task and their independence in creating a proof. For most students, Professor X very *intentionally praised what was good* in their proof attempts to encourage them to persist in the challenges. Professor X valued how strong students presenting incorrect proofs *legitimized the struggle of creating proofs* on their own, which for him represented *real mathematics*.

**The Case of BT**

Initially, BT reported being very intimidated by the course, especially because she had to present proofs to her peers. She reported that she started learning more after she could not copy other students' work. Her homework average was a 90, suggesting she earned A's often on her first try. Professor X held a higher view of BT's proving ability than she did. English is not BT's first language, which affected her confidence. Partly due to low confidence, she only presented twice during the semester and thus earned a B presentation grade.

BT reported two significant moments that helped her feel more confident. First, she solved a problem independently and was able to present it to the class, about which she reported:

> For this one, I feel like I figured it out on my own…. So that's why I feel like this was my proud moment proof.… After [this problem] I could definitely see myself growing. That's when I saw that I went from here to here [*raising her hand to indicate levels*]. That's when I started thinking mathematically more…. I felt like I started understanding more, and in a way I started enjoying the class more. I wasn't able to always understand what was put on the board, but I feel like I could grasp the idea, and, in a way, if I ever sat down and worked on it long enough I would be able to prove it.

Later, Professor X personally invited her to take Analysis 2 on the strength of her performance. Regarding Professor X's praise and invitation to take Analysis 2, BT said,

> And I was, "Huh. I might be good in this." I didn't see it, but him telling me this stuff definitely helped me believe it.… Maybe I did get something out of this. Because I don't see it in myself.… He made a big difference…. So in a way I feel like him telling me, "you can do it." It was the push that I needed. Ok, if he sees it then, you've definitely got it. You just need to work on it.

BT was aware of what she did not understand. She looked for problems that made sense to her and often went ahead in the notes to new topics that others had not studied yet. She anticipated this gave her more time and she wanted to make sure the students in the front row who "knew their stuff" would not present it before her. She was also intimidated by indirect proof, even though she felt this led her to write longer case-based proofs. Later in the course, she deliberately attempted proof by contradiction to give herself a challenge. Professor X agreed with BT's assessment of her improvement. She quickly grew to solid B-level work completing basic proofs. She did not achieve "master level" by producing more complex proofs.

**The Case of KC**

KC was a strong student who expressed appreciation for most all of Professor X's goals and values for IBL instruction. In fact, as a preservice teacher he said he wanted to use IBL in his own future high school classroom because he valued the way it helped him learn. Professor X gave very minimal feedback to KC because he thought he could figure out what was wrong and fix it. KC praised the quality of Professor X's feedback, especially how he could tell him how to correct his proof without letting him know whether the statement was true or false.

KC reported working for long periods on the proofs from this class and enjoying learning. He compared the work in this class to mathematicians' proving, except he felt they had much greater guidance and support from Professor X through the definitions, tasks, and feedback. KC enjoyed challenging problems and often got hooked on trying to see if he could solve them. He had been working extensively on P22 and planned to continue his work after the semester ended if he had not proven it yet. While appreciating the challenge, he said it was humbling to find a problem that he could not yet solve. Throughout the semester, KC was willing to attempt hard problems and Professor X commented that he presented his work well because he had thought hard about the problems at length. Professor X said it was clear that KC 100% liked the course and did hard problems and clear that he had it all in his head, with a "complete and firm grasp of everything."

**The Case of SQ**

Only one of the 10 interviewees, SQ, was overtly critical of the IBL nature of the course. Others expressed beliefs that implicitly diverged from Professor X's goals. As a preservice teacher, he thought IBL could have uses, but that instruction should usually be more direct.

SQ was very strong mathematically, but expressed frustration over the challenging nature of the course. Professor X told him he would appreciate challenges when he found something he loved and successfully overcame them, but SQ disagreed. He resented the way Professor X pushed him to do more. He wished Professor X guided him toward more efficient approaches.

SQ reported only working on the course homework for the hour before class started, but he performed well due to strong mathematical ability. He thus sought easier tasks and tried to avoid challenges. The variation in task difficulty both allowed SQ to find tasks he could complete easily before class started and allowed Professor X to implicitly push SQ toward more challenging problems if he attempted them after misjudging their difficulty. Professor X offered a telling interaction between the two:

> He probably wasn't doing any more work than looking for the easier problems, then came by my office one time to ask about a question…. I said that's all very good work and very nice and I'm really looking forward to seeing what you do from here, and he said "well I don't really want to work on it anymore." And I said you wouldn't be taking the class if you didn't want a challenge. You didn't come to college because you didn't want challenges. You came to college precisely because you do want challenge. He says, "No. Challenges make me anxious." And he actually was vibrating and sweating. And I noticed that after that when he would ask a question, he would be very nervous. Like it made him very uncomfortable when I would challenge him with a question. And yet I was doing it because he was clearly talented.

SQ seemed to understand Professor X's goals and intentions, even though he did not buy in.

## Discussion

Our results are structured as an answer to Research Question 1, identifying Professor X's primary instructional goals of *Creating Proofs* and *Overcoming Challenge*. We organized his classroom strategies to align with these goals in a partial answer to Research Question 2. We now summarize the range of student experiences of the resulting classroom environment illustrated by critical distinctions among our three cases, BT, KC, and SQ, thus answering Research Question 3. We will then return to Research Question 2 and discuss how the various strategies employed by Professor X afforded a wide range of students create their own meaningful proofs and overcome relevant challenges.

## Student Buy-in and Goal-Orientation

Our clustering of student experiences and exploration of the range of variation within each group resulted in distinctions along two primary dimensions: students' goal-orientation and their level of buy-in for Professor X's IBL instruction. Dweck & Legget (1988) demonstrated that individuals who viewed intelligence as innate and fixed in an achievement situation typically adopted a goal to demonstrate proficiency, and they persisted only in cases of perceived success while avoiding challenge when they perceive failure. In contrast, individuals who viewed intelligence as malleable and able to grow with use typically adopted a goal to increase their competence, and they persisted seeking challenge regardless of success. BT represents a case of high buy-in to the course goals through a performance orientation. She primarily avoided hard problems and developed pride in being able to complete many of the easier ones for a high grade. This success improved her confidence and she later sought some challenge by branching out to trying proof by contradiction. KC represents high buy-in with a learning orientation. He enjoyed the challenge of the class, even seeking to continue work on difficult problems after the class ended. He appreciated Professor X's IBL approach because it helped him learn and feel like a mathematician, and he wanted to adopt the approach in his own future teaching. SQ represents low buy-in with a performance orientation. Although he and Professor X both assessed that he was more than capable of doing the hardest work in the course notes, he reacted negatively and viscerally to the challenge. He expressed feelings of frustration over both the style of the course and his struggle on problems that he could not immediately solve. We observed no students with learning orientations that did not buy in. We thus generated six categories because we subdivided each of the three categories above between moderate and high achievement in proving.

## Differential Engagement of Professor Goals

Professor X consistently expressed goals of developing his students' ability to construct their own proofs and overcome meaningful mathematical challenges. Engaging a variety of students in the class, Professor X adopted several strategies that allowed students to differentially benefit from the course. Based on his judgment of their ability, he sought to give each "a problem worthy of their intellect." He subsequently offered support and feedback to enable them to be successful yet retain intellectual ownership of that success. He challenged students at different levels by offering differentiated feedback withholding (what he judged to be) just the right amount for each student to succeed. He valued success at multiple levels: 1) writing meaningful mathematics and logic, 2) developing key ideas for proofs, and 3) effectively attending to all details for a rigorous argument. He also enabled all students an appropriate entry point by reworking the content to more conceptually accessible units that afford proof without clever techniques, including problems at a wide range of difficulty throughout the course notes. Allowing students to improve and resubmit homework problems supported his focus on overcoming challenges. Professor X continually fostered his students' confidence, initially by allowing them to turn in presented proofs at the beginning of the semester, and always finding some aspect of their work to genuinely praise. Understanding that students would place different value on developing mathematical reasoning, Professor X took the long view of such difference, saying "It doesn't surprise me that many kids have different perspectives, and that's totally ok with me." He simultaneously valued what they got out of it for their current priorities and maintained hope that many would someday come back for graduate study in mathematics.

## Partitioning a Proof: An Exploratory Study on Undergraduates Comprehension of Proofs

Eyob Demeke
David Earls

California State University, Los Angeles
University of New Hampshire

*In this paper, we explore eleven undergraduate students' comprehension of two proofs taken from an undergraduate abstract algebra course. Our interpretation of what it means to understand a proof is based on a proof comprehension model developed by Mejia-Ramos, et al. (2012). This study in particular examines the extent to which undergraduate students are able to modularize a proof using the proof's key ideas. Additionally, eleven doctoral students in mathematics, referred in this paper as experts, were asked to provide modular structures for the same proofs that the undergraduate students received. We employed experts' modular structures of the proofs to analyze that of undergraduates'. The main finding of the study is that, contrary to experts' proof modularization, undergraduates partitioned the proofs in a way that failed to highlight how key components of the proofs are logically linked, suggesting an inadequate proof comprehension.*

*Key words:* Proof, Proof Comprehension, Modularization, Abstract Algebra.

Mathematics majors are expected to spend ample time on reading and writing proofs. However, despite its importance in undergraduate mathematics education, research on proof comprehension is limited. In fact, much of the proof literature focuses on students' aptitude to construct or validate proofs and less on their ability to comprehend proofs (Mejia- Ramos et al., 2012; Mejia-Ramos & Inglis, 2009). Mejia-Ramos and his colleagues (2009) systematically investigated a sample of 131 studies on proofs and they found that only three studies focused on proof comprehension. They hypothesize that the scarcity of the literature on proof comprehension is perhaps due to the lack of a model on what it means for an undergraduate student to understand a proof. In this study, we used an assessment model for proof comprehension that was developed by Mejia-Ramos, et al. (2012) to explore undergraduates' comprehension of proofs. In particular, this study seeks to examine the to extent to which undergraduates are able to modularize a proof to enhance their proof comprehension.

### Theory: Assessment Model for Proof Comprehension

Mejia-Ramos, et al. (2012) proposed that one can assess undergraduates' comprehension of a proof along seven facets. These seven facets are organized into two overarching categories: local and holistic. A local understanding of a proof is an understanding that a student can gain "either by studying a specific statement in the proof or how that statement relates to a small number of other statements within the proof" (p.5). Alternatively, undergraduates can develop a *holistic* comprehension of a proof by attending to the main ideas of the proof. According to the model, students' holistic comprehension of a proof can be assessed by asking students to identify a modular structure of the proof. A good modular structure of the proof shows an understanding of how key components or modules of the proof are logically connected to obtain the desired conclusion.

## Review of the Literature

Research looking into students' comprehension of proofs is relatively sparse. In Weber's (2012) study mathematicians reported that they measured their students' understanding of proofs by (1) asking students to construct a proof for a similar theorem to the one that was proven in class, and/or (2) asking them to reproduce a proof; and some said they do not assess their students' understanding of a proof. However, one cannot accurately capture students' comprehension of a proof by having them reproduce it (Conradie & Frith, 2000).

There are fewer studies on what students do when they read proofs for understanding. For example, Inglis and Alcock (2012) conducted a study that compared and contrasted beginning undergraduate students' proof-reading habits to those of research-active mathematicians. By studying their participants' eye movement while reading a proof, they concluded that undergraduate students, compared to the experts in their study, spend more time focusing on the "surface feature" of a mathematical proof. Based on this observation, the researchers suggest that undergraduates spend less time focusing on the logical structure of the argument; this, in turn, seems to explain why students often have difficulty understanding the logical structure of a mathematical argument, as evidenced elsewhere in the literature ( Selden & Selden, 2003).

Recent studies on novice proof readers suggests that undergraduates are not successful in gleaning understanding from the proof they see during lecture ( Lew et al, 2015). For example, students interviewed in Lew et al.'s (2015) study did not comprehend much of the content the instructor desired to convey, including the method used in the proof. Students interviewed in Selden and Selden's (2003) study also failed to understand a proof holistically since they were fixated on verifying each line and put little emphasis in attending to the overarching methods used in the proof. One purpose of this study is to build on the growing body of research on proof comprehension.

## Research Methodology

### Participants and Research Procedures

This study took place in a large public university in the northeastern United States. The content of the proof used in this study come from an introductory abstract algebra course. In the chosen research setting the standard textbook used is *Abstract Algebra: An introduction* by Hungerford (2012). The goal of the course (as stated in the syllabus) is to introduce students to the theory of algebraic structures such as rings, fields, and groups in that order.

Since the main purpose of this study is to explore undergraduates' comprehension of proofs—in particular, proofs that appear in an introductory abstract algebra course—the lead author personally approached undergraduates who had taken or were enrolled in an introductory abstract algebra course. Eleven undergraduates agreed to participate in this study and were assigned pseudonyms S1-S11. At the time of the study, six of the eleven undergraduate participants (S3, S5, S6, S7, S8, and S9) were enrolled in an introductory abstract algebra course. Seven participants—S1, S2, S3, S5, S6, S7, S8, and S9—were pursuing a major in secondary mathematics education and said they intended to be high school mathematics teacher. The remaining four students were mathematics majors.

In addition to undergraduates, we used eleven doctoral students, to conduct a fine-grained analysis of undergraduates' proof comprehension. At various times, we asked the doctoral students to provide, in writing, modular structures of the proofs. To avoid confusion, in the remainder of this paper we will refer to these doctoral student participants as experts.

In this study undergraduates were given two proofs, proofs A and B found in appendix 1 and 2, and were asked to read for understanding. We chose these proofs for various reasons, including their pedagogical value. For instance, proof A was chosen because it illustrates conditions that one can impose on integral domains to make them fields. Undergraduates were asked to read the proof until they felt they understood it and were encouraged to write and/or highlight on the proof paper as well as to think out loud while reading. Once a participant finished reading a proof, we asked her to (1) partition a proof into its modular structure and (2) explain the purpose of some assertions and how they are logically connected to prove the claim.

**Data Analysis**

Recall that eleven doctoral students in mathematics were asked to provide a modular structure for both proofs. All eleven modular structures of proof A that the doctoral students provided were studied carefully and resulted in what will hereafter be referred as the expert's modular structure. The expert's modular structure of proof A reads as follows:

> First, fix an arbitrary non-zero element $a$ (lines 1-2 in the integral domain $R$. Second, using $a \in R$, construct a map from $R$ to $R$, and then show this map is injective (Lines 1-6). Finally, using results from about maps between finite sets, argue that the map is surjective. It follows then that $a$ has a multiplicative inverse.

Similar to proof A, doctoral students' modular structures for proof B were also studied carefully and the following synthesized expert's modular structure emerged:

> First, if $H = \{e\}$ then the claim follows trivially. Second, consider the case where $H \neq \{e\}$. Using the properties of subgroups and the well-ordering axiom, proof B, in lines 2-4, argues for the existence of the smallest positive integer $k$ satisfying $g^k \in H$. Third, it shows that $< g^k > \subset H$. Finally, using the minimality of $k$ and the division algorithm the proof establishes that $H \subset < g^k >$. It follows then, $g^k$ is the generator of $H$.

Undergraduates' modular structures of each proof were then analyzed in relation to the expert's using the rubric described in Table 1.

Table 1

*Rubric to assess undergraduates' identification of modular structure of proofs*

| Rating | Criteria |
|---|---|
| Very poor | • Participant failed to provide a partition of the proof<br>• Participant wrote something completely irrelevant or incorrect.<br>• Participant seems to have copied the claim or a significant part of the proof word for word<br>• Over all, participant described how the proof is structured in way that is *very different* form the expert's modular structure for the proof. This means participant's modular structure of the proof failed to capture the purpose of each module and how they are logically connected. |

| | | |
|---|---|---|
| Poor | | • Participant wrote something relevant to the proof, but he/she failed to discuss how each module is related to one another<br>• Participant may have repeated the claim or some ideas or sentences from the proof word for word<br>• Overall, participant described how the proof was structured in a way that has *little resemblance* to the expert's modular structure for the proof |
| Satisfactory | | • Participant partitioned the proof into modules in way that resembles the expert's partition of the proof, but does not always describe the logical relationship between modules<br>• Participant did not state clearly state the purpose of some module or components of the proof<br>• Overall, participant described how the proof was structured in a way that has *some resemblance* to the *expert's* |
| Good | | • Participant explained the purpose of each module and how the modules together prove the theorem<br>• Overall, participant's description of how the proof was structured is *very similar* to that of the expert's |

## Results

An overwhelming number of undergraduates in this study provided modular structures that suggested that they either *poorly* or *very poorly* understood how the *key ideas* of the proof are logically linked to prove the claim. More specifically, most undergraduates did not identify the purpose of some of the key arguments of the proofs. For example, six students did not correctly address the purpose of showing that the kernel of $f_a$ is trivial (see lines 3-5 of proof A). Table 2 below summarizes our assessment of undergraduates' modular structure of proofs A and B.

Table 2. *Undergraduates' modular structure of proofs A and B*

| Evaluation | Undergraduate students | |
|---|---|---|
| | Proof A | Proof B |
| Very poor | S1, S2, S8, S9, S11 | S1, S2, S6, S7, S8, S9 |
| Poor | S3, S5, S6, S7 | S3, S10, S11 |
| Satisfactory | None | S5 |
| Good | S4, S10 | S4 |

As shown in Table 2, nine out of eleven undergraduate participants provided a structure for proof A that has either little or no resemblance to the expert's. Some undergraduate students, for instance S1 and S2, wrote something that either only amounts to repeating the claim word for word or is a general comment that can be said about any proof, not just proof A. For example, when asked to break the proof into components or modules specifying the logical relationship between each of the modules, S1 wrote: "proof was structured step by step". Another student, S2, said that "[the proof] was structured as a list of consecutive steps…" Note that both S1 and S2 do not provide any thoughts on the modular structure of proof A. Other participants, while correctly describing the goal of the proof A, offered a structure of the proof that is vague. For example, S3 wrote: "The proof started with stating some definitions. Then set some constraints and stated what the goal was. Proved bijection and then the goal which was that every non-zero element has a multiplicative inverse." S3's description of modular structure of proof A's is vague in that many proofs begin with definitions, constraints, and goals. Also, observe that S3 does not mention how the map $f_a$ is defined and the role it plays in proving the claim. S8, on the other hand, attended more to the writing style of the proof and much less about its content. When asked to provide a modular structure of proof A, she wrote:

> The proof had a plan. Step 2 in the proof explains where the proof is going. Step 3 also guides the reader forward letting them know when they are going next. It uses moving language all throughout, words like next, finally, since…

Far from describing key components of the proof and indicating how they are organized to prove the claim, S8 appears to focus on words of the proof rather than the idea of the proof. Also, when asked why in proof A the kernel of the map was shown to be trivial, S8 erroneously stated it was "to support the fact that there exists [sic] no zero divisors." However, the purpose of showing the map was trivial is to show that it is injective. Her response entails that she did not recall one of the properties of integral domain which is the absence of zero divisors. Therefore, it could be the case that her inadequate knowledge of meaning of important terms of the proof such as integral domains might have resulted in insufficient comprehension of the logical structure of the proof.

By contrast, two participants, S4 and S10, offered a structure of proof A that indicated some comprehension of the proof. For instance, S4 structured proof A as follows:

> Lines 1-2 set up that which to be prove
> Lines 3-6 prove that $f_a: R \to R, f_a: x \mapsto ax$ is surjective
> Lines 7-3 prove that $f_a$ is surjective
> Line 9 proves that $\forall a \in R, a \neq 0_R, a$ has a multiplicative inverse

As evidenced above, S4's modular structure of proof A does not have too much detail. Yet, it captures all *key ideas* of the proof that is noted in the expert's modular structure. In particular, both S4 and S10 described the *key* components of proof A; namely, how the map $f_a$ from $R$ to $R$ is constructed and that it is a bijection.

As shown in Table 2, a majority of undergraduates presented a modular structure for proof B that two researchers independently deemed *very different* from the expert's modular structure presented above. For instance, six students, S1, S2, S6-S9, provided a modular structure that is vague and misses *key ideas* of proof B. In describing the modular structure of proof B, S7 wrote: "the proof was divided into components that each proved a 'lemma' that was needed for the next mini proof. All these proofs were needed to prove the claim." Note that S7 does not indicate what the lemmas are and how they were used in the proof. Indeed, what S7 wrote regarding proof B can be said for just about any proof. Moreover, S7 does not correctly identify the purpose of assertions in lines 5-8. She wrote that "…the purpose of these lines [5-8] is to show there does not exist a smaller power of $k$…"

S4 is the only participant who described a modular structure for proof B in a way that was very similar to the expert's. S4 wrote:

> First, the trivial case (lines 1-2). Next, show that there is a smallest positive integer $k$ such that $g^k \in H.$ Finally, prove that $H =< g^k >$ by showing that for all $g^i \in H, i = nk.$ (lines 5-9).

First, observe that S4 correctly noted that proof B proceeds by cases. Also, he included key components of the proof such as establishing the minimality of $k$ and using the division algorithm to ultimately show that the any subgroup of a cyclic group is also cyclic. Finally, when S4 was asked to describe the goal of lines 5-8 in proof B, he correctly indicated that the purpose of arguments or statements in lines 5-8 is to show that $g^k$generates *H.*

To summarize, undergraduates in this study demonstrated limited comprehension of proofs A and B. Indeed, six out of eleven provided a modular structure that related *very poorly* with that of the experts, suggesting limited proof comprehension. One plausible explanation for participants' poor proof modular structures has to do with lack of familiarity with the tasks we asked them to do in this study. Stated differently, undergraduates, including those in this study, are rarely asked to partition a proof and asking them to do so might not necessarily reflect their understanding of the proofs. Furthermore, some undergraduates in this study may have viewed these proofs as not long enough to warrant breaking them apart. We suggest that future studies can improve on this study by first showing participants examples on what it means to modularize and then ask students to identify a proof's modular structure.

## Appendix 1: Proof A

**Direction:** Please feel free to write any of your thoughts while reading the proof below. Also please think-out-loud while reading the proof. Note that the numbers only indicate each line in the proof for follow up questions. Below you will find a proof of the following claim.

**Claim**: Let *R* be a finite integral domain. Then *R* is a field.

*Proof*. 1. Let *R* be a finite integral domain whose multiplicative identity is $1_R$ and whose additive identity is $0_R$.

2. Since *R* is a commutative ring, it suffices to show that every nonzero element in *R* has a multiplicative inverse.

3. Let *a* be a fixed nonzero element of *R* $(a \neq 0_R)$. Consider the map $f_a: R \to R$ defined by $f_a: x \to ax$. We first show that the kernel of $f_a$ is trivial.

4. Note that kernel of $f_a = \{x \in R: f_a(x) = 0_R\} = \{x \in R: ax = 0_R\}$.

5. Since *R* has no proper zero divisors, $ax = 0_R \Longrightarrow a = 0_R$ or $x = 0_R$. But, $a \neq 0_R$ thus $x = 0_R$.

6. Therefore kernel of $f_a = \{0_R\}$ and so $f_a$ is injective.

7. Next, note that $|R| \geq |f_a(R)|$. Since $f_a$ is injective, it follows that $|R| = |f_a(R)|$.

8. Because $f_a(R) \subseteq R$ and $|R| = |f_a(R)|$, we have that $f_a$ is surjective.

9. Finally, since $1_R \in R$, we have that $\exists x \in R$ such that $f_a(x) = ax = 1_R$. So $a$ has a multiplicative inverse. Therefore, $R$ is a field.

## Appendix 2: Proof B

**Direction:** Please feel free to write any of your thoughts while reading the proof below. Also please think-out-loud while reading the proof. Note that the numbers only indicate each line in the proof for follow up questions. Below you will find a proof of the following claim.

**Claim:** Any subgroup of a finite cyclic group is cyclic.

*Proof*. 1. Suppose that $G =< g >$ and $H \leq G$.

2. If $H = \{e\}$, then $H =< e >$. Otherwise, $\exists i \in \mathbb{Z}, i \neq 0$ such that $g^i \in H$.

3. Then, $g^{-i} \in H$. It follows that one of $i$ or $-i$ is a positive integer.

4. The well ordering axiom guarantees that there is a smallest positive integer *k* such that $g^k \in H$. We will show that $H =< g^k >$.

5. Clearly, $< g^k > \subseteq H$ because $H$ is closed under the operation of *G* and $g^k \in H$.

6. Suppose that $h = g^i \in H$.

7. By the division algorithm we know that $i = nk + r$ for some $0 \leq r < k$.

8. Then, $r = i - nk$. We have that

$$g^r = g^{i-nk} = g^i g^{-nk} = g^i (g^k)^{-n} \in H.$$

9. Since $g^i$ and $(g^k)^{-n}$ are both elements of *H* and *H* is a group, it follows that $r = 0$ or we would have a smaller thank *k* positive power of *g* in $H$. Conclude that $H =< g^k >$

Informal Content and Student Note-Taking in Advanced Mathematics Classes

Alex Kopp
Temple University

Tim Fukawa-Connelly
Temple University

*This study investigates four hypotheses about calculus instruction: (i) that lectures include informal content (ways of thinking and reasoning that are not captured by the formal symbolic statements), (ii) that informal content is usually presented orally but not written on the blackboard, and (iii) that students do not record the informal content that is only stated orally but do if it is written on the blackboard, and (iv) that professors often most want students to learn the content they state informally. Via interviews, we also explored why professors chose to write on the board, or not, content. We recorded 5 calculus mathematics lectures and photographed the notes of 78 students. We found that informal content was common, although most informal content was presented in a written form. Typically students recorded formal content while not recording informal content.*

*Keywords:* Lecture, Calculus, Student Learning

Many, if not all STEM majors will be exposed to a calculus course in their study, even if they intend to major in something other than mathematics. In the Fall semester of 2010 alone, over 300,000 students were taking a calculus course at the undergraduate level (Blair, Kirkman, & Maxwell, 2013). It's estimated by the Department of Commerce that STEM jobs will increase by 17% from 2008 to 2018, as opposed to 9.85 for non STEM fields, such an increase in the job market requires an equal increase in new STEM majors (Langdon, et al, 2011). Yet, relatively few students begin their undergraduate careers as STEM majors and very few students transfer in. In particular, Green noted that "not only do the science have the highest defection rates of any undergraduate major, they also have the lowest rates of recruitment from any other major" (1989, p. 478), meaning, there is (nationally) a net loss of students over the undergraduate program (Hilton & Lee, 1998). Often Calculus is both a stepping-stone and barrier into these majors and in order to increase the number of STEM majors, the number of students who succeed in calculus must increase as well. The failure rate and rate at which even successful Calculus 1 students who do not go on to Calculus 2 is high. The lack of success and persistence limits a student's opportunity to pursue a STEM career.

A major recent research project has explored the impact of various characteristics of calculus classes and how they influence student success (Mesa & Burn, 2011). They have described the typical curriculum as including limits and continuity, derivatives, integration, sequences and series. Faculty tended to focus their instruction on procedural fluency, with other aspects being less common. More, they found that lecture was the most common mode of instruction (82% of the time), and that typically presentations involved symbolic manipulations with some graphical representations as well. Yet, research on note-taking (and recall) as well as advanced mathematics classes suggests that further investigation of the actual instruction of calculus could help explain some of student's frustrations and difficulties with the class. Mathematics professors certainly hope that students gain more than procedural fluency from their classes—they want (and believe) that students need to gain understanding. While they may not have the same types of definitions for understanding that mathematics educators do, they certainly include being able to flexibly use procedures and be able to explain why the procedures work. This report seeks to explore the seeming difference between what professors intend students to gain and what students believe that classes focus on.

A pair of previous studies in proof-based mathematics classes motivated this exploration. A qualitative study (Lew, Fukawa-Connelly, Mejia-Ramos, & Weber, 2016) found that students might fail to learn what the professor intended from a lecture, even when the professor repeatedly emphasized the point. In particular, if the professor's main learning objective was about informal ways of thinking, the professor typically spoke it aloud without writing it on the board and the students failed to notice it during the lecture and did not record it in their notes. A subsequent quantitative study (Fukawa-Connelly, Weber, & Mejia-Ramos, 2017) of 11 lectures and 96 students showed that informal mathematics is regularly part of lectures in advanced mathematics, that such content is typically presented orally without the professor recording anything on the board, and that students do not typically record orally presented content. While the study did not test the claim that failure to record content in their notes lead to students being unlikely to learn it, or the converse, that recording lead to learning, there is substantial literature on the efficacy of note-taking as a learning tool. In particular, students normally forget content they do not record in their notes (c.f., Einstein, Morris, & Smith, 1985; Kiewra, 1987).

Following the previous studies of calculus and proof-based mathematics, we investigated three hypotheses and one question:

1. When lecturing about calculus instructors regularly discuss informal aspects of mathematics. Specifically, these lecturers represent mathematical concepts using informal representations, discuss methods that can be useful for completing related mathematical tasks, give informal explanations of concepts and processes, and give heuristics for approaching different types of problems.
2. When lecturers discuss informal aspects of mathematics, they usually make their comments orally and do not record them on the blackboard. The blackboard is reserved for formal mathematics, most prominently, worked examples, as well as definitions, theorems, and proofs.
3. When lectures make these comments orally, students usually do not record these comments in their notes.

The question that we explored is, "what rules and heuristics guide instructor's choices about recording content on the board (or not)?" We wanted to better understand instructor's decision-making in order to understand the conditions of instruction, and, possibly, what might be malleable about their practice.

## Methods

### Participants

We recruited participants by sending e-mails to every instructor teaching a calculus course at an institution granting doctorates in mathematics (TAs leading recitation sections were not considered instructors; for simplicity, we subsequently refer to all participants as professors, even if that is not the person's actual job). Our email asked the instructor if we could record one of their lectures and invite their students to participate via a researcher photographing their notes. A subset of professors was also asked to participate in a short post-class interview about their instruction. There was no selection process for professor interviews. Professors were not told the purpose of the study. The professors were also asked not to let the students know that we would be conducting research on their note-taking during the lecture (the professors did often want to announce that a researcher would be present and studying the class). 5 different professors participated, and the content of their course is summarized in Table 1 below.

*Table 1. Overview table of instructor, class and content*

| Instructor | Overarching Course-content | Description of content in the lesson we recorded |
|---|---|---|
| M1 | Calculus 2 | Ratio and Root tests for series convergence |
| M2 | Calculus 1 | Fundamental Theorem of Calculus |
| M3 | Calculus 1 | Fundamental Theorem of Calculus |
| M4 | Calculus 1 | Fundamental Theorem of Calculus |
| M5 | Calculus 2 | Representation of a function as a power series |

**Data collection**

For each participating, a member of the research team attended a class meeting in which an exam was not given. The researcher audiorecorded the lecture, while transcribing everything that the professor wrote on the blackboard in the researcher's notes. We also attempted a rough-count of the number of students in the class, although because we sat near the front of the room in order to have good-quality audio recordings, it was impossible to ensure that the counts were completely accurate. Each lecture was scheduled to be 70 minutes, although some were shorter than 70 minutes because the professor chose to return exams and then address individual questions. At the end of the lecture, the researcher made an announcement to the class inviting students to share their notes with the researcher, even if their notes were not of high quality or the student did not take notes at all. Collectively, 96 students across the 5 lectures agreed and the researcher photographed the notes that the students took for that lecture (no students indicated that they took no notes). Each class had between 20 and 30 students in attendance. For those professors who were interviewed, the lead author would meet with the professor outside of class and asked the professor to explain what the most important learning goals for the class were and why the professor chose to convey the ideas in the way that he or she did.

**Analyzing the lectures**

Each lecture was transcribed. The authors coded the lecture for every time one of the following were presented: definitions, propositions, proofs, examples, heuristics, pictures or graphs (these required further analysis), rules, charts (e.g., tables), conceptual examples, and contextual (real-world) examples and described the mathematical content of the lecture (often by referring to the title of the section the professor was presenting on). Any disagreements between the two researchers were resolved by discussion. We developed our categories primarily via the literature, using Fukawa-Connelly, et al's (2017) codes related to proof, and, adding codes related to the presentation of procedures given the different focus of the calculus courses. We added codes for procedures (general statement of procedures) and examples of procedures (e.g., illustrating a process or algorithm). We applied each code at the sentence-level, aggregating sets of sentences in order to capture the complete instance of a particular code. Sometimes different codes would be interspersed; for example, the professor might begin an example, give a heuristic, and then complete the example. In such a case, we would aggregate the example sentences into one unit and the heuristic sentences into another. No sentences were double-coded. In the text below, we refer to definitions, propositions, and proofs as formal mathematics because the previous literature (c.f., Davis & Hersh, 1981) has called them such. Moreover, because the calculus class is focused on procedures (Mesa & Burn, 2017), we also include any step-by-step instructions of how to complete a procedure or algorithm as formal mathematics. We refer to the other content that we coded for as informal mathematics. For space reasons, we concatenate our description of coding schemes, noting that the coding scheme for *definitions, propositions,* and *proofs* were taken directly from Fukawa-Connelly, et al (2017) and that for *informal representation* was adapted to be appropriate for calculus. Because we expected two different kinds of examples; those that illustrate definitions (or concepts) and those that illustrate processes, we differentiated between them, adopting Fukawa-Connelly et al's definition and coding of *example* as our *example of a definition*, while adding a coding structure for an *example of a process*. We used the same rule as Fukawa-Connelly, et al to code whether content was written (either on the board or in student notes).

**Analysis of professor's claims**
