CITATION: Karunakaran, S. S., Reed, Z., & Higgins, A. (Eds.). (2020). *Proceedings of the 23rd Annual Conference on Research in Undergraduate Mathematics Education.* Boston, MA.

Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-third annual Conference on Research in Undergraduate Mathematics Education in Boston, Massachusetts from February 27 - February 29, 2020.

The program included plenary addresses by Dr. Gregory Larnell, Dr. Eric Knuth, and Dr. Elise Lockwood, and the presentation of 148 contributed, preliminary, and theoretical research reports and 74 posters.

The conference was organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in the field of undergraduate mathematics education, each of which underwent a rigorous review by two or more reviewers:

- Contributed Research Reports describe completed research studies

- Preliminary Research Reports describe ongoing research projects in early stages of analysis

- Theoretical Research Reports describe new theoretical perspectives for research

- Posters are 1-page summaries of work that was presented in poster format

The conference was hosted by the Wheelock College at Boston University.

Many members of the RUME community volunteered to review submissions before the conference and during the review of the conference papers. We sincerely appreciate all of their hard work by the 165 reviewers.

We wish to acknowledge the conference program committee for their substantial contributions to RUME and our institutions. Without their support, the conference would not exist.

Finally, we wish to express our deep appreciation for Wheelock College and Boston University. Their support enabled us to have our conference and continually support our community.

Undergraduate Students' Perspectives on What Makes Problem Contexts Engaging

Tamara Stark Steven R. Jones
Brigham Young University

Using engaging problem contexts is important in instruction, and the literature contains themes of contexts being realistic, worthwhile, or enjoyable, as well as motivating. Yet, the literature largely lacks detailed student perspectives on what helps problem contexts achieve these characteristics. In this study, eleven calculus students were interviewed to identify features of problems that made them engaging. This led to a new top-level characteristic "variety," and the identification of features that helped contexts have the characteristics described in the literature. In particular, problems that were realistic/motivating contained features including: (a) expansion of awareness, (b) need for math, and/or (c) explicit purpose. Contexts that were enjoyable/motivating contained features including: (a) insertion into problem, (b) teacher's personal story, or (c) absurd story. At the end, we show the usefulness of these results by critiquing problems from the literature in terms of how engaging they might be to students.

Keywords: problem context, student engagement, realistic, enjoyable, variety

Two major reasons given for why students may develop negative feelings towards mathematics are that students cannot see a relationship between classroom mathematics and real life (Boaler, 2015; Boaler & Selling, 2017), or that students do not see mathematics as interesting or enjoyable (Brown, Brown, & Bibby, 2008; Nardi & Steward, 2003). The usage of more engaging problem contexts to introduce and develop mathematical content can help address these issues (Boaler, 2015; Crespo & Sinclair, 2008; van den Heuvel-Panhuizen, 2003). However, the literature generally lacks detailed accounts of students' perspectives on the matter, making it more difficult to ascertain if certain problem contexts actually *are* engaging to students, and what aspects of those contexts helped them be engaging (or not). This study seeks to build on the current literature through the question: What do students perceive as making problem contexts more engaging? We then show this study's potential usefulness by critiquing example problem contexts in the literature in terms of how engaging they might be to students.

Before continuing, however, we need to make a clarification between two closely related aspects of mathematical problems. First, the initial *problem context* is that used to enter students into an exploration. For example, an initial problem context might be, "Given a fixed amount of fencing, what dimensions of a rectangular field maximize the area inside?" The context is about fencing and interior area. Next, within this initial context, there may arise a "problematic situation… unsolvable by [the student's] current knowledge" (Harel, 2013, p. 122). In the example, it might be the need for justifying when certain dimensions actually *do* maximize the area. This problematic situation leads to the mathematics to be learned, in terms of techniques for identifying and guaranteeing extrema. Note that in this study, we are focused *only* on the "initial problem context" in terms of attempting to engage students' interest. We are *not* focused on the "problematic mathematical situation" that might be encountered *within* that context.

Literature Review and Framework on Engaging Context Characteristics

To begin, we reviewed the literature to identify characteristics of problem contexts associated with student engagement. First, much research, including research in Realistic Mathematics Education and in mathematical modeling, discusses *realistic* contexts (e.g., Blum, 1993; Boaler, 2015; Gravemeijer & Doorman, 1999; Kümmerer, 2001). However, Boaler (2015), cautioned that many so-called realistic contexts are "pseudocontexts," which van den Heuvel-Panhuizen and Drijvers (2014) would say is because they are not "experientially real" to students. Thus, we define a *realistic* context as one rooted in the real world containing a problem that a student could see somebody (possibly themselves) having an actual desire to solve.

As a subset of *realistic*, while a student could see someone wanting to solve a real-world problem, there is a difference in whether that problem is seen as important or worthwhile (see National Council of Teachers of Mathematics, 2000). Thus, as another characteristic, we define a *worthwhile* context as one involving a question whose answer is seen by the student as having the potential to make an impact, whether in the narrow world of the student or in the world at large. Note that a context could be realistic without necessarily being worthwhile.

Next, in contrast to the first two characteristics, some studies have mentioned "fun" or "enjoyable" as a characteristic of engaging problem contexts (Brown et al., 2008; Nardi & Steward, 2003; Schukajlow & Krug, 2014). Puzzles, games, or fun situations could potentially create engagement for students (Kebritchi, Hirumi, & Bai, 2010; Kubinova, Novotna, & Littler, 1998). However, definitions for "enjoyable" tend to be vague in the literature, so for our working definition we chose to use the broad idea of personal feelings. That is, we defined a context as *enjoyable* if it provokes a positive emotional response from the student.

Overall, the literature speaks of two main "engaging" characteristics: realistic or enjoyable (with worthwhile as a subset of realistic). We based ourselves in the literature by adopting these two characteristics as those that can make a problem engaging. Of course, we left ourselves open to the identification of additional characteristics in this study. However, within these two main characteristics, it appears that a problem that is technically "realistic" or "enjoyable" still may not been seen as *motivating* to students (see Boaler, 2015; Schukajlow & Krug, 2014). Thus, within these two characteristics, we define a secondary characteristic, *motivating*, as a context that stimulates a student's interest to continue to investigate the initial problem. In this way, while an engaging problem is either realistic or enjoyable, we claim that it must also be *motivating* to truly be engaging. We then define an *engaging problem context* as one that resides in the realistic/motivating intersection, or the enjoyable/motivating intersection, or both.

In summary, past research suggests two broad types of contexts: *realistic* or *enjoyable* (or the intersection of both). Either type must be *motivating* to be engaging. A realistic context does not necessarily need to be worthwhile to be engaging, but being worthwhile might strengthen how engaging it is. Figure 1 shows the interrelationships of these four characteristics, where an engaging context resides in the intersection of realistic/motivating, enjoyable/motivating or both.

Figure 1. Engaging contexts live in the intersection of realistic/motivating, or enjoyable/motivating, or both

Methods

For our study, we designed a two-part interview that we conducted with eleven first-semester calculus students. We chose to involve students in their early undergraduate career because: (a) they have a lot of exposure to problem contexts through their years of schooling, and (b) as older students they might better reflect on and articulate their thoughts about those contexts. In the first part of the interview, the students were shown six problems and were asked to open-endedly explain which ones they found more engaging than others. For this part, the students were not aware of the characteristics in our framework, so that their reasons were more likely to be genuinely their own. To select problems for this part, we narrowed to a specific topic to keep the mathematics generally the same. We chose to use "optimization" problems because they are seen in different mathematics courses meaning it is not *too* narrow in scope, and because optimization lends itself well to the study of context due to the variety of contexts involving maximizing or minimizing. We chose three problems shared among commonly used calculus textbooks (e.g., Stewart, 2015; Thomas, Weir, & Hass, 2014). Then, to help students be specific about what might make certain problems engaging or not, we created three problems with essentially identical mathematical solutions to the three textbook problems but with different contexts. Abbreviated versions of these problems are shown in Table 1.

Table 1. Textbook problem contexts and mathematically equivalent problems with different contexts.

Abbreviated textbook problem	Abbreviated equivalent problem with different context
A farmer has 2,400 feet of fencing and he wants to make a rectangular field that borders a straight river… What are the dimensions of the field that will give it the greatest area?	You're adding on to your home, and you're going to knock out a wall in the back to add an open room … You have enough material for 60 feet of new wall… What dimensions would give the greatest area for this new room?
You are going to launch a boat from point A on the bank of a straight river. You want to reach point B which is downstream on the opposite bank of the river… Where should you land on the opposite bank in order to reach point B as soon as possible.	You are working with a humanitarian aid group to bring safe water supply to villages. One village is located at the edge of a mountain range and its nearest water supply is up in the mountains… What path should the pipe follow in order to minimize the cost of laying the pipe?
Consider the graph of $y^2 = 2x$ and the point (1,4). Every point on the parabola is a certain distance from the point (1,4). Find the point on the parabola that is closest to the point (1,4).	You're working for NASA and a comet is making a close pass by Earth… The comet's path is modeled by the graph of $y = \sqrt{x+5}$ [Earth at origin]. To tell the public which day would be the best day to view the comet… find the point along the graph that is closest to the origin.

In the second part of the interview the students were shown the four characteristics (realistic, worthwhile, enjoyable, motivating) one at a time and a description of each characteristic was given. The students were asked to think of an example problem context they had seen that they felt exemplified that characteristic, and to discuss why. They were also asked to discuss problems they felt *failed* to have that characteristic. While worthwhile is a subset of realistic, and motivating exists only in addition to realistic or enjoyable, we still asked the students about them separately simply to permit additional opportunities for the students to discuss features that might make problem contexts more engaging. While the first part of the interview was somewhat limited due to using a specific topic area, the second part of the interview allowed the students to pull problems they had seen from a range of different classes and different topics, broadening the data set greatly. To conclude the second part of the interview, the students were also asked to identify and discuss what they considered to be the most engaging mathematics problem, overall, that they had experienced in a class.

The analysis consisted of three phases, with the "reasons" given by the students as the unit of analysis. First, we coded the students' reasons in the first part of the interview as *realistic*, *worthwhile*, and/or *enjoyable* according to their definitions, and we also used the category *other* to capture possible reasons beyond our framework. We also used the antonym codes *not realistic*, *not worthwhile*, and *not enjoyable* if a reason was given for why a context failed to have that characteristic. Each reason could additionally be coded as *motivating* if the explanations surrounding that reason suggested that the student's interest was activated because of that reason. Or, it could be coded as *not motivating* if that reason appeared to be one that turned the student off to that context. In the second phase, we looked at the instances within "other" to see if there were any top-level characteristics that the data suggested should be added to the framework (one such emerged). In the third phase, we took all student reasons from both parts of the interview that were coded as (a) realistic and motivating (or not realistic and not motivating), as well as (b) enjoyable and motivating (or not enjoyable and not motivating), to look for themes suggesting features of contexts that helped them live in the "engaging" intersections (or not). This led to the identification of three features of contexts that helped them be realistic/motivating and three features of contexts that helped them be enjoyable/motivating.

Results

The analysis of the data revealed one new main characteristic in addition to the four in our framework, as well as several problem features that helped contexts be realistic/motivating or enjoyable/motivating. Note that due to space constraints, we do not examine the first and second part of the interview separately in this report, but rather describe the resulting themes in aggregate from the first and second parts of the interview all together.

Identification of a New Characteristic to Add to the Framework: Variety

During the analysis, a strong theme emerged in the "other" category that did not fit under any of the characteristics in our framework. To introduce the theme, consider one student who was explaining how some problems that were meant to feel realistic did not seem realistic to her. She stated, "The apple problems were repetitive… When I was a little kid, apples were fine. But as you get older you want to see it in different ways. So, instead of seeing it repetitively, with the same problem over and over, you want to see different applications." Another student echoed a similar sentiment when she explained, "We were always doing rocket problems… It is more engaging when it is something I have never thought about." A third student summarized, "Have a variety of questions… Spice it up with other things, put a new spin on something. It is more enjoyable when we incorporate other things like science, literature." In fact, without being prompted, ten of the eleven students regularly expressed the need for variety in problem contexts. We thus claim *variety* to be a new fifth characteristic to add to the framework, and define it as a context that is new or different from previous contexts in the *students' experience*. As such, variety must be judged relative to commonly encountered previous contexts, suggesting the need for future research to document what those common contexts might be.

Features of Problem Contexts that Can Help them be Realistic/Motivating

When examining student reasons that fell within realistic/motivating (including possibly worthwhile) or not realistic/not motivating, three themes emerged that could help contexts be engaging. First, while the students certainly did agree with past research that problems are motivating when related to their everyday lives (e.g., Bonotto, 2005), the students in our study often expressed the desire for problem contexts to expand past their everyday lives to new views on how math can be used in real-world contexts beyond themselves. One student's example of the most realistic problem she had seen was a case of an oil spill. "The oil slick one was realistic because someone could do that. If I know how big the spill is, I can clean it up. Derivatives were used to find how big the spill was." Another student gave an example of a problem where normal distributions were used to "fine tune a medicine." He explained, "You are saving lives right there." A third student lamented, "The classrooms had these posters hanging up that said, 'Where do you use this math?'… But that did not translate into math problems we did." He wished his classes examined the contexts on the posters since he did not know how math related to them. Another student summarized that contexts can be quite realistic, "even if it is not you." These reasons suggest contexts can be realistic/motivating *without* dealing directly with the students' everyday lives, but that rather let them see *new* possibilities for mathematics. Taken together, we call this feature *expansion of awareness*, and define it as a context that permits students to see mathematics being used in a way they did not previously know it could be used.

As a caveat to the previous theme, however, there was a caution for when problems felt unrealistic. Consider an example excerpt from a student who explained, "No one does this. Sports problems, analyzing the arc of your shot, the quickness of movement. When I go to do these activities, I don't do math." Even if an expert might see mathematics as inherent to such activities, the point is that the student did not perceive mathematics as necessary in, for example, having or developing a good arch. Another student gave a similar explanation. He described a short problem where he was given the force and acceleration of an object and was asked to calculate its mass. He stated, "I cannot visualize that scenario. It would be so easy to get the mass. That is annoying because it is not realistic." He did not believe that one would know the force and the acceleration without already knowing the mass. He summarized, "Problems try too hard to feel realistic… When they are trying to pull math out of something that does not feel like it needs math to solve it." Again, regardless of an expert's perspective on the presence and necessity of mathematics in such situations, it was clear that the *students* did not see math as necessary in some of these situations. This theme suggests a context would benefit from having the feature *need for math*, which we define as a context in which a student can perceive the mathematics as being a necessary tool that a person would actually use in such a situation.

The third theme relates to helping a realistic problem also be worthwhile. Some students made comments about feeling in the dark regarding why a potential realistic problem was important. One student's discussion of the humanitarian aid problem from our study included the explanation, "The key is that it should be obvious how I am helping someone. Make that clear in the problem. I don't care nearly as much about saving cost on laying a pipe… if it is not humanitarian aid. I could abstract the problem being humanitarian aid if it is not there, but… I should not have to abstract that from the problem." The point for this student was that a problem felt much more worthwhile when the context itself gave a reason for why one should care about the problem, rather than him trying to guess from the problem what potential worthwhile uses there might be. Similarly, a student criticized the river problem as failing to be realistic because, "I just can't imagine a situation in which I care why… I cannot think of a single reason where I would actually calculate that." This theme suggests a context would benefit from having an *explicit purpose* attached to it, which we define as a specific reason given as to why the answer to such a problem would be useful or beneficial. For example, if the previously mentioned "arch of shot" context were enhanced by adding a specific reason for why knowing that would be useful, that student might have been more engaged by what was otherwise a "realistic" problem.

Features of Problem Contexts that Can Help them be Enjoyable/Motivating

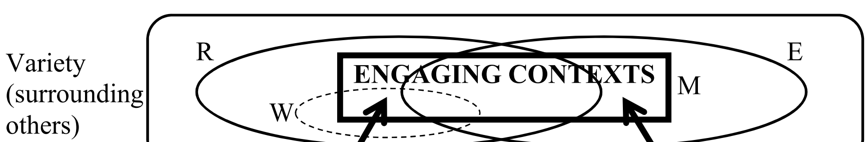
Our data also spoke to three features that problem contexts might have to help them be enjoyable and motivating. First, consider one student's explanation as to why he enjoyed the comet problem: "I can look at it at that time and get a great view." Another student explained why they enjoyed the humanitarian aid problem: "I felt like I was solving an issue." A third student put it well when she said enjoyable contexts might be those that "Give the students an opportunity to put themselves in the shoes of a person within the problem." This theme suggests one possible way to make a problem enjoyable and motivating is if the student can imagine themselves *inside* the problem context. We call this *insertion into problem* and define it as a feature of a context that lends itself well to imagining oneself inside that context.

Second, most students brought up the idea of “stories” being enjoyable and motivating. Two types of stories were discussed by students. One student explained, “My calculus teacher gave us this problem about his son who was trying to make the lantern from [the movie] Tangled. He needed to figure out how to maximize the surface area… Even though I don’t like calculus, I thought, ‘this is a really interesting problem. I kind of enjoy this.’” Another student brought up a situation where his teacher described a “potato gun” his family had and how someone thought it would shoot higher than it really could and ended up making a mess of a gazebo in a park. He stated, “Whenever they give examples from their life it usually ends up being funny and relatable.” Thus, problem contexts that contain a *teacher’s personal story* appeared to be enjoyable and motivating for students.

For the other type of story, a few students explained that sometimes a problem is so “way out there” [student quote] that it is enjoyable. This student explained, “In eighth grade we had this problem about finding ratios and bike tires. It was an absurd problem. The diameter of the tire was massive. The problem became silly and that made it motivating for me.” However, he did add the caution, “It should not be overused. Variety is important. I need some realistic problems. But occasionally putting in ridiculous problems is funny.” Another student described an enjoyable problem where a criminal used calculus to identify the darkest place along a street at night in order to commit a crime there. These contexts contained an *absurd story*, which helped them be enjoyable and motivating. The trick here may be to not overuse this type of context.

Connecting the Results to the Framework

In this study, we identified one new top-level characteristic, *variety*, for problems to be engaging. Note that variety is not contained just within realistic or enjoyable, since the student excerpts on variety included both realistic and enjoyable contexts (e.g., “science” and “literature”). We use this to build on our definition of an engaging context, by defining it as before but with the additional constraint that the context is not seen as repetitive compared to previously encountered contexts. Our study also provides several features that can help a context reside in the intersection of realistic/motivating or enjoyable/motivating. Of course, we in no way claim that these are an exhaustive list of features that could help make problems more engaging. Figure 2 shows how our results have now embellished the original framework.



Inside realistic/motivating:
(a) expansion of awareness
(b) need for math
(c) explicit purpose

Inside enjoyable/motivating:
(a) insertion into problem
(b) teacher’s personal story
(c) absurd story

Figure 2. New characteristic “variety” and (non-exhaustive) features that can help a problem context be engaging

Discussion

Our study adds to the existing literature on engaging problem contexts. For example, some research-based instructional practices within mathematics education are based heavily on presenting students with realistic problems (Blum, 1993; Gravemeijer & Doorman, 1999; Kümmerer, 2001). It is known that these problems should be experientially real to the students, but it is quite possible that an instructor could intend to create a realistic problem that ends up that missing the mark for students. The results of our study can aid instructors in identifying contexts that would engage their students by providing a useful set of features to compare against problems to see whether they would likely be perceived as engaging by students. For example, consider a problem reported on in the work of Schukajlow et al. (2012), who claimed that context ended up having no impact on how engaged students were while doing mathematical tasks. One of the "real-world, modelling contexts" they used is shown in Figure 3. In comparing our study's resulting features to this problem, we can see it fails to be engaging in several ways. We believe it fails to have an *explicit purpose* because there is no specific reason given for why the children in the scenario want to know the cable's length. We believe it fails have *need for math* because even if the children were interested in knowing that, they would likely use other methods to find the length of the cable, such as using a tape measure. While the student audience of this problem might relate to playgrounds and slides, we do not believe the context lends itself to *insertion into the problem*, because the students would not imagine themselves performing such an exploration. While it does provide a story, it seems neither personal nor absurd (nor fun in other ways). With problems like this, we are not surprised that Schukajlow et al's (2012) study produced the results it did. If they had used more a problem context with features that our results suggest are better related to student engagement, the results may have been quite different.

Playground

The Traudt family is vacationing on a farm near Schwandorf in the Bavarian Forest. There is a playground there for the children, Lina and Maria. The playground's greatest attraction is the rope slide. The steel cable of the rope slide is stretched horizontally between two posts 10 meter apart. When Lina reached the middle, the steel cable stretched so much because of her weight that it dropped by 45 cm.

How long is the steel cable now?

Figure 3. A "real-world, modelling context" from Schukajlow et al. (2012, p. 224)

Our study also helps flesh out what makes a problem context enjoyable. As we stated earlier, research promoting "enjoyable" or "fun" contexts have not clearly defined what they mean by these terms (Brown et al., 2008; Nardi & Steward, 2003). Our initial framework provided a definition that is useful by explicitly factoring in the students' emotions. We were then able to elaborate on what helps problem contexts have this characteristic by finding specific features of contexts that seemed to create a positive feeling in the student. Students enjoyed *stories*, and they enjoyed seeing themselves within a problem context. This can aid an instructor in creating problem contexts that stimulate positive emotion by trying to incorporate some of these features.

Finally, our study is important in highlighting just how critical *variety* was for the students in our study. It suggests the need for research work in engaging contexts to pay attention to what contexts are oft-used along the curriculum trajectory from lower grades to higher grades. Future research work could examine this to create a knowledge base of what contexts might be seen as too repetitive, or what contexts might be more unique and new to the students.

Undergraduates' Perceptions of the Benefits of Working Tasks Focused on Analyzing Student Thinking as an Application for Teaching in Abstract Algebra

James A. Mendoza Álvarez[1] Andrew Kercher[1] Kyle Turner[1]
[1]The University of Texas at Arlington

The Mathematical Education of Teachers as an Application of Undergraduate Mathematics project provides lessons integrated into various mathematics major courses that incorporate mathematics teaching connections as a legitimate application area of undergraduate mathematics. One feature of the lessons involves posing tasks that require undergraduates to interpret or analyze the work of another student. This paper reports on thematic analysis of hour-long interviews for eight participants enrolled in an undergraduate abstract algebra course from two different implementation sites. We focus on student work and reactions to these interpreting or analyzing student thinking (AST) applications as they relate to their perceptions regarding the use of AST applications as a mechanism to both deepen their content knowledge and improve their skills for communicating mathematics. Several participants identify positive benefits, but more research is needed to determine the how to incorporate AST applications to accommodate some participants' reluctance to engage in new mathematical contexts.

Keywords: Abstract Algebra, Preservice Secondary Mathematics Teachers, Mathematical Knowledge for Teaching

The Mathematical Education of Teachers II (MET II) Report of the Conference Board of the Mathematical Sciences (CBMS) recommended that preservice secondary mathematics teachers make explicit connections between the undergraduate mathematics content they are learning as part of their continuing education and the primary or secondary school mathematics content they will eventually teach (CBMS, 2012). Furthermore, the MET II report recommends these connections be made in classes throughout their entire degree program and not simply summarized during a culminating capstone course.

An immediate consequence of this recommendation is that mathematics knowledge for teaching must not simply be cursorily included in general undergraduate mathematics courses but in fact emphasized as an application to teaching. This paper reports on the efforts of the *Mathematical Education of Teachers as an Application of Undergraduate Mathematics* (META Math) project to study the effectiveness of lessons which include tasks or applications which focus on interpreting or analyzing student thinking (AST) in an attempt to meet this goal. In particular, we explore the following research question: How do undergraduate mathematics students perceive the effectiveness of AST applications as a mechanism to both deepen their content knowledge and improve their skills for communicating mathematics?

Background and Theoretical Perspective

Wasserman (2018) claims that "despite the strong arguments for how and why studying advanced mathematics might benefit secondary teachers, much of the research has found the opposite to be true: teachers and their students appear to gain little from a teacher's study of advanced mathematics" (p. 4). The MET II Report also asserts that "the mathematics courses [preservice secondary teachers] take emphasize preparation for graduate study or careers in business rather than advanced perspectives on the mathematics that is taught in high school" (CBMS, 2012, p. 5). Similarly, Speer, King, and Howell (2014) observed that "prospective high school mathematics teachers, who earn a mathematics major or its equivalent, do not have sufficiently deep understanding of the mathematics of the high school curriculum" (p. 107). Furthermore, prospective secondary teachers perceive their undergraduate mathematical preparation as unconnected or not useful to their teaching (e.g., Goulding, Hatch, & Rodd, 2003; Wasserman, Weber, Villanova, & Mejia-Ramos, 2018).

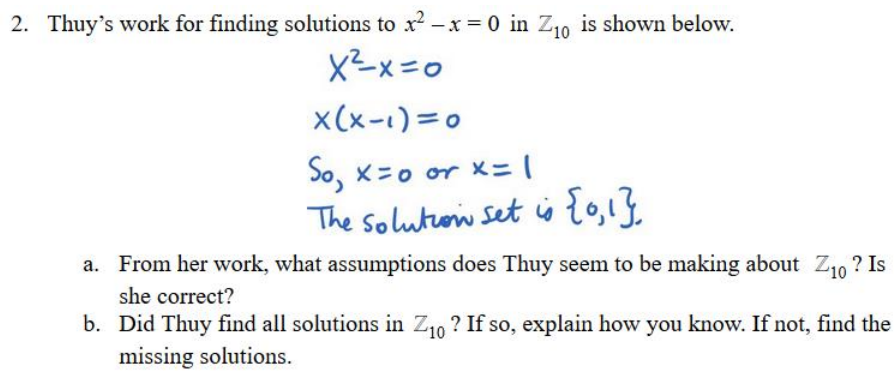
The MET II Report addresses some of these shortcomings by giving examples of several important connections between high school and undergraduate mathematics that they recommend serve as cornerstones of preservice teacher education. These connections are presented as mathematical observances, such as the fact that using inner products to extend the notions of length and angle is "extremely useful background for high school teaching" (CMBS, 2012, p. 57).

While such observations are relevant, the MET II Report does not explain how these connections are to be made explicit in practice. The restructuring of an existing curriculum to include connections for preservice teachers is nontrivially time consuming and potentially difficult for faculty who may not have experience in developing such materials (Lai, 2016; Álvarez & Burroughs, 2018; Álvarez & White, 2018). As such, the development of these materials will necessarily overlap with the study of Mathematical Knowledge for Teaching (MKT), the theory of what mathematics understanding teachers need in order to be successful educators. Originally proposed by Shulman (1986), the concept of MKT is important to preservice teacher education because it posits that traditional content knowledge is not the only mathematical prerequisite required for effective teaching. One particular aspect of this additional knowledge is the ability to "be able to hear and interpret students' emerging and incomplete thinking" (Ball, Thames, & Phelps, 2008, p. 401). Competency in these areas is often directly correlated with not only an instructor's volume of mathematical knowledge but also their appreciation of the structure of and underlying principles connecting mathematical ideas. As such, MKT requires both content knowledge and knowledge applied to teaching where the content knowledge at the secondary level might include mathematics from an advanced perspective such as that addressed in courses such as abstract algebra.

Methodology

To address MKT and the recommendations in the MET II report, the META Math Project has developed inquiry-focused lessons, which can be integrated into various mathematics major courses, that incorporate mathematics teaching connections as a legitimate application area of undergraduate mathematics. The connections, especially targeting relevance for preservice secondary mathematics teachers (PSMTs), aim to link the undergraduate content PSMTs encounter in their major courses and the pre-college content they will eventually teach. One feature of the lessons involves posing undergraduate mathematics students with tasks that require them to interpret or analyze the work of another student (see Figure 1).

This paper will focus on student perceptions of AST applications in two lessons written for an undergraduate Abstract (Modern) Algebra 1 class, "Groups of Transformations" and "Solving Equations in $\mathbb{Z}_n$", which explore how transformations can be examined via group structure and how using traditional high school algorithms for solving equations is affected by working outside of $\mathbb{R}$, respectively.



2. Thuy's work for finding solutions to $x^2 - x = 0$ in $\mathbb{Z}_{10}$ is shown below.

$$x^2 - x = 0$$
$$x(x-1) = 0$$
So, $x = 0$ or $x = 1$

The solution set is $\{0, 1\}$.

a. From her work, what assumptions does Thuy seem to be making about $\mathbb{Z}_{10}$? Is she correct?
b. Did Thuy find all solutions in $\mathbb{Z}_{10}$? If so, explain how you know. If not, find the missing solutions.

Figure 1. An assessment item from the lesson "Solving Equations in $\mathbb{Z}_n$"

To guide the design of the lessons, META Math uses the six categories of MKT identified in Ball, et. al (2008) to develop five *connections for teaching* between college-level mathematics and knowledge for teaching school mathematics: Content Knowledge, Explaining Mathematical Content, Looking Back/ Looking Forward, K-12 Student Thinking, and Guiding K-12 Students' Understanding (Arnold, Burroughs, Fulton, & Álvarez, 2020). In this paper we focus on the category called *K-12 Student Thinking*, in which undergraduates are asked to evaluate the mathematics behind a student's work and explain what that student may or may not understand. These five connections are incorporated into both the "Groups of Transformations" and "Solving Equations in $\mathbb{Z}_n$" lessons by designing an activity-based lesson (separated into pre- and class-activities), homework questions, and assessment items. Instructors were provided with an extensive annotated lesson plan to help them implement the lesson effectively.

Setting and Participants

The two Abstract (Modern) Algebra lessons were implemented by two instructors at two different universities in an upper division mathematics course in Spring 2019. One university is a small public institution and the other is a mid-sized public institution. Both are classified as Hispanic-serving Institutions in the United States (i.e. Hispanic student enrollment comprises 25% or more of total enrollment). As part of their regular coursework, all undergraduates in these sections completed a pre-activity, class activity, homework assignment, and assortment of assessment items for each lesson. For students consenting to participate in the study, their work was examined for mathematical understanding and appreciation of connections for teaching. We also invited consenting undergraduates to participate in an hour-long semi-structured interview at the end of the semester. Four participants from each institution agreed to participate in interviews. To begin the interview, we asked for the student's major and whether they intended to teach in their future (see Table 1).

Table 1: Interview participant information

Pseudonym	Major(s)	Interested in Teaching
Adam	Mathematics	No
Bonnie	Mathematics	Yes (at university level)
Christie	Mathematics	No

Diane	Mathematics	Yes (at university level)
Ella	Applied Mathematics	Possibly
Fleur	Applied Mathematics & Mechanical Engineering	Yes (at university level)
Grace	Mathematics	Yes (at university level)
Helen	Mathematics & Finance	Yes (at university level)

Data Collection and Analysis

The interviews lasted between 45-60 minutes and were audio-recorded and transcribed. During an interview, students were prompted to re-examine their work on the assessment items from each interview (e.g. Figure 1). While reconsidering their work, they were asked to provide an explanation of their thought processes where appropriate, consider alternative approaches, and discuss the potential connections to previous math content. These questions were often posed through the lens of connections for teachers, but interviewees were encouraged to discuss their own perceptions of the assessment items regardless of their intent to formally teach in a classroom environment.

Because the assessment items for each lesson necessarily included a student thinking question, much attention was paid during the interviews to this method of framing connections for teachers. While considering student thinking questions in particular, interviewees were encouraged to also consider how they might use guiding questions to motivate the hypothetical student to correct their work. This line of questioning included a discussion of why undergraduates felt that their sequence of guiding questions would be appropriate.

Finally, interviews concluded by giving the undergraduates the opportunity to discuss how the connections for teachers emphasized in these lessons were beneficial to them even if they did not foresee themselves teaching in the future. Many students took this opportunity to describe how the approach taken to presenting this material, and even mathematics in general, prepared them for their anticipated career.

We used thematic analysis (e.g., Braun & Clarke, 2006; Nowell, Norris, White, & Moules, 2017) to qualitatively analyze the interview transcriptions. Each interview was preliminarily coded for the five connections for teaching. These codes were then expanded inductively with any emergent thematic ideas. These additional codes tended to relate to teaching, the implementation of the lesson, or the format of the activities. Once each lesson was coded independently, we compared our codes until we were all in agreement. Less pervasive codes were eliminated or integrated into broader categories.

Results

Effectiveness of Student Thinking Questions

Out of the eight interview participants, three expressed their unilateral appreciation of student thinking questions, three found them to be conditionally helpful in their own learning, and one thought that student thinking questions did not improve her understanding of the underlying mathematics. Also, one student did not comment directly on her opinion of these types of questions.

Interview participants who broadly approved of student thinking questions often made note of the fact that examining another student's work forced them to consider the problem from a different perspective, thereby complexifying their understanding of the mathematical content. Bonnie verbalized this sentiment by comparing student thinking questions to questions which only require the production of a correct answer:

> Let's say you can memorize the answer. You just know the simplest path to the right answer. You'd be like, OK, I can get it. You can just find a simple answer or something that you remember your teacher told you, right? If you're presented with a wrong answer, then in fact you actually have to justify why this is wrong. You'd actually have to go back to like the main thing. Find a definition or find some reasoning as to why that's wrong.

In a similar manner, Grace said that "if I'm able to identify why it is incorrect, then I'm adding more support to my answer." Both these students emphasized the way in which student thinking questions required them to generate supporting statements or justification for mathematical work. The ability for students to "justify their conclusions… and respond to the arguments of others" is one of the Common Core State Standards for Mathematical Practice (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010); allowing preservice teachers to practice this skill in the context of connections between undergraduate and K-12 mathematical content both improves their mathematical understanding and models successful mathematical thinking skills that they will be more capable of passing on to their students.

The final student who approved of student thinking questions in all circumstances, Ella, expressed that "with math there's like so many different ways to solve one problem. I always think it's nice to know how other people think because they don't think like I do." This was a recurring theme amongst all interviewees, even those with less positive opinions of student thinking questions. For example, Diane said that she would only benefit from doing problems featuring student thinking "when it's correct," adding that "if I look at somebody's mistakes and I don't know what they're doing, it's very hard to understand what is correct and what is not." On the other hand, if student work which is correct but different from her own work is a valuable learning tool since it provides "a different perspective," and for preservice teachers can add "more tools in her toolbox to teach."

Other students with mixed opinions on student thinking questions were Adam and Helen, whose opinions mirrored those of Diane. They valued student thinking questions when the hypothetical student was doing correct but different work, while they found student thinking questions with errors misleading. Helen was particularly vehement about her discomfort with incorrect work, stating that "it would probably make me pick up a bad habit if it's wrong." She implied that not only would the student's error be confusing and cause her to second-guess her original answer, but that attempting to learn new material by examining an incorrect approach might actually cause her to internalize and reproduce the error in her subsequent work. Both students were still in agreement with Ella, however, in expressing the value of learning multiple correct approaches. Adam said that:

> What I love about math is that there's three ways to solve things. You know you can use a lot of different properties, like whatever you want to use to solve something. So if someone took a second route to something I could be like, oh, so I can solve it like that too.

Students who were ambivalent about student thinking questions, interestingly, were often simultaneously proponents of structured group work in class. Diane said that "I do tend to work with another classmate a lot. We'll bounce ideas back and forth and think that's the only way to survive."

The only interviewed student who did not, in some circumstance, feel like her understanding of mathematical content benefitted from student thinking questions was Christie. Instead, she commented on the benefits of student thinking questions from a pedagogical standpoint.

Interviewer: So how does looking at another student's work like this help you understand the material better?

Christie: I don't think it really does. But like if we talk about teaching, then just teaching like- what to put emphasis on.

This student went on to express several other ways that the lesson, in general, benefitted preservice teachers by providing valuable insight into mathematical connections between undergraduate and K-12 content, but she never commented further on student thinking questions specifically.

Benefits for Career Paths Other than Teaching

Seven of the eight interviewed students also described how student thinking questions, the lessons in general, or mathematics as a subject were able to impart a beneficial skill that they found relevant to their futures. These skills extended to fields outside of K-12 teaching.

Two students, Adam and Diane, both noted the advantages of a mathematics education to their future. Diane said that the META Math lessons "[spark] up thinking" by providing a "different perspective." She elaborates on the benefits for non-preservice teachers by adding that "even if they don't teach… they can see things differently in any kind of area." She attributes this shift in perspective to the subject as a whole, adding that "math teaches us to think critically." Adam, who anticipates working in the I.T. field, echoes this sentiment when he observes that he "can critically think now." He goes on to explain how he can apply experiences from his mathematics education to his career choice: "I approach computer problems the same way I approach a Dr. David proof. I've got to assess what the issue is, figure out what the question is asking, and [go] step by step by step by step." Christie, who also wants to work in the I.T. field, explained that the group-oriented structure of the lessons helped her prepare for experience in the workforce when she noted that "even in I.T. you work in groups." While these students did not make explicit reference to ways in which connections for preservice teachers benefited those who might not find themselves working in a K-12 classroom, they were optimistic about the positive effects of their education on their abilities.

Ella noted that it was important for experienced actuaries to be able to explain concepts and procedures to their associates. Other interviewed students explicitly referenced the ways in which the student thinking questions contained in the lessons benefitted them despite the fact that they did not anticipate careers in education. When asked to explain, their answers were similar to Ella's deconstruction of the working relationship between actuaries in that they were centered around the need to provide clear explanations of difficult topics. For example, Bonnie said that

> Even just the test questions where it's kind of like, spot what they did wrong and be able to explain to them why they did it wrong. It forces you to actually be able to do that. For instance, if that would happen in a real life scenario, you're actually be able to do that instead of just going, well it's wrong. I don't know why, but this is my right answer.

Grace mirrored this sentiment when she said that it was important for even non-teachers to be comfortable

> Not only knowing your words and what you're intending to say and different ways to say them but also seeing how another person's approaching the problem and being able to

> think the way they're thinking and see their solution. So I definitely think that even if you're not gonna be a teacher, learning like this is, I think, very beneficial.

These students noted that thinking in a way that is directed at another person's understanding is a skill that transcends the profession of teaching. Interpreting the awareness and possible misconceptions of coworkers and clients is pivotal in establishing good working rapport and a professional environment conducive to learning.

Finally, Fleur noted that, in some sense, the ability to clearly explain a difficult topic transcends the importance of simply possessing knowledge of that topic. She says,

> You might know a lot of things, you know, like math and complex stuff, but if you're not able to share that information, to communicate it well, going from the simple and going to the complex... That might not only be applicable to the teachers but just if you want to explain anything, right?

Implicit in this sentiment is the need for explanations of both simple and complex concepts to be connected and coherent when taken as a whole—a simple explanation should not preclude a teacher from extending it to a more complex explanation. Fleur's response highlights the need for general mathematics courses to emphasize connections between all types of mathematics so that teachers and other professionals who require mathematics content knowledge can provide cogent and consistent justification of all types of ideas.

Conclusion and Implications

Based on the participant interviews described, there is some evidence of the effectiveness of student thinking questions in the context of presenting connections between undergraduate and K-12 content. A majority of participants interviewed felt that these types of questions could be useful to expand their mathematical understanding of the content, either by requiring them to justify their procedure or by providing an example of an alternative or novel approach. Students were also able to recognize that the skills imparted by engaging in deep thought about another person's thinking were transferable not just to teaching but also to other fields that require the dissemination of technical knowledge.

Some students were apprehensive about student work in mathematical contexts in which they were not themselves confident. To accommodate such students, it may be advantageous to position student thinking questions at such a point in a lesson that the new material has already been explored through traditional means; this may mean including student thinking questions at the end of a class activity or on a homework assignment. Such structure would allow students more time to familiarize themselves with new mathematical ideas before using student thinking questions to make a connection to high school curriculum or explore different approaches to justifying a particular methodology.

Operationalizing the connections for teachers as outlined in the MET II Report through the use of student thinking questions appears to support the mathematical learning not only of preservice teachers but of broader categories of students as well. As our participant Fleur notes, "this is a really good skill to have—to be able to share knowledge."

Melissa H. Dancy
University of Colorado

For decades, the mathematics education research community has strived to identify, document, and disseminate instructional strategies that support student success in mathematics courses. We now have many research-based instructional strategies (RBIS) which have evidence to support claims that they can be used to help students succeed in mathematics. However, the use of such practices has not become widespread at the postsecondary level in mathematics, nor in the other STEM disciplines. This work, focused on mathematics instructors, is part of a larger project hoping to uncover more about why and how particular instructional practices spread in undergraduate mathematics, chemistry, and physics. Here, we report that single-variable calculus instructors have awareness of, and use, RBIS in their classrooms; however much of class time is spent in a lecture format. Implications of these and future results are discussed.

Keywords: instructional practice, calculus, STEM, national survey

Research-Based Instructional Strategies (RBIS) refer to the host of tools, resources, and modes of instruction that have shown promise in increasing students' engagement in learning and in leading to measurable, and lasting, learning gains. This proposal comes from a larger project tracking the implementation of RBIS in introductory postsecondary STEM courses across the country. In particular, we report on the awareness and usage of particular RBIS in single-variable calculus courses at the undergraduate level, and briefly touch on how instruction in first year mathematics courses compares to instruction in first year chemistry and physics courses.

RBIS are thus called because there is evidence that they can significantly improve learning and retention. This includes many variations of active learning (Freeman et al., 2014), flipped classrooms (Bergmann & Sams, 2012; Lage, Platt, & Treglia, 2000), peer instruction (Crouch & Mazur, 2001; Fagen, Crouch, & Mazur, 2002), formalized small-group work (D. W. Johnson & Johnson, 2009; King, 1993; Kramarski & Mevarech, 2003), and more. Implementing these practices is not easy, and doing so in ways that preserve fidelity of implementation and mirror positive outcomes is not a straightforward task (Andrews, Leonard, Colgrove, & Kalinowski, 2011; Bagley, 2015; E. Johnson et al., in press; Laursen & Rasmussen, 2019).

Our focus on introductory postsecondary STEM courses comes from their outsize impact on students' ability and interest in completing undergraduate STEM degrees (PCAST, 2012; Seymour, 2006; Seymour & Hewitt, 1997). Single-variable calculus is one of several "gateway courses," defined as a foundational course for future studies which is high-risk, in that it carries a relatively high DFW rate, and high(er)-enrollment (Koch, 2017). Shifting the instructional status quo away from straight lecture in these gateway courses has the potential to have a major positive impact on students' undergraduate education. Thus far, however, lecture continues to be the norm (Eagan, 2016; Gibbons, Villafañe, Stains, Murphy, & Raker, 2018; Henderson & Dancy, 2009; Rasmussen et al., 2016; Stains et al., 2018). To measure the changing instructional landscape, and to accelerate it, in this paper we address the following two research questions, and provide some minimal comparisons to chemistry and physics for comparison.

1. How much in-class time is being spent on lecture vs. non-lecture activities in undergraduate single-variable calculus courses?
2. What are the levels of awareness and usage of twelve RBIS among instructors of undergraduate single-variable calculus courses?

Methods

Survey Overview

Data for this project was collected via a web-based survey developed by the research team, drawing on previous experience and relevant research literature. Items and format were informed by previous large studies of chemistry (Gibbons et al., 2018; Lund & Stains, 2015; Stains et al., 2018), mathematics (Apkarian et al., 2019; E. Johnson, Keller, & Fukawa-Connelly, 2018), and physics education (Henderson & Dancy, 2009; Walter, Henderson, Beach, & Williams, 2016). The survey had a few major sections, each of which included items from previous research and validated instruments. The instructional practice section draws from the work of Landrum et al. (2017) and the Postsecondary Instructional Practices Survey (PIPS) (Walter et al., 2016). Subsequent sections of the survey contain questions about departmental climate and culture (Walter, Beach, Henderson, & Williams, 2014); instructor's beliefs about teaching, learning, and students (Aragón, Eddy, & Graham, 2018; Chan & Elliott, 2004; Dweck, Chiu, & Hong, 1995; E. Johnson et al., 2018; Meyers, Livingston Lansu, Hundal, Lekkos, & Prieto, 2006; Tollerud, 1990); and demographic questions related to both professional and personal identities and roles. Each of the items was drawn directly or indirectly from existing research and conjectures about factors affecting instructional practice in undergraduate STEM courses. This proposal draws on data from the first survey section focused on instructional practice, and from a few items in particular (see Figures 1 and 2 in section *Key Survey Items*).

Survey Distribution & Response

The American Institute of Physics Statistical Research Center converted the survey into an online version, developed a roster, and handled the distribution and collection of data. The initial roster was compiled by identifying 1012 postsecondary institutions (545 two-year colleges; 467 four-year colleges and universities) to include in our sample, and then identifying all recent instructors of introductory chemistry, mathematics, and physics courses at that institution. These instructors were then emailed an invitation to participate in the study, which they completed on their own time, within the 8-week period that the survey was open. Reminders were sent approximately every 10 days to increase response rates.

We received 3769 usable responses from instructors at 851 institutions (397 TYC; 454 4YoA). By usable, we mean that the participant consented to participate, had taught one of the target courses in the past two years, and answered at least one item on the survey. Not every participant answered every question, so the sample size varies somewhat from item to item. These responses break down among disciplines and institution types as shown in Table 1. This analysis will primarily focus on the 1349 responses from calculus instructors, however there will be times when we present tables and graphs that contextualize calculus relative to first-year chemistry and physics. The mathematics respondents were two-thirds men; four-fifths White; two-thirds hold tenured or tenure-track positions at their institution; one-third participate in

SoTL and/or RUME. We recognize the existence of response bias within our data, and that this sample is not truly representative of postsecondary calculus instructors.

Table 1. Number of respondents by discipline and institution type.

Institution Type	Chemistry	Mathematics	Physics	Total
Two-year	422	416	261	1099
Four-year	822	933	915	2670
Total	1244	1349	1176	3769

Key Survey Items

The item shown in Figure 1 required participants to report the percentage of class time spent on four activities, (for a total of 100%). We received 3641 responses which totaled 100%, 128 which totaled 0%, and 26 which totaled something else; those which did not total 100% were removed from the analysis.

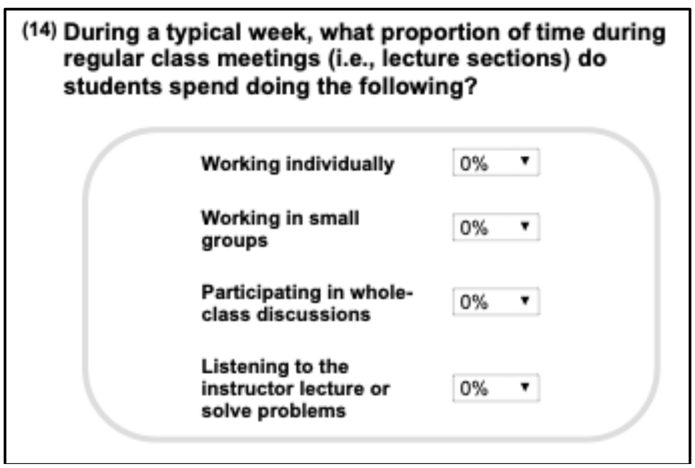

Figure 1. Survey question asking respondents to report percentage of class time.

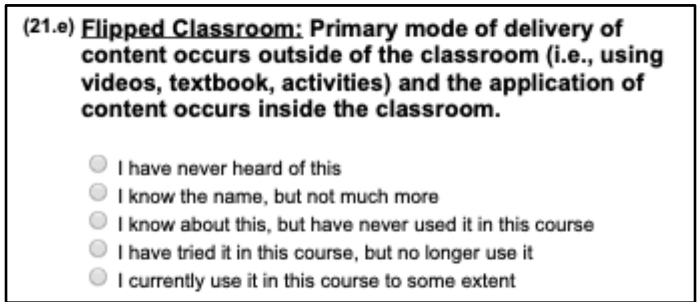
Participants were also shown a series of items about specific RBIS and asked to rate their awareness/usage of that RBIS. Each RBIS was named, defined, and participants selected one of five options ranging from “I’ve never heard of this” to “I currently use it in this course.” (See the example in Figure 2.) The format of these questions mirrors that of work in physics and chemistry education, which allows us to compare our results with those from previous work in various contexts (Henderson & Dancy, 2009; Lund & Stains, 2015). Nine RBIS were displayed to all participants, with an additional 3-6 more discipline-specific RBIS displayed to people from each discipline. In total, twelve were shown to those teaching mathematics. We drew on prior work in all three disciplines, our own experiences, and the input of other experts in our three fields to select and define our set of RBIS to ensure face validity and the ability to compare with prior work in similar areas.



(21.e) Flipped Classroom: Primary mode of delivery of content occurs outside of the classroom (i.e., using videos, textbook, activities) and the application of content occurs inside the classroom.

- I have never heard of this
- I know the name, but not much more
- I know about this, but have never used it in this course
- I have tried it in this course, but no longer use it
- I currently use it in this course to some extent

Figure 2. Example of a survey item asking about familiarity with, and use of, an RBIS

Results

Class Time

On average, calculus instructors reported that 56% of regular class time is spent with students listening to the instructor lecture or solve problems (*lecture*); the remaining 44% of class time is shared between three *non-lecture* activities. Similar averages were obtained from chemistry and physics instructors (see Table 2).

Table 2. Mean (standard deviation) of reported percentage class time for instructional practices, by discipline.

Instructional Practice	Mathematics (n=1269)	Chemistry (n=1217)	Physics (n=1141)
Students listening to the instructor lecture or solve problems	56.3 (25.3)	58.5 (25.2)	53.9 (25.6)
Students participating in whole-class discussions	15 (14.6)	10.8 (11.8)	13 (11.6)
Students working on problems in small groups	17.1 (17.9)	18.2 (19.4)	22.5 (20.5)
Students working on problems individually	11.3 (11.8)	11.6 (11.6)	10.6 (11.7)

In Figure 3 below we can see how the median report of amount of class time spent lecture, and quartiles, compare for the three STEM disciplines. The medians for each of lecture and non-lecture are quite consistent across the three groups. Physics has the largest IQR, suggesting more variance in instructional practice, and the medians of lecture and non-lecture time are the closest of the three disciplines, suggesting that lecture is less dominant in introductory physics courses than in general chemistry or single-variable calculus.

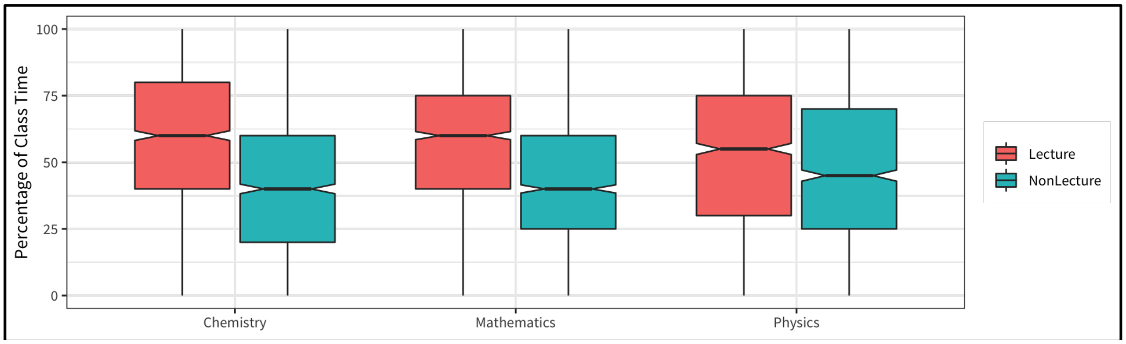


Figure 3. Notched box plots showing the median, confidence interval of the median, and IQR for reports of lecture and non-lecture in-class activities across chemistry, mathematics, and physics instructors.

Of course, averages only give one perspective on these results. Figure 4 show the distribution of responses from mathematics faculty. This distribution suggests first that respondents are more likely to select a decade than a 5% increment, hence the up-and-down pattern in the chart. The data also have negative skew, with a longer tail toward the lower percentages of class time. Thus while the median amount of calculus class time spent in lecture is around 55%, the majority of *instructors* are reporting 50-80% of class time is spent in lecture.

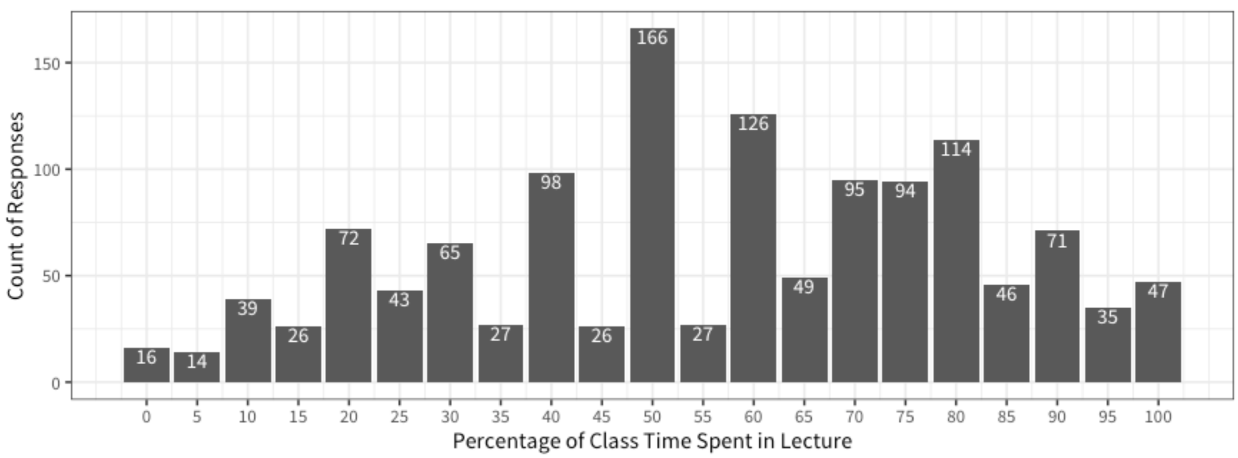

Figure 4. Distribution of responses from calculus instructors about the percentage of in-class time spent with the instructor lecturing or solving problems (n=1296).

Awareness & Usage of RBIS

For this analysis, responses are clustered into current users of an RBIS, knowledgeable non-users, and those with little-to-no knowledge. Current users are those who select “I currently use it in this class to some extent;” knowledgeable non-users are those who select “I have tried it in this course, but no longer use it,” or “I know about this, but have never used it in this course;” those with little-to-no knowledge select “I know the name, but not much more” or “I have never heard of this.” This is similar to the categorizations used in prior work in physics (Henderson & Dancy, 2009). Figure 5 shows the proportion of mathematics respondents who fit into each category for each RBIS. Note that the most well-known RBIS are not necessarily being used the most. For example, small-group work and flipped classrooms are each known by 91% of respondents, but while small-group work is also the most used RBIS (51% of respondents are current users), flipped classes are the 6th (18% current users).

As shown in Figure 5, the RBIS used by the most mathematics instructors are small-group work (51%), teaching with computer simulations and animations (45%) and think-pair-share (37%). These three RBIS are the only ones in use by more than one third of respondents. The most well-known (current users plus knowledgeable non-users) are small-group work and flipped classrooms (91% each); other RBIS known by two-thirds or more of participants are: teaching with computer simulations and animations (81%), IBL (79%), and think-pair-share (76%). The RBIS with the fewest users are: concept maps (10%), reform-oriented textbooks (12%), and POGIL (13%). Two RBIS are unknown to more than half of the respondents: concept inventories (52%) and POGIL (51%); these are followed closely by concept maps (45%), reform-oriented textbooks (42%), and peer-led team-learning (41%).

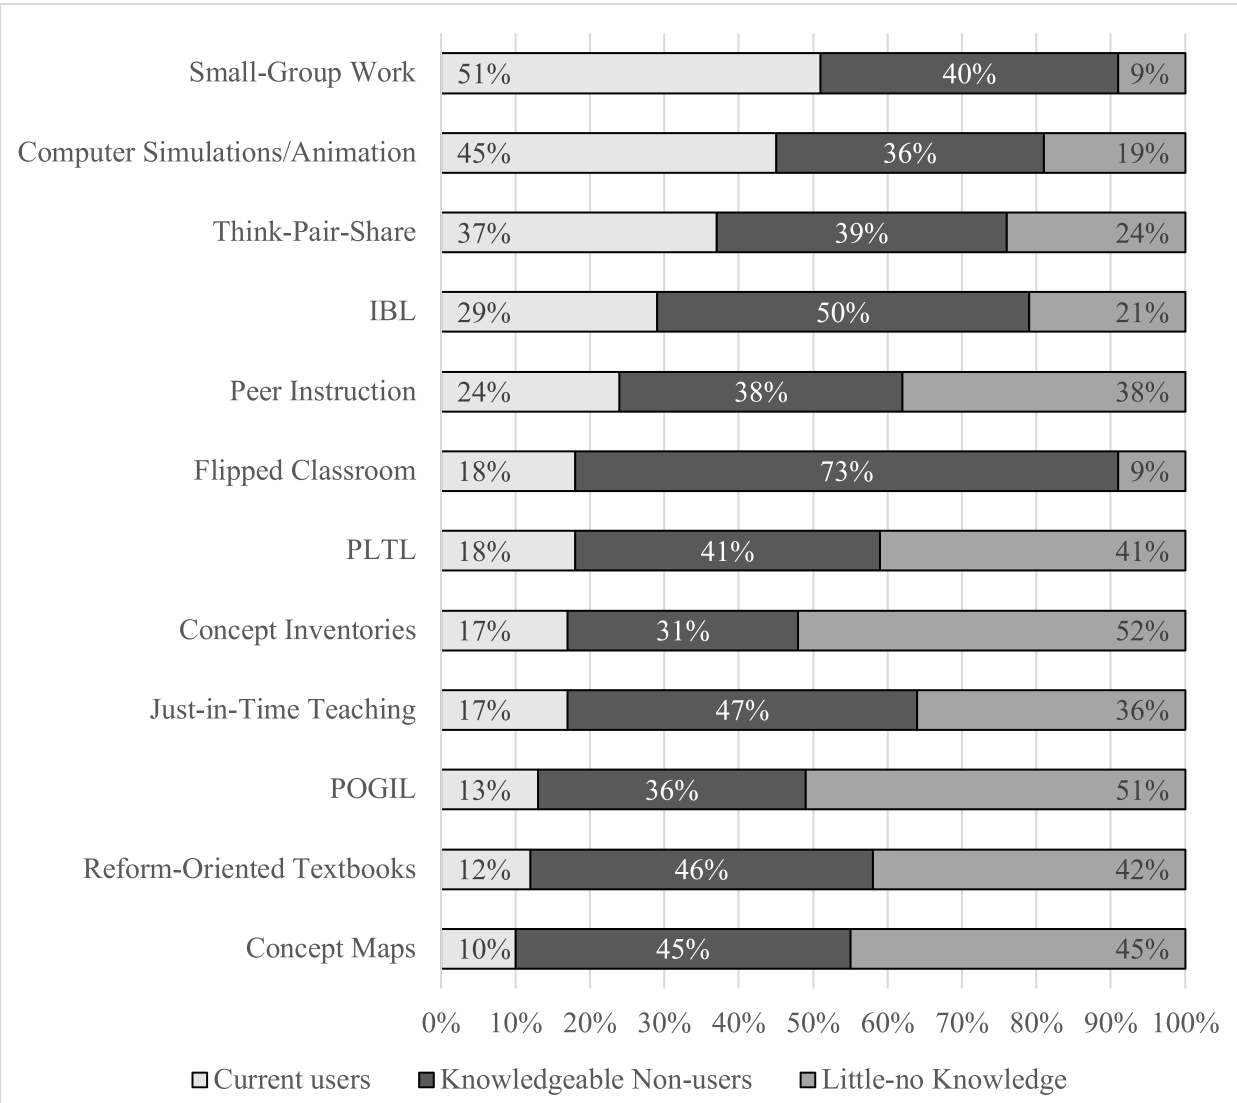

Figure 5. Responses of Mathematics Participants to RBIS questions, grouped into current users, knowledgeable non-users, and those with little to no knowledge of the RBIS. Top-to-bottom, these are ordered by most-least in use.

Further investigation into these responses indicate that knowledge and use is spread out among instructors, not concentrated in a few. Of the 1192 who responded, only 13 (1%) reported no knowledge of *any* of the RBIS on this list; a total of 75 (6%) reported knowledge of zero, one, or two RBIS from this list. In terms of usage, 207 (17%) of participants report that they are not current users of *any* RBIS; 361 (30%) are currently “low users,” using 1-2 different RBIS in their introductory calculus course; 624 (52%) are using 3+ RBIS from this list.

Discussion

Calculus instructors who responded to our survey are aware of RBIS, though we can make no claims about how they understand these RBIS or their familiarity with the research surrounding them. Despite this general awareness, most RBIS are not being used in calculus classrooms. Only three RBIS are being used by more than a third of our participants: formal small-group work, teaching with computer simulations and animations, and think-pair-share. We think it is notable that these are among the least well-defined of the RBIS asked about in the survey, in that they are implemented in a great many ways and do not have particularly concrete definitions or branding. These general RBIS stand in comparison to IBL and Peer Instruction, which are more well-defined. Additionally, in the case of IBL, there has been significant outreach efforts to build awareness and professional development efforts to support adoption (Haberler, Laursen, & Hayward, 2018). We believe these efforts are reflected in our data, with 29% of calculus instructors reporting that they are currently using IBL, and another 50% reporting that they have knowledge of it.

While the majority of our survey participants report that they have knowledge of multiple RBIS, and report using at least one in their course, on average, participants are reporting that the majority of class time is spent with “students listening to the instructor lecture or solve problems.” This indicates that lecture is still the dominant feature of many introductory STEM courses, even when (some) RBIS are being used. More detailed analysis of this data will investigate patterns about which RBIS are being used in majority-lecture courses, as well as fidelity of implementation using data from other elements of the survey. These investigations will be carried out for the chemistry and physics data sets as well, to gauge similarities and differences among instructional practices within the STEM umbrella. The ultimate goals of this project include the identification of relationships and levers between contextual factors (e.g., culture and climate of the department) and individual factors (e.g., beliefs about students and learning) and instructional practice. That information can be used to navigate change initiatives and work to increase the usage of research-based instructional strategies; we are also contributing to baseline usage information which can be used to gauge change in usage from now to the future.

University Calculus Students' Use and Understanding of Slope Conceptualizations

Susan M. Bateman
Rochester Institute of Technology

Deborah Moore-Russo
University of Oklahoma

Courtney R. Nagle
Penn State Erie, The Behrend College

Michael Pawlikowski
Depew High School

The purpose of this study is to investigate the visual and nonvisual approaches and conceptualizations of slope used by introductory calculus students when presented with a variety of tasks.

Keywords: slope, university, calculus students

The derivative concept is one of the main topics in introductory calculus. A study of experts' views of central concepts and skills in first-year calculus found that the derivative was unanimously viewed as fundamental to calculus, with three sub-concepts identified: derivative as rate of change, graphical representation of the derivative, and derivative computations (Sofronas et al., 2011). Since the calculus concept of derivative builds upon and extends students' notions of slope (Zandieh, 2000; Zandieh & Knapp, 2006), it is important to know what conceptualizations of slope students bring with them to introductory calculus and how instructors might effectively build on that foundation (Nagle, Moore-Russo, Viglietti & Martin, 2013). Furthermore, since both visual and nonvisual approaches can be used to introduce derivatives in introductory calculus the importance of knowing which approaches to slope students come equipped to build upon in calculus is vital. This study investigates the following questions based on introductory calculus students' responses to a variety of slope tasks:

1. Which conceptualizations of and approaches (*visual* or *nonvisual*) to slope are most common in students' responses?
2. Do students consistently use the same conceptualizations of and approaches to slope or do these vary based on specific tasks or questions?

Theoretical Framing

Meaning is personal and dynamic; it is the way that an individual thinks of a concept and is impacted by the individual's experiences (Vinner, 1992). This is related to Tall and Vinner's (1981) "concept image" which "consists of all the cognitive structure in an individual's mind that is associated with a given concept" (p. 151). If students are able to represent a concept in multiple ways, they have multiple meanings associated with the concept (Moore, Paoletti, & Musgrave, 2013). Since there are often multiple ways that a single concept can be conceptualized, communicated and represented (Duval, 2008), it is desirable that students develop rich, coherent systems of meanings for foundational mathematical concepts. Thompson (2013) goes into detail about the term "meaning" and emphasizes that when instructors are interacting with students what matters most are the students' "current meanings that constitute the framework within which they operate" (p. 62). Instructors should consider students' current, personal meanings by attending to how students think of, link, and organize isolated or discrepant thoughts (Dewey, 1910).

Byerley and Thompson (2017) propose that meaning is context dependent. Different contexts may trigger different meanings; and using particular approaches or representations may influence by the task, its context (Thompson, 2016) or on the extent of the connectedness of the student's ways of thinking about the concept.

The Concept of Slope

Researchers have reported numerous conceptualizations, or ways of thinking, about slope (Stump, 2001a, 2001b; ; Moore-Russo, Conner & Rugg, 2011; Nagle, Martinez-Planell & Moore-Russo, 2019), with some ways of thinking about slope being identified as more useful or productive than others (Byerley & Thompson, 2017). Stump first identified different categories of slope (1999, 2001a, 2001b), which have been revised and termed "conceptualizations" by Moore-Russo and colleagues (Moore-Russo, Conner & Rugg, 2011; Nagle & Moore-Russo, 2013b). For this paper we restructured these into five conceptualizations, each of which was separated into *visual* and *nonvisual* approaches. For details, see Table 1.

Table 1. Slope Conceptualizations and Approaches

Category	Approach	Explanation
Slope as a *Ratio*	Visual	• rise/run or vertical change divided by the horizontal change • includes cases where run equals 1 or where both values are integers
	Nonvisual	• $(y_2 - y_1)/(x_2 - x_1)$ or change in y over change in x
Slope as a *Behavior Indicator* of a Line	Visual	• line increases, decreases, is horizontal, is vertical (i.e., looks like /, \, -, |) for positive, negative, zero, undefined slope respectively
	Nonvisual	• line increases, decreases, is constant, or is not a function in other words (i.e., $y_2 > y_1$ for $x_2 > x_1$) for positive slope, (i.e., $y_2 < y_1$ for $x_2 > x_1$) for negative slope, (i.e., $y_2 = y_1$ for $x_2 > x_1$) for zero slope, or (i.e., $x_2 = x_1$ for $y_2 > y_1$) for undefined slope respectively
Slope as Denoting *Steepness* of Line's Angle of Inclination with respect to Horizontal	Visual	• relates to how inclined, tilted, slanted, or pitched a line is <u>seen</u> as being • greater value of |slope|, line is more steep (e.g., closer to vertical) • closer to zero value of |slope|, line is less steep (e.g., closer to horizontal a line is) • since horizontal lines have no tilt, they have zero slope
	Nonvisual	• relates to how extreme a line is <u>calculated</u> as being • the greater the value of |slope|, the more steep the line over an interval (e.g., the closer to infinity the value of $\|y_2 - y_1\|$ is) • the closer to zero the value of |slope|, the less steep the line over an interval (e.g., the closer to zero the value of $\|y_2 - y_1\|$ is) • since horizontal lines have $\|y_2 - y_1\|= 0$ for all y values, they have zero slope
Slope as a *Constant Parameter*	Visual	• emphasis on the uniform "straightness" of the line's entire graph (i.e., no curvature) • no matter which segment of the line is considered, the slope remains the same between any two points
	Nonvisual	• emphasis that a single constant holds a property for the line's equation/table (not dependent on input) • the slope remains the same between any two points on a line
Slope as *Determining Relationships* between lines	Visual	• two unique lines have the same slope if and only if they never intersect in two-dimensions (i.e., are parallel) • two unique lines have different slopes if and only if they intersect at a common point • two unique, nonvertical lines have negative reciprocal slopes if and only if their intersection is at a right angle (i.e., they are perpendicular)
	Nonvisual	• two unique lines have the same slope if and only if a system of these two lines has no solution (i.e., system is inconsistent since lines are parallel) • two unique lines have different slopes if and only if the system of these two lines has one solution (i.e., system is consistent; there is a shared ordered pair) • two unique, nonvertical lines have negative reciprocal slopes if and only the product of their slopes is -1 (i.e., they are perpendicular)

Research has shown that students' meanings for slope are often not connected but rather isolated and fragmented (Nagle & Moore-Russo, 2017; Hattikudur, Prather, Asquith, Knuth, Nathan & Alibali, 2011; Planinic, Milin-Sipus, Kati, Susac & Ivanjek, 2012; Lobato & Siebert, 2002), leading to particular ways of thinking about slope being triggered only in certain contexts (Byerley & Thompson, 2017). For instance, even though the mnemonic device "rise over run" is often associated with slope (Azcarate, 1992; Stump, 1999), this way of thinking about slope is not necessarily connected to thinking about slope as an angle of inclination (Nagle & Moore-Russo, 2013a; Stump, 1999).

Methods

Data were collected from a convenience sample of 231 students in 7 introductory university calculus classes. Of the 231 students, 64 were in 2 business calculus classes, 142 were in 4 STEM calculus classes, and 25 were in an honors STEM calculus class at four small universities in the northeastern United States. All four universities are located within a 3-hour drive of each other and serve students in this geographic region, all of whom are approximately the same academic level upon entry.

The data were collected using a 19-item instrument that was administered on either the first or second day of classes, prior to instruction. Students were given 40 minutes to complete the instrument with only paper and pencil. The instrument, displayed in Table 2, was designed to trigger the use of multiple slope conceptualizations.

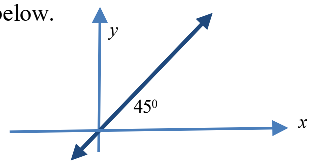
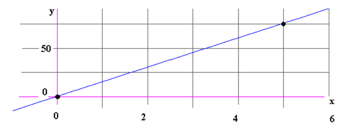
<tr><td>11</td><td>Which is true for two values of x (where $x_1 < x_2$) on the function $F(x)=mx+b$, where m= -1?
a) $F(x_1) < F(x_2)$
b) $F(x_1) > F(x_2)$
c) $F(x_1) = - F(x_2)$
d) not enough information given, need equation of function or point values
e) none of the above</td></tr>
</table>

12 Find the equation of the line below.

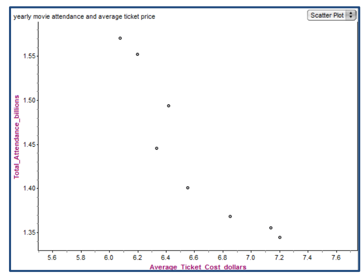


13 There are two waterslides. The first drops 12 feet for every 4 feet you move forward. The second drops 10 feet for every 4 feet you move forward. If both are the same length, which would be a faster ride? Explain your answer.

14 The following graph represents the amount Freda is paid in terms of the hours she works. Determine how many hours Freda would have to work to earn $180. Show your work.



15 The data in the scatterplot shows the relationship between the price per ticket at a movie theater and the number of people who attended the movie.

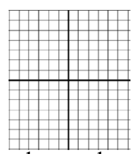


a) Use the data to predict the total attendance for each average ticket cost:
i. $6.30 ii. $6.70

b) Sketch a line on the graph above that you think represents the data well.

c) What can you say about the relationship between average ticket cost and total attendance?

16 Sketch the graph of a function with a negative slope.



17 The teachers at Riverdale High are gathering data related to students and how many pets they have. They are talking to students in groups of 10 to gather the data. The table below shows their findings.

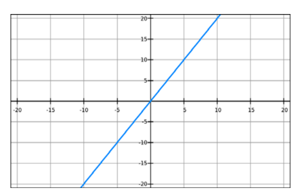
Number of Students	10	20	30	40	50	60	70	80
Total Number of Pets the Students Have	31	58	92	121	148	179	210	241

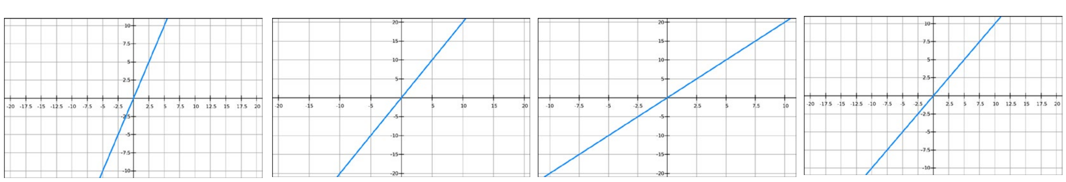
a) Would it be reasonable to use a linear function with slope of 3 to represent the following data set? Explain your answer.

b) What would the slope represent for this data set, in terms of the real life situation?

18 Given a function $y = -2x + b$, find the coordinates of a point (x, y) on the graph of this function given the information that $y = 1$ when $x = 1$.

19 Consider the graph to the right. Determine if each of the graphs below represents the same function or a different function than the graph to the right. Explain each answer.





A student response to a single item was the unit of analysis. With 231 students responding to 19 items, there should have been 4389 item responses. However, 255 of the responses were blank, which left a total of 4134 responses that were analyzed. All student responses were coded as pairs using the coding scheme displayed in Table 1 for a) presence of one of ten slope conceptualizations and b) a corresponding *visual* or *nonvisual* approach. A student's response to an item may have been coded as more than one conceptualization (i.e., *ratio*, *behavior indicator*, *steepness*, *constant parameter*, *determining relationships*) and one or both approaches (i.e., *visual*, *nonvisual*).

Findings

To address research question 1, we consider the conceptualizations of and approaches to slope most common in students' responses across all items. Table 3 below displays the conceptualization-approach counts for the 4134 responses to all 19 items. Note that only 3066 of the responses were noted as showing evidence of any slope conceptualization. The totals in the last row of Table 3 illustrate that *ratio* was the most common conceptualization and was used in approximately one-half of all responses (n=1503). *Ratio* was followed in frequency of use by *behavior indicator* (n=797), with *steepness* (n=319), *constant parameter* (n=271), and *determining relationships* (n=170) used much less frequently.

Table 3. Slope Conceptualization and Approach Use by Item and Overall

*V = *visual* only, N = *nonvisual* only, B = both

Of the 3066 coded responses, 1714 were coded with a *visual* approach only, 1268 were coded with a *nonvisual* approach only, and 84 were coded with both. Although the *visual* approach was the most common overall, the distribution across conceptualizations varied. For the *ratio* and *determining property* conceptualizations, *nonvisual* approaches were more common. *Behavior indicator* use was heavily dominated by the *visual* approach, and *steepness* and *constant parameter* were also more often used with a *visual* approach. Only a small number (n=84) of the 3060 coded responses used both *visual* and *nonvisual* approaches, and the vast majority of these (n=71) occurred within the *ratio* conceptualization

To address research question 2, we consider if students consistently use the same conceptualizations of and approaches to slope or if they vary their uses based on specific tasks or questions. Since certain tasks might elicit particular ways of thinking about slope, we first consider only the first four open-ended items of the slope instrument, which were intended to trigger student use of multiple slope conceptualizations and which numbered 897 (231 students by 4 items less 27 blank responses). All five conceptualizations were found in these four items. Examining only the first four open-ended items, the order of prevalence of conceptualization was not the same as with the entire instrument. *Ratio* was still the most prominent (n=356), followed by *constant parameter* (n=98), *steepness* (n=79), *behavior indicator* (n=63), and *determining relationships* (n=7). For these open-ended items, the approaches were almost evenly split between *visual* (n=291) and *nonvisual* (n=270). A relatively large number of the open-ended items (n=42) included both *visual* and *nonvisual* approaches, such that exactly half of the responses across all items that incorporated both approaches occurred on these four open-ended items.

Table 3 provides additional information about the conceptualization-approach pairs (henceforth simply called "pair codes") found in student responses for each individual item. No item was coded with all ten pair codes; however, items 1, 2, 4, 5, 9, 11, and 19 were coded with all five slope conceptualizations. Items 5 and 9 generated the most pair codes (n=281 and n=284, respectively) and were the items for which the conceptualization code usages was noted as the most balanced.

Some items triggered specific conceptualizations. For example, responses to item 7 were only coded as the *ratio* conceptualization, with 206 pair codes involving *ratio*. However, when considering items that triggered at least 100 pair codes in a specific conceptualization category, the majority received pair codes involving the *ratio* conceptualization (i.e., n=180 for item 3, n=126 for item 5, n=206 for item 7, n=112 for item 10, and n=107 for item 17). Two items 15 and 16 received 179 and 198, respectively, coded pairs for *behavior indicator*. Two items merited over 100 pair codes for two conceptualization categories (i.e., item 9 had 118 *ratio* coded pairs and 119 *behavior indicator* coded pairs and item 13 had 134 *ratio* coded pairs and 105 *steepness* coded pairs). Item 18 didn't trigger much slope conceptualization use with only 12 codes noted in responses. This might be expected since, despite involving a linear function, a student did not necessarily need to think about slope to generate the point's coordinates.

When considered by item, 12 items (items 1, 2, 3, 4, 5, 6, 7, 9, 10, 13, 17, 19) had at least one response that triggered both *visual* and *nonvisual* approaches within a conceptualization. However, even the most frequent occurrence of this was only 8 times for item 1. In fact, only 56 of the 231 students used both *visual* and *nonvisual* approaches within any of the five conceptualizations in their responses, and 53 of those 56 used both *visual* and *nonvisual* approaches when using the *ratio* conceptualization.

Discussion

The results suggest that *ratio* was the most common conceptualization used. This is not entirely surprising, as students often rely on the mnemonic device "slope is rise over run" and graphical interpretations (Walter & Gerson, 2007), and frequently recall slope as a number to be found using $m = \frac{y_2 - y_1}{x_2 - x_1}$ (Nagle, Martinez-Planell, & Moore-Russo, 2019). *Ratio* also appears to be a versatile conceptualization for students. Not only did it appear within responses students' responses on every item, it also was well distributed among *visual*, *nonvisual*, and both approaches. Also, it was by far the most common of the five conceptualizations for students used both *visual* and *nonvisual* approaches. The patterns in the student responses support the notion that particular items trigger certain conceptualizations for slope, and that items trigger certain conceptualization-approach pairs.

Although both *visual* and *nonvisual* approaches were used, the results showed the distribution was not particularly balanced. Approaches to *ratio* were relatively balanced, with both *visual* and *nonvisual* approaches being used quite often. *Determining property* was used mostly with a nonvisual approach where the remaining three conceptualizations (*behavior indicator, steepness,* and *constant parameter*) all tended to be approached *visually* more often than *nonvisually*. However, perhaps the most interesting result related to the approaches was that relative infrequency of students' using both *visual* and *nonvisual* approaches within a single *conceptualization*. Neither *behavior indicator* nor *determining property* involved both *visual* and *nonvisual approaches* for a single response on any item. Furthermore, *steepness* was only used both *visually* and *nonvisually* on one only response across all the items, and *constant parameter* only twelve times. These results are important because they suggest that although students might approach slope in both *visual* and *nonvisual* ways using all five of the slope conceptualizations, they may not connect those approaches and see them as complementary ways of thinking about a situation or task. In the mind of the student, the *visual* and *nonvisual* approaches may not just be seen as different approaches to the same slope conceptualization, but rather as completely distinct conceptualizations of slope that are appropriate to use in different settings and contexts.

Students' isolation of *visual* and *nonvisual* approaches to slope conceptualizations is also critical as they begin studying derivatives in calculus. For instance, the isolation of *visual* and *nonvisual* approaches to the *behavior indicator* conceptualization of slope is concerning in regards to the importance of students working fluently with this idea when making sense of the first derivative test and the relationships between a function and its derivative both analytically and graphically in a calculus setting.

Implications, Limitations, Future Work

This study expands upon previous work related to students' conceptualizations of slope by looking at the prevalence of their *visual* and *nonvisual* approaches to the various slope conceptualizations. Further, we used four of the items from a previous study, but with a larger sample size (Nagle, Moore-Russo, Viglietti & Martin, 2013). One of the limitations of the study stems from the design as a written assessment where follow-up questions could not be asked. In particular, it would be helpful to further explore whether students would combine their *visual* and *nonvisual* approaches to problems if prompted to do so, or whether these ideas remain isolated for the students.

A Preservice Teacher's Emerging Concept Image of Function: The Case of Sofia

Janessa Beach
The University of Texas at Arlington

James A. Mendoza Álvarez
The University of Texas at Arlington

For over thirty years, the mathematics education research community has investigated individuals' function conceptions and advocated the importance of a strong function conception. This is particularly important in the case of preservice secondary mathematics teachers (PSMTs) as their knowledge of function will influence their future teaching of function. This study explores how one PSMTs', Sofia's, function concept image changes when she engages with research-based tasks and explorations designed to elicit cognitive conflicts related to function conceptions. Thematic analysis methods were applied to open-ended, tasked-based pre- and post-interviews designed to evoke aspects of individuals' function concept image. Between the pre- and post-interviews, Sofia participated in a course that implemented 11 explorations on functions. Comparing the themes identified in her pre- and post-interviews, researchers identified four changes in Sofia's function concept image. These changes relate to beliefs about functions and equations, non-numerical functions, functions and graphs, and the vertical line test.

Keywords: function, concept image, preservice secondary mathematics teachers

While the study of many mathematical topics rests on the function concept (Dubinsky & Harel, 1992), it remains a difficult topic for many undergraduate students including preservice secondary mathematics teachers (PSMTs) (e.g. Carlson, 1998; Dubinsky & Wilson, 2013; Ohertman, Carlson, & Thompson, 2008; Vinner & Dreyfus, 1989; Zandieh, Ellis, & Rasmussen, 2017). This difficulty with the function concept is particularly important in the case of PSMTs as a teacher's subject matter knowledge affects both the content taught and how a teacher teaches the content (Even, 1993; Stein, Baxter, & Leinhardt, 1990). In fact, Sten et al. (1990) found that a middle school teacher possessing a rule-based conception of function depicted function to his students as merely an arithmetic operation. Watson and Harel (2013), however, found that when teachers experience studying functions at high level they are able to teach it in a way that lays the foundation for more advanced understanding. It is then essential that PSMTs gain experiences that provide the opportunity to deepen their understanding of functions.

One potential way to provide these opportunities is through a content course consisting of research-based activities designed to elicit cognitive conflicts associated with the function concept. However, limited research is available on how a content course with such activities might influence PSMTs' conceptions of function. In this study, we investigate the following research question:

> How does one PSMT's concept image of function change when she engages with research-based tasks and explorations designed to elicit cognitive conflicts related to function conceptions?

Theoretical Framework

This study draws on Tall and Vinner's (1981) theory of *concept definition* and *concept image*. A concept definition consists of the set of words an individual uses to articulate a concept, and this may differ from the formal concept definition – the definition accepted by the mathematical community (Tall & Vinner, 1981). Although many PSMTs hear and see the formal concept definition of function throughout their secondary studies, they may not actually apply it within a problem context. Tall and Vinner (1989) instead suggest that individuals employ their concept image. A concept image consists of all the memories an individual associates with a particular concept name including examples, nonexamples, relationships, visual representations, impressions, and experiences. Since an individual's concept image is formed around the associated memories, the resulting concept image may not always be coherent, may contain potentially conflicting components, and different contextual situations may evoke different memories or aspects of one's concept image (Tall & Vinner, 1981).

A concept's formation consists of an ongoing interplay between an individual's personal concept definition and concept image. In this interplay, the form of words an individual uses to describe the concept may be affected by associated examples and nonexamples and vice versa. However, once an individual forms a concept image the concept definition may be dispensed (Vinner, 1991). Understanding of a concept then centers on an individual's concept image, and it is essential PSMTs gain experience with a wide variety of examples and nonexamples of function to help form their concept images. In this study, we investigate one PSMT's function concept image as she engages with function-related tasks and explorations.

Research Literature

Research on function conceptions of secondary students, university students, and teachers can generally be divided into two categories: conceptions about function as an entity and characteristics individuals associate with functions. We will discuss each of these categories in the following sections.

Conceptions of Function as an Entity

While investigating conceptions of functions and linear transformations, Zandieh, Ellis, and Rasmussen (2017) identified five clusters of metaphorical expressions their linear algebra students used when reasoning about functions and linear transformations: *input/output*, *traveling*, *morphing*, *mapping*, and *machine*. These metaphorical expressions reveal the types of entities students associate with function. Considering the *input/output* cluster, the associated student responses portray function as an entity that accepts inputs and returns an output. The *traveling* cluster contains statements that depict function as an entity that sends or moves one object to another location. *Morphing* is characterized by references to function as an entity that transforms one object into another. Describing function as a relationship or correspondence entity between two objects is defined as the *mapping* cluster, and the *machine* cluster refers to depictions of function as machine-like-entity that causes one object to change into another.

Vinner and Dreyfus (1989) also identified six types of entities that college students and junior high school teachers associate with the function concept: *correspondence*, *dependence relation*, *rule*, *operation*, *formula*, and *representation*. Similar to Zandieh et al.'s (2017) *mapping* cluster, the *correspondence* categorization refers to descriptions of function as a correspondence, potentially arbitrary, between two sets. Students in this study also described function as a *dependence relation* entity in which there exists some sort of dependence or connection between two variables. *Rule* encompasses descriptions of function as a rule entity with some sort of regularity. The *operation* classification consists of statements that describe function as acting on a number by algebraic operations to produce an image. Vinner and Dreyfus (1989) also found that students describe function as *formula* entity which includes references to function as a formula, algebraic expression, or equation. Finally, *representation* includes descriptions of function as graphs or entities with function notation.

Conceived Characteristics of Function

In addition to conceptions about the types of entity associated with function, students and teachers alike also develop conceptions about the characteristics of function based on their experiences. These conceived characteristics include beliefs about arbitrariness, univalence, and functional notation. Particularly, Even (1993), Carlson (1998), and Vinner and Dreyfus (1989) report that college students and PSMTs believe function should be smooth, continuous, and not "too weird". These beliefs demonstrate a limited understanding of the arbitrary nature of function including potential assumption that functions are graphable with some regularity. Sierpinska (1992), Carlson (1998) and Breidenbach, Dubinsky, Hawks, and Nichols (1992) report an additional belief about arbitrariness: secondary and undergraduate students believe a function should be definable by a single algebraic formula. This conceived characteristic indicates an assumption that all functions are defined on numerical sets and by known rules.

Regarding beliefs about univalence, Even (1993) found that PSMTs understand that univalence distinguishes functions from other types of relations. However, Norman (1992) noticed that secondary teachers frequently apply the vertical line test to determine if a relation is a function even in non-Cartesian coordinate situations. PSMTs also tend to provide students with the vertical line test as a rule to follow perhaps because they do not understand why univalence in important (Even, 1993). Another conception about univalence is related to the one-to-one property. Breidenbach et al. (1992) and Dubinsky and Wilson (2013) report that students believe functions must one-to-one. This may lead to function concept images that do not include constant functions.

Students may also develop conceptions about functional notation. For instance, Vinner and Dreyfus (1989) found that college students are unfamiliar with the relationship between function notation and conceptual aspects of function. Specifically, Sajka (2003) found that a secondary student perceives 'f' as a label for function that does not carry any meaning itself; interprets the symbol '$f(x)$' and corresponding algebraic expression as the formula of the function; and confuses functional notation, $f(x+y)$, with the distributive property, $fx+fy$.

Methodology

This study took place at a large, public, urban university in the southwestern United States with an enrollment of over 42,000 undergraduate and graduate students. Due to the large enrollment of Hispanic students (greater than 30% of the student body), the university carries a U.S. Department of Education Hispanic Serving Institution designation. The university is also described as one of the most diverse national universities in the United States.

The information presented here is part of a larger study consisting of 27 PSMTs enrolled in a mathematics course with a second-semester calculus prerequisite. Materials used in this course, *Explorations on Functions and Equations* (*EFE*), were developed as a part of the *Enhancing Explorations in Functions for Preservice Secondary Mathematics Teachers* Project which was partially funded by the United States National Science Foundation. The *EFE* materials include 11 research-based tasks and explorations for use in mathematics courses for PSMTs as well as instructor materials to assist mathematicians and instructors in implementing the materials in an inquiry-based, active learning environment. Specifically, objectives of the *EFE* include deepening and broadening function-related mathematical content knowledge from school algebra to calculus by exploring relevant topics in an inquiry-based learning situation; and making connections between college mathematics and secondary school mathematics (Álvarez, Jorgensen, & Rhoads, 2019).

Implementation of the *EFE* in the course spanned the first 10 weeks of the 15-week semester. As a part of the larger study, a copy of all participants' written work was collected including written explorations, daily journals, homework, labs, exams, and a midterm project. Each class using the *EFE* materials was also video-recorded using four cameras that were each focused on a different student group.

Of the 27 students who consented to participate in the larger study, we extended invitations to 12 students to participate in video recorded, individual, pre- and post-interviews. Ten students accepted the invitation and completed a pre-interview. All 10 students who participated in the pre-interview remained in the course and were invited to a post-interview; however, only seven students chose to return for a post-interview. The pre-interviews took place within the first three weeks of the semester, and the post-interview occurred between the eleventh and fourteenth weeks of the semester. Questions in the pre- and post-interviews consisted of the same open-ended, task-based questions designed to evoke students' concept definitions and concept images of function as well as draw out their understanding of key ideas associated with function. Examples of questions include (a) how would you define function; (b) list all the distinguishing characteristics of function that you can think of; and (c) do the mathematical terms function and equation mean the same thing. For each of the questions, follow-up questions were used to encourage students to explain and clarify their answers. The post-interview also included questions related to students' perceptions of the course.

Following the completion of the pre- and post-interviews, the video recordings were linked to a pseudonym and transcribed. For the seven students who completed both a pre- and post-interview, we applied inductive thematic analysis methods to the task-based portion of the interviews in order to identify, analyze and report themes of students' function concept images. Inductive thematic analysis seeks to generate codes for data "without trying to fit it into a pre-existing coding frame (Braun & Clarke, 2006, p. 83). Using Nvivo qualitative analysis software, we generated initial codes by analyzing each participant's pre- and post-interview separately for instances that revealed some aspect of the concept image. We then reviewed the instances of each code across all students and interviews and re-coded instances as needed. The remaining codes were then organized into concept image themes, defined and named, and then used to compare aspects of each student's concept image in the pre- and post-interview.

In this study, we use the pre- and post-interview of one participant, Sofia, to report any changes in her concept image of function after interacting with the 11 research-based tasks and explorations in the *EFE*. Sofia self-identifies as a Latina whose native language is English. Prior to the start of this course, the only mathematics courses she had completed at the university level consisted of three-semester calculus sequence. At the time of the study, Sofia was concurrently enrolled in two other mathematics courses, Introduction to Proofs and Introduction to Matrices and Linear Algebra.

Results

Through the coding process described above, we identified over 20 themes, or aspects of Sofia's function concept image, between her pre- and post-interviews. While all of these themes are interesting and reveal important aspects of her concept image as a whole, for this report we will focus on eight concept image themes that, when compared between her pre- and post-interview, depict a change in her concept image: *All Functions can be Equations* (*AFE*), *Functions are Not Equations* (N_{AFE}), *Defined on Numerical Sets* (*DNS*), *Defined on Non-Numerical Sets* (N_{DNS}), *Graphs or Graphable* (*GG*), *Not all Graphable* (N_{GG}), *Vertical Line Test*

(VLT), and *Not Vertical Line Test* (N_{VLT}). Figure 1 depicts the themes that appeared in Sofia's pre-interview and those indentified in her post-interview.

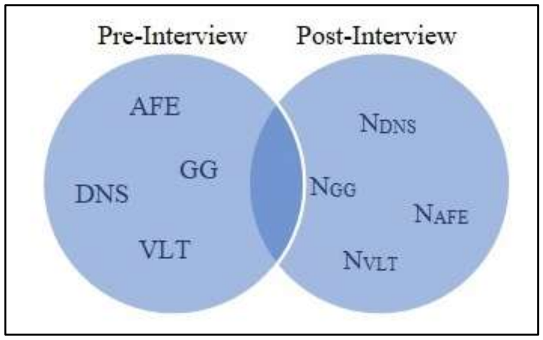

Figure 1. Aspects of Sofia's concept image in her pre- and post-interviews.

The theme *AFE* encompasses statements made by participants indicating their concept image includes the idea that all functions are or can be represented as equations. For instance when discussing whether or not function and equation mean the same thing, Sofia states in her pre-interview, "So like all functions can be equations, but all equations can't be functions." This explanation suggests that Sofia's concept image of function during the pre-interview includes a belief that all functions are equations or can be written as equations. The *AFE* theme was not, however, identified in any of her post-interview statements; rather, the N_{AFE} theme emerged in her post-interview. The N_{AFE} theme represents statements illustrating a concept image aspect in which functions are not equations. Specifically, Sofia recalls once believing that functions are equations, "but then [the students] said that was wrong in class, but [she] never really got why other than the two variable thing." Although she does not fully understand why a function is not an equation, Sofia's experience in the course has partially altered her concept image of function.

DNS represents statements that imply a concept image where functions must be defined on numerical sets, and *GG* includes comments suggesting a concept image in which all functions either are graphs or can be graphed on a coordinate plane. During her pre-interview, the researcher asked Sofia if it would be possible to have a function whose domain was not defined on a numerical set. Sofia's initial reaction is that this would not be possible. She then tries to think of an example for such a function:

> Well, I'm thinking of like graphs that I see or that I know, and it's just like the graph like, the domain is just all the x-values. But if you have it on a graph, that'd have to be like real numbers… There'd have to be real number in order to graph it. And so it can't. I don't think there's any.

This excerpt indicates that Sofia's concept image at the time of her pre-interview does not allow for any functions that cannot be graphed on a coordinate plane or those that are defined on non-numerical sets.

Another theme from Sofia's pre-interview is *VLT* which includes interview responses that suggest a concept image where all functions pass the vertical line test. In both interviews, the interviewer presented Sofia with five statements and asked which statements represented valid mathematical definitions of function. One of these statements defined function as a graph that passes the vertical line test. In her pre-interview, Sofia accepted this statement as a valid mathematical definition of function and says, "That's one of the things that we learn in, when we were taught functions, right, is that it has to like pass that line test." The acceptance of this statement reveals that Sofia's concept image in the pre-interview may only includes functions that pass the vertical line test.

While *DNS, GG,* and *VLT* all appeared in Sofia's pre-interview, none were identified in the post interview. In fact, three quite different aspects of her concept image emerged: N_{DNS}, N_{GG}, and N_{VLT}. Sofia indicated in the pre-interview that functions are only defined on numerical sets. When posed the same question about if a function could be defined on a non-numerical set in the post-interview, Sofia immediately recalls, "[The instructor] used one in class with like people and eye color… I guess people to eye color is a function." This interaction is an example of a statement coded as N_{DNS} – responses that depict that functions defined on non-numerical sets are included in an individual's the concept image.

The N_{GG} and N_{VLT} themes also appear only in Sofia's post-interview. N_{VLT} is characterized by indications that within the concept image some functions do not pass the vertical line test, and N_{GG} represents statements implying that the concept image includes functions that cannot be graphed on a coordinate plane. For instance, Sofia explains why a particular example she provided is indeed a function:

Sofia: …like it only has one output for each input and it passes that vertical test.

Interviewer: Ok. Does it have to do both? Does it have to pass the test and…

Sofia: No, because we said that not all functions are graphable. So I think as long as an input only has one output then you're good because like if it's graphable then it should pass the test. But if it's not, then it should at least have only one output for each input.

Interviewer: Could you give me an example of something like that?

Sofia: I don't know anything that's not graphable. Like off the top of my head I can't…

This conversation suggests that, at the time of the post-interview, Sofia's function concept image no longer requires all relations to pass the vertical line test in order to be considered a function. It appears this is a result of the fact that her concept image now allows for functions to not be graphable on a coordinate plane.

Discussion

In this study, we discuss four concept image themes that we identified in Sofia's pre-interview. As in the of Even's 1993 study and Vinner and Dreyfus's 1989 study, Sofia's function concept image included an expectation that "functions are (or can always be represented as) equations or formulas" (Even, 1993, p. 111). This is represented in our study by the theme *All Functions are Equations* (*AFE*). The other three themes we discuss from her pre-interview are potentially interdependent: *Defined on Numerical Sets* (*DNS*), *Graphs or Graphable* (*GG*), and *Vertical Line Test* (*VLT*). Specifically, the aspect of Sofia's concept image that suggested all functions are graphable and pass the vertical line test restricted her concept image from including functions defined on non-numerical sets. Carlson (1998) reports that college algebra students believe "all functions must be continuous" which suggests an underlying that belief, similar to Sofia's, that all functions are graphs or graphable (p. 137).

The themes presented in this report do not encompass all the aspects of Sofia's concept image identified within her pre- and post-interviews. However, these themes do depict particular changes in her concept image that occurred while she was enrolled in a course using the *EFE* materials. These changes can be linked to two specific experiences motivated by the *EFE*: an experience considering whether or not a expression of the form $f(x) = x$ should be considered an equation, and an experience considering a relation that maps people to their eye colors.

When considering whether or not function and equation mean the same thing in the post-interview, Sofia remembers deciding in class that functions are not equations, but the only distinction she recalls has to do with equations having “two variables”. At another point in the interview, she explains that her two variable distinction originated from a specific example in class. This example took place within the *EFE* lesson “Functions and Equations” in which each group was asked to share three examples of equation on the board. The instructor also added a few potential examples including “$f(x) = x$”. Students then used the definition of equation (i.e. a mathematical statement that asserts equivalence between two quantities) provided in the lesson to decide in their groups which proposed examples actually constitute as equations. Divided conclusions on $f(x) = x$ resulted in a whole-class discussion. In this discussion, some students asserted that $f(x)$ is not a quantity and therefore $f(x) = x$ cannot be considered an equation.

Sofia remembers this interaction with her classmates and draws on this experience to explain why she believes functions are not equations:

> …then when we started going into more details about equations, and um we had all our examples up and [the instructor] had a paper of all of our examples, and we decided that, I think it was some $f(x)$ function, that it wasn’t an equation because it didn’t have the relationship with two variables.

Although misunderstands the conclusion of why her classmates did not consider $f(x) = x$ to be a function, she does remember the episode, and this experience alters her post-interview function concept image.

Another experience that impacted Sofia’s concept image occurred as a result of an exploration in the *EFE* lesson “What is a function?” At the start of this lesson, student groups generated all the defining characteristics of function they could think of. The groups then shared their defining characteristics on the board and were given the opportunity to agree with or offer a counterexample for the proposed characteristics. As groups examined these statements, they were also asked to consider a few questions including, “Are all functions graphable on the Cartesian coordinate plane?” While these conversations occurred, the instructor added to the board for consideration an example of a relation mapping people to their eye colors.

This specific conversation with her group as well as the example offered by the instructor altered Sofia’s concept image of function. Particularly in the post-interview, she drew on the example of a relation mapping people to eye color to determine that functions can be defined on non-numerical sets. She also remembers discussing with her group whether or not all functions are graphable on a coordinate plane and deciding they were not. Altering this aspect of her concept image then allowed for her to alter the portion of her concept image related to the vertical line test. However, it is interesting, in light of the non-numerical example of function she provided, that she was unable to provide an example of a function that cannot be graphed. This supports the Tall and Vinner’s (1981) suggestion that aspects of an individual’s concept image may be disjoint and different contexts may evoke varying portions of one’s concept image.

Two particular experiences resulted in changes to Sofia’s function concept image. Both of these events were prompted by explorations in the *EFE* materials designed to elicit cognitive conflicts related to function conceptions. These results naturally lead to important questions for mathematics education community about course experiences. Specifically, would inserting more experiences that intend to promote cognitive conflict contribute to improving students’ function concept images? What types of experiences positively impact an individual’s function concept image? How could we interpret whether or not a course experience contributes to or detracts from students’ function concept image? The change we observed in Sofia’s concept image suggests that classroom experiences can positively affect an individual’s concept image. However, further research is needed characterize these types of experiences.

A Local Instructional Theory for the Guided Reinvention of a Classification Algorithm for Chemically Important Symmetry Groups

Anna Marie Bergman
Portland State University

In this presentation I will describe the beginning phases of a local instructional theory that has resulted from a design experiment focused on students work with symmetry groups in the context of chemistry. This local instructional theory will consist of both a generalized instructional sequence intended to support the guided reinvention of a classification algorithm for molecular structures, and the theoretical and empirical rationale for the given sequence. I will also describe the various teaching experiments and how each informed the development of the instructional sequence. The mathematical activity of the participants will be used to describe key aspects of the reinvention process.

Keywords: Realistic Mathematics Education, Abstract Algebra, Group Theory, Symmetry

Group theory, in particular symmetry groups, is an essential tool for chemists when interpreting experimental data and in predicting the macroscopic properties of materials based on molecular structure. The use of symmetry groups to describe molecular structure is often formally introduced in undergraduate inorganic chemistry courses where students are asked to categorize relatively simple molecules by their symmetries in order to find their symmetry group. While students in an inorganic chemistry course are given a pre-existing flowchart to help them determine specific point groups, the focus of the design study reported here was to investigate how students might reinvent this classification system for themselves. Therefore, the primary research question of the study was, *"How can students be supported in reinventing an algorithm for the classification of chemically important symmetry groups?"*

Background and Theoretical Framing

Abstract algebra, the larger field of mathematics in which group theory is taught is notoriously difficult for students (Larsen, 2010; Leron, Hazzan, & Zazkis, 1995; Weber & Larsen, 2008). Many of the recorded student difficulties within abstract algebra can be partially attributed to the abstract nature of the content of the course (Hazzan, 1999, 2001). Investigating the symmetry of shapes has proved to be a productive introduction for students learning abstract algebra. In fact, the investigation of the symmetries of an equilateral triangle has been successfully used as a starting point in the research-based, inquiry oriented abstract algebra course entitled *Inquiry Oriented Abstract Algebra* (*IOLA*) (Larsen, 2016). The results reported here are from a recent effort to engage students in the richness of group theory while simultaneously gaining experience with its applicability to other fields.

Realistic Mathematics Education (RME) serves as the underlying instructional design theory for this study and is built on the theoretical perspective that mathematics is first and foremost a process, a human activity (Gravemeijer & Terwel, 2000). Freudenthal (1971) described this activity as

> an activity of solving problems, of looking for problems, but it is also an activity of organizing a subject matter. This can be matter from reality which has to be organized according to mathematics patterns if problems from reality have to be solved. (p. 413)

Through the activity of *mathematizing* students can be guided in reinventing particular mathematical concepts, as opposed to learning the topic as a ready-made or previously discovered theorem. Therefore, overarching goals of RME include discovering how to provide students an opportunity to reinvent mathematics and also how to support them throughout the activity of mathematizing so that ultimately the mathematics that they develop is experienced as developing common sense (Gravemeijer, 1998).

The theoretical framework of RME has three accompanying design heuristics, which can serve as both guiding principles for instructional design and as a guide for further analysis. These heuristics include the reinvention principle, emergent models, and didactic phenomenology (Gravemeijer, 1998). A local instructional theory, LIT, (Gravemeijer, 1998) describes a generalized roadmap for student reinvention of a particular mathematical concept, in which students feel ownership over the mathematical concepts they investigate. First a context was chosen that offered an opportunity for the students to begin using their own intuitions and experiences to develop informal highly context-specific solution strategies (Gravemeijer & Doorman, 1999) which could later be used in a more formal mathematical reality. Didactical phenomenology is then used to focus on the relationship between a mathematical content and the "phenomenon" it describes and analyses, or, in short, organizes (Gravemeijer, 2004). In this sense the heuristic helps at a global level to inform a good starting point for the reinvention process. Didactical phenomenology was also used at a more local level during the teaching experiments to drive the study by helping to identify ways in which I as the researcher could support the students transform their informal approaches to the molecules into more powerful formal arguments about molecules in general (Larsen, 2018).

Lastly, the design heuristic of emergent models is useful in describing both the character, and the process of evolution of student's formal mathematical knowledge from an initial informal understanding. In Gravemeijer's (2002) description of emergent models he highlights

> ...three interrelated processes. Firstly, there is the overarching model, which first emerges as a model of informal activity, and then gradually develops into a model for more formal mathematical reasoning. Secondly, the model-of/model-for transition involves the constitution of some new mathematical reality – which can be called formal in relation to the original starting points of the students. Thirdly, in the concrete elaboration of the instructional, there is not one model, but the model is actually shaped as a series of symbolizations. (p. 3)

Methods

In order to develop the local instructional theory I conducted a design experiment to produce an initial model of successful innovation (Collective, 2003). Through a series of three teaching experiments, including a pilot study, I was able to test and refine multiple iterations of the LIT. The results shared in this contributed report include findings from all three experiments as they each informed the local instructional theory through the development process. Each of the teaching experiments were conducted with pairs of mathematics students who had no apriori experience with group theory in the context of chemistry. While none of the participants had any formal training in chemistry, the mathematical backgrounds of the participants varied across the three experiments. All students were given pseudonyms and compensated monetarily for their time. Data consisted of video recordings of each episode and all written work was also collected.

The goal of the pilot study was to explicate *a way* in which a pair of students could successfully classify chemically important point groups and so it served as a kind of an existence proof (for more detail, see Bergman & French, 2019). To better ensure that the students would be successful for the initial attempt, the pilot study (PS) was conducted with a pair of mathematics education graduate students, Emmy and Felix, each of whom had completed a graduate level course focused on classifying groups of finite order. The two main teaching experiments in the study were conducted with pairs of undergraduates. The first teaching experiment (TE1) was conducted with a pair of undergraduate mathematics students, Arthur and Joseph-Louis, who had recently completed a traditional quarter long lecture-based 300-level introductory group theory course. The final teaching experiment (TE2) was conducted with a pair of undergraduate students, Ada an electrical engineering student and Sophie a mathematics student, neither of whom had any experience with group theory. Ada and Sophie had both recently completed a 200-level linear algebra course and were provided two days of selected lessons from the Inquiry Oriented Abstract Algebra (IOAA) curriculum (Larsen, 2016) as an introduction to group theory between step 1 and step 2 of the local instructional theory outlined below.

The mathematical activity and inscriptions produced in each of the teaching experiments have been subjected to multiple cycles of iterative analysis. The purpose of this analysis has been to further refine and articulate the local instructional theory informed by the participants approaches.

Results

For the presentation, I will describe the seven steps in the reinvention process and illustrate each with examples from the design experiment. These seven steps, organized into three phases which correspond to the level of student's mathematical activity from situated to formal, constitute the framework for my local instructional theory and represent a generalized instructional sequence by which a classification algorithm for chemically important point groups might be reinvented. For this proposal I will be focusing on the beginning steps of Phase 1. This generalized sequence builds on students' own mathematical activity as they investigate select ball and stick models. The overall local instructional theory is outlined in Table 1 below.

Table 1. A Local Instructional Theory for the guided reinvention of chemically important symmetry groups.

Phase	Step	Rationale/Purpose
1. Find the unique symmetry groups of specific molecules.	1. The Measuring Symmetry Task Rank the following figures in order from least to most symmetric. 	Before investigating symmetries in three-dimensional space students are given a set of planar figures to gain familiarity with identifying various symmetries, and to generate definitions for both symmetry and symmetry equivalence.
	2. Find the symmetry group for each molecule:	Students are given ball and stick representations of three selected molecules to begin their symmetry investigation in three-dimensional space.

		Each of the molecules have different symmetry groups which corresponding to different algebraic structures. The symmetry group for water can be expressed as a direct product of two cyclic groups, $\mathbb{Z}_2 \times \mathbb{Z}_2$, ammonia's symmetry group can be expressed as a semi-direct product of two cyclic groups, D_6, and lastly the symmetry group for ethane can be expressed with three generators as a direct product of a semi-direct product and a cyclic group, $D_6 \times \mathbb{Z}_2$.
2. Develop and describe a system for finding the symmetry group for a given molecule	3. What did we do? What did we use?	Students are asked to reflect on their own activity in Phase 1 so they can begin to articulate a strategy for identifying the symmetry group of any given molecule. As students reflect on their own activity, they begin to inscribe their activity in a sort of list of directions and/or a flow chart. This provides students an opportunity to begin to define particular terms being used, in particular something analogous to principal axis, horizontal and vertical reflections.
	4. Could we describe our method for someone else?	Eventually students are asked to create a model of their approach that is understandable by some unknown future user, preferably a chemist who doesn't want to have to do as much group theory. Students may choose to include an 'instruction manual' or 'glossary' with their approach. This provides students a need to focus on the precision of their terminology and the usability of their model.
3. Develop and describe a procedure for comprehensively and efficiently identifying the symmetry group of	5. Will it work for anything? Determine if your method will work for the following molecules: Ethane (staggered)	The goal of introducing ethane in a staggered configuration is not only to show students that there are more kinds of symmetry elements, but also that there are multiple ways to construct the same symmetry group. While the symmetry group of ethane in a staggered configuration is isomorphic to that of

any given molecule.	C_2H_6	ethane in an eclipsed position, ethane in a staggered position contains an inversion center which is the third and final primitive symmetry in three-dimensional space. The introduction of the inversion center forces students to revise and expand their system.
	6. Did we get everything? Can we prove it work for anything?	The purpose for this step is twofold; first students would need to argue that they have identified all possible flavors of symmetry in 3-dimensions. Next, students would want to prove that they have all possible combinations of symmetries.
	7. Special high order groups	The goal of discussing the special groups is to show the students that there are a few special kinds of groups of very high order. These groups are either linear with an infinite rotational subgroup or have more than one rotational axis of order 3 or higher.

Step 1: The Measuring Symmetry Task

There are two primary purposes for this task, the first is to provide students an opportunity to begin treating symmetries as objects, as opposed to a property of a figure, which is a necessary when combining symmetries as group elements. The second purpose is to have students generate definitions of both symmetry and symmetry equivalence. Chemistry education researchers have found that when students learn about symmetry they often struggle with both visualizing molecules in three dimensions and also determining the relevant symmetry operations (Flint, 2011). I found similar student struggles in the pilot study and TE1 when students began their initial investigations in three-dimensional space. When considering ball and stick models the only symmetry transformation that can be physically performed is a rotation, all others are strictly mental operations. This seemed to contribute to the students in both PS and TE1 creating definitions of symmetry that were heavily focused on rotations, as seen in the excepts below.

Emmy: So in this case, since these are like 3-d symmetry means if I had a shape, if I had it oriented like this (see Figure 1) I wanna do something (she rotates the model 180 degrees) so that it's in the same orientation?

Felix: I think so.

Emmy: Ok.

Figure 1. Emmy considers a 180-degree rotation of a water molecule while describing her definition of symmetry.

> *Arthur:* If I'm looking at this in like a chemistry way in where like at any one point this thing (water) is just randomly been rotated in some configuration here and we're just constantly having some random rotation or something, like this thing (ethane) would seem much more likely to end up in a symmetric configuration than this (water) one. So I would call it more symmetric.

The measuring symmetry task (Larsen & Bartlo, 2009) has been shown to be powerful for promoting student generated definitions of both symmetry and symmetry equivalence. I found similar success in this design experiment. It is important that students have working definitions of symmetry so that they know what to attend to when given the ball and stick models and it necessary to establish a definition of equivalence because there must be an agreement on the set of objects that will constitute group elements. The definition of symmetry equivalence also establishes the combination of two symmetries as a (closed) operation on the set of symmetries.

The measuring symmetry task asks students to rank a set of figures from most to least symmetric; then to count and ultimately define the very characteristics by which students were considering when determining rank. When students were given the measuring symmetry task in both TE1 and TE2 they generated powerful definitions of both symmetry and symmetry equivalence. These definitions, Figures 2 and Figure 3 below, were leveraged frequently when the students progressed to working with three-dimensional figures in Step 2.

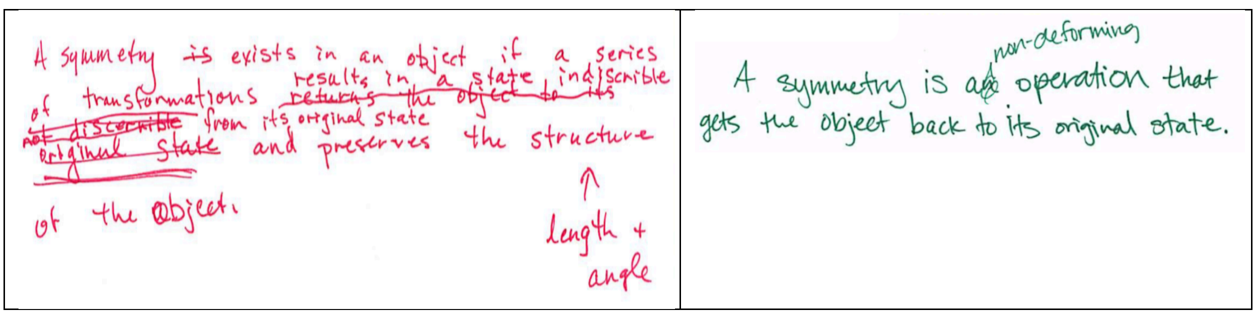

Figure 2. Student generated definitions of symmetry when beginning the Measuring Symmetries task from (a) Teaching Experiment 1 and (b) Teaching Experiment 2.

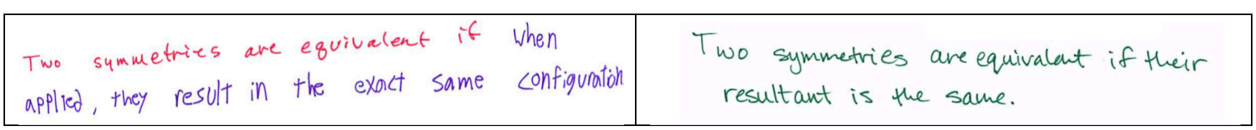

Figure 3. Student generated definitions of symmetry equivalence when beginning the Measuring Symmetries task from (a) Teaching Experiment 1 and (b) Teaching Experiment 2.

Step 2: Find the symmetry group for each of the following molecules; water, ammonia, and ethane.

The purpose for this task is first and foremost to give students experience investigating the symmetry groups of molecules with different group structures. Each of the selected molecules have different combinations of reflections and rotations, symmetries which the students already have some experience identifying from their work in Step 1. The task pushes students to describe the unique collection of symmetries for each molecule and organize them in a manner that helps them to determine what kind of group structure they will produce. I have found that in each teaching experiment the participants began their investigations with water followed by ammonia, and lastly ethane, in an eclipsed configuration.

When considering the symmetry of group for each molecule students start with some kind of inscription system that records the physical effect each symmetry has on the molecule as seen in Figure 4; which was often followed by a Cayley table as seen in Figure 5.

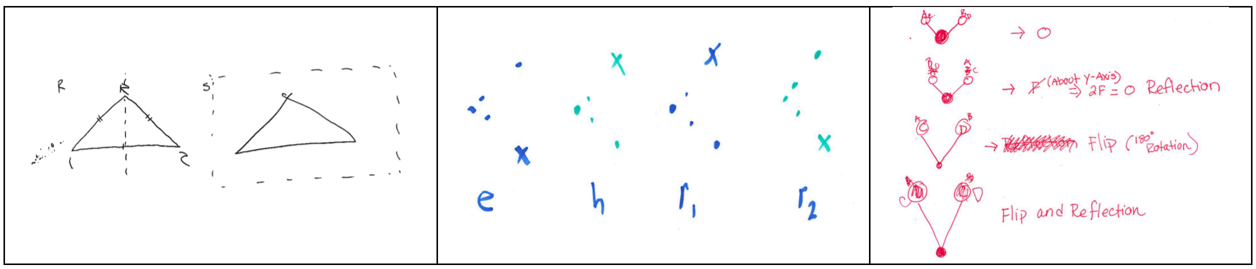

Figure 4. Student inscriptions recording the effects of various symmetries on a water molecule from (a) the Pilot Study, (b) Teaching Experiment 1, and (c) Teaching Experiment 2.

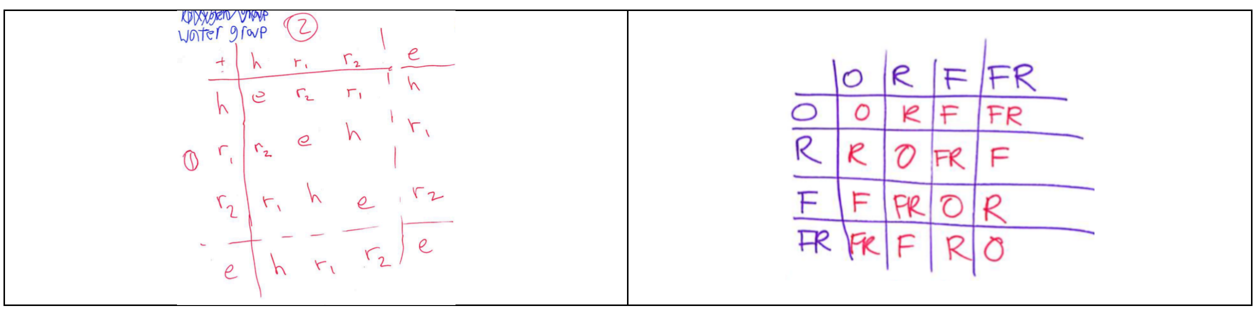

Figure 5. Student Cayley tables for the symmetries of a water molecule from (a) Teaching Experiment 1 and (b) Teaching Experiment 2.

Implications and Significance

The local instructional theory reported here has been tested with students with a wide range of mathematical backgrounds all of whom were able to engage with each task and successfully produce a classification algorithm capturing most chemical structures. Furthermore, all of the students involved expressed truly enjoying the experience and reported a sense of deeper understanding of the concepts of group theory due to their participation. Unfortunately, due to time constraints in this study, I have yet to gather evidence on how students might prove that their classification system is complete, steps 6 and 7 of the current LIT. So while a future study with additional iterations of teaching experiments are still necessary, the LIT reported here already shows potential to be implemented with all kinds of students in possibly a wide range of courses to help students experience the usefulness and applicability of group theory.

Changing the Script: How Teaching Calculus using Team-Based Learning Misaligns with Students' Views of how Learning Mathematics Occurs

Heather A. Bolles
Iowa State University

Kari N. Jurgenson
Iowa State University

Amanda R. Baker
Iowa State University

Active learning has been shown to increase student success and improve student confidence, whereas ambitious teaching potentially leads to decreased student attitudes for learning mathematics. In this study, we examined how 18 Calculus I students' beliefs, attitudes, and expectations were met or challenged across a semester when taught using Team-Based Learning, an ambitious teaching method. Results indicate that aspects of the TBL design, including initial interaction with content outside class, reduced emphasis on instructor lectures, and complexity of the tasks may have contributed to students' negative attitudes. These negative attitudes interplayed with students' beliefs about their competence to learn mathematics on their own and their beliefs about the nature of mathematics and how mathematics should be learned.

Keywords: Calculus, Team-Based Learning, Student beliefs, Student attitudes

The transition of the study of mathematics from the high school to the college level proves challenging for many students. Whether the study of mathematics at the college level demands more rigor than at the high school level or students must seek more support in college (Burrill, 2016), many calculus students display lower confidence (Sonnert & Sadler, 2015) with some opting to switch majors to avoid additional calculus (Ellis, Kelton, & Rasmussen, 2014).

The national MAA study (Bressoud, Mesa, & Rasmussen, 2015) promotes the use of "good teaching" to increase student confidence and attitudes in calculus. In addition, as documented in Freeman et al. (2014), students outperformed their peers when active learning occurred in their STEM courses. At our institution, researchers documented student success in Team-Based Learning (TBL) Calculus I both during the course (Peters et al., 2019), and in subsequent Calculus II and calculus-based physics when compared to their traditionally-taught peers (forthcoming). Based on instructor reports and supported by observations by the second author, TBL Calculus I could be classified as "ambitious teaching" since the course included team projects, unfamiliar problems on homework and exams, written and verbal explanations, and decreased reliance on lecture (Sonnert & Sadler, 2015). As reported by Larsen, Glover, & Melhuish (2015), however, ambitious teaching can lead to decreased student attitudes for learning mathematics. At our institution on their course evaluations, in spite of their success, TBL Calculus students expressed frustration with the TBL process, the workload, and the lack of instruction provided by teachers.

Research Questions

To investigate students' frustrations more closely, we conducted a study to understand students' beliefs, attitudes, and expectations, as they experienced the TBL Calculus course. The questions driving this study included (a) how did the TBL Calculus experience meet or challenge students' beliefs, attitudes, and expectations for learning calculus; and (b) what factors led to changed or unchanged beliefs and attitudes about learning mathematics when in the TBL setting?

Links to the Literature

Seeking to understand how various forms of ambitious teaching impact student beliefs, more should be understood about Team-Based Learning. Developed by Michaelsen, Knight, & Fink (2002), TBL is a flipped, active learning strategy in which students first engage with content outside of class through videos and/or readings and then meet in class with a permanent, heterogeneous team of size five to seven to work on team tasks. Students are held accountable for their work by completing individual Readiness Assessment Tests (iRATs), team Readiness Assessment Tests (tRATs), and application exercises. Administered outside class, the five-question, short-answer or multiple choice quizzes (iRATs) assess students' initial understanding of the main concepts after reading the text or watching the video(s). Students then come to class to take the same five-question quiz with their team. After which, the instructor provides lecture elaborating the big ideas and finer details of the concepts. The application exercises or team projects are rich, problem-based, group-worthy tasks given at a level of difficulty to advance individuals' learning of content and promote team development. The application exercises are designed so each team solves the same significant task, makes a specific choice for an answer, and simultaneously reports an answer. Students complete peer evaluations periodically throughout the course to assess team members.

Knowing that TBL strives to engage learners in both individual and social settings, students' beliefs about the tasks and mathematics influence their level of engagement. Students' beliefs about mathematics and how students acquire mathematical knowledge affect how students approach a course. Schoenfeld (1985) states,

> Belief systems are one's mathematical world view, the perspective with which one approaches mathematics and mathematical tasks. One's beliefs about mathematics can determine how one chooses to approach a problem, which techniques will be used or avoided, how long and how hard one will work on it, and so on. Beliefs establish the context within which resources, heuristics, and control operate (p. 45).

Students' beliefs in mathematics are individually held though, similar to knowledge, they may be socially constructed (De Corte, Eynde, & Verschaffle, 2002). De Corte et al. (2002) note that beliefs about the class context are determined by the activities, experiences, and interactions in the classroom. Therefore, if students experience classroom practices, such as, listening, watching, and mimicking things the teacher and textbook tell and show them, most students will likely learn and believe that mathematical knowledge is a form of received knowledge, not something constructed (Greeno, 1991). Schoenfeld (1992) identifies additional consequences of traditional mathematics instruction. One, when exposed to curriculum in bite-size pieces, students learn that answers and methods to problems will be provided to them; rarely will they be expected to determine the methods by themselves as they accept their passive role. Second, students come to believe they should have a ready method for the solution of a given problem and the method should produce an answer to the problem in short order.

Attitude is comprised of students' emotions associated with mathematics and their beliefs about themselves, about mathematics, and about their ability to do mathematics (McLeod, 1992). Di Martino & Zan's (2010) Three-dimensional Model for Attitude towards mathematics identifies the deep interplay between beliefs and emotions, especially when students display negative attitudes toward mathematics. The Three-dimensional Model for Attitude links emotional dimension, vision of mathematics, and perceived competence (Di Martino, 2016). Therefore, students may have a negative attitude toward mathematics due to their beliefs about mathematics, their perceived ability to do mathematics, or the emotions related to mathematics (Di Martino & Zan, 2010).

Students' motivational beliefs consider self-efficacy, value, and affect (Kitsantas, et al., 2008, & De Corte et al., 2002). A student's self-efficacy is their belief they can accomplish a task. Value emphasizes why students engage in learning and problem-solving and pursue the learning goal. Affect relates students' emotional reactions to tasks and their performance. Motivation provides the reason students engage in any pursuit, the reason students extend effort toward mathematical activity, and the extent to which students' efforts are viewed as productive (Middleton, Jansen, & Goldin, 2016). When a student engages in mathematical activity, "a combination of intrinsic, extrinsic, social, and individual factors are interrelating" (Middleton et al., 2016, p. 18).

Motivation is a regulatory process as students anticipate, engage, and reflect. When confronted with a mathematical task, students first determine the value of the task, then determine whether or not to engage, next choose a course of action, and finally evaluate their performance (Middleton et al., 2016). As a student's experiences consistently and coherently align with regard to motivational affordances, the person will likely develop a (positive or negative) long-term disposition and identity toward mathematics (Middleton et al., 2016, p. 19).

Theoretical Perspective

Researchers have long observed a link between students' beliefs about mathematics knowledge and the ways in which they engage in learning math (Garofalo, 1989; Schoenfeld, 1992). More recently, Muis and Franco (2009) found that students who viewed knowledge as tentative and complex were more likely to adopt mastery goals, and subsequently more likely to use deep processing strategies. Subsequently, a number of studies provide evidence, though not entirely conclusive, that constructivist learning environments promote more complex beliefs about knowledge (Muis, 2004). However, the relationship between students' beliefs about mathematics and their engagement in active and collaborative learning may be bidirectional. If students' views of knowledge inform their use of learning strategies and self-regulated learning, their epistemic aims (goals related to knowledge/inquiry) and epistemic beliefs (beliefs about knowledge) at the start of the course could influence the quality of their engagement in the course (Chinn, Buckland, & Samarapungavan, 2011). In this study, we hypothesized that epistemic factors might help explain persistence of or change of beliefs about mathematics and the learning of mathematics.

Research methodology

At a large, public midwestern university in Fall 2018, researchers invited all Calculus I students to participate in a study to examine differences in the beliefs, attitudes, and experiences of students. Two sections of Calculus I were taught using TBL. All other sections were traditionally taught in a lecture format. In most cases, students registered for Calculus I without knowing the method of instruction. The academic advisers may have known that students enrolling in a given section may therefore have secured a seat in a traditionally taught or TBL taught section. The information providing instructional method was neither hidden from nor broadly advertised to students.

TBL Calculus implemented the four main principles of TBL as established by Michaelsen et al. (2002). Similar to the description given in Peters et al. (2019), instructors formed heterogeneous, permanent teams, held students accountable for individual and group work, offered assignments promoting learning and team development, and frequently provided timely feedback. The two instructors varied in their teaching experience. One taught calculus for more than 40 years; the other taught calculus for more than ten years. Both taught TBL Calculus I for four semesters prior to the start of this study. The first author taught one of the TBL sections. The second author observed each of the TBL sections three times throughout the semester to identify student engagement and class activities throughout the semester.

In TBL Calculus, students had access to materials through the learning management system (LMS). All throughout the course, students could access the schedule for the iRATs, tRATs, team projects, and homework assignments as well as the videos, textbook, and reading guides. They could review this content and ask the instructors questions about the content at any time. Instructor-made videos accompanied sections of the textbook and ranged in length from 5 to 25 minutes with one to four videos per section. Instructors expected students to watch the videos and/or read the textbook prior to completing an iRAT. Students accessed the iRATs on the LMS during a limited time period. For example, an iRAT covering one or two sections of the textbook opened at 5pm on Monday evening and closed Wednesday at 7:30am, 90 minutes before class started. Once opened, students completed the 5-question multiple-choice or short-answer quiz within 35 minutes. Not informed of their iRAT results, students came to class to complete the team-version of the quiz (tRAT) during a 10-15 minute time period at the start of class. Two instructors and two teaching assistants circulated the classroom to address questions and provide assistance. After teams submitted their answers, the lead instructor lectured the remainder of the class session. Immediately following class, a 5-6 question online homework assignment opened, providing procedural practice of the new content. Students had unlimited attempts prior to the next class session to answer these questions. During the subsequent 1-2 class sessions, students completed team projects designed to engage students in rich conceptually-based problems, applying the new content and involving multiple topics. Additional online homework assignments gave students further practice with concepts and procedures.

Calculus I students enrolled in a more traditionally-taught course could attend three sessions of lecture in large classes (sized 192-360) and one recitation session (sized 32) containing a question/answer session and a quiz. Traditionally taught students completed online homework assignments once each week. All Calculus I students took the same three midterm exams and cumulative final exam.

In the third week of the semester, 606 students responded to the pre-survey asking students about their attitudes, beliefs, and experiences in mathematics. Of the 606, 102 TBL students completed the survey. We invited a subset of the TBL survey participants to complete a series of 40-60 minute semi-structured qualitative interviews about their experiences in the course. Sampling for variation in experiences, we selected students with both instructors and used feedback from instructors to select students in teams with different levels of functioning. We invited several students from each team to participate, with the goal of obtaining at least two participants per team. Finally, although the majority (80.4%) of the students in Calculus I were male, we sampled both male and female students. The result of this procedure was a sample of 18 students (12 male, 6 female) enrolled in TBL sections of Calculus I. Of these, 13 (8 male, 5 female) participated in Interview 2 and 11 (6 male, 5 female) participated in Interview 3. Interview 1 occurred during week 5 and prior to the first exam; Interview 2 took place during weeks 12-13, after the second exam; and Interview 3 occurred the following semester during weeks 7 – 9. Themes for students' statements were identified in the transcriptions using grounded theory and open coding (Glaser & Strauss, 1967; Miles & Huberman, 1994; Strauss & Corbin, 1994) and discussed amongst the three authors. The second author then coded all the transcripts.

Results of the Research

Students' comments during the interviews exposed their beliefs about the acquisition of mathematical knowledge as informed by past mathematical learning experiences. Most of these beliefs opposed the structure and philosophy behind the Team-Based Learning strategy.

The Expert Disseminates the Knowledge

Many students indicated their previous mathematics learning experiences were lecture-based. Expecting students to watch instructor-made videos or read the textbook to gain first exposure to new content challenged students' beliefs related to how knowledge is disseminated.

Will: What I've been accustomed to (in high school) is like a professor just kind of standing up and lecturing, and learning from that. And, then if I have a question afterwards, or a question on a homework problem then go ask.

Students expected, as in their previous mathematics courses, to be taught face-to-face and then be given the opportunity to practice.

Interviewer: What, if anything, seems frustrating or challenging about Team-Based Learning?

Stacy: Just the fact that we're learning with the material instead of ahead of it. We aren't given that foundation. We have to build it ourselves, and it can be very frustrating.

Students did not view the online videos and text as appropriate ways to first provide content.

When asked if they thought they learned more than, the same as, or less than if they were traditionally taught, many TBL students stated they felt they learned less mathematics than if they were in a traditionally taught calculus. Their reasons varied. Some indicated that they depended on the team and thus slacked on their own contributions. Other indicated that with no lectures, all the learning was done outside of class. Time in the TBL class was spent implementing the knowledge on the team projects.

Interviewer: What was the least helpful about your experience last semester?

Eli: Lectures. There were basically no lectures. We barely learned stuff in that class. That class is just a room to do stuff, you know? All you're learning is mainly outside of class applying it to that class. It's practice, rather.

Interviewer: Okay, so you mean you didn't like the learning outside of class?

Eli: You have to teach yourself calc outside of class if you wanna get a good grade. You have to go the extra mile cause the lectures there aren't going to teach you cause there aren't lectures, really. It's more just, 'hey, grab your white board,' and that's about it.

Most students explained during interviews their appreciation to work with other students and gain perspective of how others solved problems. However, very few felt the team work promoted actual learning. They felt their learning occurred individually outside of class, and the work during class reviewed what was self-taught. At least one student, John, recognized the potential for improved learning, when he said the more hands-on approach was "probably better learning in the long run because then you'll remember it more 'cause your brain is the thing that's doing it instead of just being told, 'hey this is how you do it.'"

Asking Questions with First Exposure

In addition to students' expectations for lecture and dissemination of mathematical knowledge during class sessions, students believed asking questions when first engaging with new material contributed to learning. Multiple students addressed frustration at not being able to ask questions when watching the videos and reading the textbook before completing the iRAT.

Amy: I'm definitely more of a person who needs like someone who knows what they're doing to explain it to me. And like, have that lecture time so if I need to ask questions, I can ask questions about like how it's being taught while it's being taught because sometimes if I learn something, but I have questions about it and I don't learn it right, then it's really hard for me to get the right way later on when I ask questions."

At least one student, Francesca, expressed appreciation at the opportunities to ask questions during class when working on team tasks. Because of this, she felt that learning was easier with TBL. "You're able to ask more questions, and be more confident with asking questions along with others on that team."

Many felt they would be able to ask questions in a traditional course when the instructor first discussed the content. However, based on focus-group sessions with traditionally-taught calculus students, questions were rarely asked in the large class sessions as students did not want to interrupt the instructor when they had stated that they had a lot of content to cover.

High Workload and Task Value

Most students interviewed agreed that the workload required too much time. The demands may have resulted in a devaluing of the tasks, thereby decreasing motivation and leading to the use of shallow strategies to complete them. Students felt rushed to watch videos, especially near the end of the semester when multiple videos were 20 or more minutes in length. Students confessed to not watching all the videos or increasing the speed on the videos prior to completing the iRATs.

The frequency of iRATs and online homework assignments frustrated students. Thomas stated, "TBL is a black hole for time for me." Will shared that all the little assignments threw him off. He felt his grades were suffering because he spent his time getting points rather than learning. Miguel said, "Since there's so much work, I was rushing to memorize things or try to understand them as fast as possible and not really get them deep in my brain till I have a deep understanding. I'd have just a basic understanding." John and Eloise stated that they resorted to the use of derivative calculators online to help complete online homework problems quickly, especially if the assistance provided the intermediate steps.

During class, students also expressed feeling rushed to complete the team projects. Eli shared that his team would come to class and encourage each other to simply get the project done as fast as they could so they could leave.

Struggle and Complexity

A few students expressed the struggle the iRATs, team projects, and exams gave them. Eloise felt she had to have team members show her how to do things. "I just feel incompetent sometimes." Stacy commented that the TBL was a struggle. "The information just isn't given to me and I have to go find it."

Part of the struggle students noticed resulted from the differences in complexity in learning mathematics at the high school level than at the college level. John summarizes, "I don't know if it's just in college, but in team-based learning at least, we put a lot of concepts together whereas in high school we'd learn one concept and we wouldn't use it again until the final." Later about a TBL project, he said,

We'd have an in-class word problem like project with our team or whatever and it'd be a concept from the first unit and a concept from the second unit and you'd have to know both of them to be able to do the problem. But it expanded your knowledge because then you learned how to do a problem with both of those concepts.

Another student identified another contrast between his high school experience and the TBL Calculus experience.

Thomas: Our high school calc was more focused like, 'Here's an exact problem, and there's one way to do that problem.' But then here in calc, there's multiple ways to tackle problems….You have three, four weeks of lecture material that you have to remember all of it for a lot of problems. Or you have to remember multiple lectures for one problem.

Interviewer: How is that different than your high school math?

Thomas: You'd have simple problems with just one step. For us, calc exams, they often involve multiple steps.

The complexity of exam problems was addressed by both TBL and traditionally-taught students, and therefore shows one challenge students see in their transition of the study of mathematics from the high school to college.

Overall, based on student-interviews, the TBL Calculus approach challenged and opposed most interviewees' beliefs about mathematics and the learning of mathematics. Students' beliefs persisted since the start of the course in that the expert in a face-to-face environment should establish the foundation of knowledge needed prior to engaging students in tasks. According to students, instructors should highlight the most effective means of solving problems for students.

Applications to and Implications for Teaching Practice

This study shows that many students, similar to those described by Bookman & Friedman (1998) after one semester of reform calculus, reported that the course required too much time outside of class and that "the course taught me very little" (Bookman & Friedman, 1998, p. 118). The negative attitudes portrayed by interviewed TBL Calculus students related to their beliefs about a low competence to learn mathematics outside class. Others expressed negative attitudes due to their belief that mathematics should be disseminated by an expert. Both sets of beliefs misaligned with the foundational structure of the TBL course. As concluded by Bookman & Friedman (1998), students in the TBL Calculus may in another year gradually adopt an attitude consistent with ambitious teaching. For our study, seven or eight weeks into the following semester did not provide sufficient time for attitudes to change. Additional investigation can be done to identify at what point and in what ways attitudes change.

For teaching purposes, students stated they needed to feel they had more control of their learning. In this particular application of TBL Calculus, this likely means a reduction in tasks completed outside of class, including shorter videos to watch and fewer and shorter online homework assignments. Decreasing the time pressures with the iRATs could also reduce anxiety for students. During class, rather than emphasizing the completion of team projects, instructors should emphasize the processing of and reflecting upon some rich questions during whole class discussions.

An additional manner in which students can perceive greater control of their learning is to help them engage in more regulatory behavior. Motivating and training students to anticipate, engage in, and reflect upon tasks could advance students' learning and potentially lend toward changed beliefs about how mathematical knowledge is acquired. This regulation also should decrease the use of shallow strategies including memorization and lend toward deeper learning strategies. Furthermore, students' application of these regulatory skills could ease students' transition in the study of mathematics from the high school to college level.

Secondary Prospective Teachers' Strategies to Determine Equivalence of Conditional Statements

Orly Buchbinder
University of New Hampshire

Sharon McCrone
University of New Hampshire

Future mathematics teachers must be able to interpret a wide range of mathematical statements, in particular conditional statements. Literature shows that even when students are familiar with conditional statements and equivalence to the contrapositive, identifying other equivalent and non-equivalent forms can be challenging. As a part of a larger grant to enhance and study prospective secondary teachers' (PSTs') mathematical knowledge for teaching proof, we analyzed data from 26 PSTs working on a task that required rewriting a conditional statement in several different forms and then determining those that were equivalent to the original statement. We identified three key strategies used to make sense of the various forms of conditional statements and to identify equivalent and non-equivalent forms: meaning making, comparing truth-values and comparing to known syntactic forms. The PSTs relied both on semantic meaning of the statements and on their formal logical knowledge to make their judgments.

Keywords: Reasoning and Proof, Conditional Statements, Preservice Teacher Education

Mathematics educators generally agree that teaching mathematics in ways that promote reasoning and proof can deepen students' understanding and support retention of knowledge (e.g., Hanna & deVillers, 2012; Harel, 2013). Furthermore, researchers and policy makers support integration of proof and reasoning across all grade levels and mathematical topics (NCTM, 2009; NGA & CCSSO, 2010). In order to bring this vision of mathematics teaching into reality, teachers need to have robust understanding of deductive reasoning, valid modes of inference, proof techniques, and other aspects, which comprise *knowledge of the logical aspects of proof* (Buchbinder & McCrone, 2018). Moreover, teachers must flexibly use this knowledge in the context of school mathematics.

As part of a larger grant to study and enhance prospective secondary teachers' (PSTs') mathematical knowledge for teaching proof, we designed instructional activities aiming to strengthen their knowledge of the logical aspects of proof. The activities were enacted in the capstone course, *Mathematical Reasoning and Proof for Secondary Teachers*, which is a blended content and pedagogy course developed as a part of the grant (Buchbinder & McCrone, 2018).

One set of such activities focused on conditional statements and logical equivalence, or the lack of thereof, between the implication $P \Rightarrow Q$ and various logical forms, such as contrapositive, converse, inverse, but also other forms such as *P if Q* or *P is necessary for Q*. The purpose of the activities was to push the PSTs thinking beyond typical "if-then" statements, in hopes that by identifying ways of moving their own understanding forward, the PSTs would strengthen their knowledge of the logical aspects of proof, which in turn, could inform their future teaching.

As researchers, we sought to understand the process by which the PSTs made sense of various logical forms of conditional statements and to identify strategies by which the PSTs determined logical equivalence. Our work was guided by the research question: How do PSTs make sense of various logical forms of conditional statements and establish equivalence between them?

Background and Theoretical Perspectives

A conditional statement (or a logical implication), denoted as $P \Rightarrow Q$, can be expressed in words as *If P then Q* or *P implies Q*. But many other equivalent forms are possible, for example, *Q if P*, *P only if Q*, *P is sufficient for Q* and *Q is necessary for P*. Formally, two statements are logically equivalent if they have the same truth tables. This definition can be used to determine that a contrapositive $\sim Q \Rightarrow \sim P$ is equivalent to $P \Rightarrow Q$. However, it cannot be applied directly to the logical forms mentioned above. The equivalence of these forms to the original implication is not obvious and many require a few logical steps to show. As an example, consider the form *P only if Q*. Taken by itself, this statement says that *P* is true only under the condition that *Q* is true. In other words, if *Q* is false, it cannot be the case that *P* is true (i.e., *P* is also false). Using such reasoning, one might recognize that *P only if Q* is equivalent to *not Q implies not P* which is the contrapositive of the statement *P implies Q*, and thus is equivalent to *P implies Q* (Chartrand, Polimeni & Zhang, 2018). This type of reasoning can be challenging, as it requires both syntactic understanding of the formal symbolic notation and the semantic understanding of the meaning of each logical form and the related wording (Weber & Alcock, 2004).

Studies have shown that mathematics majors and PSTs often misinterpret mathematical language and experience particular difficulties with conditional statements. These include confusion between an implication and its converse ($Q \Rightarrow P$) (Durand-Guerrier, 2003), interpreting an implication as a biconditional ($P \Leftrightarrow Q$) (Epp, 2003), difficulty understanding the equivalence between an implication and a contrapositive (Dawkins & Hub, 2017; Stylianides, Stylianides & Philippou, 2004) or between an implication and a disjunction ($\sim P \vee Q$) (Hawthorne & Rasmussen, 2015). However, we are not aware of studies that examined how undergraduates, in particular PSTs, make sense of logical equivalence of a broad range of logical forms of conditional statements. We see this as a crucial aspect of teacher preparation, as teachers need flexible knowledge to make sense of and rephrase their students' contributions into more precise mathematical statements in order to determine their validity.

Methods

The Conditional Statements activities took place in the capstone course, *Mathematical Reasoning and Proof for Secondary Teachers*, for which the first author served as the instructor. All PSTs enrolled in the course agreed to participate in the study: 15 PSTs in Fall 2017, and 11 PSTs in Fall 2018. All PSTs were native English speakers. At the time of data collection all PSTs were seniors, thus, they had completed most of their mathematics coursework, including several proof-based classes such as Mathematical Proof, Geometry and Abstract Algebra. Hence, the goal of the Conditional Statements activities was not to introduce PSTs to new material, but to help them refresh and strengthen their content knowledge of conditional statements. The content focus included the meaning and logical notation of the implication $P \Rightarrow Q$, recognition of hypothesis and conclusion in context specific statements worded in different forms, determining truth-value of conditional statements, and recognizing equivalent and non-equivalent logical forms such as a contrapositive $\sim Q \Rightarrow \sim P$ and a converse $Q \Rightarrow P$.

The activity that is the focus of this paper included the following tasks:

a. Working in small groups, determine which of the 11 given logical forms are equivalent to the original implication $P \Rightarrow Q$ and which are not (Fig. 1);
b. Create a poster display of the equivalent and non-equivalent statements and share those posters with other groups;

c. Discuss the answers as a whole class, clarify difficult items, and summarize main points about logical equivalence and its relationship to truth-value.

Each group received a different mathematical statement, but the logical forms were the same across all groups. The mathematical statements of each group were the following:

Group 1: A graph of an odd function passes through the origin (assume f is defined at 0).

Group 2: A number that is divisible by 6 is divisible by 3.

Group 3: Diagonals of a rectangle are congruent to each other.

Group 3

Given a true statement: ***Diagonals of a rectangle are congruent to each other.***

1. Rewrite the statement in an *If P then Q* form. Identify *P* and *Q*.
2. Using P and Q you defined above, write statements in each the forms presented below.

a) P if Q	
b) P only if Q	
c) P is necessary for Q	
d) To infer Q, it is sufficient to know P	
e) Q if P	
f) Q is sufficient for P	
g) If not P then not Q	
h) Not-Q implies not-P	
i) P is sufficient to infer Q	
j) Q is necessary for P	
k) P if and only if Q	

3. Write each statement on a separate index card using different color for true and false statements. Sort the cards in two groups: (i) cards with statements equivalent to the given statement, and (ii) cards with statements not equivalent to the given one. Be prepared to explain why placed the cards the way you did.

Figure 1. A worksheet of Group 3 (Geometry)

The inclusion of a mathematical context and symbolic form in one task aimed to support the PSTs flexible understanding and use of formal logical notation while grounding it in familiar content (Dawkins, 2017; Dubinsky & Yiparaki, 2000).

The tasks were enacted across two class periods and took about two hours to complete. The data were collected in the form of video recordings of each groups' work with a tabletop 360° video camera, a stationary camera to capture the whole class discussion, and PSTs' written work in the form of worksheets and posters. The video recording and their transcripts were the primary data source for this paper. Written artifacts served as a secondary data source.

To analyze the data, we divided the video transcripts into meaningful episodes, and used open coding (Wiersma & Jurs, 2005) and the constant comparative method (Strauss & Corbin, 1994) to identify categories of strategies the PSTs utilized to determine whether certain forms of conditional statements are logically equivalent to the implication $P \Rightarrow Q$.

Results

Our analysis revealed three main strategies in the PSTs approaches to determining logical equivalence: (1) meaning making, (2) comparing truth-values, and (3) comparing to known syntactic forms. These strategies are interrelated and some have further sub-categories, which we elaborate below. The two types of logical forms that appeared to present most challenges to the PSTs were *P only if Q*, and the statements that contained the language of *necessary* and *sufficient* condition. Thus, the data excerpts chosen to illustrate the strategies are taken from these types of statements as they provided the clearest evidence of the PSTs strategies to determine equivalence, although the strategies were observed throughout all types of logical forms. Note, the text in square brackets was added for clarification.

Strategy 1: Meaning Making

This strategy entails rephrasing of the statement (often multiple times) in search of a clearer meaning. This process included three types of sub-strategies: (a) introducing additional or substituting alternative words, (b) attempting to put a statement into an "if-then" form, and (c) relying on counterexamples and "feelings".

Rephrasing by adding or substituting words. When trying to interpret conditional statements that were worded as necessary or sufficient conditions the PSTs initially attempted to substitute open sentences for *P* and *Q*, but quickly discovered that this may result in a nonsensical statement, as shown below:

Excerpt #1. Sam: …how to write that… P is necessary for Q.

Bill: Yeah, I'm trying to think about a word…

Nate: That's a lot of is's. Cause "a quadrilateral is a rectangle is necessary for its diagonals are congruent …it's just awkwardly worded.

Laura: A quadrilateral must be a rectangle for the diagonals to be congruent.

Nate: mmm…nice change.

The PSTs also found it difficult to distinguish between necessary and sufficient conditions. The following excerpt illustrates the PSTs' confusion as they tried to word the statement: If a number is divisible by 6 then it is divisible by 3 in the form *Q is sufficient for P.*

Excerpt #2. Penny: It is sufficient to know that a number is divisible by 3…

Zoe: If it's divisible by 3 then it's satisfies that it's going to be divisible by, …no.

Linda: No, technically not.

Zoe: But that's not what it's saying, sufficient is like if it satisfies… that guarantees… so, if a number is divisible by 3, then it guarantees that it is divisible by 6.

Here, Penny tried to retain the wording of "*is sufficient*" while Zoe struggled a bit but then offered the alternate wording *if it satisfies Q, then it guarantees P*. Not all attempts to rephrase the statement preserved the meaning, but this strategy was highly prevalent and for the most part was efficient in PSTs' attempts to determine equivalence.

Rephrasing in "if-then" form. Much of the PSTs' rephrasing efforts were directed towards putting the statements into an "if-then" form (e.g., Zoe's attempts in Excerpt #2 above), even when this was not entirely appropriate. Consider the excerpt below:

Excerpt #3. Audrey: Umm…and then another one that was really confusing for us was *Q is necessary for P*. So we said, if a number is divisible by 3, it is necessary for it to be divisible by 6, but that's like opposite of what the [original] statement is saying. Cause if a number is divisible 3, it doesn't have to be divisible by 6.

Here, Audrey's group rephrased *Q is necessary for P* incorrectly as *if Q it is necessary for it to be P*, which seems to be further simplified as *if Q then P*. This changed the meaning of the statement indeed transforming it into one not equivalent to the original.

The strategy of rephrasing a statement in an "if-then" form worked for the *P if Q* statement. The PSTs put "if" at the beginning of the sentence: *if Q, P*, and added the words "follow" or "then" to correctly conclude that *P if Q* is equivalent to *if Q then P*, and thus not equivalent to the original implication. However, this strategy failed when interpreting *P only if Q* statement. The PSTs either came to impasse, not knowing how to interpret *only if Q, P* or they simply dropped the word "only," wrongly transforming the statement into *if Q then P* (see Excerpt #5 below)

Counterexamples and "Feelings." The PSTs constructed counterexamples to help them make sense of the statements. For example, Emily used the counterexample of $y = x^2$, a non-odd function passing through the origin to help her make sense of the form *P if Q* and to conclude that it is not equivalent to *P implies Q.* She said: "No, it's not equivalent. [A function] x^2 can pass through the origin. It [*P if Q*] is saying if a graph passes through the origin, then the function is odd. It's flipping it."

In both cohorts, the PSTs came up with the same counterexamples: $y = x^2$ for the statement about functions, an isosceles trapezoid to show that a quadrilateral which is not a rectangle can have congruent diagonals, and numbers 9 and 15, which are divisible by 3 but not divisible by 6. Once someone in the group introduced a counterexample into a public space, the members of the group repeatedly used it to make sense of various forms of conditional statements. However, the PSTs occasionally misused these counterexamples in statements. For instance, Derick attempted to use the function $y = x^2$ to disprove a statement "A graph of the function passes through the origin if the function is odd", which has a form *Q if P*. Derick noticed that the function $y = x^2$ satisfies *Q,* i.e. passes through the origin, but is not an odd function, and wrongly attempted to use it to disprove *Q if P*, without considering that it is equivalent to *P implies Q,* which makes his counterexample non-applicable.

As much as the use of counterexamples was prevalent in the PSTs' strategies, most frequently the PSTs simply relied on their perception to make a claim about the equivalence of statements, without providing any justification, as the next excerpt shows:

Excerpt # 4. Rebecca: Alright, next, *to infer Q is sufficient to know P.*

Logan: Logically, I think it is [equivalent].

Dylan: Really? This is definitely not logically equivalent. Knowing the function is odd is sufficient to infer the graph passes through the origin... Maybe it is.

Grace: Wait, I actually think that's equivalent. It's like exactly the same.

Dylan: Yeah, yeah actually it is equivalent. Oh yeah.

It can be argued that such words as "logically, I think" or "I feel like" (see excerpt #5 below) were used merely as a figure of speech. However, in the absence of any other justifications, we tend to interpret them as discursive mechanisms for convincing oneself or others. We also acknowledge that the PSTs' feelings were probably based on their prior knowledge of both the mathematical content, the formal logical notation, and the counterexamples discussed in their groups. All these could be used to create mental representations of statements, which could then be compared to one another to determine equivalence. However, not surprisingly, the "feelings" were not always reliable, and often led to incorrect conclusions.

Strategy 2: Comparing Truth-Values

A second key strategy the PSTs used to decide if the statements are equivalent or not, was to compare their truth-values. In group discussions, the PSTs quickly agreed that equivalent statements must have the same truth-values and that statements that have different truth-values cannot be equivalent. These conclusions were not obvious to everyone, but the PSTs eventually resolved any initial doubts within their groups, without the instructor's intervention.

A more difficult point to agree upon was whether having the same truth-value made statements equivalent. This point required more discussion and negotiation, especially, since all statements in the worksheets which had the same truth-value to the original implication were also equivalent to it. Thus, the PSTs had to come up with their own examples of statements that have the same truth-value but are not equivalent. This was not always easy, as can be seen in Dylan's comment: "I think, we agreed that if it's equivalent, the truth value has to be the same, but you can have a case that the truth value is the same, but it's not equivalent to the statement. So we were saying we found an if and only if case that was true, it's not going to be equivalent to your original statement, but you can have the same truth value."

If the truth-values could not be used to establish equivalence, the PSTs referred back to relying on meaning making and "feelings", as the next excerpt shows:

Excerpt # 5: Nate: I feel like the *only if* would be the same as saying *if Q then P*. So I think, yeah, the *P only if Q* is like saying *if Q then P*. Which is not necessarily equivalent.

Audrey: I feel like that shouldn't be equivalent.

Nate: It just can be true. Cause I feel like, I feel like…

Audrey: That's true. But doesn't mean that it's equivalent.

While attempting to rephrase *P only if Q* in an "if-then" form, Nate mistakenly transforms it into *Q implies P*, but then correctly concludes that the rephrased statement is not equivalent to *P implies Q*. Both Nate and Audrey appeal to their feelings to seal the conclusion.

Strategy 3: Compare to Known Syntactic Forms

Since all PSTs had previously successfully completed proof-oriented courses, they often drew on their familiarity with logical notation, conditional statements, and other relevant concepts. For instance, the PSTs were aware that an implication is equivalent to a contrapositive, and used it in their work, as Dana's comment shows: "I think I came to the decision that *P only if Q* is not-equivalent [to *P implies Q*]. So *P only if Q* is the same as saying *if Q is true, then P is true*. So then the contrapositive of that would be *not P implies not Q*, and that is not equivalent to *P implies Q* in the first place."

Dana's first step is an incorrect interpretation of *P only if Q* as *If Q then P*. But then she correctly states that the contrapositive of *If Q then P* is *not P implies not Q*, and correctly concludes that it cannot be equivalent to *P implies Q*.

Our PSTs also seem to have a good grasp of non-equivalence of an implication to its converse, as illustrated below.

Excerpt # 6: Angela: 'Cause doesn't the converse like by definition is the opposite truth-value of the original. That's what the converse is? Or no?

Sam: No, you can't determine truth-value by the converse. But the converse could be true in some cases. I think, yeah. It's not necessarily true, but it could be true… Technically the converse is a whole different statement in itself.

Bill: 'Cause we're reversing p and q.

Sam: Yeah, like they're never gonna be logically equivalent.

Here Sam correctly explained that although a converse can have the same truth-value as the implication, it cannot be equivalent to it. Bill justified that by saying that the converse "reverses *P* and *Q*". The other members of the group accepted this explanation. Similar conversations occurred in all other groups, and were resolved correctly without the instructor's intervention. The PSTs also recalled that a biconditional entails the truth of both an implication and its converse, and used it to justify non-equivalence of a biconditional and an implication. Note that in both excerpts above, the PSTs operated solely within a syntactic domain, without invoking semantic meaning of the statements and without appealing to examples.

The Missing Strategy: Negation

Visibly absent from PSTs' strategies was the use of negation. In our data from both cohorts, we recorded only one instance of the use of negation to make sense of *P only if Q*. Except for that instance, the PSTs avoided using negation despite having the relevant prior knowledge. The forms for which the use of negation was critical were *P only if Q*, and the *necessary* condition. Unless prompted by the instructor, the PSTs seemed unable or unwilling to introduce negation to interpret "only if" or "necessary" as "otherwise" or "if not".

Discussion

In this paper, we examined data from two cohorts of prospective secondary teachers' interactions with Conditional Statements activities in the context of a capstone course aimed to enhance their content and pedagogical knowledge of proof. The key feature of the activities was the inclusion of both the formal logical notation and mathematical context from the secondary curriculum: number and operation, geometry and functions. Our study focused on understanding how PSTs make sense of various logical forms of conditional statements and establish equivalence between them. We identified three main strategies the PSTs used to establish equivalence, or the lack thereof, between a broad range of logical forms: (1) meaning making, (2) comparing truth-values, and (3) comparing to known syntactic forms.

Semantic strategies, what we term as *meaning making*, were prevalent in the PSTs' approaches, concurring with the literature (e.g., Dubinsky & Yiparaki, 2000). The PSTs rephrased the statements multiple times to make them more comprehensible either by adding or substituting words or by putting the statements into an "if-then' form. The PSTs used counterexamples to make sense of the statements akin to experts' use of counterexamples (cf. Lockwood, Ellis, & Lynch, 2016). Our data show that in many cases these strategies proved to be helpful in determining equivalence of the various logical forms, but not always. At times, the PSTs would fall back on feelings, relying on their perceptions of the content of statements. This phenomenon reflects the nature of our data, which was captured during the natural discourse among the PSTs. We suspect that the PSTs' perceptions were grounded in prior knowledge, and the PSTs would be able to mathematically justify their thinking, if requested.

The two logical forms that were most challenging for the PSTs to interpret were: *P only if Q* and *P is necessary for Q*. Interpreting these forms requires the use of negation, which did not come naturally to our PSTs, as consistent with the literature (Dawkins, 2017). However contrary to prior studies (e.g., Dawkins & Hub, 2017; Durand-Guerrier, 2003) our PSTs seemed knowledgeable about an implication being equivalent to a contrapositive and non-equivalent to a converse. The PSTs often relied on this formal logical knowledge to determine whether certain logical forms are equivalent or not, without assessing the semantic meaning of these statements.

The studies on knowledge retention in the area of formal logic are scarce, thus, our study adds to this literature by demonstrating knowledge retention of logical aspects of proof, beyond the typical introduction to proof course. Specifically, our study identified particular aspects of this knowledge that were retained and flexibly used by PSTs to make sense of a broad range of logical forms of conditional statements, and determine their logical equivalence. Our data show that the PSTs can apply their knowledge of formal logic to the secondary school context, and use it to interpret a wide range of logical forms of conditional statements, which may come up in classroom discourse. Another contribution to the literature is the design of the Conditional Statements activity that uncovered these strategies and elicited a range of rich discussion among PSTs around the various logical forms of conditional statements.

Quantitative and qualitative evaluation of math tutoring centers is a critical step to identify characteristics of effective centers. A group of ten math tutoring centers gathered quantitative and qualitative measures of effectiveness as part of an ongoing project to identify characteristics of effective centers. This report summarizes the data collected. We will use this data in a future paper to generate testable hypotheses about characteristics of effective math tutoring centers.

Keywords: mathematics tutoring centers, evaluation, characteristics of effective centers

College-level math support programs are common throughout the United States and globally (Bressoud, Mesa, & Rasmussen, 2015; Matthews, 2013). While these programs have many forms, peer tutoring is a common one, with 89.5% percent of universities surveyed in the US reporting the use of peer tutoring (Johnson & Hanson, 2015). The math tutoring environment has the potential to engage students in a more active way compared to a typical classroom (i.e., Topping, 1996; Topping & Watson, 1996). Tutoring has been shown to impact student self-efficacy (Maxwell, 1994), confidence (Topping, 1996), and have the most impact on at-risk students (Mac an Bhiard, Morgan, & O'Shea, 2009; Rickard & Mills, 2018; Xu, Hartman, Uribe & Mencke, 2001). We study math tutoring centers that serve all students enrolled in eligible mathematics courses. Our long-term goal is to identify characteristics of successful math tutoring centers because there is no research on the characteristics of such centers that contribute to student success (Byerley et. al, 2019).

Literature Review

Although tutoring centers are common, there is little published statistical evidence of the effectiveness of math tutoring centers. One possible reason is the difficulty in measuring the impact of centers on student success (Matthews, 2013). The number of visits to the center is commonly used as a measure of the center's effectiveness, but this measure does not show that visiting the center is correlated with higher grades. In Berkopes and Abshire's (2016) study, the high number of visits by students, particularly by first-generation college students, was evidence of success. In contrast, Marr (2010) interpreted the high number of repeat tutor appointments as a weakness on the part of the tutor to assist the student effectively in their difficulties.

It is hard to imagine a study that would demonstrate that math tutor center visits cause increases in student grades because of self-selection bias (Byerley, Rickard & Campbell, 2018). Students cannot be randomly assigned to a tutoring center treatment. Large numbers of high-achieving students may not seek out tutoring services or, alternatively, more motivated students might be more likely to earn high grades and also more likely to visit the center. Several studies found positive statistical correlations between student visits to tutoring centers and student success (Cuthbert & MacGillivray, 2007; Dowling & Nolan, 2006; Mac an Bhaird, Morgan & O'Shea, 2009). However, these studies do not mitigate the self-selection bias because they do not include control variables in their linear models. In contrast, Cooper (2010) did not find a correlation between tutor center visits and course grades.

Several studies have employed more advanced regression techniques to help account for the biasing self-selection. For example, Xu and colleagues (2001) performed a regression analysis and found that, at Arizona State, visiting the tutoring center predicted higher final exam scores in College Algebra when controlling for well-known predictive variables (gender, SAT, math placement, and high school GPA). Tutoring also had a larger impact on students in the bottom quartile of SAT scores compared to the students in the top quartile (Xu et al., 2001). Byerley, Rickard, and Campbell (2018) found a statistically significant positive correlation between students' tutor center attendance at Colorado State University and Calculus II course grades when controlling for prior student aptitude, same-semester achievement, and motivation (measured by variables such as high school GPA, early test grades, and lecture attendance). Similarly, Rickard and Mills (2018) used a multiple regression model and found that when controlling from prior aptitude, each visit to the tutoring center at Oklahoma State University corresponded with an increase in students' Calculus I final course grades by 0.33%. They found that students with the lowest high school GPAs had the largest benefit from visiting the center.

These studies offer evidence that math tutor center visits can have positive impact on student success. However, these studies were conducted at single institutions and offer few clues about what characteristics of the tutoring center contributed to the effectiveness. These studies do not show if a center was effective compared to other institutions. The tutor centers themselves are likely not representative of tutor centers at a national scale: for example, Rickard and Mills (2018) report a 61% attendance rate at their tutoring center, while the national average is 40% (Johnson & Hanson, 2015). We are interested in more than whether a tutoring center is effective; we are also interested in the attributes that characterize effective tutoring centers. By comparing qualitative and quantitative data from multiple centers we will be able to generate hypotheses about common features of more effective centers.

A group of math tutor center administrators proposed a set of six dimensions that characterize centers (Byerley et al., 2019): (a) specialist vs. generalist math tutor models, (b) strength of relationship between center and math instructors, (c) type and extent of tutor training, (d) types of tutoring services, (e) physical layout and location, and (f) tutoring capacity. The current study extends this work by offering both statistical analysis of the effectiveness of ten different math tutoring centers with qualitative descriptions of the centers in terms of these previously identified dimensions. Due to space limitation, the dimensions are not redefined in this paper; understanding the tables reported in this study depends on being familiar with the six dimensions defined in previous research (Byerley et al., 2019).

Research Questions

This paper answers the following research questions for the ten mathematics tutoring centers that contributed data.

1. What percent of eligible students use the center and how often do they use it?
2. What are the characteristics of each center on each of the six dimensions proposed by Byerley and colleagues (2019)?

3. What is the correlation between visiting a center and students' grades after controlling for students' high school G.P.A. and standardized test scores?

Theoretical Perspective

This paper privileges the questions of practitioners who lead tutoring centers. We understand typical requirements of that job because we oversee or have overseen tutoring centers. Privileging the needs of center leaders often requires conducting research at odds with research guided by constructivist theoretical perspectives. For example, it is well known that passing calculus does not mean a student has constructed productive meanings for calculus. Despite this, we use students' grades in math courses as a measure of success because grades are important to students' academic progression and those in administration who monitor this. For details on the perspective we adopt, refer to the editorials on bringing research closer to practice and reducing isolation between practitioners (Cai, et. al., 2018a, 2018b).

Methods

Data collected from a convenience sample of ten universities includes characteristics of the tutoring centers as well as student academic and visit data. The data on characteristics of the tutoring centers were based on dimensions identified by Byerley and colleagues (2019). They include: the number of students eligible to use the center by virtue of being enrolled in a course served by the center, the percentage of those students who visited the center, the average number of visits to the center per eligible student, tutor hours per student visit, tutor hours per eligible student per week, and the type of tutors the center employs. Tutor hours is the total sum of all hours worked by all tutors in a given semester. In order to standardize analyses across universities, participating center leaders were surveyed to determine what student data were available to them. Initial factors considered were number of student visits to the tutoring center, duration of student visits to the tutoring center, course letter grade, course percentage grade, math placement score, standardized test scores, standardized test math subscores, high school grade point average, high school math grade point average, ethnicity, first generation status, Pell grant status, and number of math course repetitions. Many factors were excluded as not all contributors were able to obtain access to the data needed. The factors that essentially all contributors were able to procure data for were: (a) student visits to the tutoring center, (b) high school grade point average, (c) standardized test scores, and (d) course letter grade converted to grade points. These factors represent only a small portion of factors that might influence student grades in a course. It was nevertheless decided that, in order to ensure similar analyses for each institution, the research team needed to analyze data that all members could access.

Quantitative data from each institution were collected for the fall semester of 2017 and/or 2018 depending on the year data were available. For many tutoring centers, students from any course are allowed to use the tutoring center, including courses the tutoring center may not have tutors for. It was therefore decided that data would only be analyzed for students enrolled in mathematics courses for which the tutoring center purposefully serves. This includes any mathematics course for which the math center specifically provides tutors. Data for all students in a course served by the tutoring center were collected, including those who did not visit the tutoring center. Students with missing data and students who withdrew from the course were removed from the analyses, but these counts are shared in the data tables that follow. Students enrolled in multiple mathematics courses were treated as separate data points, with the number of visits to the tutoring center split equally between the courses taken.

Multiple regression analyses were conducted on the data from each tutoring center using course grades as the dependent variable and student visits to the tutoring center, high school grade point average, and standardized test scores as the independent variables. Due to many smaller enrollment courses, analyses combined all courses within each university.

In addition to collecting data and conducting statistical analysis on it, each tutor center leader wrote a qualitative description of his or her respective math center using the six dimensions from Byerley and colleagues' (2019) framework. The leaders included both positive and negative information about their centers in their descriptions, submitting information to the lead author who blinded it prior to making it available to the rest of the research team. In the future, our team and other experts will analyze blinded qualitative and quantitative features of centers to hypothesize characteristics of effective centers.

Results

While common aspects, such as hiring tutors from pool of students who made high grades in course are not included in Table 1, it describes other less obvious aspects of each center. Some aspects differ widely among center for reasons that are not evident in the table. For example, Bird U has limited physical center space; so, no professors hold office hours in the center, and students enter the center to ask questions but not stay to study. Gorilla U has a number of computers that all students on campus can use, even if not working on mathematics assignments. Dolphin U has high tutor hours per student visit because they offer appointment-based tutoring. Instructors at Dog U offer students tiny amounts of extra credit to correct their tests at the center.

Table 2 displays the statistical results from each center. The R^2 of the model represents the proportion of course grades that can be accounted for by the predictor variables. For five centers the model suggests that a higher number of center visits is predictive of higher grades. The model for Whale U, for example, predicts that if students visit the tutor center 10 times in a semester, their course grade point would be 0.16 higher. Unsurprisingly, high school GPA and standardized test scores are significant predictors of grades at all universities. Dolphin U's model suggests that a higher number of tutoring visits is predictive of lower grades. The data from Dolphin U is from the first semester the center was open, and it was known as a place for struggling students to get help despite the efforts of the director to welcome all students.

Table 3 provides information about tutor training at each center. In addition to considering the number of hours of formal training we also considered if the center had a *generalist* or *specialist* tutor model (Byerley et. al., 2019). *Specialist tutors* must meet some criteria (e.g. being an LA or grader) or complete some event (e.g., training or exam) successfully before they are allowed to tutor a particular course. For example, learning assistants attend the course they tutor to help instructors with group work. Specialists often tutor one course per semester and the tutoring center groups students by course. Cat U and Dog U use specialist tutors. Fish U, Gorilla U, Hamster U and Horse U use a mix of generalist and specialist tutors. A benefit of specialist tutors is that they know the content, the instructors, and the expectations for the course. *Generalist tutors* are allowed to tutor multiple courses without having to meet specific criteria. Dolphin U, Bird U, and Whale U use generalist tutors. Undergraduates usually tutor classes they did well in; however, in some generalist settings undergraduate tutors tutor for classes they have not taken (e.g., Business Calculus). The generalist model allows quick access to a tutor because students do not have to wait for the tutor assigned to their course to be free. However, generalist tutors face difficulties when they tutor more advanced non-coordinated courses that have different concepts, texts, and expectations.

Table 1. This table provides counts and other basic quantitative information about students and tutors at each center.

School	# of eligible students	% of students who visited	Visits/eligible student	Tutor hours/visit	Tutor hours/eligible student/week	Square footage	Drop in or appointment
Bird	1209	9.30%	1.3	0.66	0.04	450	Drop in
Cat	4304	48.40%	6.1	0.32	0.12	4700	Drop in
Dog	1335	67.80%	5.2	0.19	0.07	1738	Drop in
Dolphin	1158	11.50%	0.5	1.00	0.05	1000	Appointment
Goat	1300	16.10%	0.61	0.84	0.03	470	Drop in
Gorilla	4,217	54.40%	7.3	0.20	0.09	8000	Drop in
Fish	8292	8.61%	0.36	1.36	0.03	1607	Drop in
Hamster	6,576	26.20%	1.2	0.29	0.03	2700	Mostly drop in
Horse	2154	28.60%	1.2	1.2	0.10	960	Mostly drop in
Whale	4543	34.30%	2.1	0.48	0.07	1875	Drop in

Table 2. We used linear regression to predict math course letter grade point with number of visits, high school GPA, and SAT or ACT.

School	# of students	R^2	Increase in grade per 1 visit	Increase in grade point per 1 grade point HS GPA	Increase in grade per 1 std deviation SAT/ACT	# of withdraws incompletes
Bird	1096	0.17	0.003	1.00***	0.26***	40
Cat	3270	0.26	0.019***	1.09***	0.59***	540
Dog	1004	0.25	0.035***	0.77***	0.49***	105
Dolphin	1070	0.15	-0.034**	1.63***	Not available	87
Goat	443	0.19	-0.057***	0.57***	0.36***	18
Gorilla‡	2737	0.19	0.015***	0.67***	0.24***	447
Fish	6609	0.09	0.022***	0.71***	0.13***	639
Hamster	5151	0.17	-0.002	1.08***	0.13***	850
Horse	1971	0.12	-0.006	0.20***	0.38***	69
Whale	3453	0.23	0.016***	0.86***	0.26***	360

*** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$ 1; ‡Gorilla U used HS GPA in mathematics courses rather than overall HS GPA.

Table 3. Type of Tutors and Qualifying Criteria/Events For Tutors to Tutor a Course

Institution's types of tutors*	Qualifying Criteria/Events for Undergraduate and Graduate Tutors				
	Training		Previous/Concurrent Course Experience as…		Course-Specific Tasks
	General Tutoring (first semester)	Course-Specific	Assistant	Instructor	
Bird *UGs*	10 hrs	2-3 hrs/semester	none	none	none
Cat *UGs, GTAs*	5 hrs for GTAs before first semester; weekly meetings for new GTAs in fall	10 hrs per tutoring area if no experience for UGs & GTAs	UGs as LAs or graders, GTAs as recitation leaders	GTAs as course instructors	course-specific training exam
Dog *UGs, GTAs*	9 hours for GTAs. 17 hours for UG	weekly coordination meetings	UG and GTAs as LAs in course tutored	GTAs as course instructors	none
Dolphin *UGs*	3 hrs for UGs	none	none	none	none
Gorilla *UGs*	4 hrs for UGs	integrated in general training	none	none	exams for UGs
Goat UGs, GTAs	12 hrs for all	none	none	none	none
Fish *UGs, GTAs*	6 hrs for UGs plus pedagogy course 15 hrs GTAs	6 hrs UGs	UGs as LAs	none	none
Hamster *GTAs*	brief training on software	available but voluntary	drill section leaders	GTAs as course instructors	none
Horse *UGs, GTAs*	limited and voluntary	limited and voluntary	none	none	exams for UGs
Whale *UGs, GTAs*	5 hrs for GTAs; 4 hrs for UGs	none	none	none	none

*Only GTAs (graduate Teaching Assistants), UGs (undergraduate students), and LAs (undergraduate learning assistants) are included in the table even though many institutions reported faculty holding office hours in their centers.

Table 4. Connections between math centers and math department during data collection period.

	Connections to Department
Bird	• Math center director was also calculus coordinator. • Tutors had access to common homework sets for most classes.
Cat	• Math center director and associate director were renewable term faculty members in the math department; associate director was a course coordinator. • Math center director met monthly with all course coordinators. • 3 of 5 course coordinators voluntarily held office hours in math center. • Course coordinators and math department advisor led the course-specific training.
Dog	• Math center co-directors were both math tenure-track faculty. • All instructors held office hours in center and gave extra credit to attend center.

	• Tutors interacted with faculty often because they were LA's in their classrooms.
Dolphin	• Math center director taught calculus for the math department.
Goat	• Math center director was a tenured associate professor of mathematics • Tutors had access to a blackboard site where resources were posted.
Gorilla	• Math center director was a renewable term math faculty member. • Math center director communicated weekly with all course coordinators. • Course coordinators shared instructional materials with the math center.
Fish	• The center is in the mathematics building. • Math center director was a renewable term math faculty member. • Undergraduate learning assistants tutor in center and help with group work in math courses.
Hamster	• Math center co-directors were both renewable term math faculty members. • Since course instructors held office hours in math center, they shared information regarding the center with their students.
Horse	• Math center director taught calculus for the math department. • Tutors visited all classes served by the math center to advertise at start of term.
Whale	• Math center director was a math faculty member. • Math center organized review sessions prior to course exams.

Table 4 includes a summary of the relationship between the math departments and the ten math centers in the study sample. A variety of features indicate a strong relationship between the tutoring centers and the math departments. One feature is having faculty tutoring at the center because this makes it easier for undergraduate tutors to discuss the course they tutor with faculty.

Conclusions, Limitations and Future Work

One limitation of the data set is the use of letter grades instead of percent grades as the outcome variable in the model. Dog U did have access to course percent grades. Students who earn $\leq 60\%$ get an F; yet, a student with a grade of 59% is typically quite different than a student with a grade of 10%. To determine the effect on the model of categorizing all grades as either 0, 1, 2, 3, or 4 rather than using the percentage earned, we ran separate models for Dog U using standardized grade point and standardized percent. The coefficient for the variable "visits to the tutoring center" was the same in each model to two decimal places. In this model the effect of using grade points instead of grade percent is minimal. Note that Dog U had the strongest relationship between visits and course grade. This relationship can be visualized in Figure 1.

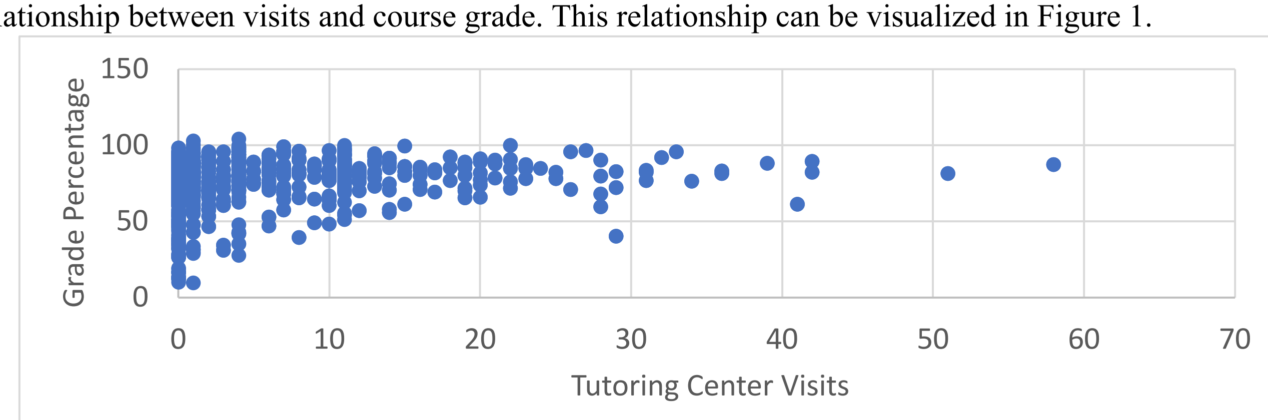

Figure 1. Relationship between grade percentage and tutor center visits at Dog U in Fall 2017.

In the future, our group will use the Delphi method to generate hypotheses about the characteristics of centers that contributed to their effectiveness (Clayton, 1997).

Acknowledgments

We are grateful for the NSF conference grant (DUE: 2645086) for tutoring center leaders. Collaboration at those conferences was the inspiration for this paper. The opinions expressed in this paper do not necessarily reflect the position, policy, or endorsement of the supporting agency.

Exploring the Knowledge Base for College Mathematics Teaching

Douglas Lyman Corey
Brigham Young University

Linlea West
Brigham Young University

Kamalani Kaluhiokalani
Brigham Young University

In this paper we explore a wide sample of currently available instructional materials intended for college mathematics instructors (textbooks, magazines, teacher editions, lesson plans, teaching articles, classroom notes for flipped classrooms, books, etc.) in order to assess how available materials are building a knowledge base for teaching. We modify a framework from Hiebert & Morris (2009) to look for key categories of knowledge that are fundamental for a knowledge base for teaching mathematics. We found that few articles contained meaningful amounts of multiple categories. We use the categories to describe the nature of current available materials and argue that a new genre of instructional material and scholarly work to create the missing knowledge is needed.

Keywords: College Mathematics Instruction, Knowledge Base for Teaching, Instructional Materials, Lesson Plans

College mathematics suffers from the same lament that Dewey (1929) pointed out about K-12 schooling in the US around a century ago, that teachers take their best ideas with them when they retire, and new teachers are forced to start over when they begin their profession. This is not true of other professions (Hiebert, Gallimore, & Stigler, 2002). A knowledge base for practicing medicine, for example, is continually being built so new doctors can build on the collective knowledge of the doctors that have come before them. In K-12 education, the prime example of sharing professional knowledge are teachers in Japan, particularly the teachers in elementary and junior high school (Hiebert et al., 2002). Researchers have called for a system to develop, store, and share a knowledge base for teaching in grades K-12, mainly through high-quality instructional products, either written or in video (Hiebert, Gallimore, & Stigler, 2002).

How is the college mathematics community doing at creating a knowledge base for teaching? There are several outlets for college mathematics instructors to share instructional knowledge with their peers: books, periodicals, lesson plans, teacher edition of textbooks, magazines, class notes or lesson plans on the web, blogs, etc. However, no one has analyzed the nature or quality of this wide breadth of products, products we refer to as *written instructional products* (WIPs). We analyze a broad sample of WIPs to better understand which WIPs might be best able to capture, or are capturing, a knowledge base for teaching college mathematics, or said another way, which WIPs might provide the best opportunity for college mathematics instructors to learn their craft. Because there has been such little work on analyzing college instructional materials, especially peer-to-peer materials, we draw heavily on work done in K-12 mathematics, where instructional materials have been more heavily studied.

Literature Review

Below we briefly highlight ideas and findings in the K-12 literature on developing a knowledge base for teaching.

Researchers have called for a system to address the lack of instructional improvement: a system for generating, storing, and sharing instructional knowledge. Such a system is called a *knowledge base for teaching* (Hiebert, Gallimore, & Stigler, 2002). The prime example of a knowledge base for teaching is junior high and elementary school teachers in Japan (Hiebert, &

Morris, 2012). With their constant learning of instruction and mathematics through lesson study, teacher math circles, and their wide proliferation of detailed lesson plans and teaching books, teachers have extensive resources to draw on as they strive to become master teachers and develop high-quality lessons.

Even though work to develop a knowledge base for teaching mathematics for US teachers began about two decades ago, few efforts have actually worked on developing specific materials for teachers. Two specific examples have emerged in the literature, both in mathematics teacher education. The University of Delaware (Hiebert & Morris, 2009) and The University of Michigan (Ball et al., 2009) each had groups developing instructional materials for mathematics courses for future elementary school teachers that used annotated lesson plans as a vehicle for storing and sharing a local knowledge base for teaching. The lesson plans took on a nonconventional role for lesson plans in the US, one in which information beyond the instructional plan was provided that would help a teacher understand the background, the content, the purpose, the potential pitfalls, etc., of the instructional choices. This information began to capture some of the thinking and reasoning of expert teacher educators and allowed consumers of the lesson plans to build their knowledge of teaching teachers.

Researchers have found evidence of effective instructional materials that might add insight to building a knowledge base for teaching. In a study by Lewis et al. (2011) researchers found that Japanese teacher's manuals have two features that are found less often in their United States counterparts: anticipation of student thinking and explicit rationale for pedagogical decisions. They found in a randomized study that US elementary school teachers who were given materials that had features identified in Japanese lesson plans had instruction that better addressed students' difficulties and had students that performed better on unit tests. In another study researchers found the highest rated lesson plans from Japan and the US were focused on "specific, varied, and detailed" instances of student mathematical thinking (Corey, Williams, Monroe, & Wagner, in submission).

Hiebert and his colleagues pointed out that storing instructional knowledge is not a trivial issue (Hiebert, Gallimore, & Stigler, 2002). They explained that to build a knowledge base for the teaching profession, knowledge must be shared, examined, revised, and grown in the public sphere of the intended audience. Such involvement appears lacking in the US teaching profession in K-12 mathematics as well as college mathematics, although it may exist in some specific local contexts. Unfortunately, the practice of writing lesson plans that share the knowledge-base of teaching is not common to US K-12 mathematics teachers (Corey et al., in submission) and such lesson plans may be difficult to produce, even with ample time, by top teachers (Ninomiya & Corey, 2016).

Hiebert (2013) argues conversations and resources for changing teaching practice all point towards more specificity. For example, He calls for conversations or resources about teaching to be around specific, lesson-level learning goals where teachers can begin to consider specific actions that are best at achieving those goals in a specific context. He explains that only by focusing on specific details can the cause-effect relationship of teaching and learning come to be understood. Hiebert says:

> In addition to unpacking the details of teaching, studying teaching means seeing the cause-effect relationship between teaching and learning that infuse an ordinary lesson. Many teachers do not appreciate that slight changes in lessons – in the ways they interact with students around content – influence directly what students learn. When teachers see the

effects of the changes they make on what and how well students learn, they can begin to appreciate the powerful impact of studying the details of teaching (p. 53).

Research Question

Our primary research question is: What categories of a knowledge base for teaching college mathematics is captured by currently available WIPs?

Theoretical Framework

We modify the framework of Hiebert & Morris (2012) of a knowledge base for teaching. Their framework includes four important categories of instructional knowledge.

1) An understanding of the learning goals of the lesson and of the rationale for using particular instructional activities to help students achieve these goals.
2) Knowledge of students' thinking [which] is often represented as responses students are likely to give to particular questions and tasks, knowledge gathered from past experiences implementing the lesson.
3) Knowledge of the curriculum as a connected set of ideas and materials.
4) Knowledge of strategies and representations for teaching toward particular learning goals. This is the heart of the lesson plans. . . . [A]ctivities are described and suggested questions and teacher responses are provided. (Hiebert & Morris, 2012)

We have adopted this framework for our current study because it should give us a way to characterize the nature of instructional resources from a broad sample. These four categories capture our view of a knowledge base for teaching. Implicit in this view is that a knowledge base for teaching is shared in specifics. For example knowledge of teaching is really knowledge of teaching specific content (specific learning goals, specific student thinking related to those goals, etc) and in specific curricular contexts, and we would extend these to include knowledge grounded in specific administrative and cultural contexts with specific student populations.

Method

Data

We sampled a variety of sources that might have instructional knowledge for college mathematics instructors (books, journals, magazines, project websites, instructional guides, shared instructional materials online, blogs, etc). Our sampling was based on searching and testing. We searched for any possible published that might qualify as a WIP and analyzed samples of the source until we felt confident we understood the nature of the WIP. Our data consists of 32 publications (books, websites, periodicals, etc). For larger publications (such as books or textbooks) samples of chapters or sections were selected, so each chapter or section was considered a WIP. We ended up with a total of 145 WIPs (articles, chapters, lesson plans, etc) from the 32 publications. We randomly selected (via random number generation) three chapters/sections from each book unless we felt like that was too few to capture the variation across chapters, then we sampled more selected purposely to capture the variation within the publication. For magazines and periodicals, we tried to sample at least five articles that were related to teaching (contain the words *students* or *teaching*) and selected the most recent articles that we had access to. We over sampled on three periodicals because they explicitly create space for sharing instructional knowledge: the *Classroom Capsules* section of *The College Mathematics Journal (CMJ),* the *Classroom Note* section of the *International Journal of Mathematical Education in Science and Technology (IJMEST),* and classroom instruction articles from *Problems, Resources, and Issues in Mathematics Undergraduate Studies (PRIMUS)*. For PRIMUS a classroom instruction article was defined as any article 1) focused on sharing instructional knowledge to other college mathematics instructors, and 2) focused on a particular mathematical topic, not an entire course or ideas across courses. We only considered WIPs that pertained to undergraduate mathematics classes, not graduate or mathematics education courses (such as mathematics for elementary school teachers). All sources are listed at the following website: https://tinyurl.com/wipvenues2019.

Coding and Analysis. The unit of analysis was the WIP (article, chapter, section, lesson plan, etc). We began coding each unit to the extent that it contained knowledge in the 4 categories of teaching knowledge explained in the Theoretical Framework section above. We did split the first category into two categories for coding, so there was a code for "understanding the learning goals of the lesson" and another for "the rationale for using particular instructional activities to help students achieve these goals." We added and modified categories during the coding process as elements arose that we thought could add insight to the nature of the WIPs in our sample. One code that we added that we will discuss in the results sections is the extent that the WIP focuses on mathematical content (content-focused). In this short paper, we only share results for the following categories: Content Focused (CF), Knowledge of Strategies and Representations (KSR), Knowledge of Student Thinking (KST), Rationale of Instructional Decisions (RID), and Knowledge of Curriculum (KC).

The extent that a WIP captured knowledge in each category of teaching knowledge was represented on a four-point scale: None, Trace, Minor Focus, and Major Focus. The code "None" represented no knowledge, "Trace" represented one mention (up to one paragraph), "Minor Focus" represented two or three instances (each instance in a separate paragraph), and "Major Focus" represented four or more instances (each instance in a separate paragraph). Only results of Major Focus codes are used to generate results for this paper.

All coding was done by two research assistants, with coding checks done by the head researcher. The research assistants coded the same WIPs until the inter-rater reliability was above 90%, after which only one coder coded each WIP. If a new code was added, the previously coded WIPs units were recoded to include the new code.

After coding was complete, WIPs were analyzed based on the codes. We performed descriptive statistics to look for patterns to understand what categories of a knowledge base for teaching were being emphasized in our sample, and which ones were not.

Results

A strong pattern in our data showed a hierarchy structure to the following codes: CF, KSR, KST, and RID. By hierarchy structure we mean that one code showed up mainly if another code was also present. Few WIPs shared knowledge of strategies and representations (KSR) that were not focused on mathematical content (CF). Few WIPs shared knowledge of student mathematical thinking (KST) that did not include KSR. Similarly with RID and KST codes. The bulk of the WIPs in our sample could be classified, then by how far toward sharing KST and RID they made it. We now share descriptions and examples of the kinds of WIPs in each of these categories: No Content, CF, CF+KSR, CF+KSR+KST, and CF+KSR+KST+RID. The KC (Knowledge of Curriculum) code did not fit well in this same structure and was relatively rare (less than 7% of all WIPs in our sample received a major emphasis on this code).

Categories

No content. There were 10 WIPs that had no mathematical content. Eight of these were from a book on Scholarship of Teaching and Learning (SoTL) for mathematicians (Dewar & Bennett, 2014). This book helps mathematicians understand how to perform SoTL to answer questions that could improve their teaching by performing small educational studies. The book shares many specific SoTL studies by mathematicians, many of which fall into this category. Many of the studies had research questions focused on course structure or administration, or general instructional strategies. An example of the latter is the effectiveness of using a game to review material periodically throughout a course.

Content Focused (CF) only. The majority of the WIPs (116 of 145, or 80%) in our sample had a major emphasis in this code, and about 60% of these did not receive any major emphasis on subsequent categories. Typical to this category were textbooks, some teacher editions of textbooks, some chapters of MAA published books (such as the Notes series), periodical articles (e.g. The Mathematics Magazine, Classroom Capsules from CMJ, some Classroom Notes from IJMEST), and some blogs (e.g. betterexplained.org). Typical examples in this category are periodical articles that show a new proof to an existing theorem that is taught in an undergraduate course, an article explaining an interesting mathematical idea or connecting two seemingly unrelated mathematical ideas, or a chapter in a book or textbook explaining mathematical content that could be taught in a mathematics course.

We tried to sample WIPs that were in some way tied to teaching (in book categories on teaching, mention students or teaching, etc) however, the majority of the WIPs in this category were focused on mathematics and related to teaching in only the slightest sense, if at all. This doesn't mean that these WIPs cannot be brought into the classroom, or are not helpful to teachers. It simply means that explanations of how to teach the content are lacking.

CF+Knowledge of Strategies and Representations (KSR) only. Only about 36% of the WIPS in the previous category (29% of all WIPs) actually provide readers specific tools for teaching the specific mathematical content, not just sharing mathematical content itself. Hiebert & Morris (2012) describe the KSR category as the "heart of the lesson plans" because it provides details for the teacher about what to do during instruction. Typical WIPs in this category were online lesson plans like those from SIMIODE.org (Systemic Initiative for Modeling Investigations and Opportunities with Differential Equations), an online database of modeling activities for differential equation courses. These activities include student handouts to walk them through the modeling activity. However, student responses to the questions on the worksheets were not discussed so they did not get coded as containing knowledge of student thinking. A couple of book chapters of a similar flavor also ended up in this category, explanations of what the teacher should do, but no (or few) supports based on student responses.

CF+KSR+Knowledge of Student Mathematical Thinking (KST) only. Only 13 out of 145 total WIPs were coded a major focus on all three of these codes. These emerged in a variety of sources. Two of them were detailed lesson plans from ProjectMaths.org which include example scripts for teachers (including student responses). Four of them were from periodicals, three were from sections of a Pathways College Algebra (Carlson, 2016) teacher edition, and one was from a section of the MAA Instructional Practices Guide. One example article from IJMEST was about a new technique for helping students evaluate triple integrals without having them sketch potentially complex shapes in order to change the bounds of integration. The article used research that showed how students struggle to sketch the three-dimensional figures required for that technique. The alternative approach uses integration by parts to evaluate the triple integral.

Although we are narrowing in on WIPs matching an increased number of knowledge categories from our framework, most of the WIPs in this category were still not very insightful. The kind of student thinking in many of the 13 WIPs were simply how teachers expected (or perhaps better described as wanted) students to solve a problem or answer a question. There were three that stood out from the others, which we discuss in our next category.

MC+KSR+KST+Rationale of Instructional Decisions (RID). Three WIPs out of the 13 in the previous category also were rated as major on the RID code. More than just adding in explanations about why certain actions were taken, these three WIPs had a different feel to them than the other 10 WIPs. Their explanations and justifications about why certain actions were taken were closely tied to the whole breadth of student mathematical thinking (correct, incorrect, misconceptions, unhelpful, helpful, naïve, advanced, etc.) not just what teachers wanted students to think. These articles tend to report an instructional problem, propose a carefully engineered instructional solution to the instructional problem, provide sufficient background information, describe and draw on student thinking (particularly unhelpful/incorrect student thinking), give specific teacher moves (often justified by how they follow from or impact specific student thinking), and 2 of the 3 give some example teacher-student interactions. We describe one of the three articles to illustrate the nature of these WIPs.

The example we use to illustrate this category is an article published in PRIMUS called *Let's Draw a Picture* (Herrera et al., 2017). In this article the authors help instructors understand how to use number line representations to help students reason about arguments in an analysis class. Herrera, et al. (2017) write that many students believe that pictures or graphs are not helpful for developing a proof because "Many analysis textbooks reinforce [this belief] by refraining from providing or referencing visual representations" (p. 47). One particular difficulty students have when working with a number line is to understand what algebraic expressions might represent (for example (B-A)/2 or (A+B)/2). The authors have specific prompts to help students build these skills. For example, one class activity is to take a number line with two points labeled A and B with A<B, and no other markings on the number line. The teacher then asks students to name a number to the right of B that can be plotted accurately and also to find a number between A and B that can be plotted accurately. The most common initial responses to the first prompt (finding a number to the right of B) are B+A, 2B, and C. Each of these warrants a class discussion about why these numbers might not work or might not be helpful. Students can then return to the problem, thinking more carefully, where some students find that the only distance they can represent is the distance between A and B. Students then work on representing that distance (B-A) and add that distance to B to get a new point on the number line to the right of B. Discussions follow about the ways to represent distances and locations on a number line.

In this short example we have a situation where college mathematics instructors are giving specific instructional moves for them to use in class, with a variety of student responses, so teachers can be prepared beforehand on how to handle the responses and help deepen students understanding and improve their thinking. Moreover, the specific prompts (we have only shared one) are aimed to build an important skill that can be widely used in an analysis class.

Discussion

Our results give a few insights about the nature of current resources for teaching college mathematics. First, although there is a wide variety of resources available the focus of the bulk of the resources is on mathematical content. One way to interpret our findings is that as a community we like to share ideas about *what* to teach, but much less about the nitty-gritty of the actual *practice of teaching* in the way described by Hiebert (2013). Even many of the resources that discuss teaching issues explicitly are focused on general instructional ideas (e.g. MAA Instructional Practices Guide). The combination of specific content with general instructional ideas leaves a lot of work to the instructor. What activities should I do in class? What can I do to make this interesting? To engage students? How will students respond? Where do students struggle with this topic? Why do they struggle? How can my activities help them to change the way they currently think? Etc. Although there will always be some adaptation required by the teacher to meet the needs of his or her individual students and fit his or her context, this situation requires the instructor to do a lot of heavy lifting in creating a high-quality lesson. Furthermore, these materials already seem to assume that instructors know how to do create and/or adapt lessons well, but where are they supposed to learn these skills in the first place?

Second, WIPs focused on teaching specific content often don't take student thinking as important considerations in making instructional considerations. Some materials that did discuss student thinking only used (or assumed) thinking from ideal students – responding as the instructor wanted them to respond, not actually taking on the variety of actual student thinking (correct and incorrect) going on in students heads. Some instructors might not consider actual student thinking as a serious issue, however, we argue that college mathematics instructors' primary medium is student mathematical thinking. The mathematical thinking of students is the raw material instructors work with and shape and refine to create deeper, broader, more robust student thinking as a result of their instructional interactions with students. It seems that WIPs would need to take student mathematical thinking seriously to give instructors powerful tools to use in their teaching. Without a focus on student mathematical thinking, conversations about instructional choices and learning about teaching will not reach the level of "seeing the cause-effect relationship between teaching and learning" explained by Hiebert (2013. p. 53).

We found it difficult to find WIPs that captured many elements of the knowledge base of teaching. Why are they so rare? There might be many reasons. For example, consider who is tasked or incentivized to produce such work. The work to create this knowledge doesn't seem to fall under traditional scholarly activities of any field, and there is no dedicated outlet for it (so no way for such work to count towards tenure and promotion). The work of generating and documenting knowledge as part of the knowledge base for teaching might look a lot more like engineering (or design) than traditional mathematics or mathematics education research. Our top WIPs were carefully engineered solutions to instructional problems, with documented student thinking as a reason for and in response to instructional decisions (activities, questions, explanations, etc). In this respect, they do not fit any genre of current scholarly work. Even in the broad field of the Scholarship of Teaching and Learning (SoTL), such work is rare (Weimer, 2006), although it still seems to us like the best place to couch such scholarly work. Without dedicated venues the college mathematics instructor community, no one would be generating or consuming WIPs that try to capture detailed instructional knowledge.

We know of college mathematics instructors that put effort into building knowledge about college mathematics teaching as a way to improve their own instruction, perhaps through disciplined methods of refining lessons over time, or by trying small experiments in class to overcome instructional problems. However, they don't do it with an eye towards sharing their knowledge so it is not documented, and of course, there is no venue to have it vetted and shared. Furthermore, the knowledge cannot be shared, examined, revised, and grown in the public sphere of the intended audience which is a necessity argued for by Hiebert, Gallimore, & Stigler (2002). So we are still left with Dewey's problem, that knowledge being taken out of the education system when the professor retires and the new professors having to largely start from scratch.

Coordinating Two Meanings of Variables in Proofs that Apply Definitions Repeatedly

Paul Christian Dawkins
Texas State University

Kyeong Hah Roh
Arizona State University

In this paper we use data from a recent teaching experiment to characterize a particular challenge in proof comprehension that arises when a proof uses the same definition multiple times in related ways. This difficulty involves coordinating the role and value of a quantified variable in the definition, a distinction we explicate in the paper. We do so by providing two proofs that exemplify the key difficulty and presenting an episode in which two students who were reading a proof together adopted alternate interpretations of a variable (one as value and the other as role), but were for a time unable to coordinate the two meanings. The primary contribution of the paper is to sensitize the research community to this challenge in a way that will help future research on students' reading of mathematical proof.

Keywords: proof comprehension, quantification, variable, universal generalization

As the body of research on undergraduate student learning of mathematical proof expands, researchers have begun to identify particular proof types and frameworks that pose unique challenges to students who read them. Recognizing these nuanced aspects of particular proofs expand our awareness of the many competencies involved in learning to read and write mathematical proofs. In this paper, we identify a specific challenge in interpretation that can arise when a proof text uses the same definition in multiple, related ways. The particular challenge we wish to highlight, which we shall define more precisely in the next section with multiple example proofs, deals with the use and meaning of variables (quantified in the definitions) in such proofs. We explore this phenomenon as it arose in a recent study of novices reading mathematical proofs, drawing implications both for researchers' awareness of the subtle challenges in reading proofs and of the role of understanding of mathematical concepts in comprehending proofs (e.g., Dawkins & Karunakaran, 2016).

Defining and Exemplifying the Phenomenon with Two Sample Proofs

The particular issue we have observed in multiple mathematical contexts can occur when a definition uses the same definition with respect to multiple, closely-related objects (call them A and B). Specifically, the definition must include some quantified variable such that the definition will require (possibly) different values of this variable for both objects (call them x_A and x_B). At this point it is important to note that the label x_A carries two meanings: the particular *value* of the variable and the *role* that variable plays in the definition. It operatively bridges between the conceptual meaning of the definition and the mechanics for how this definition will be used in proof writing. The challenge we wish to examine arises when the value of the variable for object B appears as a function of the parameter x_A. In this case, this new use of the definition distinguishes the value of the variable and its conceptual role in the definition. The example proof in Figure 1 exemplifies this phenomenon.

The variable ε in the definition plays the *role* of an error bound (Oehrtman, Swinyard, & Martin, 2014) as it does throughout analysis. However, it also is understood to stand for an arbitrary, particular *value* that is fixed throughout the text. The use of ε in the first line unifies these two meanings. The next two lines separate these meanings. When the second and third lines of proof bound the error between the sequence terms and the limits they approximate, the value $\frac{\varepsilon}{2}$ now plays the *role* of error bound while ε refers to the same *value* as in the first line.

Definition: A sequence of real numbers a_n **converges** to $L \in \mathbb{R}$ if $\forall \varepsilon > 0\ \exists N \in \mathbb{N}$ such that $\forall n \geq N$, $|a_n - L| < \varepsilon$. In this case, $\lim a_n = L$.

Theorem: Given any two convergent sequences a_n, b_n such that $\lim a_n = L$ and $\lim b_n = M$, the sequence $a_n + b_n$ converges to $L + M$.

Proof: Let $\varepsilon > 0$.
By definition of convergence, $\exists N_a \in \mathbb{N}$ such that $\forall n \geq N_a$, $|a_n - L| < \frac{\varepsilon}{2}$.
By definition of convergence, $\exists N_b \in \mathbb{N}$ such that $\forall n \geq N_b$, $|b_n - M| < \frac{\varepsilon}{2}$.
Define $N = \max\{N_a, N_b\}$.
Let $n \geq N$.
Then
$$\begin{aligned} |a_n + b_n - (L + M)| &= |a_n - L + b_n - M| \\ &\leq |a_n - L| + |b_n - M| \\ &< \tfrac{\varepsilon}{2} + \tfrac{\varepsilon}{2} = \varepsilon. \end{aligned}$$
Thus, $\lim(a_n + b_n) = L + M$.

Fig 1. Example proof in which the two meanings of ε become distinguished.

Notice that the proof also coordinates the variable N (an index bound) in multiple uses of the definition, but in this case the notation makes this division of meaning explicit. This is because different variable names are given the different index bounds for each sequence. Each value is named N to notate the shared *role*, but the subscripts distinguish the three *values*. Thus, there is not the same separation of *value* and *role* in a single expression as before. The functional dependence among the index bounds is made explicit in the fourth line. Understanding the use of the parameter N in the proof still requires making sense of this *role/value coordination*. We do not assume that being more explicit is better or will necessarily ease comprehension.

The different uses of the definition can also be distinguished in light of the proof mechanics for quantified claims. The law of universal generalization (Copi, 1954) asserts that a universal claim can be justified by proof about an arbitrary particular, as is done in this proof regarding ε. Because the definition is only being verified for the sum sequence, only its error bound need remain arbitrary. Accordingly, the proof is constructed to verify the inequality in the penultimate line with regard to the *value* ε and not a function of ε[1]. Since the definition is assumed true for the two component sequences, the existence of the index bound N may be asserted for any positive error bound, specifically the function of epsilon $\frac{\varepsilon}{2}$. Since the definition's existential claim about N is not verified using universal generalization, its existence can be satisfied using a function of other *values*, as in line 4. N is also a function of ε, but this remains implicit in the chain of quantities introduced in the text.

The second example proof was presented to students in a recent study from which we take the data presented in this report. Figure 2 displays it as it was presented to the students. This proof displays the same pattern with regard to the variable k, which plays the role of quotient in

[1] There is an alternative tradition of writing such proofs that selects an arbitrary epsilon and allows the final inequality to be proven for any constant multiple thereof. This avoids the need to apply other definitions to (non-obvious) functions of ε, but its application of proof by universal generalization is less immediate. The implications of either system for students' learning of such proofs is worth exploring, though we shall not do so here.

the case that n is divisible by d. In the proof, x is assumed to be a multiple of 6, justifying the existence of the integer k. The definition of x being a multiple of 3 is then verified with $k * 2$ playing the *role* of quotient. This fits our described pattern because the use of k in line 2 unifies the quotient *role* and *value* while the use in lines 3 and 4 distinguishes them.

Definition 1: We say the integer n is a **multiple of d** whenever there exists some integer k such that $n = k * d$. This can also be stated as "n is divisible by d" or that "d divides n."
Notice that in the case that n is a multiple of d meaning $\frac{n}{d} = k$, k is called the **quotient** of dividing n by d.

Theorem to be proven 1: For every integer x, if x is a multiple of 6, then x is a multiple of 3.

Proof 1.1: Let x be any integer that is a multiple of 6.
Then by Definition 1, there exists some k such that $x = k * 6$.
Since $6 = 2 * 3$, $x = k * 6 = (k * 2) * 3$.
Since $k * 2$ is also an integer, according to Definition 1 x is a multiple of 3.

Fig 2. Proof applying the definition of multiple twice.

Relevant Literature

As mathematics education researchers continue to explore the complexities, challenges, and opportunities of the teaching and learning of proof, it is natural that we begin to recognize the diversity among mathematical proofs. Many previous studies have explored the cognitive dimensions of familiar proof types such as contradiction (Antonini, 2003; Antonini & Mariotti, 2008), contraposition (Antonini, 2004; Stylianides, Stylianides, & Phillipou, 2004; Yopp, 2017), or induction (Harel & Brown, 2008; Arnold & Norton, 2017). More recent studies have identified more specific and subtle proof structures that students may encounter such as non-constructive existence proofs (Brown, 2017) or conditional implies conditional proof frames (Zandieh, Roh, & Knapp, 2014). While such nuanced proof techniques may appear less frequently in the curriculum than, say, proof by contradiction, they can be of unique interest to proof research. They should be studied in part because they help reveal a diversity of sense-making competencies that students must develop to read and produce proofs. They also are useful in revealing how students construe proofs.

By breaking from more standard proof frameworks, unique proof structures may afford distinct insights into how students interpret the inferential structure of proofs. As Harel and Sowder (1998) famously described, students may imitate aspects of proof writing as a ritual without unpacking their role in justification. We hope that learners of mathematical proof come to think of proofs as arguments that entail logical necessity. We still lack clear ways to operationalize this central notion. In the past, mathematics educators tried to capture this by asking students if they were absolutely convinced of the truth of claims in the presence of a valid proof (i.e. did not desire further empirical verification; Fischbein, 1982). This is not inappropriate, but appears less reliable in light of Weber, Inglis, and Mejia-Ramos' (2014) findings about how mathematicians gain conviction.

An alternative that Brown (2017) exemplifies is to study how students interpret such proof texts to reveal the inferences they perceive to be at play. She has shown how non-constructive existence proofs are fruitful in this regard because of their subtle inference structure. Such proofs serve as productive boundary objects between the community of mathematicians (of which we mathematics educators and instructors serve as representatives) and the community of novice students who are learning fluency within the genre of proof. We claim that the same can be said of proofs in the category we described above because they help reveal how students make sense of proof by universal generalization (Durand-Guerrier, 1996) and various uses of definitions in a proof text. To our knowledge, there is yet little or no research focused on student learning of the mechanics of proving quantified statements as described in the previous section.

Methods

The data we present here appeared early in a teaching experiment (Steffe & Thompson, 2000) on inference in mathematical proof. It is beyond the scope of this report to detail the experiment in full; rather, we intend only to set the stage for the episode we shall analyze. We recruited two Calculus 3 students at a medium-sized research university in the United States. The teaching experiment consisted of six one-hour sessions held outside of class time. The participants were compensated monetarily for their time. All sessions were video recorded and the participants' written notes were maintained.

The focus of the teaching experiment was to help the students learn about the force of proofs by universal generalization. The primary task we repeated throughout the experiment was to provide students with theorems to be proven and multiple proofs of related claims (the proof in Figure 2 is labelled 1.1 since it was followed by other possible proofs of the given claim). Students were tasked with deciding whether each proof justified the given theorem and, if not, to decide what claim it proved. Of those who volunteered for the study, we selected students who displayed cognitive conflict (Roh & Lee, 2018) on a screening survey. This meant that they either affirmed a mathematical claim while also affirming a proof meant to disprove that claim or they denied a mathematical claim while also affirming a proof meant to verify the claim. The task in Figure 2 was the first one presented to J and Z, who were both engineering students at the time of their participation in the study. Neither student had taken any proof-oriented university courses before participating in the study.

Analysis

The first author served as the teacher/researcher (Cobb & Steffe, 1983) and the second author served as the outside observer (Steffe & Thompson, 2000). Both authors wrote extensive field notes after each session, reviewed video, and met between sessions to form hypotheses about student learning and to plan activities and questions for the next session. Our analysis in this report focuses only on this first session with J and Z, specifically on their work to make sense of the use of definition and use of variables in the proof in Figure 2.

Rationale for this investigation

While we recognize that these students were quite novice with regard to mathematical proof, we find their initial reading activity worthy of study because it teaches us about the reading competencies that students may bring to bear when first learning proof. The proof text we provided is brief, draws upon mathematical properties that should be familiar to Calculus 3 students, and employs direct proof methods. As a result, we expect it mirrors many proof texts that students would see in a Transition to Proof course (David & Zazkis, 2019). By understanding the challenges students face in reading such texts, we may learn about the competencies that Transition to Proof instruction needs to help students develop. As of yet, our research community has relatively little research-based insight into the competencies essential to understanding proofs that might serve as learning objectives for Transition to Proof courses (some insights about competencies like reading strategies notwithstanding; e.g., Weber, 2001, 2015). In that vein, our current analysis seeks to explicate the ways of reasoning that students need to bring to bear to make sense of this proof text, as exemplified in J and Z's case. In this way, we note their difficulties in reading not as deficits in their understanding, but rather as goals for their development as novices. We are particularly interested in the role that students' understanding of the relevant mathematical concepts plays in proof understanding (Dawkins & Karunakaran, 2016), contrary to the assumption we anticipate many may hold that undergraduate students should have an adequate grasp of divisibility/multiple relations.

Results

As mentioned above, their stated task was to determine if Proof 1.1 proved Theorem 1 or something else. The interviewer assured them that the proofs were correct, but they may or not prove the given claim. J and Z took about 50 minutes discussing their initial reading of Proof 1.1, which was their first task in the experiment.

Multiples and Divisors

J began the discussion of the reading by asking about the relationship between k and x. In trying to discern this, Z linked line 1 with the statement of the theorem and explained that it proved that if a number was a multiple of 6, then it could also be a multiple of 3. Z thus saw the parallel between the first and last lines of the proof and the theorem statement. She also linked the equation in line 2 with the given definition, which J said was helpful.

Both students then expressed some difficulty understanding what values k took on. Z expressed two different ways of thinking about the multiple/divisor relation. At first, Z viewed k as the outcome of a division operation, as is suggested in the note below the definition. Alternatively, when she thought about multiples, she engaged in skip counting in which case she did not explicitly attend to a meaning for k. When the interviewer invited her to take an example she read provided (20 is a multiple of 5) and connect it to the written definition, she resorted to dividing again to render k a quotient. A consequence of this was that she began substituting values like 2 or 3 for x and dividing by 6. Her thinking about dividing did not impose the constraint that x be a multiple of 6, though they had already noted this restriction in line 1.

The interviewer pointed out that 2 and 3 were not multiples of 6 because the quotients were not integers. At this point, Z then shifted to thinking k must be a multiple of 6. It appeared that she was trying to recognize how the equation $x = k * 6$ represented the multiple of 6 property. She did not think of the composite unit $k * 6$ as the multiple of 6, so she instead wondered if k were a multiple of 6. The interviewer asked her to consider $x = 12$ to help her recognize that k could take on other values.

Even in this early stage of discussion, we note a few trends. First, J and Z worked to connect the variables to *roles* in the multiple/divisor relation. However, shifting between quotative and multiplicative meanings shifted their attention non-trivially. Z's skip-counting way of thinking about multiples did not give a role to the counter k, but her quotative meaning did not help her maintain the stated constraints on x. Furthermore, the pair initially struggled to overlay those meanings with the equations in the proof text, at least in part because they struggled to think of a product as a single unit.

Two Meanings for k Emerge

In the next part of the session, the pair worked to make sense of the third line of the proof. Z noted that "$6 = 2 * 3$" means that 6 is a multiple of 2 and 3. She describes that the proof is splitting 6 in this way. She then claims that 2 and 3 are now values for the k. One possible explanation is that she is trying to make a structural analogy between the two equations in line 3, rather than viewing the first as a (rather obvious) warrant for the second. However, she has some trouble explaining the meaning of "$(k * 2) * 3$" as it related to the definition of multiple.

J was at this point trying to make sense of these equations in the case where $x = 12$. The pair had seen that in this case $k = 2$. J further noted that 12 divided by 3 was 4, but she had trouble interpreting the expression "$(k * 2) * 3$" as expressing this same relation. While the difficulty of rendering $k * 2$ as a single unit may have played a role, we hypothesize that J was also having trouble because k was no longer unified both value and quotient role as it did in the definition and in line 2.

As the interviewer tried to help J connect the number sentence $12/3 = 4$ and the equation $x = (k * 2) * 3$, Z suggested that k is 4. We interpret this as her way of saying that, with regard to the definition of multiple of 3, the quotient was now 4. While this was numerically inaccurate regarding the equations in the proof, it demonstrated Z's recognition that line 3 is applying the definition in a new way. Accordingly, there is a new quotient when dividing by 3.

For the next few minutes as they worked to resolve this tension, J persisted in seeing k as the value of the variable, which remained 2 throughout, while Z treated k as the quotient, which was 4, relative to the property "multiple of 3." Because neither student was able to coordinate the value and role meanings for k, they both had trouble making sense of the expression $(k * 2) * 3$ in a normative manner. J had trouble seeing $k * 2$ as a unit that could fill a role in the definition. Z did not connect the compound unit $k * 2$ to the quotient of dividing by 3 because k filled that role for her.

Z then began listing various multiples of 6 and computing the values for k in line 2 and the values for k in line 3. She noted that all of the latter values were always even. When the interviewer asked her why this was true, she explained that she noticed it from "doing the math." This provides further evidence that she did not see the expression "$(k * 2)$" as equivalent to the quotient when dividing by 3.

Confirming Evidence

At this point, the interviewer had formed hypotheses about how the two students were interpreting k in different ways and having trouble coordinating the two meanings in the expression "$(k * 2)$." To confirm this, he asked them to interpret the proof when $x = -54$. They computed the quotient with 6 to be -9. Z then substituted this into the equation in line 3 of the proof, yielding -18*3. The interviewer asked the pair what the product would equal. Neither anticipated that this product would still be -54, but rather they proposed computing the product with a calculator. Z went on to affirm that the product was -54. He asked for the quotient of -54 divided by 3. Again, neither student anticipated the answer from the given information. This supported the hypothesis that neither student was currently interpreting the equation "$k * 6 = (k * 2) * 3$" as a way to coordinate divisibility by 6 with divisibility by 3.

The interviewer introduced a new approach by inviting J to divide both sides of the equation $x = (k * 2) * 3$ by 3. J accordingly wrote down the new equation "$\frac{x}{3} = k * 2$." J found this new representation very appealing. Toward the end of the interview, the group read the second theorem to be proven and Proof 2.2 as displayed in Figure 3. Consistent with their stated preference for writing the equations quotatively, the interviewer rewrote the equations in the forms: $\frac{x}{14} = k$, $\frac{x}{7} = k * 2$, and $\frac{x}{2} = k * 7$. He used these equations to further explore how J and Z were coordinating the two meanings of the variable k. He proposed an example in which x was made up of 250 groups of 14, so $x = 250 * 14$. He accompanied his explanation with gestures to represent the groups of 14 lined up next to one another. He then asked how many groups of 7 would be in x. J and Z asked him to restate and clarify the question a few times before J suggested that x would contain twice as many 7s as it does 14s. When asked how many groups of 2 were in x, J said it would be 7 times the number of 14s. While the students were able to apprehend this relationship with guidance, this interchange served to confirm that the students had not previously recognized the equations in Proof 2.2 as stating a multiplicative relationship between the various quotients.

Theorem to be proven 2: For any integer x, if x is a multiple of 2 and a multiple of 7, then x is a multiple of 14.

Proof 2.2: Let x be an integer that is a multiple of 14.
Then by definition there is some integer k such that $x = k * 14$.
This means $x = (k * 7) * 2$, so x is a multiple of 2.
This also means $x = (k * 2) * 7$, so x is a multiple of 7.
Thus, x is a multiple of 7 and a multiple of 2.

Fig 3. The final proof discussed in the first session with J and Z.

Discussion

Consistent with our stated goal to identify the particular challenges posed with the proof mechanics that arise when a proof uses a definition repeatedly, we share this episode to demonstrate the significant difficulty it poses to novice students. It was somewhat fortuitous for us in our efforts to model J and Z's reasoning that they adopted distinct meanings for k and maintained them such that we could compare their construal of the text. We had noted a similar issue in previous studies when a real analysis student said of a proof like that in Figure 1, "$\frac{\varepsilon}{2}$ is just another ε." We recognized that this student's first use of the variable referred to the value while the second referred to the role as an error bound. This epiphany that the student was explaining so succinctly demonstrated how he was coordinating the role and value to make sense of the proof technique.

J and Z learned to coordinate the two uses of k in the proof presented in Figures 2, but this seemed to involve constructing both values of k independently (for multiple of 6 and multiple of 3) before relating them multiplicatively. J and Z's pathway to coordination was not through the symbolic expression $(k * 2) * 3$ because they experienced great difficulty assigning the components of the equation to roles in the two definitions. We hypothesize that this relates closely to their meanings for multiple that seemed to exhibit different qualities when they shifted between skip counting strategies and division operations. Because they preferred thinking quotatively, we found that rewriting the equations in terms of division was productive for this pair of students, though it later become unnecessary.

This study contributes to the literature first by sensitizing researchers to the role/value duality among variables in definitions that becomes quite important in proof mechanics. In addition, our analysis should contribute to our shared appreciation of how students' meaning for mathematical concepts play in their interpretation of proof texts. We expect that the literature will benefit from more thorough investigations of how students make sense of the proof mechanics relating to quantified variables in definitions, specifically issues of arbitrariness and independence (Roh & Lee, 2011). It is to these future studies in particular that we hope our characterization of role/value coordination will contribute.

Student Verification Practices for Combinatorics Problems in a Computational Environment

Adaline De Chenne
Oregon State University

Elise Lockwood
Oregon State University

Counting problems have been shown to be challenging for students to solve correctly, and one reason is that they can be difficult to verify (e.g., Eizenberg & Zaslavsky, 2004). The field would benefit from further investigations into the nature of students' verification of counting problems. One possible avenue for verification is to have students engage with computational tools and environments. In this paper, we investigate how students verify solutions to combinatorial problems in the context of using Python computer programming. We show that students do not simply use a computed numerical answer when verifying, but they demonstrate a rich understanding between a computer program and a counting process. Further, we exhibit some affordances that using Python to verify solutions provides to the students.

Keywords: Combinatorics, Verification, Computation

Combinatorics is a field of mathematics whose use is becoming more prominent due to its applications in areas such as computer science, statistics, and communications. Despite its growing relevance, students at all ages demonstrate low success rates when solving combinatorics problems (e.g., Batanero et al., 1997; Lockwood & Gibson, 2016). Further, researchers have shown that verification of solutions is particularly difficult in counting (Eizenberg & Zaslavsky, 2004), and many students fail to detect subtle errors in problem solutions. There has been recent activity showing that computational environments can be leveraged to benefit student learning (e.g., Lockwood & De Chenne, in press), and we see an opportunity to investigate how such environments can be used to verify solutions to counting problems. In this paper, we report on a study in which undergraduate computer science students worked within a computational environment as a way to verify solutions to counting problems. We elaborate on ways in which students use relationships between counting processes and computer code to verify solutions, and we discuss affordances of the computational environment.

We seek to accomplish two goals. First, we want to provide an existence proof that students can engage in computational activity in order to verify solutions to combinatorial problems. That is, we hope to provide evidence that students are able to use a computational environment as a method of verification. Second, we seek to illustrate ways in which students leveraged the computational environment as a verification tool. Specifically, we hope to illustrate ways students use a computer program as a tool for verification that are impossible or impractical without a computer. As such, our results focus on examples of verification that were performed with a computer. We seek to answer the following research questions: *Do students engage in computational environments to verify solutions to counting problems? If so, in what ways do the students engage with a computational environment to verify solutions to a counting problem?*

Literature Review and Theoretical Perspectives

Combinatorial and Computational Activity

There has been reported evidence that one way to improve student success in combinatorics is to draw more attention to the relationships between the objects being counted and the way they are counted (Lockwood, 2014). When considering students' combinatorial thinking, we use Lockwood's (2013) model, which frames student's combinatorial thinking into three components: *Formulas/Expressions, Counting Processes,* and *Sets of Outcomes*. *Formulas/Expressions* are the mathematical expressions that yield a numerical value, such as 8*7*6. *Counting Processes* are the imagined or actual enumeration processes in which students engage, such as breaking problems into steps or cases. *Sets of Outcomes* are the elements that are being counted. Often, the cardinality of the set of outcomes determines the answer to the problem. With this framing, we wish to focus student attention to the relationship between sets of outcomes and counting processes. One way to strengthen this relationship is through the systematic listing of outcomes. While systematic listing of outcomes has been shown to be positively correlated with correctly answering combinatorics problems (Lockwood and Gibson, 2016), the sizes of many sets of outcomes can be large enough to deter listing by hand. For example, there are 10,000 possible 4-digit PINs. Partial listing also has drawbacks, as patterns may not extend to all cases and students may fail to detect subtle errors. However, by leveraging the computational speed of a computer, students can reap similar benefits of listing by hand by designing programs and algorithms to enumerate lists.

For our purposes, we define a computational environment as a computer interface capable of receiving and carrying out standard programming instructions, such as for loops, if statements, string concatenation, and integer arithmetic. For example, a Python coding interface such as CoCalc is a computational environment, whereas a four-function calculator is not. When using a computational environment to enumerate sets of outcomes via a listing process, students need to verify that the enumerated list is the desired set of outcomes. Combinatorics is notably difficult to teach and learn in part to there being few readily available solution methods, uncertainty in which methods to employ, and that two equally convincing solutions may yield different numerical values (Eizenberg and Zaslavsky, 2004). These issues persist whether or not a student uses a computational environment, making verification difficult but important.

Verification

We draw on Eizenberg and Zaslavsky (2004) to characterize verification in this study. Eizenberg and Zaslavsky (2004) detail five categories of verification schemes students employ when solving combinatorics problems: *(1) Reworking the solution* (this entails going over and checking all or parts of the solution, but without adding substantial justification)*, (2) Adding justifications to the solution* (this entails justifying components of the solution, or the solution process in a global way)*, (3) Evaluating the reasonability of the answer* (this consists of comparing the computed value to an estimated value, or comparing the computed value to the size of a more global set of outcomes)*, (4) Modifying some components of the solution* (entails either changing the representation of the solution, or using the solution method on a smaller set of outcomes)*,* and *(5) Using a different solution method and comparing answers* (this consists of calculating the answer using an alternative solution method).

In this paper, we take any instance of the above methods as evidence of verification. In particular, we take writing a computer program that lists and calculates the cardinality of a set of outcomes as a different solution method than calculating the cardinality by hand. For example, if a student calculated an answer by hand and also wrote a computer code to determine the answer, we consider this an instance of using a different solution method and comparing answers. As such, we are examining more than just ways in which students verify that a computer program correctly solves a problem; in fact, we will show that students develop rich relationships between writing code to solve a problem and solving it by hand.

Methods

Participants and Data Collection

The data presented here are from a teaching experiment (TE) (Steffe & Thompson, 2000) that consisted of 3-4 hours of contact time with each of four students in 60-90 minute individual interview sessions. In this paper, we focus on two students, Jamie and Allen (pseudonyms), during each of their final hour-long sessions. Both students were Electrical and Computer Engineering majors that were recruited from an introductory computer science course at a large university in the western United States. Both Jamie and Allan were chosen based on their responses to a recruitment questionnaire. The questionnaire indicated that neither student had taken a discrete mathematics class; Jamie had no exposure to computer programming prior to the course from which he was recruited; and Allan had moderate exposure to computer programming prior to the course from which he was recruited (he was self-taught with BASIC, Python, and C languages).

During the TEs, the students sat and worked individually at a desktop computer in the programming environment CoCalc. We gave them paper handouts of the problem statements and provided a brief introductory guide to Python syntax, and the students used CoCalc to write and run Python code. To capture the interviews, we videotaped and audiotaped the interviews, took screen recordings of the desktop computer, and scanned the students' hand-written work.

Tasks

Over the course of the TEs, we gave the students a variety of tasks in enumerative combinatorics. For each student, in the first two sessions we asked them to use a computer to list the set of outcomes of a problem. After completing these tasks, we asked them to find the number of outcomes. In the final sessions, we asked the students only to find the number of outcomes (not explicitly to list outcomes). We told the students that they were welcome to use the computer, although they could choose how to approach the problem. In the final session, after the students appeared to be satisfied with their answers, we asked them how they would verify their solution. In some instances, we asked the students to follow through with their verification scheme. We report on two tasks, the License Plate problem and the Books problem, whose statements are presented in the results section.

Data Analysis

For the results shared in this paper, the first author reviewed videotapes and transcripts of the final interview sessions. In particular, she flagged episodes in which students engaged in verification, creating a document which characterized each episode according to Eizenberg and Zaslavsky's framework. This allowed her to analyze the students' verification practices and create a narrative (Auerbach & Silverstein, 2003) about their reasoning behind their practices. We selected episodes for this report that illustrated trends seen across all of the other students, and they represent particularly insightful episodes that address the research questions.

Results

Due to space, we offer just two instances of students' verification of counting problems within a computational environment. In this section, we report on Jamie's verification techniques on the License Plate problem and Allan's verification techniques on the Books problem. We will see both students use the computational environment to engage in strategies outlined by Eizenberg & Zaslavsky (2004), and we emphasize ways in which the students verified their mathematical solutions by using a relationship between their solution and their code.

Jamie's Work on the License Plate Problem

The License Plate problem states, "A license plate consists of six characters. How many license plates consist of three numbers (from the digits 0 through 9), followed by 3 lowercase letters (from the first 5 letters in the alphabet), where repetition of characters is allowed?" This problem can be solved by reasoning about positions, where an outcome is represented by filling six positions with appropriate characters. Each of the first three positions can be filled with one of ten characters, so there are 10^3 ways to fill the first three positions. Similarly, there are 5^3 ways to fill the last three positions. As each choice of the first three positions can be followed by a choice of the last three positions, there are 10^3*5^3 possible license plates.

Jamie began the license plate problem by splitting it into two parts, first finding the number of arrangements of 0 through 9, and second finding the number of arrangements of ‘a’ through ‘e’. He reasoned that there were 10^3 ways to arrange the digits, and he described starting with 000 and incrementing to 001 and 002 until reaching 999. This logic depicts the process used in three nested for loops, each of which cycle through the digits 0 through 9. Jamie had used similar code in previous interviews. This thought process is also evidenced by the pseudocode in the upper-right corner of Figure 1. Similarly, Jamie reasoned that there were 5^3 ways to arrange the letters, and he describes a similar process of cycling through the letters. After correctly writing the number of arrangements of each part, Jamie wrote his final answer as $10^3 + 5^3$. When the interviewer asked why the operation might be addition, Jamie responded as follows:

> Yeah, I’m not quite sure why it might be plus, because I was thinking about them separately before, and I know like, if I were printing these results out I could concatenate them together and that could give me like an end result. Yeah, but as far as representing them mathematically I’m not sure why it would be plus. I don’t have a good guess for that.

We interpret that Jamie was viewing an outcome of this problem as a concatenation of two separate parts. However, despite being able to correctly count the number of arrangements of each part, he was to unable to justify that addition was the appropriate operation. We note that this issue of not being sure whether multiplication or addition is the correct operation is a perennial one in combinatorics (e.g., Kavousian, 2008; Lockwood & Purdy, 2019). Here, though, we gain insight into how the computational environment gave Jamie an opportunity to verify that his solution (and specifically the operation of addition) was incorrect.

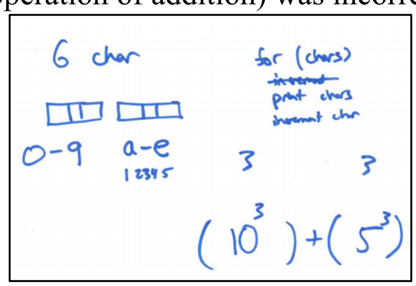

Figure 1: Jamie's initial solution to the License Plate problem.

When asked to verify his solution, Jamie chose to use the computer to implement a program that would list the set of outcomes and give the cardinality of the set. We take this as a method of verification, as it is an instance of Eizenberg and Zaslavsky’s (2004) fifth verification strategy of using a different solution method and comparing answers. After discussing pseudocode that would produce the arrangements of three numbers and pseudocode that would produce the arrangements of three letters, Jamie said the following.

> So I guess I was just kind of like trying to verify like in my head, like how do I wanna combine these together. Because if it was like two nested loops, then I would be, like, multiplying the results together, but if they were not nested it would be like adding them together.

In this quote, we take the “two nested loops” as describing the two pieces of code that would produce the arrangements of three numbers and three letters, respectively. Hence, we infer that Jamie was using the structure of his code—specifically, whether or not one process is nested within the other—to inform himself if the appropriate operation in his mathematical expression should be addition or multiplication. We suggest that this fits within yet another category of verification (such as *Adding justifications to the solution,* Eizenberg & Zaslavsky, 2004), as Jamie was leveraging the structure of the code to add justifications to the mathematical solution. After deciding that the process to generate the letters needs to be nested within the process to generate the digits, Jamie offered the following reflection.

> So maybe, I guess my thought process behind this was like, <u>add the results separately and that's going to like concatenate them together</u>, but like mathematically that wouldn't really make sense because I'm looking for combinations of like one thing on a license plate. So it's not like two separate things, like the first three plus the second three, it's all one.

This quote demonstrates Jamie's understanding of the relationship between his mathematical expression and the code he wrote to verify his solution. The underlined portion highlights how he relates the mathematical operation of addition to the computational operation of concatenation, and thus how his code corresponds to his mathematical expression.

In sum, Jamie used a computational environment to verify his solution by writing a program to print the set of outcomes of the problem. By doing so, he used a different solution method that not only allowed him to compare answers, but also to add justifications to his original solution. In particular, it allowed him to justify that his original solution was incorrect but could be corrected by replacing the operation of addition with multiplication. This is a noted difficulty in Eizenberg and Zaslavsky (2004), who stated that many students who found (or were told) that their solution was incorrect during a stage of verification were unable to correct their error.

Allen's Work on the Books Problem

The Books problem states, "Suppose you have eight books and you want to take three of them with you on vacation. How many ways are there to do this?" Although not explicitly stated in the problem, the order in which the books are chosen does not matter. This problem can be solved by counting the number of ways to arrange three of the eight books, and then dividing by the number of ways to arrange three books. To count the number of ways to arrange three of the eight books, we can reason about positions to find that there are eight ways to select the first book, and the number of ways to pick a book in each subsequent position decreases by 1. Thus, there are 8*7*6 ways to arrange three of the eight books. Here, notice that the 8*7*6 implicitly places an ordering on the three books. For any choice of three books, we can use a similar argument to show there are 3*2*1 ways to arrange them. Therefore, there are (8*7*6)/(3*2*1) ways to take three of the eight books on vacation.

Throughout the previous interviews, Allan had not encountered a problem where order does not matter. His original solution was 8*7*6, which he justified by selecting a first book in 8 ways, a second book in 7 ways, and a third book in 6 ways. While explaining his work, Allan did not address the issue of order; however, later discussion in the interview indicated that he understood the problem statement as meaning unordered selections of books.

When asked how he would verify his solution, he stated that he would use the computer to write a program to count the desired outcomes. We consider this to be verification, as it uses Eizenberg and Zaslavsky's (2004) fifth category of verification. He described the program as three nested loops, each of which cycle through the numbers 1 through 8, where an outcome was printed only if the numbers from each loops were distinct. While the code Allan described overcounts the outcomes of the given problem, it is noteworthy that it would list a set of outcomes with cardinality 8*7*6. That is, Allan correctly described code that would represent his incorrect mathematical expression. However, the following excerpt demonstrates that by writing the code, Allan became aware of the mistake in his solution. During this excerpt, Allen had written pseudocode on paper and, in response to the interviewer's question, was talking through the code and predicting what the first several outcomes of the code would be.

Interviewer: So, when you're listing those, what are, say, the first ten books that you would expect to see in your list?

Allen: The first set would be books 1,2,3, and then assuming this is the last for loop right here [underlines the 3 in 123], we should see 1,2,4 and then 1,2,5, etc., and this would go up to 8. So we'd see, eventually we'd see 1,2,8, and then that would go up to 1,3—and then, oh, I would also have to check for—different—because 1,3,2, that would not be a good combo because it already appeared up here, it's just in a different order.

We take this to be an instance of using a computational environment because Allan was describing the process his code would use, even if he had not yet implemented it. We suggest that in this case, the act of verification by using a computer program informed Allen that his initial solution was incorrect, and, more specifically, that it is incorrect due to overcounting of solutions (such as counting both 1,2,3 and 1,3,2 as distinct solutions, when they should not be).

Allen continued to explore the problem. While Allen was unable to find a mathematical expression that corrected the error in his solution, he was able to adjust his code so that solutions were no longer overcounted. Rather than checking that each character was distinct, Allen's code ensures that each character was in ascending order, as shown in Figure 2. Allen's code in Figure 2 retained the three nested loops structure that is in the previous code; however, each variable cycles through only those numbers that are greater than the preceding variable, ensuring that the printed outcome would be in ascending order. The code produces 56 outcomes, which is the correct answer to the Books problem.

```
In [7]: count = 0

        for i in range(1,9):
            for j in range(i+1,9):
                for k in range(j+1,9):
                    count = count + 1
                    print(str(i)+" "+str(j)+" "+str(k))
        print count
```

Figure 2: Allen's code to solve the Book problem.

After writing the code, Allen verified that it correctly solved the problem by evaluating the reasonability of the answer (the third category of Eizenberg and Zaslavsky, 2004), saying, "I guess it does make sense, because as we go on with each book, the number of possible combinations shrinks, like, rapidly." By this, we interpret that Allen understood that the number of outcomes that start with any digit decreases as the digit increases. This accurately reflects the code, as there are 21 outcomes starting with 1, 15 outcomes starting with 2, 10 outcomes starting with 3, 6 outcomes starting with 4, 3 outcomes starting with 5, and 1 outcome starting with 6. Allan then used the computer to conjecture, find, and verify (empirically through a number of cases) an exact formula for combinations, but those details are outside the scope of this paper.

In sum, Allan used a computational environment to verify that his original mathematical solution was incorrect by showing that the set of outcomes of the corresponding code overcounted the outcomes of the given problem. It is noteworthy that Allan did not attend to the error prior to listing the outcomes of the corresponding code. After verifying that his mathematical solution was incorrect, he was unable to find a mathematical expression to correctly solve the problem. However, Allan then used the computational environment to write code that correctly solved the problem and verified that his code was correct by evaluating the reasonability of the answer. We posit that the computational environment aided Allan in the ability to verify that his solution was incorrect, and that he would not have verified by hand, demonstrating the value of the computational environment in this example. Further, this provides another example of the computational environment being used to find and correct errors during verification, which is a noted difficulty in Eizenberg and Zaslavsky (2004).

Discussion and Conclusion

This paper demonstrates ways in which undergraduate computer science students used a computational environment to verify solutions to combinatorial problems. In particular, the computational environment was used to produce a different solution method that can be compared to a mathematical solution, to add justifications to a mathematical solution, and to show that a mathematical solution was incorrect. Importantly, the students' use of the computational environment during verification changed an incorrect answer to a correct answer in both cases. This addresses a difficulty noted by Eizenberg and Zaslavsky (2004), who indicated that many students who made attempts to verify incorrect answers were unable to detect an error or correct their solution (p. 32), even when the student was aware that the solution was incorrect. While we cannot make claims on the efficiency of using a computational environment when verifying, it does appear to provide students with additional tools that are impractical to use by hand. One such tool is that operations, such as addition and multiplication, relate to how the code is structured, such as when Jamie justified the use of multiplication because loops were nested rather than independent. Another tool is that students can demonstrate that a solution is incorrect by showing that a corresponding code outputs an incorrect set of outcomes, such as Allen did when he verified that his code overcounted outcomes. In sum, the computational environment affords students the opportunity to verify solutions by allowing them to verify more than an imagined counting process.

One limitation of our study is that the students in the TEs were Electrical and Computer Engineering majors who were recruited from a computer programming course. We can make no claim that students with less computer science experience would be comfortable engaging with programming to verify solutions. Further, the students in these TEs appeared to trust their computed solutions more than their by-hand solutions; that is, they used their computed solutions to verify their by-hand solutions. Other students, especially those with little computer science background, may be more comfortable using by-hand solutions to verify computed solutions.

These findings provide evidence of students using a computational environment to verify combinatorial problems, and they offer some methods which the students employed. In future research, it may be useful to evaluate systematically the effectiveness of verification within computational settings, perhaps comparing such activity with traditional methods of verification.

Teaching Statistics with a Critical Pedagogy

Toni DiMella
Mitchell Community College

After the country's focus shifted from K-12 towards higher education, postsecondary schools found themselves under significant public, financial, and political pressure. To close the achievement gap and meet new standards of accountability, higher education institutions began looking for methods to increase student access and success. This quantitative study measured the effectiveness of implementing a critical statistics pedagogy in an undergraduate introductory statistics classroom and its impact on course success, persistence, and mathematical empowerment. Data collected from four classes at a community college found the use of a critical pedagogy had a positive impact on students' overall achievement, increased their awareness of social justice issues, and aided in the development of their critical voice.

Keywords: critical pedagogy, social justice, math empowerment, engagement, agency.

Introduction

Mathematics can act as the gatekeeper from or the gateway to future success, both academically and personally (Lesser & Blake, 2007). In February 2009, eight years after the No Child Left Behind (NCLB) act was signed into law requiring K-12 schools to track the progress and growth of four specific subgroups, the country shifted its focus on education towards higher education, challenging the nation to have the highest proportion of college graduates in the world by 2020. As a result, higher education institutions found themselves under significant political and financial pressure. In North Carolina, General Statute 115D-31.3, which establishes performance funding for community colleges, was updated and reenacted in both 2012 and 2016. The renewed emphasis on persistence and completion, and ties to funding models, enhanced the importance of ensuring student success in mathematics courses, forcing institutions to reevaluate their mathematics curriculums. To better meet the needs of a diverse student body, close the achievement gap, and meet new standards of accountability, some researchers began to explore the use of critical pedagogies (Ukpokodu, 2011).

As community colleges have seen the number of students enrolled in statistics courses triple since 1995, implementing a critical pedagogy in a community college statistics classroom may offer a multi-tiered approach to improving student success and completion (Blair, Kirkman, & Maxwell, 2015). First, numerous studies have shown the use of a critical pedagogy to be an effective way to raise student engagement (Gutstein, 2006; Lesser, 2007). Found to be a predictor of persistence, and completion, student engagement is regarded as an important factor in determining academic success, with students with higher levels of engagement experience greater success (Alvarez-Bell, Wirtz, & Bian, 2017). Second, this approach helps to raise awareness of social justice issues and may expose biases and assumptions, empowering students to create change. Use of a critical pedagogy specifically aims to help students understand how mathematics permeates everyday life and that learning mathematics cannot be removed from understanding and the ability to influence outcomes in the real world (Ernest, 2002; Lesser & Blake, 2007). Lastly, mathematical competency acts as a 'critical filter' in higher education (Ernest, 2002). The math barrier allows mathematics courses to exist as gatekeepers to degree completion and future career opportunities. As mathematics qualifications are often an "admission ticket" to high-paying jobs, a critical pedagogy may become the gateway in moving towards a more balanced economic and social structure (Lesser & Blake, 2007).

Literature Review

Critical pedagogies engage students as critical thinkers, active learners, and challenges them to envision alternative possibilities (Nagada, Gurin, & Lopez, 2003). It achieves its goals through carefully constructed learning experiences that allow students to examine, apply, and reflect upon the content. The term critical pedagogy (CP) was first coined by Giroux (1983), but it was largely founded upon the work of Paulo Freire (Tutak, Bondy, & Adams, 2011). Freire (1970/2005) asserted that learning required the learner to be active and that knowledge is created from a shared process of inquiry, interpretation, and creation. CPs call upon students to develop a sense of agency and begin to speak with their own voices (Giroux, 1983). Freire referred to students learning to understand their lives in new ways and see themselves as transformers of those lives as developing a 'critical consciousness' (Freire, 1970/2005; Tutak et al., 2011). As students discover the source of their beliefs and what structural and ideological factors influence them, they can begin challenge the taken-for-granted ways of their world and create their own history. Freire couples these ideas into praxis which he asserted was "the action and reflection of men and women upon their world in order to transform it" (Freire, 1970/2005, p. 79).

Use of a CP with an emphasis on social justice issues has shown to raise student engagement in mathematics courses through reflective inquiry (Lesser, 2007; Voss & Rickards, 2016; Wright, 2016). Skovsmose and Gutstein are the two well-known scholars of critical mathematics pedagogy. While each offers their own unique perspective, they share a common theme of literacy. As Freire claimed that literacy is more than the ability to read and write, Skovsmose believed that mathematics encompassed much more than the ability to calculate. It is from this notion he developed his idea of *mathemacy* (Skovsmose, 1994). Skovsmose (1994) identifies the three types of knowing on which mathemacy is created from: mathematical knowing, technological knowing, and reflective knowing. One with a well-developed mathemacy has the means to evaluate, or re-evaluate, interpretations of social institutions, traditions, and proposals for political reforms (Skovsmose, 1994). Gutstein's (2006) Teaching Mathematics for Social Justice (TMfSJ) builds upon Freire's definitions of praxis by focusing on helping students to learn to 'read and write the world' with mathematics. 'Writing the world' speaks to the action piece of praxis. It is the writing, or rewriting, of what students read in the world due to a developed sense of agency and seeing oneself as being able to make change. 'Reading the world' is understanding the sociopolitical, cultural-historical conditions of one's life, community, society, and world (Freire, 1970/2005; Gutstein, 2006). To read the world with mathematics means using mathematics to understand relations of power, inequities, and disparate opportunities between different social groups, to understand explicit discrimination, and to evaluate forms of representation of mathematical data and information (Gutstein, 2003).

When students learn to "read the world" they change their orientation with mathematics from being a set of disconnected rules to a powerful tool, causing the belief that mathematics is value-free or neutral to fade (Gutstein, 2006). The non-neutrality of mathematics can easily be seen in the field of statistics. Statistical measurements reflect choices and are not neutral, value-free records of the world; data cannot exist independent from how and why it is used (Weiland, 2017). What is valuable to one group may not be to another, impacting what does and does not get counted. By analyzing data that impacts a student's personal life and community, students become aware that statistics is a powerful tool, analytically and politically.

With a focus on the ability to evaluate and synthesize numerical information, statistics classes continue to gain more students each year (Blair et al., 2015). In the *Guidelines for Assessment and Instruction in Statistics Education College Report* (GAISE), the American Statistical Association (ASA) offer six recommendations and nine learning goals for creating statistically literate students (Carver et al., 2016). Like Skovsmose's mathemacy, ASA's recommendations and learning goals call for statistical, technological, and reflective learning. Five of the goals specifically focus on reflective knowing by requiring students to be critical consumers of statistically based reported results, question the usefulness of investigative processes in statistics, produce and interpret graphical displays and numerical summaries, understand and apply statistical inference, and demonstrate an awareness of ethical issues associated with sound statistical practice (Carver et al., 2016). To achieve this level of statistical literacy, students will need to become 'statistical citizens' and develop a critical understanding of the data in order to act from a more informed position when analyzing ethical issues (Lesser & Blake, 2007).

Largely founded on Gutstein's (2006) TMfSJ and the GAISE recommendations and learning goals, Lesser's (2007) *Teaching Statistics using Social Justice* (TSSJ) is a critical statistical pedagogy that is defined as the teaching of statistics using real world examples related to social justice to enable and empower students to use statistics to 'talk back' to the world. TSSJ "incorporates and facilitates awareness of issues of social justice and prepares students not only to be competitive workers in the economy but also engaged participants in a democracy" (Lesser, 2007, p. 3). Weiland's (2017) critical statistical literacy complements Lesser's (2007) work by specifically defining what it means to be critically statistically literate. The critical statistical literacy (CSL) perspective emphasizes the importance of critically 'reading and writing the world' using statistics to explore sociopolitical contexts (Weiland, 2017). "Reading the world" in CSL includes understanding statistical language and symbols, establishing a statistical way of knowing. Including the need to identify and question data-based arguments of social structures and the evaluation of statistical sources through a social, historical, and political lens adds reflective ways of knowing, for a more critical reading of the world. The same is true for "writing the world" in CSL where one not only communicates the statistical data, but also how one's position impacts their "overall meaning making of the world" and use of statistics to investigate and respond to unjust structures (Weiland, 2017, p. 42).

Framework

As this study was completed in an introductory statistics classroom, the conceptual framework that guided the study was founded upon Gutstein's (2006) TMfSJ, Lesser's (2007) TSSJ, and Weiland's (2017) CSL. Teaching Statistics for Social Justice (TSfSJ) is a critical statistical pedagogy designed for introductory statistics classrooms as it assumes students do not have prior knowledge or experience using statistics, examining and discussing social justice issues, or implementing a critical lens. Class discussion and data sets consisted of real-world, local, nontrivial examples for students to both learn and reflect upon the context of these examples and learn how to use and apply course content (Lesser, 2007). TSfSJ was designed to: (a) increase mathematical empowerment by increasing confidence in their ability to complete statistical procedures that produce results relevant to the surrounding community, (b) instill a sense of social justice to encourage civic engagement, activate critical voice, and increase personal relevance, and (c) increase student engagement through data sets that examine social issues that are relevant to their lives to increase student success. Students were expected to use statistical methods to read and write their world using predetermined data sets examining social justice issues surrounding race, class, gender, and sexual orientation. Through reflective inquiry students discovered the importance and usefulness of statistics, developing a more positive impression of the subject (Voss & Rickards, 2016; Wright, 2016). Reading the world with statistics included "identifying and interrogating social structures and discourses that shape and are reinforced by the data-based arguments" (Weiland, 2017, p. 41) with a particular focus on power, inequities, and disparities between different social groups (Gutstein, 2003). Students then examined these arguments, via statistical analysis and class discussion, to discover what, if any, injustices are being perpetrated, uncover possible inconsistencies, determine whether to accept or reject the arguments, and provide support using statistical investigations to communicate statistical information and arguments (Carver et al., 2016; Gutstein, 2003; Lesser, 2007; Weiland, 2017).

Methods

The purpose of this study was to measure the effectiveness of implementing a critical statistics pedagogy in an undergraduate introductory statistics classroom, and its impact on course success and mathematical empowerment. Intact classroom groups were used as the control and treatment groups, as it was not possible to implement random selection of group members. Two research questions guided the study: (a) does implementing a critical pedagogy increase student success? and (b) does use of a critical pedagogy increase the student's sense of mathematical empowerment? A variety of data was collected via instructor created projects, online homework sets, tests, and surveys to measure the impact of TSfSJ. Course grades, final exam grades, and pre/post CAOS tests were used to examine student success, with success defined as completing the course with a C or higher (a numerical score of 70 or higher). Mathematical Empowerment (MP) refers the student's ability to identify the need for and ability to apply statistics to real world scenarios.

Participants

The quasi-experimental study consisted of four MAT 152 Statistical Methods I courses at Mitchell Community College (MCC). During the Fall 2017 semester, MCC had 1,091 full-time students, 2,093 part-time students, and 20 of unknown status. Of the 3,204 students, 35% of students were matriculated in a transfer degree program and 34% were dual-enrolled students either from one of three Early Colleges affiliated with MCC or from one of three local high schools attending college classes through the state's Career and College Promise program. Excluding missing data from the 20 students with unknown status, students are primarily white (70%), female (61%), and young with 77% of the students being under 25 years of age. They primarily reside in the cities of Statesville and Mooresville, at 41% and 36% respectively. To best serve their students, MCC has two campuses: Statesville and Mooresville. Statesville's 2017 population is noticeably smaller than Mooresville's total population and the demographics differ greatly among the three areas. The population of Mooresville is roughly 87% white, while Statesville is 69% white. The median incomes between the two cities vary more drastically. Statesville, zip code 28677, has a median income of approximately $41,000. Mooresville, zip codes 28115 and 28117, has median incomes of $57,000 and $80,000 respectively (U.S. Census Bureau, 2018). The difference in household income is evident in the high schools. Statesville is served by one public high school, Statesville High. In 2017, Statesville High failed to meet academic growth, incoming student readiness (percent of students considered proficient) was measured at 12.7% and served a population that was 60% economically disadvantaged ("School

Report Card for Statesville High", 2019). Mooresville is served by two public high schools, Lake Norman High and Mooresville High, both of which exceeded academic growth projections in 2017. Lake Norman High had an incoming student readiness of 59.7% and served a population that was 8.9% economically disadvantaged ("School Report Card for Lake Norman High", 2019). Mooresville High's incoming student readiness was 65.9% and its economically disadvantaged population was 30% ("School Report Card for Mooresville High School", 2019).

Data Sources and Collection

During the Fall 2017 and Spring 2018 semesters, one MAT 152 course on each campus was a part of the study. Data was collected from the Fall 2017 Statesville section (10 students) and the Mooresville section (19 students). In Spring 2018, data was collected from 19 students in Statesville and 23 students in Mooresville. Final exam scores and overall course grades were collected from all students who completed the courses. The Fall 2017 sections of MAT 152 served as the control groups and the Spring 2018 sections were the treatment groups. There were two pretests and two posttests administered to all sections included in the study on the first day and second to last day of each course to measure differences between the two groups. One of the tests was the Comprehensive Assessment of Outcomes in a First Statistics (CAOS) course. It consists of 40 multiple choice questions and assesses students' statistical reasoning after any first course in statistics with a focus on statistical literacy and conceptual understanding (Regents of the University of Minnesota, 2006). The second test administered was the Constructivist Learning Environment Survey (CLES). The CLES is a 42-item questionnaire which uses a 5-point Likert scale measuring students' classroom experiences in six categories (CLES, 2017). However, only two categories were of interest in this study: Personal Relevance and Critical Voice. Personal Relevance questions measure a students' perceived relevance of the content learned in the classroom to their out-of-school experiences. These questions examine whether not students are able to read and write the world with mathematics by being able to recognize and apply the curriculum to real world situations (Gutstein, 2006). Critical Voice questions focus on empowerment, ultimately measuring the climate of the classroom and the extent to which students feel able to question or reflect on the teaching and learning process (Lew, 2010; Taylor & Fraser, 1991).

In all four courses, Triola's (2015) *Essentials of Statistics* (5th edition) served as the course text and as a source of course material and resources. MyLabsPlus (MLP) was the courses' online homework platform, with all four courses being assigned the same questions. Final exams and unit tests were created from the textbook's testbank with all unit exams and the final exam remaining the same for each section. There were 10 labs assigned in all sections. All labs were researcher-created, required the use of technology, and were completed in the classroom. Control groups labs consisted of hypothetical scenarios that students examined with the use of online and textbook resources and their calculator. The treatment consisted of embedding an overarching focus on issues of social justice relating to race, class, gender, and sexual orientation by adding examples, questions, and data exploring these topics to the PowerPoints and labs used with the control group. Labs were similar in design and theme, but incorporated real-world, local data to be explored in addition to, or in replace of, the fictional data used in the control.

Results

A total of 12 participants were excluded due to not completing both sets of the pretests and posttests. From Fall 2017, four participants were eliminated from the Statesville control course and five from the Mooresville control course. There were two participants eliminated from the Spring 2018 Statesville treatment course and one participant from the Spring 2018 Mooresville treatment course. The type of analysis used was determined by the level of measurement of data collected.

Research Question One

Course Grades. A Kolmogorov-Smirnov Test (K-S Test) was run on each section's final course grades. For the Statesville sections, both the control ($D(10) = .186$, $p > .05$) and treatment ($D(19) = .152$, $p > .05$) were deemed to be individually normally distributed by the K-S. A Levene's Test for Equality of Variances showed that the two sections had equal variances. An independent *t*-test did not indicate a statistical difference between the treatment ($M = 83.1$, $SE = 2.94$) and control ($M = 85.61$ $SE = 3.53$), $t(27)= 0.523$, $p > .05$. The Mooresville control ($D(19) = .168$, $p > .05$) and treatment ($D(23) = .168$, $p > .05$) sections were also both normally distributed. A Levene's Test for Equality of Variances showed that the two sections did not have equal variances. An independent *t*-test did indicate a statistical difference between the treatment ($M = 91.39$, $SE = 1.69$) and control ($M = 80.65$ $SE = 3.82$), $t(24.922)= -2.573$, $p < .05$.

Final Exam Grades. A K-S Test was run on each section's final exam grades (max score of 40). Both Statesville sections were deemed to be individually normally distributed for the control ($D(10) = .186$, $p > .05$) and for the treatment ($D(19) = .154$, $p > .05$) by the K-S. A Levene's Test for Equality of Variances showed that the two sections had equal variances. The independent *t*-test did not find a statistical difference between the treatment ($M = 31.21$, $SE = 1.37$) and control ($M = 32.8$, $SE = 1.52$), $t(27) = .726$, $p > .05$. The K-S test for the Mooresville control ($D(19) = .204$, $p < .05$) and treatment ($D(23) = .190$, $p < .05$) were not found to be normally distributed. Due to the lack of normality, an independent Mann-Whitney U Test was used to compare the final course grades of the sections and found there was a statistically significant difference between the control ($Mdn = 28$) and treatment ($Mdn = 35$) sections, $U = 358.50$, $z = 3.55$.

CAOS pretest/posttest scores. An independent *t*-test showed that control groups were not statistically different from their treatment groups. Independent *t*-tests of the pretest CAOS scores confirmed that the Statesville control and treatment groups, $t(27) = -0.384$, $p > .05$. , and the Mooresville control and treatment groups, $t(40) = -1.541$, $p > .05$, did not differ statistically

For the Statesville sections, a Shapiro-Wilk (S-W) tests showed both the pretest ($W(10) = .910$, $p > 0.05$) and posttest ($W(10) = .910$, $p > 0.05$) were normally distributed for the control group and the treatment group pretests ($W(19) = .949$, $p > 0.05$) and posttests ($W(19) = .934$, $p > 0.05$). Levene's Test of Equality of Error Variance was not significant ($F(1, 27) = .033$, $p > .05$) showing the variances of the pretests for the control and treatment to be equal. Independent *t*-tests were used to explore the data. Neither the control, $t(9) = -0.9.19$, $p > .05$, nor the treatment, $t(18) = -.109$, $p > .05$, showed a significant difference between the pretest and posttest. In Mooresville, Shapiro-Wilk (S-W) tests showed both the pretest ($W(19) = .929$, $p > 0.05$) and posttest ($W(19) = .965$, $p > 0.05$) were normally distributed for the Mooresville control group. However, S-W tests showed the treatment was not normally distributed for the pretest ($W(23) = .900$ $p < 0.05$) or posttest ($W(23) = .910$, $p < 0.05$). When the outliers were removed from the data set, Shapiro-Wilk reported the treatment as normally distributed, $W(21) = .918$, $p > 0.05$. Levene's Test of Equality of Error Variance was not significant showing the variances of the pretests for the control and treatment to be equal, $F(1, 38) = 0.805$, $p > .05$. The data was retested with outliers remaining in the set. Levene's Test of Equality of Error Variance showed the variances of the two groups to be equal as the test was not found be significant ($F(1, 40) = 3.196$, $p > 0.05$). A paired t-test was used to investigate the control and a Related-Samples Wilcoxon signed rank test was used for the treatment, as the treatment was originally found not to be normally distributed. The paired t-test did not find a statistically significant difference between the pretest and posttest for the control, $t(18) = -0.637$, $p < .05$. However, the difference between the pretest ($Mdn = 16$) and the posttest ($Mdn = 18$) for the treatment was significant, $T = 188.00$, $p < .05$. When outliers were removed from the treatment, a paired t-test also found a statistical difference in the treatment group, $t(20) = -2.274$, $p < .05$.

Persistence. A population proportion test was used to measure the effect of treatment on persistence. Tests were completed via TI-84 SE with z scores rounded to the hundredths. There was found to be no statistically impact of persistence on the Statesville ($z = -0.4$, $p > .05$) or Mooresville ($z = -0.67$, $p > .05$) campuses.

Research Question Two

Two population proportion z-tests were completed on each question comparing pre/post survey data for each of the control and treatment groups with success defined as responding Almost Always or Often on positively worded questions. Except for questions PR1 and PR13 in the control, all questions were found to be significant, $p < .05$. However, for the treatment groups, all questions showed a significant increase in PR and CV, $p < .005$.Two population proportion z-tests were also completed on each negatively worded question comparing pre/post survey data for each of the control and treatment groups with success defined as responding Seldom or Almost Never on negatively worded questions. All questions were found to be significant, $p < .05$.

Conclusion

Despite its limitations, the study provided two promising findings. First, the study showed that the use of a CP in an undergraduate introductory statistics classroom has the possibility of increasing overall course success. As students need a C or better in a course to fulfill prerequisite requirements for other courses or to have the course transfer to another institution, even small increases may result in large, personal gains for the student. By earning transferrable credits, the probability a student completes their degree increases. As “educational attainment is a means of social mobility” this will have an impact on their future lives and career (Trusty & Niles, 2003). Second, the study showed gains in MP in the treatment courses. While the control found the material relevant, students were not able to “read and write” the world with statistics and identify how mathematics touched their own lives. By implementing a CP, students learned “to examine the systems and institutions that are in place and to use mathematics to evaluate and critique these systems and institutions as well as develop individual and social agency” (Leonard et al., 2010, p. 262).

The purpose of higher education has long been to help create well-rounded, forward thinking citizens; people that can gather and analyze information, use that information to address problems, and help improve society. As Stanton (1987) stated “we need a citizenry with a broad understanding of the interdependencies of peoples, social institutions, and communities and an enhanced ability both to draw upon and further develop this knowledge as they confront and solve human problems” (p. 7). By teaching statistics for social justice, students not only learn how to be better employees for the workplace, but how to be better people for all places.

Influence of Curriculum on College Students' Understanding and Reasoning about Limits

Navy Dixon, Brigham Young University
Erin Carroll, Brigham Young University
Dawn Teuscher, Brigham Young University

The Pathways to College Algebra curriculum aims to build concepts that cohere with the big ideas in Calculus, and initial results suggest improved readiness for Calculus by students who use the curriculum. Our study examines similarities and differences of Pathways and non-Pathways students understanding and reasoning about the calculus concept of the limit. We compare students' understanding of limits at the beginning and at the end of the unit. Our findings suggest that (1) students reliance on procedures, combined, or quantitative reasoning was dependent on the calculus instructors' emphasis in the class; (2) students who begin their Calculus class with high covariational reasoning gain a more sophisticated understanding of limits; and (3) when curriculum is coherent students will identify mathematical connections.

Keywords: Pathways College Algebra, Calculus, Limits, Understanding, Reasoning

Mathematics should make sense. Many professional organizations encourage *coherence* across curriculum (NCTM, 2006; NMAP, 2008; Newmann, Smith, Allensworth, & Bryk, 2001; Schmidt, Wang, & McKnight, 2005). Thompson (2008) suggests that coherence is the *ideas* and *meanings* rather than mathematical topics and orderings. Often this coherence is lacking between Calculus and its prerequisite classes, like College Algebra, which frequently focuses on calculations and procedures (see Blitzer, 2014; Sullivan, 2012). While knowing procedures may help students work out calculus problems, often it is hard for students to see how these procedures cohere with the *big ideas* in Calculus of limits, rates of change, and accumulation (see Kaput, 1979; Thompson, 1994).

Levia, Borrowman, Jones, and Teuscher (2019) reported that Pathways students, those who used *Pathways to College Algebra* (Carlson, 2016, hereafter referred to as "Pathways") reasoned about and understood limits differently compared to their non-Pathway peers after the first lesson in their Calculus class. Overall Pathways students relied on quantitative reasoning and used higher levels of covariational reasoning suggesting that the Pathways curriculum may *cohere* with students' initial limit instruction, which is an important aspect of sound curriculum (NCTM, 2006; NMAP, 2008; Newmann et al., 2001; Schmidt et al., 2005; Thompson, 2008). This coherence suggests a possible advantage for Pathways students when encountering difficult concepts such as limits for the first time. The Pathways students were also aware of the ways in which their Pathways curriculum connected to the limit concept in Calculus after just one lesson.

The Pathways curriculum aims to build algebra concepts through quantitative and covariational reasoning and the curriculum was developed to provide foundational knowledge for students, but also to cohere with big ideas in calculus. This study examines one specific area, namely how students' College Algebra experience might influence students' understanding and reasoning about limits after receiving instruction on limits. Our guiding research question is: What differences or similarities are there between calculus students who took non-Pathways algebra versus Pathways algebra, in terms of how they understand and reason about limits at the end of the unit?

Brief Background on Pathways Curriculum

The Pathways curriculum (Carlson, 2016; Carlson, Oehrtman, & Moore, 2017) was developed to provide a coherent and meaningful course for students to understand the foundational aspects of calculus. The Pathways curriculum was informed by research on learning functions (Carlson, 1995, 1998), the processes of covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002), mathematical discourse (Clark, Moore, & Carlson, 2008), and problem-solving (Carlson & Bloom, 2005). The curriculum contains modules based on research of student learning and conceptual analysis of the cognitive activities conjectured to be necessary to understand and apply the module's central ideas. Mathematics concepts included are rate of change; proportionality; functions: linear, exponential, logarithmic, polynomial, rational, and trigonometric; polar coordinates; vectors; and sequences and series. The curriculum also supports a problem solving approach to mathematics, where students are expected to engage in novel contexts and reasoning to construct mathematics.

Understanding and Reasoning about Limits

In this section, we articulate our perspective on "understanding and reasoning about limits," based on the research literature. Of course, our perspective outlined here does not contain everything that may be involved in understanding or reasoning about limits, because our study deals with understanding after an introductory unit on limits.

We define "understanding" as a student's *concept image* of limit at the end of the unit (Tall & Vinner, 1981), which we would expect to be more complete, yet have possible holes at the end of the unit. Also, because some misconceptions are nearly "unavoidable" (Davis & Vinner, 1986) and take considerable exposure to examples, counterexamples, and contexts to address (Cornu, 1991; Przenioslo, 2004; Swinyard, 2011), we are less interested in documenting student misconceptions. Rather, we are interested in comparing students' understanding with standard *informal* definitions of limit. In our study, we examined cases of both the limit at a point, $\lim_{x \to a} f(x) = L$, and the limit at infinity, $\lim_{x \to \infty} f(x) = L$. While the students in our study participated in class discussions and homework problems throughout the unit, we wanted to know how they understood and reasoned about limits at the end of the unit and in comparison to the beginning of the unit. Our informal definition of limit at a point is that the limit of $f(x)$ is L "if we can make the values of $f(x)$ arbitrarily close to L… by restricting x to be sufficiently close to a… but not equal to a" (Stewart, 2015, p. 83). Our informal definition of limit at infinity is that "the values of $f(x)$ can be made arbitrarily close to L by requiring x to be sufficiently large" (Stewart, 2015, p. 127).

We define "reasoning" through two aspects of reasoning that the literature claims are important for limits. First, Kaput (1979) stated that "virtually all of basic calculus (the study of change) achieves its primary meaning through an absolutely essential collection of motion metaphors" (p. 289). As such, changing quantities are a part of reasoning. However, standard curricula often focus heavily on algorithms for finding limits (e.g., Stewart, 2015; Thomas, Weir, & Hass, 2014). Nagle (2013) claims that this approach likely leads students to have "independent, unconnected conceptions" of limits that are based on quantities and computation (p. 3). Consequently, the way students use quantitative reasoning versus procedural reasoning is one part of their "reasoning about limits."

Second, some researchers have noted strong relationships between covariational reasoning and understanding limits, due to a limit inherently dealing with two changing quantities (Carlson et al., 2001; Carlson et al., 2002; Nagle, Tracy, Adams, & Scutella, 2017). The informal, "as x approaches a, y approaches L," strongly suggests covariation between x and y. Carlson et al.

(2002) even claimed that, “students' difficulties in learning the limit concept have been linked to impoverished covariational reasoning abilities” (p. 356). Because of the importance of covariational reasoning, we consider how students use covariational reasoning as the other part of their “reasoning about limits.”

Methods

Eight of the 11 Calculus 1 students from a prior study (Levia et al., 2019) at a large private university participated in a second interview for this study. All students had taken College Algebra from various instructors at the university in the previous year; four took Pathways (P) and the other four a non-Pathways Algebra class (N-P). The students’ College Algebra grades and Calculus pre-test scores were similar across the two groups and only one of the N-P students had completed Calculus previously in high school. Students were enrolled in four different instructors’ Calculus courses. Three of these calculus instructors emphasized conceptual understanding and one emphasized procedural knowledge. Students were interviewed a second time about limits the week after they completed their mid-term on limits in Calculus 1. We label the P students as PA, PB, PC, and PD and the N-P students as N-PA, N-PF, N-PC, and N-PD.

The interview contained the same four questions that were given in the initial interview: (1) Explain the meaning of $\lim_{x\to a} f(x) = L$. (2) If you found the limit $\lim_{x\to\infty} \frac{4x^2}{x^2-5x+6}$, , what would you be finding? (3) Select the graph(s) [among six graphs given to the students] that correspond to each limit expression, (a) $\lim_{x\to\infty} f(x) = 1$, (b) $\lim_{x\to 0^-} f(x) = -\infty$, (c) $\lim_{x\to 3^+} f(x) = 0$. (4) The equation $v_{orbit} = \sqrt{\frac{GM}{r}}$ relates a satellite’s required velocity for a stable orbit, v_{orbit}, with its distance from Earth, *r* (where *M* is the Earth’s mass and *G* is a constant). What is $\lim_{r\to\infty} v_{orbit}$? After questions 2 and 4, students were asked to identify any connections they saw from their College Algebra class that might have helped them understand limits.

We analyzed the students’ responses as follows. First, we analyzed how students used quantitative reasoning versus procedural reasoning in their responses. Quantitative reasoning was operationalized as using number sense and relationships between quantities to discuss the limits. Procedural reasoning was operationalized as using an algorithm or memorized set of steps to solve the problem, without explaining why the process worked, regardless of whether the student used the procedure correctly or not. However, if the student explained why the process worked, it was coded as quantitative reasoning, rather than procedural. We applied this analysis only to the questions 2 and 4 where students *could* potentially compute the limit.

Second, we analyzed students’ covariational reasoning behavior from question 3 according to Thompson & Carlson (2017) framework, which includes the reasoning levels: *no coordination, pre-coordination, gross coordination, coordination of values, chunky continuous covariation,* and *smooth continuous covariation*. We only analyzed question 3 because students had to discuss two quantities as they explained their answers. We used the same categories developed from the initial interview analysis (**high**: *coordination of values, chunky continuous covariation, smooth continuous covariation, gross coordination*; **mid**: *coordination of values, gross coordination*; **low**: *no coordination, pre-coordination*) (see Levia et al., 2019). Each student was placed into a category based on their overall demonstrated ability of reasoning. We also attended to whether students were *specific* about the quantities involved in the covariation, or whether they used *ambiguous* language to refer to the quantities (Leatham, Peterson, Merrill, Van Zoest, &

Stockero, 2016). If we were unsure of the quantities the student referenced, we placed the student in a lower category.

The last step of analysis was, at the end of each interview question, to infer students' understanding of limits. We documented whether the students' descriptions were mathematically correct according to our informal definitions. We also noted whether a student's descriptions were consistent across questions, including for *limit at a point* at the end of questions 1 and 3 and for *limit at infinity* at the end of questions 2, 3, and 4.

Results

Procedural versus Quantitative Reasoning

Students tended to reason about limits in one of three ways: reliance on quantitative reasoning, reliance on procedural reasoning, or reliance on combined reasoning. We found that three students (PA, N-PF, N-PA) reasoned as they had during the initial interview at the beginning of the unit. However, the remaining five students moved into different categories of reasoning. Three P students (PB, PC, PD) moved from quantitative reasoning to either combined reasoning or procedural reasoning. One N-P student (N-PD) moved from procedural to combined reasoning, and another (N-PC) moved from combined to quantitative reasoning.

During the second interview P students tended to be more reliant on procedures. For example, in the initial interview, PB reasoned quantitatively, stating: "the idea of this function itself is as x approaches infinity, … this calculation will reach a certain number." Although PB did not actually solve the limit, he discussed what the given equation meant and how he thought about and interpreted his answer. There was no reliance on procedures and he was focused on understanding what was happening with the numbers. Conversely, in the second interview, PB seemed to focus on the new rules he had learned in Calculus. On the same interview question, his response was,

> So something I learned about limits in… [Calculus 1] was that there are certain laws that we can use to kinda move things around… Ok one of the laws says that ... we can take the limit of $4x^2$ as x approaches infinity. We can kind of separate that from this and say that this is… it's the limit of $4x^2$ divided by the limit of … as x goes to infinity. We can say that it's this divided by $x^2 - 5x + 6$ [writes, $\lim_{x\to\infty} 4x^2 \div \lim_{x\to\infty} x^2 - 5x + 6$]. Which is awesome.

Here we see that PB's response is to exemplify the new "laws" (i.e., rules) he learned in Calculus. On multiple occasions, PB mentioned concepts and reasoning behind procedures. However, when given the opportunity, PB, like other P students, discussed memorized rules and procedures from his Calculus class rather than concepts he had come to understand.

On the other hand, two of the N-P students reasoned more quantitatively by the second interview. For example on question 2, N-PC got stuck in his initial interview trying to work through rules and eventually ended up giving up. However, in his second interview, he responded with,

> Whichever x is growing the fastest, that would be the limit you are approaching … So this infinity [points to x^2in the denominator] is being squared so it's going to be much bigger than this infinity [points to $5x$]. Just like 5x. Because a squared number is bigger than a non-squared number. And this number up top [points to $4x^2$] is also squared so it's going to be like the same size of infinity, but it's multiplied by 4 so this is like 4 times as great as this one down here [points to x^2]. So as x approaches infinity, these cancel out like a 1 and you're left with just the 4. So the limit is 4.

In contrast with his initial interview, N-PC provided an answer explaining why the procedure of using the exponents to find the limit worked.

Importantly, during this study we did not control for differences in Calculus instructors. Most of the P students' instructors focused on the procedural process of limits; whereas, most of the N-P students' instructors emphasized conceptual understanding. This could explain the shift in students' procedural and quantitative reasoning. This suggests that students' reliance can change depending on the instructor's orientation in just one month, which was the time between the two interviews. However, more research would need to be done to confirm this.

Covariational Reasoning

After analyzing students' interview responses for instances of covariational reasoning, we identified each student's general level of exhibited covariational reasoning, placing them in a low, mid, or high category. Here, we describe the three categories and the differences between the P and N-P students in the second interview.

High covariation. In the second interview, three P students (PA, PB, PC) exhibited "high" covariational reasoning most often. For example, when PB explained a graph in question 3, he stated:

> We can see that as our value of *x* along this line gets larger and larger [points to each value along the x-axis: 1,2,3, etc], ... this line representing our y-values, gets closer and closer to this constant value of 1.

PB saw the x-axis having intermediary values, thereby exhibiting *smooth continuous* covariation. Students who exhibited this level of covariational ability and were specific during most of their interview were placed in this "high" category.

Mid covariation. Two N-P students (N-PA, N-PF) were placed into the "mid" category. For instance, N-PF explained the correct graph for $\lim_{x\to 3+} f(x) = 0$. She stated, "As the x-values [are] approaching 3 from the right side, you can see that it's getting closer and closer to 0 for the y-value." N-PF is explicit in identifying the quantities she is explaining, but imprecisely describes how the two quantities change together. This kind of reasoning was typical for students placed in the "mid" covariation category.

Low covariation. Three students (PD, N-PC, N-PD) were placed into the "low" category. These students were generally not as specific, or were more easily confused as to which quantity they were discussing in their explanation. An example can be shown by N-PC when explaining how a graph exhibited the limit statement $\lim_{x\to 3^+} f(x) = 0$. He was unspecific and usually called both *x* and *y* "the graph." After being asked a few times to clarify, N-PC describes the graph by saying, "As it's approaching 3... sorry the graph, so as *x* is approaching 3, it's getting closer to 0." When the interviewer asked what is getting closer to 0, N-PC responded: "the graph." This student used the same pronoun for both variables; it is unclear if he was differentiating between the two as they varied together. This confusion may cause the student to see the quantities as separate, distinct objects with little or no link.

Although the students' calculus instructor seemed to influence their reliance on either quantitative or procedural reasoning, this was not the case for students' levels of covariational reasoning. There was no relationship between the instructor's foci and the students' levels of covariational reasoning. In fact, students exhibited little or no change in their covariational reasoning ability between their initial and second interviews. This suggests that students maintained their habit of covariational reasoning and applied it to their new course regardless of how the instructor reasoned. Similarly, if a course is not built with a covariational reasoning focus, students may not improve their covariational ability.

Understandings for Limit

Though no student had a perfect limit meaning, we classified their limit meaning as correct when students showed they were thinking about the input values approaching a certain point or infinity, and that the associated output values approached the limit value. This is exemplified by PC's response to question 1 in his initial interview, "We're not necessarily looking for the value of the function at a specific *x* point. But what *f(x)* is approaching at that certain point, from both sides."

During the second interview we found that some students showed a more sophisticated understanding of a limit. All of the students were asked, when using words like "closer" and "approaches," what they meant by those words. Some students described "narrowing in" on a particular y-value. They indicated that the vertical difference between the expressed y-value and limit value was decreasing. For example, N-PA describes by explaining that:

> First kind of bigger gaps and then they get tighter and tighter … the pattern appears that it gets tighter and tighter around the output of 1. So that the larger the *x*-value gets, the closer and closer the *y*-values get to being 1.

N-PA describes "tighter and tighter" gaps, or vertical distances or differences between the limit value, 1, and the output values on the graph. This suggests that this student's limit meaning is closer to the formal limit definition, and that these vertical distances suggest an understanding of the $L \pm \epsilon$ aspect of a formal limit definition. Of the three students that exhibited this kind of meaning, two of the students were P students and the other was a N-P student who took calculus previously in high school. These three students exhibited either "high" or "mid" covariational reasoning. This suggests that having a high covariational reasoning as these students entered Calculus may have helped their understanding of limits and potentially other content.

Three students demonstrated an improved, but not as sophisticated limit meaning as the previously described group of students. In the initial interviews, four students (one P and three N-P) thought the limit values meant the slope of the function at a specific point. Two of these students (one P and one N-P) continued to confuse the idea of limits and derivatives by identifying a limit as being the slope of a tangent line. This type of thinking happened for both P and N-P students and it was not unique to a specific calculus or algebra instructor. The calculus instructors motivated the need for limits by showing students that they could not calculate the slope of a line tangent to the function at just one point. This may have confused students, and they interpreted it as the limit value is the slope of the function at that point. Even after an entire unit of learning about limits, two students still had misconceptions about the meaning of a limit stemming from that limit introduction.

Connections to Algebra Experience

During the final interviews, as well as the initial interviews, the N-P students generally were explicit in stating that their College Algebra class had few connections to learning limits, and the connections they found were mainly procedures or manipulative skills. The P students expressed that their College Algebra class directly helped them with learning and understanding limits and the connections they made tended to be more about concepts and thought processes.

For example, N-PC said,

> We've used algebra like crazy. So that finally makes sense why we had to learn all that crazy stuff in 110 [College Algebra].... So like finding the domain of a function, finding asymptotes, being able to manipulate like power rules, log rules, natural log, *e*. Being able to factor and simplify and divide. Do all sorts of crazy gymnastics with algebra.

For this student, there were only basic procedures that came from his College Algebra experience and nothing that he felt helped him understand the concepts.

As opposed to the N-P students, PC said,

> We never mentioned the word 'limit' before, so that was a foreign, brand-new concept this last month. But it does relate because it's important to know the general trend of a graph when it's approaching numbers....That relates to limits because that's kind of the definition of a limit.

As PC notes, limits were never taught in the Pathways class, however he is able to recognize that the concepts he learned in College Algebra were directly related to what he was learning about limits.

Discussion

In discussing the trends seen in the results, we caution that our small sample is only suggestive, and cannot imply generalization to the larger Calculus student population. However, within our small sample, we certainly observed differences in trends for how the overall group of P students reasoned about and understood limits compared to their N-P counterparts. Of course, there was overlap in how the students reasoned about limits. For example, students from both groups were seen to reason quantitatively and procedurally. Students from both groups were seen to reason at lower and higher levels of covariational reasoning. Yet, taken in aggregate, P students who had high covariational reasoning to begin the unit, continued to have high covariational reasoning at the end of the unit regardless of their instructor. On the other hand, students' reliance on quantitative, combined, or procedural reasoning tended to be related to what their calculus instructor emphasized. As would be expected after a unit on limits, students' understanding of limits became more sophisticated and were closer to the formal definition of a limit. However, it is interesting that students who had high covariational reasoning at the beginning of the unit, which tended to be P students, tended to have a more sophisticated understanding of limits at the end of the unit.

The Pathways curriculum seems to *cohere* with students understanding of limits, which is an important aspect of sound curriculum (NCTM, 2006; NMAP, 2008; Newmann et al., 2001; Schmidt et al., 2005; Thompson, 2008). This coherence suggests a possible advantage for Pathways students when encountering the difficult limit concept. While it may only be small, if it is combined with a net advantage for other concepts as well, such as the derivative and integral, it begins to build a picture as to why Pathways students might be more successful in calculus (see Carlson, Oehrtman, & Engelke, 2010). In fact, the students themselves seemed aware of the ways in which their Pathways curriculum connected to the limit concept they learned even thinking that limits were taught during their College Algebra class, which was not the case.

How Do Students Engage with 'Practice Another Version' in Online Homework?

Allison Dorko
Oklahoma State University

Homework is one of students' opportunities to learn mathematics, but we know little about what students learn from homework or how they learn it. Online homework platforms contain a variety of resources students might access. This paper explores how students used a 'practice another version' (PAV) feature. Findings indicate students used PAV problems for extra practice, as templates, to see the steps for solving a problem, to make sense of a solution method, to troubleshoot when their own method did not work, to see the form of an answer, to maximize their score, and to check that their method was on the right track. The primary uses were for sensemaking, to see steps, or to use the problem as a template. This work lays groundwork for future work characterizing what students learn from homework and how features such as PAV help (or hinder) their learning.

Keywords: Online homework, Instructional situation, Calculus

Homework, like class time, is one of students' opportunities to learn mathematics. However, we know little about the nature of students' activity while doing homework, or what they learn from homework. Findings from research indicate undergraduate calculus students spend more time doing homework than they do in class (Ellis, Hanson, Nuñez, & Rasmussen, 2015; Krause & Putnam, 2016), but that students' reasoning in homework exercises tends to involve mimicking procedures (Lithner, 2003). Students report that homework and practice exercises are important for their learning, more so than other forms of instruction like lecture (Glass & Sue, 2008). Hence research about student learning from homework has the potential to improve homework as a learning opportunity and increase student learning outcomes in general.

Increasing sophistication in technology has resulted in more and more students having online mathematics homework. Online homework platforms often have a variety of "help" features such as links to relevant textbook sections, opportunities to work through similar examples, and hints. However, we do not know if these features help students learn. Research about student learning from homework has the potential to increase student learning by telling us more about what types of problems are best suited for homework, what sorts of resources aid in student learning, and so on.

To that end, this paper reports on a study of how three differential calculus students used the 'practice another version' feature while completing an online homework assignment about the Fundamental Theorem of Calculus Part II. In a "practice another version" (PAV) feature, the online platform supplies a problem identical to the student's assigned problem but with different numbers. Once the student inputs an answer to the practice problem, the online platform shows the solution and solution method. Krause and Putnam (2016) found students used 'see similar example'-type features more frequently than other resources (class notes, online calculators, their textbook, office hours). Hence knowing more about how students use these features and whether they support or hinder student learning can directly inform the design of better online homework assignments. This paper supports that goal by answering research question *how do students engage with PAV in an online homework assignment?*

Theoretical Framework

Homework is one component of an instructional system (Ellis et al., 2015). In this framing, instruction is the set of "interactions among teachers and students around content, in environments" (Cohen, Raudenbush, & Ball, 2003, p. 122). These interactions take place in a variety of *milieu*, each of which is a counterpart environment in which students have particular goals and resources and in which they obtain feedback on their actions. As students work on a task within a milieu, they have an opportunity to learn the *knowledge at stake* (or content). An online homework assignment is a milieu in which students work on tasks that an instructor has chosen to help them learn the knowledge at stake. Instructors also choose some of the resources students can access while doing homework. The PAV feature is one such resource. This paper focuses on how students engage with this resource. The theoretical framework also informed the work in that I viewed the particular ways in which students engaged with PAV as a consequence of their goals for the homework assignment.

Background Literature

Few studies have explored students' activity while doing homework. Dorko (accepted) found students' answers in online homework may be based on mathematical thinking, guessing, working or mimicking steps of a similar problem, copying an answer from a source (e.g., a webpage), or reasoning based on answers they think they should see (e.g., expecting some answers to be infinity and others to 0). Other research supports the finding that students often work or mimic steps of similar problems (Krause & Putnam, 2019; Lithner, 2003). When finding similar problems, students seem to attend to superficial similarities, such as two sequences with $\cos n\pi$ in the numerator (Lithner, 2003). Relying on these types of "similarities" may hurt students' learning because students may give up when following the steps of the "similar" problem does not work (Lithner, 2003).

In terms of student learning from homework, most research has focused on determining whether homework format (online, paper-and-pencil, or a combination) makes a difference in terms of student achievement. Researchers generally agree that online homework is at least as effective as paper-and-pencil homework in terms of student achievement (Babaali & Gonzalez, 2015; Burch & Kuo, 2010; Hauk et al. 2015; Halcrow & Dunnigan, 2012; Hauk, Powers, & Segalla, 2004; Hauk & Segalla, 2005; Hirsch & Weibel, 2003; LaRose, 2010; Lunsford & Pendergrass, 2016; Lenz, 2010; Weibel & Hirsch, 2002; Zerr, 2007). In terms of a more fine-grained analysis of what students learn from online homework, Dorko (2019) found online homework supported students' learning of procedures and familiarity with sequence notation. This study aims to extend the literature base by documenting how students engage with the PAV feature, laying more groundwork for studying student learning from homework and in particular how "help" features in online homework platforms can support and/or constrain it.

Data Collection and Analysis

The data presented here come from observational sessions and follow-up interviews with each of three students enrolled in differential calculus during the fall semester at a large university in the US. In the observational session, I video-recorded each student while (s)he completed an online homework assignment about the Fundamental Theorem of Calculus Part II (see the tasks for which the PAV feature was enabled in Table 1). The assignment was in a platform called WebAssign and students obtained full credit for a problem if they answered it correctly in 3 tries, partial credit for a correct answer on the 4^{th} or 5^{th} try, and no credit after that. Prior to the session, I requested that students do their homework as they would if I were not in the room, including using internet searches and so on. I did not ask students any questions during the observational session because I did not want to influence their activity. I photocopied students' scratchwork and any class notes they had referenced. Following that session, I made notes about students' observable activity. I first noted in which questions they opened PAV (Table 1). For those problems, I noted what students submitted for answers (if anything) to their own problem before opening PAV, the answers they submitted in PAV, and what they wrote and submitted after seeing the solution to the practice problem. These notes allowed me to ask more informed questions in the follow-up interviews. For example, I observed students submit what seemed like nonsense answers in the PAV problem (e.g., submitting the letter 'r' to each of three parts of a question about an integral) so in the follow-up interview, I asked why they had submitted a particular answer.

In the follow-up interview, the student and I watched the video together and I paused it every time the student opened the PAV feature. I asked questions such as why they had opened PAV at that particular time, why they had inputted a particular answer to the PAV problem, and how the PAV had helped them. I transcribed these interviews and added my notes from the observational session, then used these 'enhanced' transcripts in analysis.

Table 1. Problems for which students opened PAV (A 'Y' indicates that the student opened the PAV feature for that problem; an 'N' indicates that they did not)

		S10	S13	S15
5.5 #6	Let $G(x) = \int_3^x (t^2 - 8)dt$. Calculate G(3), G'(3), and G'(4). Find a formula for G(x).	Y	N	Y
5.5 #7	Find the formula for the function represented by $\int_{\pi/8}^x sec^2(2u)du$. F(x) = ______	Y	N	Y
5.5 #8	Find the formula for the function represented by $\int_x^0 e^{-5t}dt$. F(x) = *"Calc clip" video link*[1]	Y	N	Y[1]
5.5 #9	Find the formula for the function represented by $\int_2^{\sqrt{x}} \left(\frac{1}{3t+2}\right) dt$. F(x) =	Y	Y	Y
5.5 #10	Find the formula for the function represented by $\int_1^{x^2} (t+7)dt$. F(x) =	N	N	N
5.5 #11	Calculate the derivative. $\frac{d}{dx}\int_{\sqrt{x}}^{x^2} \tan(3t)\, dt$	Y	Y	Y
5.5 #12	Calculate the derivative. $\frac{d}{dx}\int_0^x (14t^5 - 16t^3)\, dt$	N	N	N
5.5 #13	Calculate the derivative. $\frac{d}{d\theta}\int_1^\theta$ 7cotu du	Y	Y	N

I analyzed the data using the constant comparative method (Strauss & Corbin, 1994), a systematic approach to identifying themes in data. One of my observations from watching students open PAV was that they frequently seemed to submit random numbers or letters almost immediately upon having opened the PAV screen. This represents part of how students engage

[1] S15 is the only student of the three who watched the Calc Clip, which narrated a step-by-step solution to finding the function represented by $\int_x^\pi \cos(t)dt$.

with PAV, so I analyzed the students' submissions into the practice problem as one way to lend insight into why they had opened PAV as a resource. The data I coded for this were students' submissions into PAV (which I could see in the video of the observational session) and students' answers to the question "why did you submit…" during the interview. The data fell into two categories (Table 2). The categories are not mutually exclusive; because many of the problems had multiple parts, students sometimes submitted an answer to one part based on mathematical reasoning and an answer to a different part with a random letter. The coding based on these categories is shown in Table 3.

Table 2. Themes in answer entered into PAV

Category	Criteria
Based on mathematical reasoning (MR)	The student says they wanted to check that they were thinking along the correct lines; the student submits an answer to PAV similar to work they have been doing on their own problem
Nonsense answer (NS)	The student says they typed a random letter or number in order to see the solution to the PAV; the student enters a number or letter immediately upon opening PAV

Table 3. Coding for what students submitted into PAV. A black box indicates a student did not use PAV on that particular problem. Other designators are given in Table 2.

	S10	S13	S15
5.5 #6	NS		MR
5.5 #7	NS		NS
5.5 #8	NS		NS
5.5 #9	NS	MR	NS
5.5 #10			
5.5 #11	NS	MR	MR, NS
5.5 #12			
5.5 #13	NS	MR	

A second way I sought to answer the research question was by searching for themes in why students had opened PAV and what they did once they saw the solution to the PAV problem. A first pass through all the data resulted in the following themes: sensemaking, template, troubleshooting, see form of answer, maximize score, obtain more practice, see steps, and check that one is on the right track. In order to refine the themes, determine the criteria for a data excerpt to be coded as representing a particular theme, and ensure the themes adequately described the data, I coded all the data using these themes and created a list of every instance I had coded as a particular theme. In coding the data, I coded only work a student had done or a statement specifically related to a particular problem. I did not code hypothetical statements such as "a lot of the times I'd like plug the numbers from my problem that matched up with the numbers on the practice problem" because coding only work/statements on actual problems allowed insight into the relative frequency of students' particular actions.

I used these lists to refine the criteria. I then took blank copies of the transcripts and re-coded all the data using the refined criteria to test that the criteria were specific enough and also that they described the data. The final categories and their descriptions, formed after two iterations of code/revise/code, are shown in Table 4. The results of the final coding are shown in Table 5.

Table 4. Themes in students' use of PAV

Category	Criteria
Sensemaking	Student describes using the answer from PAV to work backward; the student describes trying to understand the PAV solution or a step in it; the student describes that having read the PAV solution gave them insight or understanding into their own problem; and/or the student describes trying to follow the logic of the steps in the PAV solution; the student describes trying to work through the PAV solution steps
Template	Student says they substituted numbers from own problem into PAV steps, and does NOT say anything about having tried to understand those steps
Troubleshoot	Student has answered his/her own problem incorrectly and says (s)he opened PAV to try and diagnose where he/she made a mistake and/or to compare his/her own work to the PAV answer or solution method
See form of answer	Student says (s)he opened PAV to see what the answer would "look like"
Maximize score	Student describes wanting to see an example or do a practice problem because they have a finite number of attempts on their own problem before losing points
More practice	The researcher observes the student entering answers based on mathematical reasoning (see Table 2) or doing work/calculations with the numbers from the PAV problem for at least one part of the PAV problem; and/or the student describes doing the problem to get more practice, to see an example, and/or to check that an idea for a solution method will work. NOTE: reading through the solution is NOT doing the problem – to be coded as this category, the student has to do work with the PAV numbers and/or submit an answer based on mathematical reasoning to the PAV problem.
See steps	Student describes opening PAV to see how to do the problem
Check that one is on the right track	Student describes opening PAV to compare their work/solution (or a solution method they envision) to the PAV solution to see if their work (or idea) is correct.

Table 5. Coding based on themes (black boxes indicate the student did not use PAV on that problem)

	S10	S13	S15
5.5 #6	See steps Troubleshoot		See steps More practice Sensemaking Right track
5.5 #7	See steps Template Sensemaking		More practice See steps Sensemaking Maximize score
5.5 #8	Template See steps		Right track Sensemaking

		[redacted]	
5.5 #9	See form of answer Template See steps Right track	Senesemaking Troubleshoot	Maximize score See steps Sensemaking Template Right track
5.5 #10	[redacted]	[redacted]	[redacted]
5.5 #11	Template	Troubleshoot More practice	Sensemaking More practice
5.5 #12	[redacted]	[redacted]	[redacted]
5.5 #13	Template	Template	[redacted]

Results

The first result corresponds to the frequency with which students used PAV. Table 1 shows the problems for which PAV was available and whether students accessed PAV for that problem. Table 6 indicates the frequency of students' PAV use. While there was variation in the frequency with which students opened PAV, all students opened PAV at least once and the mean was 4.7 times ($n = 3$). The sample size is too small to conclude anything more than the fact that students do use this feature, some students more frequently than others.

Table 6. Frequency of PAV use

	S10	S13	S15
# of problems (of 8) in which student opened PAV	6 (75%)	3 (37.5%)	5 (62.5%)

The second result corresponds to the ways in which students used the PAV feature. Themes in the data indicate students opened PAV to gain extra practice, to use the worked-out solution as a template, to see the steps for solving a problem, to make sense of a solution method, to troubleshoot when their own method did not work, to see the form of an answer, to maximize their score, and to check that their method was on the right track. Of these, they most frequently used the PAV feature for sensemaking, as a template, and to see the steps to solve the problem (Table 7, specifically the rightmost column).

Table 7. Frequency of ways students used PAV

	S10	S13	S15	Row sum
Sensemaking	1	1	5	7
Template	5	1	1	7
Troubleshoot	1	2	0	3
See form of answer	1	0	0	1
Maximize score	0	0	2	2
More practice	0	1	3	4
See steps	4	0	3	7
Check that one is on the right track	1	0	3	4

As an example of how students think about PAV as a resource, S15 said of his use of PAV in problem 11, "I was just trying to understand what was happening…I was looking for similarities between what I thought was supposed to be happening and what actually was happening. And then I was trying to look at their answer and figure out the processes that they used to find that, seeing as they didn't give any of those. And then how, that if there was any, like enough similarities that like if I didn't understand the problem at all if I could plug my numbers into what they did. I try to avoid that but sometimes it comes down to it… I was able to gather what was happening from their answer. Just having something to look at, like look at their problem and look at the right answer, I was able to just, to work out what was occurring."

I coded this particular excerpt as sensemaking because S15 was trying to understand the PAV solution[2]. More broadly, the quote lends insight into why sensemaking, seeing steps, and 'template' were the most common themes. S15's goal was to understand the process and he used the similar example as an aid. However, he knew that if he could not understand it, he thought he could simply substitute his numbers into the PAV steps and obtain a correct answer for his problem. Recall that in the theoretical framing of the project, I followed Cohen, Raudenbush, and Ball (2003) as defining a milieu as a counterpart environment in which students have goals, resources, and obtain feedback on their work as they complete mathematical tasks. S15's quote is an example of how he leveraged resources to achieve two of his goals: understanding and correct completion.

Similarly, students' tendency to submit "nonsense" answers (Table 5) often reflected a goal to see how to do the problem. S10 primarily wanted to see the steps so she could use them as a template (Table 5). She said, "I just like put random things in really fast so I can see how they did it."

Discussion and Conclusions

Some answers to the research question *how do students engage with PAV in an online homework assignment?* are "frequently" (evidence: the three students access PAV a mean of 4.7 times in 8 problems), and "primarily for sensemaking, to see the steps to do the problem, and to use the steps as a template." A limitation of the analysis presented here is that it stops short of describing the details of that sensemaking and what it is students learned from the assignment. A characterization of whether or not the PAV feature helped students learn is ongoing.

Given students' overwhelming tendency to use PAV as a template for their own problem, it might seem that we should disable the PAV feature. However, results from other studies indicate this is probably insufficient for engaging students in the sorts of mathematical thinking and reasoning we would like to see in their homework. Without PAV, students frequently find worked-out solutions in their textbook and mimic those steps to solve their own problem (Dorko, accepted; Lithner, 2006, 2003). On the one hand, a student searching for a similar problem involves a bit more work than opening PAV because identifying a textbook problem as similar to one's own problem can involve some cognitive work. Lithner (2006, 2003) found students often attended to surface features in identifying similarities (e.g., two sequences with $\cos n\pi$ in the numerator) and this hurt their performance the problems had different underlying structures and required different solution methods. In contrast, students may also leverage a worked-out problem to make sense of the underlying idea (Dorko, accepted). I suggest future research investigate student learning from homework when, instead of given access to PAV, they are given hints related to the underlying structure of the problem.

---

[2] I did not code this as 'template' or 'see steps' because S15 was speaking hypothetically; the codes in Table 5 reflect codes for activity that I observed occur, or the student said occurred, in a particular problem.

Investigating the Effects of Culturally Relevant Pedagogy on College Algebra Students' Attitudes towards Mathematics

Gregory A. Downing
North Carolina Central University

College algebra continues to be a barrier for college students (particularly non-STEM majors) to graduate. The rigid teaching methods for developmental mathematics courses continues to exacerbate this issue causing failure rates among students. In an age where colleges are recruiting more students of color, these students are often regulated to these courses and are struggling to successfully complete it in one attempt. With innovate teaching strategies, this study sought to address this problem. The purpose of study was to investigate the effects of a sequence of lessons grounded in the principles of culturally relevant pedagogy on students enrolled in a college algebra course at a historically Black college/university. In particular, the study examined students' views about mathematics and its interaction with culture. Results indicated that students in this course, had positive views about this course, despite their views about mathematics coming in to the course.

Keywords: College Algebra, Equity and Diversity, Student Affect, Curriculum

College algebra continues to be a gatekeeper to graduation for many non-STEM college majors (Van Dyken, 2016). Each year, only 50% of students earn grades of A, B, or C in these courses (Ganter & Barker, 2004). This means that half the students enrolled in this entry mathematics course receive grades of D, F, or withdraw from the course. This is extremely problematic when we couple this with the fact that most college majors require students receive a C or better in this course to make adequate progress toward their degree.

Minoritized students continue to face numerous barriers to achieving in mathematics courses (Saxe & Braddy, 2015). Due to the negative side effects of "gap gazing" (Bol & Berry III, 2017; Gutiérrez, 2008) minoritized students are often regulated and oppressed under the guise of teachers "doing what is best for their students" (Higgins & Moule, 2009). This causes them to take deficit views towards the learning efforts of these students. Deficit perspectives, traditional instruction, and low expectations are factors that help influence whether students take more advanced coursework in high school. When students are not advised to take more advanced courses, they are inadequately prepared for college. This often results in students being placed in college algebra where failure rates are extremely high (Holloway, 2004). There is a clear need to help struggling students in developmental mathematics courses and to improve the way these mathematics courses are taught (e.g. Carnevale, Smith, & Melton, 2011; Fairweather, 2008; Griffith, 2010; Hurtado, Eagan, & Chang, 2010; Pascarella & Terenzini, 2005; PCAST, 2010; Rasmussen & Ellis, 2013). Researchers have explored various ways to help combat negative learning experiences for students of color by teaching for social justice and by using culturally relevant pedagogy (Gutstein, 2003; Ladson-Billings, 1995a, 1995b).

The effect of teaching with culture has been shown to have positive effects on student achievements. Studies showed that students were able to remain focused on tasks during class (Ensign, 2003) and students took a higher interest in mathematics when they were able to create problems related to their own lives (Hubert, 2014). One instructional approach that connects learning to culture is culturally relevant pedagogy. To this end, the research question that motivated this work is: *How are student's views about mathematics affected in a course centered around culturally relevant pedagogy?*

Literature Review

Gloria Ladson-Billings created a model and theoretical framework of teaching, culturally relevant pedagogy, that places cultural respect and appreciation at the center (Ladson-Billings, 1995a, 1995b, 2009). Ladson-Billings (1995b) states that culturally relevant pedagogy is "a theoretical model that not only addresses student achievement but also helps students to accept and affirm their cultural identity while developing critical perspectives that challenge inequities that schools (and other institutions) perpetuate" (p. 469). Culturally relevant pedagogy is also empowering and allows students to use cultural resources they bring to school from home in order to connect with what they are learning to society, politics, and their emotions (Ladson-Billings, 1995a). Culturally relevant pedagogy is built upon three main tenets: (1) academic achievement, (2) cultural competence, and (3) sociopolitical consciousness. Academic achievement concerns itself with student learning, focusing on what "students actually know and are able to do as a result of pedagogical interactions with skilled teachers" (Ladson-Billings, 2006b, p. 34). Cultural competence involves aiding and empowering students to recognize and honor their own cultural beliefs and practices while also acquiring access to wider cultures. Sociopolitical consciousness focuses on students becoming more conscious and aware of sociopolitical issues not only on a national or a global level, but perhaps even more so on a local level. The focus of this study is on the academic achievement tenet of culturally relevant pedagogy, thus additional relevant literature on this tenet follows.

Teachers working with and creating curricula and various curricular activities for their students in order to support student success is possible through "intensive modeling, scaffolding, and clarification of the challenging curriculum" (Morrison et al., 2008, p. 435). For example, teachers used modeling with culturally relevant pedagogy in order for mathematics to be utilized in a classroom with true constructivist teaching practices (Anhalt, Staats, Cortez, & Civil, 2018). In a study by Rubel and Chu (2012), a conceptual model for teaching was used that centered itself around three dimensions (a) teaching mathematics for understanding -- mixing mathematical concepts, procedures, and facts and also engaging students in mathematical sense-making; (b) centering instruction on students' experiences; and (c) developing students' critical consciousness through mathematics (pp. 40-41). When looking at lessons these teachers implemented (planned and enacted), it was found that teachers who had high levels of one of the dimensions also had high levels in the others. Classrooms with strong instructional environments "consistently contained tasks of high level so cognitive demand and offered students the most varied modalities of participation in mathematics" (p. 50). In weaker classroom environments students were disengaged and were prone to disruptions. These classes also "included negative intellectual support of students (by the teacher and by the other students) (p. 50).

Implications of findings by Aguirre and del Rosario Zavala (2013) suggest teachers are able to critically analyze (through self-reflection) the lessons they are offering within a specific day or an entire unit by looking at the various dimensions related to culturally relevant pedagogy. In order to maintain culturally relevant pedagogy, it begins with intentionally planning to do so, and looking at lesson plans is an integral part of promoting academic rigor amongst students.

Methods

The data for this paper was obtained from a larger dissertation study (**author citation**) which utilized an embedded mixed methods of data collection (DeCuir-Gunby & Schultz, 2017) to study the effects of culturally relevant pedagogy in one mathematics course compared to a control course that did not. In this larger study, two College Algebra and Trigonometry I courses at Bernard St. Stephen State University [pseudonym], a large HBCU in the southeast United States, were studied during the Fall 2018 semester. The two sections were taught by the researcher with one section serving as a control group (the course not receiving lessons based on culturally relevant pedagogy; yet designed lessons with effective mathematical practices (Smith & Stein, 1998; Stein, Smith, Henningsen, & Silver, 2009) and the other the experimental (intervention) group (the course where students received mathematical lessons based on the principles of culturally relevant pedagogy).

For this study, the data methods include eight (representative) student interviews conducted in the experimental group at the end of the semester after having received four lessons grounded in culturally relevant pedagogy (Matthews, Jones, & Parker, 2013) during the last half of the semester (spanning three of the five units). This data source was also triangulated with mathematics reflection journals that students completed after each experimental lesson.

Intervention

In accordance to the three paradigms of culturally relevant pedagogy (Ladson-Billings, 1995b, 2014), four lessons were developed that incorporated these dimensions. The course was divided into five units: (1) Numbers and Their Properties, (2) Linear and Quadratic Equations, (3) Graphs of Functions, (4) Higher Degree Polynomials, and (5) Exponential and Logarithmic Functions. The four lessons were incorporated into the last three units. These lessons provided students with a problem statement in which they had multiple opportunities to explore and create visual representations and vocal arguments of proposed support or denial of the statements using a data sets, mathematical manipulations, and information gleaned from websites containing information given to them by the instructor. Students also had the option and were encouraged to utilize other sources of data in order to fulfill the requirements of these assignments, frequently using their prior knowledge and past experiences of various topics in issues in society.

These lessons were intentionally developed with culturally relevant pedagogy and the population of the students in this course during this specific semester. These lessons were rated using Matthews, Jones, and Parker’s (2013) Culturally Relevant Cognitively Demanding (2011) task rubric. An example of one of the lessons was lesson three, which had the guiding questions of: What does incarceration look like in this county and the United States? Does race play a role in incarceration? In this lesson, students learned the foundations of graphing linear equations, a skill needed throughout the rest of the semester. They learn this using real incarceration data of the county where their institution was located and is also related to the race of the students in the classroom. Some of the students have had experiences with people who are incarcerated and/or are knowledgeable about the criminal justice system. Students were asked to think about the guiding questions and to use the data and their past experiences to think critically about the issue at hand which led to critical discussions of the institution of prions and their role in society and Black and African-American communities, specifically.

Results

The qualitative data presented in this section addresses the following research question related to academic achievement: *How are student views about mathematics affected in a course centered around culturally relevant pedagogy?* The reflection journals and interviews were analyzed and several themes and subthemes were identified and will be discussed below. For the purposes of this paper, the results shown will solely center around students' attitudes.

Several student attitude profiles emerged from this data, which are presented below. When describing each profile, I begin by describing who each student is in the form of a brief background to dives into who the students are, not only as learners of mathematics, but also as people. These descriptions offer more insight into who the students are beyond the information provided in the Methods section. Two students embodied each of these profiles; however, due to space, I will include only comments for one of the students.

Positive Mathematics Attitudes: Liked Mathematics Prior to this Course

This profile concerns itself with students who had positive dispositions towards the subject of mathematics and who also had positive dispositions towards the culturally relevant-based course.

Tiffany is an African-American female, first-year nursing major student who received the grade of an A in the course. She stated that mathematics is her favorite subject and she simply just "likes numbers." She attributes this partly to her mother who also likes to "do math" and does so in her career. She describes herself as a hands-on/kinesthetic learner who needs to see the mathematics that she is learning in action before she can truly feel like she understands it.

When asked about how participating in this course changed her thoughts about mathematics she enthusiastically stated:

> *Tiffany*: This course made me love math even more than I actually did. Being that I like learning stuff, I was like: oh, this is easy. This is easy. I can then relate it to the real-world stuff and everything. It was great. Yeah.

She then goes on to talk about how the course also helped reaffirm her love and abilities to do mathematics. She spends a good amount of time commenting on how this course increased her confidence in mathematics and how she was, at one point, thinking about switching to a more quantitative intensive major because of it.

> *Tiffany*: Yeah [this course increased my confidence to learn math] because now after this class, I'm like… I want to know more! Like, what else can you do with it? Yeah. I honestly, I had an opinion, like, maybe I should move my major from nursing to something dealing with math, but then it's like: not so fast! [Laughter] I think I want to stick with nursing because nursing still includes some math.

She and another student felt as if they learned a lot of mathematics throughout the course and that they enjoyed their time in the course. Both came into the course having had positive views towards mathematics and left the class feeling the same way due to the application that the mathematics afforded.

Positive Math Attitude: Just the Numbers

Students who held this disposition loved the subject of mathematics, however, that only extended to the numbers and algebraic manipulations of them devoid of the context. Asia-La'Rae, and African-American first-year student, reiterated her wish to not be in a class where culturally relevant pedagogy is done (literally) every class period. She would prefer the majority of class time be devoted to numerical manipulations and algorithmic learning of procedures. This was the preconceived notions of mathematics that she was used to and, subsequently, prefers. Students often come into mathematics courses with views of how things in a mathematics course should operate (Bennett, 2015; Cobb, Yackel, & Wood, 1992; Kuhn, 2005; Mercer, 2008) and this course conflicted with those preconceived ideas about mathematics. Challenging and pushing to change these norms can be difficult.

Asia-La'Rae elaborates on her experience in this course in the following dialogue:

Interviewer: Do you think other math classes should include lessons like these?

Asia-La'Rae: Yeah, but I will say I wouldn't do too much of it. Yeah, I guess to switch something up or do this like once every unit or every few units or something like that to kind of just get a different… A change in the class and stuff, then yes. But that's not something I would do all the time in math. No.

Interviewer: So, the only ones we did were these four. Do you think that four was too much? Too little? Just the right amount? What do you think?

Asia-La'Rae: Ummm… I don't think it was too much. I think it was a good amount and it's not like they were back to back to back. So, it was pretty good amount for what we were doing and the time we had.

Interviewer: Yeah. Time was a huge factor. So, what would you think if we would've did like one a week?

Asia-La'Rae: TOO MUCH! [Laughter]. I don't want to do that.

Asia-La'Rae's justification for why she thought lessons like these in a mathematics class should be limited came earlier in the interview when she was asked what her least favorite part of the course was.

Asia-La'Rae: Mines was actually those days where you did the comparing, you know, to stuff going on today. Sometimes, I mean, I understood it and it most definitely worked with whatever math we were doing, but sometimes I just rather just; oh yea, know the formula or know how to do it and just do the math instead of just actual like comparing it to outside world sometimes, even though I understand it but sometime I'd just rather not do that – just get straight to the point. Do the math.

Interviewer: Okay. Talk more about these lessons.

Asia-La'Rae: Yeah… [the lessons] were all relevant, I'm just saying. They most def are important to know.

Interviewer: But you'd rather just…

Asia-La'Rae: I don't know, sometimes I just, I don't feel like doing that. Like say for instance, sometimes, I don't want to answer it like, what does this graph mean, you know? I rather just... "oh yeah these are the notes for the graph Figure out those numbers and what they mean and then go about that it like… full-blown questions as if it's like reading or something of that nature because it's math and sometimes you literally want to do math numbers. That's all.

Interviewer: So, you'd rather just have the numbers – to just work with numbers?

Asia-La'Rae: Yeah.

When pressed further about her thinking on these lessons, it was revealed that she preferred mathematics devoid of context. She prefers "just the numbers" as opposed to situations where she could actually see the mathematics being used in a real-world situation. Although she still liked the course and felt like she learned, Asia-La'Rae still prefers "just the numbers" devoid of and context or applications. While the majority of students interviewed did enjoy and like (to some extent) this "change of pace" in a mathematics course, not everyone found it as helpful, and that was okay for them.

Neutral to Positive: Confidence Boost

Participants who displayed the characteristics of this profile were students who came into the course believing mathematics was simply, "ok" or they did not particularly like or love the subject, but they did not hate it either. After experiencing this course, their confidence in mathematics seemed to get a positive boost.

Matthew, an African-American male first-year student, was asked his thoughts about the subject of mathematics. His response, not surprisingly, was predicated on earlier experiences with mathematics. He stated that mathematics used to be his favorite subject, but when he got older, that changed due to bad experiences when attempting to take Calculus in high school. He had to withdraw from the course due to "how hard it was" and he attributed that to not having the right teacher who was capable of teaching him in the way that he preferred or the way that he could learn. He also stated that *"Overall, I don't have a problem with math. I think I'm actually good at it if I have a good teacher, but overall, it's okay, but it's not a big fan of mine."*

Similar to another student who exhibited the traits form this profile, Matthew, when answering a question concerning his confidence after taking this course, he stated the following:

> *Matthew*: Yeah. It boosted my confidence a lot. It really started making sense. Like I said before, it made me think I was actually good at math. It made it easier, the more math that I did… It made my confidence go to an all-time high.

Both students also expressed how they thought that the subject was "important" more so than any of the other participants, which I thought was interesting.

> *Matthew*: Yes, I do [think other math classes should include lessons like these] 'cus I feel like math is a very important subject you should have after school in the real world, but I also think it should be used in real life situations because it will open your mind up, expanding your vision, especially with real-life situation like this that's going on in the real world today.

Responses like this were surprising. Students of this profile described and acknowledged/agreed that mathematics is important, despite of their past negative experiences in mathematics, but positive experiences in this class and seeing that the mathematics they were learning being connected with the real-world and being able to see its application.

Enjoyed the Course After Entering with Negative Attitudes Towards Mathematics

Some students came into the course disliking mathematics. With this negative attitude towards mathematics, none of the student stated that they absolutely loathed the subject; however, they were very candid in their responses with regards to their feelings about the subject: their strong disliking of it. They also left the class still not particularly liking the subject; however, they did enjoy their time in the class and sees the importance and relevance of the subject, yet they still "strongly dislike" the subject.

Kanisha is an African-American female student; however, unlike the other participants interviewed, she is a non-traditional student. She is a 38-year-old woman, recently retired from serving in the military, with a 16-year-old son. She had the following to say:

> *Kanisha*: I. Don't. Like. Math. [Laughter]. I don't like math. I used to like math like um in high school. I used to get As. Algebra – As. Then I went to geometry and dropped geometry and I went to accounting and I passed that. I took accounting and college and community college and I also had to take algebra too and that's where I was just like kind of lost because there was such a big gap and I was kind of disappointed in myself because I remember getting all As. So, for graduating in 1998, I started my college in 2007 –

that's a big gap. So, it's kind of like went out the door and even; I think I took a couple college algebra courses, so even coming back to this; like my memory is really bad. Really, really bad. So, some things was kind of familiar but a lot of things like I would still have to go back like okay yeah, I might have learned this but I know it looks familiar like I remember, you know, but I don't know how to do it. So, I had to relearn it. So, yeah…. and I'm just not good with math. I'm not a big fan of math. I don't hate it 'cus I don't, but I'm not a big fan of math. Like if I had to choose, math would not be my number one.

Kanisha attributed her dislike somewhat to the fact of her past success in the subject in earlier grade levels, yet when reaching higher levels of mathematics, her success diminished as well as her disposition towards the subject. When asked if the course that she just finished taking changed her thoughts about mathematics at all, she had the following to say:

Kanisha: I would say no, but the course was helpful. Like it wasn't bad, I'm just not into math. The course was very helpful though, like very informative. I did learn, I learned some stuff. I think I'll be able to do more stuff; you know. I also think I'll be ready for the next math course I take.

Kanisha thought the class was informative and helpful. When asked if this course increased her confidence in her ability to do math, she stated:

Kanisha: Well I know I can do math. I can. It's just my comprehension is kind of slow sometimes. Yeah, I know I can do it. It's nothing that I can't do it, it just might take me a longer time. It might take some more research, some more learning but eventually I can do it. I don't believe in 'can't.'

This statement shows that she has no issues with her abilities to do the subject, only she needs more time to process information. She just needs a different set of equitable foundations in place for her to succeed in the subject. Perhaps culturally relevant pedagogy aided her in this.

Discussion and Conclusion

When the materials students engage with utilize pedagogy that was in line with students' cultures, a deeper understanding and appreciation of mathematical concepts was had by students, which was true of this present study and one also seen in by Rubel and Chu (2011). By incorporating rich mathematical problems for students to work through and think through, students were provided the opportunity to learn mathematics in a way that was meaningful and relevant for them (Anhalt et al., 2018).

Through the interviews, all students stated they enjoyed the cultural aspects of the course. Since they were able to see the connections with what they were learning and how it related to their own lives, their interest and confidence in their abilities increased. Not all students improved their attitudes towards the subject of mathematics. In particular, Kanisha and Ahshante were not completely void of negative attitudes towards the subject; however, they appreciated the change in the way the content was delivered in comparison to their previous mathematics courses.

Measuring the Effectiveness of Social Justice Pedagogy on K-8 Preservice Teachers

Gregory A. Downing
North Carolina Central University

Brittney L. Black
North Carolina State University

This study examines ways in which preservice teachers use mathematics in a social justice context. This study examines preservice teachers' conceptions of teaching mathematics using a social justice lens. Situated at a large, public, predominantly white institution in the southeast United States, where preservice teachers are not required to take a course on teaching diverse populations, participants were asked to respond to questions surrounding their experience with a mathematical social justice activity adapted from Gutstein (2005). Using the preservice teachers' responses from pre- and post-surveys, researchers were able to compare initial conceptions of teaching for social justice to understandings after an activity involving social justice topics of world wealth and population disparity. Preliminary results show that preservice teachers' attitudes shifted from naive/general notions of teaching mathematics for social justice to somewhat more concrete ideas.

Keywords: Preservice Teachers, Equity and Diversity, Instructional activities and practices

The purpose of this research is to see what, if any, knowledge preservice teachers have about topics within social justice and to see if they see the importance of using social justice in their classrooms. This is important because previous research has shown that students who are from backgrounds that are not within the dominant culture benefit from activities where they can relate content with the real world. If preservice teachers have no notions or background knowledge about social justice or whose cultural competence is low (as seen at predominantly white institutions attempting to serve underrepresented populations), then they are recklessly entering a classroom of people who do not look like them and cannot connect with the students that are found within these schools (Baily, Stribling, & McGowan, 2014). Preservice teachers should be more cognizant of teaching to a diverse population of students through social justice techniques.

The goal of this study is to examine preservice teachers' perceptions of using social justice content in mathematics classes. We want to target preservice teachers and the following research questions served as guideposts for this study: (1) *What are preservice teachers' initial conceptions of teaching for social justice?* (2) *How do preservice teachers' view the concept of social justice and its role in mathematics education?* (3) *After the intervention, what are changes in the initial conceptions of preservice teachers on teaching for social justice in mathematics?*

Theoretical Framework

Teaching mathematics for social justice has its roots grounded in critical race theory (DeCuir & Dixson, 2004; Delgado & Stefancic, 2017; Ladson-Billings & Tate, 1995). We must move towards critical mathematical literacy which emphasizes the development of the knowledge, practices, and discourses for transformative purposes (Tan, Barton, Turner, & Gutiérrez, 2012). These transformative purposes come from Freire (2000), which tells us that education should provide opportunities to understand, challenge, and recreate preconceived understandings of the self and of the world. Using Tan et al.'s (2012) framework (modified for mathematics teaching and learning only) as the source in which this research is situated (see Figure 1), in order for the teaching and learning of mathematics for social justice to become a reality, "the terms of both equity and empowerment need to be enacted" (p. 46). This study aims to illuminate how teaching mathematics for social justice can empower and provide truly equitable mathematics classroom that will strengthen students beyond school.

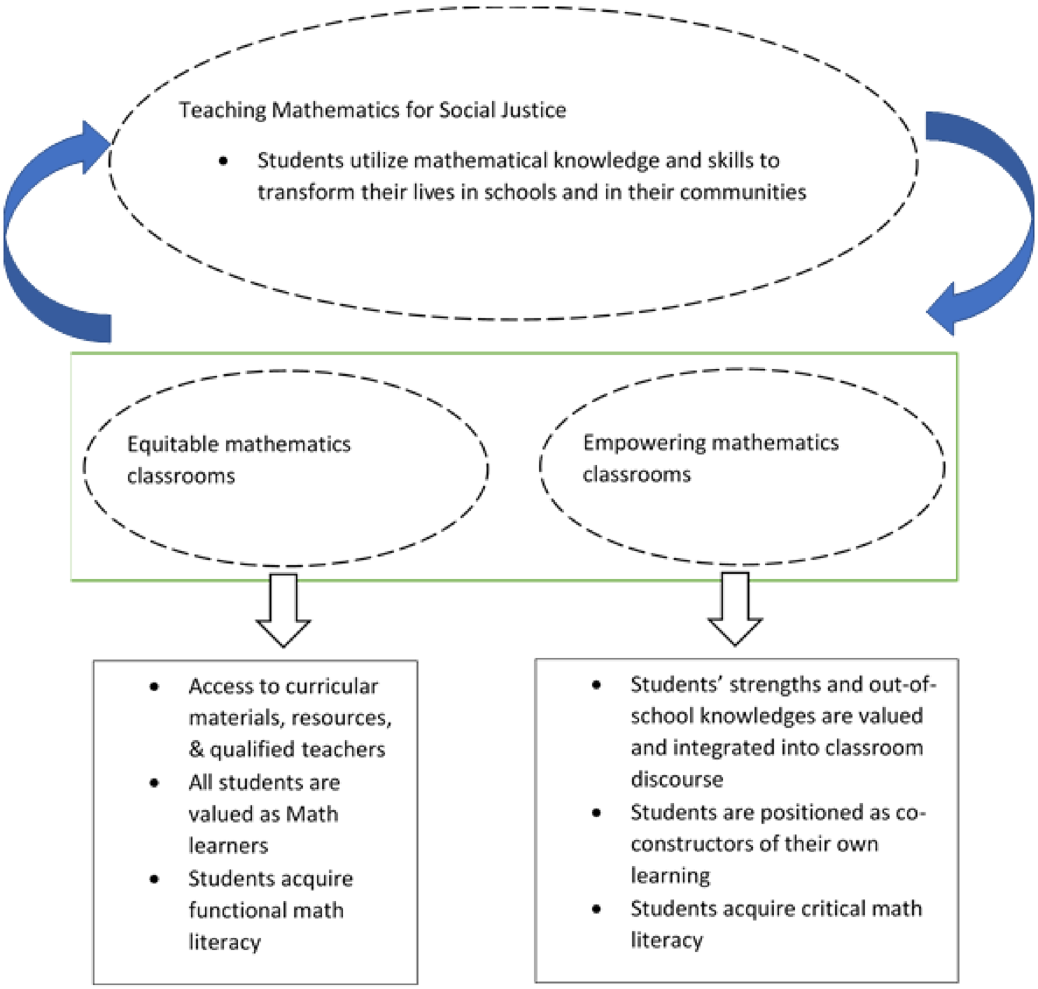

Figure 1. Modified conceptual framework on how teaching mathematics for social justice depends and supports equitable and empowering mathematics classrooms.

Literature Review

Social Justice

While there is a growing body of literature that theorizes the importance of social justice in education (Ayers, 2009; Brion-Meisels, 2009; Michie, 2009; Reynolds, 2009; Torres, 2009), there has been limited understanding of how such theory translates into practice. Researchers have tried to address how teachers engage with social justice curriculum in various forums and with various types of students (Dover, 2009; Hackman, 2005). Facilitating opportunities for university students to reach their full potential requires exposing them to a wide range of experiences, both in and out of the university environment. Students need to be challenged intellectually, as well as creatively, innovatively, politically in areas such as social justice so that they can go out into the world with their eyes, hearts and minds wide open to make it a better place (Hackman, 2005).

Equity/Diversity and Preservice Teachers

While diversity increases among the student population in public schools, the population of preservice teachers remains homogeneous – predominantly White, female, and middle class (Swartz, 2003; Barnes, 2006). One of the challenges for teacher education preparation programs is preparing preservice teachers to teach diverse student populations. An attitude of *naive egalitarianism* is prevalent among preservice teachers. This means that "preservice teachers believe each person is created equal, should have access to equal resources, and should be treated equally" (p. 34). Preservice teachers with these beliefs may lack an understanding of multicultural issues, as well as disregard effects of past and present discrimination (Causey et al., 1999; Finney & Orr, 1995).

In attempts to prepare preservice teachers for diverse student populations, teacher education programs develop multicultural education or diversity courses to address broadly defined issues such as race, class, ethnicity, gender, culture, disability, sexual orientation, and so forth (Garmon, 2004). Prior literature states some of the challenges teacher education programs experience preparing preservice teachers to teach diverse student populations (Melnick & Zeichner, 1998; Barnes, 2006; Causey et al., 1999); however, there is limited research on teacher education programs using social justice pedagogy to prepare preservice teachers to teach diverse student populations.

Teaching Mathematics for Social Justice

Prior literature tells us that if we truly wish to engage in teaching mathematics for social justice, we must attend to the "intersectional nature of justice itself" (Larnell, Bullock, & Jett, 2016). This is the idea that justice in one area (policing, housing, wealth, etc.) is linked to other issues. With that, teaching mathematics for social justice cannot be scripted nor can it be packaged as something that will work for all students in all locales (Leonard, Brooks, Barnes-Johnson, & Berry, 2010). The effort to better equip the next generation of teachers begins with these preservice teachers becoming more "self-aware, reflective, and understanding of the future populations of children that they will be held accountable for in the very near future" (Sanders, Haselden, & Moss, 2014, p. 184).

As students' mathematical ability increases, their understandings of how society works will increase as well (Gutstein, 2003). Of the research that has been conducted, very little of it has commented on the challenges that preservice teachers potentially face with such pedagogy and their possible reactions to it. This study seeks to fill these holes in the literature by providing a thorough investigation on the aforementioned holes.

Methods

Research Design and Context

This mixed methods research was conducted using a convergent mixed methodological design (Creswell & Plano Clark, 2018). This approach is the most appropriate methodological design for this study because it allows for the combination of qualitative and quantitative data in explaining and exploring phenomena. This design allows for the ability to answer the research questions using a variety of approaches in data collection.

This research was carried out at a large public university located in the southeast area of the United States. During the Spring 2017, Fall 2018, and Spring 2019 semesters, students were enrolled in either an introductory mathematics education course or one of two advanced mathematics education methods courses. Both courses were each taught by one of the researchers in this study. All survey data was blinded by the non-teaching researcher in this work.

Out of a total of 40 students that took either course, 29 completed both the pre- and post-surveys. Of these students, 22 were in the introductory, while 7 were in the advanced course. Participants included 12 males (41%) and 17 females (59%) comprised of 3 African Americans (11%), 3 Asian (11%), 1 Hispanic (4%), and 21 White (74%). All students were majoring in Mathematics Education.

Data Collection

Data collected in these courses were considered a normal part of course activities where students received a completion grade upon finishing. In the class before the activity, students were instructed to complete an eight-question open-ended (pre-)survey that gauged students' beliefs on what they think it means to teach mathematics within a social justice context. In the survey, three of the questions were demographic. Three of the questions were qualitative, requiring students to explain what they thought about the social justice and social justice mathematics pedagogy. Those questions included: *What do you think it means to teach for Social Justice?* and *How do you think teachers teach for Social Justice in mathematics?* The final qualitative question was a follow up question asking students to explain their selection from a Likert-scale agreement statement that students had to answer: *I can see myself teaching mathematics using Social Justice topics.*

The pre- and post-surveys were identical except the post-survey asked an additional question asking: *"How have your views about teaching mathematics for social justice changed since completing the pre-survey?"* with a request to explain their selection.

Intervention

In the class after the completion of the pre-survey, students participated in a mathematics activity within a social justice context (adapted from Gutstein and Peterson (2005)). During the lesson, students worked together (in small groups) to complete an activity utilizing proportions and ratios to explore the vast differences in wealth between countries around the world by combining mathematics, geography, writing, and social studies. The activity gave students an opportunity to describe and to formulate conjectures for current power and wealth disparities. During the activity, students received a blank map of the world where they had to guess how many people were in each continent/region. They then created proportions using the actual number of people in each continent/region with the number of students in the classroom to make a mathematical representation on their maps. Students then went through a similar process, but this time for the amount of wealth in the world. They represented these proportions with the number of edible treats provided (again, equal to the number of students in the class). Throughout this activity, students had to work individually and in small groups to compute the ratios and proportions and explore the vast differences between where the majority of people live versus where the majority of the wealth resides. Ultimately, through small and large group discussions, the activity connected students' feelings to the data on world wealth and whether our current world structure was "fair," what the definition of "fair" was, and who gets to decide what "fair" is. After this "intervention class," students completed a post-survey mirroring the pre-survey within three days so that the students would have ample time to reflect on the lesson and the activity.

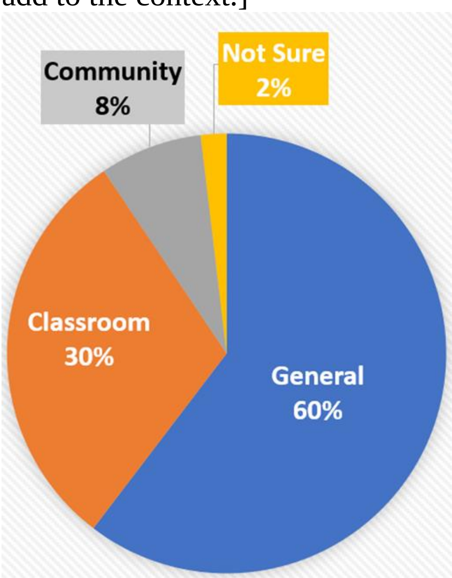
Data Analysis

Data from the pre- and post-surveys were analyzed by the authors. Analysis of the survey data began with the use of open coding in order to conceptualize what has been said by respondents (Strauss & Corbin, 1990). Codes were captured through the use of *in vivo* codes (Creswell, 2013). In order to gain reliability, two members of the analysis team independently coded and the third person mediated to address the differences and the team came to an agreement on the codes before the team progressed. Codes were then refined and a codebook was created. Analysis of the quantitative Likert question occurred using nonparametric hypothesis testing via statistical software.

Results

Research Questions 1 and 2

Preservice teacher responses were placed into three categories: General, Classroom, and Community (Figure 2). Initially, students were not confident or knowledgeable of the question: *What do you think it means to teach for Social Justice?* In the presurvey, 60 percent of the students described general statements about what it means to teach for social justice related to issues of equity and equality of individuals (General). The remaining responses, 30 percent of the preservice teachers talked about how social justice would look specifically in a classroom environment (Classroom), and then 8 percent explained how teaching social justice would look with the community in mind (Community). [Some of the responses are included in Figure 2 to add to the context.]



General	PRE
Equity and Equality	9
Help and Support	2

Figure 2. Responses from questions 4: What do you think it means to teach for Social Justice?

For the next question: *How do you think teachers teach for Social Justice in mathematics?* Student responses were placed into the same categories as previously mentioned and a Student category was added (Figure 3). The Student category included responses where participants referred to teacher-student or student-student interactions as teaching for social justice in the mathematics classroom. For the presurvey, 31 percent of the responses were placed in the student category, followed by 28 percent of responses in the classroom category. Additionally, 19 percent were general statements again related to equity and equality, while 13 percent highlighted interacting with the community as a way to teach for social justice in mathematics. The post-survey results for this same question shows a shift in the preservice teachers' responses. The participants' responses were 64 percent related to classroom interactions, while only 4 percent related to the student. The community and general categories were still consistent with the presurvey responses.

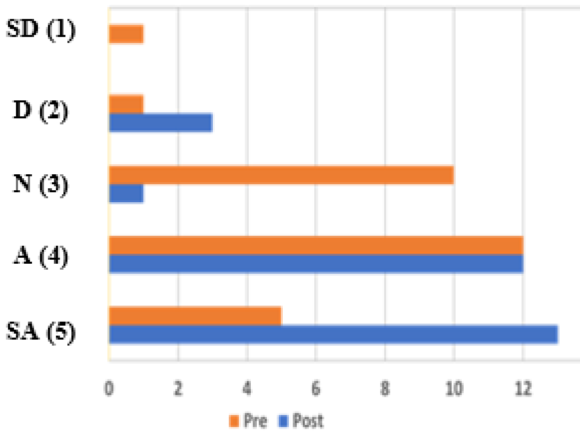
Figure 3. Responses from questions 5: How do you think teachers teach for social justice in mathematics?

Research Question 3

Question 6 was *I can see myself teaching mathematics using social justice topics*. This quantitative question was addressing research question three (left side of Figure 4). After participating in the intervention, overall, students were more positive and open to integrating social justice topics in the mathematics classroom. Most student responses on the post survey moved from general categories to classroom, teacher, and/or student related. What was more interesting are the actual movement students exhibited from pre to post (right side of Figure 4). Upward movement included seven students who shifted up from Neutral to Agree. Four students went from Neutral to Strongly Agree. One from Neutral to Strongly Agree and a Strongly Disagree to Disagree. There were two downward movements from Agree to Disagree and Neutral to Disagree.

To see if the course, as a whole showed statistically significant movement based on the interaction with social justice less, a Wilcoxon Signed Rank Test was conducted. The results of the test indicated that results from the post-survey responses was statistically significantly higher than the results from the survey responses ($Z = -2.898$, $p < 0.002$).



Student Changes	Strongly Disagree to Disagree	1
	Disagree to Agree	1
	Neutral to Disagree	1
	Neutral to Agree	7
	Agree to Disagree	1
	Agree to Strongly Agree	4
	Neutral to Strongly Agree	1
	Stayed the same	13

Figure 4. Changes pre- to post-survey for question 6: I can see myself teaching mathematics using Social Justice topics.

Discussion and Implications

Further research is needed to identify what connections there are between the social justice activities and the changes in the preservice teachers' perceptions of teaching social justice in mathematics classroom. However, these early results indicate that there may be ways to implement these strategies in more teacher education courses to prepare preservice teachers to teach diverse student populations. This research showcases the importance of preservice teachers needing exposure to teaching mathematics with a social justice lens. If they are not exposed to this style of teaching, they are less likely to either know how to do this effectively or not be privy to the benefits that their future students could experience. Due to the homogeneity of education, it becomes challenging for preservice and in-service teachers to truly find a way to debate the difficult issues that lie at the heart of social justice. It becomes safer to focus on strategies, content, and discipline in an effort to keep from having teachers and teacher educators encounter their own understandings of power, privilege and injustice. This narrow conceptualization of teaching limits the opportunities for teachers to be "relevant, purposeful, collaborative, democratic, and oriented toward social justice and equity" (Wiedeman, 2002, p. 205).

This paper presents narratives of change at three university mathematics departments in response to administrative insistence on improvements in the face of pressure from engineering colleges. Specifically, these three departments were faced with the prospect of losing calculus teaching to another unit on campus and reacted to prevent that outcome. These three departments initiated change efforts including the recruitment of newly appointed leaders to oversee improvements, and all have successfully maintained control of calculus because of perceived program improvements. Drawing on sociological perspectives, we discuss the ways in which change was navigated and negotiated at each site. We found common characterizations of change leadership limited these descriptions of complex change processes, suggesting a need to refine such characterizations in ways that capture more nuanced situations.

Keywords: Institutional change, Calculus, Leadership

Across the United States, concerns about student outcomes in calculus are driving reform efforts. Initiatives to use more student-centered pedagogy have not yet made a significant impact on teaching practices, causing leaders to consider alternatives. One such alternative is to have postsecondary calculus taught outside the mathematics department (NRC, 2013). This specter is of great concern to university mathematics departments, which traditionally provide instructional services to large proportions of undergraduates, particularly those intending to pursue STEM degrees. Removing calculus (or other) teaching from the purview of mathematics departments may decrease financial resources, including faculty and graduate student funding lines. When this specter looms, department actors face pressure to react in ways that protect resources while soothing tensions and addressing underlying concerns about student outcomes.

This paper reports on three similar cases in which the weight of concern, particularly from engineering departments, pushed university administrators to discuss the removal of calculus from the mathematics department. In these three cases, some resolution was reached through negotiations and the introduction of an actor in a new role. These three models of change in response to similar threats suggest that, with effort and collaboration, it is possible to reform calculus programs even at the eleventh hour. Though there are some similarities across these three narratives, we do not suggest that there is one “right” way to change. However, in each narrative, actors in new roles brought outside perspectives while navigating organizational politics at the department, college, and university levels to take steps in the right direction. In each case, these actors restored harmony and improved student success rates in calculus. We focus particularly on the position and roles of these actors rather than the structural changes they supervised, engaging in questions of agency and leadership that can be critical to institutional and departmental change.

Literature Highlights

Universities across the country are seeking to engage in change processes to address persistent concerns about gateway courses (Kezar, 2014; Koch, 2017). Mathematics and other STEM disciplines are contending with low passing rates in foundational courses taken by students in a variety of majors, which have an outsized impact on students' ability and likelihood to complete their degrees and pursue STEM careers (e.g., Seymour & Hewitt, 1997). In response, departmental actors are developing new structural supports and implementing research-based pedagogies. These intentional and planned programmatic changes are designed to accomplish specific goals and outcomes, which separates them from ongoing, unintended, and/or evolutionary changes (Kezar, 2014).

Efforts to enact change in higher education have been deployed at a variety of scales, ranging from individuals to entire institutions (Kezar, 2014). Here we chose to focus primarily within departments because of their relative coherence in terms of policies and norms. Individual departments are generally responsible for designing their own courses. They also represent semi-coherent cultural systems at the intersection of the institution (university) and discipline (mathematics), thus providing an avenue for students to connect to the broader (STEM) landscape (AAC&U, 2014; J. J. Lee, 2007; V. S. Lee, Hyman, & Luginbuhl, 2007). However, efforts to change instructional practice one department at a time have not shifted the status quo away from lecture (e.g., Stains et al., 2018).

Theoretical Perspective

Assessments of change initiatives that have "failed," either to initiate the desired changes or to sustain them long-term, have been attributed to many factors, including the use of implicit, underspecified, and/or narrow theories about change that do not attend to local culture and community factors (Henderson et al., 2011; Kezar, 2014; Reinholz & Apkarian, 2018; Schein, 2010). In this work, we leverage sociological and organization theory to describe and assess the change activities and their impact.

We take a sociologically oriented theoretical perspective to understanding departments and institutional change. At the macro-level, we draw on sociological institutionalism, which is part of the new institutionalism movement within political science (Hall & Taylor, 1996; Ingram & Clay, 2000), and communities of practice (COP) as operationalized by Wenger (1998) and extended by Brown and Duguid (2000). These approaches are consistent in their attention to norms and expectations that inform and constrain the choices available to institutional actors and the consequences of those choices. Both perspectives suggest that individual actors, their behaviors, and beliefs cannot be properly understood outside of the local contexts and communities that constrain not only what people think and do, but what is within the realm of perceived possibilities for thinking and doing.

To frame our results, we leverage Kezar's (2014) four-part framework for understanding change in higher education: (1) identifying the type of change; (2) unpacking the context of change; (3) considering agency and leadership throughout the change process; and (4) combining these to identify an overarching approach to change (Kezar, 2014). For our analyses, we first employed Kezar's (2014) framework to identify the type of change that occurred at each site (i.e., content, focus and sources) as well as the context of the change (e.g., institutional culture, stakeholders). Our analysis foregrounds the third frame, highlighting the roles of particular change agents as they become more central members of their new communities and make choices impacted by the context and culture of their institution (Hall & Taylor, 1996; Ingram & Clay, 2000; Kezar & Gehrke, 2015; Wenger, 1998).

Methods

This work is part of Phase 2 of the Progress through Calculus research project (PtC; NSF DUE No. 1430540; maa.org/ptc). Phase 1 of PtC involved a national survey of university mathematics departments about their Precalculus to Calculus 2 (P2C2) courses and programs; Phase 2 consists of case studies of twelve university mathematics programs. These case studies involve both qualitative and quantitative data collection. Each site was visited by research team members multiple times across two academic years, during which semi-structured interviews were conducted with at least 20 instructors, faculty members, teaching assistants, students, staff, and administrators at each site. Surveys were also distributed to students and instructors each term to gather data about instruction and students' experiences in the P2C2 courses. The design of our research questions and interview protocols draws from previous studies of college calculus (Bressoud, Mesa, & Rasmussen, 2015), and the project evolved to focus on four main themes: (1) course variations; (2) diversity, equity, and inclusivity; (3) course coordination; and (4) change. Here we draw on interview data specifically related to the theme of change.

After completing the data collection visits, project personnel reflected on the totality of the site and drafted thick descriptions. The analysis team read these thick descriptions and conducted an initial analysis of the narratives. Then, using the first two stages of Kezar's (2014) framework, we identified three sites for further analysis since many features of the type and context of change appeared to be similar. Additionally, at each site, our analysis suggested that multiple actors agreed the departmental context had improved as a result of the change process. We then began to cycle through the data and relevant research literature. These iterative phases allowed us to reflexively develop change narratives within the first three pieces of our framework, informed by research on institutionalism, institutional change, and communities of practice.

The three universities being compared in this proposal are referred to as River Rock University (RRU), Rolling Hill University (RHU), and Desert Bloom University (DBU). All three are large public universities classified as R1 institutions (doctoral institutions with very high research activity) and offer both master's and Ph.D. degree programs in mathematics (IUCPR, n.d.; NCES, 2018).

At the end of the reflexive phase, we settled on a framework for understanding change that highlighted six aspects of the process: the reason for the change, who instigated the change, the mathematics department's reaction to calls for change, the role of change agents in the mathematics department, the changes made, and continued monitoring evaluation of change. With these features in mind, the analysis team read relevant interviews from the site visit (e.g., deans, department chairs, client disciplines) in order to understand and describe nuanced features of the change process.

Results

The stories of change at RRU, DBU, and RHU all started similarly: engineering increased pressure on the math department to make changes; upper administrators got involved to force a change; and a new hire entered the scene to drive those changes. We first review the common aspects of the types of change and context for change, highlighting similarities in what led up to the change initiatives. This is followed by separate reports of who was brought to the university and in what capacity, the types of change initiated, and some consideration of leadership and agency within that initiative.

Shared Context of Change

The three institutions experienced a similar problem: high DFW rates that were affecting undergraduates majoring in engineering, the largest client discipline of the math department. While concerns had been building for some time, each institution experienced a "last straw" event. At RRU, a new placement system had recently been enforced, resulting in engineering students being placed further back in the sequence, increasing their time to graduate. At DBU, after years of dissatisfaction with the math department, a semester with particularly high DFW rates was all it took. At RHU, the calculus situation was brought to the attention of a large influential donor who demanded change and threatened to pull his donations until "they did something about the math department" (RHU, S18).

Along with high DFW rates, each engineering division also had the leverage necessary to involve upper administration, which acted as a major catalyst for addressing concerns. Through different means, the problems were brought to the attention of the Provost, who issued a similar threat to each math department: fix the problem or lose calculus (and other courses). Facing this threat, department actors negotiated with administrators and engineering faculty members to begin forging a plan for change. At all three sites, negotiations resulted in the hiring of at least one person to join the department and take on a central role to improve the calculus program.

Differentiated Responses from the Departments

Although each site hired at least one person to take the lead, newcomers' relationships to the university and department varied significantly, as did the plans for change that they created and oversaw. In this section we present narratives of each institution's change story including the department's response and position of the new hire, changes made by the new hire, and current status and continued monitoring.

River Rock University. Determined to show that they were serious about keeping their calculus courses, representatives of the mathematics department met regularly with stakeholders in engineering for several months to negotiate a plan. At this time, the engineering department was under pressure to graduate more engineers and clearly outlined their needs during early negotiations: get students through calculus faster, "fix" placement, and include more applications relevant to engineers. Leading these negotiations was the math chair at the time. His strategy was to cooperate with the engineering department while making sure he had the resources necessary to support their demands. As he described, "[T]he approach we took was to be very accommodating to their needs with the understanding that well, what they were asking was probably gonna take a little bit more in the way of resources" (RRU, Sp19). In response, the committee agreed to hire someone external to the department with the appropriate expertise to design and coordinate a new engineering calculus sequence, who we refer to as James. James was hired in a non-tenure track role, making him officially a part of the mathematics department, but in a role often viewed as peripheral by research faculty at R1 universities.

With funding in place, the new coordinator was hired to design the new engineering courses and met with a committee of content experts to create a pilot. What resulted was the curriculum was trimmed and rearranged to streamline three semesters of calculus into two semesters, and lab sections were created where students would work in small groups on applied problems. These changes also impacted graduate students' experiences with instruction at RRU. First-year graduate students went from teaching their own classes to leading lab sections for engineering calculus, which resulted in more mentoring opportunities.

Overall, the changes are perceived to be successful, as one influential department member stated, "I know the dean of the College of Engineering is very happy with the sequence. They feel the students are being better trained, better educated" (RRU, Fa17). Part of James's role is to act as the liaison between math and engineering, positioning him to act as a broker between communities. He hosts annual meetings with the engineering committee to share local data and solicit feedback. These meetings ensure that math standards are kept high as perceived by the math department while still meeting the needs of the engineering department. These meetings also serve to keep the stakeholders in communication, to ward off future issues by recognizing and addressing them in a timely manner.

Rolling Hill University. Initially, the math department at RHU was not given the chance to negotiate a solution to the problem. For some time, the math department had been perceived as having a bad attitude with an unwillingness to change. With the threat of the loss of an important donor, the Provost declared that math would become a small research department and be almost entirely stripped of their undergraduate teaching responsibilities. In reaction, the mathematics department reached out to an influential member (Don), who was at the time a research fellow outside the U.S. and unaware of the building crisis. He immediately made calls to friends in higher administration, used his status/connections to contact the Provost, managed even to contact the donor, and convinced them that he could solve communication problems between math and client disciplines and address the problems with calculus:

> [B]y me knowing these people when I called them, [...] and they said 'well nobody talks to us in the math department' and that was a big problem over time: the leadership of the math department would not listen to complaints [...] so I said that you know that they can talk to me, that I'll talk to them about it and we [will] try to do something (RHU, Sp18).

Following these conversations, it was decided that Don would return to the math department at RHU as department chair. That he was capable of contacting people across the university indicated that he arrived in this new position already having some legitimacy in multiple communities, with the potential to broker across disjoint communities with dissimilar values.

Don began immediate work to change the "face" of the department. One of his first moves was to appoint a new associate chair, Fred. Together they set out to: (1) change the impression that the department is unfriendly and uncaring toward students, and (2) improve DFW rates by supporting student learning in introductory courses. The first goal involved primarily public relations, and Don instituted a new department policy of "don't be a jerk," asking members to cooperate and work *with* others on campus. To the second, a committee was convened which outlined a three-year plan and the budget required to carry out that plan; following some negotiation this plan and the budget were approved by administrators. Both members of this new leadership team were well-known and respected faculty members in RHU, and that centrality facilitated acceptance of the changes that they introduced:

> [T]his was not going to work with folks who were not respected by their faculty at all and that they had the right... dynamic, engaging, listening personalities to do that outward outreach across campus and really listen and hear and do that gracefully, that's hard. I think the stars aligned for us that we had two super well-respected faculty within the department with the personality and leadership skills to pull this off (RHU, Sp18).

As Don and Fred became central members of the department, the community opened up to cooperating with other stakeholders and changing their departmental practices. The committee's plan included hiring math education-focused faculty, renovating the placement system, instituting a Supplemental Instruction program, improving the learning center, and developing a new co-requisite calculus course. These have all been put into place, adjusted along the way to accommodate evolving state legislature constraints.

During the first year of Don's return to RHU to make changes, the Provost who issued the initial threat was replaced but those involved continued to work for improvement. Now the status of the department seems to be stable, with improved DFW rates and, as the (new) Provost noted, "[T]he reputation that they have on campus and off I mean they- they've become you know state and national leaders in how to implement placement and co-requisite and how to be nice" (RHU, Sp18). The new attitude of department members toward collaboration across departments has resulted in maintained communication about the new program across stakeholders.

Desert Bloom University. At DBU, the Provost's threat to take calculus courses away from the math department was presented as a last resort, with the hope that mathematics, engineering, and administration could negotiate a solution which kept the calculus courses under the purview of the mathematics department. This process started with a series of meetings where each party pitted the blame on the other: "[T]here was three meetings of us yelling at each other before people calmed down and said okay what are we gonna do?" (DBU, Fa17). Eventually, it was decided to make an external hire, and an interdepartmental committee was formed to find someone to be the lead on improving the calculus courses. The committee unanimously agreed on the best candidate during the search process and hired a man we refer to as Kevork.

To avoid tension between tenure-track demands and calculus directorship, a 5-year staff appointment through the Provost's office was created for the new hire, but who would not be filling the position of a mathematics researcher nor faced with the hurdle of achieving tenure on top of managing the calculus improvement efforts. Though funding for the new hire came from the Provost's office, the math department was threatened with a hiring freeze until the position was filled, which increased pressure to find someone quickly. Kevork's position lives in between several groups within a university that had been at odds with each other, coupled with his staff appointment, put him in a peripheral position with respect to multiple communities while the expectation was for him to broker between groups and lead a new system - an inauspicious start.

Although funded and reviewed through the Provost's office, the new hire is functionally part of the math department in terms of his teaching and service requirements. He came in with big ideas for change, but in order to ensure everyone's needs were met, he spent his first year working with others to develop relationships and design a more detailed plan that addressed the needs of multiple stakeholders:

> [H]e met with the engineering departments, and he met with the chemistry department, and the physics department and all of the different, you know, areas, economics, and said 'what do your students need to know to be able to do their work successfully?' and then he met with his colleagues in the math department (DBU, Fa17).

Kevork had the idea to divide calculus into half-term modules at the time of his initial interview, which was refined and adapted to meet the constraints of the university during that first year. Following discussions, each semester of calculus was divided into two half-semester courses. This allows for finer-grained placement into the calculus sequence, more consistent waypoints for students, faster catch-up opportunities for those who fail a course, and a full seven weeks focused on infinite series. The distribution of content among these courses was done in consultation with the mathematics and other stakeholder departments to ensure alignment of objectives. Similar to RRU, the new courses presented mentoring opportunities for graduate students teaching calculus as the new calculus director worked more closely with them.

Passing rates in calculus and first-year retention rates have soared, and the math department remain satisfied with the rigor of the current courses. The interdisciplinary committee formed to find a solution continues to meet twice a semester, with the new hire also in attendance to report on the current status and preemptively address any new concerns; they currently spend a lot of time celebrating successes. The committee is charged with monitoring and evaluating student success in the calculus courses, including careful analysis of available student data.

Discussion and Conclusion

We have presented brief overviews of the processes of change in three mathematics departments when faced with the prospect of losing calculus due to the negative impact of course outcomes on large engineering schools. All three are examples of success, and all three involved the creation of new roles which connected stakeholders and concentrated responsibility in a new actor. The structural changes varied, but we focus on the variation in agency and leadership within the varied institutional contexts. The new actors were assigned different status based on their formal appointments: Don (RHU) was appointed as chair of the mathematics department, James (RRU) was hired as a non-tenure-track faculty member of the mathematics department, and Kevork (DBU) was hired as a staff member under the Provost's auspices. All three have membership in multiple communities at their respective institutions, including: the mathematics department (all), administration (Kevork, Don), and engineering (Kevork, James). Interviews with these three, and others, suggest that they are seen as legitimate participants in the communities which they have membership in, and thus are positioned to act as brokers. Deeper analysis will explore the extent to which this brokering opportunity was taken up, but it is clear that each acted as a broker in some ways (Brown & Duguid, 2000; Wenger, 1998).

Descriptions of change leadership are often collapsed into dualistic concepts like top-down vs. bottom-up and shared vs. collective approaches (Kezar, 2014). While evocative and straightforward, these phrases can obscure the complex ways in which power is distributed through formal hierarchies and social factors (Hall & Taylor, 1996; Schein, 2010; Wenger, 1998). In framing the study, we found that these categorizations were insufficient for making sense of what happened. We see many layers of change agent within each story, with varying motivations and power. For example, while at each site there was intense pressure from "the top" that catalyzed change, the strategies were designed from "the bottom" by members of the mathematics department, some of who were quite peripheral participants in that community. Our future goals include a more in-depth analysis of power, agency, and leadership factors as contextualized by the institutional contexts to provide more nuanced understandings of what constitutes a change agent in postsecondary departmental change initiatives.

Empirical Re-Conceptualization: Bridging from Empirical Patterns to Insight and Understanding

Amy Ellis	Elise Lockwood	Alison Lynch
University of Georgia	Oregon State University	CSU Monterey Bay

Identifying patterns is an important part of mathematical investigation, but many students struggle to explain or justify their pattern-based generalizations or conjectures. These findings have led some researchers to argue for a de-emphasis on pattern-based activities, but others argue that empirical investigation can support the discovery of insight into a problem's structure. We introduce a phenomenon we call empirical re-conceptualization, in which learners identify a conjecture based on an empirical pattern, and then re-interpret that conjecture from a structural perspective. We elaborate this construct by drawing on interview data from undergraduate calculus students and research mathematicians, providing a representative example of empirical re-conceptualization from each participant group. Our findings indicate that developing empirical results can foster subsequent insights, which can in turn lead to justification and proof.

Keywords: Generalization, Patterns, Conjecturing, Justification

Introduction and Motivation

Identifying patterns is a fundamental aspect of mathematical activity, with curricular materials and instructional techniques geared towards supporting students' abilities to leverage empirically-based generalizations and conjectures. However, forming pattern-based conjectures is not sufficient; it is also important for students to understand and justify the patterns they develop. A robust body of research reveals a common phenomenon whereby students are able to leverage patterns in order to develop conjectures, but then struggle to understand, explain, or justify their results (e.g., Čadež & Kolar, 2014; Mason, 1996; Pytlak, 2015; Zazkis & Liljedah, 2002). Indeed, these findings have led some researchers to argue for a de-emphasis on pattern-based activity, dismissing it as unsophisticated (e.g., Carraher et al., 2008; Mhlolo, 2016).

In contrast, we have observed a phenomenon we call *empirical re-conceptualization*, in which participants identify a pattern based on empirical evidence alone to form a conjecture, and then re-interpret their conjecture from a structural perspective. In this paper, we address the following research questions: (a) What characterizes students' and mathematicians' abilities to leverage empirical patterns to develop mathematical insights? (b) What are the potential affordances of engaging in empirical patterning activity? We describe and elaborate this construct across two participant populations, mathematicians and undergraduate students. In this manner, we highlight empirical re-conceptualization as a phenomenon that marks productive mathematical activity at multiple levels and populations. Our findings indicate that developing results from empirical patterns, even those that are poorly understood or unjustified in the moment, can serve as a launching point for subsequent insights, including verification, justification, and proof.

Literature Review and Theoretical Perspectives

There is ample evidence that students are adept at identifying and developing mathematical patterns (e.g., Blanton & Kaput, 2002; Pytlak, 2015; Rivera & Becker, 2008). However, the patterns students identify may not always be those that are mathematically useful. As Carraher et al. (2008) noted, a pattern is not a well-defined concept in mathematics, and there is little agreement on what constitutes a pattern, much less its properties and operations. Students who do identify patterns can then experience difficulties in shifting to algebraic thinking (e.g., Čadež & Kolar, 2015, Moss, Beatty, McNab, & Eisenband, 2006; Mason, 1996). Further, both secondary and undergraduate students who work with patterns struggle to justify them (Hargreaves et al., 1998; Zazkis & Liljedah, 2002). An emphasis on empirical patterning without meaning can promote the learning of routine procedures without understanding (Fou-Lai Lin et al., 2004; MacGregor & Stacey, 1995), or the generalization of a relationship divorced from the structure that produced it (Küchemann, 2010). Further, students' challenges with extending pattern generalization to meaningful learning has been shown to contribute to difficulty in multiple domains, including functions (Ellis & Grinstead, 2008; Zaslavsky, 1997), geometric relationships (Vlahović-Štetić, Pavlin-Bernardić, & Rajter, 2010), and combinatorics (Kavousian, 2008; Lockwood & Reed, 2016), among others.

Despite these drawbacks, researchers also point out the affordances of empirical investigation and pattern development. The activity of developing empirically-based conjectures can support the discovery of insight into a problem's underlying structure, which can, in turn, foster proof construction (Tall et al., 2011; de Villiers, 2010). The degree to which pattern generalization is an effective mode of proof development is an unresolved question, but there is evidence that students can engage in a dynamic interplay between empirical patterning and deductive argumentation (e.g., Schoenfeld, 1986). Similarly, research mathematicians regularly engage in experimentation and deduction as complementary activities (de Villiers, 2010). It may be that students become stuck in a focus on empirical relationships divorced from structure because they lack sufficient experience with this way of thinking. Küchemann (2010) found that with practice, students could learn to glean structure from patterns. Similarly, Tall et al. (2011) argued that attention to the similarities and differences in empirical patterns could support the development of mathematical thinking and proof. These works offer a precedent for positioning empirical patterning as a bridge to insight and deduction.

Structural reasoning. Harel and Soto (2017) introduced five major categories of structural reasoning: (a) pattern generalization, (b) reduction of an unfamiliar structure into a familiar one, (c) recognizing and operating with structure in thought, (d) epistemological justification, and (e) reasoning in terms of general structures. The first category, pattern generalization, further distinguishes between two types of generalizing: *Result pattern generalization*, and *process pattern generalization* (Harel, 2001). Result pattern generalization (RPG) is a way of thinking in which one attends solely to regularities in the result. The example Harel gives is observing that 2 is an upper bound for the sequence $\sqrt{2}$,$\sqrt{2 + \sqrt{2}}$, $\sqrt{2 + \sqrt{2 + \sqrt{2}}}$, … because the value checks for the first several terms. RPG is typically the type of pattern generalization observed in studies in which students then struggle to shift from recursive to explicit relationships or justify their patterns (e.g., Čadež & Kolar, 2015; Schliemann, Carraher, & Brizuela, 2007). When we refer to the identification of a pattern based on empirical evidence, we are referring to RPG. In contrast, process pattern generalization (PPG) entails attending to regularity in the process, even if that attention may first be initiated by noticing a regularity in the result (Harel, 2001). To extend the above example, Harel discussed how one might engage in PPG to determine that there is an invariant relationship between any two consecutive terms of the sequence, $a_{n+1} = \sqrt{a_n + 2}$, and therefore reason that all of the terms of the sequence are bounded by 2 because $\sqrt{2} < 2$.

We define empirical re-conceptualization as the process of re-interpreting a generalization or conjecture from a pattern (identified by RPG) from a structural perspective. By structural perspective, we mean the five major categories of structural reasoning, with the exception of the RPG sub-category of pattern generalization. Thus, a student could reason about the regularity in process from one term to the next of a sequence (PPG). One could also reduce unfamiliar structures into familiar ones, either by constructing new structures or by forming conceptual entities. One may also carry out structural operations in thought without performing calculations, reason in terms of general structures (either by reasoning with conceptual entities or reasoning with operations on conceptual entities), or engage in epistemological justification. In short, re-interpreting a generalization or conjecture from a structural perspective entails the ability to recognize, explore, and reason with general structures.

Figurative and operative thought. The other construct we draw upon to characterize the phenomenon of empirical re-conceptualization addresses a distinction in mental activity (Piaget, 1976, 2001; Steffe, 1991; Thompson, 1985). When engaged in figurative activity, one attends to similarity in perceptual or sensorimotor characteristics. In contrast, operative mental activity entails attending to similarity in structure or function through the coordination and transformation of mental operations. For instance, a student could associate the sine curve with circular motion through conceiving both as representing an invariant relationship of co-varying quantities (an operative association), or through conceiving both as smooth because the motion is perceived as continuous (a figurative association) (Moore et al., 2019). A shift from RPG to PPG is often accompanied by a shift from figurative to operative mental activity, and we consider operative activity to be a hallmark of the ability to reason structurally.

Methods

We drew on interview data from two participant sources, mathematicians and undergraduate students, both stemming from larger projects investigating participants' use of examples to generalize, conjecture, and prove.

Mathematician data. The mathematician data consisted of two sets of hour-long interviews. Thirteen mathematicians participated in Interview 1, and 10 continued for Interview 2. The participants included 7 professors, 3 postdoctoral researchers, and 3 lecturers. Twelve participants hold a Ph.D. in mathematics, and one holds a Ph.D. in computer science. There were 8 men and 5 women. Each interview presented two novel mathematics tasks, which were chosen to be accessible (i.e., they did not require specialized content knowledge) but not trivial (i.e., a solution was not immediately available). For the purposes of this report, we focus on the *Interesting Numbers Task* (Andreescu, Andrica, & Feng, 2007), which we phrased as follows: "Most positive integers can be expressed with the sum of two or more consecutive integers. For example, 24 = 7 + 8 + 9, and 51 = 25 + 26. A positive integer that cannot be expressed as a sum of two or more consecutive positive integers is therefore interesting. What are all the interesting numbers?" Below we highlight an exemplar from one mathematician's work on the interesting numbers task, the work of Dr. Fisher.

Undergraduate data. The undergraduate data consisted of a set of hour-long individual interviews with 10 undergraduate male calculus students. The students solved a set of tasks designed to engender generalizing activity (and ultimately to generalize the binomial theorem). For this paper, we report on the *Passwords Task*, which asked students for the number of passwords of length 3, 4, 5, and eventually length n, which consisted of the characters A or B, where repetition was allowed. We asked the students to create tables to organize passwords with a certain number of As, and we also had them reason about the total number of passwords of a given length. Below we focus on one student's work, Raoul, and his reasoning about the total number of length n AB passwords.

Analysis. All interviews were videoed and transcribed, and were also recorded with a Livescribe pen, which yields both an audio record of the interview and a pdf document of the participant's written work. We used gender-preserving pseudonyms for all participants. Using the constant-comparative method (Strauss & Corbin, 1990), we analyzed the interview data in order to identify the participants' generalizations and conjectures and to characterize the mental activity that fostered them. For the first round of analysis we drew on Ellis et al.'s (2017) *Relating-Forming-Extending* Framework for generalizing, which yielded the emergent category of empirical reconceptualization. In subsequent rounds we further examined the participants' talk, gestures, and task responses to further refine the characteristics of empirical reconceptualization.

Results

In order to characterize the participants' abilities to leverage empirical patterns to develop mathematical insights, we present two exemplar cases of empirical re-conceptualization, one from each participant group. In both cases, the participants began with an empirically-based conjecture that they did not understand and could not justify. That initial conjecture, however, then served as a launch point to engage in empirical reconceptualization.

Mathematician Case: Dr. Fisher

Dr. Fisher is a mathematics professor at a large public university. She initially approached the Interesting Numbers Task algebraically by expressing the non-interesting numbers as $m + (m+1) + \cdots + (m+k-1)$. After trying to simplify that expression, she switched to a different approach, in which she listed all of the interesting numbers by ruling out those that were non-interesting. She checked the first numbers 1 to 7 in her head, noting that 3 = 1+2, 5 = 2+3, 6 = 1+2+3, and 7 = 3+4, so only 1, 2, and 4 were interesting. Then she realized she could list all of the non-interesting numbers as sums in an organized table (Figure 1):

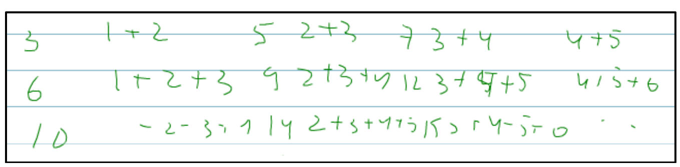

Figure 1. Dr. Fisher's initial table.

Using her table, Dr. Fisher was able to rule out every number up to 24 other than 1, 2, 4, 8, 16, 19, and 23. She recognized the pattern in the first five terms as the powers of 2 and (correctly) conjectured that the interesting numbers were the powers of 2. She made this conjecture even though she had not yet been able to rule out 19 and 23, noting that, "19 and 23 are sort of bothering me from the power of 2 that is showing up in the pattern." Dr. Fisher's conjecture emerged from RPG and figurative activity, in which she noticed a familiar pattern in the (incomplete) data. However, at this time she had no sense of why it should continue.

To determine why the powers of 2 were interesting, Dr. Fisher rewrote her table (Figure 2). She then suddenly noticed a structural pattern in the sums, observing that the sums in the second column could be obtained from the sums in the first column moving diagonally by removing the "+1". Similarly, she saw that the sums in the third column could be obtained from the sums in the second column moving diagonally by removing the "+2". In other words, when moving diagonally up the table, 1+2+3+4 becomes 2+3+4, which becomes 3+4.

1	2	3
1+2	2+3	3+4
1+2+3	2+3+4	3+4+5
1+2+3+4	2+3+4+5	3+4+5+6
1+2+3+4+5	2+3+4+5+6	3+4+5+6+7

Figure 2. Dr. Fisher's refined table attending to sums.

Dr. Fisher: Oh. I see. I see what's happening. […] So, what I see here is that they differ by 1, right? And then they differ by 2. Right? So, I have these numbers [in the first column] and then automatically get these minus 1. […] And then I automatically get those numbers minus 1 and then I get them minus 2 also. And then I get the minus 3 et cetera. So, this actually should tell me most of them by just subtracting.

This insight led Dr. Fisher to formalize the non-interesting numbers as $\binom{n}{2} - 1 - 2 - \cdots - k$, which she simplified to $\binom{n}{2} - \binom{k}{2}$. However, she still did not understand why the powers of 2 did not have that form. To try to answer that question, she returned again to the table and rewrote a third version, this time listing the values of the sums rather than the sums themselves (Figure 3). She evaluated the first row of sums (1+2, 2+3, 3+4, …), then filled in the rest of the table using the diagonal relationship she observed earlier.

3	5	7	9
6	9	12	15
10	14	18	22
15	20	25	30

Figure 3: Dr. Fisher's third refined table.

During this activity, Dr. Fisher noticed a pattern in the second row, "Now what I'm getting here is that these are multiples of 3. Yes, I got it!" To prove this observation, she represented an arbitrary element of the first row by $2k+1$, then used the diagonal relationship to justify that the next element down the diagonal would be $(2k-1) + (k-2) = 3(k-1)$. She gave a similar proof for the multiples of 5 appearing in the 4th row, then realized that a generalized version of the argument would prove that every multiple of $2k+1$ (above a certain point) will appear in the $2k$ row. Her argument proved that every multiple of an odd number is non-interesting, so every interesting number must have no odd factors (i.e. be a power of 2).

Dr. Fisher initially engaged in RPG, generating a conjecture based solely on the numerical pattern she observed in her list of interesting numbers. Once she had the conjecture, however, she shifted from figurative to operative activity, attending to how the sums changed as the number of summands and starting value changed within her table. Through her analysis of the structural relationships in the data, Dr. Fisher was able to engage in multiple rounds of PPG, forming generalizations that led to a partial proof of her conjecture.

Undergraduate Case: Raoul

Raoul was an undergraduate calculus student at a large public university. In his work on the Passwords Task, Raoul leveraged an empirical pattern to develop a conjecture that for an n-

character password made of As and Bs, there would be 2^n total passwords. In the excerpt below, Raoul explained that he saw the pattern based on his prior work determining 3-character, 4-character, and 5-character passwords. However, he did not understand why the total number of passwords was 2^n:

Raoul: Over here I get, for 3 characters, I get 8 numbers. Four characters, 8 times 2, 16. Five characters, 16 times 2. Oh! 2 power *n*.
Interviewer: Okay. Why did you think that?
Raoul: Well I guess, I just started seeing the pattern. I mean 8 is the 2 cubed. I knew that, and I knew that 5 is…no sorry, 32 is 2 power 5. I knew that too, and here is the same, 2 power 4.
Interviewer: Okay.
Raoul: So, I guess, 2 power *n*.
Interviewer: Cool and can you explain, so, why does that make sense? Does it? Why do you think that's true?
Raoul: Um, it doesn't make sense to me why it has to be 2 power *n*. Two power *n*. I have no idea.

Raoul recognized the familiar numbers 8, 16, and 32 as powers of 2, a recognition based in figurative activity. He then engaged in RPG, conjecturing that an *n*-character password would have length 2^n, but he could not justify it combinatorially. The interviewer then asked Raoul why the number of passwords doubled from 4 to 5 characters:

Interviewer: Why would it make sense, let's say from 4 to 5 it doubles, times 2. Why would there be twice as many possibilities here as there were in the 4 case?
Raoul: That's what I'm trying to think. If I can figure that out, I would be able to find why it makes sense to be 2 power n.
Interviewer: Okay, what would you guess for a 2-character password?
Raoul: Two-character passwords? Four.
Interviewer: Okay, how about for 1-character password?
Raoul: There'd be only 2. A and B, so if it's 2, AB, AA, BA, BB. Hmm. Oh, hold up.

Reflecting on a 1-character and 2-character password, Raoul experienced an insight. He began to relate the doubling phenomenon to the combinatorial context of adding another character: "So, I noticed that this is the pattern that I got with 2 characters, so what I find that, *when I increase it to 3 characters* there will be, another character will be adding up, and that could either be A or B, so the number of passwords would be doubled." Important in Raoul's explanation is his shift of attention to what occurred when he moved from the 2-character case to the 3-character case. This marked a shift to operative activity, in that he was now coordinating the mental operation of imagining what happens when increasing the password length by one character. This also fostered PPG, as Raoul could now attend to a regularity in the process and understand why the number of passwords would double each time the length grew by 1. He was then able to explain his reasoning with the case of moving from a 3-character password to a 4-character password: "One character has to be added up, and that character can either be A or B. So, for this one pattern, for 3 characters, there's going to be 2 [options], there's going to be one more pattern if I make it a 4 character."

Raoul began by making an empirically-based generalization that the total number of passwords would be 2^n, but he could not justify his general statement. However, the development of his initial generalization was still important for Raoul's progress. Before he wrote 2^n, the doubling aspect of the relationship was not foregrounded. Once Raoul had produced a generalization, the interviewer could then ask about doubling, which provided an opportunity for Raoul to shift to operative activity, PPG, and ultimately produce a combinatorial justification for why the number of passwords would double when adding a character.

Discussion and Implications

In this paper we have introduced a new phenomenon, empirical re-conceptualization, in which learners develop an initial conjecture based on empirical evidence or RPG, and then are able to re-conceptualize that generalization or conjecture from a structural perspective. Dr. Fisher began with an empirically-based conjecture, but that conjecture enabled her to then begin an in-depth investigation that supported an attention to how the sums changed as the summands and starting values change. She was able to reduce unfamiliar structures into familiar ones and reason in terms of general structures, both elements of structural reasoning. Raoul was similarly able to leverage his empirically-based generalization, 2^n, by shifting from RPG to PPG, and he did so by carrying out structural operations in thought, imagining what would occur when shifting from a 2-character password to a 3-character password, and again from a 3-character password to a 4-character password. Our findings indicate that empirical re-conceptualization can serve as a vehicle to transform empirical patterns into meaningful sources of verification, justification, and proof. This confirms de Villiers' (2010) claim that "experimental investigation can also sometimes contribute to the discovery of a hidden clue or underlying structure of a problem, leading eventually to the construction or invention of a proof" (p. 215).

Certainly, students frequently identify patterns that they do not understand or cannot justify; this remains a common problem. A danger remains that students will engage in empirical investigation but then not seek to re-conceive their resulting generalizations or conjectures structurally. Our interest is in understanding why some participants in our study were able to engage in empirical re-conceptualization, while others were not. We note that both Raoul and Dr. Fisher had mechanisms by which they could shift their attention towards structural relationships. At times this ability was spontaneous (in the case of Dr. Fisher) and at other times, it required direction from the interviewer (in the case of Raoul). This suggests that directing students towards the contextual genesis of the patterns they generalize may be an effective strategy for supporting empirical re-conceptualization. In addition, it suggests that when students engage in empirical patterning activities, it is preferable to have them do so within a particular, concrete context. Ultimately, our findings indicate that the activity of generalizing empirical patterns can serve as a bridge to more generative and productive mathematical activity.

Every Mathematics Class is Online: Students' Use of Internet Resources for Self-Directed Learning

Ander Erickson
University of Washington Tacoma

Undergraduate students make extensive use of online resources in lower-division mathematics classes. This explanatory mixed method study (Creswell & Plano Clark, 2011) explores how and why these students are using online resources for their self-directed learning in mathematics courses. Using a survey of 108 students from 13 2-year and 4-year colleges and 26 follow-up interviews, we identify the most commonly used online resources, self-reported description of how these resources are used, and students' perceptions of best practices as well as their concerns about maladaptive practices. We use an Activity Theory framework (Engeström, 1999) that directs our attention to the role that tools play in students' development over time and how these tools are leveraged to achieve learning goals. Our findings reveal undergraduate students as thoughtful and deliberate learners who make extensive use of online resources to help navigate the challenges of higher education.

Keywords: Information literacy, Multi-method, Information seeking behavior

The undergraduate student population is making increasing use of online resources in all areas of studies, but they have become a particular prominent part of mathematical study at the college level. This is attested to by the proliferation of resources which in some cases, such as Khan Academy, have become household names. Many other creators of math lecture videos routinely receive millions of views on YouTube. Students are also making use of answer engines that provide them with step-by-step answers to any math problem they choose and question answering services that host user-submitted solutions.

We employ an explanatory mixed methods study to better understand which resources students are using the most and how they are making use of these resources in order to fulfill their learning goals. We draw on Activity Theory (Engeström, 2001) to develop a model of college mathematics instruction that gives these online resources an appropriate role as part of the learning environment. By looking on institutionalized mathematics instruction as an activity system, we foreground the roles of tools and a social milieu as crucial elements of mathematical learning. This suggests that an accurate accounting of mathematics learning needs to incorporate information about how students are making use of the internet. This concern could be dismissed if the internet were not an important part of students' learning experiences but, as shall be seen below, one of the findings of this work is that a majority of undergraduate mathematics students are making extensive use of the internet and perceive that support as crucial for their success in the classroom.

Literature Review

The Internet and Student Learning

The growing body of literature on the role of the internet on student learning most often focuses on internet use that is structured by the instructor or the curriculum in some way (Lee, Cheung, & Chen, 2005; Precel, Eshet-Alkalai, & Alberton, 2009; Chen, Lambert, & Guidry, 2010), but it is much more difficult to find work that focuses on online learning specific to mathematics.

The internet and mathematics learning. One strand of research on the internet and mathematical learning focuses on uses of the internet that are built into instruction whether this takes the form of a novel online intervention created by the researchers (Rosa & Lerman, 2011; Biehler, Ben-zvi, Bakker, & Makar, 2012) or a course that is based partly, if not completely, on the internet (Timmerman, 2004; Engelbrecht & Harding, 2005; Foster, Anthony, Clements, Sarama, & Williams, 2016). An alternative approach explores how students make use of online resources that are not provided or pointed to by the instructor – we will henceforth refer to such use as self-directed online learning.

Self-directed use of online resources for mathematics classes. There are very few studies that directly address student's self-directed use of online resources in the context of mathematics instruction. A study by Anastasakis, Robinson, and Lerman (2017) surveyed 201 engineering students at a single institution. These researchers asked students to describe the instruments that they adopted and made a distinction between those resources provided by the university and those that students found on their own. They found that their participants were primarily using institutional resources and that they were generally motivated by a desire to do well on exams when they made use of external resources. Notably, this particular university had a robust learning management system which was extensively used by its students. Another study (Muir, 2014) surveyed students in grades 5 through 9, and focused primarily on students' use of Khan Academy as a supplemental resource to classroom instruction. In a couple other cases, researchers examined self-directed online learning by investigating the tracings of such exploration on the websites rather than interviewing students themselves. For example, Van de Sande (2011) studied student interactions in a free online help forum. Similarly, Puustinen, Volckaert-Legrier, Coquin, and Bernicot (2009) looked at submissions to a help forum in order to better understand how French middle school students sought out help with the mathematics that they were learning in school. By focusing on specific resources, none of these studies are able to provide any information about the prevalence of self-directed online learning nor were they able to determine which approaches were most commonly used by students.

Theoretical framework

We make use of Cultural-Historical Activity Theory (Roth & Lee, 2007) as a theory of development that acknowledges the role of the learner's environment both in terms of the people and tools that are incorporated into the activity system.

Activity Theory

Activity Theory was initially developed in order to provide an account of human development that acknowledges the role of tools and the social milieu (Vygotsky, 1997). In this study, we draw on Engeström's (2001) version of activity theory in which the activity system (see Figure 1) serves as the basic unit of analysis for understanding development over time. This perspective acknowledges that any individual/subject is part of a larger community with interactions that are influenced by rules and a division of labor. Tools, in particular, are recognized as both a means to accomplishing goals and as influences on the horizon of possibilities perceived by the subject. This highlights the importance of understanding the tools, specifically online resources, that students are employing as they progress through their classes.

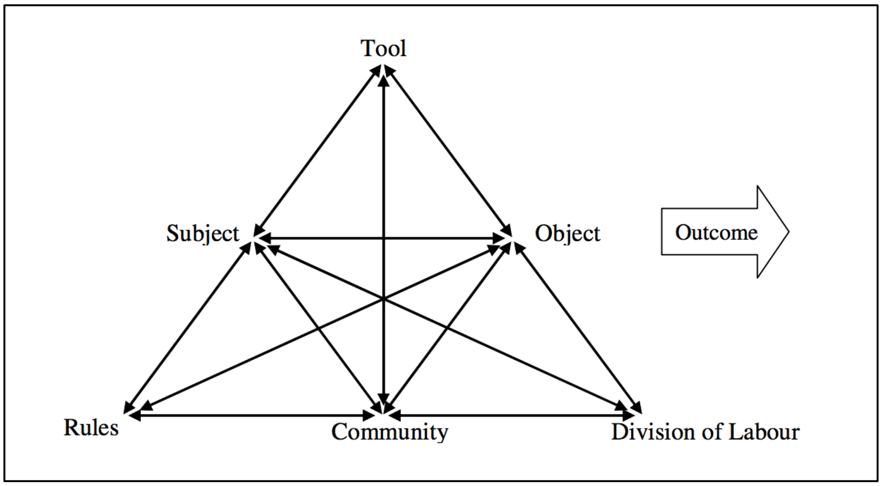

Figure 1. The activity system (Engeström, 2001)

Scanlon and Issroff (2005) made use of activity theory to examine students' evaluation of learning technologies in higher education settings. They argued that in order to reconcile seemingly contradictory responses, the entire activity system needs to be taken into account. For example, they identify seeming contradictions between how students and tutors perceived learning resources since students found a benefit in the serendipitous discoveries allowed by more open-ended resources whereas tutors felt that students would benefit more from a curated set of resources.

Accordingly, this study addresses the following research questions:

1) Which online resources are most frequently used by students as part of their self-directed mathematics study?
2) How do students make use of those online resources and for what purposes?

Methodology

In the section below, I describe the data collection procedures along with our analytical approach.

The Explanatory Sequential Mixed Methods Design

In order to provide a portrait of how students are making use of online resources in general, we distributed a survey across different institutional contexts. These surveys were supplemented by semi-structured follow-up interviews that gave participants the opportunity to elaborate on their initial survey responses. This explanatory mixed methods approach (Creswell & Clark, 2017) allows us to collect large-scale data while deepening our understanding of the quantitative findings. For example, one of the most widely-used resources across our sample was Google, but knowing that students use Google extensively does not help us understand how they are making use of the resource. The follow-up interviews allowed us to create a portrait of the various ways that Google is used to study mathematics, as will be detailed in the findings below.

The Data Sources

We surveyed 108 undergraduate students from 13 different 2-year and 4-year colleges and conducted 26 follow-up interviews with a random subset of those participants. See Table 1 for general demographic information about the participants in the survey. The demographics of the surveyed students is largely representative of the United States undergraduate population although black students and male students are under-represented in this sample. Notably, almost 42% of the surveyed students stated that they are first-generation according to the Department of Education definition[1]. About a quarter of the participants were taking a precalculus or algebra course at the time of the survey while the remainder of the students were either taking a course in the calculus series or a statistics course.

Table 1: *Demographics and Enrollment of the Student Sample (N = 108)*

Characteristic	Frequency	Percentages
Sex		
Female	62	57.4%
Male	40	37.0%
Non-binary / Third Gender	2	1.9%
Prefer to Self-Identify	3	2.8%
Prefer Not to Answer	1	0.9%
Race and Ethnicity		
Native American or Alaska Native	1	0.9%
Asian	11	10.2%
Black or African American	4	3.7%
Native Hawaiian or Other Pacific Islander	0	0%
White, Non-Hispanic or Latinx	64	59.3%
Hispanic or Latinx, Any Race	16	14.8%
Two or More Races	6	5.5%
Other	0	0%
Prefer Not to Answer	6	5.5%
First Generation Status		
Yes	45	41.7%
No	57	52.8%
Prefer Not to Answer	6	5.5%
Current Mathematics Class		
Precalculus or Earlier	28	25.9%
Calculus or Later	39	36.1%
Statistics	40	37.0%
Prefer Not to Answer	1	0.9%

Data Analysis

We report below on the quantitative results of the surveys in order to provide an overview of the resources that undergraduates are using to study mathematics. In the follow-up interviews, each participant was asked about every resource that they said that they used in the survey. They were asked how, when, and why they made use of each resource. We coded the resulting transcripts according to the resources that were referenced by the participant. We then read across every excerpt related to a given resource in order to identify themes that recurred across multiple participant responses. We report on the emergent themes below.

[1] An individual who prior to the age of 18 did not regularly reside with or receive support from a parent or guardian with a baccalaureate degree.

Results

The Pervasiveness of Self-Directed Internet Use

The survey results (see Table 2) suggest that most students in mathematics classes are making frequent use of online resources in ways that are not directed by their instructors. Over a third of surveyed students use resources in this way every day and almost 80% use them at least a few times a week. Furthermore, almost half of the students are using such resources for math courses more often than courses in other subject areas.

Table 2: *Self-Directed Use of Online Resources by Students in Mathematics Courses (n=108)*

How Often	Frequency	Percentages
Every Day	37	34.3%
A Few Times a Week	48	44.4%
About Once a Week	9	8.3%
Several Times a Semester/Quarter	5	4.6%
One or Two Times a Semester/Quarter	7	6.5%
Not at All	2	1.9%
Compared to Other Courses		
More Often	49	45.4%
About the Same	36	33.3%
Less Often	23	21.3%

Table 3: *Percentage of Students Using Selected Online Resources for Summer Mathematics Courses*

Online Resource	At Least Once a Week	Several Times a Semester/Quarter	Once or Twice a Semester/Quarter	Not at all	Do Not Recognize
Google	75.9%	9.3%	8.3%	5.5%	0.9%
YouTube	50.0%	15.7%	25%	9.3%	0%
Khan Academy	25.0%	24.1%	14.8%	27.8%	8.3%
Desmos	22.2%	17.6%	11.1%	13.9%	35.2%
Wolfram Alpha	13.9%	9.3%	11.1%	19.4%	46.3%
Symbolab	13.0%	2.8%	1.9%	8.3%	74.1%
Wikipedia	6.5%	10.1%	13.9 %	69.4%	0.9%

The most commonly used resources (see Table 3) were Google and YouTube. Notably these are tools for accessing content and not the object of students' searching in and of themselves. A majority of student made use of Khan Academy and Desmos at least once per semester/quarter with Wolfram Alpha and Symbolab being used at least once by about 35% and 18% of the surveyed students respectively. Wikipedia was an interesting outlier in that it was one of the least used of the named resources while enjoying a recognition comparable to Google and YouTube.

Patterns of Student Use of Online Resources

Our follow-up semi-structured interviews provided us with additional insight into how students were making use of these tools. Our description begins with Google and YouTube because these resources were the most used and because they occupy a unique position as search engines that bring students in contact with other resources. We will then discuss themes related to the most commonly used resources specific to mathematics instruction: Khan Academy, Desmos, Wolfram Alpha, and Symbolab.

Google. As a search engine, Google is often, though not always, the entry point for students as they seek out resources to aid in their studies. Accordingly, 24 of the 26 interviewees spoke about using Google as part of their self-directed online study. The most often stated reason for the use of Google was convenience, they could enter natural language queries and reliably receive a list of links that responded to their question. The interviewees described a few distinct types of searches using Google: (a) general topics, (b) specific types of problems, and (c) specific problems. There is an interesting overlap between (b) and (c) that has more to do with the goal of the search than with the search terms. When students are looking for a type of problem they may enter in an example problem, but they are not trying to locate a solution to that exact problem, rather they are only looking for a problem that has a family resemblance so that they can get a sense of how the solution method works – this is often expressed as a "problem with different numbers in it". On the other hand, some students are literally looking for the solution to a specific problem and Google will oftentimes provide what they need thanks to websites that host user-submitted solutions to problems such as Chegg, Yahoo Answers, or Mathway.

YouTube. All but one of the interviewees had something to say about YouTube as a source of information. It was described, first and foremost, as a supplement to in-class instruction: students spoke about teachers speaking too quickly and how YouTube would allow them to "catch up and fill in the blanks" or provide them with the opportunity to review material from earlier classes. Students had two distinct ways of interacting with the service. On the one hand, many students relied on specific providers hosted by the platform. Although, rather than advocating for the superiority of any specific speakers, students would generally advocate that others should explore until they found someone that fit their learning style. On the other hand, many interviewees described working with a variety of resources dictated by whatever came up when they searched rather than seeking out specific providers over others. Tactics used to choose specific videos included focusing on the number of likes, the view-count, or the date a video was posted. Finally, interviewees often spoke of the importance of video resources for providing a verbal and/or visual perspective that might not be otherwise available. This visualization component sometimes literally referred to problems that required graphing but students also spoke about the importance of seeing a problem worked out in front of them with an accompanying commentary.

Khan Academy. This resource was often encountered by students before they had entered college through word-of-mouth whether via parents, teachers, or peers. Another reason for the popularity of Khan Academy was its frequent appearance as a search result when a student looked up a topic or question on Google or YouTube. As noted above, many students would default to picking one of the initial search results and so it follows that Khan Academy's prominent placement would contribute to its popularity as a resource. Beyond early adoption and prominent placement in search results, students consistently attributed their use of Khan Academy to reliably clear explanations, availability of worked-out examples and a large quantity of practice problems. They also praised Khan Academy for having videos that correspond to almost any imaginable mathematics topic but this was tempered by a lack of material related to the type of mathematics encountered in upper-division classes. Mathematics majors who had previously made extensive use of Khan Academy would describe a move away from the resource as they realized that it was no longer helpful as they moved into proof-based classes.

Desmos. In contrast with other resources, students were most often introduced to Desmos by an instructor. They emphasized the ease if using the online graphing calculator, comparing it favorably to the actual graphing calculators that they were often required to purchase for college math classes. Furthermore, Desmos was described as a tool that facilitated a deeper understanding of mathematical concepts through their ability to easily zoom in and out of functions and to quickly identify points of intersection.

Wolfram Alpha and Symbolab. Both of these applications are answer engines that can provide step-by-step solutions for a wide variety of math problems although Wolfram Alpha currently requires that users pay a subscription fee in order to get access to all the steps. Students emphasized that they were making use of those solutions in order to better understand how to solve particular types of problems and not to be given answers. These answer engines were particularly attractive to students because of their intuitive interfaces but there was another theme of warning spoken by students who said that it was easy to get overly-dependent on these applications. A student spoke of developing test anxiety because they were too used to being able to look up solutions and others said that they made intentional moves to use them less when they began to get concerned that the answer engines were hindering rather than helping their learning. Notably, these were the only online resources that elicited such warnings.

Discussion and Conclusion

Our survey results provide evidence that undergraduate students extensively use online resources in self-directed ways for mathematics courses. Further, we identified the most commonly-used resources used by these students: Google, YouTube, Khan Academy, Desmos, Wolfram Alpha, and Symbolab. These tools are used by students to supplement in-class instruction with additional lectures, develop a better understanding of how to solve different types of problems, seek out help with specific problems, and provide visual representations that would not be easily available through other means. As is always the case when newly created tools are incorporated into an activity system, it would not necessarily be helpful to ask whether the system previously lacked something that these tools are now supplying. Rather, it may be more accurate to say that the existence of the tools changes the way that the activity is carried out, at least by a sizable subset of students. They can now fast-forward and rewind lectures by different teachers and so now that is a standard way to come to better understand mathematical concepts. They can now cross-reference their work with completely worked out problems whenever they feel less than confident and so that becomes a part of how they study. This research project suggests that, for good or for ill, these online resources are now an important part of the phenomenon of learning mathematics at the college level and should continue to be the subject of study. Accordingly, the next step in our research will be the observation and interviewing of students as they make use of online resources in ways that we found to commonly recur in the present study. This data will allow us to better understand how students are interacting with these resources in a moment-by-moment way and support an analysis of the benefit and drawbacks of these interactions.

Investigating Combinatorial Provers' Cognitive Models of Multiplication

Sarah A. Erickson
Oregon State University

Elise Lockwood
Oregon State University

Abstract: Combinatorial proof is an important topic both for combinatorics education and proof education researchers, but relatively little has been studied about the teaching and learning of combinatorial proof. In this paper, we focus on one specific phenomenon that emerged during interviews with mathematicians and students who were experienced provers. In particular, participants used a wide variety of cognitive models to interpret multiplication by a constant when reasoning about binomial identities, some of which seemed to be more (or less) effective in helping produce a combinatorial proof. We present these cognitive models and describe episodes that illustrate implications of these cognitive models for our participants' work. Our findings both inform research on combinatorial proof and highlight the importance of understanding subtleties of the familiar operation of multiplication.

Keywords: Combinatorial proof, Multiplication, Counting problems

Introduction

Combinatorics is an increasingly important branch of mathematics, and one class of combinatorics problems, combinatorial proof of binomial identities[1], comes up in discrete mathematics, statistics, number theory, and a variety of other contexts. From our experience working with students in the classroom and research settings (e.g. Lockwood, Reed, & Erickson, 2019), we know that these problems can be tricky even for accomplished counters, and yet this topic has received relatively little attention from the mathematics education research community. A binomial identity is an equation involving one or more binomial coefficients, such as: $\binom{n}{k}k = n\binom{n-1}{k-1}$. In this paper, we take *combinatorial proof* to mean any proof that establishes the veracity of a binomial identity by arguing that each side enumerates the same (finite) set[2]. The validity of these arguments is rooted in the fact that a set can have only one cardinality.

For example, to prove the above binomial identity, one could argue that each side counts the number of committees of size *k* with a chairperson that can be formed from a group of *n* people. In this case, the right-hand side counts this set because there are *n* possible people who could be the chairperson, and then out of the remaining *n-1* people left, there are $\binom{n-1}{k-1}$ ways of selecting the remaining *k-1* people on the committee. As a lead-in to the rest of this paper, we offer the following two questions to provoke thought (we present our research questions at the end of the Multiplication and Counting section). First, w*hy does* $\binom{n}{k}k$ *also count the number of committees of size* k *with a chairperson that can be formed from* n *people?* Second*, how are you thinking of the multiplication of the binomial coefficient by k, and what cognitive model of multiplication are you using?*

[1] Combinatorial proof is a proof technique that can be applied to other types of theorems as well, but we focus on binomial identities in this paper as that was the focus of our research endeavors.

[2] We acknowledge that authors such as Lockwood et al. (2019) and Rosen (2012) have articulated two types of combinatorial proof where one type is that described above, and the second type involves arguing that each side of a binomial identity counts a different set and creates a bijection between the two sets. We do not focus on bijective proofs in this paper.

Literature Review and Theoretical Perspective

Previous Work on Combinatorial Proof

We identified only two prior studies that focused on undergraduate students' thinking about and engagement in combinatorial proof. Engelke Infante and CadwalladerOlsker (2010, 2011) looked at students' solutions to exam questions asking for a combinatorial proof of two binomial identities. They examined the solutions to see what difficulties arose for the students and found that the students appeared to struggle with (a) language mimicking, (b) inflexibility of context, (c) misunderstanding of combinatorial functions, and (d) failure to count the same set (p. 95-96). Engelke Infante and CadwalladerOlsker's (2011) also argued that the students may have engaged in *pseudo-semantic proof production*, which is based on the distinction between semantic and syntactic proof production (Weber and Alcock, 2004). Engelke Infante and CadwalladerOlsker (2011) defined pseudo-semantic proof production as "the attempt to engage in a semantic proof production process, but relying on the syntax of a previously encountered proof when faced with a term that the student cannot explain" (p. 96). This research provides evidence that combinatorial proof can be difficult for students and that they may try to imitate enumerative arguments they previously encounted if they get stuck. Engelke and CadwalladerOlsker (2010) also found that having students write a specific "How many?" question when engaging in combinatorial proof may help them be more successful.

More recently, we conducted a 15-session teaching experiment (Steffe & Thompson, 2000) that covered a variety of combinatorics topics with two vector-calculus students (Lockwood et al., 2019). The last three sessions of the teaching experiment were centered around combinatorial proof of binomial identities, and we found that the students seemed to benefit from two particular instantiations: (a) focusing on a particular context (e.g. counting passwords or committees), and (b) considering specific values of n or other variables appearing in the identity to be proven. We also found that a potentially useful way to prepare students for combinatorial proof is to give them opportunities to generalize while solving counting problems and ask them to solve counting problems two different ways. We used Lockwood's (2013) model of students' combinatorial thinking to frame our findings, and we argued that even though the model was originally conceived to study student thinking while solving counting problems (in other words, questions asking "How many…?), it is also an effective lens when studying combinatorial proof.

This prior work on combinatorial proof is valuable and may help give instructors more pedagogical ideas when covering combinatorial proof. However, questions regarding student thinking about combinatorial proof still remain unanswered, and addressing these gaps in the literature is one goal of the research discussed in this paper.

Multiplication and Counting

As Lockwood et al. (2019) pointed out, interpreting mathematical operations as part of a counting process (Lockwood, 2013) is a key aspect of combinatorial proof. Binomial identities may contain many different mathematical operations, but in this paper we focus on multiplication. Multiplication is a familiar operation to students, yet as Batanero, Navarro-Pelayo, and Godino (1997) found, students do not always know when to multiply while solving counting problems and can confuse situations requiring multiplication versus addition (see also Kavousian, 2008). Numerous researchers have studied how young children think about multiplication of positive whole numbers (e.g., Greer, 1992; Mulligan & Mitchelmore, 1997; Tillema, 2013), yet little work has been done investigating how undergraduate students might conceptualize multiplication. Mulligan and Mitchelmore (1997) used five problem types involving multiplication in their study on young children's reasoning about multiplication, which they referred to as *semantic structures*. These are summarized in Table 1. Some of these semantic structures will be important for our discussion later in the Results section.

Table 1. Mulligan and Mitchelmore's (1997) semantic structures of multiplication.

Semantic Structures for Multiplication	Example
Equivalent groups	3 baskets, each with 5 kittens
Multiplicative Comparison	3 times as many kittens as puppies
Rectangular Array	6 rows, each with 4 four kittens
Cartesian product	The number of possible kitten-puppy pairs
Rate	If each kitten has 2 balls of yarn, how many balls of yarn would 3 kittens have?

While little work has been done studying (potentially) different ways that undergraduate students conceptualize multiplication, there has been some work looking at student thinking about the Multiplication Principle[3] (MP), a guiding principle describing when to multiply when solving counting problems. Lockwood, Reed, and Caughman (2017) found that textbook statements of the MP vary significantly more than the statements of key definitions and theorems in other domains, and then building off of this textbook analysis, Lockwood and Purdy (2019) studied two undergraduate students' reinvention of the MP. Lockwood and Purdy (2019) found that even students who can successfully solve counting problems involving multiplication may struggle to characterize when to multiply, and they found that the MP contains important subtleties that textbooks do not always explicitly address.

These studies reveal that multiplication has a varied and nuanced nature that may go unappreciated in undergraduate discrete-mathematics classrooms. In this paper, we attempt to address the following research questions: *(a) What cognitive models of scalar multiplication do undergraduate students use when engaging in combinatorial proof? (b) What are the implications of various cognitive models of scalar multiplication for students' engagement with combinatorial proof?* Here, scalar multiplication refers to multiplication by a single positive integer constant *k*, such as $\binom{n}{k}k$. We use the term *cognitive models* to mean someone's personal representation of what a given instance of the operation of multiplication entails. This construct is similar to Mulligan and Mitchelmore's (1997) semantic structures; however, our use of cognitive models is intended to go deeper than a classification of pre-existing problem types and attempts to capture their mental representations of what multiplication is doing in a binomial identity[4]. We narrow our results to scalar multiplication (as opposed to other expressions involving multiplication that may occur in a binomial identity, such as $\binom{n}{k}\binom{k}{m}$) due to space limitations.

[3] We provide Tucker's (2002) statement of the MP: "Suppose a procedure can be broken down into *m* successive (ordered) stages, with r_1 different outcomes in the first stage, r_2 different outcomes in the second stage, …, and r_m different outcomes in the *m*th stage. If the number of outcomes at each stage is independent of the choices in the previous stages, and if the composite outcomes are all distinct, then the total procedure has $r_1 \times r_2 \times \cdots \times r_m$ different composite outcomes" (pg. 170).

[4] Mulligan and Mitchelmore (1997) studied children's *intuitive models* of multiplication in their research; however, this construct was used to refer to children's multiplicative calculation strategies. We felt it was not relevant to our work studying counters' interpretations of generalized identities involving multiplication.

Methods

We conducted video-recorded, semi-structured, task-based interviews (Hunting, 1997) with five undergraduate students and eight mathematicians. We recruited students from upper-division mathematics courses at a large university in the western United States (desiring students who understood what a mathematical proof is), and we recruited mathematicians from three universities in the western United States. All of the mathematicians in our study had experience conducting mathematics research, and we included both mathematicians who did and did not research combinatorics. Each student participated in five hour-long individual interviews, and each mathematician participated in a single, 90-minute individual interview. The students were asked to solve combinatorics problems, give counting arguments for the veracity of binomial identities, and answer reflection questions about their approach to and reasoning about combinatorial proof. The mathematicians were asked to give combinatorial proofs of various binomial identities and answer reflection questions about their approach to, reasoning about, and pedagogical opinions regarding combinatorial proof. These interviews were part of a larger study aimed at understanding mathematicians' and upper-division undergraduate students' reasoning and beliefs about combinatorial proof.

To analyze these data, the first author re-watched the interviews videos, making note of key episodes related to our research questions and looking for emergent themes and coding according to the *grounded theory* qualitative research methodology (Charmaz & Belgrave, 2007). We coded which cognitive models the mathematicians and students used for multiplication based off of Mulligan and Mitchelmore's (1997) semantic structures, and we also examined the data for other emergent cognitive models that did not align with these semantic structures. Relevant portions of the videos were transcribed. We also followed Lockwood et al. (2019) in using Lockwood's (2013) model of students' combinatorial thinking as an analytical lens for interpreting students' combinatorial proof activity.

Results

Combinatorial Provers Used a Variety of Cognitive Models of Multiplication

We were surprised by the variety of cognitive models of multiplication (summarized in Table 2) that the mathematicians and students used while engaged in combinatorial proof.

Table 2. Cognitive models of scalar multiplication used by students and mathematicians interpreting $\binom{n}{k}k$.

Cognitive Model of Multiplication	Example from the Data Applied to $\binom{n}{k}k$
Equivalent groups	k copies of each k-sized committee
Scaling factor[5]	Each k-sized committee is scaled by a factor of k
Inverse of a probability	The multiplicative inverse of the solution to, "If there is a 1-in-k chance that a committee will form at all, what is the probability that a certain committee will form?"
Element selection	Interpreting k as $\binom{k}{1}$, that is, making a selection of 1 from k people after forming a k-sized committee

As can be seen from Table 2, one of our participants' cognitive models, *equivalent groups*, that aligned with one of Mulligan and Mitchelmore's (1997) semantic structures, while others

[5] The idea of multiplication as applying a scaling factor to some quantity may be related to *linear meanings* of multiplication (Tillema, 2013).

did not. The diversity of cognitive models in our data corroborates previous findings (e.g., Lockwood et al., 2017; Lockwood & Purdy, 2019) that while multiplication is a familiar operation, its representations can vary when used in counting and contains subtleties not always appreciated by students and instructors. Perhaps it is not surprising that the students' conceptions of multiplication in a combinatorial context differed from the multiplicative semantic structures used in studies of K-12 children, but we nevertheless did not expect the variety we encountered.

For example, to illustrate the *inverse of a probability* cognitive model of scalar multiplication, we discuss Riley's work on the following problem, *Write down a counting problem whose answer is* $15 \times \binom{14}{3}$. We will refer to this as the Reverse Counting problem. We acknowledge that the Reverse Counting problem does not ask for a combinatorial proof. However, aligning with Lockwood et al. (2019) we believe that interpreting expressions as having an underlying counting process (Lockwood, 2013) is a critical component of writing a combinatorial proof. In addition, this type of activity is consistent with Engelke and CadwalladerOlsker's (2010) study showing that having students write a specific "How many?" question can facilitate more successful combinatorial proof activity. Thus, we consider Riley's work interpreting $15 \times \binom{14}{3}$ as the solution to a counting problem to be relevant to our research questions about combinatorial proof.

Riley quickly realized that they could use the context of forming congressional committees of size 3 from 14 different senators to interpret $\binom{14}{3}$. However, they struggled to incorporate the multiplication by 15. They first thought that a solution might be, "There are 15 congressional committees, each should be size 3, and there are 14 candidates for each council, and membership in one council does preclude membership in another council." Riley soon realized though that the solution to this counting problem would be $\binom{14}{3}^{15}$, not $15 \times \binom{14}{3}$. After spending some more time thinking, they gave the following solution:

> There is a 1 over 15 chance that a congressional committee will be formed. Given that probability and the fact that there are 14 candidates for the council and three positions, what is the multiplicative inverse of the probability that a given council will be selected? Because you have to overcome the probability that it won't happen at all.

This was a fascinating interpretation of multiplication by 15 that we had neither expected nor encountered previously in our experience teaching combinatorics or conducting combinatorics education research. It suggests that some undergraduate students can more easily interpret multiplication in a probabilistic context than a combinatorial context, which corroborates Lockwood & Purdy's (2019) finding that even successful counters can struggle to articulate when to multiply while counting. However, while Riley's solution to the Reverse Counting Problem was certainly interesting, it was not correct since their solution was not a counting problem. To come up with a correct solution, Riley had to shift to the *element selection* cognitive model of scalar multiplication, which we will discuss in the next section.

A Particularly Useful Cognitive Model of Multiplication for Combinatorial Provers

Revisiting the research questions, we found there was surprising variety in the cognitive models of scalar multiplication that students and experts used when trying to write a combinatorial proof (or give a combinatorial interpretation of an expression). In this section we will discuss which cognitive models of multiplication may be easier or more difficult for students to use when constructing a combinatorial proof. Of the cognitive models outlined in Table 2, only two of them—equivalent groups and element selection—were utilized to come up with a correct combinatorial proof. However, as we will see, these two cognitive models may not be equally useful for students. In fact, only one participant (one of the mathematicians) was able to use equivalent groups successfully, while all five of the undergraduate student participants eventually used element selection effectively.

A combinatorial proof utilizing equivalent groups. One of the eight expert mathematicians interviewed, Emery, successfully proved $\binom{n}{k}k = n\binom{n-1}{k-1}$ using equivalent groups. We do not include all of the details of their work, but they were able to conceive of $\binom{n}{k}k$ as counting the number of ways to make *k* copies of all possible *k*-sized subsets that can be formed from *n* distinct objects. They argued that $n\binom{n-1}{k-1}$ counts the same multiset, because for every fixed object there are $\binom{n-1}{k-1}$ ways to select the remaining *k-1* objects to make a subset of size *k*. This process will also generate *k* copies of each subset (one copy for each of the *k* objects that are fixed), and so the left- and right-hand sides of the identity count the same multiset.

While this combinatorial proof is correct, we hypothesize that constructing an argument that enumerates a multiset containing duplicate objects may be challenging for students. It is not trivial to see that $n\binom{n-1}{k-1}$ counts a collection of size-*k* subsets each with *k* copies, and combination problems that allow for repetition (i.e. copies of some elements) are generally more difficult for students than those that do not allow repetition. Indeed, none of the students used this cognitive model of multiplication to prove any of the binomial identities we gave them.

Element selection was productive for student combinatorial provers. As we saw previously, some cognitive models of multiplication did not facilitate successful combinatorial proof activity for students. However, we found that a particular instantiation seemed to help all five student participants conceptualize "$\times\ k$" as a stage in the MP with *k* options, which we refer to as using the *element selection* cognitive model of multiplication. This cognitive model was so helpful that it occurred in every successful combinatorial proof of a binomial identity involving multiplication by a student participant in our study. The instantiation that helped students use this cognitive model was to represent *k* as $\binom{k}{1}$ in binomial identities involving multiplication by *k*. To illustrate how this instantiation and cognitive model seemed productive for students, we turn to Adrien's work.

Like Riley, Adrien struggled with the Reverse Counting Problem, and after they entertained some ideas that were unproductive, we suggested that they recall that $15 = \binom{15}{1}$. The moment we drew their attention to this fact, they immediately articulated that $15 \times \binom{14}{3}$ could count the number of ways to elect a club president and then a 3-person committee from a set of 15 club members. We asked them if writing 15 as $\binom{15}{1}$ was helpful, and Adrien responded:

> So when I was reading it like this, the way I was reading it was as taking the combination—you have 14 you choose 3. I was thinking of, like, scaling that number somehow. So, I was still thinking of it in terms of that number. But then, when you write it like this, it's like, oh, so you started with 15, took 1 specifically, so now it seems like a 2-step process—like, two separate parts of the problem, rather than one part of the problem and, like, oh, how do I scale that?

We interpret this to mean that Adrien initially used the *scaling factor* cognitive model of multiplication, which was unproductive for them. Once they represented 15 as $\binom{15}{1}$, however, Adrien was able to use *element selection* to correctly argue that $15 \times \binom{14}{3}$ could count committees with a club president. Interpreting operations (such as multiplication) in this manner is a critical step in constructing a combinatorial proof, as argued by Lockwood et al. (2019).

Progressing through subsequent problems in our interviews, Adrien proved several more binomial identities using element selection and the $k = \binom{k}{1}$ instantiation. These include one of the more challenging identities we gave students in the interviews, $n2^{n-1} = \sum_{i=1}^{n} \binom{n}{i} i$. When we first gave Adrien this identity, they initially worked some without making progress, and then we suggested that they write down the identity making the substitution *n=5*. Once Adrien did this, they then re-wrote the summation replacing *i* with $\binom{i}{1}$ and were able to recognize the terms in the summation as choosing *i* from a set of *n* distinct things, and then selecting one of those *i* chosen things. (See Figure 1.) Adrien then gave a nice combinatorial proof of the identity in the context of selecting a finalist from *n* people after two selection rounds:

Interviewer: What would you say both sides are counting?

Adrien: So, you have a group of *n* people, and you're trying to select one of them in two stages specifically. So, you have your first stage, where you just select some group of people—it doesn't matter how large it is—and then out of those candidates you then select the final one. And this [left-hand side] sort of does that in the opposite direction. It's, like, it counts, okay, who was the final one? And then who made it to the second round?

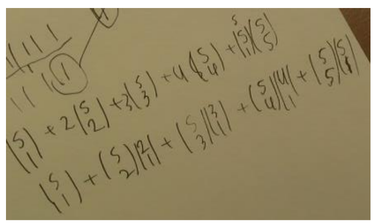

Figure 1. Adrien's work proving $n2^{n-1} = \sum_{i=1}^{n} \binom{n}{i} i$.

We see here again that using the element selection cognitive model to represent scalar multiplication was productive in Adrien's combinatorial proof activity.

Conclusions and Implications

Multiplication is a familiar operation for undergraduate students, and yet we have seen that there are implications for the particular ways in which they reason about it. Combinatorial proof and similar types of problems are a context where the subtleties of multiplication emerge, and we see that it is not a trivial topic, even for upper-division mathematics students. While much work has been done examining the ways that K-12 students reason about multiplication (e.g., Greer, 1992; Mulligan & Mitchelmore, 1997; Tillema, 2013), our study indicates that examining undergraduate students' conceptions of multiplication in combinatorial contexts may be fruitful. While some work has begun to investigate this topic (e.g. Lockwood & Purdy, 2019), how undergraduate students think about and handle the subtleties and variety of cognitive models of multiplication in combinatorial contexts remains largely unknown. Finally, our work suggests that from a pedagogical perspective, some cognitive models of multiplication seem to be more productive for students engaging in combinatorial proof activity than others. Encouraging students to think of multiplication by *k* as $\binom{k}{1}$ if they are stuck may help them more easily see the binomial identity they are working with as corresponding to an underlying counting process that uses the MP (Lockwood, 2013; Lockwood et al., 2019).

A Model for Assessing ITP Students' Ability to Validate Mathematical Arguments

Joshua B. Fagan
United States Military Academy at West Point

In this paper I discuss the process of creating a closed-form multiple-choice assessment of students' ability to validate mathematical arguments at the introduction to proof (ITP) level. This process involved: (1) creating and validating a framework of common validity issues (CVI) in proof writing as a basis for assessment creation through a mathematician survey $(n = 228)$ *and two focus groups (*$n = 4$ *&* $n = 7$*); (2) creating and piloting an open version of the assessment as a means to create distractors for the closed assessment; (3) creating, piloting* $(n = 187)$ *and analyzing the results from the closed form assessment; and (4) conducting interviews with student participants after the pilot to determine the process that students took during the pilot. The results of the processes offer an assessment that, with some refinement, can measure students' ability to validate mathematical arguments from several perspectives in the ITP setting.*

Keywords: Proof, Proof Validation, Assessment, Introduction to Proof

Introduction

Students in advanced mathematics courses spend significant time both constructing and reading proofs. Ostensibly, the rationale for focusing heavily on these two activities is to learn how to construct valid arguments, and to learn the mathematic domain through gaining understanding and conviction in the truth of the mathematical statements (e.g., theorems, lemmas, corollaries, etc.) which define the domain. The former reasoning represents the need to develop the skill of proof constructing, while in the latter, the proofs represent the justifications that each statement is in fact true, further solidifying the primacy of proofs and skills related to proving in the undergraduate settings. One possible hurdle in these curricular efforts is the students' ability to recognize whether an argument is in fact a valid proof. This ability may have an effect on students' conviction with regards to proofs, as well as their ability to understand and construct proofs. Researchers have shown that the relationship between conviction and validity is tenuous for students (Segal, 1999; Weber, 2010) but they have argued that this relationship is important for students to strengthen during their undergraduate course work in mathematics (Selden & Selden, 1995, 2003). It has also been suggested that comprehending and constructing proofs are in some way related to the ability to validate (see Mejía-Ramos, Fuller, Weber, Rhoads, & Samkoff, 2012; Selden & Selden, 1995, 2003), but to date no research has formalized how these relationships are exhibited in practice.

As so, many of these constructs seem to relate to the students' ability to validate mathematical arguments. It becomes necessary to have a systematic means of measuring students' validating ability. By having such a tool, future research could clarify the relationships between validating ability and conviction, proof comprehension and proof construction. The aim of this research was to create a research instrument for measuring students' ability to validate mathematical arguments in the introduction to proof (ITP) setting. The main product of this treatise is a discussion on the methodology undertaken in creating the Assessment of Student Argument Validating Ability (ASAVA). While analysis has begun in earnest on the ASAVA itself, the final product is still in development and requires a final phase of data collection and analysis.

Literature and Theoretical Perspective

In this section, I present an overview of what the literature conveys about undergraduate mathematics majors' ability to validate mathematical arguments as well as a brief presentation of the Common Validity Issue (CVI) framing, the theoretical framing used to guide the creation of the ASAVA. For consistency, I use the phrase *mathematical argument* or just *argument* in place of *proof* and *purported proof*, as in many cases the arguments from this and other studies relevant to validity are often not valid proofs due to the fact they in some way fail to actually prove.

Foundational studies performed by Selden and Selden (1995, 2003) suggest that unaided ITP students are no better than chance at determining the validity of arguments, but with guided intervention can be led to be more reliable in their validation judgments. Alcock and Weber (2005) observed that by the time students are in a real analysis course there are specific aspects of mathematical arguments students have learned to focus on to aid in determining the validity of an argument. Moreover, they noted that these students tend to focus on the veracity of statements rather than the tenability of the statements themselves, meaning students were more concerned with what was or was not true rather than what was or was not supported by the argumentative process employed in a particular argument. Inglis and Alcock (2012) compared the approach that ITP students took in validating arguments to those taken by expert mathematicians. They found that these students tended to fixate on the correctness of mathematical computations, echoing the finds published by Knuth (2002) a decade earlier. They also found that mathematicians were far more active in their *zooming in* – an act described by Weber and Mejía-Ramos' (2011) as focusing on individual portions of an argument rather than on the overall structure – than the students. Additionally, Inglis and Alcock (2012) results supported Selden and Selden's (2003) earlier findings that these students are unreliable in their validating of mathematical arguments. This body of research suggests that ITP students have an underdeveloped sense of validity in the context of mathematical arguments and exhibit behaviors which are dissimilar from their expert mathematics counterparts.

Validity and the Objective/Subjective Dilemma

Proof validation can be thought of as, "The reading of, and reflection on proofs to determine their correctness" (Selden & Selden, 2003, p. 5). Here the literature, as well as my theoretical orientation, recognizes validating as a subjective endeavor dependent on both context and the individual who is validating. This subjectivity at first may appear to make the act of judging and declare an argument wholly valid or invalid as disingenuous. However, I claim that there are validity issues which are so egregious that mathematicians will accept them as universal within the ITP context, thus limiting or removing altogether the effect of the subjective nature of validity. As such, a consensus process was needed to identify arguments that are universally deemed valid or invalid to construct an assessment which meaningfully asks students in the ITP setting to make binary validity judgements despite the normally non-binary nature of validity in mathematics generally.

CVI Framing

One major area not previously explored by current research is a codification of the aspects of proof which ITP students confound when they validate arguments. To better understand this, the CVI framing (Fagan, 2019) was developed as a tool to give specificity to the character of validity issues commonly found in student proofs at the ITP level. This framing consists of six categorizations (see Table 1) extracted from the literature (Alcock & Weber, 2005; Hazzan &

Leron, 1996; Selden & Selden, 1987, 2003; Weber & Alcock, 2005; Weber, 2001) and certified by mathematicians as authentic at the ITP level. In this study, the CVI framework is used as a means of qualifying the validity issues within the arguments of the ASAVA.

Table 1. The Common Validity Issue framework.

Issue (Abbr.)	**Definition**
Assuming the Conclusion (AC)	An argument assumes the consequent (conclusion) of the proposition it is claiming to prove and attempts to show that the antecedent is a direct consequence.
Circular Reasoning (CR)	An argument assumes the consequent (or antecedent) of the statement it is claiming to prove and comes to a trivial conclusion, namely the consequent (or antecedent) once again. Within an argument a claim is made and used to argue to trivial ends, the claim itself. ($P \rightarrow Q \rightarrow \cdots \rightarrow P$). An argument uses the proposition it is trying to prove.
Logical Gap (LG)	An argument omits a portion of reasoning; the argument has a hole. This could be thought of as a lack of a data → warranting → claim turn, or any individual portion of one where such would seem prudent.
Misuse of Notation (MN)	Within an argument, proper notation or variable naming conventions are not adhered to, or notation and variable naming conventions are used inconsistently.
Warranting (W)	Within an argument, an error in justification is made either explicitly or implicitly. This can take the form of an incorrect explicit warrant, or an incorrect implicit warrant which may emerge as an arithmetic or computational error.
Weakening the Theorem (WT)	An argument proves less than what is implied by the statement being proven or begins by assuming more than is permissible.

Though not an explicit part of the CVI framing, *valid* arguments (i.e., proofs) are an important aspect of assessing students' ability to validate arguments. I define valid arguments throughout the study as arguments which do not include the above CVI framing issues. This is an important consideration because if there are no valid arguments to validate amongst a set of invalid arguments, then only some of students' ability is tested, thus the idea of valid not only needs to be defined, but such items become an important barometer for students' true ability to validate.

Limiting Scope

For the standard ITP course (David & Zazkis, 2017), the norm is to introduce students to a wide variety of proof methods (Fagan & Melhuish, 2018). I focused solely on direct proofs in creating the ASAVA to give a clean connection between a student's score and their ability without the possible confounding effect that multiple proof types might introduce. In the example in Figure 1, the proof framework is indicative of a direct proof, where for a conditional statement, $P \rightarrow Q$, the antecedent, P, is assumed true and the desired conclusion is that the consequent, Q, is also true[1]. While it would be interesting to use this assessment to explore students' ability to validate multiple proof types, for now, to assure the best possible instrument and reduce the number of variables in task creation, proof will be defined in terms of direct proofs only.

Theorem: If M is a compact set, then each infinite subset of M has a limit point.

Proof:
Let M be a compact set and N be any infinite subset of M.
$\vdots$
Therefore, N has a limit point. $\square$

Figure 1. The first level proof framework as defined by Selden and Selden (2003) of a direct proof.

Assessments

Educational assessments – especially those designed specifically for research – are tools for observing, documenting, and quantifying a phenomenon (see, Pellegrino, Chudowsky, & Glaser, 2001), but rarely do assessments measure said phenomenon in a straightforward way. On this matter, Mislevy, Steinberg and Almond (2003) noted,

> In assessment, the data are the particular things students say, do, or create in a handful of particular situations, such as essays, diagrams, marks on answer sheets, oral presentations, and utterances in a conversation. Usually our interest lies not so much in these particulars but in the clues they hold about what students know or can do as cast in more general terms. (p. 9)

The overarching implication is that the data from an assessment often means more than the discrete responses to questions and says more about the individual's understanding or ability than the individual tasks.

Test theory

The set of responses which are gathered to evaluate the effectiveness of an assessment must be analyzed to determine the veracity of the assessments capability to meaningfully make inferences about the test taker on a given subject. Classical test theory (CTT) and item response theory (IRT) are the two main forms of analysis which inform this evaluative effort for assessment creation. In modern computer age, IRT became the more common approach as it is often considered the superior method of assessment analysis (Embretson & Reise, 2000).

Characteristic curves for each dichotomous item embody the item's difficulty and discrimination as part of the IRT analysis of an assessment. Using the probability function in Figure 2, these characteristic curves represent the likelihood that an individual with ability θ will get the correct answer for that item. Baker (2001) defines difficulty as a location index for each item on the ability spectrum, where an item with high or low difficulty is associated with high or low ability respectively, and the probability of getting a correct response is .5 for any one item.

$$P(\theta) = \frac{1}{1 + e^{-a_i(\theta - b_i)}}$$

Figure 2. IRT employs a two-parameter logistic model where for any dichotomous item, i, the probability of a correct response, $P(\theta)$, based upon the ability, θ, defined by the item's discrimination (a_i) and difficulty (b_i).

[1] Note that this proof method easily supports proofs which have multiple cases or are proofs of biconditional statements. One such proof could be accomplished by two direct proofs.

Instrument Design

The process for building a large scale student assessment has been outlined in the development of three distinct assessment (Carlson, Oehrtman, Engelke, 2010; Mejía-Ramos, Lew, de la Torre, & Weber, 2018; Melhuish, 2019), all of which borrow from the work on the Force Concept Inventory and Mechanics Baseline Test (Hestenes, Wells, Swackhammer, 1992; Hestenes, & Wells, 1992). As with the work of Mejía-Ramos et al. (2018), the assessment of students' proof validation ability does not strictly fit the model of being a concept inventory. While concept inventories explore students' understanding of a broad set of concepts, the ASAVA is, as yet, focused only on students' ability to validate a subset of proofs from a singular mathematical context, ITP. Despite this difference, the mapping supplied by these concept inventories is still the most comprehensive and sensible solution.

The process of developing the ASAVA involved two phases of assessment creation. Phase one involved developing and analyzing an open-ended survey to create a semi-closed assessment. Phase two involved piloting and analyzing the resultant semi-closed assessment. I will discuss each phase briefly in the following sections. To clarify the conversation, I use the term testlet to denote a theorem, its argument, and all the open-ended or multiple-choice questions dedicated to that theorem/argument pair. I define the terms stem, key, and distractor as they are the major parts of any multiple-choice question: the stem is the question, the key is the correct choice, and the distractors are the set of plausible but incorrect choices (Haladyna, 2004).

Phase 1 – Open-Ended Survey Development and Analysis

Phase one involved multiple steps, the first, and most important of which, was validating the framework and arguments, which are the focus for each item of the student open-ended survey and semi-closed assessment. This validation process involved creating/collecting arguments and expert (i.e., active mathematician) endorsement of said arguments in terms of validity. The process breaks into two stages; (1) item creation[2] and mathematician survey ($n = 228$); and (2) two mathematician focus groups ($n = 4$ and $n = 7$). Next, I constructed, ran, and analyzed the student open-ended surveys ($n = 68$) based upon the twelve best performing items from the mathematician survey, which process gave me a set of possible distractors for the semi-closed assessment that was to follow.

The arguments for each item on the mathematician and student open-ended surveys were a collection of: (1) altered and unaltered student work collected from a pair of ITP courses offered at a large public university in the United States; (2) work collected from the internet site Mathematics Stack Exchange; or (3) altered and unaltered versions of proofs from the common ITP texts (see David & Zazkis, 2017; Fagan & Melhuish, 2018). Arguments were selected based upon their fit within the greater framing of the CVI framework and altered so each argument at most included a single validity issue.

Phase 2 – Semi-Closed Assessment Pilot

The semi-closed assessment was a collection of the eleven best performing items from the student open-ended survey, where each student saw only eight[3]: at least one from each categorization from the CVI framing, and two valid arguments. Each argument was part of a larger testlet – visualized in Figure 3 – aimed at testing students validating ability from two

[2] All told there were 30 arguments to 22 propositions in Phase 1.
[3] The assessment at this point was an anchored assessment with each student seeing the same five arguments and three randomly selected but semi-evenly distributed arguments.

perspectives: (1) their ability to determine the Boolean validity of an argument, and (2) their ability to identify the specific validity issue of an argument. This was accomplished in each testlet by first asking students to decide if an argument was either wholly valid or invalid, and then asking them their rationale based upon a set of possible responses that included a key and a set of distractors. A total of 187 undergraduate students from universities across the US who were at least enrolled in an ITP course – though many had taken more proof-based courses – took part in the semi-closed assessment pilot.

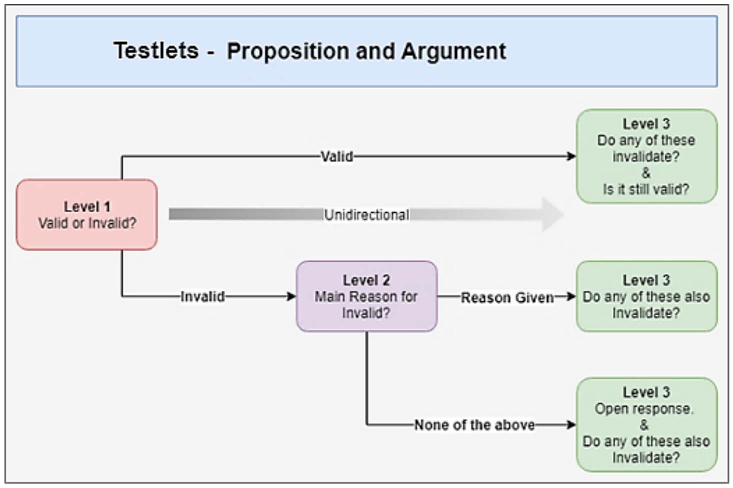

Figure 3. The structure of each testlet was designed to make the validating task non-trivial and to allow students to change their mind about the validity of an argument.

After the pilot, six students were selected to take part in hour long interviews. The participants were selected to account for a wide variety of scores from the semi-closed pilot. The interviews and interview analysis[4] focused on (1) what students were attending to when they were taking the assessment (i.e., were they actually validating or were they doing something else), (2) the quality of the assessment (i.e., were items, distractors, concepts or other ideas worded in problematic ways or incomprehensible due to a lack of explicit explanation or lack of students' prior knowledge), and (3) if students' scores could be accounted for by their ability to validate as opposed to other possible explanations.

Example Testlet

In this section, I present a single testlet from the ASAVA, though the methodology employed is the main contribution of this treatise. I do this to give a deeper understanding of the end product of the process undertaken, not as a means of presenting the overall product as it still needs refinement. This testlet, $T5$ (see Figure 4), was an invalid item with a CVI issue of LG. Each testlet was scored as 1, 0, or -1, with overall scores ranging from negative eight to eight, $[-8,8]$. Consistent with the overall design of the assessment, for $T5$ a score of 1 meant that the student was able to both correctly identify the argument as invalid *and* identify the reason the argument was invalid. A score of 0 meant the student at first identified the argument as valid, but after being asked to decide if any of the key or distractors invalidated the argument, they correctly changed their mind and identified that both the argument was invalid and the correct reason it was invalid. Finally, a score of -1 meant the student was both unable to accomplish the Boolean validation and identify the reason the argument was invalid.

[4] The interviews were analyzed using thematic analysis (Braun & Clarke, 2006).

Proposition: For arbitrary set A, B, and C;

$$(A - C) - (B - C) \subseteq A - B.$$

Argument: Let $x \in (A - C) - (B - C)$. That means that $x \in A$ and $x \notin (B - C)$ which implies that $x \notin B$. Therefore, we can conclude that $(A - C) - (B - C) \subseteq A - B$.

Figure 4.The proposition and argument for testlet $T5$ whose CVI categorization was determined by mathematicians to be LG.

The discrimination for $T5$ was calculated at $d = 15.5592$ with a peak information of 60.52218 at an ability of 0.4590. At first, this made $T5$ appear to be an undesirable outlier as such high discrimination and peak information are not expected in human testing. After further investigation (see Table 2), $T5$ turned out to be a rare case of an item working beyond the norm for human testing. The analysis undertaken suggests that testlet $T5$ performed very well, and that the calculated discrimination was a fair understanding of the testlet's performance in relation to the other testlets from the ASAVA. Overall, students' outcomes on this testlet align in a synchronistic fashion with their overall outcomes, implying testlet $T5$ was not an outlier, but a highly consistent measure.

Table 2. Testlet $T5$ performance against overall performance.

	Total Score																
T5 Score	-8	-7	-6	-5	-4	-3	-2	-1	0	1	2	3	4	5	6	7	8
-1	4	3		1	5	4	8	4	5	5	2						
0			1	2		1	5	1	3	1		1	1	2	1		
1											4	2	7	1	14	1	3

Discussion

The main goal of this treatise was to communicate the process by which the research tool, the ASAVA, was developed for measuring ITP students' ability to validate mathematical arguments. The process requires some extension to refine the product of the ASAVA, but the results of the initial process are promising. Items like testlet $T5$ represent a promising representation of what the process outlined in this study can produce. While it is conceivable this study will lead to an assessment focused on validating many types of proofs from a variety of mathematical contexts (e.g., ITP, Algebra, Analysis, and Topology), it is not so at this point. Additionally, while the theoretical framing points to an assessment that measures students' ability to validate both from a Boolean perspective (i.e., valid or invalid) and from an issue identification perspective (i.e., where has the argument failed?), the scoring that was initially put into place does not wholly embrace this sentiment.

Future Efforts

To finalize the ASAVA, a few final refinements must be undertaken. These refinements include (1) generating a more comprehensive scoring system that is both holistic (i.e., total ability) and dual perspective sensitive (i.e., Boolean vs issue identification), (2) removing the anchored structure from the assessment, and (3) collecting and analyzing a second set of student data (i.e., assessment and interviews) to take into account these refinements. Once this process is undertaken, this tool can be used alone or in conjunction with other assessments to answer questions relating to conviction, comprehension, and construction as outlined in the introduction of this study.

Characterizing Student Engagement in a Post-Secondary Precalculus Class

David Fifty
University of New Hampshire

Dr. Orly Buchbinder

Dr. Sharon McCrone
University of New Hampshire

This paper reports on several aspects of a larger study aiming to characterize the engagement of students in a Precalculus class at a four-year public university. In line with policy suggestions that advocate for the development of flexibility in mathematics problem solving, we conducted a teaching experiment which utilized a set of "multiple solutions activities" to expose students to alternative solution methods while providing opportunities to examine and critique the reasoning of others. In addition, the instructor and teaching assistant of the course attempted to use these activities to explicitly negotiate productive norms and practices. Nevertheless, several detrimental norms emerged in the class, as the effectiveness of the activities was hindered by several propensity factors, particularly students' prior knowledge and self-regulation.

Keywords: Social Norms. Sociomathematical Norms. Developmental Mathematics. Precalculus.

Purpose

It has long been advocated that post-secondary developmental mathematics courses, such as Precalculus, would benefit from a greater focus on the development of students' argumentation skills, reasoning strategies, and flexible knowledge (Chiaravalloti, 2009; Partanen & Kaasila, 2014; Star & Rittle-Johnson, 2008). Such change of teaching focus could be more conducive of student learning than traditional Precalculus courses, which often tend to emphasize mastering algorithms and reviewing remedial content (Cox, 2015; Grubb, 2013; Mesa et al., 2011). This emphasis usually does not require students to change their mathematical practices and habits, which might have contributed to the need for remediation in the first place (Carlson et al., 2010; Goudas & Boylan, 2013).

Recent policy documents advocate for the importance of students developing *flexibility* in mathematics problem solving, which typically refers to the ability to generate, use, and evaluate multiple solution methods for given problems (Common Core State Standards Initiative, 2010; National Council of Teachers of Mathematics, 2006; Star et al., 2015). In addition to improving students' conceptual and procedural knowledge, developing flexibility often coincides with providing opportunities for students to practice reasoning skills (Star & Rittle-Johnson, 2009). Developing flexibility may require a form of engagement that students are not accustomed to, which may even contrast with their own preferences. Typically, students with insufficient mathematical skills and backgrounds tend to prefer a dependent learning style that is oriented towards mastering algorithms (Chiaravalloti, 2009; Partanen & Kaasila, 2014). Thus, to develop flexibility in developmental mathematics classes, it is important for instructors to negotiate norms and practices that encourage engagement that focuses on utilizing these skills.

This paper reports on a teaching experiment in a post-secondary Precalculus class at a four-year public university. The course instructor, who is the first author of this paper, utilized a sequence of activities that were designed for students to critique and compare multiple solution methods in small groups, thereby providing opportunities to develop flexible knowledge and reasoning skills. Throughout the course, and specifically when enacting these activities, the instructor and teaching assistant tried to explicitly initiate the negotiation of productive norms and mathematical practices to improve students' mathematical engagement. We analyzed the in-class engagement of two groups of students working on these activities to answer the following research question: what sociomathematical norms and social norms developed in these groups over the semester and what propensity factors mediated the emergence of these norms?

Framework

As our theoretical lens we adopt two frameworks: the interpretive framework by Yackel and Cobb (1996) and the opportunity-propensity framework by Byrnes and Miller (2007), which we detail below. We used the interpretive framework to identify emerging norms, and the opportunity-propensity framework to gauge possible reasons for the emergence of these norms.

The **emergent perspective** characterizes classroom activity from both social and psychological perspectives. From a social perspective, student and teacher interactions in a classroom are regulated by various types of *norms* (Cobb et al., 2001). For example, *social norms* characterize the classroom participation structure and *sociomathematical norms* are those specific to mathematical aspects of students' activity (Yackel & Cobb, 1996). For example, the requirement to justify one's mathematical work is a social norm, whereas what constitutes a mathematical justification is a sociomathematical norm. Students' participation in the negotiation of a norm coincides with each individual's reorganization of their own values and beliefs. Thus, norms and beliefs are said to co-develop, as each of the social constructs is reflexively related to a psychological construct, as shown in the interpretive framework (Figure 1).

Social Perspective		Psychological Perspective
Classroom Social Norms	⟷	Beliefs about one's own role, others' roles, and the general nature of mathematical activity in school
Sooiciomathematical Norms	⟷	Mathematical values and beliefs
Classroom/Communal mathematical practices	⟷	Mathematical reasoning and individual activity

Figure 1. Interpretive Framework (Yackel & Cobb, 1996)

The **opportunity-propensity framework** has previously been used as a theoretical basis for examining the development of flexibility and explaining variance in students' achievement in mathematics (Star et al., 2015; Byrnes & Miller, 2007). The framework outlines two types of factors that mediate students' engagement: opportunity factors and propensity factors. *Opportunity factors* refer to the culturally defined contexts where students are presented with content or skills to learn or practice within a particular domain. These can be formal or informal, and may vary in quantity and quality. Examples of opportunity factors include the types of instructional materials used and a teacher's questioning techniques.

Conversely, *propensity factors* refer to students' willingness or ability to learn content or skills after it has been presented or exposed to them. Byrnes and Miller (2007) report that most propensity factors fit into three categories: ability to take advantage of opportunities, willingness to do so, or factors regarding self-regulation. Self-regulation refers to the means of processing learning material, such as a group's ability to organize and utilize effective learning strategies.

The two frameworks complement each other to help characterize students' engagement. Specifically, the opportunity-propensity framework helps to understand the co-development of psychological and sociological constructs in the classroom, identified through the interpretive framework. Opportunity factors characterize the local social and mathematical contexts in which students engage and in which norms are implicitly or explicitly negotiated. For example, the development of the social norm of *trying to understand others' solutions* may be mediated by providing opportunities to engage in frequent, meaningful discussions. The propensity factors help to understand possible reasons for why certain contexts have been less conducive to student engagement or lack of students' uptake of particular learning opportunities.

Data Sources and Methods

The data were collected in a post-secondary Precalculus class with an instructor and teaching assistant who were Mathematics Education PhD candidates that had each previously taught the course. A majority of the nearly eighty students were retaking the course because they did not earn a sufficient grade the previous semester to meet the pre-requisite for Calculus 1. The class met three days a week for a fifty-minute lecture, during which, the instructor, aided by two learning assistants, engaged students in problem solving in small groups. Two days a week students meet in smaller sections of about 25 students for a lab period, where the instructor and/or the teaching assistant facilitated group-work around solving problems.

A sequence of four *multiple solutions activities* was designed to provide students with opportunities to develop flexible knowledge by evaluating and critiquing different mathematical arguments. These activities were anticipated to improve students' knowledge of strategies, which is critical to the development of flexibility (Star & Rittle-Johnson, 2008). The activities were designed for students to work on in groups of three or four during their lab period. These groups remained constant throughout the semester.

Each activity was composed of three phases. The first phase required students to solve a mathematics problem and to formulate a grading key for it. Second, students were to use their grading key to evaluate three fictitious students' sample solutions to that same problem. By design, the solutions contained intentional mathematical or notational errors and/or incorporated methods or strategies that students had not been previously exposed to in the course. Besides representing a valuable learning opportunity for students, this design would help us identify emerging norms. After evaluating the solutions, students responded to reflection questions that required them to compare and contrast the three solutions. For the last phase of the activity, the instructor and teaching assistant facilitated a class discussion to highlight key aspects of the solutions while also explicitly negotiating particular norms, such as: an acceptable mathematical solution may follow any mathematically valid approach and that solutions must contain explanations. Sustaining such norms in the course would provide opportunities to develop students' flexibility and reasoning skills. These activities served as an essential data source for the study. Six groups of four students were video-recorded using 360-degree cameras during these activities and their written work was collected.

Analysis

The video data was analyzed by classifying utterances and activity within the interpretive framework (Figure 1). Since norms are a social construct, we identified their emergence through interactions between members of the class. Errors and alternative methods included in the sample solutions were intended to represent violations of various conjectured sociomathematical norms, hence students' discussions around these errors and methods were pivotal to our analysis. By coding students' utterances and activity, we hoped to determine whether students deemed these errors and methods as legitimate or not, thus elucidating the development of sociomathematical norms in the groups. For example, both solutions in Figure 2 demonstrate incorrect and inconsistent notation, among other errors. Both groups were quick to condemn the incorrect notation of Tom's final answer, which supported the conjecture that students deemed it necessary for an answer to have the correct notation; this will be further discussed below.

Conjectures of social norms evolved similarly. Our analysis would start with proposed norms. During our coding of utterances and classroom activity, we would try to identify occurrences when students appeared to violate our hypothesized norms. Our proposed norm would garner support if the violation was delegitimized by others. Legitimization on the other hand would require us to revise our proposed norm. Thus, our proposed norms would evolve and gain more support with subsequent iterations of analysis and coding.

Because groups worked separately on the first two phases of the activities, the norms we discuss here are those that were constituted within the students' groups. After identifying norms, we used the opportunity-propensity framework to explain factors affecting their emergence. Consideration of both frameworks led to a more detailed understanding of students' engagement.

In this paper, we focus on two groups of four students each; Group 1: Wes, Ted, Herbert, and Cullen, and Group 2: Molly, Steve, Peter, and Chad (all names are pseudonyms). All eight students were taking the course for the second time. We primarily draw upon parts of our analysis of the first activity of the semester to demonstrate patterns of norms that developed, and were mostly sustained, within the groups over the semester.

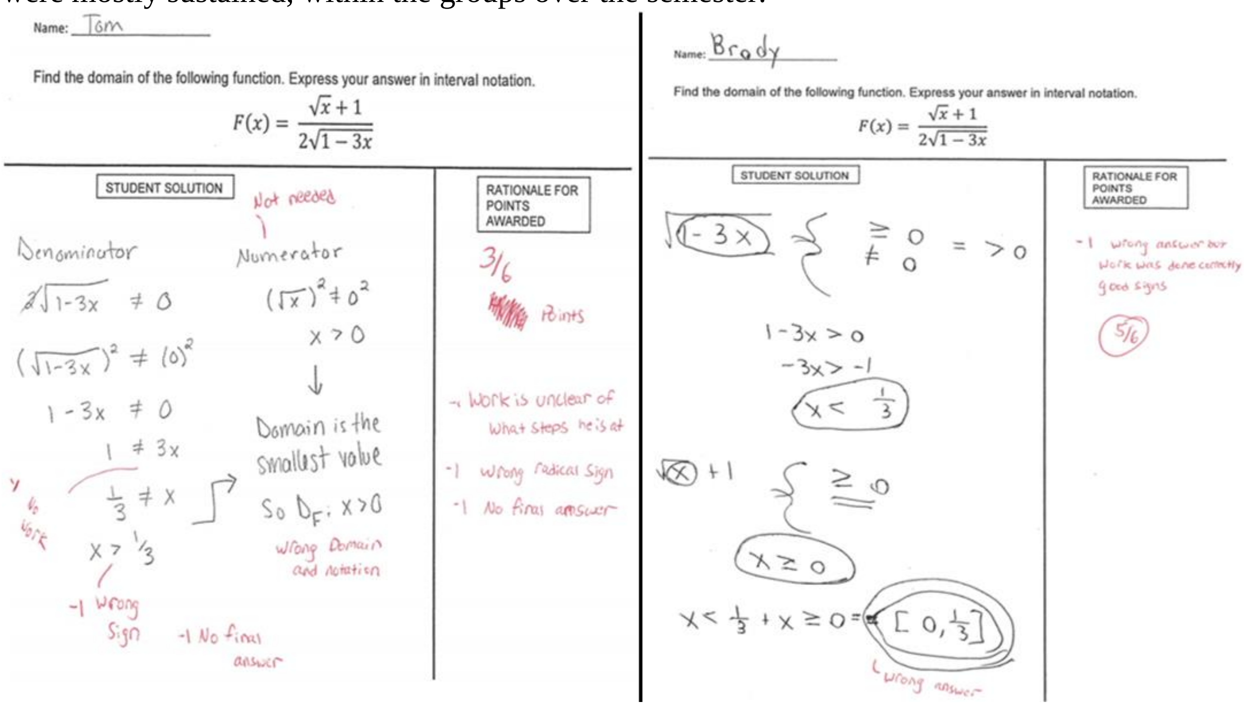

Figure 2. Two solutions from the first multiple solutions activity. The writing in red is that of Wes, from Group 1.

Results

The Role of Notation in What Constitutes an Acceptable Solution

Our analysis revealed that notation played a key role in characterizing the sociomathematical norm of what constitutes an acceptable mathematical solution. Students were keen to be consistent with the instructor and teaching assistant's explicit messages of what notation is improper and what type of notation is beneficial for clearly communicating one's mathematical work. During an activity on finding the inverse of a function f, students were quick to condemn solutions that did not label the inverse function as f^{-1} in the final answer, which was previously stressed by the instructor. But in situations where the instructor and teaching assistant did not previously comment, students' consideration of notation was limited.

The first activity of the semester asked students to find the domain of a function; two of the sample solutions from this activity are included in Figure 2. One of the notational errors in Tom's solution is his incorrect use of a "not-equal" sign, which he eventually incorrectly switched to a "greater-than" inequality. In Group 1, Ted inquired as to whether inequalities were needed for this problem. Wes delegitimized this concern with a shrug, Cullen expressed that he used the same notation as Tom did in his solution, and Herbert suggested that Ted was technically right but that "you don't need to make a big deal about it." The reaction in Group 2 was very similar, as Steve pointed out that, "[Tom] did the whole way it can't equal until the end where he just rewrote it [with the greater than sign]." Molly suggested to Steve that the notation inaccuracies did not matter, as long as the notation was correct at the end, which Steve agreed to.

The notation in Brody's solution did not adhere to standard notation established in class, and included improperly used symbols for informal arguments without clear description (Figure 2). Yet neither of the two groups discussed the poor notation; the only critique of Brody's solution was his incorrect answer. In fact, both groups complimented the work. Group 1 went as far to express that the only thing wrong with the solution was the answer.

The examples above help illustrate one component of the sociomathematical norm of what constitutes an acceptable solution that developed within the groups: *an acceptable solution only needs correct notation in the final answer*. This view was mediated by the propensity factor of deficient prior knowledge. Many of the students had an underdeveloped understanding of mathematical notation. For example, Steve was unable to recognize the interval notation in Brody's solution despite the fact that he had recently taken a quiz on interval notation.

These outcomes illustrate that the instructor's expectations that students will learn proper notation through implicit negotiations that are constituted primarily by modeling in class were overly optimistic. In this case, these opportunities provided to students to learn proper mathematical notation were clearly insufficient. Although the instructor and the teaching assistant were more explicit about the use of notation during the whole class discussions, their efforts were often ineffective for other reasons, which will be discussed later.

Unnecessary to Investigate Alternative Approaches

One social norm that emerged in both groups, and was especially apparent in Group 1, was that it was *unnecessary to interpret alternative approaches*. For example, in the first phase of the activity, when finding the domain of the function themselves, both groups' original answers differed from those of Tom and Brody. The groups did not consider the restriction imposed by the square root in the numerator, but Tom and Brody's solutions did.

As Group 1 attended to the sample solutions, they noticed that Tom and Brody considered the root in the numerator to determine the domain. At first, all group members expressed that it was not needed and some would frequently repeat, "Domain is in the denominator." But eventually the group expressed uncertainty to the role of the numerator. Despite this confusion and doubt, no one in the group attempted to interpret the numerator's role in the other solutions. In general, when the two groups did not understand an alternative approach or strategy, their reaction was often to dismiss, denounce, give up, or some combination of the three.

It was apparent that two propensity factors helped mediate this social norm. The first is students' prior knowledge; their underdeveloped understanding of the concept of domain hindered their ability to productively work on the activity. For much of the semester, it was clear that the students in Group 1 focused on replicating algorithms, of which they did not have a deep understanding, and as result, they implemented the algorithms partially and inconsistently. This preference did not help students effectively develop their understanding of key mathematical concepts, hindering their work on multiple solutions activities. Secondly, the self-regulation within the group was limited. During this activity, the group utilized strategies to confirm the domain restriction caused by the denominator, such as evaluating the denominator with particular inputs. These same strategies could have been effective in understanding the role of the numerator in finding the domain of the function. But despite being familiar with these strategies, the students were unable to determine how to utilize them.

In general, students in both groups were hesitant to learn about multiple approaches and analyze the solutions of others, and expressed their preference for mastering one method instead, as they had done in their prior courses. The students described this difference in a conversation with the instructor:

Steve: That was also like last semester they constantly drilled that in our head that there was only one way to do it.

Molly: Yeah. So that's why I feel like a lot of us, or at least personally why I'm struggling.

Steve: It's a lot different.

Molly: I don't have a set rule to like follow.

Attentiveness in Whole Class Discussions

The class discussion phase represented an opportunity for the instructor and teaching assistant to use the activity as a medium to explicitly negotiate norms that aid the development of flexibility and improve engagement. In relation to the sociomathematical norm discussed earlier, the instructor and teaching assistant stressed that one purpose for writing solutions and using proper notation was to communicate one’s understanding to others; they emphasized the need for using conventional notation lest one’s work would be interpreted differently than intended.

Yet our analysis showed that during this crucial time of the whole class discussion, the students would often disengage, and ignore the instructor and teaching assistant. Students instead would often look out the windows, draw on their papers, or use their phones. This is indicative of a social norm that being attentive during class discussions is not important.

Here, propensity factors relating to students’ unwillingness to take advantage of opportunities to engage in the discussions hindered the development of productive classroom norms. In particular, lack of interest and motivation may have been predominant factors: students were eager to pack up and leave since the discussions occurred near the end of class. The lack of motivation might have been supported by students’ recognition that their participation in the discussions was not graded or the perception that these discussions did not align with traditional assignments and assessments that they expected to receive. Due to this low engagement, unproductive norms were mostly sustained throughout the semester or their change was limited.

Discussion

Our study aimed to characterize students’ engagement in a Precalculus class by examining what social and sociomathematical norms developed among groups of students over the semester, and what propensity factors mediated the emergence of these norms. In particular, we focused on students’ engagement with multiple solutions activities, which aimed to develop their flexible knowledge. The data presented in this paper aims to illustrate some of the norms that emerged in our data, however space constraints do not allow for the inclusion of all of the identified norms.

Our data show that despite the instructors’ attempts to negotiate productive norms while engaging students in mathematical activities that foster flexible solution strategies, the students developed social and sociomathematical norms within their groups that were often detrimental to their own learning. For example, our study revealed several characterizations of the sociomathematical norm of what constitutes an acceptable mathematical solution that developed within these groups, such as (a) it has to follow the algorithm shown in class (Fifty, Buchbinder, & McCrone, 2019), (b) it results in a correct answer, even if the steps are flawed (Fifty, Buchbinder, & McCrone, 2020), and (c) following conventional notation is only important in the final answer, as illustrated above.

Some of the social norms that our study identified were the lack of attentiveness during class discussion and resistance to interpret alternative solutions. Our data show that these social norms acted as barriers to the instructor and teaching assistant's efforts to promote flexible knowledge. For example, because the students were not attentive during the class discussions it should come as no surprise that the groups did not benefit from the instructor and teaching assistant's negotiations. Furthermore, this lack of attentiveness reduces the instructor and teaching assistant’s influence on the development of norms within the groups. These findings represent an instance where social norms may constrain the development of sociomathematical norms.

We attribute some of the students’ reluctance to learn about multiple approaches for solving particular mathematical problems to the effects of detrimental beliefs about the nature of mathematical activity the students came to expect in a Precalulus course. These beliefs could be a consequence of unproductive norms developed in their prior mathematics courses, especially in the previous Precalulus course, as suggested by Steve and Molly’s conversation detailed above. As described by the emergent perspective, norms and beliefs co-develop (Cobb et al., 2001). Even though norms recede with the conclusion of a course, students' beliefs, affected by the development of these norms, may persist and can act as barriers to the negotiation of other norms in subsequent classes. Consequently, our data suggests that instituting productive norms, particularly in developmental courses, can be a gradual process.

To better understand the emergence of these detrimental social and sociomathematical norms, we considered possible opportunity and propensity factors that might have influenced students’ engagement in the multiple solutions activities (Byrnes & Miller, 2007). Some of specific propensity factors that we explored were the roles of students’ prior knowledge, motivation, and utilization of effective learning strategies. Better understanding these propensity factors can help educators reconfigure opportunities to improve students' engagement. For example, given that students seemed unmotivated to engage and participate in the class discussions, one possible way to inspire change would be to more explicitly connect these class discussions to assessment in the course. This could change the social norms that develop in the class, and consequently lead to improved development of students' flexible knowledge.

Despite the wide recognition of the importance of flexible knowledge, exploration of how teachers may provide instruction to facilitate its development in authentic environments remains largely unexplored (Star et al., 2015). Our design and use of multiple solutions activities help fill this gap in the research. The first two phases of the activities presented opportunities for students to discern different methods, while the reflection questions and the class discussion intended to explicate comparisons and clarify nuanced differences between the solutions. This focus on flexibility did not hinder the progression through the curriculum, as each activity was situated within the relevant mathematical context. Additionally, the activities provided opportunities to emphasize general mathematical principles, such as the value of adhering to conventional notation.

Chavrusa-Style Learning in Mathematics Classrooms: Instructor and Student Perspectives

Rochy Flint
Columbia University

Baldwin Mei
Columbia University

MathChavrusa is a novel application of Talmudic study techniques into the context of mathematics education, emphasizing long-term, partnered text study and problem solving. This study implemented MathChavrusa in semester long graduate mathematics courses, collecting data from both instructor and student perspectives on the effectiveness of MathChavrusa in facilitating student understanding of course material and engagement in communicating mathematics. Results indicated that students largely had a positive impression of MathChavrusa, highlighting its impact on student engagement, creating a conducive environment for asking peer-peer and peer-instructor questions, and was a factor in better understanding course materials. This study model has the potential to enhance student engagement in mathematics classrooms and could be adopted more broadly.

Keywords: Peer Learning in Mathematics, Math Chavrusa, Student Centered Learning

Introduction

There is an increasing body of research suggesting that peer learning is beneficial for students in all phases of academic progress (Snyder et al., 2016; Sacerdote, 2011; Tsuei, 2012; Robinson et al., 2005). Though a relatively recent area of interest in educational research, peer learning has been a tradition in Jewish culture, utilized since the first or second century CE in chavrusa Talmudic instruction. Chavrusa, meaning "friendship" or "companionship" in Hebrew, refers to the practice of paired or small group study of the Talmud typically focused around reading, analyzing, and discussing passages in the text. Importantly, the chavrusa method consciously recognizes and embraces the social aspect of learning and its ability to construct new meaning from the materials via debating each individual's perspective (Pace, 1992; Kent, 2010).

MathChavrusa is the application of the Talmudic chavrusa model to the study of mathematics. As practiced in traditional chavrusa learning, MathChavrusa divides the class into one on one peer groups that persist throughout the semester and are either assigned by the instructor or chosen by students. This model is distinct from other peer learning models in a number of respects: (a) limiting the peer size to two creates an atmosphere of intimacy which reduces social anxiety, making it more likely that students will have the courage to ask questions without fear of judgment, (b) the active role each student adopts in a direct dialogue limits external distraction, (c) the discussion model engages students across a variety of levels of academic performance, where advanced students can adopt the role of teacher. Throughout the course, groups are tasked with supporting each other in understanding the material the instructor presents in class. This includes group reading, problem solving, content projects, and homework sets aimed to provide students with multiple methods of interacting with the course material. Emphasis in class is placed on group readings and problem solving, as they are intended to supplement lectures and provide additional background on the subject matter. These activities typically last at least twenty minutes per class to provide groups with ample time to interpret and discuss the implications and connections that supplementary materials bring to bear on the lecture topic. Projects and homework sets remain the students' responsibility outside the classroom: the former are an outlet for students to explore topics beyond the scope of the course, and the latter provide reinforcement of course topics between meetings. Projects and homework sets are then shared with the class as a whole so that all MathChavrusa groups can learn from each other's research.

In this study, we aimed to demonstrate the effectiveness and feasibility of the MathChavrusa model in increasing student engagement, mastery of content, and sense of community within the classroom. Mixed methods of quantitative and qualitative data from three semester-long graduate mathematics courses were collected to assess students' beliefs regarding MathChavrusa's effect on their course experience as a whole, including its influence on each student's course material mastery, peer engagement, and personal involvement. Instructor perspectives came from direct observation, verbal feedback from MathChavrusa pairs during discussion with the instructor immediately after each class session, and reflective essays written by each student at the culmination of each course. Student perspectives came from the student author's observations, from interviews conducted by the student author with a random selection of individual students from each course in which MathChavrusa was implemented, and from formal Likert scale survey results. An instructor-student collaboration was chosen for the format of this paper to overcome instructor bias and to increase the generalizability of these findings to the academic pedagogical system as a whole.

Literature Review

Peer learning is an established practice in mathematics education and comes in myriad forms to suit specific needs and purposes. For instance, groupwork has been used for both short-term and long-term classroom learning arrangements. As an example, a short-term arrangement may take the form of a think-pair-share. Generally, a wide range of activities that contribute towards classroom culture, teaching, review, and assessment can also be done in a brief peer learning context (Udvari-Solner & Kluth, 2018). Such short-term activities are promising, as students have been observed to have an increased understanding of course material and improved interpersonal attitudes after participating in group work (Springer et al., 1999).

Long term forms of peer learning that run over the course of a semester or more have also been implemented, and these are typically characterized by more structured task requirements and grouping criteria (Lindboe, 1998; Quitadamo et al., 2009). Various factors can be controlled in these lengthier groupings, including student ability matching, group objectives, and individual responsibilities. In this context, there are contrasting results as to the usefulness of groupwork in improving mathematical achievement. Meta-analysis of studies performed by Springer et al. (1999) indicated that there was little support that long term groupwork improved mathematical achievement. On the other hand, the same study found that longer grouping periods seemed to improve students' attitudes towards each other and to approaching course material, suggesting that there is still value in such arrangements. Another study by Sofroniou and Poutos (2016) found that by integrating problem-based learning and mixed ability grouping, previously lower achieving students had reduced levels of stress when approaching mathematical problems. Overall, the participants of the study also showed improvements in their content area understanding, measured by the increase in final exam scores in the group participating in peer learning. Lindboe (1998) found similar results when working with lower achieving students. Specifically, when these students worked as peer instructors with each other in undergraduate mathematics courses, their ability to share pedagogical and learning strategies as well as provide social and emotional support for each other improved mathematical achievement. However, despite this body of research demonstrating benefits of group work in higher education, there are situations in which students may be uncomfortable working closely with their peers. In a study looking into attitudes towards groupwork across business administrations, educational settings, and mathematics students, business administration students viewed groupwork more negatively than the comparison groups (Gottschall and Garcia-Bayonas, 2008). The results suggest that though peer learning is shown as beneficial and worth exploring, thoughtfulness should be exercised to ensure that these initiatives resonate with the particular student body.

A subset of the aforementioned long-term peer learning is the Chavrusa method. Research indicates that chavrusa learning is currently seeing increased and expanded use outside its traditional Talmudic setting. For instance, South Korea has seen chavrusa-styled private academies, *hagwons*, emerge in the past decade, supplementing more traditional, mechanical cram schools (Choi, 2017). The model is influencing public education, with the Korean Federation of Teachers' Associations coming to an agreement with the Havruta Cultural Association to train teachers in utilizing chavrusa methods in the classroom (JTA, 2019). Medical education has drawn certain ideas from traditional Talmudic learning, incorporating student-centered, self-directed learning in small group settings. In these models, the role of teachers becomes integrated with group learning as well: rather than solely as experts in their fields, teachers become role models and mentors within a socially interactive framework of group discussion (Notzer et. al., 1998). Similarly, studies within the physical therapy discipline have also confirmed the effectiveness of structured group learning, noting statistically significant improvements between pre and post chavrusa style group-driven academic and motivational interventions (Chung & Lee, 2019).

Methodology

Data was collected from 44 students in three graduate mathematics content courses in the form of reflections, surveys, and post-course interviews. The reflections were collected by the instructor, while the post-course interviews were conducted by the student collaborator. Reflections consisted of written feedback on MathChavrusa and the course as a whole. Likert scale surveys consisted of statements and questions about MathChavrusa specifically. These were collected anonymously, and students were asked to respond to each statement with strongly disagree, disagree, neutral, agree, and strongly agree, with the numbers 1, 2, 3, 4, and 5 representing each of these responses respectively. Respondents were also given the opportunity to write comments about MathChavrusa overall, which were also recorded on the survey handout. Interviews were conducted several weeks after the course completion and were structured around questions designed to compare and contrast with the survey results as well as to identify student background and post course content mastery.

Instructor Perspective on MathChavrusa

By implementing MathChavrusa, the instructor's initial goals were four-fold: to deepen students' understanding of course materials, to strengthen students' communication skills in mathematics, to build a community of relationships and collaboration centered on coursework, and to motivate students to initiate self-driven study from the course "textbook"/readings.

Many of these goals materialized as the course progressed. Students became more adept at reading mathematical texts without direct instruction. Relationships formed between students that expanded beyond the discipline and took on an inherently social and interactive quality. There was a high level of student interaction between groups as well. Students became more proactive and courageous in voicing their questions and deepening clarity on the subject matter.

To evaluate the quality of learning more directly, MathChavrusa pairs were asked to select and teach homework problem sets to the class, and to engage in post-class discussions with the instructor. Within the classroom, student engagement was also assessed by observing how often students turned to their partner or to another group for clarification or instruction. Student engagement was also indirectly assessed by the frequency and the complexity of questions posed by chavrusa partners during office hours. According to the instructor's observations, the more time added to MathChavrusa, the more students actively engaged with the course materials. Students gave attention to their mobile phones less often, were communicating mathematics more explicitly, and were generally more focused on the task at hand. Throughout the courses, students consistently requested more MathChavrusa time. From the onset the instructor observed moments of student excitement while engaging in MathChavrusa reading materials and expressing they "got it". For example, "I can finally see the process of continuous deformation and how the coffee cup is homeomorphic to a doughnut". Students frequently drew on diverse perspectives and were delighted to share how they approached the same problems differently.

As courses moved along, the MathChavrusa structure took on an evolving dynamic. Most of the pairings were of students at mutually similar academic levels. This allowed students to discover insights and work symbiotically. During review sections, and at the students' request, pairs were changed to have "stronger" and "weaker" academic partners. This alternative model worked well for review and summative learning processes. Another organic evolvement was that chavrusa partners filled in the gaps for their own partners, recording lectures, taking notes, and providing verbal reviews for the other in the event of absence. These dynamic changes reflect the importance of consistency, alongside openness to integrating student feedback and needs as the unique structure of each class's pairings present themselves.

An additional benefit that played out as a byproduct of the MathChavrusa model was the drastic transformation of students who entered the course with performance anxiety. While initially fearful and hesitant to present, the format allowed these same students to flourish and overcome their initially hesitancy. By the end of each course, not a single student was held back by fear of presenting and each developed a confident and engaged presentation style.

Many students expressed that struggling through problem sets became more enjoyable and productive, noting that, "having someone to work with really enriched my understanding of the material, and lightened my frustration with solving problems because we struggled together and pieced our ideas together. This was much different from my undergrad where I was isolated, and I had no one to turn to when I struggled." This sentiment was indicative of a theme throughout other students' reflections.

A key performance indicator is test scores. Test score performance was higher in all three iterations of MathChavrusa as compared to courses delivering the same content without MathChavrusa. Only the classes that incorporated MathChavrusa had 100% passing rates, which is unusual for a high-level mathematics content course.

One of the struggles in the MathChavrusa structure is that some pairs seemed to develop a stronger bond than others, which led to different levels of engagement. While all pairs engaged in the course tasks, there was a strong correlation with pair likability and enthusiastic engagement. This did not necessarily translate to varied test scores but did affect perceived students' positive attitudes in the classroom.

Instructor observations are essentially limited by potential subjectivity and bias. To complement this perspective, an instructor-student collaboration was formed to provide increased objectivity and overcome instructor blind spots.

Student Perspective on MathChavrusa

MathChavrusa shares many similarities with models of groupwork prevalent in education today, but also has critical differences that make the experience for the students distinct from schema such as think-pair-share. What follows is a summary of post-course feedback received from students who have experienced MathChavrusa. This feedback was collected in two forms: ten interviews conducted by the student author, as well as analysis from post-course Likert scale surveys completed by students. Four of the interviewees experienced MathChavrusa in two courses. A summary of the statistics from the surveys is shown below in Table 1.

Table 1. MathChavrusa feedback survey summary

Survey Results		
Questions	μ Mean	σ Standard Deviation
1) The MathChavrusa format improved my ability to learn the content for this course.	4.16	0.82
2) The format of MathChavrusa increased my ability to stay engaged.	4.19	0.82
3) The format of MathChavrusa helped me feel more prepared to speak in class.	3.68	1.04
4) The format of MathChavrusa stimulated my interest in reading about course content outside of class.	3.69	0.76
5) The format of MathChavrusa helped me understand key ideas in the course.	4.03	0.81
6) The format of MathChavrusa helped me feel comfortable approaching the instructor with questions or comments.	3.86	1.02
7) I learned more when I worked with my MathChavrusa.	4.19	0.95
8) My MathChavrusa and I worked well together.	4.51	0.91
9) I found it helpful to get feedback from my MathChavrusa on my own performance.	4.24	0.90
10) I needed more instructor guidance during MathChavrusa time.	2.97	1.27
11) My MathChavrusa and I helped each other out during the course.	4.35	0.93
12) I collaborated with my MathChavrusa outside of school.	3.97	1.41
13) The MathChavrusa format contributed to my success.	4.00	1.11
*1, 2, 3, 4, and 5 correspond to strongly disagree, disagree, neutral, agree, and strongly agree		

Benefits of MathChavrusa

Students across all three courses seemed to have positive impressions of MathChavrusa, with all survey questions except one scoring above neutral on the Likert scale. Survey results indicated that students attributed working with their MathChavrusa as a factor in better understanding course materials, with $\mu = 4.16$ and 4.03 for questions 1 and 5 in the survey, respectively. Additionally, student engagement was positively affected by MathChavrusa, with $\mu = 4.19$ for question 2. On an interpersonal level, student responses were even more positive. Question 8, 9, and 11 inquired about peer to peer interactions, with responses of 4.51, 4.24, and 4.35 respectively, indicating a high level of comfort and camaraderie in each MathChavrusa.

These observations were supported and supplemented by students who participated in the interviews. Students stated that MathChavrusa gave them an outlet to easily ask questions to their partner when in need of guidance, and most of the time this allowed them to understand formerly confusing concepts. Beyond clearing up information, MathChavrusa also led to pairs developing organic support systems and specializations, with interviews highlighting various role divisions unique to each MathChavrusa pair. In addition, the act of asking questions within each MathChavrusa led to increased interactions with the class as a whole, with interviewees stating that they often asked MathChavrusa groups around them for advice when internal problem solving was insufficient. This formed bonds between classmates and contributed to newer students finding long-term acquaintances for future classes. In terms of class culture, students remarked that as a whole, the emphasis on peer learning and communication "broke the walls in the classroom," allowing for a comfortable setting to interact with classmates and ask questions freely.

The interviews also produced responses not covered by the survey. An important element of MathChavrusa is joint text study, which some students felt was helpful. Specifically, they appreciated the time given to work on problems directly related to materials presented by the instructor in class, stating that such practice helped make connections and rectify misconceptions in the material. Students also mentioned that they liked the MathChavrusa format as it was a break from traditional lecture-based learning and provided variety within class sessions. Similarly, students appreciated time prescribed for interacting with other MathChavrusa groups, as these interactions resulted in exchanges in knowledge and perspectives that proved valuable in developing each person's depth of understanding.

Considerations for Implementing MathChavrusa

Though generally positive towards MathChavrusa, student interviews illuminated a few important implementation details that need to be carefully considered when utilizing MathChavrusa. First among these is the effectiveness of collaborative reading. While the goal of MathChavrusa is for students to learn new material via textbook reading, students found it challenging and at times confusing. Students from two of the three classes indicated that some readings emphasized concepts and material beyond the scope of the course lectures. Though interesting, these types of texts were found to be confusing as they didn't address fundamental misunderstandings students had about in-class material and assumed competency in recently learned material. Students believed that readings more focused on content directly related to what was being introduced in class would have better improved their grasp of the course material, as well as enable them to then understand the enrichment materials. Related to this, students felt that the collaborative problem-solving portion of MathChavrusa was very useful for improving their understanding, as it gave direct, concrete examples of how material could be presented, as well as opportunities for step-by-step walkthroughs to clarify the logic behind how each step was achieved.

Another salient point students mentioned was the nature of MathChavrusa pairings. Students were given the choice of picking their partner or being randomly assigned, and with class composition and preference for choosing partners, this often resulted in students of similar mathematical backgrounds to be placed together long term. However, students found at times that it was difficult to make sense of concepts when both partners were unable to see the reasoning behind concepts and problems, especially in content dense or unfamiliar areas of the courses. At these points, those interviewed would often attempt to turn to either the instructor or surrounding groups for help, though the latter yielded mixed results due to other groups also being confused and the former only being able to help a limited number of groups during MathChavrusa time. As such, students suggested mixed ability pairings for part of the class, to have at least one person in the group be able to guide the MathChavrusa through difficult content. It should be noted however that students in general enjoyed the freedom they had in selecting their partner, and suggestions for mixed ability pairing only wanted them temporarily to allow for clarification of unclear ideas. Also, though most pairings seemed to be amicable with each other, there were instances of students not getting along with their MathChavrusa partner, which could impact the long term learning outcomes of those students.

Conclusion

MathChavrusa has shown promise as a structure for mathematical learning in postsecondary classrooms. Its emphasis on collaborative text study, problem solving, and long-term peer support enables students to improve their ability to learn mathematics and increases engagement. Moreover, it enables students to discover and implement appropriate strategies necessary to succeed. Students have generally indicated that working closely over a long period of time with their partner developed a positive classroom culture where they felt more comfortable engaging with the instructor and their peers. This in turn led to the development of organic support networks, where students would collaborate on problem sets and in-class materials frequently. Overall, students were positively affected by MathChavrusa and indicated that they learned more. However, feedback also suggests that the implementation can be improved, with important considerations being the interactions between MathChavrusa partners, the significance of readings towards course goals, and ensuring student ability grouping is appropriate for students to grasp course materials.

Future Research

This study provides a foundation analysis of the MathChavrusa model, and suggests the need for further research utilizing objective, performance-based measures of academic performance. Limitations of this study include focusing on the observation of one instructor and one student subject to personal biases. Additionally, further research should isolate the essential components of the MathChavrusa model (social learning, accessibility of instruction, novelty and variety of new academic activities, increased frequency of check-ins with peers and the instructor) for scaling and implementation purposes. It would also be interesting to explore whether student enthusiasm and adaptability vary based on undergraduate versus graduate mathematics courses, as well as the adaptations MathChavrusa needs to make when applied to courses of varying course content areas and academic difficulty.

What Comes to Mind? A Case Study of Concept Images In Topology

Keith Gallagher
West Virginia University

Nicole Engelke Infante
West Virginia University

Prior research has shown that students tend to reason in terms of the informal components of their concept images rather than rely on formal concept definitions when working with topics in mathematics. However, students' concept images may be incomplete or inaccurate, or students' evoked concept images may exclude important features of concepts or classes of examples. This report describes two students' evoked concept images of concepts in general topology as revealed through their completion of proof tasks as well as some of the effects those images had on their success in proving. We also discuss the impact of the students' exploration of their example spaces on their concept images and on their proof writing.

Keywords: topology, proof, concept image, examples

Introduction

Students' concept images can have a substantial impact on their abilities to solve problems in mathematics (Moore, 1994; Rösken & Rolka, 2007; Tall & Vinner, 1981; Vinner, 1983). *Concept image* refers to "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (Tall & Vinner, 1981, p. 152), while the term *concept definition* describes "a form of words used to specify that concept" (ibid., p. 152), with the formal concept definition being the one presented to students in a mathematics course. As teachers, we may hope that presenting students with a formal concept definition is sufficient for them to solve problems and that students will develop an appropriate concept image to represent the concept. This is, however, not generally the case – in fact, students typically do not consult with the concept definition at all, instead relying entirely on informal aspects of their concept images when responding to a given prompt (Vinner, 1983). Students may retain their concept image of a topic while being unable to produce a definition (Moore, 1994). These factors make the concept image of critical importance for students when solving problems or producing proofs.

A student's consideration of a topic begins with their evoked concept image. Tall and Vinner (1981) defined the *evoked concept image* to be "the portion of the concept image which is activated at a particular time" (p. 152). The totality of an individual's concept image may be sufficient to solve a problem, but the limitation of what is evoked at a given time may act as a barrier to the recognition of key ideas (Raman, 2003). For instance, a student's evoked concept image may be restricted to prototypical examples (Presmeg, 1992) held by the student which, though accurate, may not represent the full breadth of possibilities. This may prove to be especially problematic for the generation of counterexamples, which may require the recognition of highly esoteric cases. Such problems might be mitigated by expansion of the student's example space, i.e., the full collection of mathematical objects the student perceives as examples (Mason & Watson, 2008; Watson & Mason, 2005). Measures to optimize the accessibility (Goldenberg & Mason, 2008) and the generativity (Sinclair, Watson, Zazkis, & Mason, 2011) of the student's example space may improve students' recognition of these cases. Furthermore, a learner's concept image may contain conflicting elements, and the learner may not be aware of this potential conflict until forced to directly grapple with the inconsistency in their concept image (Davis & Vinner, 1986). The inspection of examples may also help students face and overcome these cognitive conflicts.

Our study investigated students' concept images and their effects on students' proof writing in general topology. Studies in topology have explored undergraduates' transitions into axiomatic reasoning (Cheshire, 2017) as well as students' development of schema for reasoning about a topology generated by a basis (Berger & Stewart, 2018, 2019); the latter of these demonstrated that students' schemas for topological concepts may develop very slowly in spite of direct instruction on such topics. Our previous work explored the role that visual representations played in the proof writing process of Stacey, an undergraduate taking a first course in general topology and how those representations helped her to identify the key idea of a proof (Gallagher & Engelke Infante, 2019). The current study addresses the question "How are undergraduates' concept images of topics in general topology structured, and how do their concept images affect their proof writing?"

Limitations in students' concept images can lead to great difficulty in proof construction and in general understanding. A first step toward supporting students' construction of complete, appropriate, and accessible concept images is to gain some insight into students' existing cognitive structures and the nature and limitations thereof. In this paper, we discuss components of the concept images of Tom and Stacey, two undergraduates taking a first course in general topology. We also discuss instances in which limitations or inaccuracies in these students' concept images hindered their understanding or their ability to solve problems, and we describe our informal efforts made toward restructuring their concept images to facilitate knowledge building.

Theoretical Perspective

Moore's (1994) concept-understanding scheme describes the interplay among three features of a student's knowledge about a concept: concept image, concept definition, and concept usage. The last of these "refers to the ways one operates with the concept in generating or using examples or in doing proofs" (ibid., p. 252). According to Moore's scheme, students may have a conceptual understanding of the topics involved in a particular conjecture, but they may still struggle to generate a proof due to a lack of experience or fluency in working with those ideas. Students may not be familiar with notation or language conventions regarding a given concept, or they may not know which of multiple notations might be the most efficient choice for a given application. There are also standard formulations which are used in proofs of certain concepts. For example, in proofs of ε-δ continuity in $\mathbb{R}^2$, the standard procedure is typically to fix an arbitrary $\varepsilon > 0$ and then use algebra to determine the corresponding δ. This formulation follows from the definition of continuity, but a student's ability to repeat this definition does not guarantee the student's knowledge of this proof scheme.

We will also utilize the notions of accessibility (Goldenberg & Mason, 2008) and generativity (Sinclair et al., 2011) of students' example spaces. Students may possess knowledge of examples, yet these examples may not come to mind readily for students in many situations. For instance, when prompted to generate examples of functions, many students may volunteer a number of commonly used functions such as $f(x) = x^2$ or $g(x) = e^x$; it may require quite a bit of probing to get students to consider more esoteric functions such as piecewise-defined functions or functions defined on discrete domains. The students may be aware of these examples, but such examples may be less immediately accessible due to infrequency of use, a perceived lack of importance, or other factors. The generativity of a student's example space refers to that student's ability to create new examples. This ability may depend upon students' abilities to recognize the dimensions of possible variation and range of permissible change within a class of examples (Mason & Watson, 2008); Marton and Tsui (2004) have suggested that students' abilities to generate new examples may not depend only on their exposure to various examples but on their experience identifying dimensions of possible variation.

Methods

Student volunteers were recruited from an introductory undergraduate course in general topology to attend weekly, one-hour Group Study Sessions. The first author acted as Facilitator during all sessions. During each session, volunteers were given either a statement to prove, a statement to disprove, or both if time permitted. Our intent was to create an environment that resembled an authentic studying environment as closely as possible. To that end, volunteers were encouraged to collaborate on all tasks, and they were permitted to use textbooks and class notes as desired. Volunteers were encouraged to speak aloud as they worked, and the Facilitator sometimes asked probing questions to gain more information about the volunteers' comments. The Facilitator sometimes intervened when it seemed that the volunteers would make no further progress on their own. All sessions were video recorded, and videos were transcribed.

Neither of the authors taught the topology course from which the student volunteers were recruited, but the first author attended all class meetings (except for exam days) to make note of topics covered recently by the instructor. Weekly proof tasks were chosen to align with the content recently covered in class. As compensation for the volunteers' participation, the first author offered additional office hours to help them with topology.

Data analysis is ongoing. Our data were initially coded to identify the production and modification of drawings, construction or discussion of examples, and any verbal utterances that might give insight into our students' concept images. Thematic analysis (Braun & Clark, 2006) was applied to these codes to identify prominent elements of Tom's and Stacey's concept images. In this report we discuss the emergent themes of *discrete sets versus continuous sets, connected sets versus disconnected sets,* and *open sets versus closed sets*.

Results

Discrete Sets Versus Continuous Sets

Throughout the course of this study, examples of sets and set imagery were predominantly continuous rather than discrete. For example, in Session 1, Stacey and Tom struggled to make sense of what the notation $f^{-1}(\bigcap_{i\in I} U_i)$ might represent. Recognizing that this notation represented a set, Stacey wrote the set $(2,3]$ on the chalkboard and asked if the "inverse" of this set would "be all of the other elements other than this?" confusing the notation for preimage with the concept of set complement. Stacey, working alone in Session 4, explored the set $[0,1)$ as an example of a set which might be both open and closed.

Session 5 was the first time a discrete set arose in the context of a problem involving topological properties (as opposed to purely set theoretical notions), and this was merely incidental to the students' choice to examine a continuous set. The students' task in Session 5 was to disprove that the boundary of an arbitrary set A must be both open and closed. Stacey quickly surmised (and proved) that the boundary of A must be closed. To disprove that the boundary of A must be open, Tom and Stacey chose to examine the boundary of the set $A = (0,1)$. Using a number line, they identified the boundary as consisting of the points 0 and 1, but when asked to use notation to write the boundary of A, they appeared to struggle. Stacey initially wrote the boundary as $\{0\},\{1\}$. Seemingly unsure, Tom asked if 0 and 1 should be in the same set; Stacey changed her inscription to read $\{0,1\}$, but she continued to stare at it for several seconds in silence as if considering whether this was an improvement over her original pair of singletons.

This led to an unexpectedly frank conversation about the students' preferences for continuous sets over discrete ones. Referring to the set $\{0,1\}$, Tom admitted, "It's difficult to think that a point is a closed set... it's just weird because it doesn't seem like it's a set at all," and shortly after, Stacey added that "It's harder to work with, I feel like, sometimes… like if you're putting a neighborhood in it, it's easier to think you have all these infinite points." We find this result somewhat surprising, as the concept of sets is often introduced using discrete sets rather than intervals and open regions, yet the students in our study seem uncomfortable reasoning about discrete sets. However, the students' topology instructor introduced the course with a thorough discussion of metric spaces, so it is not entirely unreasonable that the students' concept images should be dominated by intervals and open balls.

Connected Sets Versus Disconnected Sets

Although Stacey's and Tom's concept images of sets seemed to include images of disconnected sets, evidence of their evoked concept images suggests that connected sets featured prominently in their minds. In one such instance, Stacey's attachment to connected sets initially prevented her from discovering a counterexample, but she was able to circumvent this difficulty by exploring her example space.

Stacey worked alone in Session 6 on the topic of product spaces. Product spaces were defined in class by means of a basis for the topology; to explore and develop Stacey's understanding of this definition, we asked her to disprove the following statement:

> Let $(X_1, \mathcal{T}_1), (X_2, \mathcal{T}_2), \dots, (X_n, \mathcal{T}_n)$ be topological spaces. Then the set $\prod_{i=1}^{n} X_i$, together with the collection $\mathcal{T}$ of subsets of $\prod_{i=1}^{n} X_i$ of the form $O_1 \times O_2 \times \dots \times O_n$, where each O_i is open in X_i, is a topological space.

Orientation to this problem appeared to be somewhat challenging for Stacey; she expressed unsureness about what individual elements and open sets of such a space might look like in terms of notation. After some discussion with the Facilitator to establish this distinction, Stacey chose to explore $\mathbb{R} \times \mathbb{R}$ as a potential counterexample to the claim, but Stacey showed significant difficulty in understanding this problem, so discussion continued to provide the appropriate scaffolds to allow Stacey to work on the problem.

Working from her knowledge that open intervals are open sets in $\mathbb{R}$, she first generated the set $(-1,1) \times (-2,2)$ and sketched the corresponding open rectangle on a coordinate plane (Figure 1, left). She later generated the set $(1,3) \times (1,3)$ (Figure 1, center), followed by $(1,2) \times (3,4)$ (Figure 1, right) to see if "ones that don't intersect" might violate one of the properties given in the definition of a topology.

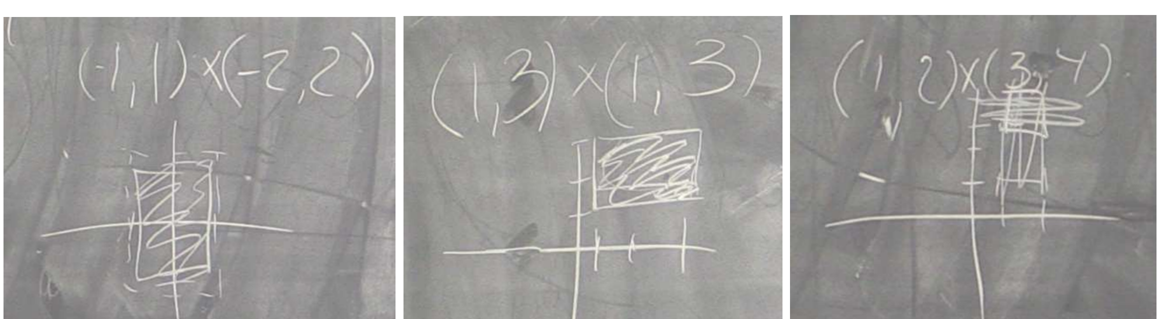

Figure 1:Stacey's examples of open rectangles from Session 6.

At this point, Stacey revealed that she had been viewing sets like $(-1,1) \times (-2,2)$ as the *intersection* of two sets: the tubes formed by $(-1,1) \times \mathbb{R}$ and $\mathbb{R} \times (-2,2)$. The Facilitator established the distinction between the ideas of set product and intersection, prompting Stacey to consider the genuine intersection $(-1,1) \times (-1,1) \cap (-2,2) \times (-2,2)$ (Figure 2).

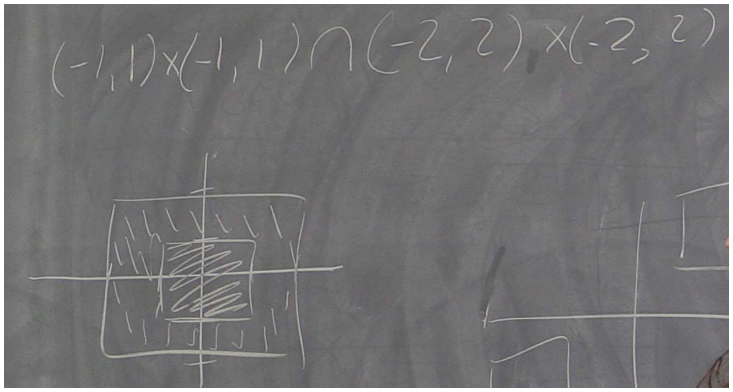

Figure 2: Stacey's example of an intersection of Cartesian products in Session 6.

This seemed to trigger an epiphany (Figure 3): “If you did like, the union of two that were like, say you have like, this open interval over here [drawing], and this one here that are both cross products of things that are, and you did the union of those, you wouldn’t be able to write that as like, an open set cross the open set.” Stacey then went on to produce the specific example $(1,2) \times (1,2) \cup (-1,-2) \times (-1,-2)$ (later recognizing that she had written the interval $(-2,-1)$ with the endpoints in the incorrect order), and labeling her drawing accordingly.

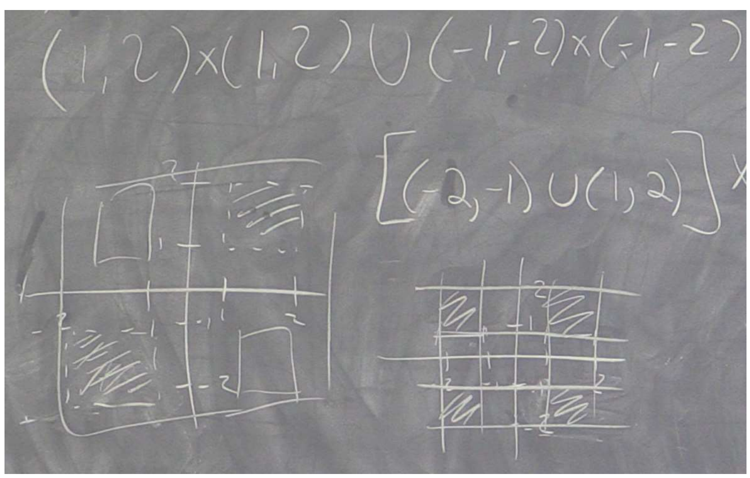

Figure 3:Stacey's counterexample in Session 6.

Open Sets Versus Closed Sets

The idea that the properties of openness and closedness of sets should be mutually exclusive featured prominently in Stacey’s concept image. This misconception was so deeply rooted in Stacey’s mind that it became problematic during Session 4, and Stacey was only able to progress through a proof after directly confronting her misconception. Stacey’s investigation of a concrete example of a set which was neither open nor closed seemed to facilitate her internal restructuring of her concept image. However, even after the error was addressed, it reappeared in Stacey’s reasoning from time to time in future sessions.

The idea that a given set must be exclusively open or closed was most evident and most troublesome in Session 4, and it actually prevented Stacey from applying the definitions of open and closed sets to write a proof. Stacey was asked to prove the following:

> Let $(X, \mathcal{T})$ be a topological space. Prove that $\emptyset, X$ are closed sets, that a finite union of closed sets is a closed set, and an arbitrary intersection of closed sets is a closed set.

She began by reciting that "the definition of a closed set is that its complement is open." She hesitantly identified that the complement of the null set is X, explaining that "for some reason that's tripping me up, because, in X, the complement of the null set … would be X, and we want to say that X is closed, so that can't fit the definition because we need X to be open for the null set to be closed. Or is the null set like a special case with that?" Although the definition of a closed set does not prohibit X from being both open and closed, Stacey suggests here that if X is open, this violates this definition. In order for the null set to be closed, Stacey seemed to require that it be a special case which *violates* the definition. Stacey's cognitive dissonance was so strong that she asked "I *am* trying to actually prove – I'm not trying to disprove this one?"

Stacey addressed her confusion directly in the following exchange:

> *Stacey*: I just can't get out of the habit, $\mathcal{T}$ is open sets. If X is in $\mathcal{T}$, then it has to be an open set, and it can't also be a closed set. But you said there could be open and closed.
> *Facilitator*: Why can't X be closed if it's open?
> *Stacey*: Because [pause] if X isn't closed then its complement [mumbling] open. [pause] Is it, if something is [pause, writing "$[0,1)$"] like is that technically open? Or closed? Or is there like, both?

Following a brief discussion of this example, it was agreed upon that the interval $[0,1)$ is neither open nor closed in the standard topology on the real numbers. This seemed to remove some sort of conceptual barrier for Stacey: after considering this example, she nervously proposed, "If you have an open set, whose complement is still open, then you can consider it a closed set?" She then identified that X was an open set, hence the null set was a closed set, but because the null set is in $\mathcal{T}$, it must also be an open set. She similarly concluded that X was both open and closed.

Despite the revelation that a set might be both open and closed, Stacey's instinctual notion that these properties should be mutually exclusive arose on later occasions. In Session 5, Stacey proposed proving that the boundary of a set A is not an open set by showing that its complement must be open – that is, by showing that the boundary of A is closed. A brief reminder from the Facilitator was sufficient for Stacey to realize her error in reasoning and seek a different strategy.

Conclusions

The limitations in Tom's and Stacey's concept images discussed in our results may each be problematic in their own ways. While a propensity for thinking about continuous sets over discrete sets did not appear to be immediately limiting for Tom and Stacey in the instances described above, consideration of discrete sets is sometimes relevant for the generation of counterexamples in topology. Furthermore, topologies can be defined on discrete sets as well as continuous ones, and students should be able to apply topological ideas to discrete sets. We saw above that Stacey's inclination toward thinking about connected sets over disconnected ones in a product of topological spaces caused a delay in her recognition of the necessary counterexample in Session 6. The perceived mutual exclusivity of openness and closedness of sets acted as a substantial hindrance to Stacey's ability to construct a relatively simple proof in Session 4.

While Stacey initially seemed to be convinced that an open set could not be closed and vice versa, it does not seem to be the case that discrete sets and disconnected sets were not part of Tom's and Stacey's concept images, though perhaps they were not present in their *evoked* concept images. The preference for continuous sets over discrete ones may simply be a difference in accessibility of examples in the example space. We see this in the students' reactions to the discovery that the boundary of the set $(0,1)$ was the set $\{0,1\}$ – they expressed discomfort with the idea, but ultimately were able to accept it. Similarly, despite Stacey's generation of several examples of connected sets in Session 6, she discovered the counterexample of a disconnected set without direct intervention from the Facilitator. This is indicative of the generativity of Stacey's example space, as she is able to manipulate the dimensions of possible variation and their ranges of permissible change in order to generate new kinds of examples.

Tom's and Stacey's abilities to use concepts seemed to be inhibited by the apparent mismatches between their concept images and the concept definitions (Moore, 1994). This was apparent in Stacey's work in Session 4: her inability to adapt to the possibility of a set that is both open and closed, which is allowed by the definitions of these terms but was forbidden by her concept image, significantly hindered her progress in Session 4 and continued to cause problems for her in later sessions. This kind of mismatch created a roadblock in Session 6 as well, as Stacey's concept image of open sets in the product topology as rectangles impeded her recognition of the possibility of taking the union of two such sets. Although this kind of conflict did not seem to hinder Tom and Stacey's success in the context of continuous versus discrete sets, it did give them pause for a moment and introduced doubt, suggesting that it could be problematic in other contexts.

In the case of each dichotomy discussed in our Results, Tom's and Stacey's explorations of their example spaces led to new insights about concepts. In Session 4, even discussion of an inappropriate example (in the sense that Stacey tried and failed to generate a set that was both open and closed) appeared sufficient to help Stacey overcome a pronounced cognitive conflict. It may be the case that even the attempt to produce an example helped to augment or correct Stacey's concept image, or perhaps the awareness that more than two options (open or closed) existed allowed Stacey to accept other possibilities. These results suggest that students' explorations of their example spaces may be beneficial for expanding and correcting students' concept images and for overcoming cognitive conflict by correcting misalignments between the concept image and the formal concept definition.

An Investigation of an Effective Mathematical Reader and His Interactions and Beliefs About Mathematics and Mathematics Textbooks: The Case of Shawn

Julia Judson-Garcia

Barbara Villatoro
Arizona State University

Inyoung Lee
Arizona State University

Previous literature has yet to document whether students do not read their mathematics textbooks because they choose not to or because students are unable to read them effectively. This report is a case study investigating the relationship between a student's beliefs about textbooks to learn mathematics and their readings of mathematical text. We find that students may choose not to utilize textbooks as part of their learning despite being effective mathematical readers. Future research should investigate the relationship between what students think it means to understand mathematics and their beliefs about learning through interactions with mathematics textbooks.

Keywords: Reading mathematics, Mathematics textbooks, Effective mathematical reader

Introduction

Mathematics textbooks are an important part of many undergraduate mathematics courses. Instructors of college mathematics regularly assign and expect students to carefully read mathematical text to aid them in developing an understanding of mathematical ideas (Weinberg & Wiesner, 2011). Despite the importance attributed by educators to students reading the textbook as a part of the learning process, literature indicates that students rarely do so, even when instructed (Shepherd, Selden, & Selden, 2009). Cowen emphasized that a goal for instructors should be to teach students to read and understand mathematics in order to provide a path for understanding mathematics, rather than only mastering procedural skills (1991). However, there is no research documenting why students do not read their mathematics textbooks; is it because students choose not to or is it because they are unable to read them effectively, (Shepherd et al., 2009)?

Students' beliefs about learning mathematics has a large impact on how they behave while doing mathematics (Schoenfeld, 1985). Schoenfeld observed that students tend to memorize steps and then practice carrying out these steps, while focusing on whether their answer is correct, rather than why it is reasonable (1985). We believe this behavior is deeply rooted in students' belief that mathematics has pre-existing procedures and results in students learning mathematics passively. Students' beliefs about what it means to learn mathematics is formed through their experiences during their educational careers. As such, their beliefs about what it means to understand mathematics will affect whether students will read mathematics with a goal to develop, or not develop, meanings.

Literature Review and Research Questions

Over the past two decades, research on the use of mathematics textbooks by students has increased (e.g. Berger, 2016, 2019a, 2019b; Lithner, 2003; Österholm, 2006, 2008; Rezat 2006, 2008, 2013; Shepherd, Selden, & Selden, 2009, 2011, 2012; Shepherd & van de Sande, 2014). The researchers of these studies largely focus on how students are reading their textbooks and the students' abilities to accurately solve similar problems to what appears in the reading. Research on why students do or do not read mathematics textbooks as a part of their learning process and the meanings that they construct while reading is limited.

We asked students at a large southwestern university in the United States in two Calculus I courses and one Calculus II in Spring 2018 to choose how strongly they agreed or disagreed with the following statement: I prefer textbooks that focus on showing me what to do and giving me practice doing it. In Calculus I, 77 students (81.9%) somewhat or strongly agreed with the statement, and in Calculus II 30 students (79%) somewhat or strongly agreed with the statement. Weinberg, Wiesner, Benesh, and Boester (2012) reported students claimed that working through example problems in their textbook was to gain understanding of the mathematics. From the same study, 89.4% of the students who responded, reported spending most of their time looking at examples; only 24.7% of the students indicated reading the chapter introductions where the authors develop the concepts and connections to the other concepts in the textbook. Weinberg et al. (2012 reported that what those students meant by "understand mathematics" was to be able to reproduce the steps in the examples to solve a similar problem). Understanding that students' goals for reading and interacting with their textbook are likely different than the goals the instructor or author would have for the student is important in order to help explain how students' beliefs about understanding a mathematical textbook will impact the meanings they create while reading.

There have also been a handful of studies focusing on reading strategies for comprehension related to mathematical texts (Carter & Dean, 2006; Shepherd & van de Sande, 2014), effectiveness of reading strategies based on accuracy of solving problems similar to those in the text (Shepherd et al., 2009), how students read mathematical content-specific texts differently than historical texts (Österholm, 2006), and the ways to categorize students based on their exhibited behavior while reading (Berger, 2019a, Shepherd & van de Sande, 2014). However, even when students exhibited good reading strategies for comprehension, according to the Constructively Responsive Reading (CRR) framework (Pressley & Afflerbach, 1995), there was little evidence to support that the strategies were useful for comprehending mathematical text and its concepts (Shepherd, Selden, & Selden, 2009). Research on how students actually read and use their mathematics textbooks is limited (Shepherd, Selden, & Selden, 2012; Rezat, 2009; Weinberg et al., 2012).

Therefore, research focusing on the relationship between students' beliefs about what it means to learn and understand mathematics, their reasons for utilizing the mathematics textbook, and their beliefs about developing meanings while reading a mathematics textbook is novel and leads us to our questions:

RQ1: For what reasons are students choosing not to utilize the mathematics textbook as a part of their learning process?

RQ2: What relationship is there between the students' beliefs about the role of the textbook in their learning process, what it means to learn and understand mathematics, and the meanings they construct while reading the textbook?

Theoretical Perspective

To characterize students' meanings while reading a mathematical textbook, we must acknowledge that their behaviors and beliefs are individual experiences constructed over time, and therefore we still consider these aspects important when investigating students' meanings while they read a mathematical text.

Previous literature has taken the sociocultural perspective, which supports the categorization of students in the studies based on observable behaviors (reading styles) (Berger, 2019a, Shepherd & van de Sande, 2014). Also notable is reader-oriented theory, in which the reader is viewed as actively constructing meaning from a text though the reading process, but as Weinberg and Wiesner (2011) suggest, many theorists use various perspectives to interpret the views that the textbook is an object and the reader's response to a textbook can also be isolated as an object. Thus, we acknowledge that the frameworks described in previous literature (Berger, 2019a, Shepherd & van de Sande, 2014) offer ways in which to describe students' behaviors while reading mathematical text including *reading for meaning* (Shepherd, 2012). These studies, however, fail to capture the students' beliefs about the role of the textbook in their learning process, what it means to learn and understand mathematics, and the meanings they construct while reading the textbook. We will use the description *effective mathematical reader* to describe someone who consistently constructs meanings in the moment.

Methodology

At the beginning of 2019 spring semester, Calculus 1 students at a large southwestern university in the United States were surveyed to learn about their textbook usage in previous math classes. Of the 154 students enrolled 136 responded. We then scored students' answers focusing on how often students engaged in reading mathematics textbooks in various scenarios and in what ways students use a textbook to prepare for an exam. Using the scores we sorted students into a 3 by 3 table identifying students as low, medium, or high engagement, and as low, medium, or high use for exam prep. We contacted students, via email, categorized in the low engagement and low use for exam preparation (LL), medium engagement and medium use for exam preparation (MM), and high engagement and high use for exam preparation (HH). From the 38 contacted (not all respsoned), we selected 15 students, 6 HH, 5 MM, and 4 LL to interview. Our goal was to have 5 students in each category of LL, MM, and HH, however, only 4 LL responded. All the students agreed to participate in the interviews on a voluntary basis and were compensated monetarily for their time.

We conducted three 90-minute clinical interviews (Clement, 2000) with each students. The first interview took place 4-5 weeks after the beginning of the semester and each interview after was approximately 4-5 weeks after the previous. For each interview, we used the required online textbook, *Calculus: Newton Meets Technology* (Thompson & Ashbrook, 2019). It is important to note that the course and textbook specifically focus on developing a conceptual understanding of calculus. During each interview, students answered questions regarding their current uses of the textbook, and their meanings related to the passages prior to reading passages. Then, students were asked to read several passages from the textbook aloud (as they would normally read the text independently) and to share the meanings they interpreted from reading. Students read the passages displayed on a computer screen and were instructed to use the cursor to point to what they were reading or referencing at any moment. The computer was connected to an iPad to display students' written work on the computer screen, and we captured students' gestures, audio, and work simultaneously using *Camtasia*.

Results

We will focus on the survey conducted at the beginning and end of the semester and the three interviews conducted with one of the LL student's, whom we will call Shawn. Shawn received an A for his course grade. We chose to focus on Shawn as a case study for this article for two reasons. First, his interviews indicated that he is an effective mathematical reader who chose not to use textbooks as part of his learning process in previous math courses. Second, Shawn's interviews and survey responses provided insight into (a) his reasons behind his initial decision not to utilize the textbook, (b) a transition in both his beliefs about textbook reading as a part of his learning process, and (c) for his meaning for what it means to understand mathematics. Thus, we believe that Shawn represents an informative case study for discussion of how a student's beliefs about what it means to understand mathematics is related to their reading behavior, and to being an effective mathematical reader.

Previous Experience Survey

Shawn indicated in the first survey that he read assigned sections from the textbook in previous courses but did not read unassigned sections. He did not use the textbook when completing homework, to preview for class, nor after class to understand material covered during class. Shawn also indicated that in prior math courses his only use of the textbook when studying for tests was to find additional problems to practice. The researchers asked if he agreed with the statement: “In previous math classes, I succeeded by making connections among ideas. Shawn indicated that he somewhat disagreed with the statement. When prompted to describe what “making connections among ideas” meant to him, he said “[...] memorizing processes and applying them to other related problems. This is like memorizing basic algebra and being able to apply it to all other forms of math.”

Interviews

Beliefs regarding use of textbook. At the start of each interview students were asked about their textbook usage. During this part of the first interview, Shawn told the interviewer that he didn’t use the textbook in previous math classes because he didn’t need to read in order to pass tests. He found that going to class and completing the homework was sufficient. Shawn mentioned that available time was an influencing factor in his decision to read the textbook or not, and that even when reading the assigned sections he would spend at most 30 minutes with the textbook before class to get what he described as a “general sense of the topic”. He conveyed that he did not read the textbook after class, preferring instead to ask any questions he had during office hours. Shawn mentioned in all three interviews that for the current calculus class he found that reading the textbook before class was helpful, and in the third interview he claimed that his struggle with the current material was, in part, due to the fact that he had not been reading the textbook.

During the first interview, Shawn stated time constraints as a reason to not read or interact with certain features in the textbook. For example, when asked about his skimming of a reflection question during the first interview Shawn said, “I skim it exactly like that. I will look at it and ask myself if I can do this really quick, and if I can’t do it really quick, I will ask if I really want to… and the answer is no.” While reading, Shawn would sometimes skip parts of the text, stating that he did not think that passage was necessary, or that he got the gist of what the passage was talking about. Additionally, there were times when Shawn indicated that he wasn’t sure of the meaning of the passage he just read, but that he would not spend more time reading the passage at that point since he had already learned that topic. Shawn felt he understood the material well enough, so to him, it wasn’t worth the time to try to make sense of that particular passage.

Reading the passages from the textbook. While reading the passages in the text, Shawn demonstrated that he is an advanced reader with effective mathematical reading strategies compatible with descriptions by Berger (2019a) and Shepherd & van de Sande (2014). We offer Figure 1 and Figure 2, with their respective transcripts, to provide evidence that Shawn is an effective mathematics reader.

Excerpt 1.

The Meaning of "Essentially Equal To …"

The idea of a number L being essentially equal to a number represented by a sequence of numbers is that you can make the difference between L and values of all but a finite number of terms in the sequence as small as you please.

Consider the sequence

$$1.9, 1.99, 1.999, \cdots$$

No matter how small a difference from 2 we desire, we can find a term in this sequence so all terms after it are closer to 2 than that difference.

Figure 1. A passage from Shawn's 2nd interview. From Section 4.9: Exact Rate of Change Functions.

Shawn: (Reads Figure 1.) I'm just going to look over this again to try to comprehend what that was. The idea of a number L, that's weird because L is a letter. The number L being essentially equal to, I guess it's a variable, being essentially equal to a number represented by a series of numbers. So L is about equal to a...number represented by a sequence of numbers. So all of this (points to sequence $1.9, 1.99, 1.99$) represents two, I am assuming, and L is essentially equal to two.

Shawn monitored his reading for comprehension by summarizing in his own words what he interpreted the passage to mean. Across his three interviews, he often reread more carefully after he stated he did not know what a passage meant similar to his behavior seen in his reading above.

Excerpt 2.

When we say that $r_f(x_0)$ is the momentary (exact) rate of change of f at x_0, we mean that the value of $f(x_0 + dx)$ is essentially equal to the value of $f(x_0) + r_f(x_0)dx$ as dx varies through a sufficiently small interval containing x_0.

Figure 2. A passage from Shawn's 2nd interview that follows Figure 1 in the textbook. From Section 4.9: Exact Rate of Change Functions.

Shawn: (Reading Figure 2.) When we say that r sub f of x is the momentary exact rate of change of f at x, we mean that the value of f of x plus dx is essentially equal to the value of f of x plus r f of x times dx as x varies through a sufficiently small interval containing that.

Hmmm. I'm going to look over this because that doesn't makes sense. Okay, so the rate of change is this (highlights $r_f(x_0)$) and the momentary exact rate of change of f at..(rereads) is the momentary exact rate of change at f. Okay, so f of x and this (points to $r_f(x_0)$) are equal to each other, I guess. (Rereads) is the moment exact rate of change at f. Yeah, seems that they are equal to each other. We mean that the value of (pauses)…No. This (points to "f at x_0") might be accumulation and that's (points to $r_f(x_0)$) just rate of change. We mean that the value of maybe the accumulation at the initial value plus the change is essentially equal to the accumulation plus…Oh! That makes sense. So, you have the initial value plus the change time the or, the rate time the change within an interval (pointing to $f(x_0) + r_f(x_0)dx$) or something like that. And this (highlighting $f(x_0+dx)$) is just the accumulation at that same value. So it's the initial plus the change is equal to that (pointing to $f(x_0)+r_f(x_0)dx$). That makes sense.

Interviewer: Okay and then when you say the accumulation part…(doesn't finish question).

Shawn: The accumulation, um, well they both are. This (pointing to $f(x_0)+r_f(x_0)dx$) is just say it in a different way. So this (pointing to $f(x_0+dx)$) is the accumulation, at like, we have an initial point (pointing to x_0 in $f(x_0+dx)$) plus uh this change (pointing to dx in $f(x_0+dx)$). So let's say this point (pointing to $x_0$in $f(x_0+dx)$) is like point five and this change (pointing to dx in $f(x_0+dx)$) is point 5, so this (pointing to $f(x_0+dx)$) is the accumulation at one. And this (pointing to $f(x_0)+r_f(x_0)dx$) is the accumulation at point five (pointing to $f(x_0)$) plus the rate (points to $r_f(x_0)$) times point five (points to dx). I am assuming it ($r_f(x_0)dx$) would give you another accumulation and you add that on to the initial accumulation and you would get the same accumulation.

In the second excerpt, Shawn read through in a similar manner as he did in the first excerpt and then dissected the text into pieces. We noticed Shawn read mathematical expressions literally in the first read through, but after stating that what he read did not make sense, he reread the mathematical expressions with meaning. In response to his perceived conflict between what he read and his meanings, Shawn created his own example to clarify what he thought the interviewer might be asking him in the moment (even though the interviewer never finished the question). Additionally, in Shawn's third interview, he created examples to understand what he was reading without any prompting by the interviewer.

Other observations. Due to space limitations we list effective mathematical reading strategies Shawn displayed without supporting evidence. Across the three interviews Shawn demonstrated he is an effective mathematical reader using the following mathematical reading strategies: (a) monitoring for reading comprehension, (b) rereading more carefully when necessary and skimming familiar content, (c) summarizing in his own words passages and big ideas he considers the text to be explaining, (d) verbalizing connections between various portions of the text with other parts of the text, (e) verbalizing connections between various portions of the text with his meanings from class, (f) reading mathematical expressions with meaning, and (g) creating his own examples to compare with various parts of the textbook.

End of the Semester Survey

Concluding the semester, Shawn completed a survey similar to the survey given at the beginning of the semester and was recategorized as a student with medium engagement and low textbook usage for exam preparation. Shawn's reported textbook usage increased in three out of five categories related to engagement and three out of six categories for exam preparation. He reported increased textbook usage in reading unassigned sections, finding examples to help with homework, previewing material before class, reading explanations of concepts, completing the chapter review, and reviewing key terms. The one category regarding engagement that Shawn's usage decreased in was reading assigned sections. The two categories regarding test preparation where his usage decreased was reworking assigned and working unassigned problems in preparation for an exam. His responses to the remaining category in engagement (reading after class) and the remaining category in test preparation (looking for solved problems) were the same.

At the end of the semester, Shawn "strongly agrees" that he succeeded in the current math class by making connections amongst ideas. His meaning for what it means to make connections among ideas changed from "[...]memorizing process and applying them to other related problems." to "[...] understanding concepts and applying them to other concepts".

In response to the question "Has your personal meaning for what it means to understand a mathematical idea changed from the beginning of the course to now?" Shawn responded "Before mathematical ideas were understanding how to use a formula, but now it is understanding concepts. Instead of memorizing formulas, you memorize formulas and concepts."

Conclusions and Discussion

Due to space limitations, we do not argue that Shawn constructed strong or weak meanings while reading because that would require a more in-depth analysis of the passages and the concepts Shawn read about during the interviews. Rather, we claim that Shawn is an example of an effective mathematical reader. We conjecture that Shawn is not unique as a student who is an effective mathematical reader who chooses not to use the textbook often for the purpose of learning mathematics; addressing Shepherd et al.'s call to action (2009) to understand why so few students utilize the textbook as a part of their learning process. His reasons for not utilizing the textbook is due to time and believing that he can learn from other mediums more efficiently.

An extension of this case study should focus on what proportion of students are effective mathematical readers who choose not to read their textbook and why. If a significant portion of students are like Shawn, effective mathematical readers who are choosing not to utilize the textbook, then the reasons why they have made that choice, and reasons for shifts in beliefs as seen in Shawn's survey responses can inform educators on how to address the lack of textbook utilization by students.

Comparing Shawn's responses in the surveys indicated two shifts in Shawn's beliefs. The first shift was in Shawn's belief about utilizing the textbook to understand mathematics. Initially, Shawn believed that reading the textbook was unnecessary to understand mathematics. At the end of the semester he said that pre-reading was an important part of understanding the class lecture.

The second shift was in Shawn's beliefs about what it means to understand mathematics. At the beginning of the semester his meaning for what it means to understand mathematics was computational and focused on the memorization of algebraic processes. However, at the end of the semester he had expanded his meaning beyond computations to also include a focus on mathematical concepts. Additionally, two of the categories where his textbook usage decreased in frequency were when working problems (computational focus) while several of the categories in which his usage increased involved him reading to understand mathematical concepts (conceptual focus). The shift in Shawn's beliefs about what it means to understand mathematics is also supported by his responses to the survey questions. Future research should investigate this relationship more extensively.

Our future research will focus on the relationship between students' meanings, students' beliefs about the role of the textbook in their learning process, and the students' beliefs about what it means to learn and understand mathematics. Moreover, what influence do students' current meanings have on the meanings they construct from reading a textbook?

Investigating Instructors' Perceptions of IBL: A Systemic Functional Linguistic Approach

Saba Gerami
University of Michigan

Vilma Mesa
University of Michigan

Inquiry-Based Learning (IBL) teaching practices have been hard to characterize in mathematics education research, as mathematics instructors interpret and engage with these practices in different ways. Using systemic functional linguistics (SFL), specifically the appraisal framework (Martin & White, 2005), we analyzed responses to the question "what is IBL" given by 12 mathematics instructors who were teaching with IBL. Our analysis was guided by the following question: What do the language choices of a group of undergraduate mathematics IBL instructors reveal about their perceptions of IBL? We identified how the instructors opened up, closed down, and changed the strength and focus of their messages through their grammatical and lexical choices. We found that instructors softened their language when defining IBL but used sharper and intensified language with less room for negotiation when talking about teacher and student roles in IBL classrooms.

Keywords: Inquiry-Based Learning, Undergraduate, Mathematics, Discourse Analysis, Systemic Functional Linguistics

Inquiry-based learning (IBL) is a form of student-centered instructional practices implemented in undergraduate mathematics classrooms. The IBL literature defines IBL as a form of active learning in which students interact with a carefully scaffolded curriculum—usually a set of problems or a list of definitions and theorems—individually or in groups under the instructor's supervision (Ernst, Hodge, & Yoshinobu, 2017; Yoshinobu & Jones, 2012; 2013). Even though the uptake of reformed teaching practices, such as IBL, has been slow among undergraduate mathematics instructors, instructors are becoming "increasingly aware of the value of inquiry-based instruction" (Laursen & Rasmussen, 2019). Many factors such as class size, students' experience with IBL, instructor's skill level and experience with IBL, institutional resources, and course topic affect implementation of IBL (Ernst et al., 2017). Thus, as IBL grows in popularity among mathematics faculty, how IBL is interpreted and enacted in the classroom has diversified to the point that IBL is currently called the "Big Tent" for all varieties of IBL (Laursen & Rasmussen, 2019). Considering that the IBL literature provides no consistent definition of IBL, we believe it is important to understand how mathematics instructors understand IBL, how their understandings vary, and how these understandings affect their decisions when implementing IBL. In this paper, we aim to explore the meanings that instructors give to IBL. Thus, we started by asking a simple question: How do undergraduate mathematics instructors talk about IBL? To answer this question, we use systemic functional linguistics (SFL, Halliday, 1985) to analyze interview data with 12 undergraduate mathematics IBL instructors. SFL allows us to draw meaning based on the lexicogrammatical choices that instructors make, consciously or unconsciously, as they speak. More specifically, we focus on their appraisal decisions and ask: What do the language choices of a group of undergraduate mathematics IBL instructors reveal about their perceptions of IBL?

Supporting Literature

IBL, as a way of teaching undergraduate mathematics, is traced back to Robert Lee Moore (1882–1974), an American topologist also known for his unconventional graduate teaching methods (Yoshinobu & Jones, 2013). Moore provided his students with a set of axioms, definitions, and theorems and asked his students to prove as many theorems as possible, without any assistance from outside sources or peers (Dancis & Davidson, 1970; Jones, 1977; Mahavier, 1999; Zitarelli, 2004). A few of Moore's students and colleagues taught their classes using various modifications of Moore's method, which seems to be the precursor of IBL as it is used today (see e.g., Dancis & Davidson, 1970; Mahavier, 1999). In contrast to Moore's method, students in IBL classrooms are invited to collaborate with each other, propose ideas to solve the problems, and engage with their peers' mathematical ideas. The instructor orchestrates student discussions and guides them towards the main mathematical goals. Today, IBL is practiced and implemented in many ways (Laursen & Rasmussen, 2019).

As IBL has emerged from college educators' practical work rather than from research (Laursen & Rasmussen, 2019), the mathematics education literature has been conceptualizing IBL either in contrast to lecturing or to instruction guided by core principles (e.g., Ernst et al.'s, 2017, twin pillars; Laursen & Rasmussen's, 2019, four pillars). Lack of a consistent conceptualization of IBL in undergraduate mathematics literature and the numerous ways of implementing IBL leave room for instructors' interpretation of what IBL is and how it is implemented, and may damp efforts to understand its impact on student learning. A clearer conceptualization of IBL needs to start with clarity about the multiple implicit meanings IBL may have.

SFL as a Tool for Analyzing Discourse

SFL, as a model of language (Halliday, 1985) provides various tools for analyzing and drawing implicit meanings from language. By facilitating the "exploration of meaning in context through text-based grammar," SFL allows the researcher to realize the different ways that the writer or the speaker made grammatical choices—not necessarily conscious—to convey meanings (Schleppegrell, 2012, p. 21). Text, "as a social exchange of meanings" (Halliday & Hasan, 1985, p. 11), is used to make three types of meanings: representing an experience, enacting a relationship between the speaker and the listener or the writer and the reader, and connecting the unit of analysis to the other parts of the larger text (Schleppegrell, 2012; Thompson, 2014). SFL has been used for drawing meaning from language, spoken or written, in K-12 mathematics education research. Using SFL, O'Halloran (2000) identified the multisemiotic nature of mathematics discourse in high school trigonometry classrooms; Zolkower and Shreyar (2007) described how a sixth grade mathematics teacher mediated classroom discussions; González and Herbst (2013) investigated the development of oral proofs by ninth graders in a geometry class; and Kosko and Herbst (2012) analyzed how high school geometry teachers used modality (using words such as *may* or *should* to express a measure of indeterminacy) in teacher-to-teacher talk to reveal teachers' perspectives regarding the norms of teaching geometry. In each of these cases, SFL allowed the researchers to systematically investigate meaning from the choices that speakers and writers made when speaking or writing using a variety of SFL frameworks.

We chose SFL because it provides a system for organizing "collection of choices that speakers have when using specific linguistic resources" (González & Herbst, 2013), which is particularly useful, precisely because IBL has emerged from practitioners which suggests that multiple interpretations (and implementations) of IBL exist. Describing what IBL entails has been a goal for IBL scholars; we believe that a well-developed analytical system allows us to detect the nuances of instructors' perceptions of IBL. Compared to thematic analysis that uses open coding of text data, SFL provides established frameworks of grammatical and lexical choices, allowing the researchers to systemically analyze attitudes expressed via language that go undetected using thematic analysis. Thus, SFL minimizes subjectivity and increases the validity of our claims regarding IBL instructor's perceptions of IBL.

Methods

We conducted an appraisal analysis to investigate the evaluative function of text data collected from hour-long semi-structured interviews with 12 undergraduate mathematics IBL instructors in 2012 who were part of a larger study (*N*=70) that investigated how faculty used inquiry-based learning in their courses. The 12 instructors were selected purposefully to be interviewed, in order to have variation in terms of IBL teaching experience (5 participants self-identified as beginner/novice [BN] IBL users and 7 self-identified as advanced/expert [AE] IBL users) and level of the courses in which they used IBL (4 lower division [LD], 6 upper division [UD], and 2 future teachers [FT]).

Coding and Analysis

In order to answer the research question of this study, we analyzed the responses to the first question in the interview: What is inquiry-based learning? This allowed us to ensure that the analysis would yield useful information before engaging in a more systematic analysis of the full interview (e.g., What conditions are present in a successful IBL class? What are helpful aspects of IBL method?). To prepare the data for analysis, we (Saba and Vilma) parsed the responses provided by each instructor into sentences, which became our units of analysis. For each aspect of the framework (discussed below), we coded all the sentences for one instructor at a time and checked our coding with each other before moving to the next instructor. We discussed all the discrepancies until we reached agreement.

The appraisal framework "systematizes a varied set of linguistic resources that speakers and writers use to negotiate evaluations with their addressees and to construct solidarity around shared values" (Thompson, 2014, p. 80). This framework consists of three aspects: attitude, engagement, and graduation. While attitude focuses on how the speaker talks about something or someone (good or bad), engagement and graduation reveal the speaker's choices in negotiating solidarity with the listener and weakening or intensifying the message respectively. In this paper, we report on our results from the analysis of engagement and graduation. Elsewhere (Gerami & Mesa, 2019), we reported our results from the attitude analysis.

Engagement analysis focuses on the ways that writers and speakers open up or close down space for negotiation their evaluation of a phenomenon with the audience. Monogloss engagement refers to statements in which the speaker or the writer leaves no room for negotiation; the engagement is heterogloss when the speaker or the writer opens up space for negotiation. What is evaluated is referred to as the target of engagement. Two main sources—modality and interpersonal projection—are used to invite other perspectives to negotiate the message regarding the target with the audience. Modality points to the extent that a proposition is valid using terms of probability and usuality (e.g., might, may, often, sometimes, always) versus being imposed using terms of obligation (e.g., should, must, have to). For instance, in the sentence "I sometimes have my students work in groups on the problems," the appraisal analysis suggests that the speaker is using *sometimes* to make room for other possibilities for additional activities that can be done in class (at *other* times). Interpersonal projection refers to the use of terms such as *I suppose, I think,* and *to me* by the speaker, which are all considered heteroglossic language. In the two sentences "I think I am doing well in this course" and "I am doing well in this course," the former sentence uses tentative language (*I think*) that is open to the possibility of a rebuttal, that the audience may have a different opinion than what is expressed. The second sentence, in contrast, leaves no room for negotiation.

Graduation analysis focuses on the ways that writers and speakers adjust the strength and focus of their message (Derewianka, 2013). Force is used to increase or decrease the strength of a message regarding a target. For instance, in the sentence "The homework was too hard this time," *too* is used to increase the strength of the difficulty of the homework. Focus is used to sharpen or broaden the options of the target in a message. For instance, in the sentence "You must practice all kind of problem solving," the message regarding problem solving is broadened to all types of problems by using the word *all*. However, in the sentence "You must practice authentic problem solving," the speaker sharpens the focus of the message about the problem to communicate that the problem was of a specific kind, as it was an authentic one.

Results

In terms of engagement, we found that the participants (referred to in here by the letter T and a unique number between 1 and 12) opened up the dialogue when they talked about IBL and closed down the dialogue when they talked about student roles and teacher roles in IBL classrooms. In their responses to "What is IBL?," 11 of the 12 instructors started their responses with heterogloss elements, mainly in form of interpersonal projections:

T4: Um well <u>I think</u> it's learning that's very much driven by um sort of the students their understanding of the subject. [BN, UD]

T8: Well <u>I would say</u> it's about making the students discover the material for themselves … [AE, FT]

T11: Well <u>I guess to me</u> inquiry-based learning is a process by which … [AE, UD]

The instructors' lexical and grammatical choices in these sentences show that they are open for negotiation and alternative interpretation as they talked about IBL by emphasizing that their definition was rather personal than general. Eight of these 11 instructors continued with heterogloss engagement throughout their responses, (e.g., "[IBL] <u>can be</u> in that way a learning process versus being fed") while three of them included some monogloss engagement (e.g., "That [the goal of IBL] <u>is</u> captured and implemented in IBL by careful preparation of mathematical materials"). Only one instructor's response included monogloss engagement throughout the response:

T12: <u>It's</u> basically um <u>it's</u> an approach where the students are um the focus as opposed to the instructor. And um <u>the idea is</u> that students spend their time in various ways but uh <u>the main thing is</u> that they need to be making sense of the mathematics for themselves and the instructor is there more to be a guide or a coach. [AE, UD]

Despite the frequent use of heterogloss engagement when defining IBL, monogloss engagement was more often detected when the instructors talked about the role of the students and instructor in IBL classrooms. This implies that the participants tended to leave less room for negotiation when they talked about student and teacher roles in their definitions of IBL. It is important to note that the phrasing of the interview question was conducive to garner a monogloss response: "What is inquiry-based learning?" as opposed to a phrasing that could be conducive to generate a more heterogloss response such as "How do <u>you</u> define IBL?" or "What is IBL <u>to you</u>?".

Regarding graduation, we found that the instructors softened the focus of their language when they talked about IBL and increased the intensity of their language, and sharpened the focus when they talked about student and teacher roles in IBL classrooms. Force was seldom detected in the instructors' responses with IBL as the target. With student role as the target, force was raised in eight instructors' responses, while it was lowered in one instructor's response. Similarly, with teacher role as the target, force was raised in eight instructors' responses, while force was lowered in one instructor's response.

T12: … the main thing is that they [the students] need to be making sense of the mathematics for themselves and the instructor is there more to be a guide or a coach. (force raised, target: student role) [AE, UD]

T5: I think it is important to uh give them the right problem set the right time uh at the right amount. (force raised, target: teacher role) [BN, UD]

When referring to IBL, the instructors more frequently softened than sharpened the focus and, when referring to teacher and student roles, the focus was more frequently sharpened than softened:

T7: One might think about it [IBL] as sort of a sliding scale in the extent to which the instructor um is uh making things move along. (focus softened, target: IBL) [AE, LD]

T3: I think about it [IBL] as … basically, getting them to generate solutions to problems without you ever having to explicitly show them how to solve these problems. (focus sharpened, target: student role) [BN, LD]

T7 used two sets of terms 'sort of' and 'a sliding scale' to broaden the options when talking about IBL, resulting in softening of the focus. In T3's quote, the instructor's use of *basically* narrows down the roles that students play in IBL classrooms, sharpening the focus of student role. In sum, graduation analysis revealed that the instructors lowered the intensity and softened their language as they talked about IBL, while they used more intensified and sharper lexical and grammatical choices when talking about student role and teacher role in IBL classrooms.

Discussion

Using the appraisal framework, we drew meanings from the implicit ways the instructors' talked about their perceptions of IBL, the parts that they depended on more heavily, and the parts they paid less attention to. Specifically, our findings show that the participants softened their language and opened room for negotiations and alternative interpretations when defining IBL, but used sharper and intensified language with less room for negotiation when talking about teacher and student roles in IBL classrooms.

First, the instructors opening up space when they talked about IBL suggests that they were aware of the various implementations of IBL or that they implemented IBL differently than how it was typically described in 2012, when the interviews were conducted. Second, when the instructors talked about the roles of students and teacher, their language choices did not leave room for negotiation, which suggests that they, consciously or unconsciously, expect their students and themselves to assume very clear and specific roles in IBL classrooms. This is revealed by language choices that suggest they may not be considering alternative implementations of IBL when it came to their *own teaching*. Third, preliminary findings of the second interview question (What conditions are present in a successful IBL class?) that we did not include due to space limitations, indicate that the instructors intensified student roles more often than teacher roles, which express an unbalanced student-instructor power relationship in IBL classrooms, in spite of IBL being declared as a strategy in which the instructor stops being "the sage on the stage." Alternatively, intensifying the student roles may be expressing the instructors' difficulties in reflecting on their own role and practices. This tension may also be the consequence of conceptualization of IBL by Ernst and colleagues (2017) and Yoshinobu and Jones (2013), that were common at the time of the interviews, and that depended heavily on the roles of students to capture the 'twin pillars' of IBL: (i) students engage deeply with mathematical tasks and (ii) opportunities for collaboration with peers are provided. Note that the actors in both of these principles are students; the twin pillars do not describe the role of the instructor: note that in the second statement of the pillar, the actor is not explicitly stated. In the most recent conceptualization of inquiry-based mathematics education Laursen and Rasmussen (2019) added two more pillars: (iii) "instructors inquire into student thinking" and (iv) "instructors foster equity in their design and facilitation choices" (p. 138). These added statements make the role of the instructor quite explicit. We venture that the interviews in our study provide a way for capturing the perceived meaning of IBL at a time in which the role of the instructor was in need of clearer definition.

An Analysis of Opportunities for Reasoning-and-Proving in a University Precalculus Textbook

Joash M. Geteregechi
Syracuse University

Anne N. Waswa
University of Georgia

In this study, we provide an analysis of opportunities for undergraduate students to engage in the skill of reasoning-and-proving in a precalculus textbook in a medium-sized university in North Eastern USA. To investigate these opportunities, we focused our analysis on the frequency and nature of reasoning-and-proving opportunities available in both the exercises and narrative section of the book. Findings indicate that there were more reasoning-and-proving opportunities in the narrative section of the book than in the student exercises section. Furthermore, the opportunities in the student exercises section were predominantly of the particular nature while those in the narrative section were general. Implications of these findings are discussed.

Keywords: Textbook Analysis, Reasoning-and-Proving, Precalculus

One of the most important skills in the learning of mathematics at higher levels is the ability to engage in reasoning-and-proving (Stylianides, 2009). Thus, it is important that preparatory mathematics courses provide students with opportunities for engaging in and reflecting on the skill of reasoning-and-proving. An important learning resource that forms an integral part of most mathematics courses at the college level is the textbook. The textbook is not only an important resource that most instructors draw from, but also provides practice problems for the students (Grouws, Smith, & Sztajn, 2004).

A number of researchers (e.g., Hanna & de Bruyn, 1999; Newton & Newton, 2007; Stylianides, 2009) have examined the opportunities available for mathematics students to engage in reasoning-and-proving. Most of these studies, however, focused on school mathematics as well as on instructors' role as curriculum interpreters and implementers. Studies that focus exclusively on undergraduate mathematics are rare. In particular, research on opportunities for reasoning-and-proving available to students in textbooks for preparatory courses such as precalculus are scarce. One of the reasons for this could be the perception that instructors have more influence on student learning than textbooks and other curriculum materials. However, studies (e.g., Porter, 2002; Stylianides, 2009) have shown that mathematics textbooks still remain a major influence on what and how mathematics students learn. Thus, one way of contributing to the ongoing efforts to increase student success in university mathematics courses is to examine the reasoning-and-proving opportunities available for students in preparatory courses. In this study, we sought to investigate the frequency and nature of reasoning-and-proving opportunities available in a precalculus course textbook at a mid-sized private research university in North-Eastern United States. We also investigate the distribution of such opportunities across various sections (such as narrative and exercises) of the book.

Background and Theoretical Framework

Reasoning and proving are among the most important components of the discipline of mathematics (Hanna, 2000; Stylianides, 2009, Stylianou, Blanton & Knuth, 2010). These processes play a central role in both making sense of mathematical statements (Arcavi, 2003; Hanna, 2000; National Council of Teachers of Mathematics [NCTM], 2009; Yackel & Hanna, 2003) and assessing the truth of such statements (Harel & Sowder, 1998). In this sense, therefore, reasoning and proving can serve as powerful tools for exploring mathematical ideas in order to enhance meaningful learning of mathematics. According to Otten, Males, and Gilbertson (2014) engaging in the process of proving is often wide and incorporates aspects of reasoning such as “empirical explorations, conjecturing, justifying, refining, explaining, and so forth” (p. 107). For this reason, it can be argued that the processes of reasoning and proving are intertwined and happen concurrently. In light of this fact, the hyphenated term reasoning-and-proving that highlights the nature of the intertwinement of the two processes has emerged in mathematics education literature (Stylianides, 2009). Consistent with this view, therefore, we use the hyphenated term reasoning-and-proving (RP) for the rest of this paper.

According to Hanna (2000), the process of RP defines the nature of mathematics and is so important that “one cannot be said to have learned mathematics” (p.24) unless they have learned to engage in the process in some way. Despite the importance of RP in doing mathematics, studies have shown that most undergraduate students, including those majoring in mathematics, struggle in mathematics courses that require various forms of RP (Recio & Godina, 2001; Selden & Selden, 2003; Sowder & Harel, 2003; Weber, 2001). In order to address this problem and help students succeed in such courses, many universities offer prerequisite courses that are often meant to prepare students for other courses. One such preparatory course that is common in many universities is precalculus. In many cases, universities give a calculus readiness exam to students and then use those results to recommend that some students take the precalculus course before they start the calculus sequence. However, studies (e.g., Sonnert & Sadler, 2014) have shown that precalculus courses do not necessarily get students ready for taking calculus courses and that several students who take precalculus still fail calculus courses. This calls to question the impact of taking precalculus courses as a way of preparing students to succeed in calculus. As a preparatory course, it is expected that precalculus courses would offer students several opportunities to engage in RP as an important aspect of doing mathematics.

Analytic Framework

Many studies on textbook analysis (e.g., Li, 2000; Senk, Thompson, & Johnson, 2008) have called for the inclusion of both text exposition and student exercise sections in analyzing textbooks for RP opportunities. Text exposition section (sometimes called narrative section) refers to parts of the book that provide information (e.g., theorems, properties, propositions, formulas, etc.) to the reader and to which the reader does not have to take any active role other than reading it. Students exercise sections, on the other hand, are parts of the book that require students to participate in various ways such as completing a task or answering a question.

By drawing from the reasoning-and-proving standard of the NCTM (2000) and other studies that contained aspects of the processes of RP (e.g., Valverde, Bianchi, Wolfe, Schmidt & Houang, 2002), Thompson, Senk, and Johnson (2012) developed an analytic framework for investigating RP opportunities in mathematics textbooks. This framework provides ways of identifying various types of justifications and RP opportunities in textbooks. Moreover, the framework included dimensions for both student exercises and text exposition sections of the textbooks hence heeding the earlier calls by researchers such as Li (2000). Based on the necessity principle (Harel & Tall, 1991) that regards the importance of students being able to see the need for reasoning and proof, Otten, Gilbertson, Males, and Clark (2014) made slight modifications to Thompson et al.’s (2012) framework that included the characterization of the nature of mathematical statements around RP opportunities as *general, particular,* and *general with particular instantiation provided*. A *particular* statement concerns a specific mathematical object or a finite set of objects while a general statement concerns all objects in a given class without exceptions (Otten et al., 2014). A *general with particular instantiation* statement, on the other hand, concerns all objects in a given class but for which one member of the class has been provided for use in reasoning. We found these characterizations of RP opportunities useful since they have a great influence on the kinds of learning opportunities for students.

Method

We analyzed the fifth edition of *Functions Modeling Change* by Connally, Hughes-Hallet, and Gleason (2015). Most chapters in this textbook were structured such that they contained the following parts: chapter sections, chapter summary, strengthen your understanding, and skills refresher. Each chapter section was designed to address particular concepts in the chapter. For example, the chapter named trigonometry and periodic functions had sections such as sinusoidal functions, the tangent function, among others. The chapter summary appeared near the end of each chapter and listed the main ideas (and formulas) in the chapter. The strengthen your understanding section had exercises in form of declarative statements to which students were supposed to supply either a true or false answer. The skill refresher sections provided solved examples and exercises targeted at various key ideas in the chapter. Most student exercises appeared at the end of each chapter section (named section exercises) and the end of the chapter summary (named chapter review exercises). Chapter review exercises tended to cover content from the whole chapter in which they were located. For the purposes of this study, we focused only on the content of the sections and the accompanying section exercises since most of the other sections contained most items that are related to the ones on these sections.

From the preface section of the book, we identified the idea of functions and their properties as the core concept of the textbook. Therefore, we sought to analyze chapters and sections that addressed the idea of functions in a general way as opposed to specific types of functions. We identified two chapters (chapter 2 and 6) as well as parts of chapter one (section 1.1 and section 1.2) as ones that met our criteria. Chapter 2 had a total of six sections (here in called lessons) while chapter 6 had three. Since all identified lessons from the named chapters addressed different ideas about functions in general, we chose to analyze all of them (9 lessons in total).

For each lesson that we sampled, we examined the statements in the examples as well as the expository text and coded them for RP opportunity. Some of the codes related to RP include *make a conjecture, fill in blanks of a conjecture, investigate a conjecture, construct a proof, develop a rationale, outline a proof, fill in blanks in a proof, evaluate or correct an argument or proof,* and *find a counterexample.* We then characterized the nature of these opportunities as either *general, particular,* or *general with particular instantiation provided.* We conducted similar analytic procedures for the student exercises. It is worth noting that some exercises and examples had several sub-items. In such cases, we treated each sub-item as separate items since we noticed that different sub-items could elicit RP opportunities of different kinds.

Results

We present the results of this study in two parts; the first part provides the results for the text exposition section of the textbook while the second part presents the results from the student exercises section. For each part, we investigated both the type of RP opportunities as well as a characterization of the nature of such opportunities.

Reasoning-and-Proving in Text Exposition

Frequency of reasoning-and-proving statements. Table 1 shows the frequency of mathematical statements related to RP in the text exposition section from the three chapters. There was a total of 11 lessons spread across three chapters. Two lessons were from chapter one, six from chapter two, and three from chapter six. The three lessons from chapter six had a total of 19 statements related to RP while the two from chapter 1 had 12. These two chapters, therefore, had the highest average number of RP statements per lesson, that is, 6.33 and 6 respectively. Chapter 2 had the least number of RP statements averaging at 4.5 per lesson.

Table 1. Frequency of Reasoning-and-Proving statements in text exposition.

Chapter	Number of exposition lessons analyzed	Number of RP statements	Average RP statements per lesson
Chapter 1	2	12	6
Chapter 2	6	27	4.5
Chapter 6	3	19	6.33

A notable finding from the textbook exposition section was that most of the RP statements appeared as theorems, postulates, properties, or generalizations following an exploration of a few specific cases. An example of an RP statement from the book was provided when the author was arguing in support of the domain and range of the function $g(x) = \frac{1}{x-2}$:

> "The range is all real numbers that the formula can return as output. It is not possible for $g(x)$ to equal zero since 1 divided by a real number is never zero. All real numbers except zero are possible output values, since all nonzero real numbers have reciprocals". (p. 80)

Since this statement offers an argumentation for a stated claim, it is hoped that readers of the book would provide similar argumentation when solving problems about domain and range. As indicated in the discussion of the framework, providing an argument for why a claim is true or not is one of the RP opportunities. We noticed that although the author offered arguments such as the one above for most examples, the wording of the examples themselves did not explicitly call for the provision of such arguments. Failure to provide such prompts, as will be illustrated later, led us to code some items in the student exercise section as not involving RP when they otherwise would.

Nature of reasoning-and-proving statements in text exposition. We characterized the above RP statements for their nature based on recommendations by Otten et al. (2014). These involved a determination of whether the statements were particular, general, or general with particular instantiation. The results are provided in Table 2.

Table 2 shows that, on overall, general statements were more prevalent in chapters 1 and 2 than either particular or general with particular instantiation statements. There were 9 and 14 general statements in chapter 1 and 2 respectively while there were 2 such statements for each of the chapters. On the contrary, chapter 6 had more particular statements (12) than either general (7) or general with particular instantiation statements (0).

As indicated earlier, most of the general statements in the exposition section appeared as formulas, properties, propositions, generalizations from particular cases, among others. While most of these statements were presented following a logical sequence and deductive reasoning, it is also important to note that readers were not required to take any active role in this process

Table 2. Nature of Reasoning-and-Proving statements in text exposition.

Chapter	No. of general statements	No. of Particular statements	No. of General statements with particular instantiation
Chapter 1	9	2	1
Chapter 2	14	2	11
Chapter 6	7	12	0

other than just reading the text. We see learning in this manner as less cognitively engaging than, say, in cases where readers are asked to answer certain questions as part of the development of these general statements. An example of a general statement that appeared in the exposition section of the book is where the author stated that,

> "In general, we can identify an increasing or decreasing function from its graph as follows: The graph of an increasing function rises when read from left to right. The graph of a decreasing function falls when read from left to right". (p.12)

This general statement was preceded by a few specific cases and then followed by two examples that seemingly aimed at reinforcing the generalization. However, the examples that followed this general statement did not involve any prompt for RP and we coded them as non-RP examples.

Reasoning-and-Proving in Student Exercises Section

Frequency of reasoning-and-proving in student exercises. Each of the lessons from the three chapters had several student exercises at the end. Chapter 2 had the highest number of exercises (419) due to the fact that it had more lessons than the other two chapters combined (5). Chapter 1 and 6 had 115 and 290 student exercises respectively. In total, therefore, we analyzed 824 student exercises.

Table 3. Frequency of Reasoning-and-Proving statements in student exercises.

Chapter	Number of exercises	Number of RP prompts	Number of RP prompts per lesson
Chapter 1	115	8	4
Chapter 2	419	32	5.3
Chapter 6	290	23	7.7

Table 3 shows that, though not a lot, every chapter had some exercises that appeared to involve students in reasoning-and-proving. The percentage of RP prompts out of the total number of exercises was between 7-8% for each of the three chapters. Despite having relatively fewer exercises, chapter 6 had more RP opportunities (7.7 per lesson) than chapter 2 (5.3 per lesson) and chapter 1 (4 per lesson). The increase in the number of opportunities with chapter numbers could be due to the fact that higher chapters often have most definitions and basic concepts already laid out from the introductory chapters. This means that the chapters could then focus more on deeper thinking that involves students in reasoning-and-proving. Indeed, in our analysis, we found more definitions in the text exposition of chapter one than in each of the other two chapters.

It is important to note that, we considered student exercises as RP exercises only if they explicitly indicated so. This means that some of the exercises that we skipped may still elicit RP depending on who is doing them. This happened mostly for questions that did not explicitly ask students to justify or explain their solutions. Although such questions in the exposition section may have been done with complete logical arguments, we assumed that unless students are asked to provide such justifications and arguments, then, they may not do so. For example, an exercise such as “during which time intervals is the function increasing?” (p. 16) was not coded as a RP exercise. However, the exercise “Does the population of the town grow faster between t = 5 and t = 10 years, or between t = 15 and t = 30 years? Explain” (p. 16) was coded as a RP exercise since a non-proof argument is expected from the student. Indeed, several exercises could have been coded as involving reasoning-and-proving if they were modified slightly to involve prompts such as explain, why, how do you know, provide a counter example, among others.

Nature of reasoning-and-proving in student exercises. Table 4 shows the nature of the reasoning-and-proving opportunities in student exercises above. In general, there were more exercises of the particular nature than the other two categories. Exercises of the general with particular instantiation nature were the least prevalent in the exercises.

Table 4. Nature of Reasoning-and-Proving statements in student exercises.

Chapter	Number of general exercises (per lesson)	Number of particular exercises (per lesson)	No. of General with particular instantiation exercises (per lesson)
Chapter 1	1(0.5)	7(3.5)	0(0)
Chapter 2	8 (1.3)	20(3.3)	4(.7)
Chapter 6	9 (3)	5(1.7)	9(3)

Chapter 1 and 2 had the most exercises of the particular nature per lesson (3.5 and 3.3 respectively) while chapter 6 had the least (1.7 per lesson). There were more general exercises per lesson (3) in chapter 6 than there were in chapter 1 and 2 (0.5 and 1.3 respectively). As for general with particular instantiation, chapter 6 had the most (3 per lesson). Chapter 2 had only 0.7 exercises of this nature while chapter 1 had none.

Since particular exercises were the most prevalent, it is worthwhile to provide some detail about such exercises. In reasoning with exercises of a particular nature, students often do not need to generalize their results to all cases. Rather, they do so for just one case or a finite number of cases. Furthermore, it is often easy for students to use the statements provided in the exposition section of the textbook (e.g., theorems, postulates, formulas, among others) in answering exercises of the particular nature. Bearing in mind that students are not required to take any active role in the generation of these statements, one can argue that RP exercises of a particular nature are not often the most fruitful in engaging learners in deeper learning. In reasoning with general or general with particular instantiation exercises, more creativity and a deeper understanding is often required from the students.

Discussion

Before discussing the results of this study, we would like to point out that our analysis focused only on a few chapters of a university precalculus course textbook. Therefore, we are not suggesting that the results are generalizable to the whole textbook or to other situations. However, within the sampled chapters and lessons, we observed trends that could offer valuable insights about the frequency and nature of RP opportunities in the textbook. For example, we discovered that most RP opportunities were in the text exposition section than in the student exercises section. Most RP statements in the textbook exposition were presented in form of theorems, formulas, postulates, properties, or generalizations following consideration of a few specific cases. A similar distribution of RP opportunities was reported by Otten et al. (2014) who investigated high school geometry textbooks. Although the above statements in the text exposition could be designed in a way that requires active participation from students, the way they were presented in the textbook did not require that. It is, therefore, reasonable to assume that while some students could find ways of actively engaging in the generation of such statements, there are still those who would choose to read along. Furthermore, most of the examples following the statements were often followed by particular examples that did not have any prompt for reasoning-and-proving. However, in solving these examples, the author often presented complete and coherent arguments using the statements provided in the text exposition section. Similarly, in the student exercises section, only a few items had such prompts. Given that some exercises and examples had such prompts while others did not, we claim that this situation might be confusing to students in the sense that they may not know when it is necessary to engage in RP actions. In other words, this scenario is against the necessity principle as articulated by Harel and Tall (1991).

In regard to the nature of RP opportunities, student exercises had more opportunities of the particular nature while text exposition had more statements of the general nature. Since statements in the textbook exposition do not crequire active student participation, it is reasonable to conclude that students using the textbook have more opportunity to engage in RP with particular cases than with general ones. Although particular statements are still useful in heling students see the general (Cuoco, Goldenberg, & Mark, 1996; Reid & Knipping, 2010) the insufficiency of opportunities of the general nature, we argue, does not enhance students' ability to reason deductively- a very important skill in most of mathematics. This finding is consistent with other studies such as Harel and Sowder (2007), Herbst and Brach (2006), and Selden and Selden (2003).

A major recommendation that we suggest from this study would be to increase RP opportunities across all sections of the precalculus textbook. There should be a fair distribution of such RP opportunities such that students have sufficient opportunity to engage with statements of *general*, *particular*, and *general with particular instantiation* nature. This is likely to deepen student understanding of precalculus material and hence lead to student success in calculus and, possibly, other mathematics courses offered at the university level.

An Investigation of a Student's Constructed Meanings for Animations in Construction of a Hypothetical Learning Trajectory

Aysia M. Guy
Arizona State University

This study reports results of an investigation into the meanings a precalculus student constructs as she views an animation independently and describes her image of the problem context as it influences her ability to construct meanings in a novel problem context. Using an exploratory teaching interview, the student's initial meanings and image of the problem context shifted once the animation was utilized as a didactic object. An analysis of her meanings and prior research are used to modify a hypothetical learning trajectory for supporting students in their emergence of productive images of novel problem contexts to construct meaningful and appropriate formulas and graphs. The results and the construction of a hypothetical learning trajectory of this study can potentially be useful for a teachers' awareness of students' constructed meanings while designing or selecting mathematical tasks that incorporate applets and animations in her instruction.

Keywords: Hypothetical Learning Trajectories, Quantitative Reasoning, Problem Solving, Applets

Introduction

Prior research has shown students have difficulty with knowing how to approach and productively solve novel application problems (e.g. Carlson & Bloom, 2005; Lesh, 1985; Lester, 1994; Schoenfeld, 2007). Moore and Carlson (2012) illustrated one of the primary issues of students' difficulty in constructing meaningful and appropriate formulas is due to their inability to conceptualize suitable images of the quantities and their relationships within the context of a novel problem. In addition, Carlson & Bloom (2005) expressed that one's initial conceptualization of the quantitative relationships is grounded in how one makes sense of and organizes information from the problem context. The process of writing a formula requires students to represent the covariation between two quantities and to conceptualize variables as a representation of all the values that a quantity can assume (Stalvey & Vidakovic, 2015; Trigueros & Ursini, 2003). Consequently, students have shown difficulty in connecting their reasoning processes for constructing a formula and an appropriate graph (Carlson, Jacob, Coe, Larsen, Hsu, 2002).

As technology improves, instructors are including different mediums of technology in undergraduate mathematics courses that are designed to support students' mathematical learning. Minimal research has shown how applets and animations can be used for improving students' learning, instruction, and performance (Scheiter, Gerjets, & Schuh, 2010; Bérancourt, & Tversky, 2000; Höffler, & Leutner, 2007; Ploetzner, Lippitsch, Galmbacher, Heuer, & Scherrer, 2009). Thompson (2002) stated that the use of diagrams, applets, animations, and other visual aids are most productive for students' learning when utilized as *didactic objects*. For instance, an applet is considered a didactic object once it is used as a tool in which a teacher intends to produce classroom discussions and generate reflective discourse centered around a particular theme or way of thinking. Spector (2016) advocated that the goal of effectively integrating technology, such as an applet, into learning and instruction should maintain a focus on the content and problem-solving activities rather than the technology itself. The idea of effectively integrating and using an applet in the classroom is demonstrated through student's ability to modify or adjust current knowledge to successfully satisfy the requirements of a novel problem (e.g. the quantities and their relationship).

Based on this research, one of the focuses of this study is on the meanings that students develop and how those meanings are formed while viewing an animation. I elaborate on Moore & Carlson's (2012) construct of *image of the problem context* to describe a student's understanding of a problem context as he or she views static images and animations. The driving focus of this study is the awareness of students' constructed meanings that may differ from either that of the teacher's image of what they hoped students to learn or the intended meaning(s) of the designer. Thus, my two research questions were:

RQ1: What meanings do students construct when viewing an animation, independently?

RQ2: How are students' meanings and understandings of a problem affected by watching an animation?

Literature Review and Theoretical Perspective

In order to describe a student's understanding of a problem's context, the theory of *quantitative reasoning* functions as a lens to describe a student's image of the problem context and explain the ways in which students think when engaging in a problem-solving activity. Thompson's (1994, 2011) theory of *quantitative reasoning* describes a *quantity* as a conceived quality of something that is seen as a measurable attribute, either explicitly or implicitly. The notion of conceiving of an appropriate unit of measurement and assigning a numerical value to a quantity is known as the process of *quantification*. A quantity produced by the resultant of conceiving two quantities is called a *quantitative operation*. For instance, the new dimensions of the base of a box after cutting equal sized square cutouts from each corner being additively compared to the original dimensions of a box's base is a notion of performing a quantitative operation. Someone who has conceived three quantities, in which two of the quantities determine the third, is called a *quantitative relationship*. A network of quantitative relationships is referred to as a *quantitative structure.* Essentially, the analysis of a situation into a quantitative structure is better known as *quantitative reasoning*, which describes the initial conceptualizations of quantities and their relationships during the orientation phase. The act of reasoning quantitatively is directly related to the cognitive actions of attempting to construct a mental representation of the problem situation.

The emergence of students' image of the problem's context is related to whether a student can conceive and relate quantities varying. Furthermore, a student's constructed image of the problem's context is known to influence their ability to construct a formula or a graph (Moore & Carlson, 2012). One of the main requirements of creating a meaningful and robust formula or graph is to have a productive image of how two quantities vary simultaneously. The use of *image* is consistent with Carlson et al.'s (2002) notion of an image that consists of the mental pictures, visual representations, meanings, and properties associated with a concept and as the carrier of mental operations. In this study, I conjecture that the emergence of student's image of a problem's context can be supported by questions with a scaffold and the use of an animation as a didactic object. The object only becomes didactic once it is used as a tool in which the teacher can produce classroom discussions and generate reflective discourse around a preferred theme or way of thinking (Cobb, Boufi, McClain, & Whitenack, 1997; Thompson, Philipp, Thompson, & Boyd, 1994; Thompson, 2002).

Prior to selecting an applet and tasks, I considered the student learning goal(s) of the course, the learning activities that can achieve those goals, and the potential thinking and learning that can occur for students throughout the lesson. The process of predicting a learning path that may occur for students' and characterizing the expected tendencies of student learning are actions towards forming a hypothetical learning trajectory (HLT). Simon & Tzur (2004) explains that a teacher's HLT for her students is composed of the teacher's goal for students' learning, the mathematical tasks used to promote student learning, and hypotheses about the process of the students' learning. I hypothesize that act of generating a HLT can be used as a mechanism for selecting and implementing applets that can support students' mathematical learning.

Box Problem Applet & Initial HLT

The Box Problem (BP) activity (Carlson et al., 2018) was created to support students in developing and acquiring the ability to form a mental image of the quantities, their limitations, and their relationship in the situation of constructing a box from a sheet of paper. The activity is based on a real-life situation of cutting 4 equal-sized squares from the corners of an 8.5" by 11" sheet of paper, then folding the sides to form a box. As a student conceives of an image of the sheet of paper forming into various box configurations, he or she must attend to the quantities and develop the ability to imagine the covariation of two or more quantities in the problem situation. For instance, as the length of the size of the cutout increases, then the height of the box increases and the base of the decreases. Based on their conceptualization of the quantities and their relationship, the student must construct a formula and graph that illustrates the relationship between the volume of the box and the length of the equal-sized cutout.

The Box Problem (BP) applet (Figure 1), created in GeoGebra (n.d.) by Grant Sanders and based on the written activity described above, can be a powerful tool for supporting students in reasoning about values of two or more quantities varying simultaneously as one moves the "Cutout Length" slider (i.e. increases the length of cutout) and forms various dimensions of the box can obtain.

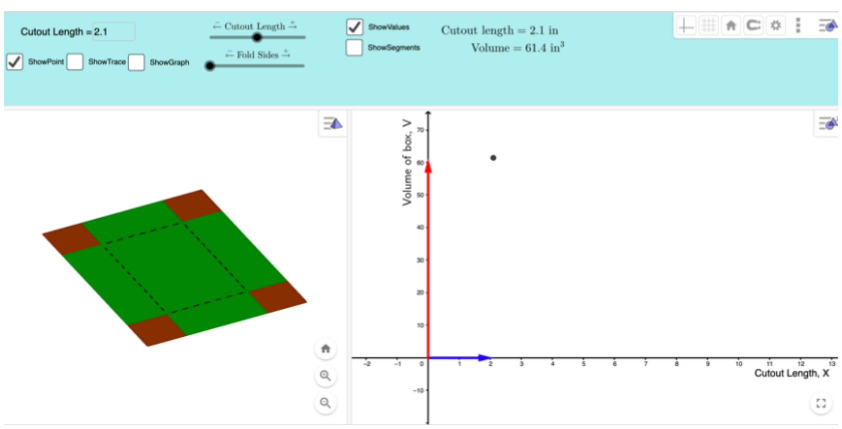

Figure 1. A screenshot of the Box Problem Applet

The following are initial learning goals for a HLT for the Box Problem applet that would support students in developing strategies for making sense of and constructing a productive image of the novel problem context and determine meaningful formulas and graphs:

1. Conceptualize the length of the cutouts, the length and the width of the base, the height and the volume of the box as measurable attributes.
2. Conceptualize the height of the box as equal to the length of the square cutout.

3. Identify the relationship between the variations of the dimensions of the base and the volume of the box with the variation of the length of the cutout.
4. Appropriately conceptualize the dynamic relationship of the dimensions of the box (width, length, height, volume) and the length of the square cutout.
5. Reason about the relationship between the quantities and potentially imagine, then produce a graph that displays the relationship between the volume of the box and the length of the cutout.

Methodology

An undergraduate student was selected from *Pathways Precalculus* (Carlson, Oehrtman, & Moore, 2018) course based on her low grade in the course at the respectable time. The student was videotaped, and all written materials were done on an iPad, then converted to a pdf for analysis. The study was conducted using an exploratory teaching methodology (Castillo-Garsow, 2010), in which the exploratory teaching interview (ETI) consisted of a teaching agent, a single student, and a video camera for recording the single teaching episode. The goal of an ETI is to uncover student's thinking as the student engages with a written mathematical problem or a series of mathematical problems (Castillo-Garsow, 2010).

During each session, I showed the student, Lucie, a static image of the BP applet with four tasks to investigate the meanings she constructed as she viewed the static image and animation independently. I continuously characterized the student's image of the problem in accordance to how productive their image is for successfully achieving the appropriate formula or graph. In correlation with Byerley & Thompson's (2017) definition of "productive mathematical meanings", I define a *productive image* as a mental image that possess a quantitative structure of the problem's context that would be productive for students' long term ability to orient towards and reason through the process of solving mathematical tasks. Towards the end of the interview, I judged the student's image as unproductive when it began to lead them down an unwanted path of reasoning. This action resulted into an intervention where I began to utilize the animation as a didactic object to further support the development of the student's image of the problem's context. The choice to intervene and make suggestions was another way to generate more data about the student's mathematics (Steffe & Thompson, 2000) and enabled the student to potentially complete the tasks easier than before.

Results

The exploratory teaching interview began by displaying a static image of a sheet of paper (Task 1) with the following prompt, "If you start off with a 13″ by 15″ sheet of paper and want to construct a box that is formed by cutting equal-sized squares from each corner of the paper, how do you imagine the box being formed?" Lucie proceeded to describe an image of cutting four square cutouts, then folding the sides to create a box. Then, Lucie viewed the animation and was asked to determine, Does the cutouts of the corner of the sheet of paper have to be square? Or can they be triangles or rectangles?" Lucie describes her initial conception of what quantities comprise the construction of a box to clarify her justification that rectangular, rather than triangular corner cutouts, will produce a box.

Task 2 displayed a static image of various box configurations with the sides of the cutouts labeled *x* with their corresponding values. Lucie was prompted to describe what was shown in the image. Her description entailed her image of the variable x to represent the length of the cutout as a quantity. Lucie stated, "the bigger the cutout length, the smaller the box, but the taller it is”, which indicated she visualized changes in two quantities as the length of the cutout increased. In relation to the height, Lucie stated that the size of the cutouts determined the height of the box. However, in Excerpt 1, her image of constructing the box entailed the variation between the length of the cutout and the base of the box, then the height of the box as a resultant.

Excerpt 1

Interviewer: What do you believe forms the height of the box?

Lucie: Umm.. I believe, I guess I would say the cutouts. The size of the cutouts determines the height of the box.

Interviewer: And, what all do you see is varying in the various images?

Lucie: Um, the cutout to the boxes varying the size, like the area of the box and then the height of the box..

Excerpt 1 displays Lucie’s current image of the box’s quantitative structure did not entail the variable x to represent both quantities, the height of the box and the length of the cutout. After watching the animation that displayed the variation in the different forms of box configurations, Lucie described an image of an input-output table that could be formed from the animation. This description supported her conjecture that the length of the cutout would be the input and the volume as the output, with no mention of the base of the box and the height as determinants of the volume.

In Task 3, the prompt required Lucie to rely on her image of the problem context to construct a formula and graph of the problem description. The third static image and animation of the BP applet displayed colored line segments that represent the original length of the sheet of paper and the variations in the length of the size of the cutout, the height, and base of the box as they vary in tandem. Lucie’s image of the problem continuously changed as she viewed both the static image and animation independently. In tandem, Lucie continued to define (and redefine) her formula that determined the volume of the box given the length of the cutout. Her written work is displayed in Figure 2.

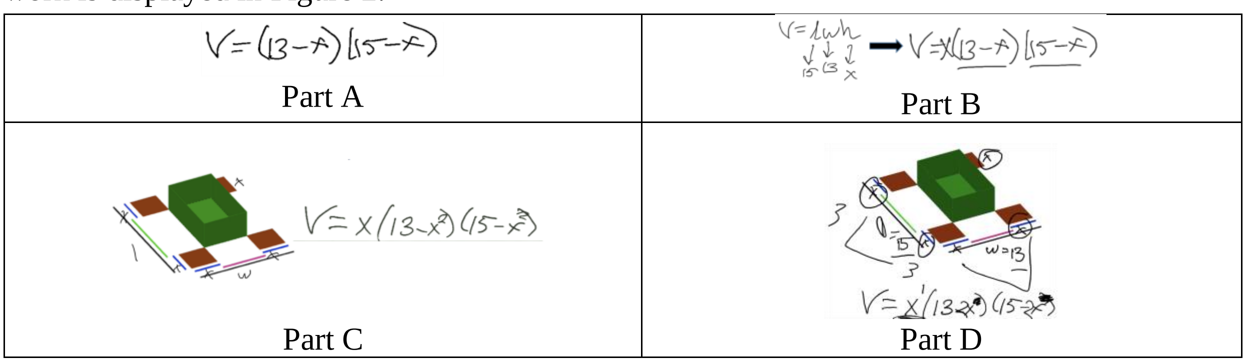

Figure 2. Lucie’s work throughout the interview for defining a formula that represents the relationship between the volume of the box and length of the four equal cutouts.

Part A of the figure shows Lucie’s initial formula for predicting the volume given the length of the side of the cutout. When asked what all quantities determine the volume of the box, Lucie redefined her formula in Part B. From this evidence, Lucie did not conceive of the height as a quantity. Part B further supports the claim; Lucie added on x without referring to x as the height, but as a resultant of folding the sides into a box. After watching the animation, Lucie commented about the four brown squares’ varying lengths that need to be accounted for. She then redefined her formula in (Figure 2, Part C). At that moment Lucie was not advancing her thinking, so I decided that it would be productive to utilize the static images and animations as didactic objects. I then suggested that Lucie determine the volume of the box when $x = 3$. She then focused on how the box configuration changed as the length of the cutout increases. The discussion resulted in Lucie's revised formula (Part D) to accurately represent the quantitative relationships.

Following the construction of a formula, Task 4 prompted her to sketch a graph that relates the volume of the box in terms of the length of the side of the cutout. Lucie stated that she could not draw a graph and she didn't know where to begin. I displayed static images of a graph with various coordinate points as the length of the cutout increases (refer to Figure 1, right panel). Excerpt 2 shows Lucie's response to viewing the static images.

Excerpt 2

Lucie: What I'm trying to figure out is the little black dot on the graph as well. I thought, maybe it was the limit but I'm not sure, I think it's the ...um..(Lucie slides between static images).. I don't know.

This excerpt provides evidence that, at the moment, Lucie had not conceptualized what a coordinate point on a graph represents. However, after watching the animation, that displays the tracing of a graph as the length of the cutout increases, her meaning(s) for what the black dot represented changes. The resulting interactions are provided in Excerpt 3.

Excerpt 3

Lucie: … So, I think the black curved line on the graph represents the whole, like all the possibilities and then maybe the limit at the top, like all the various volumes and the cutout lengths. Then I think that the black dot we've been following up there (slides finger along the graph of the animation) and also with this, (points to the animation) this is where that specific box is, if that makes any sense.

….

Interviewer: So, why do you think it was increasing and then it got to this peak and then it started to decrease? What do you think that happened?

Lucie: So, at first that was like kind of hard to process to relate because that's what I look at is like could be the ball being thrown but kind of describing and talking through like what that little point means and like the limits I think it gets bigger and then smaller I think when the cut out is it looks like about two inches the volume.

Conclusion and Discussion

Several changes occurred in Lucie's image of the problem context and her constructed meanings for the quantities within the situation. Lucie's difficulties in constructing an appropriate formula to determine the volume of the box, given the length of the cutout, were due to her inability to conceptualize how the quantities vary simultaneously. The findings suggest that the use of the animation as a didactic object, in which I created a discussion around the animation, gave Lucie the opportunity to reflect and make connections between her image of the problem context and the symbolic representation in her formula(s). As a result, I conjecture the applet (when used as a didactic object) can be a powerful tool for supporting students in developing the foundational reasoning skills needed for imagining the covariation between two quantities. The results further suggested that the use of the animation can have a positive impact on students' meanings and understanding of a multiplicative object, in which students can conceive graphs as records of simultaneous variation (Thompson, 2002). Lastly, I conjecture that a student's prior knowledge affects their ability to construct productive images of the quantities in an applied context. This can potentially lead to problems when implementing an applet or animation in instruction, as for some students, they are focused more on the technology and how to use it rather than on the quantitative relationships displayed in the applet.

Based on my analysis of the results and prior research, I constructed a HLT, presented in Table 1, that can be used in conjunction of an applet as a didactic object to support students' construction of a productive image of quantitative relationships within the BP activity. The trajectory is comprised of five constructs that are identified as productive images to support students' mathematical reasoning, while engaging in the BP activity and the use of the animation. For each construct, there is a list of learning goals to support students in developing

Constructed Hypothetical Learning Trajectory	
Constructs	Learning Goals
Part 1: Emergence of students' image of a problem's context (Moore & Carlson, 2012)	• Conceiving the length of the cutouts, the length and width of the base, the height and the volume of the box as measurable attributes. • The height of the box possesses a direct relationship with the length of the cutout.
Part 2: Covariational reasoning (Carlson et al.,2002; Thompson & Carlson, 2017)	• As the length of the cutout increases, the height of the box increases; the length and width of the base decreases; and volume of the box initially increases, then decreases at some length of the cutout. • Identified direction of variation in quantities can be used to construct a verbal representation of the process of determining various box configurations and their dimensions.
Part 3: Emergent Symbol Meaning (O'Bryan, 2018)	• Verbal representation can be transformed into symbolic representation by defining variables in correspondence with (1) the verbal phrases and (2) the description of the problem context. • Reflection of evaluating a model for the problem's context can be used for verification of understanding the construction of a meaningful formula.
Part 4: Multiplicative object and multiple representation (Moore & Thompson, 2015)	• A point within a graph is the covariation between two quantities in tandem. • A graph is a collection of quantities' covariation. • The problem context, verbal representation, symbolic representation, evaluation processes, and a point or coordinate point within the graph possess a non-linear connection.

Table 2. The Constructed Hypothetical Learning Trajectory

strategies for making sense of and constructing a productive image of the novel problem context and determine meaningful formulas and graphs. The aim of this study is to contribute to the field of mathematics education's knowledge of students' learning processes and how they can be supported in reasoning quantitatively. A future study involving the implementation of this implicitly based learning trajectory will allow the researcher to investigate a classroom of students' image of a problem context to support students reasoning skills to solve other novel problem contexts.

Jessica Webb
University of Memphis

This study reports psychometric evidence for using the high school version of the revised Self-Efficacy to Teach Statistics (SETS-HS) instrument in a retrospective pre-post format with for pre-service mathematics teachers. Analyses at the subscale level indicate adequate internal consistency for "before" and "now" ratings and a high correlation between subscale scores across both ratings. Analyses of individual items' item means, item-subscale total correlations, and the frequency of item mentions in open-ended items are summarized. The retrospective pre-post format yielded SETS-HS scores with some adequate psychometric properties, suggesting a single administration instead of two separate administrations does not degrade the measurements.

Keywords: Pre-Service Mathematics Teachers, Self-Efficacy to Teach Statistics

Within the past decade, the focus on preparation of K-12 mathematics teachers to teach statistics has increased as a result of the inclusion of substantial statistical content in the Common Core State Standards for Mathematics (CCSSM) in grades 6-8 and high school (National Governors Association Center for Best Practice & Council of Chief State School Officers, 2010) and other state standards, as well as recommendations for appropriate content and supports for K-12 mathematics teachers provided by the American Statistical Association's *Statistical Education of Teachers* report (Franklin et al., 2015). Relatedly, several findings resulting from a cross-institutional mixed methods study of 200+ pre-service secondary mathematics teachers (PSMTs) (Lovett & Lee, 2017, 2018) demonstrate that current efforts in teacher preparation are not adequate for preparing future teachers to meet the demands of the newer statistics standards. Specifically, approximately 75% of PSMTs did not demonstrate the necessary statistics content knowledge related to K-12 statistics standards, PSMTs felt least confident to teach statistics as compared to other content areas (i.e., algebra, etc.), and PSMTs' self-efficacy to teach statistics was only weakly correlated with their content knowledge.

To meet the demand for high quality materials in order for teacher educators to increase PSMT preparedness and self-efficacy to teach statistics, online modules have been developed by a National Science Foundation-funded project, *Enhancing Statistics Teacher Education with E-Modules (ESTEEM).* The learning opportunities within the *ESTEEM* modules provide critical experiences in pre-service teachers' statistics teaching self-efficacy development. For example, participants engage in statistical investigations, watch video cases of real classrooms, discuss and reflect in forums, and analyze tasks for their potential to promote statistical habits of mind.

Statistics teaching efficacy is an important construct in pre-service mathematics teacher development as teacher beliefs are known to impact their practices in the classroom and, in turn, impact student attitudes, motivation, and achievement (Zee & Koomen, 2016). To date, only one instrument measuring statistics teaching efficacy has been validated with pre-service secondary mathematics teachers in the United States, the high school version of the Self-Efficacy to Teach Statistics (SETS-HS) instrument. However, all validation efforts have focused on a single administration of the instrument, generally towards the end of a teacher preparation program (Harrell-Williams, Sorto, et al., 2014; Harrell-Williams, Lovett, Lee, et al., 2019; Harrell-Williams, Lovett, Lesser, et al., 2019).

However, within the field of program evaluation, the benefits of the retrospective pre-post methodology have been espoused for several decades (Pratt, McGuigan, & Katzev, 2000). Unlike conducting separate pre- and post- measurements at the beginning and conclusion of a program, the retrospective pre-post approach involves a single time-point, simultaneous measurement of both "pre" and "post" data. In addition to the obvious time-saving nature of a single administration, an additional benefit of this approach is that participants have the same frame of reference when answering the items, which has implications for the design of educational intervention studies using the SETS-HS instrument. Hence, this study addresses this gap in the SETS-related literature by reporting psychometric results from the use of the revised SETS-HS in a retrospective pre-post design where pre-service mathematics teachers (PMTs) are asked to rate both their self-efficacy to teach statistics "before" engaging in educational materials focused on statistics pedagogy and "now", after the completion of about two weeks' worth of learning. Specifically, the following research questions were addressed:

1. How well do the subscales perform in terms of internal consistency?
2. How well do the items perform in terms of item means and inter-item correlations?
3. Does the frequency of item number mention in the open-ended items concur with the item means of the Likert-scale items?

Method

Context and Participants

Participants were 187 PMTs from twelve institutions across the United States that offer undergraduate or M.A.T. programs in mathematics teacher preparation covering elementary, middle or secondary grades certification. The number of PMTs per institution ranged from 3 to 26. These institutions are field test sites for the *ESTEEM* project. The sample was mostly female (73.4%), which follows current teacher demographics in the United States (Taie & Goldring, 2017). Demographics regarding ethnicity were not collected.

Participants completed the retrospective SETS survey during 2018-19 after completing the *ESTEEM* foundational module within one of their courses. The module includes 16 to 18 hours of material providing PMTs important experiences with the basics of what it means to teach statistics. The module is organized into two major sections, each one consisting of materials to read and watch, a data investigation using the online tool CODAP, and discussion forums to synthesize and apply participants' learning. The modules are designed to be flexible in that they can be used in a purely online setting but could also be used in a hybrid or face-to-face setting. To maximize the available data, those PMTs who completed items for entire subscales were used, resulting in subscale-specific sample sizes. In addition to 155 participants who completed all three subscales, 23 additional PMTs completed both Level A & B subscales but not Level C, while 9 more completed only the Level A subscale.

Instrument

The revised high school version of the Self-Efficacy to Teach Statistics instrument (SETS-HS) asked the PMTs to indicate their confidence to "teach high school students the skills necessary to successfully complete" 44 statistics tasks using a 6-point Likert scale, with 1 = *not at all confident* and 6 = *completely confident*. Similar to the original SETS-HS, the items were written to mirror the developmental levels (Levels A, B, C) of the *Guidelines for Assessment and Instruction in Statistics Education* (GAISE) *Pre-K-12 Report* (Franklin et al., 2007) and cover most statistical content in the CCSSM for grades 6-8 and the two data analysis strands in high school. Three subscale scores are computed: "Level A - Reading the Data", "Level B - Reading Between the Data", and "Level C - Reading Beyond the Data". Refer to Table 2 for a summary of item content by subscale.

While no factor analysis and reliability results have been published yet on the revised version, the development and validity evidence for the original SETS-HS instrument are documented in Harrell-Williams, Lovett, Lee, et al. (2019) and Harrell-Williams, Lovett, Lesser, et al. (2019). Items in the current version were revised based on (1) psychometric analysis results, (2) feedback from interviews and focus groups consisting of previous/current SETS users, mathematics educators, PSMTs, HS math teachers, and (3) the desire to include more items in the "pose" and "collect" stages in statistical investigation cycle in order to possibly align with stage-based scores on the Levels of Conceptual Understanding in Statistics assessment (LOCUS; Jacobbe, 2015; Jacobbe et al., 2014).

This study used a retrospective pre-post approach for the 44 SETS-HS items. For each item, PMTs reported their confidence to teach each of the statistical concepts, prior to and after their engagement in the *ESTEEM* module. The PMTs also responded to open-ended questions at the end of each subscale to indicate (a) the items they felt most confident to teach and (b) the items they felt least confident to teach, along with their rationale for that ranking.

Analysis

The analyses of the Likert items fall under two categories. At the subscale level, Cronbach's alpha was calculated as reliability estimates for both the "before" and "now" scores and Pearson correlations were estimated between the "before" and "now" scores for each of the three subscales. Item means and item-total correlations were obtained for each item as measures of classical test theory item difficulty and discrimination, respectively. For the analysis of the open-ended items, the item that each student specifically mentioned in their response (by item number or wording) was recorded. Responses that did not explicitly mention a survey item were not included. Frequently, responses mentioned more than one item. The analysis involved creating a frequency distribution for the number of times that each item was mentioned as the hardest item for a PST to endorse with a response of "completely confident", and the number of times that each item was mentioned as the easiest item for a PST to endorse with a response of "completely confident".

Results

Subscale Analyses

The Cronbach's alpha reliability estimates for the subscales for both "before" and "now" ratings were greater than or equal to .93, indicating very little measurement error in the subscale scores (See Table 1). The correlations between a PMT's subscale scores for "before" and "now" ratings were slightly over .60, indicating a strong relationship between the ratings.

Table 1. Subscale-Level Results

Subscale	No. Items	"Before"			"Now"			Corr. Across Ratings
		Alpha	Mean	SD	Alpha	Mean	SD	
Level A	12	.94	36.10	12.14	.93	52.77	9.25	0.61
Level B	15	.96	42.07	16.19	.94	60.62	12.91	0.62
Level C	17	.97	43.80	18.82	.96	62.15	17.96	0.62

Item-Level Analyses

All of the item-total correlations were greater than 0.55, indicating that higher ratings on each item were related to higher scores on the subscales. Item means were generally higher for level A items and lower for level B and C items, with the "now" ratings averaging about a full point higher than "before" ratings. Item standard deviations (SDs) decreased for some items in the "now" ratings, with "before" SDs ranging from 1.2 to 1.5 and "now" SDs ranging from .9 to 1.5.

Table 2. Item Statistics and Frequency of Item Mentions in Open-Ended Responses

Scale	Item & Topic	"Before" Items			"Now" Items			Least Confident Mentions	Most Confident Mentions
		M	SD	*r*	M	SD	*r*

Note: M = Mean. SD = Standard Deviation. *r* = Item - Subscale Total Correlation. NM = Not mentioned in question responses. Level A: *n* = 187, Level B: *n* =178, Level C: *n* = 155.

Open-Ended Items: Frequency of Mention

The open-ended questions asked the PMTs to think only about the SETS items within each subscale, so the results are presented by subscale. In subscale A, each item was mentioned in both the least and most confident responses. PMTs indicated feeling least confident to teach about sources of variability (#3, 20%) and using technology to explore and summarize data (#11, 14%; #12, 20%). However, two of the technology items were also among the three most frequently mentioned items that PMTs reported feeling the most confident to teach (#11, 24%; #12, 20%), with item 6 (create graphical display) mentioned the most frequently (27%). These results are consistent with the item analysis results, although open-ended results seem to depend on whether PMTs answered based on their initial confidence or after the two-week learning experience. Ratings for item 3 (lowest mean in both the “before” and “now” ratings) and item 6 (second highest mean in the “before” ratings and the highest mean in the “now” ratings) were consistent. However, item 12 moved from the third lowest mean in the “before” ratings to the fifth highest mean in the “now” ratings, and item 11’s mean was relatively low in the “before” ratings but third highest in the “now” ratings. This is likely due to technology use in the learning modules.

In subscale B, all items were mentioned in both the least and most confident responses, except #25 (sampling variability), which was never identified as a most confident topic. PMTs indicated feeling least confident about items 22 (sampling error, 18%) and 18 (correlation, 14%) and most confident about items 17 (boxplots, 25%) and 21 (sample representativeness, 15%). Again, these results are mostly consistent with the item analysis results. The item mean for 22 was third lowest “before” and the lowest “now” rating. Item 18 had a mean that moved from fourth lowest to fifth lowest. Item 21 had the highest mean in both “before” and “now” ratings. Item 17 had a mean around the middle “before” ratings, but increased to the second highest “now” rating.

In subscale C, only 1 of the 17 items was not identified as a least confident topic (#40, point estimates), and only 1 item was not identified as a most confident topic (#43, build physical simulation). In the topics the PMTs identified as being least confident to teach, items about two-way tables (#30, 32%; #31, 25%; #29, 23%) and using technology to run a simulation (#44, 22%) were mentioned the most. PMTs identified item 35 (interpret slope and intercept) as being their most confident topic to teach (29%). In the item analysis, items 30 and 31 had the lowest means in both the “before” and “now” ratings, while item 29 was sixth lowest in the “before” ratings and eighth lowest in the “now” ratings. Item 35 had the highest mean both in the “before” and “now” ratings.

Discussion

The purpose of this paper was to explore initial psychometric evidence for a retrospective pre-post format of the revised SETS-HS instrument. The subscale scores for both the “before” and “now” ratings from retrospective pre-post approach of the SETS-HS exhibited acceptable internal consistency for both the “before” and “now” ratings, suggesting strong inter-item correlations within each subscale. The Cronbach’s alpha estimates (all greater than .90) were similar to those reported in previous studies of the SETS-HS using middle grades and high school PMTs (Harrell-Williams, Sorto, et al., 2014; Harrell-Williams, Lovett, Pierce, et al., 2017; Harrell-Williams, Lovett, Lee, et al., 2019).

At the item level, there was reasonable variability in the item means, both within and across subscales, for both the “before” and “now” ratings. As expected, the item means increased for the “now” ratings as compared to the “before” ratings, but no ceiling effect was observed in “now” ratings. Additionally, item means for subscales B and C were lower than those for A, similar to previous studies using a single-time point measure of “now” ratings (Harrell-Williams, Sorto, et al., 2014; Harrell-Williams, Lovett, Pierce, et al., 2017; Harrell-Williams, Lovett, Lee, et al., 2019).

Based on the results of the analyses conducted here, the scores from responses obtained so far during the *ESTEEM* project have reasonable reliability, difficulty (i.e. item means), and discrimination (i.e. item-score correlation) estimates, indicating that the retrospective pre-post version does not necessarily degrade the psychometric properties of the scores.

Implications

These results have important implications for the use of retrospective forms in research and practice. In ratings prior to exposure to new content (at the start of a course or a new module), PMTs might overestimate their self-efficacy regarding specific topics because they do not anticipate the extent or complexity of the topic. After exposure to strategies for teaching that content, their interpretation of the items might change, possibly leading to indications of no change in efficacy or even a decrease in self-efficacy scores. As previous noted, a benefit of the retrospective pre-post approach is that the PMTs will have the same reference point when responding to the “before” and “now” items. Additionally, this format reduces the amount of time required for collecting baseline PMT data at the start of a class, module, or research project, freeing up valuable instructional time or allowing for other baseline data, such as demographic data or prior knowledge, to be collected in its place without adding to response fatigue.

Students’ Interpretations of the Prompts for Proving Tasks: “Prove” and “Show”

Jihye Hwang
Michigan State University

Shiv Smith Karunakaran
Michigan State University

Proving can be a process for communicating mathematics and people communicating need to be familiar with the language of mathematics. This study focuses on the prompts used for proving tasks not only because the wording of these prompts may impact students’ modes of argumentation, but also because students might bring their preconceptions about these prompts from previous mathematical and non– mathematical experiences. The current study examined how Calculus I students interpret prompts, such as “prove” and “show.” Data was from 131 survey responses and three interviews reveal that these students possibly interpret different prompts in different ways, which can create a gap between students’ interpretations and instructors’ or researchers’ intentions. This suggests that instructors and researchers may need to be more deliberate in choosing such prompts.

Keywords: Proving, Prompts, Language

Proving and proof have been emphasized across K–16 education (Barker et al., 2004; National Council of Teachers of Mathematics, 2000). Among the various roles, some researchers have stressed communication as one important aspect of proof. A proof is a way of communicating mathematical knowledge not only between mathematics researchers but also between teachers and students (de Villiers, 1990; Hanna, 2000). Mathematicians use proof as a way of reporting and distributing mathematical knowledge to society (de Villiers, 1990). Similarly, in certain mathematics classrooms, teachers routinely ask students to prove a mathematical statement, and students respond to the question by attempting to generate a mathematical argument.

For proof to be a way of communication, participants in the dialogue need to be familiar with the discourse surrounding proof (Lew & Mejía–Ramos, 2019). Without knowledge about the specific discourse, it is hard for students to be engaged, and it might affect students’ chance of effective engagement in the mathematics classroom (Lew & Mejía–Ramos, 2019). Hence, students need to learn the discourse, which can be conventions in proving, such as mathematics–specific use of words, grammar, and pattern and formality of argument. There exist, however, few studies focusing in on such conventions in proving. Among the few, Lew and Mejía–Ramos (2019) studied the conventions within written proofs. Based on undergraduates and mathematicians’ responses to the given arguments which had some nonconventional use of mathematics language, the authors found themes of conventions in proof writing.

Although students’ proof responses are important to investigate, we need to examine how we pose questions to students that are intended to elicit mathematical arguments as responses. In this study, we focus on the prompts for proving tasks, which are used in the imperatives of the sentence, such as “prove,” “show,” “explain,” and “convince a classmate.” The following is our research question for the larger study (the complete results of which are not described here): *How do Calculus I students interpret and respond to different prompts, such as “prove,” “show,” “explain,” and “convince a classmate,” for proving tasks?*

Rationale

We had two reasons for choosing to study the prompts for proving. First, the prompts for proving tasks may have an impact on students' modes of argumentation. For example, suppose students are given "show A" where A is a mathematical statement. On the one hand, Alcock (2013) claimed "prove" and "show" are synonymous for mathematicians. On the other hand, Dreyfus (1999) questioned whether the prompt "show" has the implication to produce inductive arguments. Even before students might engage with the mathematical content in a given problem, students need to decide the type of argument or the level of formality of the argument that they need to produce. Hence, if the expectations teachers and students have for a given prompt are different, that inconsistency might negatively impact students' learning of proving (Dawkins & Roh, 2016). Also, it possibly affects the accuracy of student assessments, which is critical for both research and teaching (Morgan, 1998; Schleppegrell, 2007; Weber, 2014).

Our second reason is that students might have some expectations or prebuilt conceptions about each of the prompts. Some of the prompts use words that students commonly use or hear in various non–mathematical contexts. Students might have preconceptions of the words through such experiences, and these preconceptions possibly affect students' understanding of the prompts as part of their mathematics register, which is sometimes referred to as semantic contamination (Pimm, 1987). Mejía–Ramos and Inglis (2011) examined the possible differences in students' responses to "prove" and "proof." The authors presented mathematical arguments and asked questions to students by using either "Is the argument proof of the claim?" or "Does the argument prove the claim?" (Mejía–Ramos & Inglis, 2011, p. 22). Their data revealed that students might consider "proof" to require more formality than "prove." Some students responded that the given argument is "proving" the statement even if the argument is judged not to be a proof. This result aligned with the authors' analysis of using the words "prove" and "proof" from the British National Corpus World Edition, which is a collection of current English language usage. The analysis indicated that "proof" is more used in formal contexts and "prove" is more used in informal contexts. This analysis and the results might mean that students' conception of the prompts might be affected by its use in other contexts as well.

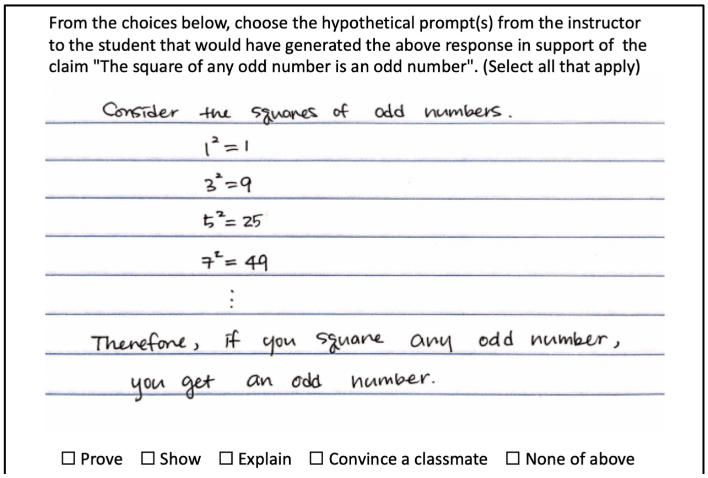
Because students might have come to the proving situation with their previous knowledge about the prompts, and that can possibly affect their learning of proving, there is a need for research about how students interpret and respond to the prompts for proving tasks. In this study, we plan to focus on Calculus I students' interpretations of the prompts because they usually have not experienced a proof–based undergraduate mathematics course. Hence, the population might be appropriate to discuss their previously constructed knowledge from their K–12 mathematics education about the prompts for proving tasks. Therefore, in this study, our objectives were: 1) to describe meanings of each prompt for each participant, 2) to explain connections between prompts for each participant, and 3) to investigate how differently and similarly students interpret the four different prompts.

Our results reveal that students' interpretation of these prompts vary depending on the individual, but these interpretations may not be stable. Taking space constraints into consideration, the current paper reports only on two prompts: "prove" and "show."

Methods

In the reported study, we used surveys and interviews as the main sources of data. The survey consisted of the following: 1) questions asking about participants' mathematical backgrounds; 2) choosing between hypothetical prompts, "prove," "show," "explain," and "convince a classmate," which would have generated given mathematical arguments (see an example in

Figure 1) with optional open–ended asking for the rationale for their choice; and 3) Likert–type questions asking about relationships between the prompts (see Figure 2). We received 265 response from Calculus I students, and we refined our data to 131 responses based on their reliability (e.g., not having the same response to all Likert–type questions). After refining, we analyzed the data by looking for patterns, consistencies and inconsistencies among the "choosing hypothetical prompts" tasks and the Likert–type questions. Based on these patterns, we solicited participants who were found to be exemplars for the type of responses found.



From the choices below, choose the hypothetical prompt(s) from the instructor to the student that would have generated the above response in support of the claim "The square of any odd number is an odd number". (Select all that apply)

Consider the squares of odd numbers.

$1^2=1$

$3^2=9$

$5^2=25$

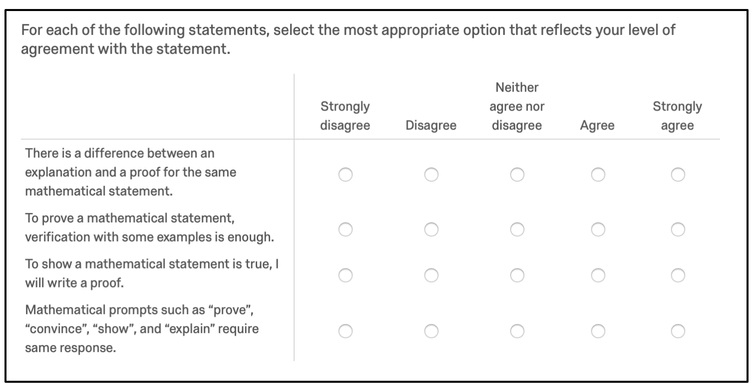
$7^2=49$

$\vdots$

Therefore, if you square any odd number, you get an odd number.

☐ Prove ☐ Show ☐ Explain ☐ Convince a classmate ☐ None of above

Figure 1. An example of a "choosing hypothetical prompts" task.



For each of the following statements, select the most appropriate option that reflects your level of agreement with the statement.

	Strongly disagree	Disagree	Neither agree nor disagree	Agree	Strongly agree
There is a difference between an explanation and a proof for the same mathematical statement.	○	○	○	○	○
To prove a mathematical statement, verification with some examples is enough.	○	○	○	○	○
To show a mathematical statement is true, I will write a proof.	○	○	○	○	○
Mathematical prompts such as "prove", "convince", "show", and "explain" require same response.	○	○	○	○	○

Figure 2. Examples of Likert–type survey items offered to Calculus I students.

We had three participants (Dave, Emma, and Sean; all pseudonyms) that responded to our request for interviews. Before doing interviews, we analyzed their survey responses more deeply and created a narrative for the possible meaning of the prompts and relationships between the prompts for each. During the interview, participants were asked again about their mathematical backgrounds and the "choosing hypothetical prompts" tasks, and in addition we asked about their rationales for choosing and not choosing each prompt. Also, we added a sorting task: participants received six different arguments for the same mathematical statement, and they sorted the arguments to appropriate prompts. Then, for each of the arguments, participants described their rationale for assigning or not assigning the argument to each prompt. The interviews were transcribed and coded by each prompt when participants were mentioning and/or describing their interpretations of the prompts. Based on the coding, we are developing each participant's narrative for each prompt.

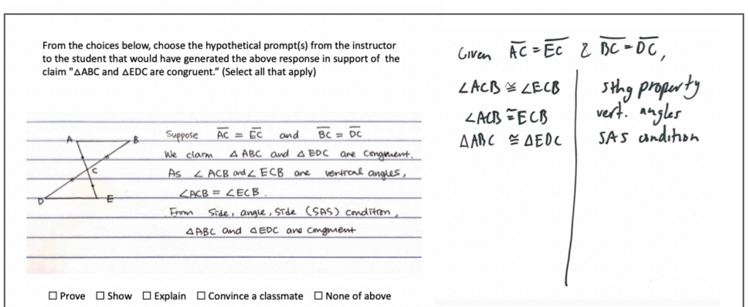
At the beginning of each survey and interview, students were asked to share their mathematical background and major at the university. This was to anticipate their past mathematical proving experiences. With a social constructivist view, students' past experiences offered their learning possibilities of the prompts in the past (Cobb & Yackel, 1996), and researchers investigated possible effects of the context on students' concept of the prompts (Noddings, 1990). For example, Emma, one of the interview participants, referenced her high school mathematics experience when she explained her choice of the prompts during the interview. Hence, we thought it might be helpful to know participants' past mathematics experiences before we started the tasks.

Results

We present the results from the study by focusing on the two prompts: "prove" and "show." Taking the space constraints into consideration, we present a selection of the results about the "prove" prompt, the "show" prompt, and present one possible relationship between the two prompts. For a more complete description of the results of the larger study, please refer to Author (date).

Interpretations of the "Prove" Prompt

Response to "prove" prompt must adhere to a preconceived form. In the survey, only Dave indicated that there should be certain rules that the specific argument generated in response to the "prove" prompt must follow. He wrote, "Prove, one I like because it brings to mind 'proofs', is a very strong indicator to me that I need to write out a response showing that a statement is true by identifying and analyzing theorems." He elaborated on this notion during his interview. In fact, during the interviews, both Dave and Emma claimed that the prompt "prove" requires the generation of an argument that has a series of sequential statements and refers to some mathematical property that satisfies a seemingly arbitrary level of generality. Dave referred such mathematical property as "theory", and it is a necessary part of a response for "prove." On the other hand, Emma's response to the prompt "prove" is more formal and technical. After she rejected S2 as a response to "prove," she suggested a form of two–column proof to describe the kind of argument that she was thinking appropriate for the prompt "prove" (see Figure 3). During the interview, she claimed that "prove" requires formal words such as "given," and "suppose," which she claimed are commonly used by professional mathematicians. Sean also claimed that a response to the prompt "prove" should not include certain less formal words that may detract from its form. For instance, he claimed that the argument prompted by "prove" cannot have the word "you" in it, which implied a more casual situation to him.



S2 from the survey and the interview

Emma's rough response for the prompt "prove" instead of S2

Figure 3. The argument S2 (left–hand side) and Emma's response (right–hand side).

In summary, all three participants seemed to indicate that any response to the "prove" prompt needs to adhere to some preconceived form or rules. We are not completely privy to what the students conceive to be their exact form of or rules for the responses to the "prove" prompt. However, they do provide some glimpses into certain aspects of these forms or rules, and as such, it seems reasonable that the "prove" prompt elicits the deployment of these forms or rules.

Students might not have a consistent notion of proof and the prompt "prove." Our analysis revealed that post–secondary calculus students understandably have an inconsistent notion of proof. As discussed elsewhere, Emma's interpretation of the prompt "prove" seems to indicate that she expects a response that adheres to a strict preconceived form (see Figure 3). However, Sean's response to the prompt "prove" requires multiple arguments from multiple perspectives. For him, it was not enough to use one method to qualify the prompt "prove." In fact, among the nine given arguments, he did not choose one of the arguments as appropriate for the prompt "prove." Further, to construct appropriate arguments for the prompt "prove," he said he would combine three arguments from the provided arguments.

In contrast to the survey results (see Table 1), none of the interview participants agreed on counting an inductive argument as appropriate for the prompt "prove." This result might have suggested that our interview participants have at least some requirements for proof. Dave and Emma claimed that the prompt "prove" requires some level of generality and universality, not just displaying coincidences. Although Sean rejected inductive arguments with few examples as responses to the "prove" prompt, he reported that an argument with "a large enough data set" for the given statement would be appropriate for the prompt "prove." In addition, he rejected the deductive argument S2 (see Figure 3) by claiming that actual measuring of the angles would be needed for the argument if it were to be counted as an appropriate response to the prompt "prove." This indicated that Sean thinks an inductive argument is acceptable as a response to the prompt "prove" in certain cases and not others. This aligns with the survey result that he is one of the 30 students who chose "Neither" for the question "To prove a mathematical statement, verification with some examples is enough" (see Table 1).

Table 1. Survey results for whether an inductive argument is appropriate for "prove" and "show"

		Q14. To prove a mathematical statement, verification with some examples is enough					
		Strongly Disagree (SD)	Disagree (D)	Neither (N)	Agree (A)	Strongly Agree (SA)	Total
Q6. It is not enough to write some example when I asked to show the given statement	SD	1	3	1	2	2	9
	D	4	10	5	20	0	39
	N	0	5	15	12	1	33
	A	4	14	9	16	0	43
	SA	0	2	0	3	2	7
	Total	9	34	30	53	5	131

Interpretations of the "Show" Prompt

"Show" means demonstration. For our interview participants, the prompt "show" might mean demonstration rather than explaining why the given statement is true in detail. Sean claimed an argument prompted by "show" does not come with full sentences or paragraphs, and Emma also claimed the prompt "show" needs less sentences. It seemed the participants' function of having more words in an argument was explanatory in nature, because Emma and Dave's responses implied that the more words an argument has, the less readers of the argument needed to fill the gap between the lines. Emma said that the argument prompted by "show" can leave the most possibility of interpretation to the reader among the four given prompts. She does not expect to write every part of her thinking process in the argument. Similarly, Dave claimed that the prompt "show" asks how the given statement works, but not in a way that describes why nor helps someone to understand the statement. Both Emma and Dave implied that demonstration is a key point of the argument prompted by "show."

"Show" can lead to various form of arguments. Our interview participants' responses to the tasks implied the argument prompted by "show" can include visual arguments and inductive arguments, as well as deductive arguments. They claimed that the argument prompted by "show" could have "straight equations," "calculation," and "technical algebra." In fact, in the sorting task, all three interview participants chose an argument with only algebraic work present without a single word as a response to the "show" prompt. This aligns with the survey results in that some of the survey participants emphasized the importance of number and equations in their written response to the "show" prompt.

In addition, Emma and Dave claimed that a visual argument, which they described as using some visual representations such as graphs or charts, can be counted as a response to "show." Emma claimed that the prompt "show" is the most "visual–slanted" prompt. After she saw an argument that relies on the graphic calculator, she chose that one as appropriate for "show." With that claim, she used analogies from daily life to describe the meaning of the "show" prompt. The following is one such analogy:

> Emma: Okay, I think to me, a graph– It probably makes more sense to say that show is the most visual–slanted of all of these prompts. In everyday language, if someone says 'Show me how you like your shirts to be cut' … I would either bring them an actual shirt and say, 'I want it cut like this,' or I would draw them a diagram and say, 'Okay, here is my measurements' ... Like the architects do, where they have the brackets, and they're like '14 inches across here, 21 across here.'

The above excerpt indicates that Emma thinks a visual argument is an appropriate response for the prompt "show." Dave also chose "show" for the same argument as it is presenting the statement visually. In addition to visual arguments, both Dave and Emma claimed that measuring the angles is appropriate for the prompt "show." Emma did not choose "show" for the deductive argument S2 (see Figure 3). However, she claimed that she would choose "show" if the argument included measuring the angles.

One Possible Interpretation of the relationship between "Prove" and "Show"

Based on that the types of arguments prompted by "show," including deductive arguments, it seemed reasonable to assume that, if one argument satisfies the prompt "prove," then the argument satisfies the prompt "show" as well. Dave claimed that "if you prove something, you've essentially shown it." He claimed that this is because the "prove" prompt requires calculations written in an appropriate order, and to "show" implies that "you just write out your calculations, you have your answer at the bottom and you're done." Emma also mentioned that she cannot think of an example that satisfies "prove" but does not "show." Furthermore, she claimed that "prove" requires the most strict and thorough argument, which in turn also satisfies the ones stemming from the other prompts. However, both Dave and Emma claimed that the other direction is not possible. That is, the arguments generated in response to "show" would not satisfy the requirements to be a response to "prove." Dave stated that the response to the "show" prompt "wouldn't satisfy for a proof". And Emma claimed that "show" and "prove" are "quite close", but "prove" is a bit more demanding of the properties or form required of the response. This implies that a response for "show" may not fulfill the requirements of a response for "prove."

In summary, our data analysis revealed that students have their own interpretation for the "prove" and "show" prompts. For the prompt "prove," participants emphasized certain requirements for the form of the response, although their understanding of "prove" might not be fully developed yet. Students indicated that the prompt "show" can have various interpretations, with seemingly the common goal of demonstration. That is, the argument prompted by "show" can either include inductive reasoning, rely on a diagram, and/or reason deductively. Also, the responses for "prove" seem to automatically satisfy the "show" prompt, but not vice–versa.

Discussion

Our research demonstrates the possibility of different interpretations of different prompts, especially for the prompts "prove" and "show." The results were inconsistent with the commonly accepted notion that these prompts are synonymous for professional mathematicians (Alcock, 2013). Thus, asking students to "prove" and/or "show" without considering their possible differences in meaning for students can have negative impacts on accuracy of assessment for teachers, and on interpretations of research data for researchers since the desired intent for a task and the implementation of the task by students can be different. This is similar to situations that happen when designing classroom tasks or curriculum (Remillard, 2005; Stein, Grover, & Henningsen, 1996). Hence, choosing prompts more deliberately or having more description about the intent of the task might help preciseness of the response from the students. Therefore, we claim that researchers and teachers may need to analyze carefully how research or teaching tasks are implemented and whether they align with their intended interpretation.

There are certainly values to our current study and future directions to pursue, but also some limitations that exist. Some of our participants seemed to be developing their interpretations of the prompts during the interview and their involvement in our study itself might have implied there exists certain differences between the prompts for the participants. In addition, we do not completely know whether students are actually influenced by the prompt. In fact, Emma claimed that she usually does not consider the meaning of prompt, and if so, it depends on how careful she is being in the moment. However, we posit that if the participants developed interpretations of the prompts during our study, it is also possible that they develop such interpretations while interacting with other non–research related tasks. We do not claim that students are always careful about the prompts and have static interpretations of the prompts. Rather, we claim that there exists the possibility that students' interpretations of the tasks can influence their responses.

Future Teachers' Use of Multiplication and Division to Formulate Linear Equations

Andrew Izsák
Tufts University

Sybilla Beckmann
University of Georgia

We report results from administering a paper-and-pencil survey to 56 future middle grades and secondary grades mathematics teachers enrolled in teacher preparation programs at two large public universities in the Southeast. We intentionally designed one task on the survey so that it could be used with the variable-parts perspective on proportional relationships. The task asked teachers to show relationships among quantities described in the text by drawing a picture of the situation, writing an equation, and writing a few sentences to explain their equation. Analysis of the responses led to three results: (a) most future teachers represented relationships between parts and wholes appropriately, either by comparing parts to parts or by combining parts to make wholes, (b) future teachers were successful using division as often as multiplication when writing linear equations that combined two different units, and (c) when future teachers made errors using multiplication, reversal errors were the most common.

Keywords: Teacher education, multiplication and division, proportional relationships, linear equations, reversal errors

Background

Strengthening the teaching and learning of algebra remains a central challenge for mathematics education in the United States (e.g., National Mathematics Advisory Panel, 2008; RAND Mathematics Study Panel, 2003; Stevens, Ellis, Blanton, & Brizuela, 2017). Past research has identified several areas of frequent difficulty, including interpretations or meanings for the letter x (e.g., Filloy, Rajano, & Solares, 2010; Kieran, 1992, Küchemann, 1981), interpretations of the equal sign (e.g., Kieran, 1992; Stevens et al, 2017), and inappropriate extrapolation of rules for symbolic manipulation (e.g., Matz, 1982). Results from the present report contribute to research on a further area of difficulty often referred to as the reversal error (e.g., Clement, 1982; Soniera, González-Calero, & Arnau, 2018).

Clement (1982) reported results from administering a written test to 150 college freshman engineering students. One of the test items asked the students to: "Write an equation using the variables S and P to represent the following statement: 'There are six times as many students as professors at this university.'" Only 63% of the students answered with the correct equation $S = 6P$, and the most common incorrect answer was $6S = P$. Clement examined two possible sources for this reversal of the normative location for the letters S and P. For the first source, termed *word order matching*, students simply follow the word order when writing terms left to right. They read the phrase "six times as many students" and write $6S$; and, they continue by reading the phrase "as professors" and completing their equation, $6S = P$. For the second source, termed *static comparison*, students attend to the relative sizes of the two groups and use the equation $6S = P$ to express a correspondence or co-occurrence of the group of students and the group of professors. Clement also presented sample protocols in which students wrote both $6S = P$ and $6P = S$ back-to-back but then settled on the former. These results suggest that challenges expressing relationships among quantities with an equation can be deep seated.

More recently, Soniera et al. (2018) reported two experiments with future primary teachers in Spain in which they examined *word order matching* and *static comparison* as sources for reversal errors. In the first experiment, the researchers found no statistically significant difference in the incidence of reversal errors in two groups, where one group was asked to build equations using names for quantities that referred only to objects (i.e., professors and students) and a second group was asked to build equations using names that referred to numbers of objects (i.e., number of professors and number of students). Thus, more precise meanings for literal symbols, alone, did not result in statistically significant differences in the rate of reversal errors. In the second experiment, the researchers did report statistically significant differences depending on whether the sentence structure supported using *word order matching* to arrive at a correct equation or a reversal error. Similar to the original students-professors problems, all the Spanish-language descriptions used constructions indicating multiplicative comparisons.

When multiplicative comparison language is included in the stem of a task, as was the case with tasks used by Clement (1982) and by Soniera et al. (2018), it is hard to determine whether such language led students to make reversal errors that they might not make otherwise. In the present study, we examined the equations that 56 future middle and secondary teachers in United States wrote in response to a task that described a situation *without* any multiplicative comparison language. The task, described in greater detail below, asked future teachers to make a math drawing of the described situation, write an equation, and provide an explanation for the equation. Our research question was the following: What can we say about the range of ways that future teachers coordinate quantities when writing equations, correct or incorrect, in response to this task? As we report below, reversal errors still dominated the incorrect equations.

The Present Study

The present report is from an on-going study in which we are investigating how a coherent approach to topics related to multiplication can help future teachers see a common structure that connects a range of topics in the multiplicative conceptual field (Vergnaud, 1983, 1988). Such topics include multiplication and division with whole numbers and with fractions, proportional relationships, and linear equations. We express that structure through the annotated multiplication equation shown in Figure 1. The most important ideas are intertwining multiplication with measurement and viewing multiplication as arising when a given quantity is simultaneously measured in two different units, which we refer to as base units and groups.

N	$\bullet$	M	$=$	P
How many base units make one group?		How many equal groups make the product amount?		How many base units make the product amount?

Figure 1. An annotated meaning for multiplication.

In past reports, we have given theoretical presentations of multiplication as a coherent operation that organizes topics in the multiplicative conceptual field and have identified several consequences of systematically analyzing problem situations using a consistent meaning of multiplication (e.g., Beckmann & Izsák, 2015; Izsák & Beckmann, 2019). We have also reported empirical results from content courses taught in which future teachers leveraged our structural approach to multiplication to generate and explain multiple, sound methods for dividing by fractions (Izsák, Kulow, Stevenson, Ölmez, & Beckmann, 2019), solving proportions (Beckmann, Izsák, Ölmez, 2015; Izsák et al., 2019), and generating and explaining equations (Beckmann & Kulow, 2017). The present report extends our prior results by examining capacities that future teachers bring, prior to instruction in the measurement meaning of multiplication summarized in Figure 1, for reasoning about proportional relationships and equations that model problem situations.

In the rest of this section, we explain enough about our approach to multiplication and equations to motivate the design of the task at the center of this report. Our discussion also sets up key results that we present later. We begin by pointing out, using the meaning for multiplication summarized in Figure 1, that there are two ways to form a proportional relationship. First, one can fix N and let X and Y co-vary in the equation $N \cdot X = Y$. This perspective on proportional relationships, which we refer to as *multiple batches*, is well-represented in discussions of unit rates (e.g., Kaput & West, 1994) and composed unit reasoning (e.g., Lobato & Ellis, 2010). Second, one can fix M and let X and Y co-vary in the equation $X \cdot M = Y$. This perspective on proportional relationships we refer to as *variable parts*. Elsewhere (Beckmann & Izsák, 2015) we have argued that the variable-parts perspective has been largely overlooked but holds promise for understanding connections between proportional relationships and geometric similarity, including slope of a line. Because we see promise in developing the variable-parts perspective, we include it in the content courses we teach for future teachers.

In the present report, we examine capacities of future teachers to reason about the Sand and Gravel task (see Figure 2 and 3), a task we designed to afford opportunities to reason about proportional relationships and equations from the variable-parts perspective. In particular, we examine teachers' performance before instruction in multiplication or variable parts.

Consider this information about a fleet of trucks carrying sand and gravel:

- There are nine trucks, each carrying the same weight.
- Four of those trucks are filled with sand; Five are filled with gravel.
- All together, the four sand trucks are carrying a total of X tons.
- All together, the five gravel trucks are carrying a total of Y tons.

a. Make a math drawing to show the relationship between the quantities of sand and gravel. Indicate where X and Y are in your drawing.
b. Write a few sentences to explain how to develop an equation relating X and Y, reasoning about the quantities of sand and gravel. Interpret the equal sign in your equation.

Figure 2. Parts (a) and (b) of a variable-parts task for generating equations.

In this situation, each truck is a variable part. The first key feature of the variable-parts perspective is that each truck carries the same weight. The second key feature of the variable-parts perspective is that number of trucks remains fixed, but the weight of each truck varies depending on the total tons of sand and gravel.

We present two different solutions the Sand and Gravel task that use variable-parts reasoning. In the first solution, one can express the number of tons in one truck, $X/4$ tons for one truck of sand and $Y/5$ tons for one truck of gravel. The constraint that each truck carries the same weight justifies the equation $X/4 = Y/5$. In the second solution, one can compare the number of trucks carrying sand to the number of trucks carrying gravel. In particular, 5/4 of the number of trucks carrying sand is the same as the number of trucks carrying gravel. Therefore, 5/4 of the weight of sand is the same as the weight of gravel. This perspective leads to a second equation, $X \cdot 5/4 = Y$, following the meaning of multiplication shown in Figure 1.

We designed parts (a) and (b) of the task (Figure 2) to simulate initial portions of semi-structured cognitive interviews, which we have conducted with smaller numbers of future teachers using similar tasks. Part (a) mimics a common practice we use during interviews and class—draw a picture. A drawing also serves as a check on reading comprehension. Part (b) mimics a typical follow-up question in which we ask future teachers to explain their reasoning.

We designed parts (c) and (d) of the task (Figure 3) so see if future teachers could interpret the constant of proportionality, 5/4, from a variable-parts perspective and then use that interpretation to formulate an equation. Part (c) asks future teachers to interpret the constant of proportionality as the measure of one total quantity (e.g., tons of gravel) in term of another total quantity (e.g., tons of sand). Part (d) asks future teachers to use the measurement 5/4 that relates the total tons of sand and total tons of gravel to formulate an equation like $X \cdot 5/4 = Y$.

c. If 4 sand trucks make one load, how many loads make the total weight of 5 gravel trucks exactly?
d. Using your answer to part (c), write a few sentences to explain how to develop an equation relating *X* (tons of sand all together in 4 trucks) and *Y* (tons of gravel all together in 5 trucks) by reasoning about the weights of sand and gravel. Interpret the equal sign in your equation.

Figure 3. Parts (c) and (d) of a variable-parts task for generating equations.

Methods

We administered a paper-and-pencil survey to 56 future middle and secondary mathematics teachers enrolled in preparation programs at two large public universities in the Southeast. We recruited the future teachers using an approved IRB protocol and paid each participant \$50. The survey was treated as a homework assignment. We distributed copies of the survey in class and collected them 1 week later.

The full survey consisted of six items about proportional relationships and equations, including the Sand and Gravel task shown in Figure 2 and Figure 3. To analyze responses to parts (a) and (b) (Figure 2), for each of the 56 responses, we examined the future teachers' drawings, their equations for the situation, and their written explanations for their equations. We examined these responses to infer the future teachers' interpretations of the described situation and how they made sense of their work, including when it was non-normative. In some cases, we could see from drawings that a future teacher assigned *X* and/or *Y* to be the weight of just one truck, which is at odds with statements in the task. In other cases, future teachers wrote that they were using the equal-sign to indicate the co-occurrence of weights of sand of and gravel.

The first author used a bottom-up approach to coding the future teachers' responses. He used iterative cycles in which he first noted similarities across different responses, generated initial categories, and then refined those categories through additional cycles. The categories were based on expert judgement about which quantities future teachers used, how they related those quantities in equations, and how they explained their equations. The second author then took those categories as the basis for her own, independent coding of the data. The authors resolved discrepancies through discussion and reevaluation of student work.

To analyze each of the 56 participants' responses to parts (c) and (d) (see Figure 3), we examined whether the participant formulated a new equation or stated a new relationship in words in part (d), or explained an equation or relationship differently than in part (b).

Results

Equations and Interpretations Formulated in Parts (a) and (b)

Table 1 summarizes the categories into which we placed responses to parts (a) and (b) of the Sand and Gravel task, provides example equations for each category, and lists counts for each category. We make several points. First, 23 of the 56 teachers (41%) both wrote correct equations where the number and type of unit on the left hand and right hand sides of the equal sign were the same and justified those equations using relationships in the situation. Second, when future teachers wrote correct equations in two units (e.g., trucks and tons), about half the time they did so using division to equate the weight of one truck of sand with the weight of one truck of gravel (i.e., X/4 = Y/5). A about one quarter of the correct equations were based on using 4/5 as a multiplier operating on tons of gravel or 5/4 as a multiplier operating on tons of sand. These are the two solutions explained above. Third, in six cases (11%), future teachers wrote correct equations in just one unit. In equations of the form $X + Y = 9k$, future teachers explained that k was the weight of one truck and so expressed all terms in tons. In the equation 4/9 + 5/9 = 9/9, all the terms were expressed in parts, where one part corresponded to one truck.

Fourth, of the remaining 33 future teachers, six (11%) provided no equation and six (11%) gave explanations for their equations that seemed based on rote translation from text to equation without consideration for particular relationships between trucks and tons. For example, one teacher wrote $4/5 = X/Y$ and explained that he or she was "matching like terms on top and bottom." Another teacher wrote $4/X = 5/Y$ and explained "X and Y with 4 and 5 are proportional." Fifth, the most frequent error (13 cases, 23%) was the reversal error discussed above. Seven future teachers wrote $4X = 5Y$, when $4Y = 5X$ would have been correct, and six incorporated similar reversal errors when adding parts of sand and gravel to make a whole.

Finally, nearly all future teachers represented relationships between parts and parts or parts and wholes appropriately. This held even when they mixed units, as in the equation $X + 1 = Y$, in which a future teacher added X tons of sand and one truck of sand to arrive at Y tons of gravel. The future teachers never equated an expression for just the trucks of sand, or the trucks of gravel, with an expression for the trucks of sand and gravel combined.

These results demonstrate that nearly all the future teachers engaged in reasonable sense making about parts and wholes when coordinating equations with the problem situation, that some were more successful than others when combining the units of tons and trucks, and that combining the units of tons and trucks using multiplication was particularly challenging.

Additional Equations and Interpretations Formulated in Parts (c) and (d)

There were 29 responses to parts (c) and (d) (see Figure 3) in which future teachers produced either an equation or a description of the relationship between X and Y that was different from their response to part (b). Of these responses, 22 were correct and seven were incorrect.

Correct responses. We classified the 22 correct responses into three categories. In first category, six future teachers wrote $5/4\ X = Y$ or $Y = 5/4\ X$. All but one response seemed to draw on the interpretation of 5/4 from part (c) either to develop an equation or to interpret an equation that was derived through algebraic manipulation. Thus, the prompt in part (c) to consider the four trucks of sand as a unit led to interpreting 5/4 as a single multiplier, appropriately.

In the second category, 10 future teachers developed an equation other than $5/4\ X = Y$ or $Y = 5/4\ X$ and oftentimes used 5/4 in a way other than as a single multiplier. One future teacher stated: "If, we look at X as the whole since 4 trucks make 1 load, then Y would be 5/4 loads" and wrote $X/4 \bullet 5 : Y$. Another future teacher seemed to interpret 5/4 as an invariant ratio expressed both in trucks and in tons when writing 5/4 = *Y*/*X* and explaining: “If I’m using 4 trucks to load an equivalent of a 5 truck load and the proportion is 5/4 (gravel to sand), then it’ll equal the same proportion for the amount of sand and gravel.”

In the third category, six future teachers described the relationship between *X* and *Y* in ways that suggested that they did some additional productive thinking after responding to part (b). For example, one future teacher who had previously produced 4/5 *Y* = *X* and 5/4 *X* = *Y* noted the reciprocal relationship: “I am comparing 4 truck loads (of equal wt per truck) and 5 truck loads. They will remain reciprocals of each other.”

Responses with incorrect equations. Seven responses in part (d) included an equation or expressed a relationship that was normatively incorrect. Of these, five included an equation with a reversal error involving the fraction 5/4 or 4/5. As one example, a future teacher wrote the equation 5/4 *Y* = *X* and explained: “In part C, I found that 5 gravel trucks makes 5/4 loads. So since *Y* represents tons of gravel all together in 5 trucks, then I came up with 5/4 *Y*.” Perhaps this future teacher viewed 5/4 *Y* as expressing that 5/4 corresponds with or makes *Y*. Another future teacher, who gave the answer 4/5 in part (c), produced the equation *Y* = 4/5 *X* and explained: “A load of *X* is 4 trucks and *Y* has 5 trucks so a load of *Y* would be 4/5 of *X*.” Because this future teacher was not confused about the numbers of trucks corresponding with *X* and *Y*, perhaps he or she meant that *Y* corresponds with *X*, which consists of 4/5 as much.

Discussion and Conclusion

This study suggests that the field still does not have adequate understandings of difficulties that college students face generating linear equations and, therefore, does not have the knowledge base to support them in coordinating such equations and problem situations more successfully. We would like to understand underlying causes that result in less than half the future teachers in our sample generating and explaining equations for a situation like that presented in the Sand and Gravel task. Previous studies that have reported reversal errors (e.g., Clement, 1982; Soniera et al., 2018) have relied on tasks that included the words “times,” “times as much,” or phrases of the form “for every __ there are __,” which could lead participants towards errors based on word order matching or static comparison. In contrast, the Sand and Gravel task did not use any such language. Because we presented a bulleted list to highlight the different quantities separately, and asked future teachers to make math drawings before generating equations, our results about reversals (that include fractions not mentioned in the problem statement) suggest that word order matching or static comparison are incomplete explanations for such errors. While acknowledging that future teachers sometimes use non-normative but sensible interpretations of notations, we suspect that interactions among understandings of multiplication as a model of problem situations and meanings for the equal sign contributed to the reversal errors we observed.

We designed the Sand and Gravel task to foster variable-parts reasoning as an avenue into developing and explaining linear equations in a standard $y = \mathrm{m}x$ form by interpreting the constant of proportionality, or rate, as the answer to a measurement question that relates total quantities. That only a few of the future teachers did so, even after being prompted with a measurement question in parts (c) and (d), suggests that developing this aspect of the variable-parts perspective will require focused instruction. On an optimistic note, even without instruction, the measurement question in part (c) and the request to use its answer to develop an equation in part (d) did seem to lead to some potentially productive ideas about how to relate the variables *X* and *Y*, even if they did not always lead to correct equations.

Pre-service mathematics teachers need to have an advanced perspective of geometry concepts and be able to extend and generalize the geometry content they will teach. This study documents the continued refinement of a geometry lesson using computer programming and GeoGebra to iteratively teach generalization over the concept of interior and exterior angles in polygons and, ultimately, helps to refine a previously developed genetic decomposition for continued improvement of this and future lessons.

Keywords: Preservice Teachers, Polygons, APOS, Genetic Decomposition

In order for preservice teachers to be successful in their mathematics teaching career, they must master the subjects they will be teaching. Shulman (1987) asserts that "teaching necessarily begins with a teacher's understanding of what is to be learned and how it is to be taught" (p. 7). Teachers must be able to provide multiple representations and alternative explanations of the same concepts. Jones (2000) simply stated that effective geometry teachers must know "a good deal of geometry" (p. 109). However, as preservice teachers advance in their training, the amount of geometry being taught decreases, sometimes disappearing completely at the university level. Consequently, teachers are often expected to teach geometry at both the elementary and secondary levels when, in fact, they have done very little with geometry since they were in secondary school (Jones, 2000). Ward (2004) observed that preservice teachers did not recall important high school concepts before a lesson, but could apply formulas after a lesson on a concept while still holding on to contradictory concept images. Usiskin et al. (2003) hold preservice teachers need an "advanced perspective" on their geometry concepts in order to teach for understanding. They assert teachers need to know how to extend and generalize the content they teach. Dindyal's (2007) study of high school students' conception of the sum of the interior and exterior angles of a polygon found that students could recognize patterns, but encountered conceptual obstacles to generalization.

APOS theory is a framework for investigating how a mathematics learner acquires and uses knowledge about a specific mathematical concept, where a learner must have appropriate mental structures in order to acquire a specific mathematical concept (Dubinsky & McDonald, 2001). The degree to which the learner has constructed the required mental structures needed for the mathematical idea is described by four levels in APOS theory: Action, Process, Object, and Schema (Asiala et al., 1996). Actions are interiorized as Processes, and Processes are encapsulated into mental Objects. APOS practitioners do not believe the progression of a learner is linear through the constructs, rather learners may move back and forth as well as hold positions between levels. A genetic decomposition (GD) is critical in APOS theory to understand how students conceptualize a mathematical idea (Arnon et al., 2014). The GD is a hypothetical model of mental constructions required by the learner for a given mathematical concept, and it details the types of behaviors a student might exhibit at the Action, Process, Object, or Schema levels. This type of detail informs the pedagogy about a concept and provides researchers clarity in determining where students are on the APOS scale over a concept.

APOS theory also states that computer programming activities can act as a catalyst in developing the associated constructions of mathematical concepts (Dubinsky & Tall, 1991). In 2011, a team of researchers (Jenkins et al., 2012; Stenger et al., 2017) developed an instructional model (IM) that uses such computer programming activities to promote mathematical reasoning and explicitly teach generalization and abstraction. The computer programming exercises are designed to stimulate the development of mental constructions that support the transfer of learning in a mathematics context, specifically abstraction and generalization. The approach is modeled on APOS theory and constructivist pedagogy and uses computer programming as a laboratory for the learner to explore the behavior for a specific concept under investigation. This IM exploits iterative thinking to encourage learners to generalize and abstract.

The GD for this project comes from a pilot study (Jackson, Stenger, Jerkins, & Terwilliger, 2019) and was developed for the study of interior and exterior angles of regular polygons. It begins with the behaviors a learner may exhibit at the pre-Action level and then delineates the Action, Process, and Object level indicators. Employing the instructional model developed by Jenkins et al. (2012) as a guide, the researchers then developed this study's instruction using this foundation and utilizing two iterative approaches designed to parallel the construction of this geometry concept. This report details the investigation of the proposed genetic decomposition.

Methodology

We applied an iterative-based IM (Jenkins et al., 2012) to the concept of interior and exterior angles in polygons to a geometry content class for elementary education majors (N=12, all female). The class was randomly split into two groups of six students each. The lesson was identical for each group up until the computer programming stage of the IM. Before enrolling in the course, all of the students had taken a prerequisite mathematics class, either Pre-Calculus Algebra or Finite Math. All participants completed a pre-test before any instruction and a post-test once the instruction was complete. The course final exam also assessed students on these same topics. At various points during their instruction, the students completed response sheets about specific topics or events just covered. These motivating questions were created for participants to answer during their exploration. Special attention was paid to the form of statements in the classroom activities so that general expressions were a natural outcome of the exercise. In the lesson development, conjectures and proofs were created using the general expressions. Learners were guided into making conjectures during the lesson and, using the general expression they discovered, made convincing arguments about their conjectures.

To begin the lesson, a pre-test over the concept was taken by all learners. Questions asked students to calculate the measures of the exterior and interior angles of a regular octagon and to write a convincing argument for their answers. A final question which included an aerial view of the Pentagon (that we have labeled the "Pentagon problem") reads as follows:

> At the Pentagon, a courtyard is enclosed by the interior of the inmost wall. A sidewalk runs along the exterior of this courtyard. When it is cleaned (by power-washing), the machine can cover the entire width of the sidewalk in one pass. However, it must make turns at each angle, and the design of the machine makes turning more expensive. Outside of the normal cost of cleaning the entire sidewalk, an extra "turning expense" is

always added to the final bill. If $10 is charged for each **degree** of turn needed (not each turn, but each **degree** of turn), how much extra can the Department of Defense expect to be added to their bill as a "turning expense"? Would the turning cost be less if the building were shaped like a rectangle instead of a pentagon? Explain your answer.

Next, relevant background and definitions were presented by the facilitator. A brief lecture on the definition and characteristics of a polygon began the instructional process. Examples of polygons were shown and on each, the interior and exterior angles were highlighted and defined. An emphasis was then placed on exterior angles, and each was highlighted on an image of a hexagon projected on a screen. At this time, the groups were divided based on the type of computer programming used for instruction. During the computer programming stage, one group used Python programming and the other used GeoGebra, which is a web-based application for teaching and learning mathematics and science.

The Python group began with a brief introduction to the language and then learners wrote programs to produce tables depicting the measure of exterior and interior angles in polygons, iterating the number of sides. Participants were asked to add instructions to their programs to show what the measure of a regular polygon's exterior angles would be as the number of sides increased. Learners were encouraged to experiment with their computer programs and make observations about any relationships. Once the initial table was constructed, the participants were ushered through a series of program modifications and written responses, including writing a convincing argument (i.e., proof) that as the number of sides of a polygon increases, the measure of each of its exterior angles decreases. Next, the students were instructed to tinker with their programs in order to produce a third column, one that depicted the measure of interior angles in a regular n-gon. Learners wrote programs to show those measures and were then encouraged to experiment with their programs and make observations about any relationships. The IM was designed so that repetition with various program modifications would stimulate the desire to generalize the observed behavior and make conjectures about the mathematical construct.

In the GeoGebra group, the instruction continued with each participant being given a handout of the same image that had been projected and told to cut out each exterior angle and put them together, allowing them to "discover" that they formed a circle. GeoGebra was then used to show this same concept on various polygons. Next, a more traditional type of lecture was employed about curves and polygons in the plane, convex and concave figures, polygonal curves, triangles, quadrilaterals, and regular polygons. The lecturer then returned to GeoGebra to revisit the specific topic of interior and exterior angles of regular polygons, showing iterations of regular polygons with more and more sides. The students eventually acknowledged that the polygon came to look like a circle. A further discussion was then conducted on the measure of interior and exterior angles of these figures as the number of sides approached infinity. A worksheet was distributed after the instruction which emphasized the classification of triangles, polygon identification, measures of individual interior and exterior angles in a polygon, and the sum of the measures of all interior and exterior angles in a regular polygon.

In both groups, motivating questions were presented periodically throughout the instruction by the facilitator, and participants were guided until the necessary general expressions were uncovered. Finally, a conjecture was made by the facilitator and a convincing argument was presented using a discovered general expression. Learners were then asked to make their own conjectures and convincing arguments. Participants wrote responses to questions and reflections on their observations on response sheets, including generalizations of behavior observed in their activities. Observations on the relationship between the number of sides of a polygon and the measure of its exterior angles were solicited, and participants were taught how to denote the general expressions in mathematical language (e.g., $(180 - 360/n)$). At the conclusion of the lesson, participants took a post-test which contained the exact same questions as the pre-test. On the end-of-semester final exam, the instructor incorporated seven questions particular to the instruction from this study that covered various levels in APOS, as well as the Pentagon problem (from the pre-test and post-test). Also added was a new problem, the "Linear Pair" problem shown in Figure 1, which was designed to aid in assessing the Process level of conception.

24. Shown below is a "close-in" view of the interior and exterior angles of two regular polygons, where they meet at one pair of their adjacent sides. Which polygon, A or B, do you think has the most sides? Explain your answer.

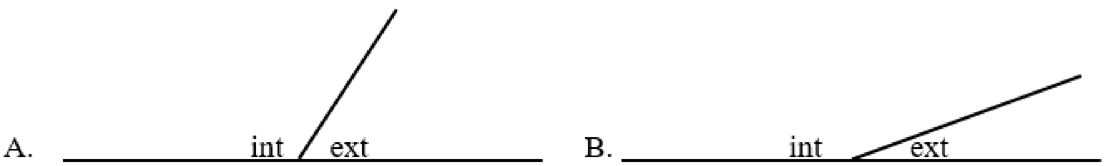

Figure 1: Linear Pair problem

All of the data collected from pre-tests, post-tests, and the final exam was reviewed and scored using APOS theory (Asiala et al., 1996) as a guide. In our study, a ranked set of scores was devised to denote pre-Action (0), Action (1), Process (2), and Object (3) levels based on the genetic decomposition and recorded for each subject's submissions. Three scorers ranked each participant. In the event that authors disagreed, a discussion and further analysis of the data was used to reach consensus. The GD was used as a guide to evaluate responses.

Genetic Decomposition

A genetic decomposition details the types of behaviors a student might exhibit at the Pre-Action, Action, Process, Object, and Schema levels. This type of detail informs the pedagogy of a particular concept. Additionally, it can provide researchers clarity in determining where students are on the APOS scale over a concept. An initial genetic decomposition for interior and exterior angles of polygons was developed in a prior study (Jackson et al., 2019) and does not include Schema. It reads as follows:

Genetic Decomposition for Interior and Exterior Angles of a Polygon

Pre-Action. Students may not know what a polygon is. They may not know what an interior or exterior angle is.

Action. At the action level, the learner has been given the formula for finding the measure of an exterior angle in a regular polygon. Then, the learner can take the number of sides in a polygon, plug it into the formula, and then calculate what that measure is. Additionally, they read or are told that the measure of an interior angle of a regular polygon is (180º - the measure of the exterior angle) and are then able to plug in the previously determined value into this formula to find that measure of this interior angle.

Students, in this case, will not be picturing a triangle in their mind but are only strictly adhering to the given formula. They may not even see the relationship between an interior and exterior angle. Also, they do not notice that as the number of sides of the regular polygon increases, the measure of the exterior angles decreases, and the measure of the interior angles increases. However, if the learner does start to recognize that as the sides of a regular polygon increase in number, the measure of its exterior angles decreases or the measure of its interior angles increases, they are starting to imagine the process in their mind, making a step toward generalizing the relationship between the number of sides in a polygon and the measure of its exterior/interior angles.

Process. At the process level, students begin to imagine in their minds what happens as the number of sides in a regular polygon increases. They start to play that pattern as sort of a video sequence in their mind. They might first imagine an equilateral triangle in their minds and visualize its exterior angle. Next, the students could think of a square and visualize its exterior angle. This process would continue with a regular pentagon, a regular hexagon, a regular heptagon, etc. As they do this, they picture in their minds that the measure of the exterior angle decreases as the number of sides increase. Alternatively, a student might think of the sequence numerically as 360/3, 360/4, 360/5, 360/6, etc., and notice that this numerical calculation of the exterior angle is decreasing each time. In both cases, the student has learned to generalize the behavior of how this relationship of the number of sides in a regular polygon and the measure of its exterior/interior angles is related.

Object. At the object level, they might see the interior/exterior angle relationship as a linear pair, recognizing them as an entity so that one angle does not need a specific measure to know the measure of the other, but that if one angle has a measure of α, then they know that the other has a measure of $(180 - \alpha)$. They might see the process of adding more and more sides as a totality, imagining the sides moving toward an infinite number (and even completing the process), where the polygon is now a circle.

Results

Generally speaking, most of the students made some improvement during the lesson. Eleven of the twelve participants ranked at pre-Action (0) level on the pre-test. Only four participants were still at this level on the post-test. Five students were at Action (1) level, two were at Process (2) level, and one student was at Object (3) level on the post-test.

Minimal Recall of Important Geometry Concepts

The pre-test shows many pre-Action samples and a lack of deep understanding of this concept by most participants. This was seen by many students guessing at measurements of the interior and exterior angles of an octagon. Most students either thought the interior and exterior angles were the same or they reversed the definitions and measures of each.

To illustrate, student LP01 had the same measures and explanations for the interior and exterior angles. “There are 8 sides, and if each exterior angle equals 45, then it will add up to 360.” Regarding the interior angle, she said the exact same thing, only changing the word “exterior” to “interior.” Student LP12 gave an incomplete and incorrect description of both exterior and interior angles. She said that the measure of any exterior angle would be between 90° and 180°, explaining that “all exterior angles of a regular polygon are obtuse angles.” Conversely, she thought that all interior angles had to have a measure between 0° and 90°, but then noted that the interior angle in a regular octagon “will be supplementary to the exterior angle.”

Memorizing Formulas and Calculating Angle Measurements

On the final exam, a question asking for the measure of the interior angle in a regular octagon was answered correctly by *all* participants. On another question asking students to sketch and label the interior and exterior angles of a hexagon, all but one student answered the question correctly. This question reads as follows: "Sketch a regular hexagon, label one set of interior and exterior angles, and determine the measure of an exterior and interior angle. Show your work and explain your answers." One student's (LP06) response is shown in Figure 2.

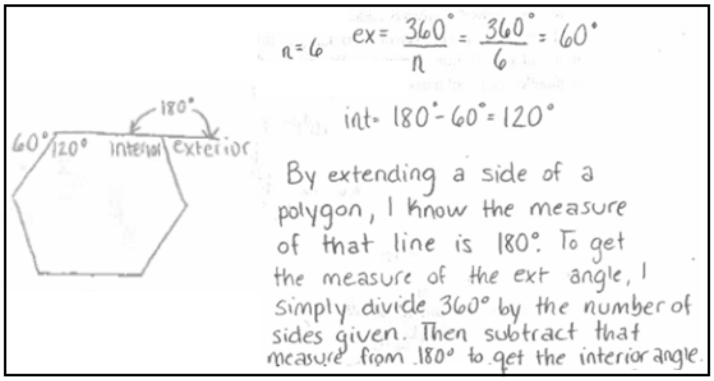

Figure 2: Student response to final exam question

Understanding Linear Pair Relationship

Another question on the final exam asked students to examine the linear pair relationship. Student LP12 stated: "The measure of any interior angle of a regular octagon will be 135º because the exterior and interior angles are a linear pair. Since these angles are a linear pair, you can take 45º and subtract it from 180º; the difference will be the interior angles measurement."

All of the students answered the Linear Pair problem (shown earlier in Figure 1) correctly.

The Pentagon Problem

Only one student, LP04, answered the Pentagon problem correctly on the final exam, even though this was the third time they all had seen the problem. This student was able to apply the concepts from the instruction, particularly the iteration of sides and noting the measure of exterior angles. Her explanation suggests she was able to see the process as a totality, recognizing that the sum was always 360º. She calculated the measure of the interior angles in a pentagon (72º) and a rectangle (90º) and multiplied each by the number of sides to get a total of 360º. She then reaffirmed that "the turning cost would not be less if the building was a rectangle because the sum of all exterior angles is 360º, so the price will be the same *no matter what polygon it is* [emphasis added]."

Revising the Genetic Decomposition

Based on analysis of student responses with respect to the GD, the researchers made the following additions:

Pre-Action. The learners may not know how to calculate the measure of interior or exterior angles. They might simply guess at angle measure based on observation and/or estimation. Students may think that the measure of an exterior angle is always obtuse and that an interior angle is always acute, or vice-versa.

Action. No additions.

Process. No additions.

Object. Students recognize the difference between more sides and longer sides. They should see that as the number of sides increases, the measure of the interior angles increases and that, at the same time, the measure of the exterior angles decreases; but, while the *sum* of the measures of interior angles grows, the *sum* of the measures of exterior angles remains 360º. The learners are aware that even if the side lengths or overall area of the polygon increases, it does not affect the sum of the measures of interior or exterior angles. Students are able to view the process of summing the exterior angles as a totality, recognizing that the sum is always 360º.

Discussion and Conclusion

In this study, student work on pre-tests, post-tests, and final exams was analyzed for three goals: (1) to test and refine a proposed genetic decomposition, (2) to determine pre-service elementary teacher (PSET) readiness to apply, extend, and generalize the content they will teach, and (3) to improve the instructional model designed to teach generalization over this concept. PSETs did not come into the lesson with a deep understanding of the concept, and their improvement during the lesson can be largely attributed to memorizing formulas. Still, progress was made toward all three goals.

After the IM, all PSETs could calculate angle measures using memorized formulas and recite general statements about relationships (e.g., sum is 360). This is good news, but the goal of the IM is, in APOS terms, to push the learner beyond the action level to a higher level of conception. It can be argued that all of the PSETs did acquire a more advanced standpoint on the geometry concept than was evidenced in the pre-test. This was shown by student work on the final exam.

All students answered the Linear Pair problem correctly, a question encountered for the first time on the final exam. Their responses indicated an advanced perspective for the problem and required, according to the GD, a process conception. However, having acquired this advanced perspective on the concept, they were not able to apply their understanding to the Pentagon problem (featured on all three assessments). Situating the content in an applied setting added a layer of complexity that was seemingly insurmountable. In the context of an APOS framework, PSETs could imagine the process of exterior angle measures decreasing as the number of sides increased, as shown on the final exam's Linear Pair problem. Yet, only one participant showed evidence she could encapsulate the process into an object (e.g., finish the motion of sides increasing and exterior angle measure decreasing) and view it as a totality. That is, she saw the sum of the measure of the exterior angles is 360 degrees regardless of the number of sides. When asked, all students could state that the sum of the exterior angles was 360 degrees (Action level), but only a couple demonstrated a Process conception of these angles always summing to 360 even when the number of sides increased and the exterior angle measure decreased. Only one student had a conception robust enough to transfer this knowledge to the new setting, and recognize that the extension or generalization of the concept allowed it to "fit" perfectly or apply. This student was previously assessed at an Object conception on the post-test according to the GD, and she was the only student who solved the Pentagon problem correctly. This student's work suggests that solving the application problem may have been the action that pushed her to encapsulate the process of sides increasing and exterior angle measure decreasing into an Object conception of the sum as 360 degrees.

For future work, a description of Schema should be developed that describes the coordination of the processes described above and incorporates the role of the applied problem. When the GD reflects this new result, the IM should be modified to account for it.

A Comprehensive Hypothetical Learning Trajectory for the Chain Rule, Implicit Differentiation, and Related Rates: Part II, a Small-Scale Teaching Experiment

Haley Jeppson
Brigham Young University

Steven R. Jones
Brigham Young University

Students learn more deeply when conceptual understanding is at the forefront and connections are made between topics. With this in mind, we have created a hypothetical learning trajectory (HLT) for the chain rule, related rates, and implicit differentiation to teach them in a conceptual, connected way. In a previous paper we outlined the creation of the HLT based on nested multivariation (NM). In this second paper we describe a small-scale teaching experiment done to test the HLT. Our results suggest NM was an appropriate construct to base the HLT on, and we report on these students' developing understandings. Based on the results, we made final adjustments to the HLT in preparation for a full-scale classroom teaching experiment.

Keywords: chain rule, implicit differentiation, related rates, multivariation, covariation

Among the goals of mathematics education are (a) conceptual understanding and (b) connections across topics (Hiebert & Carpenter, 1992; Hiebert et al., 1997; Schoenfeld, 1988). As a key part of undergraduate education for STEM students, calculus education should especially aspire to meeting these goals. Yet there are topics within calculus that are still often treated as separate, and often procedurally, even though they could be taught in a conceptual, connected way. In particular, the topics of the chain rule, implicit differentiation, and related rates contain powerful, interrelated ideas (see Austin, Barry, & Berman, 2000). Although researchers have suggested conceptual connections between them (Clark et al., 1997; Cottrill, 1999; Infante, 2007; Martin, 2000), these topics tend to be examined in isolation of each other, inhibiting our ability to create instruction that tightly connects them. We propose to unify these topics into a coherent whole through the construct of nested multivariation (NM) (Jones, 2018), defined in the next section. In a first paper (Jeppson & Jones, 2020), we outlined the development of a hypothetical learning trajectory (HLT) (Simon, 1995) for teaching this portion of the calculus curriculum in a conceptual, connected way. In this second paper, we describe a small-scale teaching experiment done to test this HLT. In particular, this study is meant to address three questions: (1) How was NM used by students as they progressed through the HLT? (2) What kind of understandings did students develop for these three topics? (3) Where did students struggle in a way that suggested a need to revise the HLT?

Nested Multivariation

Previous research states that covariation is important for these topics (Infante, 2007). Yet, we realized that because multiple quantities are in play it may be more appropriate to conceptualize these topics through *multivariation* (Jones, 2018), which builds on and extends covariation. In brief, multivariation refers to situations in which *more* than two quantities may change in relation to each other. While multivariation refers to the situation, the reasoning used in such situations is called *multivariational reasoning*. Next, Jones (2018) used the term *nested multivariation* specifically for situations with a function composition structure, $f(g(x))$. That is, if x changes, it induces a change in g, which in turns induces a change in f. If one interprets the derivative fundamentally as a rate of change, as we do, then NM is inherent to each of the chain rule, implicit differentiation, and related rates. The chain rule says that for a function composition,

$f(g(x))$, then $df/dx = df/dg \cdot dg/dx$. In other words, the covariational relationship between x and f is uniquely determined by the NM relationship going from changes in x to changes in g to changes in f. For instance, suppose g changes twice as fast as x (i.e., $dg/dx = 2$) and f changes three times as fast as g (i.e. $df/dg = 3$). Then for a change in x, the corresponding change in f is $3{\cdot}2 = 6$ times as large (i.e. $df/dx = 6$). The multiplicative nature of the chain rule comes from scaling the change in f relative to g (df/dg) by how much g changed with respect to x (dg/dx).

Similarly, we see NM inherent in implicit differentiation and related rates. We define an *implicit function* as one in which one variable in an equation is conceptualized as a function of another variable in that same equation, such as thinking of y in $x^2 + y^2 = 1$ as a function of x (by restricting the range). This leads to the function composition $[y(x)]^2$. NM is present in $d[y^2]/dx$ through the nested changes $x \rightarrow y \rightarrow y^2$. For related rates problems, we define a *function of an implicit variable* as a variable in an equation conceptualized as a function of another variable *not* present in the equation. For example, thinking of x and y in $x^2 + y^2 = 1$ as functions of t makes the equation $[x(t)]^2 + [y(t)]^2 = 1$. A related rates problem is finding the rate of change of one variable with respect to the implicit variable, when the rate of change of the other with respect to the implicit variable is known. This again similarly leads to NM for the derivatives $d[x^2]/dt$ and $d[y^2]/dt$ through the nested changes $t \rightarrow x \rightarrow x^2$ and $t \rightarrow y \rightarrow y^2$.

Research on the Chain Rule, Implicit Differentiation, and Related Rates

Before showing our HLT, we briefly acquaint the reader with the research on these topics that helped lead to our HLT. Some background studies on the derivative suggest the importance of quantitative meanings of the derivative as a multiplicative comparison between changes (e.g., Thompson, 1994). We made sure that our HLT opened by developing this meaning for derivatives. In addition, the scant research on the chain rule suggests the importance of basing the chain rule in the students' understanding of function composition (Clark, et al, 1997; Cottril, et al, 1997). With regard to related rates, Infante's (2007) dissertation contained several items that helped create our HLT. First, Infante made sure to build on chain rule understanding while exploring related rates. Second, Infante used a "delta equation" of the form $\Delta x/\Delta t = \Delta x/\Delta y \cdot \Delta y/\Delta t$ to connect related rates problems to that chain rule understanding. We did so, as well, but elected to use a differential "*d*" equation, $dx/dt = dx/dy \cdot dy/dt$, instead. Third, Infante highlighted the importance of making "time" an explicit quantity in related rates. Fourth, Infante noted that students rarely referred back to the diagram or model, so we regularly asked them the meaning of each variable to help make connections back to the diagram or model. Greater details on how this research literature scaffolded our HLT is given in Jeppson & Jones (2020).

Our (Much Abbreviated) Hypothetical Learning Trajectory

Simon (1995) defined HLTs as consisting of learning goals, learning activities, and a hypothesized learning process. In our previous paper (Jeppson & Jones, 2020), we outlined the creation of an HLT. In brief, our HLT contained five stages, meant to be traversed over four 50-minute interview sessions. Each stage had one overarching learning goal, accomplished by meeting several subgoals inside that stage, as shown in Table 1. Table 2 then shows abbreviated versions of the learning activities and key questions meant to accomplish the goals.

Table 1. The Hypothetical Learning Trajectory's Learning Goals

Stage	Description of Goal
Stage 1	**Develop the multiplicative nature of the chain rule.**
1a	Interpret *df/dg* as how many times as large the change in *f* is than the change in *g*.
1b	Interpret *dg/dx* as how many times as large the change in *g* is than the change in *x*.

1c	Interpret *df/dx* as how many times as large the change in *f* is than the change in *x*.
1d	Conceptualize how changes in *x* affect changes in the other two variables simultaneously.
1e	After finding specific values of *dg/dx* and *df/dg*, construct $df/dx = df/dg \cdot dg/dx$ at a point.
Stage 2	**Generalize the chain rule and gain procedural fluency.**
2a	Continue to construct the multiplicative nature of the chain rule.
2b	Generalize the chain rule to any function composition *f(g(x))*.
2c	Gain procedural fluency with the application of the chain rule.
Stage 3	**Develop the idea of variables being functions of the implicit variable time and recognize subsequent existence of compositions of functions.**
3a	If variables change with time, conceptualize them as functions of time and represent them as such
3b	Create compositions of functions structure for functions of implicit variables
3c	Recognize the need for, and correctly use, the chain rule for functions of implicit variables
Stage 4	**Develop the idea of implicit functions and recognize existence of compositions of functions.**
4a	Given an equation with variables *x* and *y*, conceptualize *y* as an implicit function of *x*, or *x* as an implicit function of *y*. Represent these symbolically as *y(x)* or *x(y)*.
4b	Recognize the need for the chain rule in taking the derivative of an implicit function
Stage 5	**Extend ideas to more complicated implicit differentiation and related rates contexts.**
5a	Continue to gain competence in recognizing compositions of functions in these types of problems
5b	Recognize need to use the chain rule for functions of implicit variables or implicit functions
5c	Gain procedural fluency with more complicated related rates and implicit differentiation problems

Table 2. Abbreviated Activities in the HLT and Relation to Subgoals

Abbreviated Activity Contexts	Sample key questions (related to HLT subgoals)
Stage 1: "Let's say you make $9/hr at your job and you're obsessed with chocolate… You can buy 0.15 lbs of chocolate per dollar." [A similar context/questions are used relating temperature, expected attendance at a carnival, and revenue. A third is then used relating time elapsed, distance run, and calories burned.]	1a-b: What is the value and meaning of *dD/dh* (and *dc/dD*) in our context? What are the units of *dD/dh* (and *dc/dD*)? 1c-d: If we could find *dc/dh*, what would that mean in our context? 1e: What is the value of *dc/dh*? How do you know?
Stage 2: [Build on previous *running context*] "Let's say you run at a constant rate of 0.1 miles/minute… Consider the functions $D(t) = 0.1t$ and $c(D) = 20D^2 + 40D$." [This is then repeated for the same context but new functions $D(t) = 2^t$ and $c(D) = D^3$.]	2a: What are *dD/dt* and *dc/dD* at 20 minutes? What is an equation for $c(D(t))$? What is *dc/dt* at 20 minutes? 2b: How can you use what you have found so far to write an equation for *dc/dt* at any time *t*? What patterns do you notice? Given any function for $c(D(t))$, what is *dc/dt*?
Stage 2: Given $g(x) = \sin(f(x))$, calculate *dg/dx*. [Repeated for $h(x) = \sin(x^2)$ and $g(x) = (\sin(x))^2$.]	2c: How can you relate what you have found so far to write an equation that gives *dg/dx* for any *x*?
Stage 3: "The body of a snowman is in the shape of a sphere whose radius is melting at a rate of 0.25 ft/hr. Assuming the body stays spherical, how fast is the volume changing when the radius is equal to 2 ft? Remember that for a sphere, $V = (4/3)\pi r^3$."	3a-b: What are all of the things that are changing with time? How can we write that symbolically? 3c: What are we trying to find? How can you represent it as a derivative? How can you represent 0.25 ft/hr as a derivative? How can we find *dV/dt*?
Stage 4: "A blue square with side length *x* has a corner cut out, also in the shape of a square of side length *y*. The leftover blue area must always equal 1, $x^2 - y^2 = 1$. As *x* changes, by how much does *y* have to change?" [A second problem is then given, which shows the equation $x^2 + [f(x)]^2 = 9$ and asks what *df/dx* is.]	4a: Can you write what we are trying to find as a derivative? How does $[y(x)]^2$ relate to what we have been discussing in our previous sessions? How much does the blue area change as *x* changes (i.e. *d[blue]/dx*)? 4b: What is the difference between dx^2/dx and dy^2/dx? How do our previous discussions relate to finding dy^2/dx?
Stage 5: (1) Related rates problem involving a shuttle launching upward at a rate of 0.2 miles/second and finding the rate at which the angle of observation is increasing. (2) Related rates problem involving an airplane flying horizontally 1 mile in altitude and finding the rate at which the distance to a station on the ground is change. (3) Implicit differentiation problem to find *dy/dx* for equation $\sqrt{x+y} = x^4 + y^4$.	5a-c: Allow students more independence in conceptualizing the problem, the functions, and the derivatives, and in solving the problem. Instructor reminds students to consider ideas already discussed in previous sessions.

Methods

To test our HLT, Author1 conducted small-scale teaching experiments with four students taking first-semester calculus for the first time. The teaching experiment was done with each student individually, over four 50-minute interview sessions, to focus on each student's personal developing understanding. In their class, the students had been introduced to the derivative, but had not yet seen any of the material covered in our HLT. We analyzed the interview data in three major phases. In the first phase, we marked any time nested multivariational reasoning (NMR) was used by the students throughout the sessions. To help identify instances of NMR, we took Carlson et al.'s (2002) and Thompson and Carlson's (2017) frameworks for covariational reasoning and imagined what might be analogous mental actions for NMR (for more details, see Jeppson, 2019). We then looked for themes in terms of how students used NMR as they learned these three topics. In the second phase, we broke each student's data along the five stages of the HLT and identified all of the units of data related to each of the learning subgoals in that stage. We also looked for pieces of data that suggested a student either had an incorrect understanding related to the subgoals or was inhibited in reaching them. For each subgoal, we looked at a given student's data related to that subgoal and made a determination as to whether their understanding related to that subgoal was "complete", "incomplete", or "missing." Complete understanding meant there were multiple units of data suggesting understanding of the subgoal. Incomplete understanding meant there was some evidence of reaching the subgoal but where there was not sufficient evidence to be certain of their understanding, or if there was some evidence of a misunderstanding related to that subgoal. Missing understanding means there was no evidence of understanding the subgoal. Lastly, in the third phase, we identified places in each stage of the HLT where the four students tended to struggle, suggesting a need to revise the HLT.

Results

Use of NMR in the HLT

NMR was most obviously observed in stage 1 as students used it to make sense of the way the variables in function compositions were related to and depended on one another. They also frequently used it as they first thought about the different rates within the function composition, how the quantities changed together, and how two rates could multiply to make a third rate. For example, in the chocolate context in stage 1 (see Table 2), Student A exemplified typical thinking to find the derivative, dc/dh, of the function composition $c(D(h))$. She said she could multiply the two derivatives because, "You know that you get 0.15 lbs per every…dollar. But, you can't go from pounds to hours because there is a medium ground you have to hit first before you can get to that… This [0.15 lbs/dollar] would just symbolize 1/9 of an hour, and then you would multiply it by 9 so it would give you, for the full hour, how much." Such reasoning allowed the students to build intuition for the multiplicative nature of the chain rule, in which two rates multiply to give a third rate. Reasoning like this in the other stage 1 contexts as well led all four students to observe patterns that helped develop and generalize the chain rule structure.

One important result was that, while it took instructional investment to develop this initial understanding of multiplying rates, the students were able to frequently use it later without needing to recreate it. Most instances of NMR after stage 1 were recognizing the existence of a nested relationship and the need for the chain rule in differentiation. However, it was also true that using NMR proved important for the students in reasoning about how the quantities changed together within related rates contexts and implicit function equations, such as interpreting the nested relationship structure between quantities and how that related to function composition.

Students' Developing Understandings as They Progressed Through the HLT

Stage 1. All of the students exhibited evidence for *complete* understanding (as defined in the methods) of the first three subgoals in stage 1 by interpreting different derivatives within function compositions. For example, Student D explained *dc/dD* = 0.15 by first identifying the units "lbs/dollar" and stating, "For every dollar that I have… I would be able to get 0.15 [lbs]." Similar interpretations were made for other derivatives in stage 1. The students also all used NMR to discuss the relationships between the three variables in function compositions, exhibiting *complete* understanding for subgoal 1d. For example, in the chocolate context Student A said, "The chocolate is dependent on the amount of dollars which is dependent on the hours." Lastly, as seen in the example in the previous subsection, all of the students used NMR develop the multiplicative nature of the chain rule at a point, demonstrating *complete* understanding of subgoal 1e. In summary, the students demonstrated *complete* understanding for all subgoals in stage 1, suggesting that there was no need to revise the HLT for stage 1.

Stage 2. In the running context with functions (Table 2), the students found derivative values at specific values for *D* and *c*, and again used the multiplicative nature of the chain rule to then find *dc/dt* for those values. This showed *complete* understanding for subgoal 2a. To progress toward subgoal 2b, the students were then asked to find equations for $c(D(t))$ and *dc/dt*, which was the first time they were asked to make connections between the chain rule and symbolic expressions. In doing so, the students were asked how to differentiate symbolically given a composition of functions. Until this point, they had identified that $dD/dt \cdot dc/dD = dc/dt,$ but with this prompt, they were able to reverse it to $dc/dt = dD/dt \cdot dc/dD.$ For example, Student B said, "If we take the derivative of the inside times the derivative of the entire thing, we can find the derivative of the composition of function, *dc/dt*."

However, Student B encountered a difficulty related to subgoal 2b. After finding a correct symbolic form for the chain rule, he came up with an incorrect conclusion. Using a kinematics example, he stated that if we knew acceleration and position, but not velocity, then, "plugging these, a function inside a function, I can make the relation… So, position has velocity as a derivative, and the derivate of velocity is going to be acceleration… the function itself can be combined… and I can find derivatives." Here Student B was suggesting that any time three variables were related to one another, in apparently *any* way, they could automatically be placed into a composition of functions (e.g., perhaps $a(v(s))$) and the chain rule could be used to find a missing rate). Because of this incorrect conclusion, Student B was the only one to have *incomplete* understanding for subgoal 2b.

When finding the derivative of $h(x) = \sin(x^2)$, three students connected their understanding of rates with physical quantities to abstract symbols. However, Student C struggled in recognizing the composition of functions. He compared it to the running problem and said, "I feel like I had 3 things [in the running problem]. We had *d*, *t*, and *c*… But here, I am not sure if we even have three things. I think sine comes in somewhere and cosine but I am not exactly sure how." While Student C had some understanding, we labelled it *incomplete*. The struggles of Students B and C generalizing the chain rule to symbolic expressions seemed to come from underdeveloped understandings of function composition (cf. Clark, et al, 1997). Thus, even anticipating this difficulty, we still underestimated how big the difficulty might be.

Stage 3. In the snowman problem, the students all gained the ability to recognize that a quantity changing can be considered a function of time. For example, all noted that volume and radius changed with time, and when Author1 suggested that they can be thought of as functions of time, the students wrote them symbolically as $V(t)$ and $r(t)$ and used these representations in the rest of the problem. Given the overall thinking students used, we considered this to demonstrate *complete* understanding of subgoal 3a. The students also understood that these functions corresponded to the quantities in $V = (4/3)\pi r^3$, allowing them to reconceptualize it as $V(t) = (4/3)\pi[r(t)]^3$. By recognizing the function composition structure in $[r(t)]^3$, the students reached subgoal 3b. In moving toward subgoal 3c, Student C was initially unsure of how to get from the formula relating V and r to the rate of change of volume. To get there, he first identifed the given rate, $dr/dt = 0.25$ ft/hr, and the rate that he was trying to find, dV/dt. To find dV/dt, he eventually recognized that he could multiply dr/dt and dV/dt, to create the "d equation" $dV/dt = dr/dt \cdot dV/dr$. In this way, he made a strong connection to the chain rule he had developed in stages 1 and 2. Student D's work was similar to C. Students A and Student B also recognized V and r as functions of the implicit variable time, but without using a d equation. After creating an equation that related volume, radius, and time, both of them recognized immediately the existence of a composition of functions, $[r(t)]^3$, and the need to use the chain rule in taking the derivative. These connections suggest *complete* understanding for 3c.

Student D did struggle in a specific way during stage 3, due to misunderstandings between a derivative value and an average rate of change. Because of this, he did not know how to complete the process of solving for dV/dt. Thus, while he did recognize the need for the chain rule, he was unable to work it out, and we determined he had *incomplete* understanding for 3c. In our analysis, this appeared more to be an issue with how he first learned derivatives than with our HLT. However, it does reinforce the need for derivatives to be taught previously in a conceptual way that can be built on and elaborated on within these three topics.

Stage 4. For the implicit differentiation problem in this stage, all of the students exhibited evidence of conceptualizing y as an implicit function of x. They represented it symbolically as $y(x)$ and substituted that into the equation: $x^2 - [y(x)]^2 = 1$. Due to the relations of these acts to earlier thinking, we considered this as evidence for *complete* understanding for subgoal 4a. Then, as an example, Student B pointed to $[y(x)]^2$ and stated that it was "a function within a function." This helped him see the function composition structure and the nested changes $x \to y \to y^2$. However, when Student B differentiated the equation, he wrote the incorrect result $2x - 2[y(x)] = 0$. Author1 prompted him to look at his previous work in other problems, after which he recognized the need to multiply *both* the rates dy^2/dy and dy/dx together to get $d[y^2]/dx$. This seemed to be an important step in making sure that his previous understanding of the chain rule was connected to his understanding of implicit differentiation. In the end, all students exhibited *complete* understanding of subgoals 4a and 4b by conceptualizing implicit functions and recognizing the need for the chain rule in implicit differentiation.

Stage 5. In this last stage, all of the students became adept at recognizing compositions of functions in these types of problems, satisfying subgoal 5a. However, a major issue was that the students moved through these problems more slowly than anticipated. We had expected that their previous experiences would allow them to do these three problems more independently in one 50-minute session. Student A was the only one to even reach the implicit differentiation problem. This suggests a need to revise this portion of our HLT to better scaffold it for students.

Further, for the implicit differentiation problem, Student A first subtracted $x^4 + y^4$ to make the equation $\sqrt{x+y} - x^4 - y^4 = 0$, with a constant on one side of the equals. While not wrong, it was unnecessary and seemed to stem from a limited understanding of this type of problem. We realized that because both prior implicit differentiation problems had constants on one side of the equals, $x^2 - y^2 = 1$ and $x^2 + [f(x)]^3 = 9$, she may have come to believe that implicit differentiation was only possible in this form. As such, this suggested another needed revision to the HLT.

Similarly, in the two related rates problems, all four students seemed to not realize that they could take the derivative of both sides of the equation with respect to time. For example, the shuttle problem led to the equation $\tan(\theta) = d/2$, which the students correctly conceptualized as $\tan(\theta(t)) = d(t)/2$. Yet, instead of applying the chain rule to $\tan(\theta(t))$, all of them tried solving for θ to get $\theta(t) = \arctan(d(t)/2)$. While not wrong, it drastically complicated the procedures. We realized that all previous cases had the format of $h(x) = f(g(x))$, and that they may have tried to follow that format here, as well. As such, this exposed another needed revision to the HLT.

Discussion and Revisions to the HLT

This study was aimed at testing our HLT in a small-scale experiment. This study suggested NM was a reasonable construct on which to base an HLT for these topics. It also confirmed that there are several important background understandings that must be in place for these deeper topics in calculus to be well understood. For example, Oehrtman, Carlson, and Thompson (2008) explain that it is critical for students to understand functions in order to understand calculus, and Clark et al (1997) speak of needing to understand function composition in particular. This was the case for our students, as seen by the difficulties Student B and C. It also seems critical that students understand derivatives quantitatively as a multiplicative comparison of changes (Jones, 2017; Thompson, 1994). This impacted Student D's ability to progress in stage 3.

Further, our study demonstrated the need for revising the HLT in three ways. First, during stage 2, students may need more time becoming familiar with "inside" versus "outside" components of a function composition. Second, the students' tendencies to solve equations for a single variable (in related rates) or to get a constant on one side of the equals (in implicit differentiation) implies that in stage 4 it may be necessary for students to better understand these equation structures. For example, Mirin and Zazkis (2019) have recently suggested the need for students to conceptualize each "side" of an equation as separate functions that are equal to each other. For example, $x^2 + y^2 = 1$ can be conceptualized as $f(x) = x^2 + y^2$ and $g(x) = 1$. The derivatives of these equal functions can be thought of as equal. Such understanding might have helped the students realize that $\tan(\theta(t)) = d(t)/2$ does not need to be solved for θ, or that $\sqrt{x + y} = x^4 + y^4$ does not need to be set equal to 0. Rather, each "side" in these two equations can be thought of as a separate function for which the chain rule can be used. Third, it became clear that stage 5 was not adequately set up to help the students take what they had recently developed and use it proficiently for those three more complicated problems. Rather than expect students to be fairly autonomous at this point, the same types of questions used in previous stages should be explicitly repeated in stage 5. We believe this may help the students make connections more quickly and be able to solve those problems a little more efficiently. While these changes do require more time earlier on, they may pay off in a more efficient stage 5.

Conclusions

Overall, this small-scale teaching experiment suggested that NM is a reasonable construct on which to base an HLT for the chain rule, related rates, and implicit differentiation. The students used NMR frequently to create the chain rule structure and to see that structure in related rates and implicit differentiation. This study allowed us to see how individual students' understanding developed over the course of our HLT. Some difficulties were detected along the way that have permitted revisions to our original HLT. Through this, we now view our HLT as prepared to transition from a small-scale, interview-style test to a full-scale, whole-classroom teaching experiment. This subsequent experiment would be necessary to see how this HLT might function with all the complicating dynamics of an entire classroom.

Tutoring Beyond Show and Tell: An Existence Proof

Carolyn Johns
The Ohio State University

Drop-in tutoring has been shown to positively impact grades. However, little is known about what occurs in drop-in tutoring. This study sought to fill this gap by answering the following research questions: 1) How do tutors interact with students? 2) What factors influence tutors' decisions regarding how to navigate interactions? 3) How do these factors impact tutors' interactions? This study provides a descriptive case study of one tutor's practices in the context of drop-in undergraduate Calculus I tutoring. Natural tutor session recordings and stimulated recall interviews were collected. Multiple lenses, including teacher decision-making, social and socio-mathematical norms, responsive teaching, and cognitive apprenticeship, were utilized during analysis. Results found tutor-student interaction patterns are more complex than previously reported in the literature. In addition, results suggest tutors are capable of changing their practices within the short time span of a semester and further, tutors are capable of enacting "best practice" teaching strategies.

Keywords: Tutoring Practices, Calculus, Stimulated-Recall Interviews

Introduction

In 2010, the Characteristics of Successful Programs in College Calculus study sought to gain insight into the institutional characteristics of successful calculus programs. Undergraduate mathematics tutoring, or the presence of a learning center, was cited as one of the primary features of institutions with successful calculus programs (Bressoud, Mesa, & Rasmussen, 2015). In addition, 97% of the institutions surveyed offered some form of calculus tutoring with the majority offering tutoring by undergraduates. Further, attending drop-in tutoring has been shown to positively impact calculus performance as measured by final course grades (Rickard & Mills, 2018). This indicates tutoring plays an important role in undergraduate mathematics education, yet little is known about what occurs in drop-in tutoring or the work these tutors do.

What research exists on tutoring is often context independent, examining the general pedagogical practices of tutors, such as tutor questioning (Graesser & Person, 1994). In addition, studies often examine the practices of 'expert' tutors, most of whom have had teaching experience (Arcavi & Schoenfeld, 1992; Schoenfeld, et al., 1992), as well as explore tutor moves in the context working with a student to learn a pre-determined topic in a fixed amount of time and number of sessions (Arcavi & Schoenfeld, 1992; Chi, 1996; Graesser & Person, 1994; Schoenfeld, et al., 1992). Little research has attended to the specific context of undergraduate tutors working in a drop-in tutoring site. In particular, research has yet to examine the practices of the same tutor across multiple sessions and over an extended period of time.

The aim of this study was to provide descriptive case studies on tutoring practices in the specific context of drop-in undergraduate Calculus I tutoring. In particular, it sought to answer the following research questions:

1) How do tutors interact with students?
2) What factors influence tutors' decisions regarding how to navigate interactions?
3) How do these factors impact tutors' interactions with students?

This study establishes baseline data on which to build future studies regarding tutors and tutoring practices.

Literature Review

This work was grounded in two conceptual principles: 1) in response to others, humans make decisions based on what they assume is important, drawing from what they notice in the course of interactions (Herbst & Chazan, 2003) and 2) responses humans make in the course of interactions draw on current understandings of the event, such as its circumstances and content, and resources they have at their disposal (Schoenfeld, 2011). The data was analyzed with this in mind to examine the tutor's references to factors which influence decisions. We elaborate in detail in the following section how these points shaped the analysis of data in this study.

We also drew on literature regarding teaching practices that support student learning. In order to create a learning environment that supports students' conceptual understanding, certain social and socio-mathematical norms are accepted as critical to be negotiated by the instructor and student (Cobb, et al. 1992; Cobb & Yackel, 1996; Yackel & Cobb, 1996). Further, scholars have argued that in order to encourage the student to be an active participant and build on students' thinking, instructors need to develop eliciting skills to engage the student in the interaction and draw out the students' thinking. While the student is talking, the instructor needs to listen to the student in order to build an understanding of what the student is thinking (Teuscher, Moore, & Carlson, 2016). Instructors should not be listening for specific answer but instead engage in listening in order to negotiate meaning with the student they are working with (Davis, 1997). Tesucher et al. describe the instructor's cognitive process in listening to the student, "de-centering". In de-centering, the instructor builds a model, or way of explaining the student's understanding based on what the student communicates. The instructor then uses this mental model to make in-the-moment instructional decisions on how to proceed.

Methods

The case presented was part of a larger study conducted using a multiple case study approach with each case being a Calculus I tutor in their first year of tutoring. This report will focus on one these cases, Jason. Jason was a junior biomedical engineering major with no previous tutoring experience working in the Calculus I room in a drop-in tutoring center.

In the center, students came to the tutoring room either with questions in mind or to work on their homework and ask questions as they arose. Typically, students asked for help on a specific homework task rather than for help understanding a general concept. Tutors generally helped students with their particular task and then moved on to the next student. A typical tutoring session lasted 5-15 minutes. While tutors may have worked with a particular student in the past, it was more likely they had not worked together before.

As part of his training requirements, Jason recorded three tutoring sessions at four points during his first year of tutoring for a total of 12 sessions. A session was defined as an interaction with an individual student, typically on one task. At each of the four points in time, Jason had approximately two weeks to audio record his three sessions and submit the recordings and photographs of the task and written work. Jason collected a set of recordings during his first weeks as a tutor (beginning of September), halfway through his first semester (mid-October), at the end of his first semester (December), and at the beginning of the subsequent semester (January). It was left to Jason to select the sessions he recorded and submitted. These recordings and photographs constituted the tutor session data for the study.

In addition, Jason met with the researcher twice to discuss his recorded tutoring sessions. Each meeting was conducted as a stimulated recall interview, having Jason listen to each of his sessions. At key points while listening to the session, the interviewer stopped to ask Jason to explain what he thought was going on, why he did what he did, or what he was trying to do or get at. This allowed the researcher to better understand Jason's decision making and thought processes rather than making assumptions. In addition, during the interviews, the researcher asked Jason questions regarding his beliefs about tutoring and learning.

Data Analysis

Analysis of the data occurred in waves and was conducted on a group of four tutors. First, each tutor's tutoring sessions from September and October were transcribed and indexed to describe the actions of each talking turn. Then these transcripts were open coded to look for patterns of behavior to begin to formulate hypotheses regarding these behaviors and possible rationales. Session transcripts were then marked for passages where these behavior patterns emerged. It was at these marked points in the tutoring sessions that during the stimulated recall interviews, tutors were asked questions regarding their thoughts and behaviors. In addition, the hypotheses for factors influencing the tutors' behaviors were also addressed through additional interview questions.

After conducting the first interview, the interview transcript was analyzed using a grounded theory approach to look for themes which emerged from the data. This phase of the analysis drew on several bodies of literature. Because this was an exploratory study seeking to find baseline data on tutoring, the exact frameworks which may have been useful in examining tutoring sessions were not known. Employing grounded theory techniques allowed the researcher to look for aspects of the data which come out as key features. However, of particular note was the literature on social norms (Cobb, et al. 1992), decentering (Teuscher, Moore, & Carlson, 2016), and teacher decision making (Schoenfeld, 2011).

During analysis, social and socio-mathematical norms were inferred based on the patterns of interactions. Tutoring sessions were examined for negotiation of norms such as justifying answers, the student writing, or pushing against the idea of the tutor as the authority on mathematics (Cobb, et al., 1992; Yackel & Cobb, 1996). Further, tutors' rationale for their behaviors attempting to negotiate these norms was analyzed. To analyze the data for decentering, Ader and Carlson's (2018) levels of decentering framework was employed. The framework provides observable instructor behaviors as indicators they are working at a particular level of decentering.

In light of the analysis of the first interview, an initial model accounting for Jason's decision-making and factors influencing his work was constructed. Jason's tutoring sessions from December and January were then analyzed and again marked for stimulated recall interview questions. In particular, these sessions and the second interview were examined for data which confirmed or contradicted the existing theory.

Results

Research Question 1: How do tutors interact with students?

In many ways, Jason's tutoring was fairly consistent over time. One of the major changes was his increase in use and variety of questions. Throughout Jason's tutoring, the students appeared inclined to write, talk, and ask questions without being told. Jason maintained these social norms by allowing students to work on their own without taking over. Because Jason felt understanding the student's thinking was important, he allowed students to explain their reasoning with Jason asking questions to better gauge their understanding. Jason listened to his students and, based on what he understood their thinking to be, would respond to students in a way that addressed the student's individual thinking. Jason was consistently working at decentering level three or four (Ader & Carlson, 2018). For example, in a problem taking the limit as x goes to zero of a rational function, the student suggested an incorrect method for solving the task.

Student: =Okay and would I multiply by one over x squared? Or one over x to the fourth?

Tutor: So when you expand this, the highest power is gonna be x to the fourth, so you would do um divide by x to the fourth.

When asked what he thought the student was thinking and why he responded the way he did, Jason said,

> So I think what they were thinking is like when you take the limit as x is approaching infinity, like they're taught to divide by the highest power and then that eliminates all the other terms essentially…I think what I was thinking is if they like continued on the path that they were going and either saw one way or another if it worked or didn't work they would still I guess learn.

Jason indicated he thought the student was thinking about applying a method using for limits at infinity with rational expressions. Because of this, he answered the student's question as if the method were valid in the scenario in order to allow the student to explore the incorrect path, working at decentering level four.

However, the manner in which Jason responded to students changed over time. In Jason's September sessions, his responses often took the form of explanations while in his October session, these responses were information gathering questions (Boaler & Brodie, 2004). In December, Jason asked a range of questions for a variety of purposes.

In addition, Jason applied practices from cognitive apprenticeship (Collins, Brown, & Newman, 1989). Jason listened to his students in order to determine the level of help they needed. He would adjust his level of help based on what he perceived to be the student's understanding. Jason strived to have students do as much on their own as possible but when they were stuck, he would offer scaffolding to assist them. If scaffolding did not work, he would model. Jason wanted to avoid modelling and only used it as a last resort. Jason said he wanted the student to be "in the driver's seat".

Research Question 2: What factors influence tutors' decisions regarding how to navigate interactions?

In working with students, Jason drew on his own mathematical thinking and experience learning calculus to direct him to possible difficulties as well as ways of assisting students past those difficulties. He also drew on his accumulating experience working with students. Jason learned common errors and ways to address those errors. Further, it was important to Jason that he not only helped students solve the task at hand but that he also worked with them in a way that they could solve future tasks on their own.

Research Question 3: How do influencing factors impact tutor interactions with students?

Jason's behaviors were not predictable in the same way as other tutors in the larger study. This was partly because Jason's students would offer their own thoughts unsolicited. This led to Jason's decision-making (Figure 1) being centered-around student behaviors as they were the primary directors of the sessions. The branches in Jason's decision-making tree depended on whether or not students offered thinking, the type of thinking they offered, the correctness of students' mathematics, and the questions students asked. This follows from Jason's priorities. Jason wanted students to do the work on their own and be the "driver" of the session. Jason only wanted to be involved when asked. When students were stuck, Jason preferred to help by giving hints rather than telling.

Jason prioritized determining what students were thinking to give direction to the sessions. All of Jason's sessions started with students expressing what they were thinking. Even when students were not sure how to start the problem, they would generally offer some thoughts. When students were unable to offer an idea of how to start the problem, Jason would ask a general question, such as how to approach problems of that type, consistent with his priority to give students hints rather than answers. However, in his earliest sessions, Jason would at times tell students what he noticed in the problem that indicated to him what to do. In doing this, Jason would also tell the student what to do. Jason admitted that when he first started tutoring, he was guided by a priority to get the answer. Later, however, Jason said he aimed to get students more involved and work with their ways of thinking. Jason would ask students questions to provoke different ways of thinking about what was causing them difficulty.

The way Jason responded to students during the introduction corresponded to broader patterns throughout his sessions. Jason's responses to student impasses were each unique because students were able to express very specific difficulties. For example, throughout Jason's sessions, he was primarily silent unless directly asked a question or the student made a mistake. This allowed students to offer their own knowledge of what to do, how to do it, and facts. This aligned with Jason's priority that students do their own work as much as possible. When Jason did prompt students to continue working, he would do it with a question about what to do next or how to do something.

However, there were two situations in which Jason would directly explain. One was when explicitly asked a question and the other was when he had tried to ask questions but the student was still not able to move forward. In both situations, Jason would not only explain what the student was not understanding, but also why it was the case. As previously stated, occasionally in his earliest sessions, Jason would tell a student what to do or how to do something when he saw they made a misstep. However, for the most part, Jason would address procedural mistakes by asking how they got their answer so he could determine how to address the cause of the error. At other times, Jason would allow students to explore the incorrect path so they could realize the error on their own.

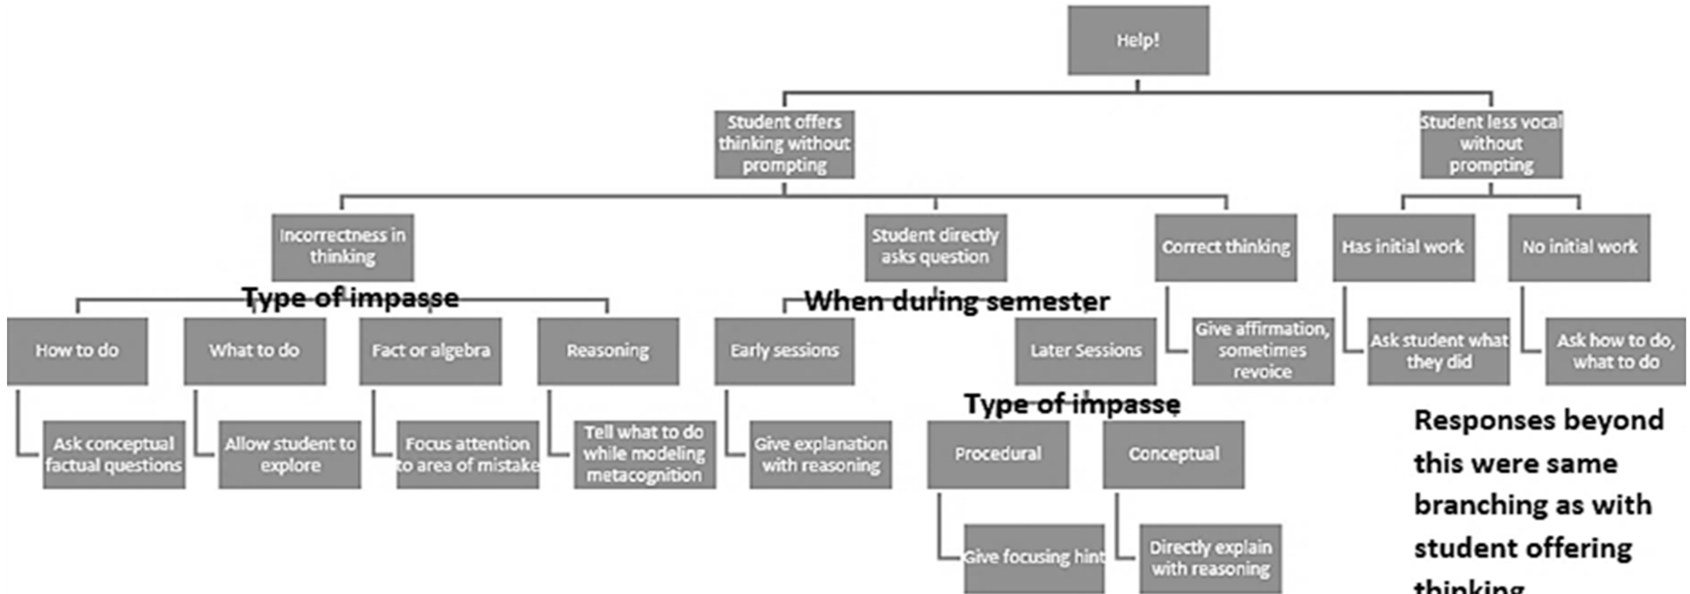

Figure 1. Jason's decision-making tree

Discussion and Future Directions

In contrast to previous research findings (Graesser et al., 1995), the current study indicates that at times tutors do use sophisticated pedagogical strategies. Although the goal of the study was not to confirm or refute presence of specific pedagogical strategies, it became evident that Jason engaged in strategies such as scaffolding, converging on shared meaning, error diagnosing, and addressing motivation. As such all features of Graeser et al.'s sophisticated pedagogical strategies were present in Jason's work. Further, in contrast with Chi's (1996) findings, Jason attempted to understand and build on student thinking, allowing students to dictate the direction of the session. In addition, when Jason sought out student thinking, he tried to address any misunderstandings he uncovered.

Further, although the goal of this work was not to assess the effectiveness of tutor moves, productive tutor moves identified in previous literature were present. For example, Jason allowed students to attempt to work on their own. In addition, Jason used questions to help students determine and explain their steps, providing explanations only if the student was unable to do so (VanLehn et al., 2003). Jason used questions and hints to help students (Lepper & Woolverton, 2002). Further, Jason referenced using various types of knowledge during his work and expressed a desire to be empathetic toward students. Jason used indirect criticism to avoid being harsh but also refrained from overpraising. Jason also described making decisions based on pedagogical knowledge for teaching (Gutstein and Mack, 1999). Findings demonstrated that tutors are capable of interacting with students in ways that align with best practices. While it is not known whether Jason would have demonstrated these best practices in the absence of training, data revealed that even first-year tutors are able to interact with students in ways that moved beyond show and tell. Tutors are capable of trying to understand student thinking and make moves based on responses to questions tutors asked. In addition, Jason either developed or held pedagogical content knowledge (Hill et al., 2008) in ways that allowed him to better assist students. This study indicates tutors are capable of enacting evidence-based pedagogy. Future research can look more closely at tutoring behaviors using frameworks such as the NCTM Mathematical Teaching Practices (2014) to look for direct evidence of the presence or absences of evidence-based best practices.

Further, Jason was able to enhance his practices even within the timespan of a few months. While the goal of this study was not to uncover reasons for these changes, it seems reasonable to consider two factors. First, tutor behaviors may have changed over time simply due to the experience gained working with students. Second, changes may have been due to tutor training. It is plausible to assume that both factors contributed to developing pedagogies. That tutor training can change over a short timespan indicates tutor training is not a futile effort. Although tutors often only work at a center for one to two years, training may make an impact quickly. This also indicates that time and money spent on tutor training may be worthwhile. The current study did not examine how the tutors' ongoing training during data collection influenced their practices and beliefs. It is not clear whether and how the Jason's practices and rationales for their decision-making would have differed had they not undergone training or been subject to alternative training. Future work can examine the impact of the training curriculum on tutors' practices. It is important to understand how different components of the training programs may influence tutors and specific aspects of their work.

Student Self- and Simulated Peer-Evaluation of Proof Comprehension: Tina

Aubrey Kemp
California State University, Bakersfield

Darryl Chamberlain Jr.
University of Florida

Laurel Cooley
Brooklyn College

Valerie Miller
Georgia State University

Draga Vidakovic
Georgia State University

Research shows that students in mathematics can benefit from participating in self- and peer-evaluation. However, many students lack the self-confidence in their ability to grade their peers' work and often provide feedback that is unhelpful. This study investigates the criteria used by a student to evaluate responses to questions on an assignment pertaining to comprehension of a proof by contradiction. Two interviews were conducted with the student more than one year apart in which she evaluated her own responses and responses written by an instructor to the questions in the assignment. Through the lens of achievement goals, results provided show a shift in the way she used her criteria to provide evaluations of these responses. Further, analysis indicates students may benefit from regular activities and practice in self-/peer- evaluation of proofs without assigning a grade to help their reflection and sense-making abilities.

Key Words: Self-Evaluation, Peer-Evaluation, Proof Comprehension, Indirect Proof

Introduction

Many studies have investigated the effects of self- and peer-assessment/evaluation on student performance and understanding of mathematical concepts (e.g., Beumann & Wegner, 2018; Scott, 2017; Dupeyrat et al., 2011, Brookhart et al., 2004; Stallings & Tascoine, 1996). Beumann and Wegner (2018) explain there are three key dimensions of self-evaluation: use of criteria to self-evaluate learning, interactive dialogue between the teacher and student, and assigning a grade to the work. With regard to student use of criteria in self-evaluation, Stallings and Tascoine (1996) state that students originally did not include the idea of conceptual understanding in their criteria, and tended to weigh effort heavily in their self-evaluations. Research shows that students sometimes underestimate their comprehension, but more frequently overestimate it (Lin, Moore, & Zabrucky, 2001). Beumann and Wegner (2018) call for more research on how students assign the grades associated with their self-assessment and invite others to investigate topics with self-assessment in mathematics.

Researchers state that both peer- and self-assessment methods improve student autonomy and learning and help foster skills associated with metacognition (Brown & Knight, 2012; Elwood & Klenowski, 2002). While much research supports the use of peer-assessment, Wen and Tsai (2006) found many students lacked the self-confidence in their ability to grade their peers' work and were apprehensive about criticism from their peers. Brophy (2005) implies student concern about peer comparisons are likely to distract their focus while attempting to understand a concept. Scott (2014, 2017) suggests *simulated peer-assessment* as an alternative to peer-assessment, in which students are provided with an anonymous example of an incorrect solution to a question and asked to provide feedback after analyzing it. By removing real student work, it may remove issues such as "apprehension about being criticised, provision of deleterious feedback, influence of social relationships, and differing peer abilities," (Scott, 2017, p. 111). In this study, explanatory qualitative case study methodology (Baxter & Jack, 2008) is utilized to consider a student's simulated peer-evaluation and self-evaluation responses to a proof comprehension activity.

We use this type of case study methodology to explain a shift in this student's evaluation criteria over time and present results and discussion on the following research questions: What criteria does an undergraduate mathematics major use in evaluating responses to questions about proof comprehension? In what ways do these criteria change (a) depending on whether the student is partaking in self-evaluation or simulated peer-evaluation and/or (b) over time (after completing other upper level mathematics courses such as Modern Algebra I, Analysis I and II, etc.)? Results of this paper imply practice in student self- and peer- evaluation of a proof comprehension activity without assigning a grade may help students to improve their sense-making abilities. In particular, by better evaluating their own work, students can reflect on their understanding to better develop mathematical concepts and proof skills.

Theoretical Framework

There are four achievement goals described in Elliot (1999) and Pintrich (2000) that will be used in this report to analyze data and describe results: Performance approach, performance avoidance, mastery approach, and mastery avoidance. Performance-oriented goals represent those in which a student may tend to compare themselves to others or focus on a grade, while mastery-oriented goals are those that focus on learning and understanding a mathematical task. We summarize these goal orientations in Table 1 below as they pertain to approach and avoidance states, as adapted from Pintrich (2000).

Table 1. Goal orientations and approach/avoidance states, as adapted from Pintrich (2000).

	Approach State	Avoidance State
Performance Orientation	• Focus on being the smartest or best in comparison to others • Use standards such as being the best performer in the class, receiving the highest grade, etc.	• Focus on avoiding inferiority or looking dumb in comparison to others. • Use standards such as not being the worst in the class, not receiving the lowest grade, etc.
Mastery Orientation	• Focus on mastering learning and understanding • Use standards such as deep understanding, self-improvement, etc.	• Focus on avoiding misunderstanding or avoiding not mastering a task • Use standards such as not being wrong, not doing things incorrectly on a task, etc.

Kroll and Ford (1992) assert that students with poor error detection skills and overrated comprehension were significantly more performance goal oriented. Research shows there are at least three sources of information that students may use for self-assessment: absolute standards (requirements of a task), self-referenced standards (one's own past performance), and social comparative standards (performance of others) (Wayment & Taylor, 1995). Dupeyrat et al. (2011) suggest that further research be done to investigate what type of information students use in their self-assessment process, which may help advance the understanding of biases in self-assessment and the relationships these have to mastery and performance goals. For this study, these goals were used to analyze the biases and criteria used by a student to identify how her goals motivated her evaluation of responses to a mathematical task.

Methodology

Case Study Selection

This research study was conducted at a large, public university located in an urban center in the southeastern United States. The initial phase of data collection took place in October 2017 in an introduction to proofs course. Of the 14 students enrolled at the time of recruitment, two math majors were asked to voluntarily participate in interviews for this study. These two students were targeted because the instructor perceived one to be an "average" student and the other to be a "strong" student based on past grades and their progress in the current course. The idea behind selecting two students with varying mathematical skill sets was to investigate how different students perceive and evaluate understanding in proof comprehension. By considering an "average" and a "strong" student in an introduction to proofs course, we hoped to find possible trends in the thinking of mathematics majors to design activities that would assist in helping students better excel in their future mathematics courses. For space limitations, we only focus on results from the "average" student, Tina. The courses taken and grades earned by Tina prior to the first interview included: Calculus I (B), Calculus II (B), Calculus III (C), Ordinary Differential Equations (B), Linear Algebra I (C), Mathematical Statistics I (A). Tina earned a C in the introduction to proof course in which she was recruited. The courses Tina completed and grades earned after this course, prior to the second interview included: Mathematical Statistics II (B), Analysis I (C), Linear Algebra II (B), Applied Combinatorics (A-), Analysis II (B-), and Introduction to Statistical Methods (A-). Tina consistently attended and was an active participant during the introduction to proof class and attended office hours as necessary.

The Task

As part of the curriculum for the introduction to proofs course from which Tina was recruited, students completed an assignment outside of the classroom pertaining to proof comprehension. This assignment included an indirect proof that $\sqrt{2}$ is irrational (see Table 2). Tina was asked to read the proposition and proof and answer the questions also seen in Table 2. Since this proof is not a typical proof provided to students for this statement, it may allow the opportunity to probe for students' problem-solving skills and sense-making abilities. We note responses to this task when it was assigned is what we refer to as *initial* or *original* data.

Table 2. Proof comprehension assignment given in class (including the proof and questions).

Proposition: $\sqrt{2}$ is irrational. **Proof**: 1. Let $A = \{b \in N: \exists a \in N \ni a^2 = 2b^2\}$. 2. Suppose A is nonempty. Then by WOP, A has a least element b_0. Let $a_0^2 \in N$ be such that $a_0^2 = 2b_0^2$. 3. Then a_0^2 is even which implies a_0 is even. 4. Substituting $a_0 = 2k$, we have $(2k)^2 = 2b_0^2$, and so $b_0^2 = 2k^2$ is even.	Questions: 1. Explain the purpose of statement #1. 2. Why does a_0^2 being even imply a_0 is even? 3. How do we know $\frac{a_0}{2}$ and $\frac{b_0}{2}$ are natural numbers?

5. Thus b_0 is even. 6. Now $\frac{a_0}{2}$ and $\frac{b_0}{2}$ are natural numbers and $\left(\frac{a_0}{2}\right)^2 = \frac{a_0^2}{4} = \frac{2b_0^2}{4} = \frac{b_0^2}{2} = 2\left(\frac{b_0}{2}\right)^2$. 7. Therefore $\frac{b_0}{2} \in A$, which is a contradiction. 8. Thus A is empty and $\sqrt{2}$ is irrational.	4. How do we know $\frac{b_0}{2} \in A$? 5. Why does $\frac{b_0}{2} \in A$ imply we have a contradiction? In particular, be sure to address what is being contradicted and why this completes the proof.

In April 2018, as part of an interview, Tina was given typed versions of her own and instructor responses to these questions, and told they were from two random students. Tina was asked to analyze each student's responses and provide her thoughts about them. We deem this as *simulated peer-evaluation*, similar to simulated peer-assessment described in Scott (2014, 2017), since there was some form of anonymity and no indication that Tina realized one of the responses was her own from the assignment six months prior. Tina was given about 30 minutes to read and write her comments to the two students' responses. This was followed by the semi-structured interview to probe for elaboration on her comments.

Finally, in May 2019, as part of a similar interview, Tina was given the same responses to the questions and asked to comment on them. However, now a self-evaluation task, she was informed that Student 1's responses were her own from 17 months prior (also given in her handwriting now) and the others were from a key, or instructor responses. Tina was given time to read and write her comments about these responses which was followed by a similar interview as before. This change in format between interviews was to help answer the research question pertaining to criteria used in self-evaluation versus simulated peer-evaluation. Both interviews were audio and video recorded and transcribed. Using the achievement goal framework (Elliot,1999; Pintrich 2000) described above, researchers analyzed all of Tina's written and verbal comments from both interviews. Analyses were compiled and discussed to identify trends in the data. Results from this analysis are presented in the following section.

Results

To answer the research questions in this paper, results are presented through the lens of the achievement goals described in Table 1 (Elliot,1999; Pintrich 2000). To illustrate many of the criteria identified as important to Tina, we provide her comments during both interviews pertaining to her own and the instructor responses to the comprehension question, "Why does a_0^2 being even imply a_0 is even?" (Table 2, Question two). Her comments for this question were chosen for this paper as they were representative of her overall achievement goals and criteria that were exhibited during her interviews.

Simulated Peer-Evaluation Interview (April 2018)

We provide the responses Tina was given to evaluate in both the simulated peer-evaluation and self-evaluation tasks during the interviews in Table 3. As seen in the table, Tina's response proved that the square of an even number is also even, erroneously asserting a direct proof of the converse of the statement proves the original statement. Then, we provide Tina's comments about these student responses in the 2018 simulated peer evaluation interview in Table 4.

Table 3. Anonymous, typed responses presented to Tina in first interview.

Question 2	Student 1 *(Tina's response on the original assignment in October 2017)*	Student 2 *(Instructor solution)*
Why does a_0^2 being even imply a_0 is even?	$a^2 = 2b^2 \leftarrow a^2$ here is even ⇨ Implies a is also an even number, if we have an even number => n = 2k If we square it $n^2 = (4k^2) => n^2 = 2(2k^2) => 2k^2 = m$, m is an integer and $n^2 = 2m$, which is an even number.	Suppose a_0 is odd. Then $a_0^2 = (2k+1)^2 = (4k^2+4k)+1$, an odd. Thus, by contraposition we have if a_0^2 is even then a_0 is even.

Table 4. April 2018 Simulated Peer-Evaluation Comments.

Written Comments - Student 1 Response	Written Comments - Student 2 Response
"This response is more accurate and a direct way to explain statement #3. By justifying what an even number is $\boxed{n = 2k} \leftarrow$ and explaining from there, directly, it is a straight forward way to help the proof of #3."	"This response is also true and I would say that the first response explains the statement more accurately."
Verbal Comments - Both Responses	
"This is my personal way of algebra, the best way to explain something like that; This one [pointing to Student 2] is good too but I feel like Student 1 is using the definition of even number, but you didn't' even have to use the definition of odd [pointing to Student 2]. So my preference is Student 1."	

In her comments to each response during the simulated peer-evaluation task, Tina talked about how well the response was *explaining* an idea. For example, in Table 4, she used phrases such as "a direct way to explain statement #3", "explains the statement more accurately", and "the best way to explain". Not included here, in her verbal comments about the responses for question three of the assignment, Tina stated, "Student 1…would be helpful to explain it to someone else, if someone was sitting there…" This is just one example of Tina focusing on the students' abilities to explain concepts to another person. By using phrases such as "a straightforward way to help the proof of #3" and focusing understanding and explaining ideas to another person, Tina indicated holding a mastery orientation with a tendency towards mastery approach versus mastery avoidance. We note that she displayed some signs of mastery avoidance in that she avoided faulting student work, even in situations when it was obvious that some statements did not make sense. This was consistent throughout her interview.

Self-Evaluation Interview (May 2019)

In May 2019, Tina was given the same responses and explicitly told the two sets of responses were her own (in her handwriting) and an instructor's. We note that since the last interview, she had completed several upper level math courses, listed in the *Case Study Selection* section of this paper. In Table 5 below, we present Tina's comments during this self-evaluation task.

Table 5. May 2019 Self-Evaluation Comments.

<table>
<tr><td><u>Written Comments - Her Own Response</u>
“The response is clear, uses aglebra to explain the question also uses previous knowledge of integers/even numbers. And is also broken down.”</td><td><u>Written Comments - Instructor Response</u>
“The response uses previous knowledge of contraposition which tells the grader/student has connected previous knowledge with current knowledge.”</td></tr>
<tr><td colspan="2"><u>Verbal Comments - Both Responses</u>
“For number 2, Student 1 it was clear, it was very broken down, it was understandable, and it was student language, and I felt using algebra to explain was neat…using the knowledge of integers, the previous knowledge and all of that…Here [pointing to the key]…it was using the contraposition…basically, uses previous knowledge. To use that is one level above Student 1 which means that the key answer was connecting the material together which is needed…”</td></tr>
</table>

A large shift in the type of comments made by Tina was noted in the analysis. She focused on how she believed an instructor or grader would read the response rather than how well ideas were explained. Although she continued to employ phrases like, “uses algebra to explain”, there were several instances in which she explicitly referred to a grader, saying things like “uses previous knowledge of contraposition which tells the grader/student has connected previous knowledge with current knowledge.” She often specified that she preferred her own responses to the instructor responses because of how they were “more broken down” and referred to her own work as using “student language,” as in Table 5. She also implied that since the instructor solution used a proof by contraposition, it was “one level above Student 1.” The analysis indicated she was trying to explain that a grader would be more satisfied to see a student using a proof by contraposition instead of a direct proof because she perceived it to be more advanced.

We note that even though Tina was aware Student 1 was her own work, she referred to these responses as “Student 1” during the interview. It may be possible this was to help her feel comfortable evaluating her own work while minimizing the feeling that she was being graded. This would support Scott (2017), since Tina may have been apprehensive about being criticized, which is a reason the author argues for simulated peer-assessment. It is also possible that after completing more upper level coursework, Tina may have begun to rely on self-referenced standards (one’s own past performance) and was conditioned to think about which response she felt would earn more points on an assignment instead of which response made the most sense to her. Often, she implied the more information a response had, the better it was. This, coupled with her focus on grades or being graded during the self-evaluation task, implies she developed a tendency to think a teacher would prefer unnecessarily providing knowledge in a response.

The summative analysis indicated Tina was focusing on how someone else would be analyzing or grading the responses instead of how someone else would be understanding the response as an explanation. Directly comparing her own responses to another and focusing on which would be assessed higher is evidence she was operating with a performance goal orientation with a tendency towards performance approach instead of performance avoidance. Tina’s lack of ability to find errors within her own responses and often favoring them over the instructor responses is consistent with Dupeyrat et al. (2011) and Kroll and Ford (1992) in that students with poor error detection skills and over-rated comprehension were significantly more performance goal oriented.

Discussion and Concluding Remarks

The purpose of this study was to identify criteria used by a student in simulated peer-evaluation and self-evaluation, how these criteria change over time/with more coursework, and how they change based on whether the student is comparing responses via simulated peer-evaluation or self-evaluation. Tina demonstrated that she felt the use of algebra/symbols, the amount of knowledge shown (focusing on making connections between previous and current knowledge), and how detailed a response was were important criteria in her evaluation. In the simulated peer-evaluation, she focused on how each response explained an idea if someone (typically a peer or fellow student) was reading it. In the self-evaluation task, Tina was more focused on how each response would be assessed if a grader were reading it. Thus, her orientation during the simulated peer-evaluation task was more focused on mastery, while her orientation during the self-evaluation task was more focused on performance.

We hypothesize that this shift in focus occurred for one or both of two reasons: (a) the ways in which she perceived to have been graded throughout her college experience had caused her to focus on how the responses would earn points on an assessment, or (b) since she was made aware one of the responses was hers and one was the instructor response in the self-evaluation task, she personalized the responses and began to reason where she should earn at least partial credit for her responses. The data indicate that in the self-evaluation task, she was conditioned to focus on a grade and was relying on her previous college mathematics performances and assessments to evaluate these responses. This is evidence she began to use her past performance experiences to analyze these responses (e.g., Butler, 1995; Régner, Escribe, & Dupeyrat, 2007). However, analysis indicated a shift in the information Tina used for assessment from absolute standards (requirements of a task) to self-referenced standards (one's own past performance) in a way that may have hindered her learning and proof comprehension, since her focus was no longer on sense-making. Thus, evaluation tasks or activities more focused on sense-making with no grade attached may be beneficial for students' proof comprehension skills. Such activities may help shift this focus from assessment to understanding, from performance to mastery goals.

Future research could further investigate differences in how students peer- and self- evaluate and how these methods change over time. Specifically, investigation into the differences in achievement goals of students in peer- and self- evaluations and how these affect student biases in evaluations/understanding would be useful. Through these types of investigations, researchers can identify obstacles math majors face in introduction to proofs courses that, if overcome, could help them develop a better foundation for evaluating their own work and thus, opportunity to better understand mathematical concepts and develop proof skills. There were several limitations to this study, one of which was this is one case study. Although Tina represented an "average" student in October 2017, this does not mean all average students would have similar responses, as each student constructs knowledge uniquely.

A Calculus Student's Thinking about the Idea of Constant Rate of Change

Ishtesa Khan
Arizona State University

This study focuses on a student's thinking about a constant rate of change in the context of a conceptual approach of calculus (DIRACC). DIRACC calculus defines a constant rate of change as variations measured in two covarying quantities being proportional to each other. This paper also presents a theoretical framework that characterizes students thinking about the constant rate of change in relation to variation and covariation.

Keywords: calculus, constant rate of change, differentials, proportional reasoning, covariational reasoning.

Introduction

The idea of the rate of change and the constant rate of change play critical roles in calculus. Thompson (1994a) investigated some fifth grader's concept of speed, its relationship to concepts of rate and revealed a lack of productive distinction between the concept of ratio or proportionality, and the concept of rate. Another research by Thompson (1994b) about students' images of rate and understanding of Fundamental Theorem of Calculus (FTC) reported unproductive meanings for the concept of rate in calculus students. My primary goal is to study how students think about the idea of a constant rate of change conceptually, and therefore, I refer to a conceptual approach of calculus curriculum DIRACC (Thompson & Ashbrook, 2019). DIRACC calculus treats differentials as variables explicitly. A differential in 'x' is a variable whose value varies through the interval $(0, \Delta x]$ repeatedly (Thompson & Dreyfus, 2016). Therefore, dy is a variable whose value varies through the interval $(0, mdx]$, where m is the constant rate of change when dy is a variation in y as the value y varies in relation to the variable dx. To understand the rate of change function and the constant rate of change function conceptually, envisioning differentials as variables are central in DIRACC. When f represents a functional relationship between the variables x (independent) and y (dependent), and we say x varies smoothly through its domain, the differentials in x as dx are small variations in the variable's value as dx vary within tiny intervals of infinitesimal length (Δx) in x's values. Therefore, a function has a rate of change at the moment if, over a suitably small interval of x containing the moment, f's value varies at essentially a constant rate with respect to x.

In this study, I developed a two-dimensional theoretical framework to explain students thinking about the idea of the constant rate of change with respect to students thinking about variation and covariation. This study focuses on the idea of a constant rate of change using the notion of differentials (as variables) being proportionally related quantities. The research question motivated this investigation is: - How do students think about the idea of the constant rate of change in DIRACC?

Literature Review

Mathematics educators have been interested in students' understanding of proportionality, rate and ratio; conceptualization of rate of change functions, derivatives and differentiation in terms of modeling and graphical approach; and mathematicians' conceptual approaches for differentials and infinitesimals for some time being (Pulos & Tourniaire, 1985; Doerr & O'Neil, 2011; Orton, 1983 & Yoon, Byerley & Thompson, 2015). Results of these studies have provided insights to investigate students' understanding of the idea of a constant rate of change function and differentials as varying quantities and being proportional in variation of their measures. Thompson (2008) discusses that the constant rate of change is foundational to understand linear functions and subordinate ideas as the average rate of change, proportionality, and slope. Studies have discussed the disconnections students, and many teachers have as they see these ideas as a separate set of procedures and as associated with unrelated contexts (Lobato, 2006; Lobato & Siebart, 2002; Lobato & Thanheiser, 2002 & Coe, 2007). According to Thompson (2008), the common meanings students and teachers have for constant rate of change is insufficient to understand the foundation of linear functions. Hackworth (1995) reveals that students' meanings for a constant rate of change rarely includes thinking about two quantities changing together and do not involve all the possible changes in the value of one quantity being proportional to corresponding changes in the value of other.

There have been researches in the field of mathematics education that address the issue of students' images of two varying quantities changing with respect to one another (Carlson, 1998; Carlson, Persson & Smith, 2003; Carlson, Jacobs, Coe, Larsen & Hsu, 2002). Thompson & Carlson (2017), revisited the covariational reasoning framework and clarified that variational reasoning is a person's thinking of variation of a quantity, covariational reasoning is how a person envisions the change in one quantity or variables value is related to change in another quantity or variable's value; and how the person envisions both varying simultaneously with respect to one another. Castillo-Garsow (2013;2012 & 2010) argued that smooth images of change are more potent over chunky images of change. According to Castillo-Garsow (2013), smooth thinking allows students to think about completed change and change in progress within intervals and from one interval to another. To investigate students' thinking about a constant rate of change in this study I will be aware of 'chunky thinking' and 'smooth thinking' to make sense of students' cognitive activities during the tasks. Ely & Ellis (2018) argue that scaling-continuous reasoning is a productive way of thinking about key ideas in calculus like variation of quantities, the instantaneous rate of change, limit, differentiation, and the definite integral. By saying 'scaling-continuous reasoning,' the authors elaborated Leibniz's notion of infinitesimal increments. Their study entails the importance of continuous covariational reasoning (Thompson & Carlson, 2017) epistemologically for students to develop the foundational ideas of calculus. However, scaling continuous thinking does not rely on the image of motion (according to Newton) or an underlying parameter. Having Leibniz in mind, the authors proposed scaling-continuous reasoning as an alternative approach to smooth-continuous covariational reasoning, which aligns with Newton's way of calculus. Newton and Leibniz independently invented Calculus during the last third of the 17th century (Kleiner, 2001). They conceptually approached the concept of derivative differently. For Newton, the fundamental concept of Calculus is to recognize variables vary with time, and they vary at some rate every moment. DIRACC curriculum takes Newton's approach of Calculus as the underlying conceptual framework.

Thompson & Dreyfus (2016) surveyed seventeen textbooks, where they found that most of these do not mention differentials at all for single-variable calculus. According to them, "*a differential in* $'x'$ *is a variable whose value varies through the interval* $(0, \Delta x]$ *repeatedly.*" Therefore, dy is a variable whose value varies through the interval $(0, mdx]$, where m is the constant rate of change when dy is a variation in y as the value y varies in relation to the variable dx. In this approach, the idea of the differential is not based on the idea of derivative; instead, a differential is introduced consistently with a linear variation prior to the concept of derivative. Linear variation essentially represents the proportional relationships between the differentials (two covarying quantities) dy and dx, where m is the proportionality constant.

Theoretical Framework

In this paper, I am presenting a theoretical framework that emerged from a conceptual analysis of the idea constant rate of change in relation to variational and covariational reasoning. I have used some well-developed constructs and explained how they support the data analysis. Therefore, I suggest a two-dimensional theoretical framework- levels of students' thinking about the idea constant rate of change with respect to levels of students thinking about variation and covariation of varying quantities (variables).

Levels of Students' Thinking about the Idea of Constant Rate of Change-

Level 5 (L5CROC)- students think of the constant rate of change as a relationship between two covarying quantities remaining same. If y is a varying quantity that changes with respect to another varying quantity x then the rate of change $dy/dx = m(\Leftrightarrow dy = m.dx)$ always remain constant. In this level, students treat 'dx' and 'dy' as variables, and these variables represent tiny variations among x and y. Students thinking about a constant rate of change in this level entail strong proportional reasoning. Their meanings for the average rate of change for any function (linear/non-linear) in a tiny interval also entail proportional reasoning.

Level 4 (L4CROC)- students think about the constant rate of change as a relationship between two covarying quantities remaining same. If y is a varying quantity that changes with respect to another varying quantity x, then the rate of change $dy/dx = m$ $(\Leftrightarrow dy = m.dx)$ always remain constant. In this level, students treat dx and dy as small changes (not variations) in fixed intervals of changes (Δx and Δy). Students thinking about the average rate of change for tiny intervals in this level can also entail strong proportional reasoning for linear functions. However, their meanings for an average rate of change for any non-linear function in a tiny interval not necessarily entail proportional reasoning.

Level 3 (L3CROC)- students think about the constant rate of change as a relationship between two covarying quantities remaining same. If y is a varying quantity that changes with respect to another varying quantity x, then the rate of change $\Delta y/\Delta x = m$ $(\Leftrightarrow \Delta y = m.\Delta x)$ always remain constant. Students think about the constant rate of change in terms of fixed intervals (perceivable chunks) and fixed arbitrary small amount of change within those intervals in the domain. Students thinking about the average rate of change within those fixed intervals are associated with proportionality but their thinking about the average rate of change smaller changes within those fixed intervals not necessarily entail proportional reasoning for linear and non-linear functions.

Level 2 (L2CROC)- students think about the constant rate of change as a relationship between a varying quantity and a fixed number. For any value of x, they think y as a constant number that can be represented as a horizontal line graphically. In this level, students' thinking about the constant rate of change is not associated with proportionality.

Level 1 (L1CROC)- students' thinking about the constant rate of change as a relationship between two numbers (quantitative reasoning for this level of thinking is less reliable). Students' struggle to imagine the graphical representation of two quantities remain linear in this level, and their meaning for the idea of a constant rate of change lack proportional reasoning.

Levels of Students' Thinking about Variation and Covariation of Quantities-

Level 5 (L5VCO)- students' thinking about a variation of a varying quantity and covariation between two or more covarying quantities consistent with 'smooth-continuous variation/covariation' discussed by Thompson & Carlson (2017). A student thinks 'dx' and 'dy' as varying values of 'x' and 'y' changing by intervals anticipating that within each interval the variable's value varies smoothly and continuously. Also, for y as a variable depending on variable x, a student in this level envisions dy changing simultaneously with respect to dx smoothly and continuously and the ratio of the varying values of y and x remains same.

Level 4 (L4VCO)- students' thinking about variation and covariation is consistent with the construct 'scaling-continuous variation/covariation' discussed by Ely & Ellis (2018). A student using scaling-continuous reasoning does not necessarily treat dy and dx as varying values. However, they consider dy and dx as such tinier changes in such a scale that the smaller and smaller increment in quantities creates an image that can be an alternative to treat dy and dx as variables.

Level 3 (L3VCO)- students' thinking about variation and covariation align with 'chunky continuous variation/covariation'(Thompson & Carlson, 2017). A student thinks about variation of a variable's value or covariation between two covarying quantities as changing by intervals of fixed sizes. In this level, students treat dy and dx as smaller changes within a larger fixed amount of changes as Δy and Δx.

Level 2 (L2VCO)- students' thinking about variation and covariation is consistent with gross variation and coordination of values (Thompson & Carlson, 2017). A student in this level envisions some relationship of increasing or decreasing pattern when the quantities vary, but a student gives little or no attention how their values are changing within the quantities or if there is any multiplicative link between overall changes in two quantities values.

Level 1 (L1VCO)- in this level a student's thinking of variation or covariation can be consistent with any of the following constructs discussed in Thompson & Carlson (2017)- Discrete variation, no variation, variable as symbol, precoordination of values and no coordination.

A student in L5CROC is likely to associate with L5VCO. Thinking about differentials as variables is an outcome of being able to think in L5VCO. A student thinking about a constant rate of change in L4CROC can be associated with L4VCO or L3VCO. Students' sophistication of thinking about the average rate of change for non-linear function in a tiny interval will help to distinguish between L4VCO and L3VCO. As Ely & Ellis (2018) described scaling-continuous reasoning as an alternative of smooth-covariational reasoning and therefore, L4VCO might have some association with L5CROC but not as strong enough as L5VCO. Students having chunky continuous variation and covariation thinking L3VCO can be associated with L4CROC an L3CROC. The difference between association with L4CROC and L3CROC depends on students thinking about changes in terms of 'dx' and 'dy' as smaller changes within 'Δy' and 'Δx' or students thinking about the constant rate of change only in terms of 'Δy' and 'Δx'. The association between L2CROC with L2VCO and L1VCO and L1CROC with L2VCO and L1VCO can be flexible enough as all these levels produce weaker variational and covariational reasoning with unproductive meanings for the idea of a constant rate of change.

Methods

I used Exploratory Teaching Interview (ETI), which is inspired by one of the elements of Teaching Experiment (Steffe & Thompson, 2000). An ETI is a one-on-one interview consist of an interviewer, a single student, and video/audio recording devices. ETI was an appropriate methodology for this study as the spontaneous nature of creating on-moment hypotheses would support the research question to construct a model of students' understanding of the constant rate of change. The subject, Anna (pseudonym) who participated as an interviewee was a Calc 2 student. Anna was already exposed to the idea of the rate of change functions and accumulation function in Calc 1 using DIRACC. The methods of data analysis used in this study are qualitative analysis that is supported by grounded theory (Strauss & Corbin, 1994) and conceptual analysis (von Glaserfeld, 1995; Thompson, 2008) parallelly to construct a model of Anna's thinking.

The first interview question was 'What comes to your mind when you hear the term *constant rate of change*?'. The goal was to learn about Anna's free response to this question and her overall thinking about the idea constant rate of change. There were three other tasks for the ETI-

Task 1. *Jim ran 100 meters at a constant speed. He moved 0.6706 meters from 2.1 seconds after the clock started to 2.2 seconds after the clock started. What was Jim's speed from 6.81 seconds after starting to 6.87 seconds after starting?* The goal for using this task was to investigate whether Anna can reason that while Jim ran 100 meters at a constant speed, the speed remains the same for any fraction amount of time.

Task 2. *A common definition of a constant rate of change is given in section 3.15-*

y varies at a constant rate with respect to x if for a fixed amount of change in x (i.e., Δx) the amount of change in y (i.e., Δy) is constant. And another definition for the constant rate of change mentioned in 4.1 is- constant rate of change always involves two quantities varying together smoothly and continuously. Two quantities vary at a constant rate with respect to each other if, and only if, variations in one are proportional to variations in the other. Suppose that y varies at a constant rate with respect to x. Then dx is a variation (large or tiny) in x as x varies, and dy is a variation in y as the value of y varies in relation to the variation dx.

The relationship between variations is $dy = m \cdot dx$ for some number m.

Q. Do you think these two definitions have the same meanings for the constant rate of change? If yes, then why do you think they are same. If no, explain why they are not. The goal of this task was to investigate Anna's thinking about variation within a variable's value and her thinking about the constant rate of change in terms of differentials.

Task 3. The purpose of this task was to investigate Anna's understanding of the constant rate of change entailing proportional relationship within a large interval and super tiny interval. In this task, I used a GC animation file that showed a function's average rate of change over a tiny interval. However, from a zooming out position, the tangent line appears to be intersecting the graph of the function instead of being tangent over the interval. There is an image of the GC animation.

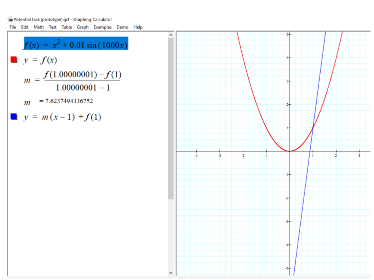

Figure 1. A picture of the GC animation.

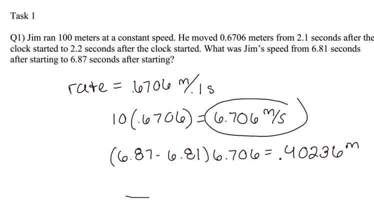
Results

The interviewer initially asked Anna to explain what comes to her mind when she hears the term *a constant rate of change*. Anna responded that she thinks about a rate of something that is changing with time and the rate remains the same relative to the time. According to Anna, her thinking about the rate of change of any quantity relative to time is a result of the kind of examples and instructions she had received from her DIRACC experience. Then the following interaction took place-

Interviewer: Do you think it is necessary that the change of a quantity needs to be with respect to time only or you imagine any two quantities changing with respect to one another?

Anna: Any two quantities; if you have a rate of change of a quantity relative to another quantity as long as they are proportional and related, they have a constant rate of change.

While working on task 1, Anna first figured out Jim's constant speed in meters per second. To her, if Jim moved .6706 meters in 0.1 seconds then in one second Jim has moved 6.706 meters, and his speed is 6.706 m/s. She went continued by calculating Jim's distance traveled from 6.81 seconds to 6.87 seconds but then realized that she had gone beyond the question that was posed. Anna mentioned that Jim's speed remains the same as 6.706 m/s as he is running 100 meters at the same speed. She described, the distance with respect to time remains proportional in this situation. While working on the task, she wrote speed as time and explained that she feels comfortable to think about speed as a rate of distance with respect to time. Here we present her work for the task below-



Task 1

Q1) Jim ran 100 meters at a constant speed. He moved 0.6706 meters from 2.1 seconds after the clock started to 2.2 seconds after the clock started. What was Jim's speed from 6.81 seconds after starting to 6.87 seconds after starting?

rate = .6706 m/.1 s

10(.6706) = 6.706 m/s

(6.87 - 6.81) 6.706 = .40236 m

Figure2. Anna's work for Task 1.

The thinking Anna exhibited when responding to Task 2 revealed her conception of the idea of change and the notion of differential when considering a context involving a constant rate of change. To Anna, initially, both definitions seemed similar. The interviewer asked her to explain why they seemed the same to her; she took some time to think about it and decided they are not the same. She answered by saying that Δx intervals are fixed and dx is a change since x starts varying within any interval. Anna conveyed that, it is possible to make the size of Δx's very, very small, but they would still be fixed. Anna relied on dx to vary the variable x. She mentioned that she was not paying enough attention to the vocabulary of the textbook and used her common language-

Interviewer: In your common language, do you think Δx and dx have the same meanings?

Anna: No. Δx is a fixed interval, and fixed change and dx is a movement of x within that interval.

Interviewer: How would you describe the movement dx?

Anna: the change in x.

Interviewer: As you said, Δx represents a change in x, and dx also represents change in x. Are the changes the same or different?

Anna- Δx is fixed, and dx varies. dx is never fixed; it is always varying.

For task 3, the interviewer explained what appears in GC window and asked how the tangent line for the function f would look like over the tiny interval between 1 and 0.00000001. Anna said there would be a little straight line touching the curve near that interval. The interviewer then graphed it, and an intersecting line appeared. Anna mentioned that it is not what she expected it, but the tangent line would be touching the curve over that tiny segment. Anna further explained that she expected to see a small portion of the original function where the tangent line would look like it touches the graph of the function. The interviewer zoomed into the tiny interval, and Anna mentioned that then it looked like what she expected. The interviewer zoomed enough, and a triangle showed up in GC graph over the interval between 0.00000001 and 1. The interviewer asked how the change in x is related to the change in y over that interval. Anna mentioned that they are changing together at a constant rate. The following interaction occurred-

Interviewer: Can you tell what the constant rate of change is within the interval between 1 and 0.00000001?

Anna: (focusing on the triangle that appears in GC and the average rate of change in GC window) hypotenuse of the triangle is the constant rate of change m for this section.

Interviewer: How would you represent the relationship between two covarying quantities within this interval?

Anna: dy is equal to this m times dx (she writes $dy = (7.6240)dx$).

Interviewer: So, you mean within this interval the variation in dy and the variation in dx....(did not let the interviewer finish)

Anna: the variations in dy and the variation in dx are going to be proportional to each other.

Discussion and Conclusion

The findings suggest that Anna was consistent in thinking about the proportional relationship between two covarying quantities throughout the tasks focused on the idea of a constant rate of change. The tasks presented in this study do not focus explicitly on how students think about variation in a variable's value. However, tasks 2 and 3 provide some insights on students thinking about variation within a variable's value. Anna demonstrated an awareness of the difference between the notion of change and the notion of differential, a critical distinction DIRACC intends for students to make. Her thinking about the idea of a constant rate of change aligns with the L5CROC described in the theoretical framework. Her thinking about the idea of a constant rate of change entails proportional reasoning between two covarying quantities. Anna's thinking about variation and covariation was close to L5VCO. It is difficult to make explicit comment about her variational thinking as none of the tasks mentioned in this study investigates students' thinking about variation in a variable's value in detail. However, Anna showed no signs of chunky thinking about variation in any of the tasks. Anna treated dx, a differential as a varying quantity in both tasks 2 and 3.

Therefore, DIRACC, as a conceptual approach of calculus, has potential to encourage students' thinking about variation in a variable's value and covariation when two quantities are varying together smoothly and continuously. The revised definition of the idea of a constant rate of change in terms of differential in DIRACC entails proportional reasoning when calculus students think about the idea of a constant rate of change. The theoretical framework mentioned in this paper can also be used to explain precalculus and traditional calculus students' thinking about the idea of a constant rate of change in association with variational and covariational thinking.

The Role of Gestures in Teaching and Learning Proof by Mathematical Induction

Vladislav Kokushkin
Virginia Tech

When talking about mathematics, teachers and learners actively use hand gestures to support their speech as well as to describe ideas that are not expressed verbally. In this study, I investigate the gestures that were utilized by an instructor and his students during a teaching episode on proof by mathematical induction. Alibali and Nathan's (2012) typology of gestures are employed to code the observed gestures. The study reveals that the use of gestures plays an integral role in teaching and learning induction. I show that pointing gestures helped to reduce ambiguity in classroom discussion, representational gestures were useful in describing specific subcomponents of induction, and, finally, metaphoric gestures were independently introduced by a teacher and students to describe the nature of proof by mathematical induction.

Keywords: gestures, embodied cognition, proofs, mathematical induction.

Literature Review

A number of scholars argue that gestures convey meaning and should be considered as an important part of communication (Lakoff & Nunes, 2000; Goldin-Meadow, 2003; Radford, 2003). People use gestures not only to support their speech, but also to describe ideas that are not expressed verbally, even without realizing it. Goldin-Meadow (1997) characterized gesture as a "window to the mind". For this reason, gestures have become the focus of attention for many psychologists, neuroscientists and educators; a comprehensive analysis of gestures may help to understand the way of human's thinking.

The investigation of gestures in mathematics takes place within a philosophical perspective that frames cognition as an embodied phenomenon. Wilson (2002) described the nature of embodied cognition by noting that "the mind should be understood in the context of its relationship to a physical body that interacts with the world" (p. 625). As a result, human cognition has deep roots in sensorimotor processing. Alibali and Nathan (2012) argued that the cognition is embodied in two senses – being based in perception and action, and being grounded in physical environment.

Gestures play an important role in the learning and development of children (Piaget, 1959). Research confirms that gesturing facilitates students' learning of mathematics in different contexts, such as learning to count (Alibali & diRusso, 1999), symmetry (Valenzeno, Alibali & Klatzky, 2003), equivalence (Singer & Goldin-Meadow, 2005), ratio and proportion (Abrahamson, 2003), motion and graphing (Nemirovsky, Tierney & Wright, 1998). Students often benefit from their gesturing while engaging in challenging, abstract mathematics since the hand gestures help to convey meaning without requiring an overwhelming amount of cognitive resources (Cook, Duffy & Fenn, 2013; Goldin-Meadow, Nusbaum, Kelly & Wagner, 2001). Gestures may help to represent concepts students find difficult to remember and allow learners to coordinate abstract mathematical relationships when processing multiple tasks (Alibali & Nathan, 2012; Ping & Goldin-Meadow, 2010). Gestures, therefore, are key elements in students' processes for knowledge objectification. Gestures help learners to put together different pieces of information and understand conceptually difficult mathematical objects.

Gestures are also actively used by teachers (Flevares & Perry, 2001; Neill, 1991). Literature suggests that students may benefit from their teachers' gestures. Research confirms that learners can detect conceptual information expressed in gestures, and that information that teachers express in gestures facilitates learning (Kelly & Church, 1998). Many studies have shown improvement in students' performance on a posttest after lessons taught by a teacher actively using gestures, compared to lessons that did not contain gestures (Church, Ayman-Nolley, & Mahootian, 2004).

Understanding the connections between different mathematical objects plays an important role in learning mathematics, and guiding students to make those connections is an important aspect of instruction. Several studies aimed to identify how teachers communicate connections among ideas in instruction in classroom settings (for example, Richland, Zur, & Holyoak, 2007). Their findings confirm that teachers often employ gestures to refer to the ideas being connected.

Proof by mathematical induction is known to be conceptually difficult for undergraduate students (Harel, 2002; Movshovitz-Hadar, 1993; Stylianides, Stylianides, & Philippou, 2007). This method is used to prove that the statement P(n) holds for any natural number n. To prove P(n) by mathematical induction, one must check two assumptions: (a) the validity of P(1) (the base case), and (b) if the statement P(k) is true for some natural number k, than it is also true for P(k+1) (inductive implication). The purpose of this case study is to investigate the role of gesturing in teaching and learning proof by mathematical induction. More specifically, the study is guided by the following research questions:

- *How does the instructor use gestures in teaching proof by mathematical induction?*
- *How do students use gestures in learning proof by mathematical induction?*

Theoretical Framework

I draw on Alibali and Nathan's (2012) typology of gestures manifesting embodied cognition. *Pointing gestures* reflect the grounding of cognition in the physical environment. This type of gestures is the most commonly used in mathematics (Alibali, Nathan & Fujimori, 2011). Pointing gestures are usually used to indicate objects, location, inscriptions or students.

Representational gestures convey simulations of action and perception and depict semantic content, literally or metaphorically, with the help of handshape or motion trajectory. According to Alibali and Nathan (2012), actions and perceptions are intimately linked: "when humans perceive objects, they automatically activate actions appropriate for manipulating or interacting with those objects" (p. 254). From this perspective, actions and perceptions are similar and it does not really matter what exactly, action or perception, a gesture represents.

Metaphoric gestures are a subset of representational gestures and reflect conceptual metaphors that are grounded in the body. These metaphors transmit understanding and perceptions of the reality. The conceptual metaphors that underlie mathematical ideas are often expressed in the gestures that humans produce when speaking about these ideas. Thus, metaphoric gestures provide evidence for psychological underpinnings of mathematical concepts.

Data Source

The study utilized a 40-minute teaching episode on proof by mathematical induction in a large research university in the southeastern United States. The course is a junior-level mathematics course designed to teach mathematics major students typical mathematical proof techniques. The participants were a white male mathematics professor and 20 students, who agreed to participate in the study. The video-data were part of a larger project studying teacher-students' interactions during instruction on mathematical induction. The videotapes were completely transcribed by the author, and the segments of classroom discourse when the teacher or a student gestured were marked and recorded on the transcripts. These segments were then analyzed qualitatively for the types of gestures that were used and the role the gestures played in facilitating the construction of shared meaning between the teacher and students.

Methods and Procedures

Before documenting any of the teacher's gestures, the author watched the videotapes and read the transcripts a few times. Then, using classroom videotapes, all of the teacher's and students' gestures were time indexed for starting time and duration, and classified in accordance with Alibali and Nathan's (2012) framework. Given that gestures occur very quickly, I re-watched the videotapes to assure that all the gestures and accompanying speech were documented. The gestural episodes that did not refer to mathematical instruction or mathematical conversation were omitted from the analysis.

Results and Discussion

In total, there were 132 instances of teacher gesturing and 15 incidents of student gestures. The huge difference between the number of teacher and student gestures may be explained by the fact that the observed teaching episode was an introduction to proof by mathematical induction, and, therefore, a considerable part of classroom discourse was held by the instructor. I report on the use of gesturing in accordance with Alibali and Nathan's (2012) typology.

Pointing gestures

Alibali and Nathan (2012) argue that pointing gestures reveal indexing of speech to the environment. In this subsection, I present how the instructor and students utilized pointing gestures to index mathematical ideas in proof by induction to the physical world.

The data confirm Alibali, Nathan and Fujimori's (2011) claim that pointing gestures constitute a majority of gesturing: 70% of the teacher's and 54% of the students' gestures may be characterized as pointing gestures. All the instances of pointing gestures were accompanied by an utterance "this," "that," or "it," or by addressing a mathematical symbol written on the board. The use of pointing gestures not only supported verbal communication between teacher and students, but also helped to circumvent the ambiguity of the words "this" and "it" in a classroom discourse.

Figure 1. Example of a pointing gesture.

One of the key aspects of teaching proof by mathematical induction is helping students distinguish between the truth for proposition P(k) versus the implication P(k) → P(k+1). During the observed teaching episode, the instructor purposefully pointed to either P(k) or to the sign of implication written on the board to indicate which one he referred to (Figure 1). However, students' responses show that they did struggle to understand the difference:

Teacher: What integers do we know that the proposition works for? … I know, **it** works for 1. How do I know, **it** works for 2?
Student: I'm saying that there is an integer $k \geq 1$. So, we can say that k is equal to 1. So, we only know that k works for 1 and 2.
Teacher: How do we know that **it** works for 2, that's my question… How do we know that **it** works for 3?
Student: Because the P(k), k is equal to 1.

Here, the student conflated the truth for proposition P(1) with the truth for implication $P(1) \rightarrow P(2)$. In this example, the teacher's word "it" was not supported with the corresponding pointing gesture and, consequently, could lead to confusion among the students.

Representational gestures

As it was noted by Alibali and Nathan (2012), "representational gestures simulate real-world objects that ground or give meaning to mathematical ideas" (p. 264). The present subsection describes how this type of gesture was employed in the classroom.

Any statement that may be proved by mathematical induction contains quantifiers. In order to prove that implication $P(k) \rightarrow P(k+1)$ is valid *for any* k, one should first assume that P(k) is true *for some arbitrary* natural k. The difference between these two quantifiers is subtle but critical. That is why it is crucial for students to understand the role of quantifiers in proof by induction.

The instructor and students used representational gestures in multiple ways. However, a large majority of teacher's gestures were aimed to represent quantifiers "for all", "for any" and "for some". The instructor repeatedly relied on the hand gestures that appeared like a fountain (spreading out and up) when he referred to the goal of the task – to prove the validity of proposition P(k) *for all* positive integers:

Teacher: Ok, let's put your ideas together. We know that P(1) is true. And there is some $k \geq 1$ s.t. the proposition is true for k implies the proposition is true for k+1. Is that enough to know that the proposition is true **for all** (Figure 2) natural numbers?

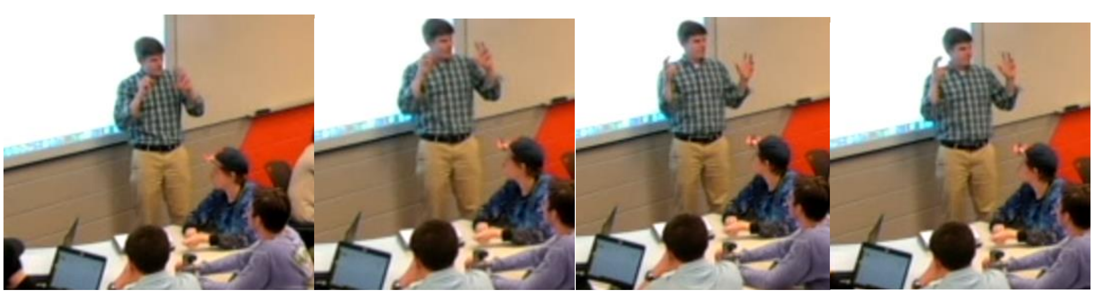

Figure 2. Example of a representational gesture used by a teacher to illustrate the quantifier "for all" ("fountain gesture").

In contrast to the "fountain" illustrating "for all" quantifier, the teacher temporarily fixed his hands motionless in the air to indicated that he fixed "some arbitrary" integer k:

Teacher: The “for all” is really important here as we just saw. So, if for all n, working for n implies working for n+1. We’d be done. Now I’m not gonna get really picky about this, but some people will want you to change the letter here. Because with n we’re talking about general statement that’s supposed to work for all n. And I might switch it to k for the step that [one of the students] was just talking about because I might want to say ‘ok I’m just talking about some arbitrary value (Figure 3). I’m not talking about all natural numbers anymore.’

Figure 3. Example of a representational gesture used by a teacher to illustrate the quantifier “for some arbitrary” (“rigid hands”).

Another purpose of using representational gestures was to attract students’ attention to the logical implication between propositions P(k) and P(k+1). Norton and Arnold (2017) showed that the implication P(k)→P(k+1) may be considered as either an action that transforms P(k) into P(k+1) or as an object representing an invariant relationship between P(k) and P(k+1). Dubinsky (1991) hypothesized that treating implication as a single object is crucial for promoting students’ understanding proof by induction. For this reason, the implication P(k)→P(k+1) deserved considerable attention during the observed teaching episode.

The teacher actively involved hand gesturing to facilitate the discussion on implication between P(k) and P(k+1). Typically, he used his hands in the air to track the trajectory of transition P(k) ↔ P(k+1):

Teacher: I know P(k+1) only in this [motions forward] direction. You can do an induction in both directions. You can try to show that P(k+1) **implies** P(k) (Figure 4).

Figure 4. Example of a representational gesture used by a teacher to illustrate the implication.

The students, in their turn, used similar gestures describing implication.

Teacher: All I see is 1!
Student 1: But it works for all integers.
Student 2: When k is 1 and we know 1 works then P(1+1) works (Figure 5), so 2 works.

Figure 5. Example of a representational gesture used by a student to illustrate the implication.

Metaphoric gestures

Through metaphoric gestures people put an abstract idea into a more literal, concrete form. Metaphoric gestures are similar to representational gestures in that they have a narrative character, but the images produced relate to abstract objects and processes. McNeill (1992) proposed that mathematicians have distinctive gestures for mathematical terms, and that these gestures are "somewhere on the road to a gesture language, but not all the way there" (p. 164). Thus, these are metaphoric gestures, where abstract mathematical objects are situated.

The teacher used metaphor "engine" to informally describe the idea of proof by mathematical induction:

Teacher: … So there's a lot of conjectures y'all been struggling to prove that kinda go on forever. Like that Fibonacci one where every third….umm...element of the Fibonacci sequence is even. And you start going and going and going and you can't go on forever. This [points to inductive implication] goes on forever for you. This is the **engine** that's doing all the work for you. So that's what we want to try to do. Is try to apply this **engine**.

Interestingly, a metaphoric gesture reminiscent of an engine was introduced by one of the students right before the teacher used the metaphor "engine" for the first time:

Student: Then you can plug 2 back in for k and **the logic repeats itself**.

The student revolved his hands around each other to support his idea about the repeating logic. Notably the teacher was not looking at the gesturing student (Figure 6). For this reason, it seems that the teacher *independently* came up with the gesture (Figure 7), which was employed whenever the metaphor "engine" was used.

Figure 6. One of the students is using a revolving hand. Gesturing student is put inside a white circle.

Figure7. The teacher uses hands revolving around each other to address to the metaphor "engine".

Conclusion

In line with prior research (e.g., Alibali & diRusso, 1999; Valenzeno et al., 2003; Singer & Goldin-Meadow, 2005; Abrahamson, 2003; Nemirovsky, Tierney & Wright, 1998)), the teacher and students actively used gestures in classroom discourse, and different types of gestures played different roles in mathematical conversation. This study contributes to prior research by demonstrating how different kinds of gestures played different roles in discourse on mathematical induction. Pointing gestures reduced ambiguity when the teacher was using the words "it," "this, or "that." Using this type of gesture, the instructor attempted to disambiguate the students' conflation between the truth for proposition P(k) versus the implication P(k) → P(k+1). When the ambiguous word "this" was pronounced without gesturing, some of the students immediately became confused. Thus, the study confirms students' difficulty identified in the research literature about distinguishing P(k) and P(k) → P(k+1) (Dubinsky, 1991; Norton & Arnold, 2017), and suggests pointing gestures as an instructional tool for ameliorating this difficulty. Further, the teacher employed numerous representing gestures to draw students' attention to the subcomponents of mathematical induction, such as quantification and logical implication. Some of these gestures were readily adopted by students. Finally, the results confirm the hypothesis that people deliberately employ metaphoric gestures when talking about abstract mathematics (McNeil, 1992; Alibali & Nathan, 2012). In this study, metaphoric gesture of "revolving hands" was independently used by teacher and students when talking about the "engine" metaphor, describing the nature of proof by mathematical induction. Future research may be conducted on comparison other instructors' gestures in teaching proof by mathematical induction.

One Mathematician's Epistemology of Proof and its Implications for her Comments and Marks on Students' Proofs

Igor' Kontorovich
The University of Auckland

Balacheff (2008) offers the notion of epistemology of proof to account for researchers' views on what a mathematical proof is from a teaching-learning perspective. This study argues that an awareness of mathematicians' epistemologies of proof might provide insight into their rationales and actions when teaching university students how to prove. This argument is illustrated by the case of one mathematician who provided comments and marks on proofs submitted by her graduate students as part of her course instruction of topology. A commognitive framework is mobilized to discern the mathematician's epistemology of proof.

Keywords: commognition, mathematicians' pedagogy, proof and proving, topology, university mathematics education

Introduction and Background

In the last few decades, several scholars have recognized that researchers use the notions of 'proof' and 'proving' in profoundly different ways (e.g., Reid, 2005). Balacheff (2008) maintains that these usages come hand in hand with researchers' *epistemologies of proof* and *rationalities*. The former notion captures one's relationship with truth and validity as it determines one's "view of what a mathematical proof is from a teaching-learning point of view" (p. 502). The latter notion is associated with "the system of the criteria or rules mobilized when one has to make choices or decisions, or to perform judgements" (p. 502). Balacheff illustrates research rationality by the choice of a theoretical framework, questions to explore, and methodology. He also argues that awareness of researchers' epistemologies of proof is instrumental in interpreting their research rationalities and findings.

This study extends Balacheff's (2008) perspective beyond researchers and proposes that an awareness of teachers' epistemologies of proof might be valuable for making sense of their proof-related rationalities and practices, including mathematicians' teaching of mathematics to university students. Then comes the question of how mathematicians' epistemologies of proof can become accessible. In contrast to those researchers who explicate their epistemologies in their papers (see Balacheff, 2008 and Reid, 2005 for analyses and examples), there might be not many mathematicians who voluntarily share their well-defined views (Sfard, 1998). One way around this could be to solicit these views through direct questioning (Alcock, 2010; Harel & Sowder, 2009; Weber, 2012). An alternative approach taken in this study assumes that a discourse – talk and practices – that mathematicians propagate in their classrooms can be productively leveraged to construct their epistemologies of proof; if not in an exhaustive sense, then at least to delineate some of its key features.

Let me illustrate the above assumption with university courses that the literature often names 'transition-to-proof' (e.g., Alcock, 2010; Moore, 2016). Even before dwelling on the pedagogies and curricula of these courses, their title tells us something about the epistemologies of the mathematicians who institutionalized them. Indeed, the word 'transition' summons a discourse where the prior mathematics education of students taking such a course is positioned as not having addressed proofs in the same way that this course does. Also, while most mathematics courses are structured around specific content areas (e.g., calculus, linear algebra, topology), this course posits that it is possible to learn and teach proofs as a single content-general activity. (To appreciate the particularity of this position, consider the last time you encountered a course entitled 'transition-to-problem solving' or 'transition-to-definitions'.) I am acquainted with a few mathematicians who reject these positions under the premise that proving is fundamental to all mathematics disciplines, and thus it should be discussed in all content-specific courses. Some of these mathematicians eschew teaching 'transition-to-proof' courses to keep a 'corrupted' practice at arm's length. Such eschewing showcases how teachers can enact their epistemologies of proof even without entering a classroom.

To illustrate the potential usefulness of the extended notion of Balacheff, I explore the *enactments* and *affordances* of the epistemology of proof of one mathematician. The enactments under scrutiny pertain to the written feedback that she provided on students' homework assignments as part of the course instruction. The focus on feedback-providing has been instigated by recent studies arguing for the instrumentality of this practice for students' proof comprehension, capability to write proofs, and development of the notion of proof (Miller, Infante, & Weber, 2018; Moore, 2016; Moore, Byrne, Hanusch, & Fukawa-Connelly, 2016). Borrowing from Hutchby (2001), I associate 'affordances' with "functional and relational aspects which frame, while not determining, the possibilities for agentic action in relation to an object" (p. 444). In this study, the agentic actions are the mathematician's teaching and the students' learning how to prove. The central agent of this study is a practicing topologist whose actions unfolded in a topology course that she taught to a small group of graduate students.

Theoretical Framework

I draw on Sfard's (2008) communicational framework of *commognition*[1] to capitalize on its epistemological and analytical potential. This framework has been widely acknowledged by the international mathematics education community (e.g., Felton & Nathan, 2009; Sriraman, 2009; Wing, 2011), and specifically, by researchers interested in university teaching and learning (e.g., Nardi, Ryve, Stadler & Viirman, 2014). Commognition focuses on *discourses*, which are defined as "different types of communication, set apart by their objects, the kinds of mediators used, and the rules followed by participants and thus defining different communities of communicating actors" (Sfard, 2008, p. 93). Proving, from this standpoint, can be viewed as a constituent of a broader mathematical discourse, where particular routines and narratives are endorsed (i.e. sanctioned as 'proofs') by those who are positioned as a mathematical authority in their communities[2]. This view is in accord with the social perspective on proving as a human endeavor that aims "to persuade the appropriate mathematical community to accept the knowledge as warranted" (Ernest, 1994, p. 34). In a university setting, a communication of this ilk is typical to courses where students are asked to capture their knowledge in texts and submit them for warranting by a mathematician, who is the course representative of a broader mathematics community.

Some scholars expand the original scope of commognition to account for the practices of mathematics teaching (e.g., Nachlieli & Tabach, 2015). Combining this framework with Cultural Historical Activity Theory (Engeström, 1987; Roth & Lee, 2007), Nachlieli and Tabach (2015) define *teaching* as a communicational activity where a pedagogue leads a classroom discourse

[1] The neologism brings to the fore the intimate relations between communication and cognition, which is the cornerstone of the framework.
[2] Sfard (2008) distinguishes between discourses through keywords, visual mediators, routines and narratives. For the purposes of this study, it is sufficient to associate routines and narratives with specific mathematical processes and their outcomes.

with the aim of bringing a change to the individual discourses of the students. Changing one's discourse in a lasting way is a commognitive interpretation for *learning*.

One of the cornerstones of commognition is *objectification*. This term is used to refer to a special way of verbal communication about non-tangibles (e.g., mathematical concepts) as living outside of human discourses, just as their material congeners do. Objectification is achieved through the mechanisms of *reification* and *alienation*. "Reification is the act of replacing sentences about processes and actions with propositions about states and objects" (Sfard, 2008, p. 44). Alienation erases the human agency from a narrative, which results in impersonal sentences (an elaborated example is presented in the section on Dr Brownstone's epistemology of proof).

The Study

Dr Brownstone, who is in the focus of this study, actively participates in (at least) two communities of a mathematical discourse: a research community that redefines the edges of topology as a mathematical discipline; and a course community that, at the time of data collection, encompassed students at the beginning of their professional journeys, while possessing a sizable experience in university-level mathematics already. This study delineates key features of Dr Brownstone's epistemology of proof through attending to its enactments in and affordances to discourses that took place in the course. The delineation revolves around written constituents of these discourses: *texts* that students submitted as a response to homework assignments asking them to prove mathematical statements, and *feedback* (i.e. comments and marks) that Dr Brownstone provided on them.

I report on an explorative case study, the data for which were collected from a one-semester long course in topology that was offered in a large English-speaking university in the Southern Hemisphere[3]. The course was concerned with standard topics in point-set topology (e.g., continuity, convergence, compactness) and in algebraic topology (e.g., covering spaces, fundamental groups, homology theory). Overall, six students participated in the course, four of whom were studying towards post-graduate degrees in mathematics, one student who was completing his undergraduate major in mathematics, and another student who was a beginning university lecturer who, in her own words, "was filling educational holes".

Dr Brownstone is a well-regarded topologist with dozens of publications in professional journals. She has more than a decade of teaching experience in school and university mathematics, and a genuine interest in improving her students' learning. Towards the middle and at the end of a twelve-week long semester, Dr Brownstone designed two homework assignments that were intended for individual solution by the course students. The assignments comprised of four and five problems respectively that asked students to prove topological statements (see Figure 1 for example). The students were given nearly two weeks to complete each assignment, each of which contributed 7.5% to their final grade.

The data for this study came from: (i) written comments and marks that Dr Brownstone provided on students' submissions as part of her course teaching, and (ii) audio-recorded semi-structured interviews that I conducted with her a few days before and after she completed (i). In the one-hour-long session that preceded (i), Dr Brownstone shared her general approach to assessing students' assignments and situated it in the broader set of her pedagogical views. The session ended with Dr Brownstone asking, "So how do you want me to go around [assessing] the assignments this time?" and me proposing that she apply her regular assessment practices. My

[3] This general description is aimed at protecting the confidentiality of Dr Brownstone and her students.

response was driven by the acknowledgment of her teaching professionalism and this study's interest in her routinized teaching practices. When asked a posteriori about how her assessment was different from usual, she replied, "I assessed in a way that I would usually do. Since I knew that we were going to talk about it, maybe I was a bit more detailed in my comments to the students."

Cantor's ternary set, C, is defined to be the intersection of the sequence $C_0, C_1, \ldots$, where $C_0 = [0,1]$ and for $i > 0$, C_i is the union of 2^i closed intervals obtained from the 2^{i-1} closed intervals of C_{i-1} by removing from each of these intervals the open middle third of the interval. Thus

$$C_1 = \left[0, \frac{1}{3}\right] \cup \left[\frac{2}{3}, 1\right], C_2 = \left[0, \frac{1}{9}\right] \cup \left[\frac{2}{9}, \frac{1}{3}\right] \cup \left[\frac{2}{3}, \frac{7}{9}\right] \cup \left[\frac{8}{9}, 1\right], \text{ etc.}$$

Prove that C is homeomorphic to $\mathbf{2}^{\mathbb{N}}$ where $\mathbf{2} = \{0,1\}$ and has the discrete topology, and $\mathbf{2}^{\mathbb{N}} = \prod_{\alpha \in \mathbb{N}} X_\alpha$ where $X_\alpha = \mathbf{2}$ for each $\alpha \in \mathbb{N}$.

Figure 1. A task from the course homework assignment

Once the students submitted their assignments, I marked and commented on their solutions to each problem in parallel to Dr Brownstone and without accessing her feedback. When doing so, I attempted to mobilize a social perspective on proof as a preparatory step to analyzing Dr Brownstone's feedback, which I expected to be driven by epistemologically different perspectives. Then, I systematically juxtaposed both feedbacks through the constant comparison technique (Glaser & Strauss, 1967). To be explicit, by engaging in the same practice as Dr Brownstone, I aimed at raising my own sensitivity to the choices of and rationalities behind the actions that she carried out.

My analysis of Dr Brownstone's feedback started with identifying words and phrases that appeared frequently in her comments and continued to identifying patterns in their usage. The patterns emerged from iterated examinations of the relationships between Dr Brownstone's marks, general-level comments that she provided on texts that students submitted as a response to a problem, and line-by-line comments that referred to particular sentences and inferences that students made. Emerging patterns were contrasted within each assignment and between assignments submitted by different students. Some clarification questions and hypotheses emerged at this stage, and they were discussed through a forty-minute long interview with Dr Brownstone. There, she was asked to elaborate on selected comments and clarify her intentions and messages to the students. These elaborations and clarifications led to another analytical cycle that resulted in identifying preliminary features of her epistemology of proof. These features were discussed with her in another half-an-hour-long interview, which led to additional rounds of analysis and modification.

Dr Brownstone's Epistemology of Proof

I start with central features that were identified in regard to Dr Brownstone's epistemology of proof. The space limitations allow me to give only one example of how this epistemology was enacted. Additional examples will be shared in my research presentation.

Proofs as objects requiring detection and representation

When providing feedback on students' texts, Dr Brownstone extensively used the word 'proof'. While commenting on 'proofs' in the assignments that requested students to prove mathematical statements may seem like the most obvious thing to do, commognition is sensitive to instances where an interlocutor refers to discursive creations as self-sustaining entities rather than to the human actions that produced them. In conjugation with such adjectives as ‘correct’, ‘clear’ and ‘thorough’, ‘proofs’ almost start to sound like material objects that are capable of living outside the course discourse that the students and Dr Brownstone maintained through writing[4]. Such objectified talk also delivers the message that the property of proof-ness is ingrained in the texts that the students submitted regardless of time, place, and the reading audience.

The general-level comments that Brownstone provided were saturated with sentences attesting to the students’ mathematizing. For instance, “you articulate your arguments very well”, “you have a very good grasp of how to accurately express terms”, and “a well presented proof”. Indeed, once a ‘proof’ is treated as an extra-discursive “thing-in-the-world”, the students’ role becomes to “articulate”, “express” and “present” it. Metaphorically speaking, such a relation between ‘proofs’ and students resembles the relation between a client and an attorney: the client exists regardless of the attorney’s actions, but these actions are still of significance in the court of law. In our case, the assignment requests “to prove” mathematical statements ensured the existence of ‘proofs’ regardless of whether students detect them or not. Once detected, the students’ role becomes to represent ‘proofs’ properly, i.e. in alignment with the rules of a literate mathematical discourse.

Interestingly, the interviews revealed that in the course discourse, a ‘detection of proofs’ is not always tantamount to ‘students constructing proving texts by themselves’. There were cases in which Dr Brownstone was convinced that the students were using external resources, such as the internet. Sometimes she even shaped their ‘proof-detection’ by intentionally name-dropping mathematical notions in the formulations of the problems in order to lead students towards particular resources (e.g., a product topology and Cantor set in Figure 1). For example, regarding the problem in Figure 1 she explained:

> I am absolutely sure they used external resources through the problem, and in this particular problem I’m happy with it. Because my goal for them is to understand what is going on with product topology and also get the benefit of finding out a bit more about a Cantor set.

Thus, in some cases, course students were expected to realize the metaphor of proof-detection almost literally.

In the interviews, Dr Brownstone drew parallels between her epistemology of proof in the teaching-learning context and practices that are characteristic to her research discourse. In her words,

> In a sense, I think of assignments as reflecting what you would do normally in a research publication. […] Because there are two elements to a proof, loosely speaking: one, is this spark of insight as the how the proof works – what makes it go through. And the other is writing it down in a logical manner, which supports the idea and makes it true mathematically for the editor and reviewers. So they [the course students] have to obviously have the idea of how the proof works, how you get from here to here. And then, they have to write it down in the way that conveys to me that it is logical.

This excerpt illustrates that in her research discourse, Dr Brownstone also distinguished between detecting a ‘proof’ (“the spark of insight”) and representing it (“writing it down”) for an editor and reviewers. Furthermore, she considers the activity of students submitting written texts for her

[4] In this section onwards, I use ‘proof’ to signal to the readers that Dr Brownstone’s epistemology is under discussion and to remind them that alternative discursive approaches could be used.

assessment as a course counterpart of the research practice of submitting a manuscript to a journal.

Example of implication of the above epistemology

One notable characteristic of Dr Brownstone's feedback pertains to what may seem like a mismatch between the high marks that she allocated to students' texts and the seriousness of their flaws that she pointed out in her comments. For instance, in his response to the problem in Figure 1, one of the students stated that "$2^{\mathbb{N}}$ has a discrete topology", which suggests that any set of infinite binary sequences is open. However, the assigned problem stated that the set 2={0,1} is the one having a discrete topology, while $2^{\mathbb{N}}$ is an infinite product with a conventional product topology. In this way, the chain of logical arguments that the student developed on his way to the desired homomorphism contained a faulty assumption. Yet, he received five marks out of six. When asked in the interview to elaborate on her rationale behind this mark, Dr Brownstone explained:

Dr Brownstone: The components of what he is doing are on the right track. Because he misinterpreted the product topology he is going to fail, he is not about to prove it [the homomorphism] because he is not proving the right thing […]. But the basic idea, the format of his proof is correct, he just misinterpreted the topology on $2^{\mathbb{N}}$, which was one of the things that I was hoping he would take out of this question. […] I must've thought that he did everything else very well because I've taken only one mark off.

Igor': What is "everything else" in this case?

Dr Brownstone: Well, the components of the proof are to describe the Cantor set in a way that you can talk about a bijection with the $2^{\mathbb{N}}$, and then you need to show that it is bijection, and then you about to show that it is open and continuous. But setting up this bijection is key. […] So he has understood all of that but he has misinterpreted the topology on $2^{\mathbb{N}}$.

This excerpt shows that Dr Brownstone expected students' 'proofs' to contain three 'components': capturing the Cantor set in a way that allows manipulation, creating a bijection with $2^{\mathbb{N}}$, and showing that the bijection is continuous and open. These components were evident in the text that the student submitted: he presented a general point *x* in the Cantor set as $\sum_{i=1}^{\infty} \frac{x_i}{3^i}$ (xi∈{0 or 2}), and he introduced a bijective function *F* that matches the set to the infinite binary sequence $\left(\frac{x_1}{2},\ \frac{x_2}{2},\ \ldots\right)$. The assumed discreteness yielded that *F* is trivially open, and then the student proceeded to show its continuity. Accordingly, while he did not prove the assigned statement, he engaged with the expected 'components' of the sought 'proof'.

Dr Brownstone's assessment of Diego's text illustrates a broader pattern suggesting that her marks and comments did not always deliver the same message. Nearly all the marks that Dr Brownstone allocated were either full or one less than full, which might have been read by the students as acknowledging their submissions as high quality. However, the line-by-line comments often pointed at multiple issues requiring the students' attention. In the interviews, Dr Brownstone explained that she typically takes marks off for incorrect arguments, omitted cases, and additional instances where the "proof did not go through". She also explained that "to take more points off would not give students an adequate mark for what they have done". Full-mark texts tended to be accompanied by many comments as well, via which Dr Brownstone sought additional explanations, pointed at confusions with terminology and notation, and raised questions about mathematical entities that the students used without explicit defining.

Commognitively speaking, the comments demonstrated Dr Brownstone enacting her role as a teacher who leads students' mathematical discourses to better align with mathematical rules.

However, her marks signaled that abiding by some of these rules is more important than others. These practices resonate with her epistemology of proof: the issues justifying a mark reduction could be ascribed to detection of expected ‘proof-components’, while other issues pertain to ‘proof-representation’. Stretching the metaphor of a court of law, Dr Brownstone can be viewed as an honest judge who does not punish a client who is innocent (i.e. “a proof that goes through”) even when there are ‘holes’ in the client’s representation.

Concluding Remarks

The theoretical contribution of this study is the expansion of the domain of Balacheff’s (2008) notion of epistemology of proof to include mathematicians – key participants in a discourse through which university students learn how to prove. I use ‘expand’ and ‘include’ to highlight that mathematicians’ epistemologies can come into being through disciplined inquiry (Shulman, 1997) and through the encounter with epistemologies of mathematics education researchers (cf. Barad, 2007). My aim of coupling these epistemologies is two-fold. First, it is intended to afford further research on potential gaps between declared and enacted epistemologies of mathematicians (e.g., Davis & Hersh, 1981; Mura, 1983). Second, epistemological incommensurability of ‘typical’ mathematicians and researchers who keep up with contemporary theories in mathematics education is well known (e.g., Sfard, 2008). The proposed extension turns this incommensurability into an asset that can be leveraged to gain deeper insights into mathematicians’ teaching rationalities and actions.

The extended definition proposes that a mathematician’s epistemology of proof is idiosyncratic. For instance, the detection and representation constituents of Dr Brownstone’s epistemology do not allow it to be labelled as an instance of some ‘extreme’ perspective (e.g., purely Platonist or fully social). However, some of its features resonate with the voices of additional mathematicians. Indeed, it is not rare to find mathematicians who use the objectified ‘proof’, and argue that it should ‘stand alone’ based on its ‘components’ (e.g., Rota, 1993). Thurston (1994) elaborates on the importance of communication of proof within the mathematics community. Accordingly, it is plausible that some aspects of Dr Brownstone’s epistemology are more representative of a broader mathematics community than it could be assumed.

Strengths and limits could be discerned in the enactment of any epistemology of proof, and Dr Brownstone’s one is not an exception. Imagine, for instance, how useful her component-based epistemology would be when instructing students on how to prove a homeomorphism. Also, this epistemology summons an organic marking scheme where points are allocated based on the number of ‘proof-components’ that were detected. According to the presented analysis, the issues emerged when Dr Brownstone endorsed the validity of ‘proof-components’, but she was not fully satisfied with their representation. In some cases, this yield a discrepancy between her comments pointing the student towards all the changes that need to be made, and the full marks that she still allocated to the submission. This case invites further research on how mathematicians’ epistemologies of proof afford their teaching and students’ learning.

Minding the Gaps: Algebra Skills of University Calculus Students

Keri Kornelson
University of Oklahoma

Deborah Moore-Russo
University of Oklahoma

Stacy Reeder
University of Oklahoma

This study builds on existing research detailing calculus students' algebraic errors ("gaps") by connecting data from a standardized, proprietary placement instrument. Results suggest skills that are rarely versus commonly demonstrated prior to calculus. We also report on success and failure for students in the STEM-track Calculus 1 based on the different skills.

Keywords: calculus, algebra, misconceptions, prior knowledge, mathematics placement

National data indicate that about half of freshman who declare STEM majors as they enter college leave these fields before graduation (Chen, 2013). Since most STEM degrees require the completion of at least one calculus course, calculus serves as the gateway course to success in a STEM field. Bressoud, Mesa, and Rasmussen (2015) assert that requiring a calculus course often creates an insurmountable hurdle or, at the very least, one that discourages students from pursuing STEM degrees. Research supports this assertion and has shown that more than half of students are deterred from pursuing a career in STEM due to their difficulties in completing calculus (Crisp, Nora, & Taggart, 2009; Mervis, 2010).

Most university calculus mathematics instructors are aware that students in their courses face challenges. Some of these challenges are related to students transitioning from high school to university mathematics courses (Clark & Lovric, 2009; Seldon, 2005) whether it be due to the difference in cultures of the two environments (Brinkworth, McCann, Matthews & Nordström, 2009; Moore-Russo, Wilsey, Parthum & Lewis, 2017) or the different perspectives that high school teachers have compared to university instructors (Hong et al., 2009). However, some of the challenges are related specifically to how student think about mathematics material prerequisite to calculus (Nagle, Moore-Russo, Viglietti & Martin, 2013). Most calculus students enter college having taken algebra and precalculus in high school (Bressoud, 2015), and may even have performed well in those courses. Still, they enter their university calculus classes with varied and numerous challenges involving algebra content (Cangelosi, Madrid, Cooper, Olson & Hartter, 2013; Reeder, 2017; Salazar, 2014; Top, 2018). Understanding how to navigate the challenges students will face with algebra in university calculus courses should be of concern to calculus instructors and the mathematics education community.

Many universities, frustrated by underperformance in mathematics, are focusing on student success in early mathematics courses in light of placement (e.g., Pleitz, MacDougall, Terry, Buckley, & Campbell, 2015; Revak, Frickenstein, & Cribb, 2000). Many are relying on various data beyond high school grades and course completion to help place students in mathematics courses that are at the appropriate level for them (Ratterree, 2018). Often placement assessment data come from in-house placement exams developed by the college or university, standardized assessment scores such as the ACT or SAT, proprietary assessments (e.g., Accuplacer, ALEKS-PPL), or the combination of a standardized assessment and other criteria (Heiny, Heiny, & Raymond, 2017). Regardless of the assessment, it is common for universities to utilize some method to determine appropriate placement of students in college level mathematics, including introductory calculus, in order to support student success. The purpose of this study is to examine the use of a common mathematics placement instrument to shed light on which algebra skills and abilities align to student success or failure in calculus, first with respect to common errors and second with respect to course outcomes.

Theoretical Framing

To distinguish between knowing a subject and knowing how to teach it (Ball & Bass 2000), Shulman (1986) introduced the concept of pedagogical content knowledge (PCK) as a category of mathematical content knowledge unique to teaching. PCK should be distinguished from subject matter knowledge, general pedagogical knowledge (e.g., understanding of assessment, classroom management, educational aims), and context knowledge (i.e., understanding of the particular educational institution and students). Among other things, PCK involves "… the conceptions and preconceptions that students … bring with them to the learning" (Shulman, 1986, p. 9). Ball, Thames, and Phelps (2008) elaborated on Shulman's earlier work to define three domains within PCK, one of which was the knowledge of content and students (KCS). KCS includes what instructors know about the mathematics to be taught and about the students in their classrooms. KCS involves instructors using their knowledge of students' previous educational experiences, students' emerging and incomplete thinking, and the content struggles that are common to students in their classes to structure instruction so that lectures, discussion topics, tasks, and examples that are implemented in class are appropriate for students.

Simon (1995) based his idea of *hypothetical learning trajectories* on the works of constructivists, such as Cobb and Yackel (1996), indicating that teachers should understand the typical trajectory for their students understanding of mathematical concepts. Simon argues that teachers need to know what path to take with their instruction so as to build on students' prior knowledge. Based on an assessment of students' difficulties learning the subject matter, teachers need to devise a new path, or paths, until the goal is achieved.

Background

Stewart's (2017) recent book features studies that analyze the occurrence of algebra errors by students in undergraduate mathematics courses. They describe categories of algebra mistakes that they found on exams or other assessment instruments. Also included are studies (e.g., McGowen, 2017) that discuss ways to prevent algebra mistakes in more advanced courses. The general consensus is that algebraic errors in calculus, and even more advanced courses, are challenging and require study.

To employ KCS, calculus instructors need to be aware of the algebraic skills that their students demonstrate. Of course, students are individuals and there is not a one-size-fits-all. Still, the general information on common algebra errors would be valuable for calculus instructors in their planning of their instruction, especially in light of the growing popularity of co-requisite instruction (Vestal, Brandenburger, & Furth, 2015). It would be helpful to instructors if they were able to determine how robust students' facility with algebraic skills is and if there are certain areas in algebra that may be more challenging for students than others. A calculus instructor might be inclined to just send the students back to an algebra or precalculus course. However, if students do actually have facility with most of the algebra content, with just a few gaps, then it seems most prudent for instructors to "mind the gaps." We adopt this expression that is commonly announced in the London Underground Subway system (aka the "Tube") for passengers who are boarding the trains but have to navigate the space between the platform and the train. Instructors should be helping students navigate their algebraic gaps so that they are able to board the train to STEM majors successfully. However, this is only possible if those gaps are identified.

For this reason, the current study involves a data set gathered from the mathematics placement instrument administered to incoming calculus students. These data show, in fine-grained detail, exactly which algebraic skills calculus students demonstrated (i.e., they were able to perform tasks related to this skill) on the placement instrument. We compare this information with the algebraic topics where errors are most likely to occur on calculus exams (Stewart & Reeder, 2017). The specific research questions for this study are now listed.

1. Previous research has put forward areas of observed algebraic difficulties in students' calculus work. Which algebraic skills associated with these difficulties are students able to successfully demonstrate during placement into calculus? Which are they not able to demonstrate?
2. Which of the least commonly demonstrated algebraic skills correspond with students who successfully complete the STEM-track Calculus 1 course? Does a student's prior demonstration of the skills that align with frequent algebra errors in calculus correspond with a difference between success and failure in the STEM-track Calculus 1 course?

Methods

Data were collected in fall 2018 at a comprehensive, doctoral-granting university with more than 30,000 students (49% male, 64% white, 48% receiving some need-based financial aid). This study considers only those students enrolled in a STEM-track Calculus 1 class in fall 2018. These students tend to be primarily engineering and natural science majors, including a few math majors, similar to the calculus composition reported by Bressoud (2015). The study only considers those students described above who were placed into the course via the placement instrument and not those who were placed into the course by taking the prerequisite university precalculus course.

At this university, all incoming and transfer students were placed into their first math course after taking a proctored ALEKS-PPL placement instrument. This placement instrument was developed as a product of Knowledge Space Theory, which is deeply described in Doignon and Falmagne (1999). Falmagne, Cosyn, Doignon, and Thiéry (2006) outline the theoretical and historical development of the instrument. The first detailed implementation analysis was conducted by Reddy and Harper (2013) showing that, over several years and hundreds of students, ALEKS-PPL accurately placed students into math courses through Calculus 1. This placement instrument determines a student's abilities on 314 distinct mathematical skills (their "knowledge state") in the areas of arithmetic, geometry, algebra, functions, and precalculus.

The placement instrument returns a knowledge state for each student, i.e. a vector of 314 binary entries, where a 1 indicates students have demonstrated evidence of the mathematical skill and a 0 indicates they have not. If students in the study had multiple attempts at the placement, their maximum scores for each skill were recorded in the data set. Thus, students who demonstrated a particular skill on at least one of their attempts would have been marked as demonstrating that skill. Any students whose data resulted in mismatches in student identification numbers and ALEKS identifiers were removed prior to de-identification. The result was valid data for N=166 students. Altogether, there were 52,124 units (166 students x 314 skills) that were analyzed for the study.

The research team used the work of Stewart and Reeder (Reeder 2017; Reeder & Stewart, 2017, Stewart, Reeder, Raymond & Troup 2018) to identify categories of algebraic errors that calculus students commonly exhibit. These categories include – *simplifying* (SI), *distributive property* (DP), *variable isolation* (VI), *operations with rational expressions* (RE), and *operations with radicals* (RA). A category that is not explicitly algebraic, but that anecdotally results in many calculus errors, was *composition of functions* (CF). For the current study, all six categories were considered.

> **ALGE062:** **Solving a rational equation that simplifies to quadratic: Binomial denominators and numerators.**
>
> **Solve for** x.
>
> $$\frac{x-3}{x-7}+1=\frac{x-5}{x-6}$$

Figure 1: Sample task from placement instrument for the A062 skill in RE (ALEKS/McGraw Hill, 2016).

Using the categories for algebraic errors, the team then reviewed the skill descriptions for the placement instrument (Higher Education Math Placement, 2019) to determine which skills tested by the placement instrument aligned with the six categories (SI, DP, VI, RE, RA, CF). The research team identified 36 skills that aligned. See Table 1 for the matching of these 36 placement instrument skills to the common algebraic error categories. Note that the item codes have been modified from those used by ALEKS/McGraw Hill. ALGE, the code used to refer to algebra, has been replaced with A, and FUN, the code used to refer to functions, was replaced with F. An example of an A062 skill (ALEKS/McGraw Hill, 2016), which we connect to the RE category, is found in Figure 1.

Table 1. Placement skills aligned with the categories of algebra errors observed in calculus exams.

Simplifying	Distributive Property	Variable Isolation	Operations with Rational Expressions	Operations with Radicals	Composition of Functions
A034	A033	A011	A053	A088	F022
A080	A180	A013	A054	A089	
A084	A604	A179	A056	A090	
A710	A606	A743	A057	A091	
A798	A735	A744	A058		
A640	A835	A810	A060		
A811			A062		
			A205		
			A206		
			A620		
			A622		
			A767		

Table 2. Skills from placement instrument, ranked from most rare to most common. Score is the fraction of students (N=166) who demonstrated the skill on the placement instrument. (Higher Education, 2019).

Code	Category	Score	Description Given by Placement Provider
			Rare Skills
A062	RE	0.20	Solving a rational expression that simplifies to quadratic: Binomial denominators and numerators.
A057	RE	0.23	Adding rational expressions with different denominators: ax, bx.
A622	RE	0.24	Adding rational expressions with different denominators: x+a, x+b.
A091	RA	0.24	Solving a radical equation that simplifies to quadratic: One radical.
A206	RE	0.28	Solving a rational equation that simplifies to linear: Unlike binomial denominators.
A767	RE	0.29	Complex fraction simplifying: GCF and quadratic factoring.
A640	SI	0.35	Simplifying a product of radical expressions: Multivariate.
A084	SI	0.36	Simplifying a sum or difference of radical expressions: Multivariate.
A811	SI	0.36	Simplifying a higher radical expression: Multivariate.
F022	CF	0.43	Composition of two functions: Basic.
A088	RA	0.47	Rationalizing the denominator of radical expression using conjugates.
A034	SI	0.51	Simplifying a ratio of multivariate polynomials.
			Common Skills
A058	RE	0.80	Simplifying complex fraction involving multivariate monomials.
A056	RE	0.82	Adding rational expressions with common denominators and binomial numerators.
A620	RE	0.94	Multiplying rational expressions involving quadratics with leading coefficients of 1.
A080	SI	0.98	Simplifying a radical expression with an even exponent.
A710	SI	0.99	Simplifying a ratio of polynomials: Problem type 1.
A735	DP	0.99	Multiplying univariate polynomial by monomial with positive coeff.
A835	DP	0.99	Multiplying a multivariate polynomial by a monomial.
A179	VI	0.99	Solving a linear equation with several occurrences of the variable: Fractional forms.
A744	VI	0.99	Algebraic symbol manipulation (isolating variable in an equation): Problem type 2.
A053	RE	0.99	Multiplying rational expressions involving multivariate monomials.
A054	RE	0.99	Dividing rational expressions involving multivariate monomials.
A798	SI	1.00	Simplifying a sum or difference of two univariate polynomials.
A033	DP	1.00	Multiplying binomials with leading coefficients of 1.
A180	DP	1.00	Multiplication involving binomials and trinomials in two variables.
A604	DP	1.00	Distributive property: Integer coefficients.
A606	DP	1.00	Distributive property: Whole number coefficients.
A011	VI	1.00	Solving a linear equation with several occurrences of the variable: Variables on the same side and distribution.
A013	VI	1.00	Solving a linear equation with several occurrences of the variable: Variables on both sides and distribution.
A743	VI	1.00	Algebraic symbol manipulation (isolating variable in an equation): Problem type 1.
A810	VI	1.00	Introduction to algebraic symbol manipulation.
A060	RE	1.00	Solving a rational equation that simplifies to linear: Denominator x.
A205	RE	1.00	Solving a rational equation that simplifies to linear: Denominator x+a.
A089	RA	1.00	Solving a radical equation that simplifies to linear: One radical.
A090	RA	1.00	Solving a radical equation that simplifies to linear: Two radicals.

In order to also look at the grades the students received in their Calculus 1 course, a college employee (not on the research team) linked placement instrument results and course grades the students in the study. The de-identified data were then shared with the research team.

Results and Analysis

In Table 2, each skill listed in Table 1 is given with a brief description (*Higher Education Math Placement*, 2019) and the fraction of our sample of students who demonstrated acquisition of that skill on the placement instrument. Since each of the 166 students had placed into Calculus 1 via the placement instrument, all had demonstrated many of the 314 skills, so it is not surprising to see many skills that every student had demonstrated.

The skills are listed in Table 2 by increasing order of demonstration by the students (i.e., from the most difficult of the 36 skills that are listed in Table 1, for students in the sample, to the easiest). Interestingly, they separate into two distinct categories. There are 12 skills with scores that are quite low, ranging from 20%-51% of students. We call these **rare skills** for students to have demonstrated prior to calculus. However, the remaining 24 skills have success rates over 80% (13 were demonstrated by every student), so we denote these **common skills** for students have demonstrated prior to calculus.

The rare skills include many from the *operations with rational expressions* (RE) category; see Figure 1 for an example. We also see students having difficulty with topics from the *operations with radicals* (RA), *simplifying* (SI), and *composition of functions* (CF) categories. A large number of students entering calculus had not demonstrated the following crucial skills for calculus: composing functions, adding rational expressions with different denominators, and solving equations involving radicals. Therefore, instructors should look for ways to revisit and review these topics, possibly in a just-in-time approach, to help assist students in gaining acquisition of these skills.

On the other hand, the population had demonstrated every skill relating to the *distributive property* (DP) and *variable isolation* (VI). In these areas, calculus students tend to make errors even though they demonstrated these skills on the placement instrument prior to the course. This implies that an intervention targeting these skills should not focus on re-teaching algebraic content, but rather on mitigating other factors that could be causing mistakes.

Next, we restrict our analysis to the 12 rare skills and ask if any of these correspond with student success in their introductory calculus course. We divided our population into the group of students who completed their Calculus 1 course with an A, B, or C and those who received a D, F, or W in the course. We looked at the fraction from each group that had each of the 12 rare skills. The results are shown in Table 3.

Table 3. Skills from placement instrument by student course success. Score is the fraction of students (N=138 or N=28) who demonstrated the skill on the placement instrument.

Course Grade for Student	N	Skill											
		F 022	A 034	A 057	A 062	A 084	A 088	A 091	A 206	A 622	A 640	A 767	A 811
ABC	138	.44	.54	.23	.20	.36	.44	.23	.27	.25	.34	.31	.36
DFW	28	.39	.32	.29	.21	.32	.61	.29	.36	.21	.39	.18	.36

The results are mixed. We see that half of the skills (A057, A062, A088, A091, A206, and A640) were more commonly demonstrated by students who were *not* successful in the course than among those who were. There were only two skills (A034 and A767) that were clearly demonstrated more often by successful students, both involving operations on rational functions. Even composition of functions (F022) did not correlate strongly with student success. From this, we might conclude that students who exhibit enough skills to be placed into calculus can be successful even if they are initially lacking some key algebra skills.

Discussion

Stewart (2017, p. vii) states that, "as the complexity of mathematical ideas increases rapidly, the unresolved high school algebra problems mount up progressively and continue to create further distress." Our goal in this paper was to identify algebra skills that students do and do not demonstrate prior to entering an introductory calculus course, so that instructors will better understand how to plan instruction so that students are successful. We also wanted to know if students' incoming algebra skills impacted their grades in calculus.

In light of the first research question, we matched the algebraic areas where calculus students most often make mistakes, identified by Stewart and Reeder (2017), to items on the placement assessment. This allowed us to analyze students' prior demonstrated skills in those areas. The matched skills fell into two distinct categories. Some algebra skills were demonstrated by nearly all students; yet, prior research shows that calculus students still make errors in those areas. Other skills were not widely demonstrated prior to the calculus course, identifying areas where instructors might intervene with supplemental instruction.

For the second research question, with the exception of simplifying rational functions, we did not find any correspondence between the least commonly demonstrated algebraic skills and students who successfully completed the calculus with a grade of A, B or C. In fact, when looking at the students who were not successful in the course, those students had demonstrated half of the rare skills in greater numbers than the successful students prior to the start of the course. While it is possible that the skills not yet demonstrated by the students where not of importance for succeeding in the course, another more likely explanation is that the placement instrument accurately placed students who had sufficient backgrounds such that they were able to, for the most part, acquire these skills during the calculus course.

Implications and Future Work

The results of this study help differentiate between skills that are rarely and commonly demonstrated prior to calculus. This information should be useful to calculus instructors as they plan instruction since knowing what students understand and where they are likely to make mistakes is a large part of the KCS used by course instructors. The findings will help calculus instructors mind the gaps. It is particularly vital information for those who work with calculus co-requisite models, that is, implementing remediation of prerequisite material alongside the topics in a Calculus I course (e.g., Vandenbussche, Ritter, & Scherrer, 2018). Future work in this area should consider the extent to which calculus instructors, even those not teaching co-requisite courses, are aware of the algebraic errors that incoming calculus students make to determine how they take this into consideration in their instruction.

Acknowledgements

The authors would like to thank Justin Wollenberg and Matthew Grover, the university employees who gathered and de-identified the placement data used on this project.

Construction of a Mathematics Learning Assistant's Fragile Mathematics Identity

Nancy Emerson Kress
University of Colorado Boulder

This paper shares results of a discourse analysis of an interview with a female student who was working as an undergraduate mathematics tutor and learning assistant. The student is shown to have developed a mathematics identity made up of a strong identity as a doer of mathematics and a weak sense of belonging within her mathematics community. I use robust mathematics identity to refer to a mathematics identity that includes both a strong identity as a doer of mathematics and a sense of belonging in mathematics. A fragile mathematics identity is one in which one or the other of these constructs is not present. This interpretation of these terms is closely aligned with, but slightly different from, the way these terms are used in other literature in the field. This student is shown to have a fragile, rather than robust, mathematics identity.

Keywords: Mathematics Identity, Sense of Belonging, Learning Assistant, Discourse Analysis

Problem Statement, Background and Context

Women and people of color are persistently underrepresented in the field of mathematics. While women make up approximately half the students in college Calculus 1 courses they are much more likely than their white male peers to drop out of mathematics after the first semester of Calculus (Ellis, Fosdick & Rasmussen, 2016). Students of color often experience high school learning environments that are under resourced and do not provide access to high level mathematics courses. These learning experiences can lead to placement into Precalculus rather than Calculus in their first semester in college, a reality that places an additional barrier to continuing in mathematics or mathematics dependent fields of study. Increased use of active, inquiry and reform based instructional practices in college math courses has been associated with greater rates of persistence in mathematics (Freeman et al., 2014; Laursen, Hassi, Kogan, & Weston, 2014), at least through these early undergraduate courses. However, students who are members of persistently underrepresented groups in mathematics continue to describe their experiences in these courses less positively than their white male peers (Voigt, 2017). In order to support a diverse mathematics population to participate in doing mathematics, it is essential to understand the structures that support positive math experiences and pathways for development of robust mathematics identities among members of marginalized groups in mathematics.

The experience of working and helping other students as a tutor or as a Learning Assistant (LA) more generally, may offer a role of legitimate participation (Wenger, 1998) that could potentially counteract some of the marginalization experienced by women and people of color in mathematics and mathematics classes. More specifically, I am interested in learning whether these roles may support development of more robust mathematics identities and hold potential as a pathway to central participation (Wenger, 1998) in mathematics for the LAs themselves. In the longer term, if the experience of working as an LA proves to be positive, and this experience is shown to support development of robust mathematics identities for the students working in these roles, this could possibly lead to a more diverse group of mathematics instructors and to more positive experiences for women and students of color in mathematics courses more generally.

The research question in this article was: How do experiences as a female working as a tutor in the Mathematics Academic Resource Center impact mathematics identity development in ways that afford and/or undermine access to a role of central participation in mathematics?

Literature Review: Understanding Mathematics Identity

Mathematics education research on mathematics identity includes work related to perceptions and understandings of what it means to do mathematics, some of which use the term "identity as a doer of mathematics" (e.g. Boaler & Greeno, 2000; Langer-Osuna, 2011; Park, Kondrak, Ward, & Streamer, 2018), and also work related to the sense of self in relation to mathematics, particularly with regard to gender, race, ethnicity and/or culture, some of which use the term "sense of belonging in mathematics" (e.g. Good, Rattan, & Dweck, 2012; Radovic, Black, Salas, & Williams, 2017; Solomon, 2012).

Identity as a doer of mathematics refers to students' vision and understanding of themselves and the nature of their participation in what they understand to be the practices of doing mathematics. Articles that attend to students' "identity as a doer of mathematics" (Cobb, Gresalfi, & Hodge, 2009, p. 44) include those in which authors use "mathematics identity" more narrowly in reference to people's vision of their ability to do mathematics successfully (Pietri et al. 2018; Nasir et al. 2008) or their decision regarding whether or not to participate in what they perceive to be the practices of doing mathematics (e.g. Boaler & Greeno, 2000). Much of this research attends primarily to the ways such decisions are made, or the social processes through which such visions or identities are formed (Boaler & Greeno, 2000; Langer-Osuna, 2011; Turner, Dominguez, Maldonado, & Empson, 2013), with the primary concern being the degree to which students come to see themselves as what is sometimes called a "math person."

Sense of belonging in mathematics relates to students' sense of being valued as themselves (their racial, ethnic, gender, cultural and class identities are honored) and for their own unique ways of doing mathematics and connecting mathematics to their lives. The term "sense of belonging" is related to Langer-Osuna & Esmonde's category of "membership identity" (2017) which is based on social membership(s) related to race, gender, language, culture, etc. Good, Rattan & Dweck (2012) claim that sense of belonging "involves one's personal belief that one is an accepted member of an academic community whose presence and contributions are valued" (p. 701). The mathematics education research that attends to matters related to sense of belonging addresses how and to what degree students feel fully accepted in mathematics spaces.

The concept of robust mathematics identity is present in a limited number of mathematics education articles. This term appears in the literature to describe mathematics identities that support students' persistence in mathematics through resilience strategies (Joseph, Hailu, & Boston, 2017), resistance to dominant discourses about who does mathematics (Stinson, 2008) and maintenance of high levels of academic achievement in spite of "marginalization, stereotyping and other forms of racialization" (McGee, 2015, p. 599). McGee (2015) also develops the concept of fragile mathematics identity to describe mathematics identities that develop primarily in response and reaction to racialization and racial stereotypes, and which aligns conceptually with mathematics identities that develop in reaction and response to gendered experiences in mathematics. Gutierrez (2018) states that "beyond being seen as a legitimate participant (a "doer" of mathematics), a student should be able to feel whole as a person – to draw upon all of their cultural and linguistic resources – while participating in school mathematics" (p. 1). When I use the term "robust mathematics identity" I am referring to a mathematics identity that consists of both positive identity as a doer of mathematics and also positive sense of belonging in mathematics. I suggest that experiences in mathematics that support students' development of robust mathematics identities may support students to persist in mathematics because of, rather than in spite, of those experiences.

Theoretical Framework

Students who become participants (Wenger, 1998) within their mathematics learning communities take up a form of learning that supports their ability to envision themselves pursuing further study in mathematics (Boaler & Greeno, 2000; Cobb & Hodge, 2002), and social contexts have been shown to impact the ways that people learn and do mathematics (Nasir, Hand, & Taylor, 2008). Students' development of an identity as a doer of mathematics depends on their vision of themselves that aligns with their perception of what it means to do mathematics (Boaler & Greeno, 2000). In other words, students who experience roles as central participants in mathematics learning communities, and whose experiences of doing mathematics in those communities align with their visions of themselves as people, are more likely to develop identities as doers of mathematics and to persist in mathematics or STEM fields of study.

Boaler & Greeno (2000), citing Holland, Lachicotte, Skinner & Cain (1998) and stating that they are building on the theory that "identities develop in and through social practice," use the term "'positional identity' to refer to the way in which people comprehend and enact their positions in the worlds in which they live" (p. 173). This attention to people's positions in the world points to the importance of drawing from research on the sociopolitical nature of mathematics and mathematics learning experiences (Gutiérrez, 2013; Nasir & McKinney de Royston, 2013; Valero, 2004). Aguirre et. al. (2017) state that "a sociopolitical approach allows us to see the historical legacy of mathematics as a tool of oppression as well as a product of our humanity" (p. 125). Taking a sociopolitical perspective enables me to attend to the ways that "people's positions in the worlds in which they live" (Boaler & Greeno, 2000) are related to their positions in the mathematics worlds in which they take part.

Research has demonstrated that members of certain populations (e.g. students of color and women) experience reduced opportunities to participate in the learning and doing of mathematics due to structures which are systematic and pervasive (e.g. Berry, Ellis, & Hughes, 2014; Langer-Osuna, 2011). This restricted access to roles of central participation is accompanied by limitations on access to agentive participation through which people are able to influence the nature of mathematics and mathematics communities. Varelas, Settlage & Mensah (2015) describe agency as a person's capacity to engage with cultural schemas and mobilize resources in ways that did not exist before, creating new contexts and practices (p. 439). This process is central to the capacity of new participants to participate in and shape the nature of mathematics.

This research has taken up sociocultural learning theory to help contextualize how students develop mathematics identities, the nature of such identities as fluid and socially constructed within mathematics learning environments, and the ways that students themselves enact agency over the development of their own mathematics identities as well as mathematics itself.

Research Methods

The Subject and Context of the Interview

The interview which provided the data for this paper was conducted with a white female undergraduate student named Tara (a pseudonym). Tara held a position as a mathematics learning assistant (LA) and, in association with that position, she was working as a tutor in the Mathematics Resource Center (MRC), a context which I will describe in more detail below. Tara was a sophomore at Large University at the time of the interview. She was majoring in mathematics with a focus on secondary education in preparation for teaching and had taken multiple math courses during both college and high school.

The interview was conducted in the MRC, which is a large, open room that is well-lit with large windows where undergraduate students enrolled in mathematics classes can come for tutoring and support. The tutors sit at tables around the periphery of the room, and they each have a sign indicating the name of the course to which they are primarily assigned and available to provide assistance. Each tutoring space has a chalkboard that the tutors often use when providing explanations, and occasionally tutors and students use the chalkboards together as a space to work collaboratively. The interview was conducted during a quiet time in the MRC, and we began by clarifying that students looking for tutoring would take priority, meaning that we would pause the interview, and I would step aside, if any students came by looking for tutoring.

Data Collection and Preparation

The data analyzed for this paper is comprised of a transcription of data from the first 19 minutes of an original audio recording of a 38-minute interview with Tara. The interview segment chosen for this analysis consists of narrative in which Tara describes her mathematical experiences in ways that provide insight into the discursive construction of her mathematics identity. In one segment Tara talks about her own identity as a doer of mathematics and her views about the type of math classes she imagines she would like to teach one day. In another segment she describes some of her experiences as a tutor in the MRC, including her sense that she is not often asked for help and some of her thoughts about the reasons behind that. She also describes numerous aspects of her experience as a female student in mathematics and in her life outside of mathematics communities.

Methods of Analysis

The interview used for this paper was analyzed with the goal of understanding the construction of Tara's mathematics identity, including how Tara makes sense of her role and position within various contexts inside and outside of mathematics. Particular attention was paid to how Tara's mathematics identity was associated with affordances and/or constraints with regard to her access to a role of central participation in mathematics.

My approach to this analysis incorporated "the social psychological tripartite model of identity (Brewer and Gardner 1996; Sedikides and Brewer 2001) into an interactional sociolinguistic framework for the purposes of discourse analysis" (Cohen, 2010, p. 69). Cohen (2010), citing Auer (1992) and Williams (2008), claims that "good interactional analysis can maintain a dynamic view of identity and yet account for the more stable 'brought along' features" (p. 69). This claim highlights the importance of recognizing identity construction as fluid and responsive to social contexts, while still honoring the ways that an individual maintains agency and ownership of their own identity. The tripartite model of identity attends to personal, relational, and collective aspects of identity construction and provides the ability to understand the role of each of these three layers in the construction of identity. This approach enables me to consider how Tara constructs her positive identity as a doer of mathematics relative to personal, "brought-along" experiences, in relation to a specific teacher, and in the collective context of her mathematics education classes. I am also able to consider how Tara's weak sense of belonging in mathematics is constructed personally with regard to how she sees her identity as a female impacting her work as a tutor in the MRC, relationally in reference to interactions with students, and collectively in contexts where she sees very few other female students. This weak sense of belonging is at the heart of Tara's struggle to access a role as a central member of the mathematics community of practice or to develop a robust mathematics identity.

In this analysis I also attend to Tara's use of other contexts outside of mathematics at Large University in her construction of her identity. This portion of the analysis is informed by Modan and Schuman's (2010) work on invoking place in identity construction in which they state, "likewise, the relationships among narratives can be structured through the relationships between the social meanings of the places where the narratives are located" (Modan & Schuman, 2010, p. 85). "More specific to spatial concerns, scholars such as Hill (1995) have shown that speakers use spatial shifts between deictic centers to set up moral geographies in which alignments between people and places set up reputations for both" (Modan & Schuman, 2010, p. 85). Tara explicitly references her high school experiences in an apparent effort to add credibility to the construction of her positive identity as a doer of mathematics, and she makes reference to her sorority in a way that serves as a contrasting image, perhaps illustrating her full membership in a social context where she can enact her identity as a female without restrictions or repercussions.

Findings

Construction of an Identity as a Doer of Mathematics

Personal: Brought along identity as good at math. During the early portion of my conversation with Tara she establishes her view of herself as someone who both likes and is good at math. Her explanation of why she would like to eventually teach high school honors Precalculus includes the statements "'cause I love math" and also "I wanna teach honors trig precalc, it's my favorite math." The following except from the interview transcript demonstrates Tara's confidence in her mathematical abilities while also indicating that her positive identity as a doer of mathematics is, at least largely, "brought-along" from her high school days. Tara is responding to a question about why she thinks she would like to teach honors Precalculus.

> *Tara*: I was always in honors classes and I can, like, relate to those kids a little bit more… A lotta times we're like not the best students because if you're advanced in high school it's usually not 'cause you've worked hard for it, it's because you were naturally born with that gift and so, like, math just comes easy to you,… like I was in honors trig and, like, I never did my homework and still, like, pulled a 98 percent in that class.

Tara constructs herself as someone who was always good at math in high school. In the following segment, however, Tara describes some struggles that she had with Calculus 2:

> *Tara*: In high school my calc BC teacher, and she actually was my calc 3 teacher too, she was a great teacher and people did really well in her class. I struggled, really like every time she explained things it just like … I'm terrible at Calc 2 anyways. It proved to be the same thing in college, even when I put, like, forth, like, a lot of effort. But the way she explained things just, like, never made sense with my mind, and she was so good at math, and so advanced, that, like, she couldn't, like, dumb it down enough for me to be like "oh now I see it now."

The strength of Tara's brought along identity as someone who loves mathematics and is good at doing mathematics is evidenced by the fact that the challenges she faced in her Calculus 2 class do not appear to have undermined the strength of her identity as a doer of mathematics. In her explanation of why she would like to teach Precalculus someday she states, referencing her college coursework, "I've mastered these skills, like it's my fourth year taking classes like this, so, like, how do I, like, go back to, like, when I remembered that I didn't know how to do it."

Relational: A teacher who made it easy to put in effort. Tara's brought along identity as a doer of mathematics is reinforced through her experiences taking Calculus, both 1 and 2, in spite of her claim that Calculus 2 was difficult for her in both high school and college. This strengthening of her identity, at a stage when it could well have been undermined due to her challenges with the content, took place in relation to her positive experience with a particular instructor. She describes some aspects of that experience in the following interview segment:

Tara: Um, I think the biggest one is my Calc 1 and Calc 2 instructor. … if he would have taught Calc 3 this semester, I, I would have been in Calc 3 this semester. But um, I think the biggest thing is that he just, like, was very available to students… and he, like, explained things very clearly and I also think he was just, like, really excited about the material which made you, like, feel more comfortable…. I've had some math teachers, like at (institution blinded), that I felt like I could never go into their office hours 'cause I didn't like them as a person or, like, I didn't feel comfortable going into their office hours, but with him I'd feel comfortable. I took 8 AM math two semesters in a row 'cause I liked him, so definitely, like, he made it easy to put in a lot of effort.

Collective: Math education track. Tara notes an important difference between her experiences in mathematics education courses and those in her other mathematics classes. She states, "since I'm in secondary education, like, there's more women in those classes." Tara's descriptions of her experiences indicate that the only context that seems to support her effort to maintain her brought along identity as a doer of mathematics is her secondary education courses.

Invoking another place: High School. Tara constructs her identity as a doer of mathematics partly around other aspects and details of her life that extend well beyond her individual relationship with mathematics. She shares that "both my parents were math majors at UCLA, and my dad is currently a math teacher at one of the public high schools by me," referring to where she grew up. Furthermore, Tara's personal experiences that have contributed to her strong positive identity as a doer of mathematics occurred mostly prior to her arrival at Large University. She relies heavily on her high school experiences (e.g. "I was always in honors classes" and "I was in honors trig"), much more than those she's had in college, when she makes claims supporting her identity as someone who is good at mathematics.

Summarizing the evolution of Tara's identity as a doer of mathematics. Tara's brought along identity as a doer of mathematics, which was largely developed during high school, is maintained and reinforced through her experience with a university Calculus instructor she liked and enjoyed learning from, as well as through her experiences in secondary education.

Coping with a Limited Sense of Belonging in Mathematics.

Personal: being young and female. Tara talks extensively about her experiences as a female mathematics student. Her descriptions of these experiences shed light on how stereotypes about women in mathematics have limited her sense of belonging in mathematics.

Tara: my first time in the MRC I helped, like, a lot of people, …and then, like, it's definitely died down. I think just 'cause, like … I mean this could be like stereotypical to say, but like, I'm young looking and I'm also like… a female.

Relational: Students in the MRC. Tara's description of the evolution of her experiences as a mathematics tutor lead with her description of her personal identity as a young female, described in the previous section, and this explanation continues with the following observation in relation to students seeking tutoring in the MRC:

Tara: I think, like, that also is like, people who sitting in the MRC are like, "Oh, she's not the first person I'm 'gonna go to," even in the Precalc they're like "I'm 'gonna go to someone else first before I go to her."

Tara continues with additional reflection on the ways that her youthful appearance seems to affect students' willingness to seek and accept her help with mathematics:

Tara: everyone, they're like no way you're older than me and I'm, like, "yah." Like they're, like that is, they're like "yah, I feel so dumb." It doesn't mean anything… like 'cause I'm younger than you, like, doesn't mean anything, so I think a lot of times people associate age with, like, wisdom and, like, knowledge.

Collective: Math classes. Tara's efforts to make sense of her experiences as a female student doing mathematics outside of her education classes reflect an apparent sense of isolation. She notes that, "I have not had a single female math teacher." She also describes the population of women who are members of her sorority:

Tara: there's only two of us who are math majors, um, and there's probably like a handful of us that are, like, engineering…. Since I'm in secondary education, like, there's more women in those classes. …I have a class in the engineering center and like walking to the engineering center I'm like "wow, I only see men right now." …It's more like visual than like people being like "oh you can't do this because you're, like, a female.

Interviewer: Are there ways that, as a group of females in that class, you support each other?

Tara: …in my number theory class it's definitely, like, there's a math major and … she's like "yah, I think our professor likes us cause we're, like, women in the STEM field." …. She's like "there's not a lot of women in my classes" and there's a lot, like, more women in that class, definitely, but I think we do, like, make comments about it sometimes.

Interviewer: What about in the MRC? Do the women, do the other female tutors, are there people that you're friends with? Or not so much?

Tara: We don't really talk about that, 'cause I don't think it comes up that much, 'cause I don't see them that often. But I bet it's on everyone's mind.

Invoking another place: A sorority. Tara's invocation of her sorority provides a backdrop that reinforces her identity as a female and her commitment to performing her gender identity in ways that feel authentic. At no point in her interview does she indicate that she performs her identity differently within mathematics spaces, but rather that her identity as a female impacts the ways that others view her and also affects how she experiences her mathematics classes.

Conclusion

Analysis of this interview data makes clear that working as an LA and/or tutor may not contribute to the development of a robust mathematics identity or to a central participatory role in mathematics; if it contributes to these constructs it does so incompletely or with qualifications. This story serves as a reminder of the power of the hegemony in mathematics communities and the ways that experiences in mathematics among women and students of color that result in persistence in mathematics frequently do so in spite of, rather than because of, those experiences.

I claim that hegemony works in mathematics to perpetuate the current balance of gender and race groups in mathematics, and the homogeneity of the population of people doing mathematics serves to constrain the nature of interaction and collaboration, the strategies and methods for solving problems, and the applications and uses to which mathematics is applied. This work contributes to our understanding of how some students may experience participation in mathematics communities through an in-depth analysis of one particular students' mathematics identity development. This work increases our knowledge about and understanding of the social problem of mathematics as a persistently white male field.

Framework for Characterizing University Students' Reorganization of School Mathematics Understandings in Their Collegiate Mathematics Learning

Younhee Lee
Southern Connecticut State University

In an attempt to address the problem of discontinuity between school mathematics and collegiate mathematics, the current study aimed at characterizing how university students' previous knowledge constructed in school mathematics can be reorganized in their learning of collegiate mathematics. To this end, a construct called transformative transition and its accompanying categorical framework were developed and explained with student data. A transformative transition involves a qualitative leap in existing understandings as an individual encounters a new construct and integrates it into his/her cognitive system. Its four categories—extending, deepening, unifying, and strengthening—delineate different ways in which that qualitative leap might take place. Results from the analysis of interviews with six mathematics-intensive majors revealed that the context in which the participants could actively revisit, observe, reflect on, and interrelate their existing understandings at a higher level and from a different angle helped them to reorganize their school mathematics understandings.

Keywords: Double discontinuity, Unique factorization theorem, Transformative transition

As suggested by Klein (1908/1924), the *double discontinuity* refers to the disconnect that prospective teachers experience as they first encounter college mathematics as students coupled with the disconnect that they experience as they re-enter the school mathematics classroom as teachers. As corroborated more recently (e.g., Cofer, 2015; Ticknor, 2012), in both transitions, their school mathematics understandings can remain isolated from and unaffected by their knowledge construction of collegiate mathematics. The goal of this study was to address the question of "how might university students come to see school mathematics from an advanced viewpoint in their learning of collegiate mathematics?" and to observe, document, and explain important growth in university students' understandings that builds on connections between school and collegiate mathematics.

Teachers of collegiate mathematics can better support their students when they understand how construction of new knowledge can be accompanied by understanding of how the new piece of knowledge can possibly fit into what a learner has previously learned. The current study aimed at characterizing such knowledge development by investigating the ways in which mathematics-intensive majors—i.e., mathematics majors and secondary mathematics education majors—reorganize their school mathematics understandings within teaching interview [TI] context based on Abstraction-in-Context [AiC] framework (Dreyfus, Hershkowitz, & Schwarz, 2015) and abstract algebra content. An empirical merit of the current study is to move forward our discussion of the double discontinuity problem that was centered on a deficit in students' understandings by characterizing meaningful ways students reorganize their existing understanding of school mathematics in collegiate mathematical learning.

Framework

Fundamental to the problem of double discontinuity is the way that individuals construct new knowledge in their learning of collegiate mathematics. I examined the problem through the lens of knowledge construction theories and the literature on the nature and development of an individual's mathematical understandings from which a construct called transformative transition and its accompanying categorical framework emerged. In this study, a *transformative transition* refers to a particular kind of change in one's mathematical understandings that occurs as an individual encounters and integrates a new (to the learner) construct to his/her cognitive system. The change is of a particular kind in the sense that in order for the change to qualify as a transformative transition, (a) his/her existing understandings are transformed as a new construct is integrated into a learner's cognitive system and (b) the transformation involves a qualitative leap in the existing understandings. The use of the word *transition* in the transformative transition has to do with my goal of conceptualizing a notion that contrasts with a transition characterized by disconnection in one's understandings as in the double discontinuity problem.

The review of literature suggested that four constructs (breadth, depth, coherence, connectedness) were commonly used to typify the quality of one's mathematical understanding in the field. The four different qualities of mathematical understanding gave rise to each of the four categories as follows.

1. Extending category: A learner makes a transformative transition by increasing the boundary of contexts in which a set of existing understandings are situated in the individual's mind in the learning of a new construct.
2. Deepening category: A learner makes a transformative transition by increasing the depth level of existing understandings of a certain, single mathematical notion in the learning of a new construct.
3. Unifying category: A learner makes a transformative transition by increasing the extent to which, in the learning of a new construct, seemingly disparate concepts are viewed as instantiations of an overarching idea.
4. Strengthening category: A learner makes a transformative transition by increasing the strength of the link between existing understandings of more than one mathematical construct in the learning of a new construct.

Note that, in this EDUS framework (Lee, 2019; Lee & Heid, 2018), the deepening category captures how one's understandings of a *single* mathematical notion such as function may deepen, whereas the extending, strengthening, and unifying categories capture how existing understandings of *multiple* notions may form a different relationship in one's mind. Figure 1 depicts how each of the extending, strengthening, and unifying might be reflected in the change of the relationship between existing understandings in one's mind.

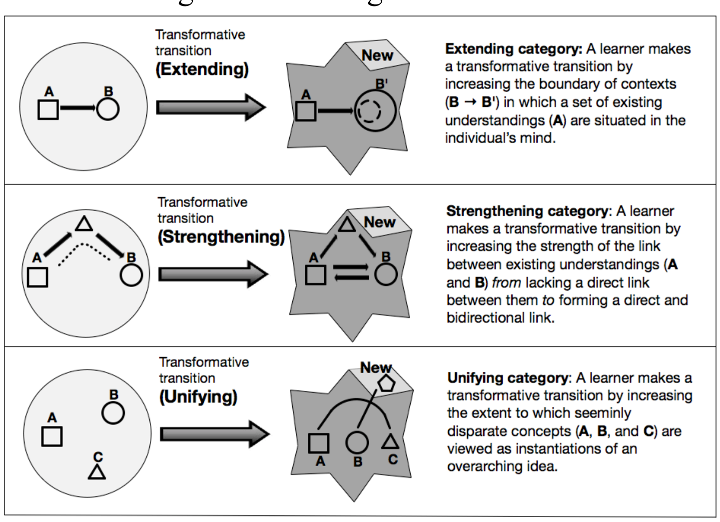

Figure 1. Extending, strengthening, and unifying: Different types of relationship change

To describe a qualitative leap in a transformative transition, levels for identifying student's progress in the deepening category were adapted from APOS theory (Arnon et al., 2014; Dubinsky, Dautermann, Leron, & Zazkis, 1994); for the other three categories, levels were adapted from Piaget and Garcia's triad (1983/1989) (see Table 1). This set of categories with corresponding levels under each category provided a lens to analyze and describe transformative transitions in the current study.

Table 1: Four categories for transformative transitions and levels in each category

Categories for transformative transition	Levels (as descriptors of transformative transition)	Levels adapted from …
Deepening	Action → Process → Object	APOS theory
Extending	Intra → Inter → Trans	Piaget and Garcia's triad
Strengthening	Intra → Inter → Trans	
Unifying	Intra → Inter → Trans	

Due to limited space, this paper focuses on the process of *unifying* and explains the three levels in the unifying category using the mathematical context involving factorization. From a knowledgeable outsider's perspective, a decomposition aspect of factorization can be seen as an overarching notion underlying many different mathematical procedures, such as factoring a whole number, factoring a polynomial, and factorization of a matrix which underlies Gaussian elimination. However, a learner might have disconnected conceptions on factorization of integers and factorization of polynomials and work with them in an entirely different mindset without recognizing an overarching notion underlying them. Such a tendency to work with them in isolation from each other indicates *intra-object level understanding of factorization*.

As the learner begins to coordinate and find similarities between the two factorizations (and, even further, among decompositions of other objects such as functions under composition and matrices under multiplication), s/he comes to understand that some aspects of several constructs can be explained by the same, overarching idea, but it may be still difficult to coordinate all relevant constructs related to factorization in order to produce the desired results in the problem given. This intermediate step of starting to see some similarities but not being able to coordinate them fully indicates *inter-object level understanding of factorization*.

Finally, at the *trans-object level*, when the learner attempts to compare sets of polynomials and integers or to describe his/her meaning of factorization, s/he demonstrates a coherent schema of his/her constructs related to factorization by building his/her explanations on specific overarching ideas which underlie factorization of integers and factorization of polynomials. There exist several overarching ideas that serve as connectors of the two constructs: decomposition, reducible, irreducible, unit, uniqueness of complete factorization, and so on.

Methods

The data were gathered using (a) AiC-based teaching interviews [TI] and (b) pre- and post-TI clinical interviews. To be specific, Hershkowitz and colleagues (2001) define teaching interview as an interview in which the interviewer asks questions with didactic purposes: "(a) to cause [student] to explain what she was doing and why and (b) to induce her to reflect on what she was doing and thus possibly progress beyond the point she would have reached without the interviewer" (p. 204). The design of TI in this study built on an assumption that instructional context grounded in the AiC framework (Dreyfus et al., 2015) can support university students to reflect on and reorganize their school mathematics knowledge in their learning of collegiate mathematics. AiC framework explains construction of new knowledge as the result of vertically reorganizing existing understandings—e.g., discovering regularities in solving different types of linear equations. AiC framework extends the line of research on knowledge construction by providing a model for abstraction process.

To put it simply, their model suggests that a learner's existing understandings serve as building blocks for constructing new knowledge and, through a chain of nested epistemic actions (so called recognizing, building-with, and constructing actions), his/her existing understandings are reorganized to produce a new construct. In their model, a new construct emerges in a problem context in which existing understandings of a learner, as they are, are not sufficient for the problem-solving or fully justifying the learner's own claim. In such a context, existing understandings that were recalled and activated are assembled and reflected in a novel (to the subject) way in building-with actions. In this process, I view that the learner's existing understandings co-develop as a new construct is being developed in his/her constructing actions.

The mathematical tasks in the TI of the current study were designed so that participants can build on what they had previously known about polynomials, factoring, and equation-solving to construct abstract algebra ideas, such as irreducible, reducible, units, and the unique factorization theorem of a polynomial (for example, see CORE-Q4 in Figure 2). Also, in pre- and post-TI interviews, I asked a similar set of questions to observe changes in their school mathematics understandings of polynomials, factoring, and equation-solving before and after a series of TIs (for example, see PRE/POST-Q8 in Figure 2).

CORE-Q4: Please factor completely the same set of polynomials over each of the number systems, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$ and $\mathbb{C}$ and record your results in the following table.

	$P_1(x) = x^4 - 12x^2 + 36$	$P_2(x) = x^5 - x^2$	$P_3(x) = 4x + 16x^3$	$P_4(x) = 12$	$P_5(x) = 4x^2 + 2x - 20$	$P_6(x) = 2x^3 - 10x^2 + 8x$
Over $\mathbb{Z}$						
Over $\mathbb{Q}$						
Over $\mathbb{R}$						
Over $\mathbb{C}$						

How would you describe what happened in this table in a general way? Or, how can you make some general statement about your answers in this table?

PRE-Q8 (and POST-Q8): According to the Common Core State Standards high school students need to *Understand that polynomials form a system analogous to the integers*. In what sense do you think they are analogous?

Figure 2. Examples of Tasks used in TI and pre- and post-TI interviews

Four mathematics majors (Jason, Calvin, Helen, and Andy; pseudonyms) and two secondary mathematics education majors (Sam and Lucy; pseudonyms) at a large Mid-Atlantic university who had not taken an abstract algebra course at the time of interview participated in this study. Each of the participants engaged in five to nine 60-minute interviews. All interviews were video-recorded, transcribed, and coded based on the levels and categories in the EDUS framework. In this paper, however, findings and discussions are centered on the unifying category due to limited space.

Findings

The diagram presented in Figure 3 provides an overview of how participants' understandings of factorization were advanced in (and distributed among) the three levels: intra (U1), inter (U2), and trans (U3). Specifically, five of the six participants (except for Helen) demonstrated understandings at U2 or U3 during POST-TI interviews, whereas only two participants (Jason and Calvin) did so during PRE-TI interviews. This trend of shifting from U1 to U3 implies that participants might have come to view previously disparate ideas (e.g., factorization of integers and factorization of polynomials) as instantiations of an overarching idea (e.g., decomposition) as a result of engaging in the teaching interviews and, perhaps, by participating in the pre-TI interview.

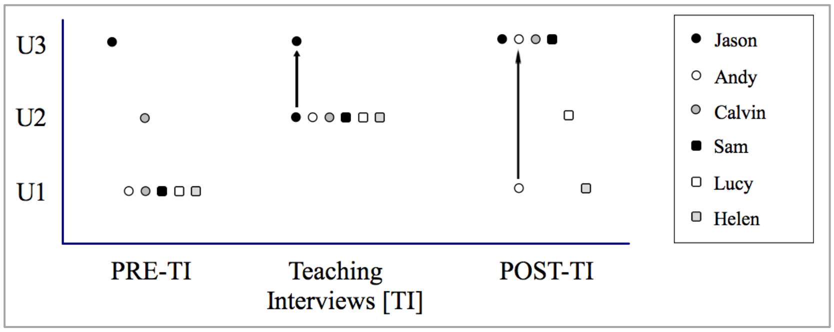

Figure 3. Participants' understandings of factorization with respect to unifying

The current section provides descriptions of transformative transition in the unifying category by building on Jason's, Andy's, and Sam's cases. Although, at a glance, the unifying process might be viewed as a linear process from U1 to U2 to U3, the data revealed that the process is not necessarily linear. Jason's understanding of factorization, for example, shifted from U3 to U2, then back to U3. In **PRE-Q8**, Jason demonstrated his unified understanding of factorization as decomposition, which he applied to the set of integers and the set of polynomials, in order to explain how polynomials form a system analogous to integers (suggesting U3). However, in **CORE-Q4** during TIs, Jason's understanding of factorization shifted back to U2 in his attempt to coordinate the case like $4x$ with the statement that he assumed to be true (i.e., the product of two irreducible polynomials is a reducible polynomial). He attempted to resolve this issue but was not successful at fully coordinating them until he figured out the idea of unit plays a crucial role in avoiding trivial factorization. During TIs and in **POST-Q8**, he concluded "multiplying by units doesn't change reducibility" and observed if a polynomial cannot be reduced in a nontrivial way, it needs to be considered irreducible. This allowed him to explain factorization across different expressions in a unified and coherent way, suggesting Jason's understanding of factorization shifted to U3.

Piaget's constructivist approach to a learner's schema development explains this phenomenon of stepping-back-and-forward as a growth in one's understanding. It is possible when a learner encounters a new experience, the subject struggles to assimilate the new experience and accommodate the existing schema to reach equilibrium status. It seemed that, for Jason, explaining factorization of polynomials with a leading coefficient $\neq 1$ and using the concepts of reducible or irreducible in that explanation was an unfamiliar experience and, through this experience, he further developed his existing schema of factorization with a new component of unit concept. This kind of schema development is a characteristic of the unifying process because the additional component to the schema (i.e., unit idea) allowed him to use it as an overarching idea to see the sameness in complete factorization across different expressions. Hence, the shifts from U3 to U2 to U3 can be considered ultimately a unifying process.

Whereas Jason's unifying process took almost one interview for him to get to a solid conclusion, some unifying processes seemed to happen immediately. For example, an immediate shift from U1 to U3 was observed in Andy's response to **POST-Q8**. The following excerpts show how Andy arrived at a conclusion that "polynomials are, it's a system where they're composed of smaller polynomials just like integers."

Andy: We've talked about this before and I had no idea what that meant [*this refers to the question in* **POST-Q8**].

Interviewer: How about now?

Andy: How about now? Understand that polynomials form a system. [*Andy reads the problem in a whisper*] It still doesn't make sense to me.

Interviewer: Can we think back to what we did so far in our past five interviews?

Andy: Well we talked about factoring, what it means to be completely factored, and over certain domains how things change. So I guess **polynomials form a system, and now it's the integers in the sense that some polynomials can be factored, whereas some integers can be factored**. And some polynomials are composite the same as some integers are composite. So you can have like prime polynomials like you have prime integers. You have composite polynomials; you have composite integers. So **polynomials are–it's a system where they're composed of smaller polynomials just like integers.** There are numbers that are composed of smaller integers. I guess in that sense–they're analogous in that sense.

Andy's explanation about the analogous nature between the set of integers and the set of polynomials centered on overarching ideas such as decomposition, reducible, and irreducible. With the ideas activated at that moment (i.e., polynomials, integers, factoring, reducible, irreducible, etc.), Andy seemed to provide a fully developed articulation about relationship among those ideas, especially about how they are analogous (suggesting U3). However, his initial response, "still doesn't make sense", indicates that what came to his mind first was no association between them (suggesting U1).

From an observer's perspective, one's understanding is only inferable from his/her articulation of the insights into the given problem in the moment. Hence, Andy's understandings as inferred from his articulation in **POST-Q8** does suggest a shift from U1 to U3. However, one might wonder to what extent such an immediate shift from U1 to U3 that skips an intermediate level of U2 provides evidence of a shift in his actual cognitive structure (which is not directly accessible). A possible explanation is that the *sudden* shift from U1 to U3 in Andy's responses could have been the matter of recognizing the relevance between factorization and the problem context of **POST-Q8**, rather than the function of an actual change in his cognitive structure relevant to factorization. Reflection on the past TIs (prompted by the interviewer) could have triggered him to bring in previously established relationships in his mind between factorization of integers and factorization of polynomials.

While Andy's data only *tentatively* suggested a growth of his understanding from U1 to U3, other participants' data suggested more convincing evidence that they came to develop a decomposition view in both factorization of integers and factorization of polynomials (as an overarching perspective). For example, the comparison of Sam's responses to **PRE/POST-Q8** and the data triangulation afforded by his retrospective statements strongly suggested a growth in his understandings. While Sam responded to **PRE-Q8** that he is "not sure how to interpret that standard," his response to **POST-Q8** reflected his overarching understanding of factorization that applies to both the set of integers and the set of polynomials. In **POST-Q8**, he responded, "I think it is saying… that their students need to understand that the set of polynomials and the set of integers kind of carry similar rules." He used examples of irreducible elements from each set, 5 and $x + 4$, to show how the rule of reducibility applies to both. He also explained how factorization similarly applies to both sets as follows: "whenever I see an expression and it gets factored, ... I am going to see now that it was split up into two or possibly more things that can be multiplied together to get back your original expression." This seemingly basic decomposition view that might be helpful to obtain trans-object level, however, may not naturally develop in students.

Several retrospective statements made by Sam (as follows in the bullet points) illustrated an old way he had thought about factorization and suggested his previously held view that separates factorization of polynomials from factorization of integers.

- "I had only ever thought of factoring in terms of polynomials and not in terms of numbers";
- "It was weird to think about [factoring a number and factoring a polynomial altogether] for the first time, I guess, but I'm actually seeing more similarities between the two now than **differences**, now that I think about it";
- "Whenever I saw it like this [*this refers to a problem, "How can you factor 60?"*], the term 'factor' had a much **different meaning** to me than if I was given the quadratic equation."

This indicates his understanding of factorization was at intra-object level originally. It seems possible, in school mathematics, students come to activate different schemas of factorization depending on the appearance/inscriptions of problems that students are solving. The series of questions during the TIs influenced participants to take a much deeper look into factoring and define it more carefully so that it explains all cases consistently and comprehensively. As such, the questioning seemed to have provided a chance for them to develop a coherent and unified approach to factoring in general.

Discussions

Freudenthal (1978/2004) noted that "Mathematics exercised on a lower level becomes mathematics observed on the higher level" (p. 61). This implies collegiate mathematic learning can provide a perfect chance for university students to illuminate their existing understandings from a different angle and reorganize them into a more coherent entity (not only as a chance to construct new knowledge). However, in a lecture-based approach, Hazzan (2001) observed that university students only partially internalized definitions, propositions, and proofs, or reduced the abstraction level of concepts by forcing them into a familiar context. Hazzan noted it was probably so because, from the world of their subjective knowledge, there was little sensible connection to the formally presented definitions, propositions, and their proofs. Based on Hazzan's study, I doubt my participants could have made the same transformative transitions if they were simply given formal definitions of abstract algebra ideas that I used in TIs (instead of constructing their own definitions). Hence, I suggest collegiate mathematics instructors to look for, develop, and integrate in their instruction the context in which university students can actively revisit, observe, reflect on, and interrelate their existing understandings at a higher level and from a different angle, to help them develop their mathematical knowledge into a coherent entity.

This study examined how eight students in an introduction to proof (ITP) course viewed a "cheating scandal" where their peers submitted homework containing solutions found on the web. Drawing on their weekly log entries, the analysis focuses on the students' reasoning about the difference between acceptable and unacceptable use of internet resources in learning mathematics. One pattern was that students' view of the relationship between beliefs about mathematics and the work of learning mathematics grounded their views of "cheating." Specifically, some felt that an implicit didactical contract required that model solutions should be available when one learned new material. The case raises the general issue of the relationship between the process of learning mathematics and the appropriate use of external resources. It suggests that instructors may need to re-examine the role of homework, especially its assessment, in their courses, so that productive struggle is valued, not avoided.

Keywords: Proof, Homework, Academic Integrity

There exists a broad literature on cheating at the collegiate level (Kleiner & Lord, 1999; Lathrop & Foss, 2000; McCabe, Butterfield & Treviño, 2012). Cheating is typically defined as an action of fraudulently deceiving or violating rules, including (1) use of paid or unpaid surrogate to complete assignments or assessments (2) unauthorized collaboration on assignments or assessments and (3) unauthorized coaching on assessments (Lathrop & Foss, 2000). This definition is broadly consistent with those typically printed in course syllabi and that are aligned with university academic honesty policies. According to McCabe and colleagues who led the International Center for Academic Integrity (ICAI) student surveys on academic integrity, 68% of undergraduates admit to cheating on tests or written assignments (McCabe, Butterfield, and Treviño, 2012). According to a 1999 U.S. News and World Reports Study, 80 % of students report having engaged in some form of cheating and 90% of those who reported cheating said they had never felt negative consequence for having done so. One of the factors related to the urgency of the issue is the "shifting sociocultural view on the morality of cheating" (Trenholm, 2007). Trenholm reports that a societal shift in focus towards products (degree, GPA, grade on homework) as opposed to processes (grappling with difficult material until one understands it) provides a context in which cheating is seen more as a pragmatic than moral issue (Kleiner & Lord, 1999).

Though there is a wide literature on cheating in collegiate classes generally, the case of upper division mathematics is of interest because both the nature of the work and the student population differs from the case of collegiate work in general (Smith et al., 2017). The character of out-of-class mathematical work required of students in upper division courses has typically involved the experience of exploring novel tasks and formulating arguments, which is a shift from presenting students with opportunities to practice using concepts or algorithms they have learned in class. Under these assumptions, homework is often allocated a substantial part of course grades to encourage students to spend significant time on working on tasks outside of class time. However, the availability of online sources of mathematical work, both open access and for-profit, has exploded in recent years, making the issue of students' access to these sources an issue for mathematics instructors at all levels when they design and assess student work. Understanding what students say about the phenomenon can help instructors of such courses consider how to re-shape their courses so as to respond to both (1) the learning needs of their students around the role of the work of others in learning mathematics and (2) the reality that so much of the traditional canon of problems exists now online, both for free and for purchase.

Setting

This paper considers data of students making sense of the phenomenon of "cheating" by using unauthorized online sources and turning them in as their own within an Introduction to Proof (ITP) course at a large midwestern university. The data was collected as part of a larger NSF-funded grant that involves collecting longitudinal data on a sample of mathematics students as they progress from their ITP course through their upper division mathematics coursework.

The project seeks to understand how ITP students navigate challenges such as completing homework sets that demand a different kind of organization of work and a different character of mathematical work than they have engaged with in the past. In particular, we are interested in the growth and development of students' autonomy and agency in their mathematical work as they navigate upper division coursework in mathematics. Thus, when it became clear to the instructors and the research team how widespread the practice of using unauthorized online sources was in the class (upon scrutiny, every section turned up multiple instances of the use of unauthorized, paid, internet sources on one homework set), we sought to understand students' perspectives regarding the use of online sources for homework.

To give some context for the analysis in this paper, about halfway through the semester (following a particularly long homework assignment), one of the instructors for the course alerted the instructional team that four students had turned in exactly the same solution to a homework task. The solution differed from the previously distributed solutions and the instructor suspected that the online student work subscription service Chegg was the source of the work in question. In response, the course coordinator and instructors opened their own Chegg account in order to monitor activity on the site around the homework questions and to assess the depth of materials available on the site. They confirmed that Chegg was the source of the suspicious student solutions in question and then systematically examined other papers for similar anomalies. Accordingly, the instructional team decided to change the homework grading policy for the remainder of the semester by focusing on homework completion.

The syllabus for the course contained two explicit academic integrity statements. The first statement came from the university code of honor: "I will strive to uphold values of the highest ethical standard. I will practice honesty in my work, foster honesty in my peers, and take pride in knowing that honor in ownership is worth more than grades." The second came from the course Academic Honesty statement: "…unless authorized by your instructor, you are expected to complete all course assignments, including homework, lab work, quizzes, tests, and exams, without any source… Students who violate academic integrity rules may receive a penalty grade, including a failing grade on the assignment or in the course."

In one section of the ITP class, an instructor explicitly talked with students in his section (one of five) about the academic honesty policy in the syllabus, while also encouraging joint work and collaboration outside of class and emphasizing the need for students to come away from a collaborative work experience with a personal understanding. One other section was observed by the project team to have had a similar discussion, if brief, about the intentions and role of out-of-class collaboration in completing class work. By design in this course, students had ample access to external supports: access to a mathematics learning center (MLC), the online platform Piazza, and instructor office hours. In addition, they had access to an extensive "examples document" that provides the tasks worked on in class. Further, the solutions to each assignment were released immediately *following* students turning it in.

Participants

The eight focal participants for this analysis come from two sections (of five) of the ITP course. With respect to the topic at hand, we have the most detailed evidence from these students' homework logs. As part of our broader project goal focusing on students' experience in ITP courses, our participants regularly wrote reflections about their process of navigating challenges in the ITP course. Thus, when the cheating scandal broke, we added a reflection entry prompting them to offer their views of it. The text of our prompt appears in Figure 1. Additionally, we also have corroborative evidence from regular observations conducted during the semester and interviews with the course coordinator.

> In posing these questions (below) to you, I am <u>not</u> asking how you personally choose to use or not use information from the web. I am interested in your views of the issues involved.
> - Do you think that looking on the web for solutions to homework problems and submitting them as your own work is "cheating"? Why or why not?
> - What do you think of the reasoning of the instructional team (including your instructor) that including someone else's solution does not help you prepare for the exams?
> - What do you think about the penalty imposed for "cheating": zero for the homework and you can't drop that particular HW grade?

Figure 1. Prompt given to students inquiring about their views on "cheating" and use of external resources.

As suggested by the questions we asked them (above), we were interested in (1) nuance in their perspective around using online sources, (2) the role of homework in learning the course content with some degree of autonomy (indexed by preparedness for exams) and (3) their perspective on the instructional response in the ITP class, including alternative options.

Theoretical Framework

In teaching mathematics, students, teachers, and other stakeholders associate expectations with what mathematics is taught and how it is taught (i.e. obligations that each undertakes and benefits from, and the means by which they envision satisfying the obligations, as well as the consequences for not satisfying them). A *didactical contract* is an interpretation of the set of these expectations and obligations (Brousseau & Warfield, 2014). We view our observations and interviews as providing different and complementary windows into the didactical contract in effect in one particular introduction to proof course. Further, we propose that this theoretical tool is a useful lens for examining students' interpretations of their rights and responsibilities more broadly.

Speaking to the source of these rights and responsibilities, many development researchers have distinguished between heteronomy and autonomy in moral reasoning (Kohlberg, 1976; Piaget & Inhelder, 1969). Heteronomy is the orientation that the source of direction for right behavior comes from dictates or principles from outside (e.g., an adult, parent, or recognized powerful authority). Autonomy, by contrast, is the view that the source of guidance for right behavior is the individual's own principles or sense-making. In the present context, we have external authority that is represented by the university guidelines for academic honesty/dishonesty outlining what is acceptable and unacceptable practice in completing and presenting one's academic work. These guidelines were developed well before the emergence and wide use of "internet resources" like Chegg. On the other hand, students in this course had access to many related sources of "good mathematical reasoning" on specific tasks (e.g., guidance from instructors in the MLC and office hours). These "legitimate" sources of the content and format of "good proofs" raise reasoning challenges for students: What distinguishes acceptable forms of assistance from unacceptable?

Analysis and Findings

For each prompt, participants' responses were grouped into thematic units that captured the essence of each part of their responses to the questions. Following the initial process of thematic grouping, the themes were re-organized to collect common themes across participants together. In this way, the analysis converged on a set of common themes that still preserved the essence of the diversity of themes represented in the data. The first issue our analysis addresses is the range and variability around where participants drew the line around what constitutes acceptable versus unacceptable use of internet resources. A second focus is the source of morality in terms of the role that external directives versus internal convictions played in students' reasoning about what constitutes acceptable/unacceptable behavior. A third focus is how students conceptualized the relationship between learning/understanding and internet resources. Students' logs also prompted them to consider the instructional response in their class, and some went on to discuss their perspective on potential instructional responses that address the issues of fairness and learning. Our analysis of students' perspectives provides a springboard into the discussions and conclusions of this paper, including potential instructor responses to the reality of resources like Chegg being part of the instructional ecology.

Defining Boundary Conditions

To give a sense for the complexity of students' reasoning about what constitutes cheating, consider a vignette that participant G made up to help himself think through the moral issues involved in the use of outside resources in homework completion:

> "Student A and B both go to MLC at the same time, working on the same problem such that the same teaching assistant helps both of them on the problem at the same time on the blackboard. Student A just continues writing on his own, while student B is copying what he saw. Then student C comes in, and without asking anything, but only reading what is on the board, he gets the answer. Then TA teach[es] the same stuff to student D who comes in later. They all have the same way of proof. Suppose that student E saw the work, not on the board but on a website instead, and complete his homework. Who is cheating?"

All eight participants responded with nuance around the issue of using internet-based resources for homework, all citing conditions under which using internet-based resources would and would not be considered cheating. For most, the important distinction was whether a student engaged in original thinking in using the resource, especially after having gotten stuck in working on one's own (participant M) and "not brainlessly copying down answers" (participant F, with a similar sentiment in the logs of participants O, K, G, H, D, M, N). Under the condition that one is not intentionally copying for the purpose of passing off another's work as one's own, participant K went so far as to say that looking [online] for an answer and using it to get one's own can even be better than powering through on one's own. With respect to the use of particular resources, one student explicitly discussed Chegg as a "gray area" (participant N) because it is a paid service as opposed to a public one, where two others found no problem with Chegg because it is a resource that students theoretically have available to them (participants F and D). One participant (M) preferred getting help from resources tied to the course such as Piazza or the Math Learning Center to seeking assistance online. However, M's reasons concerned the lack of information about how one's specific instructor grades proofs. Participant F offered a contrasting view where internet resources were preferable to use when stuck because they were anonymous and didn't bother the professor, teaching assistant, or other students.

Internal Versus External Orientation Concerning Impact of Copying

Participants were divided in their focus on whether copying could help/hurt with *external performance* (participants H: "problems on exam could be different so copying can hurt", O: "getting closure on HW problems could help solve future problems", G: "looking at others' solutions can help you prepare"). Instead, other participants focused on the negative impact of copying on personal understanding (e.g., N and F). The preparation issue extends beyond the academic context. Some students appeared to be skeptical about whether finding other solutions undermines preparation, for the class, but also more generally in the world of work. For example, consider the following segment from a classroom observation completed just after the use of Chegg was discovered:

> At the beginning of class, a male student is discussing differences between working in industry in academia with his peers. He claims that 90% of students in the class will be going into industry. Another student argues that it is ridiculous that everyone in industry uses calculators and googles things – why are calculators not permitted in classes? A third student then claims that the professors in this class keep saying that they need to go through rigorous and technical proofs, but in industry people just google things. The student recognizes that in academia people need to come up with new stuff that can't just be googled. However, why can't we use google since 90% of us are going into industry [referring back to the first student's claim]. People use computers and "cheat" all the time. He closes by agreeing that the situation [of not being allowed to use internet resources] is kind of annoying.

Connections between views on internet resource usage and views of mathematics learning

Explicit in two students' logs (O and D) were references to using online sources in order to obtain models for the purpose of understanding assigned problems. Participant O went so far as to say that if one had not been taught specific techniques to solve assigned problems then one "had" to google the problem in order to find out what techniques they should use. Such an assertion belies a commitment to the view that mathematics learning involves merely learning to apply a suite of algorithms or techniques appropriately. That is, assigning tasks for which one needs to develop a chain of reasoning or a technique that has not been explicitly taught is seen as a violation in expectations about the nature of mathematics learning (and thus, what mathematics teaching should entail). The purpose of homework in this model of teaching and learning is to practice known techniques. While O's log was notable for its explicit invocation of this view, this perspective on mathematics learning has been a common theme in our prior interviews of ITP students reflecting on the differences between their lower division mathematics experience and proof-intensive upper-division courses (Author, 20xx). In contrast to O's perspective, participants H, M, and K invoked the perspective that mathematics learning is about engaging in reasoning and thus copying solutions from the internet undercuts the purpose of the course (reasoning). Two other students (F and N) thought copying solutions was detrimental to learning (participant N: Chegg is bad for learning because you are not truly synthesizing the material; participant F: Writing new solutions is helpful because you recognize how to solve new problems in the future). However, the nature of "understanding" was never unpacked further in these students' logs. Thus, it is possible they believed that copying using Chegg doesn't help one learn the material, but that "learning the material" still could focus on known algorithm application.

Views on Instructional Response

With respect to our third question, participants were split on their level of sympathy to those who engaged in using unauthorized internet resources. Some (D and F) offered reasons why students may engage in this behavior (participant D: "necessary" if one can't make it to office hours; participant F: helpful to get closure if one is struggling, especially when the grade is based on correctness). Participant G remarked that students cheat because they want their grades, and they already don't have enough time for their work and sleep. When the homework seems too hard and there is no help through sanctioned methods on the weekend, then students naturally turn to the internet. In contrast, participant K was strongly unsympathetic to those who had been caught with copied solutions because of inequity in grading relative to students who had been playing by the rules. One theme that repeatedly emerged was students' worry over whether it could be possible for a student to be falsely identified as cheating when, because there is a canonical proof approach, their work could look like someone else's or an online source (H, O, and K). With respect to the move to completion as opposed to correctness grades, K remarked that he still planned to give his best effort on subsequent homework, and the move to completion made him feel like he didn't have to get everything exactly right. (However, we note that in a later interview with K, he mentioned that in practice, he had been less motivated to put in as much effort on the homework following the shift to grading for completion).

Discussion and Conclusions

Instructors may assume that students and instructors have a shared understanding of how to appropriately use sources, cite sources, and collaborate. Our modest analysis shows that these issues are more nebulous and complex for students than they may appear on the surface, especially as pertains to their work in upper-division mathematics, which has a different character than their lower division coursework and also other courses that require academic writing. A discussion of student reflections on cheating is important for course instructors because without it, instructors might try, as one TA did, to admonish their students to "Stop cheating!" However, this approach is unlikely to be successful because students may (1) honestly not know how to think about the role of the work of others in their learning activity in upper division courses and (2) it leaves completely open what exactly the students are supposed to stop. In fact, without further elaboration, instructors could be admonishing students to stop forms of activity that may actually be instrumental in their learning. Indeed, our participants did by and large seem to agree that a boundary around acceptable usage is that some understanding of the proof had to be generated by the student through sense-making. Backwards engineering or processing a proof that they found was different in their view than "brainless copying."

Since students have access to written academic integrity policies and many other forms of external guidance and yet copying solutions persists, we do not believe the most effective response is to make sure students understand the ground rules about what is and is not sanctioned. Instead, our perspective is that platforms such as Chegg are a part of the ecology of resources available to students that we need to be aware of and be more proactive in engaging with and designing experiences for students that still achieve our goals and maintain a level playing field. In a similar vein, Lang (2013) urges professors to move away from considering the dispositional factors that may make cheating more likely and instead focus on contextual factors that influence cheating. In his synthesis of cheating at the collegiate level, he identified four classroom-level conditions that can induce cheating: (1) Emphasis on performance, (2) High stakes on the outcomes of the performance, (3) Extrinsic motivation for success and (4) Low expectation of success.

The work of Mejía-Ramos et al. (2012) in delineating a framework for assessing proof comprehension provides some ideas in the direction of other forms of questions instructors can ask that tap into a deeper synthesis of the material than the commonly employed approach of asking students to reproduce complete arguments (that may be more possible to search and copy wholesale from the web). Asking students more open-ended questions or to generate their own questions can both quell cheating and also communicate a different image of the discipline to them—that they *should* be asking questions. With references to the findings of the analysis, it is worth considering whether extensive access to "model" tasks (as was the case in this particular ITP course) has the effect of reifying a view of mathematics learning as being primarily about learning to recognize and adapt model solutions. This is particularly salient in a course like Introduction to Proof where one of the meta goals for the course is to prepare students to engage in productive struggle (Hiebert & Grouws, 2007) and to become more comfortable grappling with tasks for which they will *not* have a model solution to base their work on.

In the context of collegiate mathematics, and calculus in particular, Reinholz and colleagues have been experimenting with a technique called Peer-Assisted Reflection (PAR) (Reinholz, 2015; 2016). Empowering students with the responsibility as a class to generate their own criteria for what makes a good proof and then engaging students in judging the quality of their own proofs or proofs of their peers may help shift disciplinary authority to the students. While turning in assignments and receiving a score can communicate that the teacher decides what is and is not good mathematical work, the PAR approach can help students self-assess their own work, understand flaws in work they might encounter on the internet, and also send the strong and disciplinarily authentic message that grading and proof quality is not a judgment up to the mercurial whims of one professor.

While this study is modest in its scope, it is hoped that it will spark a discussion about the ways in which upper-level mathematics instructors can respond to the fact of the widespread availability of solutions on the internet in ways that promote the learning goals of these courses.

A Conceptual Analysis for Optimizing Two-Variable Functions in Linear Programming

Biyao Liang, University of Georgia
Yufeng Ying, University of Georgia
Kevin C. Moore, University of Georgia

Secondary mathematics curricula predominantly present linear programming by introducing the corner point principle and formulating steps for a solution. The teaching and learning of this topic often overlook justification for the principle and procedures. Drawing on six clinical interviews with an in-service teacher, we illustrate how her covariational reasoning supported conceiving quantities' multi-variation entailed by an objective function and its constraints (a system of inequalities). We build upon this teacher's understandings to propose a conceptual analysis for optimizing two-variable objective functions in the context of linear programming.

Keywords: Linear Programming, Two-Variable Function, Covariational Reasoning

A linear programming problem is a common type of optimization problem in mathematics. Secondary mathematics curricula often introduce linear programming in two-dimensions that involves finding the maximum or minimum value of a two-variable linear function under a domain restricted by a system of two-variable inequalities. Undergraduate mathematics curricula expand this type of problems to *n*-dimensions, which requires more complicated algorithms (e.g., numerical optimization methods) to locate optimal solutions efficiently. Regardless, linear programming is a rich context for creating problems that provide students opportunities to apply mathematical knowledge to model authentic real-world situations.

Despite its merits, linear programming has received a general lack of attention from the mathematics education community. Understanding and solving linear programming problems at a secondary level requires a student to draw on a web of mathematical ideas, including finding intersections of two lines, reasoning with multi-variations of quantities, representing quantitative relationships (both inequality and equality relationships) algebraically and graphically, and so on. In this paper, we focus on the optimization of two-variable objective functions. In particular, we expound upon the question: *What mental actions and operations are involved in constructing productive meanings for optimizing an objective function?* By "productive," we refer to meanings that allow an individual to provide a justification for why a procedure works and that allow an individual to make sense of a variety of situations and ideas in coherent ways.

Background

An objective function in the context of two-dimensional linear programming is a two-variable function in the form of $z = f(x, y)$, where $f(x, y) = ax + by$. Throughout this paper, we maintain the convention of treating x and y as representing input values of the objective function and z as representing output values. Given extant literature on students' difficulty with coordinating two co-varying quantities in various contexts (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Castillo-Garsow, Johnson, & Moore, 2013; Johnson, 2015; Moore, Stevens, Paoletti, Hobson, & Liang, 2019), we conjecture it is also challenging for students to simultaneously coordinate three quantities and anticipate the variation of value z in relation to the covariation of x and y, given the coefficients a and b. Moreover, reasoning with an objective function in the context of linear programming is more cognitively demanding because it requires an individual to go beyond describing quantities' multi-variation qualitatively to locate the optimal output of the objective function under certain constraints of x and y.

Extant secondary curricula often simplify the treatment of this topic as evaluating an objective function at corner points of a feasible region and comparing their outputs, often called vertices method (Figure 1, left) (e.g., Larson, Boswell, Kanold, & Stiff, 2001; Long & Ashley, 2008; Ryan, Doubet, Fabricant, & Rockbill, 1993; Senk et al., 1993). An underlying assumption of this approach is the *corner point principle*, which states that if there is a unique optimal solution to a linear programming problem, it must lie at a vertex of the feasible region. Most secondary curricula omit the proof of this principle and, instead, formulate steps for a solution using the vertices method (e.g., Larson et al., 2001; Long & Ashley, 2008; Ryan et al., 1993). One deficiency of this treatment is that it does not focus on the logico-mathematical operations (Piaget, 1976, 2001) that will afford students understandings of properties of the principle (e.g., why is it sufficient to only attend to corner points but not other points in the feasible region?).

Another approach introduced in textbooks and literature is parameterizing the value z and graphing a family of parallel lines (or level curves) of $y = -\frac{a}{b}x + \frac{z}{b}$, where $\frac{z}{b}$ is the y-intercept of the line (Figure 1, middle) (Edwards, Chelst, Principato, & Wilhelm, 2015; Fey, Hirsch, Hart, Schoen, & Watkins, 2009; Moon, 2019; Ryan et al., 1993; Senk et al., 1993; Shama & Dreyfus, 1994). Each line represents a collection of x-y pairs that satisfy the relationship for a fixed z value. Hence, the optimization problem is transformed into finding the x-y pair(s) that allow(s) the level curve to have a maximum or minimum y-intercept (and, thus, z). A third approach is visualizing the feasible region and the objective function in a three-dimensional coordinate system and describing the optimal solution as existing on the maximum (or minimum) vertical projection of the feasible region (Figure 1, right) (Brzezinski, 2017).

Detailed analysis and comparison of these methods are beyond the scope of this paper, and we consider each approach can be productive if students understand its rationale and underlying quantitative meanings. In the following, we aim at proposing an alternative approach to optimizing objective functions from a covariational perspective and discussing its affordances.

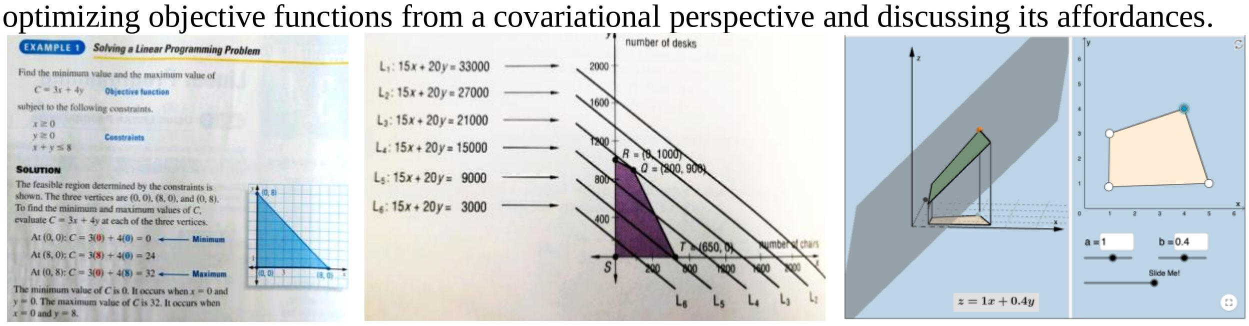

Figure 1. Curriculum examples of the vertices method (Larson et al., 2001, p. 164), level curve method (Senk et al., 1993, p. 288), and 3D graph method (Brzezinski, 2017).

Methodology

We adopt the epistemology of radical constructivism, believing that each individual constructs her or his knowledge in ways idiosyncratic and viable to herself or himself. We do not have access to anyone else's personal knowledge and, at best, can construct *hypothetical models* of others' knowledge that prove viable in our interactions with them. In proposing the following *conceptual analysis* (Thompson, 2008), we draw on our models of an in-service teacher's thinking and hypothesize productive meanings for optimizing objective functions based on our interactions with her. Specifically, the first author conducted six one-hour long clinical interviews with Jaime, who graduated from a secondary mathematics education program in the southeastern United States. At the time of the study, Jaime had completed her first year of full-time teaching at a public high school. Over the year of her teaching, Jaime taught Geometry

Support and Accelerated Geometry/Algebra II, and linear programming was the last topic of Algebra II. The interviews occurred during the summer following her first-year teaching. The interviewer started by asking Jaime to discuss her lesson goals, tasks used, and experience with working with students, and then shifted to ask her to engage in novel problems. While we acknowledge that such interactions could result in shifts in Jaime's thinking, our goal with the interviews was to interact with her in ways that focused on her mathematical meanings. Namely, although the interviewer continually attempted to elicit and perturb Jaime's thinking in order to construct a profile of her available meanings, she did not attempt to support Jaime in reconciling her experienced perturbations by providing systematic intervention to engender learning.

In reporting on our results, we primarily drew on Jaime's activities in two tasks (Figure 2): (1) A Trip to Sugar Bowl, a task Jaime used in class, and (2) Election Advertising, a task we adapted from the Core-Plus Curriculum (Fey et al., 2009).

Task	Solution
A Trip to Sugar Bowl. A tourism agency can sell up to 1200 travel packages for the Sugar Bowl college football postseason game in New Orleans. The package includes airfare, weekend accommodations, and the choice of two types of flights: a nonstop flight or a two-stop flight. The nonstop flight can carry up to 150 passengers, and the two- stop flight can carry up to 100 passengers. The agency can locate no more than 10 planes for the travel packages. Each package with a nonstop flight sells for $1200, and each package with a two-stop flight sells for $900. Assume that each plane will carry the maximum number of passengers. *What is the maximum revenue for the given constraints and give the combination of flights that achieves this maximum?*	x=number of nonstop flights; y=number of two-stop flights **Constraints**: $x + y \leq 10$; $150x + 100y \leq 1200$ **Objective function**: $P(x, y)$ $= 1200 \cdot 150x + 900 \cdot 100y$ **Optimal solution** occurs at $(x, y) =$ (8,0) and $P(8,0) = 1200 \times 150 \times 8 + 900 \times 100 \times 0 = 1{,}440{,}000$  Note: Due to certain reasons, Jaime set up the objective function as $P = 1200x + 900y$, which corresponded to an optimal solution of (4,6). We discussed the following data in terms of her solution.
Election Advertising. When candidates plan their campaigns, they have choices to make about spending for advertising. Suppose that advisers told one candidate that radio and television ads might reach different audiences in the following ways: • Every dollar spent on radio advertising will assure that the candidate's message will reach 5 Democratic voters, 2 Republican voters, and 4 Independent voters. • Every dollar spent on television advertising will assure that the candidate's message will reach 4 Democratic voters, 4 Republican voters, and 1 Independent voter. The candidate's goals are to reach at least 20,000 Democratic voters, 12,000 Republican voters, and 8,000 Independent voters with a minimum total advertising expense. *What is the advertising plan that can minimize total advertising expense? What is the expense?*	r=dollars spent on radio; t=dollars spent on TV **Constraints**: $5r + 4t \geq 20{,}000$; $2r + 4t \geq 12{,}000$ $4r + t \geq 8000$ **Objective function**: $P(r, t) = r + t$ **Optimal solution** occurs at $(r, t) = (2666.67, 1666.67)$ and $P(r, t) = 2666.67 + 1666.67 = 4333.34$ 
Figure 2. A Trip to Sugar Bowl and Election Advertising.

The Case of Jaime

In this section, we illustrate Jaime's meanings for optimizing objective functions in three aspects: (1) her meanings for the relationship between an objective function and its constraints, (2) her meanings for the corner point principle, and (3) her meanings for an optimal solution in relation to quantities' amounts of change. We note that our intention is to provide vignettes of her thinking that inform the conceptual analysis we will propose in the next section; our intention is not to depict a development or progression of Jaime's thinking during the six interviews.

Relationship Between an Objective Function and its Constraint

In A Trip to Sugar Bowl, Jaime discussed her meanings for the objective function, $P = 1200x + 900y$, in terms of the three quantities' variation:

So I mean, one unit of increase of, like one extra nonstop flight, is going to make you more money than adding one extra two-stop flights because it's worth more. So the P will increase more, so when you have more nonstop flights. So it's a matter of like, do we just buy a bunch of nonstop flights, even though that means you are selling no two-stop, or do you need some sort of a balance there?

Building upon her reasoning, the interviewer questioned her why the "balance" could exist given the fact that each nonstop flight could produce more revenue. Then she responded:

Jaime: There's got to be a balance to how many you sell. So like, let's say, at most, you sell all 10 flights to be nonstop flights, that means that at most you are making $12,000. That means that you are assuming that you can't make any more than 12,000. Like there's not a way to combine the amount of nonstops and two-stops, that you won't go over that.

[The interview asked her why there is such a potential of selling less nonstop flights but having higher revenue.]

Jaime: Because if for every two nonstop flights you would sell [*5s pauses*], not sure how to say this, two-stops [*8s pauses*], trying to take like there is a, there is a point where, let's say you knock out [*3s pauses*], like it becomes more beneficial to have more two-stop flights, because like those times the 900 is worth more than the amount you would have gotten with nonstop flights. I can't think of that number off the top of my head.

Interviewer: Yeah, but that won't happen, right? Because you always multiply it by 900.

Jaime: Yes, but, I don't know.

As the conversation continued, Jaime remained perturbed in terms of why the optimal solution did not occur when the number of nonstop flights is ten. In fact, although $(x, y) = (10,0)$ satisfies $x + y \leq 10$, it was outside the feasible region due to the presence of the other constraint, $150x + 100y \leq 1200$. However, we did not observe Jaime raising this constraint to explain. We note that this excerpt happened after she applied the vertices method to find the optimal solution. Thus, we inferred she likely was not aware that it was simultaneously taking into account both constraints that led to an optimal solution occurred at (4,6) instead of (10,0). Her success in carrying out a series of calculations to evaluate the objective function at each corner point did not necessarily lead to an understanding about how multiple constraints interact to impact the output of an objective function. However, we acknowledge that Jaime's meanings for $P = 1200x + 900y$ and $x + y \leq 10$ were supported by aspects of quantitative and covariational reasoning; she discussed how the three quantities vary together and anticipated having ten nonstop flights might result in a greater P. We illustrate later how she leveraged these ways of thinking to reason with quantities' variation with respect to *multiple* constraints.

A "Justification" of the Corner Point Principle

Observing that Jaime's solution to Election Advertising was compatible with the vertices method, the interviewer asked her why it was sufficient to only attend to the corner points but not other points within the feasible region. She explained:

Because each one satisfies a pair. So O is where this [*pointing to "*$4r + t \geq 8000$*" she wrote on a paper*], you have r and t, that's, that works for $4r$ plus t equals to 8000 and for r is equal to zero. And then P does the same thing for this one [*pointing to "*$5r + 4t \geq 20{,}000$*"*], and this one [*pointing to "*$4r + t \geq 8000$*"*]. Q does it for this one [*pointing to "*$2r + 4t \geq 12{,}000$*"*] and this one [*pointing to "*$5r + 4t \geq 20{,}000$*"*], so on. The corner points are showing you like this is the most amount or the minimum value that will satisfy at least two equalities at once. Okay, so you are not having to think about like, okay, this minimum value plus all these other ones, so you have to worry about the other ones, you can just take a look at that minimum.

We interpret that Jaime was making two implicit assumptions here. First, she considered each corner point simultaneously satisfied the *equation* versions of two inequalities (either involving the minimum or maximum output of an inequality), which necessarily led to an optimal solution relative to those two inequalities. Second, by comparing the solutions of different equation pairs, she could obtain a final optimal solution regarding the entire system of inequalities. In fact, an optimal solution relative to two inequalities can occur at non-intersection points (e.g., Point P is the interaction of $5r + 4t = 20{,}000$ and $4r + t = 8{,}000$, but Point Q leads to a more optimal solution, see Figure 2), and sometimes intersection points are not in a feasible region (e.g., the intersection of $4r + t = 8000$ and $2r + 4t = 12{,}000$). We argue that Jaime's explanation was a contraindication that she was consciously aware of the rationale underlying the vertices method. Although her explanations appeared to be compatible with the calculational procedures she carried out, e.g., equating two equations to find the coordinate values of the intersection point, the mathematical assumptions she made were incoherent to the vertices method from our perspective. More importantly, we note that her explanation did not account for aspects of the objective function. We inferred that she conceived an optimal solution more as a result of finding extremes regarding a system of constraints than as a result of an interplay between the coefficients of the objective function and those of the inequalities. Next, we illustrate how reasoning with quantities' amounts of change (the mathematical meanings of the coefficients), supported Jaime's anticipation of how an objective function's output varies in a feasible region.

A Justification Using Amounts of Change

In the same context of Election Advertising, the interviewer drew her attention to the segment OP and asked her to describe the variation of P with respect to the segment. Jaime reasoned that because from Point O to Point P, we were spending $1090.91 more on radio and saving $4363.64 on television (see her annotations in Figure 3, left), the total amount of money spent should decrease in general. Observing that Jaime used the coordinates of Point O and Point P to make her claim, the interviewer asked her to discuss points in between Point O and Point P, whose coordinate values were not displayed at the time. Jaime claimed the relationship should hold, explaining "the amount that you are saving and spending is the same because you are moving along the slope [*gesturing along the segment OP*]." Then, she transformed each equation into the slope-intercept form (Figure 3, right) and described:

Because this is saying for every one increase, one unit increase in television, there's one-fourth decrease in radio. So [*7s pauses*] that means that if you decrease the television by four, then you are adding one to the radio. If t is negative four, so if I'm spending $4 less on television, that means I'd saved a dollar on the radio [*referring to "*$1 = -\frac{1}{4}(-4)$*" in Figure 3, right*]…So if you want r equals to 1 and t has to be this [*referring to the "*$-\frac{5}{4}$*" of "*$1 = \frac{-4}{5}(-\frac{5}{4})$*"*], so you are still saving more than you are spending because you are saving a dollar and 25 cents and you are spending 1 dollar. And so Q is better than P. So, for every dollar we are spending on the radio, we are only saving 50 cents [*referring to "*$1 = -2(-\frac{-1}{2})$*"*]. So we are, we are spending more than we are saving at that point. So now S is not as beneficial as Q."

Jaime's meanings for slope in terms of amounts of change in two quantities supported her comparison of the outputs of the objective function with respect to the boundary points, by which she justified the optimal solution should occur at Point Q. We contrast her thinking here with that discussed in the previous two sections, where she did not simultaneously account for quantities' amounts of change implied by the objective function and its constraints.

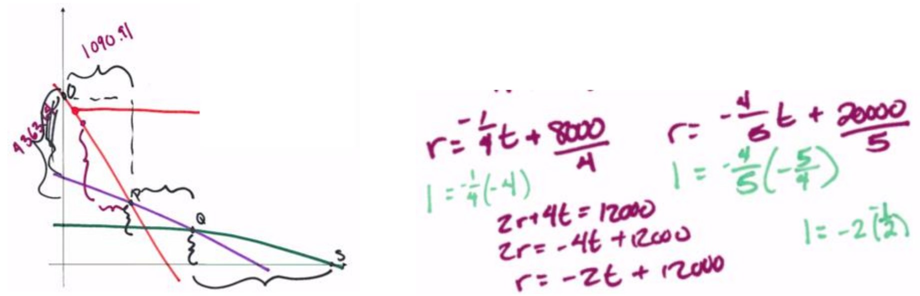

Figure 3. Jaime's (left) graphical and (right) algebraic illustration of amounts of change in Election Advertising.

However, Jamie did not continue to apply this way of reasoning to discuss other points of the feasible region. When asked to discuss points in the interior, she responded:

> Well, these [*pointing to the horizontal red segment in Figure 3, left*] are all the places where r and t, the combination of r and t is greater than this inequality [*referring to* $4r + t \geq 8000$]. Then that's giving us more than we need. And so for r plus t, we just want the minimum amount that we would have to spend, the minimum amount we have to spend is the equality part, not the greater than part. So that's all the combinations of r and t that's greater than 8000, which means that we are not looking at like a minimum amount that we would be spending on r and t for that function, the least amount that we could spend and still make this true, is all of the points on that line. So our r and t, like the point of the P equals r plus t is to figure out all of the places where like you are just satisfying that equality.

For Jaime, points satisfying the strict inequality necessarily led to less optimal (or higher) P values when compared to points satisfying the corresponding equality because "that's giving us more than we need." We interpret this as being consistent with her previous explanation that only points satisfying an equality were worth taking into account. Together, we hypothesize that she likely conflated the minimum of the output of an inequality and that of an objective function or, at least, made an association between them. Due to time constraints, we did not follow-up on her to test this hypothesis with other contexts, such as contexts including a combination of greater- than and less-than inequalities or including an objective function involving a minus sign. We are also unsure whether she could reason with the covariation of r and t entailed by the red segment and its influence on the output value P.

A Conceptual Analysis and its Implication

In summary, leveraging quantities' amounts of change afforded Jaime an understanding of how the output of an objective function varies with respect to points on a feasible region's boundary. Although she did not apply a similar way of reasoning to discuss points in the interior, we conjecture that it can serve as a conceptual tool for constructing productive meanings for optimizing objective functions. We outline a conceptual analysis as the following:

Consider an objective function, $P(x, y) = 2x + 3y$, under the constraints of $x + y \leq 3$ and $x + 2y \leq 4$, and the goal is to maximize P (see Figure 4 (left) for an illustration):

- Understanding that any point within the feasible region is less optimal than a reference point on the boundary:

- Choosing a point (x_1, y_1) in the interior of the feasible region, there is always a reference point, (x_1, y_2), on the boundary such that $y_1 < y_2$, and thus $P\ (x_1, y_1) < P(x_1, y_2)$; similarly, we can always find a reference point, (x_2, y_1), on the boundary such that $x_1 < x_2$, and thus $P\ (x_1, y_1) < P(x_2, y_1)$.

- Understanding that any non-endpoints on the boundary of $x + 2y = 4$ (i.e., Segment P_1P_2) are less optimal than one endpoint (i.e., Point P_1 or P_2) of the same boundary:
  - Understanding of $x + 2y = 4$ or $y = -0.5x + 2$: for any change in x, say Δx, y always changes by $-0.5\Delta x$
  - Understanding of $P\ (x, y) = 2x + 3y$: when x changes by Δx and y changes by $-0.5\Delta x$, P changes by $2 \times \Delta x + 3 \times (-0.5)\Delta x = 0.5\Delta x$.
  - Understanding that P increases from Point P_1 to Point P_2 (because Δx is positive) or P decreases from Point P_2 to Point P_1 (because Δx is negative).
- Applying the same way of reasoning to the boundary of $x + y = 3$ to anticipate P increases from Point P_3 to Point P_2 or decreases from Point P_2 to Point P_3.
- Coordinating direction of change in P with respect to points on the entire boundary to determine Point P_2 as producing the highest P value.

Critical to this conceptual analysis is an image of how P varies as x and y co-vary in the interior and along the boundary of a feasible region (Figure 4, left). This conceptualization extends the current theorization of covariational reasoning (Carlson et al., 2002), specifically amounts of change reasoning, from the context of single-variable functions to two-variable functions. Moreover, it does not require an individual to find an optimal solution by evaluating the objective function at *all* corner points. This affordance is significant in that it is coherent to an approach to solving n-dimensional linear programming problems. When dealing with n-dimensional problems, evaluating an objective function at each corner point of a feasible region (a polyhedron) is inefficient. In 1940s, George Dantzig, introduced the simplex method in numerical optimization as an algorithm for walking along the edges of a polyhedron to a corner point with a more optimal solution (Figure 4, right). Although the algorithm for determining the direction of walking is more complex in n-dimensions than what we have proposed for two-dimensions, we hypothesize that our suggested ways of thinking could provide students with a foundation for reasoning with more advanced optimization problems and algorithms.

We call for future research to continue to test and refine this model by interacting with students and teachers in similar or different linear programming contexts. Mathematics teachers can also foster students in constructing such an image of multi-variation of quantities regarding an objective function. These efforts will allow us to gain further insights into the affordances and limitations of such meaning for optimizing two-variable objective functions.

Making Sense of Irrational Exponents: University Students Explore

Ofer Marmur
Simon Fraser University

Rina Zazkis
Simon Fraser University

We investigate how students make sense of irrational exponents. The data is comprised of 32 interviews with university students, which revolved around a task designed to examine students sensemaking processes involved in the understanding of the concept. Both the task design and data analysis relied on the concept of sensemaking trajectories, blending the notions of sensemaking and (hypothetical/actual) learning trajectories. The findings focus on three kinds of reasoning utilized in the participants' sensemaking trajectories while working with irrational exponents: even/odd numbers and functions; range of exponent values; and exponentiation as repeated multiplication. These findings reveal students' conceptual development of irrational exponents, and could in turn be used for the refinement of tasks aimed at promoting students' comprehension of the topic.

Keywords: irrational exponents, sensemaking, learning trajectories

Mathematics education research has devoted considerable attention to both topics of irrational numbers (e.g., Kidron, 2018; Sirotic & Zazkis, 2007) and exponents (e.g., Levenson, 2012; Pitta-Pantazi, Christou, & Zachariades, 2007). However, students' understanding of the concept that emerges from the combination of the two – that is, irrational exponents – has not yet been sufficiently explored (e.g., Wasserman, Weber, Villanueva, & Mejia-Ramos, 2018). In this paper, we continue our research on irrational exponents (Marmur & Zazkis, 2019) and investigate how university students make sense of $f(x) = x^{\sqrt{2}}$. In particular, we examined students' work on a task involving different graphs of $y = x^{\alpha}$, where $\alpha \in \mathbb{Q}$ and "close" to $\sqrt{2}$.

Theoretical Framing

Our theoretical framing is informed by two constructs: *hypothetical learning trajectory* (HLT; Simon, 1995) and the notion of *sensemaking* (e.g., Weinberg, Wiesner, & Fukawa-Connelly, 2014). According to Simon (1995), an HLT describes a prediction of a route in which students' learning may occur. It is comprised of three parts: a learning goal, instructional activities planned to fulfill the goal, and a conjectured learning process predicting students' thinking and understanding during the different stages of these activities. When implemented with students, an HLT could then be compared with the learning process that occurs in reality, referred to as an *actual learning trajectory* (ALT; Clements & Sarama, 2004). The construct of learning trajectories has been used to bridge the work of researchers and teachers, as it "supports the content-specific documentation of common milestones and learning environments that support students' progression" (Andrews-Larson, Wawro, & Zandieh, 2017, p. 809).

Students' thinking and learning is closely related to the notion of sensemaking. That is, when students are facing a novel task or unfamiliar content, they attempt to make sense of what is involved by restructuring knowledge structures that are founded on prior mathematical knowledge (Scheiner, 2016). Informed by research in psychology and information systems, Weinberg et al. (2014) described sensemaking in the mathematics classroom as "the process by which students interpret and construct meaning for the activities, personal interactions, and discourse in which they participate; sense making also focuses on the individual student's mental schemas that shape this process of meaning construction" (p. 169). In our view, this description is not restricted to a classroom and is applicable to any engagement with mathematics.

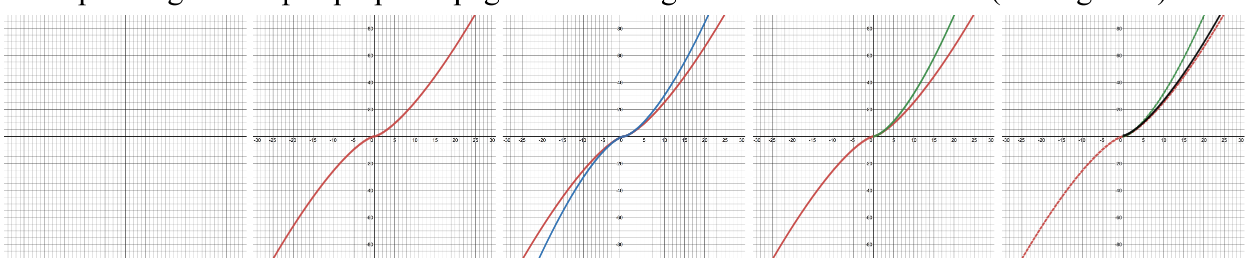
Accordingly, we focus on one of the sensemaking frames suggested by Weinberg et al. (2014) – *content-oriented sensemaking* – which describes a situation where students encounter gaps about the meaning of certain mathematical content or concepts. The sensemaking of the mathematical situation subsequently involves a learner "bridging the gap" by "drawing upon his or her ideas, thoughts, conceptions, attitudes, beliefs, intuitions, and knowledge" (ibid, p. 170).

We draw on both constructs of sensemaking and learning trajectories and suggest the blended concept of *sensemaking trajectory*, which involves a sensemaking goal, activities or tasks towards the goal, and a hypothetical/actual sensemaking path through the stages of the activities. Accordingly, we ask the following research questions: *What are students' sensemaking trajectories as they work on a task that involves an irrational exponent? In particular, how do they make sense of the graph of* $f(x) = x^{\sqrt{2}}$ *and associated mathematical ideas involved in the construction of the graph?*

Method

The Task and Considerations in its Design

How does the graph of $f(x) = x^{\sqrt{2}}$ look like? This question typically presents a novelty to students who are familiar with irrational numbers and operations on rational exponents, however have not yet considered the meaning of an irrational exponent. Accordingly, we designed a task based on our hypothetical sensemaking trajectory (HST) for interpreting an irrational exponent of x. The task was presented in an individual interview setting and included five stages corresponding to five pre-prepared pages that were given to the interviewees (see Figure 1).



(a) Empty graph paper (b) $y = x^{1.4}$ (red) (c) $y = x^{1.48}$ (blue) (d) $y = x^{1.5}$ (green) (e) $y = x^{\sqrt{2}}$ (black)

Figure 1: The five stages of the task

In Stage-1 of the interview, the participants were given an empty graph paper and asked to sketch $f(x) = x^{\sqrt{2}}$ (see Figure 1a). We conjectured that in the initial exploration stage, the participants would draw on their familiarity with the graphs of $y = x^n$, $n \in \mathbb{N}$, and based on $\sqrt{2}$ being between 1 and 2 would sketch a concave and monotonically increasing function in the first quadrant, starting from $(0,0)$, and "in between" $y = x^1$ and $y = x^2$. Subsequently, we suspected the participants to have some question marks regarding the meaning of $f(x) = x^{\sqrt{2}}$ for $x < 0$, and accordingly accounted for different options in their potential sketches (see first row in Figure 2 from left to right): a "cubic-like" graph, a "parabola-like" graph, claiming that the graph does not exist for $x < 0$, or leaving the graph blank for $x < 0$ as a result of being unsure of how to sketch it or whether it exists there. Alternatively, we conjectured participants might utilize other ideas for making sense of the task, such as attempting a table of values or calculating the derivative of $f(x) = x^{\sqrt{2}}$, which we did not expect would serve as productive avenues (and accordingly classified these as "Other").

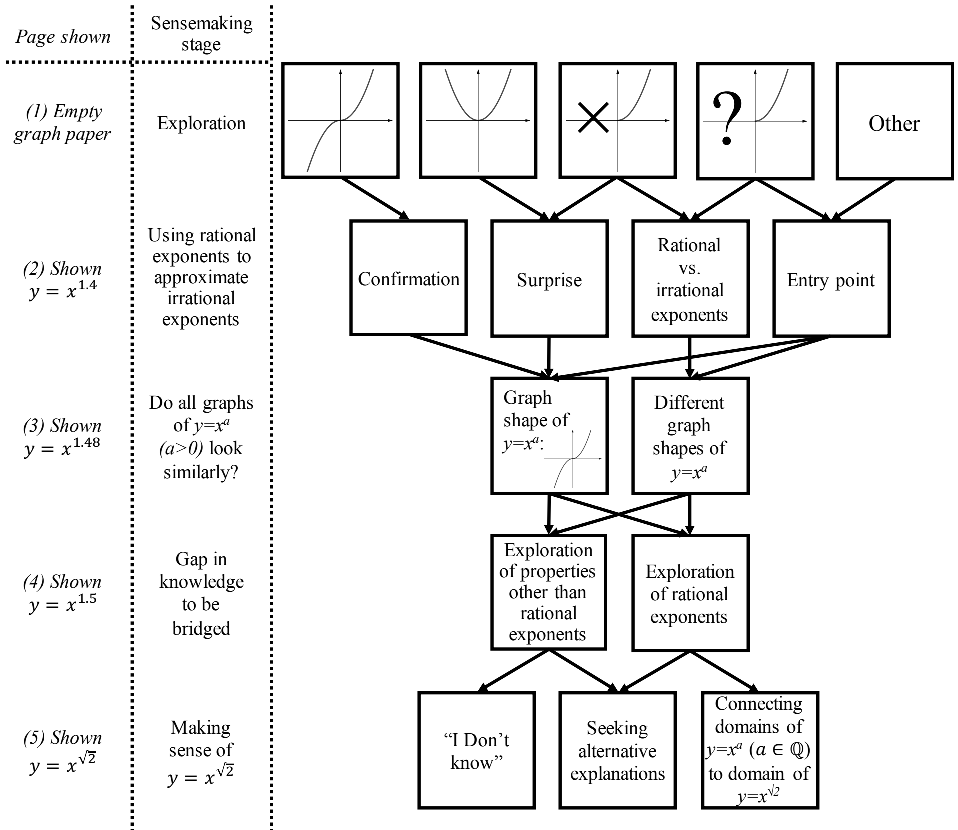


Figure 2: Hypothetical sensemaking trajectories for the $f(x) = x^{\sqrt{2}}$ task

Regardless of the initial response, in Stage-2 of the interview the participants were presented with the graph of $y = x^{1.4}$ (Figure 1b) and asked if this helped in constructing the required $f(x) = x^{\sqrt{2}}$. In case the participant was struggling in how to approach the task in Stage-1 of the interview, we expected the presented graph to serve as an "entry point" for making sense of $x^{\sqrt{2}}$ by using a rational exponent to approximate $\sqrt{2}$. In case the participant questioned whether $f(x) = x^{\sqrt{2}}$ is defined for $x < 0$, we expected the presented graph to focus his/her attention to differences between rational and irrational exponents. Alternatively, we expected the presented graph could confirm the participants' initial thoughts in case they had sketched a "cubic-like" function in Stage-1 of the interview; or be perceived as a mathematical surprise in case they had anticipated a different graph earlier. As a general rule, we anticipated the interviewees would sketch $f(x) = x^{\sqrt{2}}$ similar to $y = x^{1.4}$, an expectation that was further established in our design of the task, when the participants were presented with both graphs of $y = x^{1.4}$ and $y = x^{1.48}$ in Stage-3 (Figure 1c). Note that the exponent 1.48 was chosen purposefully, as this is the only number between 1.4 and 1.5 with two digits after the decimal point for which the graph has a similar shape to $y = x^{1.4}$. According to our conjectured HST, the interviewee would assume that $f(x) = x^{\sqrt{2}}$ is "in between" the graphs of $y = x^{1.4}$ and $y = x^{1.48}$ as $1.4 < \sqrt{2} < 1.48$. Alternatively, we suspected some interviewees may suggest different looking graphs based on other exponent choices.

Subsequently, in Stage-4 of the interview we presented the graphs of $y = x^{1.4}$ and $y = x^{1.5}$ (Figure 1d), illustrating that as opposed to $y = x^{1.4}$, the graph of $y = x^{1.5}$ is not defined for $x < 0$. Had this not been attended to earlier, we suspected the difference between the two graphs to invoke a cognitive conflict (e.g., Fischbein, 1987) that would accentuate the gap in the participant's knowledge, consequently highlighting the need for bridging and sensemaking of the mathematics involved. This gap could be bridged by reinterpreting the rational exponents involved (that is, $x^{1.4} = x^{\frac{7}{5}} = \sqrt[5]{x^7}$ and $x^{1.5} = x^{\frac{3}{2}} = \sqrt{x^3}$), attending to the domain of the related functions, and then extrapolating the conclusions to irrational exponents as a limit of rational ones. Alternatively, we suspected the participants might focus on more "peripheral" properties, other than rational exponents, when trying to make sense of the graphs. Regardless of the participants' reasoning, in the last stage of the interview they were presented with the graph of $f(x) = x^{\sqrt{2}}$ alongside $y = x^{1.4}$ and $y = x^{1.5}$ (Figure 1e), which was intended to confirm or confront previous conclusions on the shape, as well as allow them another opportunity to make sense of $x^{\sqrt{2}}$. Figure 2 presents a visual illustration of our conjectured HSTs.

Data Collection and Analysis

The participants of the study were 32 university students from STEM fields (25 undergraduate students and 7 graduate students), who were individually interviewed following the five stages as detailed above. The interviews were typically about 30-minute long, though ranged from 15-50 minutes. All interviews were audio-recorded and subsequently transcribed.

In the analysis we first explored all Actual Sensemaking Trajectories (ASTs) individually, and in particular how these compared to our conjectured HSTs. Subsequently, we focused on the reasoning the participants provided as they attempted to make sense of the task, which led to a categorization of the different ASTs based on prominent repeating themes.

Findings

While the interviews inquired into students' sensemaking of irrational exponents, the analysis additionally revealed the participants' reasoning and sensemaking of related mathematical ideas, such as rational exponents, approximation of irrational numbers by rational ones, even/odd functions and numbers, and the meaning of exponentiation in general. Given the page limit for this paper, we focus here on three repeating themes of reasoning we found in the sensemaking trajectories. Illustrations of ASTs in these themes are presented in Figure 3.

Even/Odd Reasoning

Students demonstrating what we call "even/odd reasoning" attempted to make sense of the different graphs by conflating the idea of even/odd numbers with the concept of even/odd functions. For functions in the form $f(x) = x^n$ ($n \in \mathbb{N}$), $f(x)$ is an even (odd) function if and only if n is an even (odd) number. It seems this idea was overgeneralized to any exponent in order to make sense of the newly encountered mathematical situations. A recurring theme found in the data was that students perceived a number as even (odd) if the last digit in its decimal representation was even (odd). Interpreting the number in the exponent accordingly, students then concluded on the evenness/oddness of the function. Based on this line of reasoning, $\sqrt{2}$ was not perceived as even (or odd) as it does not have a last digit in its decimal representation, and this was then used to explain the graph of $y = x^{\sqrt{2}}$. We illustrate this kind of reasoning by focusing on the case of Emma (see Figure 3a), who used even/odd reasoning in Stage-1 and Stage-4 of her interview.

In Stage-1 of the interview, Emma attempted to find different function values of $f(x) = x^{\sqrt{2}}$ for various values of x. In the following interview excerpt Emma uses even/odd reasoning to justify why $f(-1) = -1$ in her opinion, after having explained that $f(1) = 1$. In particular, note her explanation for $\sqrt{2}$ being "not even" and the graph of $y = x^{\sqrt{2}}$ behaving "like odd":

Emma: The y is going to be negative because we see that it's not like an even power so […] x is going to be -1 and the y is going to be -1. […]

Interviewer: Ok. Can I ask how you know it's not an even power?

E: […] Because it [$\sqrt{2}$] never ends like you don't know if it ends with like 3 or 2 or like with an even or an odd number because it's ever going. You can always add a 2 and make it even and you can always add a 3 and make it uneven.

I: Ok. So you don't know if an irrational is even or odd because it never ends?

E: Yeah. So it's definitely not even but it's also not odd so you don't know what to do with it so I just decided that it's maybe, maybe it's like odd.

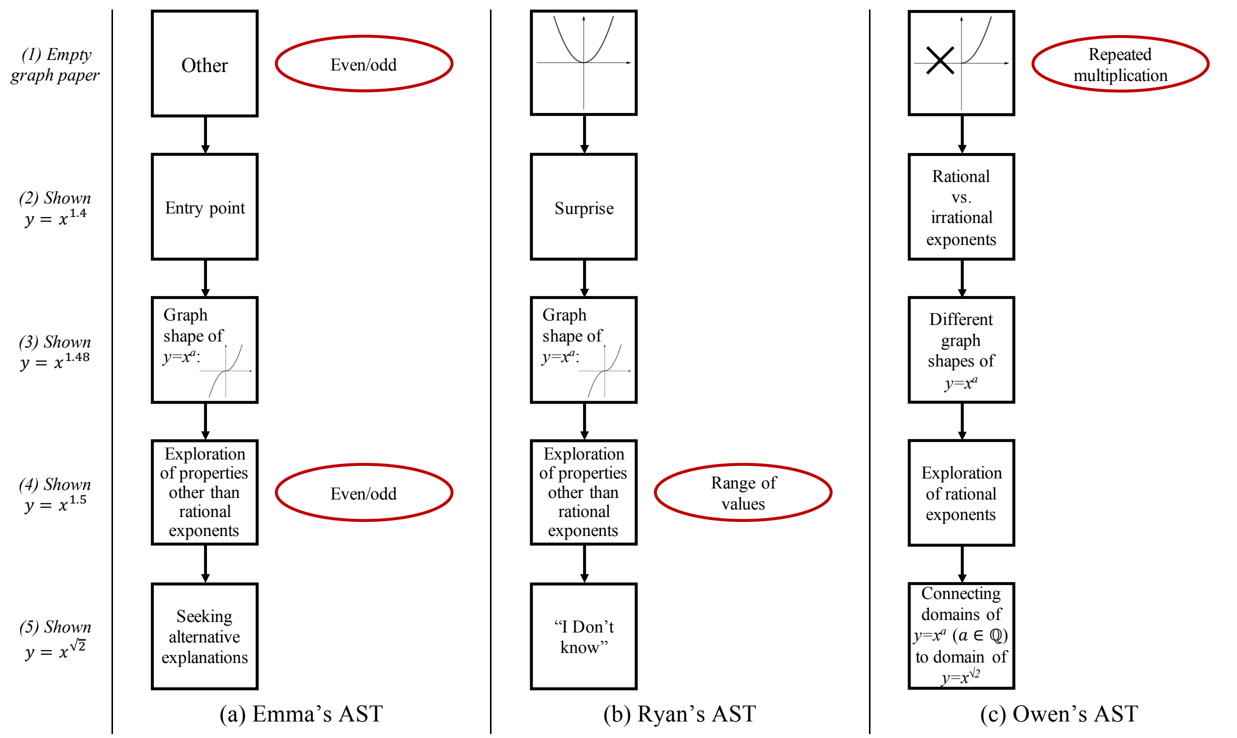

Figure 3: AST reasoning-themes: (a) Evenness/oddness; (b) Range of exponent values; (c) Repeated multiplication

In Stage-2 of the interview, when presented with the graph of $y = x^{1.4}$ and asked to draw the graph of $y = x^{\sqrt{2}}$, Emma sketched a similar graph to $y = x^{1.4}$, explaining that "it's just gonna follow where it's already going". Continuing this line of thought, in Stage-3 she drew the graph "in between" $y = x^{1.4}$ and $y = x^{1.48}$. However, Stage-4 introduced a cognitive conflict for Emma, for whom it did not make sense that the graph of $y = x^{1.5}$ was not defined for $x < 0$, which she again explained based on even/odd considerations:

E: To me it doesn't make sense that it stops [the graph of $y = x^{1.5}$]. […] If we look at these numbers and we […] multiply the power by 10. And we have 14 and 15. 14 is an even number. Which means the red [$y = x^{1.4}$] is an even graph. 15 is not an even number which means it's like an odd powered graph. […] Like to me it's like why is the red one continuing and the green one [$y = x^{1.5}$] not continuing? Like if, if this is an odd?

Lastly, in Stage-5, when shown the actual graph of $y = x^{\sqrt{2}}$, she struggled to make sense of it and returned to the idea she had expressed earlier regarding the "never-ending" decimal representation of $\sqrt{2}$ as an underlying explanation for the graph.

Reasoning based on a Range of Exponent Values

The way in which participants in this reasoning theme made sense of the graphs was by providing ranges of exponent values for which the graphs behaved similarly, alongside a particular value for which there was an abrupt change in how the corresponding graph would behave. To elaborate, one of the repeated claims was that functions in the form $y = x^{\alpha}$ would look similarly for α values between 1 and 1.5, and have a different shape for α values between 1.5 and 2. As illustration, we focus on Ryan's AST (see Figure 3b). In line with our original expectations regarding the participants' HSTs, it was only in Stage-4 of the interview, which introduced a cognitive conflict, that Ryan re-evaluated his initial sensemaking reasoning – in this case by suggesting the explanation stems from a particular range of exponent values.

In Stage-1 of the interview Ryan sketched a "parabola-like" graph, and was subsequently surprised when presented with $y = x^{1.4}$ in Stage-2. Ryan attempted to look for underlying explanations, and when examining the graphs of $y = x^{1.48}$ and $y = x^{1.4}$ in Stage-3, he described a dynamic change that occurs in the graph behaviors as the exponents increase in value: "So, it gets steeper as it gets closer to [exponent] 2." This may already be regarded as an initial attempt to make sense of the graphs by alluding to a range of exponent values. This idea was further developed by Ryan in Stage-4, when trying to explain the difference in the graph of $y = x^{1.5}$, as illustrated in the following excerpt (we note that also Ryan used the words "odd" and "even"; however, as opposed to the previous theme, his terminology was more accurate, and "odd"/"even" were discussed only regarding functions):

R: I suppose there is a range, or a limit in that it behaves odd, like an odd function only at a certain range, so I suppose if you change 1.4 to 1.48, in that it would just be like a range here, and then a range here, and those ranges behave like odd. So when, for example, x to the power n, if n is between those two [pointing to the graphs of $y = x^{1.48}$ and $y = x^{1.4}$], then it behaves like an odd function. Anything else, it loses the odd function property.

[…]

R: $y = x^n$ [also writes this], so if n is in between, say lower band is number here, equals to, n is between 1.4999 whatever, then this thing [x^n] behaves like an odd function. [writes: $\square \leq n \leq 1.4999 \rightarrow$ odd]

I: Is $\sqrt{2}$ in between these two numbers?

R: It's 1.4… [says "dot dot dot"], yeah. […] So, I don't know what the lower band is, hypothetically say it's around 1.39 or something.

Based on this "range-of-exponent-values reasoning", Ryan subsequently drew the graph of $y = x^{\sqrt{2}}$ between the graphs of $y = x^{1.4}$ and $y = x^{1.5}$ in the first quadrant, and continued the graph in the third quadrant – creating a graph of an odd function. However, when presented with the actual graph of $y = x^{\sqrt{2}}$ in Stage-5 of the interview, Ryan could not figure out the reasoning for the shape of the graph, and only referred again to his idea of ranges of exponent values as a way to make sense of the graphs.

Repeated-Multiplication Reasoning

In this reasoning theme, students referred to what we regard as a prevalent concept image of exponents, when understood only as repeated multiplication. This resulted in struggles when trying to make sense of irrational exponents, demonstrated by claims such as "If something is an irrational number, how can you multiply something by itself a certain number of times, like by an irrational number?" While such reasoning often hindered the participants' sensemaking process, we illustrate this theme with the case of Owen (see Figure 3c), who managed to overcome this issue by referring to mathematical formalism.

In Stage-1 of the interview, Owen claimed $y = x^{\sqrt{2}}$ is not defined for $x < 0$, though justified this incorrectly based on a view of exponentiation as repeated multiplication: "Because the exponents are multiplied, like for example 2^2 is just 2 multiplied by itself two times [...] As we have a negative number to an irrational number like $\sqrt{2}$, you don't necessarily know how many times it's multiplied by itself." When subsequently asked about $(-1)^{1.4}$, Owen again used repeated-multiplication reasoning to discard the option of this number being defined.

However, when shown that $y = x^{1.4}$ is defined also for $x < 0$ in Stage-2, Owen took a long pause, after which he wrote $x^{\frac{7}{5}}$ on the page, converted it to $\sqrt[5]{x^7}$, and provided proper explanations for the function domain. In the following two stages of the interview, Owen succeeded in explaining the presented graphs based on rules of rational exponents. Additionally, it seemed that being exposed to several graphs in the form of $y = x^{\alpha}$, $\alpha \in \mathbb{Q}$, supported Owen's sensemaking process of using these graphs to approximate $y = x^{\sqrt{2}}$. Lastly, when shown the graph of $y = x^{\sqrt{2}}$ in Stage-5 of the interview, Owen provided decent reasoning for $y = x^{\sqrt{2}}$ not being defined for $x < 0$: "So, because there are so many approximations for $y = x^{\sqrt{2}}$, and all of them don't necessarily agree with each other, some of them might exist there, some of them might not exist – [...] you can't be certain that the graph exists for x negative."

Conclusion

The motivation for this study stemmed from a gap of knowledge students have regarding the meaning of irrational exponents. The tendency to overlook irrational numbers during students' mathematical education has been recognized by Wu (2011), who noticed that in school mathematics, any property that is valid for rational numbers is automatically considered valid also for real numbers, without mathematical justification. Our findings, pointing towards students' difficulties to provide meaning to $x^{\sqrt{2}}$, suggest this "irrational gap" extends to tertiary mathematics education as well.

Overall, the ASTs the participating students went through as they were working on the $y = x^{\sqrt{2}}$ task, were generally in line with our conjectured HSTs, though revealed particular and elaborated reasoning, as well as areas of struggle. As hypothetical learning processes and the design of learning activities have a symbiotic relationship (Simon, 1995), it is the detailed analysis of students' reasoning that provides a better understanding of students' conceptual development, which could subsequently be used for the design of instructional tasks. In the findings presented herein, we focused on three kinds of reasoning students utilized when attempting to make sense of $y = x^{\sqrt{2}}$: even/odd reasoning (conflating even/odd numbers and functions); reasoning based on a range of exponent values (where the graph gradually changes as the exponent value grows); and repeated-multiplication reasoning (understanding exponentiation as repeated multiplication). These provided insight not only into the participants' comprehension of irrational exponents, but also into their understanding of rational exponents, number properties, function graphs, and the meaning of exponentiation in general. These findings call for further research that inquires into students' conceptual development of irrational exponents.

One of the ways in which university math departments across the country are making efforts to improve their introductory math courses is by implementing or increasing the level of course coordination for their Precalculus to Calculus 2 sequence. This not only entails creating uniform course elements across different sections but also includes efforts to build a community among the instructors of the course. While many coordinators have the common goal of improving student success, we explore what guides their actions to see this accomplished, what we refer to as their orientation toward coordination. The orientation of a coordinator encompasses their beliefs, values and knowledge of mathematics and teaching. In this proposal we introduce and elaborate on two orientations toward coordination that arose from interviews with course coordinators from a variety of institutions across the country. We also discuss the importance of both orientations as they relate to drivers of change.

Keywords: Course coordinators, orientation, leadership, change

Introduction

Course coordination for multi-section introductory mathematics courses such as precalculus and calculus is one way in which universities across the country are attempting to improve instruction and the consistency and quality of students' learning experiences. Because multi-section introductory mathematics courses are often taught by a range of instructors (including graduate students, career line faculty, and ladder rank faculty), course coordination can help mitigate against uneven student experiences that can disadvantage students in different sections of the same course. Such uneven experiences include different content emphasis or coverage, different grading schemes, and different quality enactments of active learning. These differences in learning experiences are potentially problematic because they offer different opportunities for students to learn the intended content, and hence be adequately prepared for subsequent courses. As such, course coordination can be an important contributor to student success.

One of the first studies of course coordination in mathematics departments investigated the *coordination system* at five mathematics departments identified as having relatively more successful Calculus 1 programs (Rasmussen & Ellis, 2015). The phrase coordination system is used to evoke the image of coordination that goes beyond surface features of uniform course components (e.g. syllabus, textbook, homework, exams) to include efforts to build a community of instructors working together to create rigorous courses and high-quality learning experiences for students. In this study the authors identified concrete actions that the course coordinators took to provide both logistical support that promotes greater course uniformity and hence more equitable student experiences as well as just-in-time professional development support for teaching difficult topics, implementing active learning, pacing, etc. Rasmussen and Ellis (2015) liken the role of course coordinator to that of a *choice architect*, which comes from the work of Thaler and Sunstein's (2008) work in behavioral economics. A choice architect is someone who is able to structure choices for others in ways that can "nudge" them to make particular choices while still maintaining the feeling of independence. For example, one of the things that course coordinators at the five mathematics departments, studied by Rasmussen and Ellis, did was to make instructors' lives easier by providing a range of default options, including homework sets, class activities that actively engage students, pacing guides, etc. Instructors had leeway in how they made use of these options and thus maintained pedagogical autonomy. They further argue that this framing of a coordination system is consistent with effective change strategies identified by Henderson, Beach, and Finkelstein (2011).

In ongoing work at a different set of mathematics departments, Rasmussen et al. (2019) conducted five case studies of mathematics departments that have successfully initiated and sustained active learning in their Precalculus to Calculus 2 (P2C2) curricula. These researchers highlight the different ways that coordinators across the five sites make instructors' lives easier and build community among instructors. Williams et al. (2019) further analyzed these five sites to highlight the ways that coordinators can function as change agents by leveraging the following three key drivers for change: providing materials and tools, encouraging collaboration and communication, and encouraging (and providing) professional development. An important contribution of the work by Williams and colleagues is the strong connection between ongoing mathematics department change efforts and the substantive and growing literature focused on change in higher education (e.g., Shadle, Marker, & Earl, 2017).

One thing that is common (and abundantly clear) from this prior work is the critical role of the course coordinator in a coordination system. Hence, a better understanding of what values, beliefs, dispositions, etc. toward this work is needed. In conceptualizing these aspects of coordinators, we are inspired by the work of Thompson, Philipp, Thompson, and Boyd (1994), who examined the influence that teachers' conceptions have on their implementation of innovative curricula. In particular, they identified two contrasting orientations toward mathematics teaching: calculational orientation and a conceptual orientation. They illustrated how these different orientations have significant consequences for how teachers interact with students and content and hence offer different opportunities for learning. Similarly, we were curious to better understand coordinators' conceptions toward coordination because such beliefs and understandings profoundly influence how they interact with their colleagues and the consequent opportunities for professional growth. Thus, the research question that drives the analysis presented here is: *What orientations do course coordinators take toward their work?*

The potential contribution of this analysis is both pragmatic and theoretical. Pragmatically, a deeper understanding of the orientations of course coordinators offers mathematics departments a language for thinking about what their goals of coordination are and who, either in their department or new hires, would have the perspective on coordination that is likely to be able to enact their goals. Theoretically, this work contributes to conceptualizing the role of coordinators and coordination systems more generally.

Theoretical Background

To frame course coordinator orientations we draw on Philipp's (2007) comprehensive review of mathematics teachers' beliefs and affect, where beliefs are described as the "lenses through which one looks when interpreting the world," and affect is thought of as "a disposition or tendency one takes toward some aspect of his or her world" (p. 258). Our use of the term “orientation” encompasses both beliefs and affect as described by Philipp. In his chapter, Philipp attends to the differences and similarities between a teacher’s affect, beliefs, belief systems, conceptions, identity, knowledge and values as these terms are inconsistently used in the literature. Each has a unique impact on the way a teacher interacts with their classroom and can provide researchers with new perspectives on how to measure teacher development. While these terms require a localized focus, Philipp also steps back to discuss the existence of a teacher’s orientation as it encapsulates a variety of the localized terminology and requires a broader focus from a researcher’s perspective to better understand teacher impact in the classroom.

As described in Thompson et al.’s (1994) paper, varying teacher orientations can produce markedly different discussions in the classroom due to what the teacher considers valuable information. For example, a teacher with a calculational orientation will consider a procedural answer to the question, “How did you get that answer?” as all that is needed, whereas a teacher with a conceptual orientation is more interested in how the student is thinking about the quantities that are used and the relationships between them (Philipp, 2007; Thompson et al., 1994). The orientation of a teacher emphasizes the goals and intentions of the teacher as enacted through their actions and discourse in the classroom. We draw a parallel between the orientations of a teacher and the orientations that a coordinator may have, as their goals and intentions for how the course should be run are enacted through their actions and influenced by their beliefs, knowledge and values.

Methods

This study is part of a larger national study investigating Precalculus through Calculus 2 (P2C2) programs and student supports at the post-secondary level. As part of this larger study a census survey was conducted of all mathematics departments that offer a graduate degree in mathematics (Rasmussen, et al., 2019) and twelve institutions were selected as case study sites based on what the research team viewed as noteworthy or otherwise interesting features of their P2C2 programs. These features included ones previously identified as being associated with successful Calculus 1 programs, one of which being course coordination (Hagman, 2019; Rasmussen, Ellis & Zazkis, 2014). After the project team’s initial site visits and data collection, seven sites were identified as leveraging a coordination system that went beyond simply implementing uniform course elements (e.g., syllabus, textbook) to also include intentional efforts to build a community among instructors. In order to answer our research question, we conducted 13 interviews (2018-2019 academic year) with 19 P2C2 coordinators across the seven sites. We conducted 10 individual interviews and three group interviews that included two or more coordinators.

Interviews were audio-recorded and transcribed for analysis. We conducted a thematic analysis (Braun & Clark, 2006) to identify orientations coordinators take towards their work. Each researcher opened coded the transcripts for three sites, with at least two researchers coding the same site and comparing codes to reach consensus. The research team met to discuss and revise codes and group them by theme, reaching consensus on the grouping and descriptions of the categories. This phase of analysis resulted in 11 categories (henceforth referred to as themes) that shed light on these coordinators’ approach to their role. Each theme consisted of three or more codes from the first round of coding. The research team then engaged in further axial coding and identified two orientations towards coordination that encapsulated 10 of our 11 themes (with the theme of Personal Qualities not fitting into either orientation).

Findings and Results

Our analysis of the coordinator interviews resulted in identification of two distinct orientations to coordination. We refer to these two orientations as a Humanistic-Growth Orientation and a Knowledge-Managerial Orientation. We next illustrate each of these orientations, using interview excerpts that were selected to be representative of each respective theme within the orientation.

Humanistic-Growth Orientation

Five themes were identified during analysis that we later grouped to define the broader category that we call Humanistic-Growth Orientation toward coordination. These five themes are: a) intentional instructor support, b) interested in relationships, c) community builder, d) attends to student experience, and e) flexible. Together, these themes describe the orientation of a coordinator that incorporates humanistic values and a belief in the potential for professional growth of the instructors under their purview. For the purposes of this proposal we highlight three of these themes: intentional instructor support, community builder, and flexible.

Intentional instructor support. This theme goes beyond providing resources and materials for the instructors of the course to make their lives easier (which aligns more with a Knowledge-Managerial Orientation). All of the actions categorized under this theme are deliberately made by the coordinator to support instructors' improvement of their teaching. One example of this is exhibited by a coordinator describing their goals and intentions for coordination:

> The coordination is to try to get them [instructors] up to speed for thinking about how students learn math, how to help students be successful, how to help students connect to the ideas that are being taught in this specific class, but also for them to think a little bit more carefully about how they present things.

This coordinator is not only attending to student experiences from a content perspective, but is addressing the ways in which they can intentionally help instructors think about how to provide a more thoughtful and enriching experience for the students in the classroom. The following quote describes the level of intentionality of a coordinator that provides this type of support:

> But to the extent that I have been effective as a coordinator... I think it's been as a result of my intentions to influence instruction and influence the instructors' confidence with respect to teaching. I don't think that that view of coordinating is shared amongst others necessarily. I think the others really do view their role as being not only including, but limited to the managerial aspects. And that is very much secondary in my view.

While these quotes describe just two aspects of intentional instructor support, we noticed other actions of the coordinators that reflect this theme such as providing professional development opportunities, observing instructors' classes and giving feedback, supporting instructors to be reflective practitioners, as well as willing to be the "scapegoat" (as opposed to letting the instructor take the heat) when students are upset with how the course is being run.

Community builder. There was evidence of various community building efforts in all 13 interviews. Some of the actions that we identified to build community were: valuing contributions and feedback, getting people to work as a team, getting instructors excited about the course, and generating buy-in for the philosophy of the course. Some of these efforts are characterized well by a coordinator that had the following to say about coordination, "Coordination is not autonomy. It's about a team effort and setting up best practices that everyone follows." Many of the coordinators from our interviews reflected similar beliefs and viewed the coordination practices as a collective effort. A related aspect of community building was an intentional effort by the coordinator to distribute power amongst the instructors of the course. For example, a coordinator at a large research university reflected on their own work as coordinator:

> I do my best to structure those meetings to give the impression, not entirely artificial, that we're kind of engaged in a collective enterprise to improve all of our students' learning. So, I truly try to position myself as a co-participant in that process. Not somebody who's necessarily dictating to everyone else, you know, what to do or how to teach, but, you know, I'll pose particular questions or issues and invite people to offer their own perspectives and that sort of thing. And again, I'm sort of trying to nudge things along in particular directions and buy things in particular ways. But, I want individual instructors to feel like they have some agency over the direction of the course for everybody. And I think that this would result in kind of a sense of, at the very least, sort of codependence amongst the instructors where they are all like, we'll have lunch together, that sort of thing.

The efforts to build community vary from coordinator to coordinator, but the goal to establish a community is central to this theme.

Flexible. Most coordinators lead nonhomogeneous groups of instructors. In many circumstances, the heterogeneity of the instructors exists in the experience that they have teaching the course or teaching in general. As a means to provide the necessary support for the instructors as a collective, we saw that some coordinators would adhere to varying levels of coordination practices as described by a coordinator when asked about instructor autonomy:

> The degree of autonomy that instructors want when they're teaching the course is directly related to how many times they've taught the course or their experience with the course. The [graduate] student that's teaching Calc 2 for the very first time doesn't want any autonomy. They want to come in and they want to talk to me about here's what I'm doing next. 'How do you do this? What are the things that you emphasize?'… so, usually the greener the teacher, the less autonomy they want. Whereas the person that's taught the course over and over again has got- they have a good handle on it and they tend to not- they just have it down.

By incorporating a flexible approach to coordinating, the coordinator is able to provide a tailored experience for each instructor that has the potential to generate more buy-in from the instructors and foster a collaborative team environment.

Knowledge-Managerial Orientation

The themes from this analysis that shed light on a Knowledge-Managerial Orientation to coordination include the following aspects of coordination: a) course content and curriculum, b) organizing and attending to the details of the course, c) communication, d) knowledge of the course history (including department and university structure), and e) knowledge of teaching the course. While every coordinator described performing actions of one form or another from this orientation, in this proposal we only detail the themes of course historians and communication.

Course historian. Coordinators who discussed their role as a course historian demonstrated a rich knowledge of both the coordination structure and history as well as knowledge of the larger departmental and university system in which coordination is embedded. Notably, coordinators leveraged this knowledge to work towards sustaining and facilitating change because they knew what worked well and what has been met with resistance. For example, one coordinator said:

> We don't give ... a common exam. And I was sort of toying with the idea of maybe we should give a common exam, and I was told ... that would require a departmental vote. Only because it's calculus and people care about what calculus is… Because I will have tenured faculty teaching, often there is … a limit that's been made, not explicit, but implicitly clear to me about like you can't just take total control of this course. … It's not like it [a common exam] would never happen, but it would not be as simple thing that I could just decree that that's going to happen. So, it would take a lot of work.

This excerpt highlights an understanding of some of the departmental barriers to change and includes an understanding of ways to work within the system to facilitate changes for a course. Being a course historian also requires a continuous involvement within the coordination structures so that one's understanding and knowledge remains current and relevant. A participant highlighted this when they said a coordinator must be embedded within the department and ask, "'Hey, how are you? How are things going? Do you want to teach again?' or like, 'What are you doing now?' Like you have to be able to be part of the social network of the department in a way." The coordinator's involvement within the department is integral to their effectiveness. In addition to the importance of having this knowledge of the course history to make content or policy changes, coordinators that demonstrate a Knowledge-Managerial Orientation to coordination also draw on this knowledge when communicating department and university policies to instructors who are likely less familiar with this information.

Communication. The communication aspect of the Knowledge-Managerial Orientation to coordination includes both communicating important content and logistics about the course to instructors and being responsive to student and instructor emails. Some coordinators created a document or a set of examples to communicate important content, saying things like:

> We have these 62-page documents that are the expected learning outcomes for our calculus course that I developed. And it was so I can just be like, 'Hey grad student, this is the course, and it's a lot of high-level things. Students should be able to do blank... all organized in some hierarchical way. And that took a lot of experience to write that thing and now it, it's a lot of detail and it's all organized, and then it's communicated and disseminated.

Other coordinators communicated key content by drawing attention to it during formal or informal meetings/discussions with instructors. One coordinator acknowledged that he likes to allow room for instructors to have agency in the course in addition to clearly communicating important content, saying:

> If there's a certain thing that I really, really want to test students on ... I might, like say to them, 'Hey, try to implement something in your class, try to do something like problem number 25 on page 381.' Yeah, I might say something like that, but I try not to, I try not to overstep that with other people.

All of the themes encapsulated by the Knowledge-Managerial Orientation to coordination illuminate an approach that allows for the coordination structure to be implemented in an organized way, clearly communicating the coordinated elements and expectations to instructors. Coordinators who embrace this orientation leverage their knowledge of the students and their experience teaching the course to create appropriate resources and coordinated elements. Additionally, this approach allows for a coordination system that is well-informed by the course history, and departmental culture/policy surrounding it.

Discussion

All of the coordinators in our study demonstrated aspects of Knowledge-Managerial Orientation to coordination, highlighting the importance of being familiar with the course they are coordinating as well as creating and sharing resources with instructors teaching the course. This is not surprising since uniform course elements are a key component of coordination. The coordinators that also demonstrated a Humanistic-Growth Orientation, however, tended to focus more on this aspect of their role when discussing their perspectives and experiences coordinating P2C2 courses, often framing the Knowledge-Managerial aspects from a Humanistic-Growth Orientation. It is important to note that while not every coordinator demonstrated a Humanistic-Growth Orientation toward their coordination work, those that did were deliberate and prioritized personal and professional growth to improve the quality and effectiveness of their P2C2 courses.

We see a similar level of intention from the coordinators in the study by Williams et al. (2019) as various coordinators deliberately take action to improve student success by acting on three drivers of change to implement and sustain more active learning in their P2C2 sequences. These drivers, providing materials and tools, encouraging collaboration and communication, and encouraging (and providing) professional development nicely align with the two orientations presented in this proposal. Providing materials and tools is an action taken by coordinators with a Knowledge-Managerial Orientation while encouraging collaboration and professional development are two actions taken by coordinators that approach their work with a Humanistic-Growth Orientation. Thus, by encouraging coordinators to initiate change through an approach to coordination that incorporates both the Humanistic-Growth and Knowledge-Managerial Orientations, math departments across the country could reap the potential benefits of increased active learning in P2C2 classes.

By attending to these drivers and orientations, math departments now have the language and research evidence to support their goals of improving or implementing active learning and coordination. Drawing on the data from a census survey sent to all Ph.D. and master's granting institutions across the country, we know that there is a need for the improvement of professional development support as well active learning practices in the classroom (Rasmussen, et al., 2019). Math departments reported valuing active learning and professional development, but also reported not being very successful at each. In fact, 44% of math departments saw active learning as very important, 47% saw it as somewhat important and 9% did not see it being important. However, when asked about how successful they were at implementing active learning, only 15% of the 199 math departments reported that their program was very successful. Similarly, with graduate teaching assistant (GTA) professional development, 50% and 32% of the math departments saw it as very and somewhat important (respectively), while only 29% of the respondents reported being very successful at it. Clearly, math departments across the country are looking for ways to improve their active learning and professional development efforts, and effective course coordination is one opportunity to achieve this goal.

Our hope is that by bringing awareness to coordinators' orientation(s) we are not only supporting math departments in search of coordinators but are also encouraging coordinators themselves to reflect on how they approach their role and how they can act on the available drivers for change at their institutions. By providing this perspective towards coordination, we also hope that this empowers math departments across the country to improve their active learning and professional development efforts. The next step in our work surrounding P2C2 coordinators' orientations will be to analyze the instructor and GTA interviews to compare and contrast what is valued in terms of effective coordination.

Get That Basket! Deciphering Student Strategies in the Linear Algebra Game Vector Unknown

Matthew Mauntel
Florida State University

Benjamin Levine
Arizona State University

David Plaxco
Clayton State University

Michelle Zandieh
Arizona State University

We present results of a grounded analysis of individual interviews in which students play Vector Unknown - a video game designed to support students who are taking their first semester of linear algebra. We categorized strategies students employed while playing the game. These strategies range from less-anticipatory button-pushing to more sophisticated strategies based on approximating solutions and choosing vectors based on their direction. We also found that students focus on numeric and geometric aspects of the game interface, which provides additional insight into their strategies. These results have informed revisions to the game and also inform our team's plans for incorporating the game into classroom instruction.

Keywords: Linear Algebra, Game-Based Learning, Inquiry-Oriented Instruction

Linear algebra is an important course for students in the STEM disciplines because of its unifying power within mathematics and its applicability to areas outside of mathematics. Research in linear algebra has evolved over the last twenty years from the pioneering work at the turn of the century (e.g., Dorier & Sierpinska, 2001; Harel, 1999; Hillel, 2000) to more recent work on improvements to teaching and learning using Tall's three worlds (Stewart & Thomas, 2010), models (e.g., Trigueros, 2018), dynamic geometry systems (e.g., Sinclair & Tabaghi, 2010) and everyday examples (e.g., Adiredja, Bélanger-Rioux, & Zandieh, 2019). Our work is most closely aligned with the curriculum design work of the Inquiry-Oriented Linear Algebra (IOLA) group (e.g., Andrews-Larson, Wawro, & Zandieh, 2017; Wawro, Rasmussen, Zandieh, Sweeney, & Larson, 2012; Zandieh, Wawro, & Rasmussen, 2017). The goal of our project is to explore Linear Algebra in the context of a video game developed from the IOLA curricular materials. In recent years, game-based learning (GBL) has become popular because of its ability to motivate students. Bakker vanden Heuvel-Panhuizen, and Robitzsch (2015) found that students who played mathematical games tended to spend more time on these games when compared to the amount of time spent on their normal math homework. Part of the reason can be attributed Gee's (2003) concept of skills as strategies, which states that players are more likely to practice necessary skills when they are seen as strategies for a larger goal. We view video games as providing an avenue to support and motivate students' development of understanding Linear Algebra concepts drawing on theories from Realistic Mathematics Education (RME), IOLA, and GBL (Authors, 2018, Authors, 2019).

Literature Review

Realistic Mathematics Education

This project leverages the activities of the IOLA curriculum (http://iola.math.vt.edu), which is a set of research-based curricular and instructional materials based on RME design principles and designed to move students through the different levels of mathematical activity from an experientially realistic situation to a formal mathematical understanding (Wawro, Rasmussen, Zandieh, & Larson, 2013). The curriculum begins with a task called the Magic Carpet Ride (MCR) task, which asks students to use two forms of transportation (represented by the vectors <3,1> and <1,2>) to reach Uncle Cramer's house located at (107, 64). The primary goal of the remaining tasks in this first unit is to support students' generalization lessons learned in their earlier activity and develop the formal constructs of linear independence and span.

Game–based learning (GBL) is the use of games (including video games) for educational purposes. While GBL has gained popularity in recent years (Gee, 2003; Gresalfi & Barnes, 2016; Foster & Shah, 2015; Shih & Shih, 2015) there are few games for higher levels of mathematics. Gee (2005) notes that well-designed games present players with well-ordered problems that allow the players to learn crucial skills necessary for gameplay. According to Gee, players also engage in cycles of expertise where they encounter difficult problems, solve them, practice and master them, and then are confronted with new problems that will challenge the assumptions of the initial problems, requiring them to apply their skills in a new context. Williams-Pierce (2017) notes that players of educational mathematics games go through several stages beginning with understanding how the game works and culminating in predictive behaviors that are optimal for higher-level mathematical activity. This difference between lesser-anticipatory and more anticipatory strategies can be seen in mathematical context in Hollebrands (2007) who noted that students engaged with Geometer's Sketchpad (GSP) in two key ways, proactive and reactive. Students who engaged in a proactive way used GSP to test theories, while reactive users reacted to the information presented to them on screen, but were not able to anticipate how their actions would change the on screen environment. This indicates that understanding how students anticipate using mathematical tools and games is key to interpreting their use of tools/games.

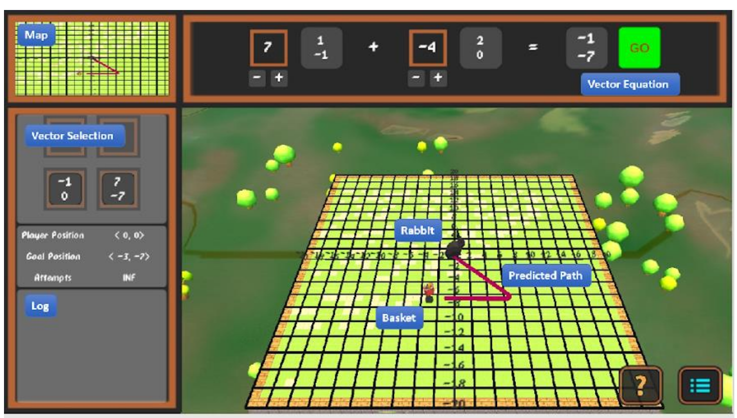

Figure 1. Sample Screen from the Game Vector Unknown.

Vector Unknown Gameplay

The game currently consists of five levels with our analysis investigating gameplay of levels 1, 2, and 5. In each level, four vectors are generated at random under the constraint that there are two pairs of linearly dependent vectors. To play, students guide the rabbit to the basket by selecting one or two vectors from the Vector Selection, placing them into the vector equation, adjusting the scalars, and pressing GO. During Level 1, players have a Predicted Path which highlights the path of the Rabbit before the player presses GO, providing players with a geometric representation of the Vector Equation. Level 2 is designed to force players who solely rely on the Predicted Path to consider the Vector Equation by removing the Predicted Path. On level 5, the Predicted Path returns, but players must now obtain several keys to unlock a lock that covers the goal forcing them to consider vectors originating from points other than the origin.

Methods

Data Collection

We interviewed five participants from a multi-purpose regional university in the southeastern United States. These participants were selected from 11 interviews comprising the total data corpus because they had not completed a first course in linear algebra. The participants came from a diverse background, including two black men, two black women, and one Asian woman. Each participant was interviewed for approximately one hour, during which they were asked to complete three levels of the *Vector Unknown* game. As needed, the interviewer provided help on how to navigate the game's screens and use the controls. The interviewer asked scripted questions along with impromptu follow-up questions. Impromptu questions were asked to further clarify and explore the participants' thinking about gameplay as well as any mathematical insights or strategies the participant developed during gameplay.

Analysis

Team members transcribed the interviews and documented student gameplay during the interview by noting significant interactions with the game's interface. Specifically, we documented moments in which the player chose or replaced vectors or when the player changed the scalar amounts for vectors in the vector equation. Consistent with grounded theory (Strauss & Corbin, 1994), team members then conducted an iterative grounded analysis of the interviews. This process began with multiple cycles of open coding and discussions during which team members agreed on interpretations of participants' statements and actions.

Table 1: Examples of codes from the first round of coding

Categories		**Examples**	
Focus on the vector equation	**Erp**: replaces a vector	**Es**: manipulates scalars	**Erv**: Removes a vector
Features of the game	**Fdl**: Data Log	**Fpp**: Player Position	**Fca**: Camera Angle
Focus on gameplay	**Pg**: Presses Go	**Pcomp**: Anticipates gameplay complexity	**Pu**: Undoing a Move
Conceptualizing a Vector	**Vd**: Testing the direction of a vector	**Vp**: Visualization and trace of vector path	**Vq**: Use of scalars or vectors components to reach quadrants
Student-expressed strategy	**Sc**: Connecting b/t representations	**Sp**: Previously used strategy	**Sr**: Retrospectively expresses a strategy
Focus on graphical game components	**Gdir**: Displacement (Direction)	**Gdis**: Displacement (direction and displacement)	**Gpp**: Refers to the predictive path

After initial coding, the research team grouped the codes into six broad categories (Table 1). The first category - Focus on the vector equation - includes student actions such as the introduction and removal of a vector or the manipulation of a scalar in the game interface. A second category - Features of the game - includes instances in which the student mentions using various features included in the game's interface, such as referencing the Data Log or the locations of the player or goal. The third category - Focus on gameplay - contains codes of student actions as they play the game, such as pressing GO or undoing a move. The fourth category - Conceptualizing a vector - includes codes about how the student expresses the ways in which they are Conceptualizing a vector, such as defining what the components of a vector are or testing its direction. Another category denotes Student-expressed strategies, such as focusing on one coordinate at a time or reusing a previous strategy. The final category - Focus on the graphical game components - such as the direction of the purple projected path or the graphical displacement from the goal.

Results

The initial codes are of a relatively fine grain size, but were important pieces into the analyzing the student strategies. Knowing what specific components of the game the student attended to while playing the game as well as how the student understood the vector equation and graphical component at different points in gameplay allowed us to discover several themes. These themes are seen across multiple students and can also be used to describe the strategies the student uses as they are introduced to the game and how their strategies evolve as they progress with each level. In this section, we use excerpts from four participants' gameplay to discuss the themes we developed. For each theme, we recognized that students were focusing to varying degrees on the geometric and numeric aspects of the game's interface. When a participant's strategy focused primarily on the vector equation without mentioning the Predicted Path or the graphical component of the interface, we called the strategy ***numeric***. When a strategy focused primarily on either the Predicted Path or the graph, we called the strategy ***geometric***.

There were several themes we found when analyzing student strategies. We characterized the first theme, ***button-pushing***, as rapidly adjustment of scalars and switching vectors. We denoted button-pushing as ***less-anticipatory*** when the player expressed surprise when reacting to a consequence of their actions. For example, Mouse[1] after quickly alternating the scalar keys made the following comment "what if I press the button that's ... the rabbit's going to go down. ohhh, yeah." Here, the tone of Mouse's "ohhh, yeah" comment indicated his surprise which lead us to describe his activity as *less-anticipatory* ***button-pushing***. His reference to going down with the Predictive Path indicated that he was attending to the *geometric* aspects of the game. Another student Gwen, employed a less-anticipatory button-pushing strategy as evidenced from her describing her gameplay as "messing around", "mindlessly clicking", and "throwing in numbers to get the answer" while quickly adjusting vectors and scalars in Levels 1 and 2. She did not reference the Predicted Path, but instead frequently referenced the Vector Equation and its components, indicating that her ***button-pushing*** was *less-anticipatory* and *numeric*.

As participants played the game more extensively, participants began to engage in *more-anticipatory* ***button-pushing*** which involved switching out vectors and scalars, but not as quickly and the sense of surprise is replaced by a knowledge of the results prior to pushing a button. Mouse's gameplay shifted from less-anticipatory to more-anticipatory throughout the interview. This is evidenced by a decrease in the number of times Mouse switched between increasing and decreasing the scalar for a given vector when he was button-pushing. For instance, in Level 1, Mouse expressed surprise when the predictive path of the linear

[1] Students chose their own pseudonyms.

combination moved toward the goal. In contrast, while playing Level 5, Mouse put in the first vector he clicked on the "+" scalar and then uttered "Oh -" before clicking the "-" scalar. We see this as a more-anticipatory button-pushing because his actions indicate he is expecting *one* of the scalars (+ or -) to move the predictive path closer to the goal position.

We characterized ***quadrantal*** themed strategies as strategies that involve choosing vectors based upon the signs of the coordinates. This theme manifested as participants choose a starting vector in the same quadrant of the goal, or more generally a vector that could be scaled in a direction heading towards the goal. For example, Latia noted the following:

> So I know that the basket is on <-6,6>, and my initial thought was use, to start with either my <-3,9> or my <-1,3> because it is in the second quadrant and then, since I already know I'm at negative six, six, I was trying to think of what I could use so that if I multiplied those two numbers I could get to my basket.

Here, Latia made her initial vector choices by matching the signs of the goal position with that of the potential vector choices placing her strategy in the *numeric* category.

The third type of strategy was ***focus on one coordinate*** where the participant focused on trying to match one coordinate of the result of the vector equation with one coordinate of the goal position. Lance expressed this strategy as follows:

> Uhhmm, so when I started, when I saw my vector choices, I started to see the, um, almost all connections of like how certain, um, how um, I was manipulating them individually based off of like ys first and then the xs. And so I was trying to find paths and where, where I get my first, um, my first um, coordinate and my y.

Here Lance focused on reaching the y-coordinate of the goal first. The strategy is *numeric* as he did not have the Predicted Path when playing this level and did not refer to any geometric components.

Another student, Zo, noted that when she was trying to get to the basket at <-18,-1> from <-18,-9>:

> I have to go up eight but I don't know how I'm about to do that. There's no, like, straight line in these numbers so I can't do that. But, uh, I'm just going to trial and error it 'cause I don't know how else to do this.

Zo's strategy was clearly to match the -18 and then go up 8 indicating she was attending to the *geometric* aspects of the game.

The fourth strategy observed was a ***focus on one vector*.** In this strategy, participants chose one vector, scaled it as close to the goal as possible - potentially going past the goal - and reducing the scalar, and then chose another vector and either scaled it to the answer or alternated adjusting scalars to reach the goal. In contrast, Mouse on Level 1 scaled one vector <-5,10> by 1 and then by 2 to reach the goal at <-11,8>. After which he commented that he had gone too far (referring to the Predicted Path) and reduced the scalar by 1. He then began to scale the other vector. Mouse's focus on the Predicted Path categorizes his strategy as *geometric*. Latia and Gwen also employed this strategy with the Predicted Path. While we did not observe a *numeric* example of ***focus on one vector***, we can imagine that a student would focus on adjusting the scalar on one vector until the result of the vector equation is close to the goal.

Examples of Strategies as Seen in Latia's Interview

Latia began with **less-anticipatory *button-pushing*** expressed by Latia as "playing with numbers", but quickly figured out that there was a link between the scalars and the geometric support noting that the predictive path doubled when she increased the scalar on a vector from 1 to 2. During the first level she relied on the geometric support to find the goal, but has clearly began to connect the two most notably stating that she made vector and scalar choices based upon the quadrant of goal expressing ***quadrantal*** reasoning. Also, of note, she mentions that she eliminated a vector choice because she did not want to go past the goal. Latia also ***focuses on one vector*** as indicated by choosing one vector, scaling it to what she believes is an appropriate distance to the goal, and then putting in a second vector and adjust it. This is followed by an adjustment to the first vector to reach the goal.

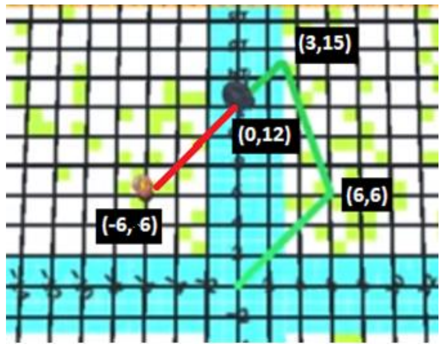

Figure 2. Latia Gameplay during Level 2.

During the second level (see Figure 2), Latia chose the vector <-3,-3> and the scalar -2 and pressed GO to take her to <6,6>. She then used a ***quadrantal*** strategy to chooses the vector <-1,3> and scales the vector by 3 attempting to ***focus on one vector*** to get close to the goal. She assumed that bunny will always start from zero and is surprised to find out it does not return to the origin after pressing GO. Noting that she wanted to go down and to the left, she utilized **more-anticipatory *button-pushing*** to test the direction of the vector <-1,-1>. This is an extension of **quadrantal reasoning** to a point that is not the origin. She noted that rabbit has to go down 6 and to the left 6 and scales <-1,-1> by 6 to reach the goal connecting the vector equation and its ***geometric*** interpretation without a reliance on predictive path. Latia replayed Level 2 with a goal at <-2,10> and mentioned that her strategy is to go past the goal and return, **repeating the strategy** used in a previous level playthrough and defying her intuition from the Level 1 playthrough. After not being able to visualize a solution with the given vectors, Latia solved the system of equations on a piece of paper indicating a flexibility in thinking and approach to completing the game.

Comparing conditions: Standard Basis Vectors

Both Mouse and Latia experienced Standard Basis Vectors (SBVs) on Level 2 and responded differently. On Level 1, Mouse relied more on the predictive path that resulted from ***button-pushing*** and looked at (and solved) the vector equation produced in the Data Log upon completion of the level. When he moved to Level 2, he sought to learn how the vector equation worked and focused on how the scalars related to the direction the rabbit traveled. The inclusion of SBVs allowed Mouse to focus more on the numerical components and see how the scalars affect the resultant vector. When asked about how he solved the level, he responded:

> I saw the position which is three and the other position which is negative five. So, I kinda made it to where I'm trying to get it to where the vector has three and five […]. I'm guessing that if I multiply negative one to negative three it will get three and negative one again to negative five.

Latia completed Level 1 and one attempt at Level 2 before she encounters SBVs. On opening Level 1, she noticed the vector equation and began to make sense of how the scalars and the equation relate to the graphical component of the game. On Level 2, she continued to explore this connection and gained a working understanding of how the resultant vector relates to the rabbit's motion, adjusting her strategy when starting away from the origin. When given SBVs, she ***focused on one vector*** and explained that the orientation of the vector does not matter because the negative scalar can flip directions. Latia said that the inclusion of the SBVs made the level easier to manage, which allowed her to use both vector slots comfortably.

Both students used the SBVs as a way to validate their understanding garnered from previous levels. Mouse used them to gain a better understanding on how the vector equation operates while Latia uses them to incorporate two vectors into the equation. Although this is the first time Latia used both vector slots, she began to gain the understanding in her first attempt at Level 2 when she has a starting position off the origin and needed only one vector to reach the goal from her second position.

Discussion

Throughout our analysis we found that students began with less-anticipatory gameplay. This early gameplay resembled the GBL version of reactive strategies (Hollenbrands, 2007) or Zone 1 and 2 gameplay (Williams-Pierce, 2017) which focuses on students understanding how the controls of the game function. Over time, most students shifted to more-anticipatory gameplay allowing them to develop complex strategies aligning with a shift to the GBL version proactive strategies (Hollenbrands, 2007). This is in line with Williams-Pierce's (2017) Zone 3 where players begin to anticipate what is desirable in their gameplay. This desirability is expressed in our themes as players making initial choices that they know will get them closer to the goal such as ***quadrantal strategy***, ***focusing on one vector,*** and ***focus on one coordinate***. Eventually, we found that at least one student Latia made a hypothesis about the direction of a vector and utilized the game to test the hypothesis. This aligns with students using GSP to test hypothesis (Hollenbrands, 2007) as a tenant of proactive strategies and of the characterization of Zone 4 gameplay (Williams-Pierce, 2017). Finally, Latia's reuse of a previous strategy is a key indicator that a student has moved to Zone 5 of mathematical gameplay which is ripe for mathematical discovery and advancement. A key result of our analysis is that as students spend more time playing they game they were able to anticipate what would happen in the game allowing for a greater variety of theories to form which could be valuable points of departure for educators using the game with students either inside or outside of class. about gameplay and used the game to test their theories.

In addition to analyzing student thinking and gameplay, this study served to inform further development of the videogame. For example, a new iteration of the game was created that included a difficulty setting of easy, medium, and hard. The entire easy level includes pair of vectors that are multiples of a standard basis element while higher difficulties exclude standard basis vectors. Further exploration will include interviewing more students to find some of the strategies that we speculated would exist such as the *numeric* ***focus on one vector*** strategy. Finally we wish to explore how the game can be integrated in an IOLA classroom with a particular focus on building on the student strategies discovered.

Calculus Students' Epistemologies of Mathematics: The Case for a Dynamic Interpretation

Caroline J. Merighi
Tufts University

Students' epistemologies (beliefs about mathematical knowledge) play a significant role in how they learn mathematics. Much prior work in this area describes student epistemologies as unitary, where evidence of a particular epistemology is taken to represent that student's singular epistemology of mathematics. Most argue that these epistemologies stem from their experiences across their mathematics classes. This study set out to examine students' epistemologies in introductory calculus and how those epistemologies influence and reflect students' experiences in mathematics courses. To a significant extent, it confirms results from prior studies. However, through one-on-one it finds more variability in students' epistemologies than most of the literature has described. That variability is significant for helping educators think about how to help students learn mathematics in general, and calculus in particular.

Keywords: calculus, epistemologies, beliefs, context

Introduction

An important yet often implicit aspect of mathematics courses is what students learn about the nature of mathematics knowledge and what it means to do mathematics. These beliefs about the nature of mathematics and mathematical knowledge are an important part of learning (Schoenfeld, 1985). I use "epistemologies of mathematics" to mean a person's set of beliefs about the nature of mathematical knowledge, including their beliefs about what counts as valid mathematical knowledge, where mathematical knowledge comes from, and what it means to do mathematics. In this paper, I focus on the epistemologies of mathematics held by students taking introductory calculus courses. Even high-performing students leave calculus courses with weak understandings of key calculus concepts (Selden, Selden, Hauk, & Mason, 2000). It is possible that students' epistemologies play a role in this, but currently no systematic data has been collected and analyzed to examine this possibility. This study addresses this research gap by examining calculus students' epistemological beliefs about mathematics.

The research question I focus on is: What kinds of epistemologies of mathematics do beginning calculus students hold? Through analysis of in-depth interview data, I will provide evidence that (a) Individual students exhibit multiple, seemingly contradictory epistemologies of mathematics, and (b) when students experienced conflicts between their formal mathematical knowledge and their own intuitive knowledge, they did not attempt to reconcile the conflict.

Theoretical Framework

A core idea that underlies this study is that students' mathematical thinking is often dynamic and sensitive to context, rather than stable and unitary. Research supports the dynamic and context-dependent nature of students' cognitive understandings, so a natural extension of these theories is that students' epistemological beliefs may also be dynamic and dependent on context. This stance builds broadly on earlier work that establishes knowledge as constructed by individuals in social context, (e.g., Piaget, 1966; von Glaserfeld, 1989; Vygotsky, 1978).

While some studies have examined undergraduate students' ideas about mathematics (e.g., Richland, Stigler, & Holyoak, 2012), relatively little is known about epistemological beliefs in the specific case of beginning calculus students. Muis' (2004) review of the literature on epistemologies of mathematics specifically calls for investigation on students' epistemologies in calculus and whether and how they may differ from their epistemologies in other areas of mathematics. However, a relatively robust body of literature (e.g., Carey & Smith, 1993; Elby & Hammer, 2001; Hammer, 1994; Hammer & Elby, 2003) has investigated student epistemologies in introductory college physics courses and found evidence that students who view physics as a coherent system of ideas learn the core ideas of introductory physics more successfully (in the sense that they have more correct conceptual understandings of basic physics phenomena) than those who view physics as a set of facts and formulas to be memorized.

Examining how calculus students' epistemological beliefs vary and shift in different contexts gives insight not only into the nature of their beliefs but also into the relationship between those beliefs and the types of mathematical reasoning in which students engage. This has implications for both research and instruction. If researchers do not attend to the context of their data collection, they may mischaracterize student epistemologies as stable beliefs. Instructors may attempt to *confront and replace* "unproductive epistemologies" when it may be more appropriate to encourage students to *activate different epistemological resources* that they already have.

Methods

Course Setting and Participants

The data for this study are drawn from a first-semester calculus course (Calculus I) at a small research university in the northeastern United States. The course was a standard introductory-level calculus course on polynomial, rational, trigonometric, exponential, and logarithmic functions of a single real variable. The specific topics covered were limits and continuity, derivatives and techniques of differentiation, related rates, definite integrals, and the Fundamental Theorem of Calculus. The course did not include any specific pedagogical innovations nor elements explicitly aimed at examining or changing students' epistemologies of mathematics. All 41 students from one section of the course were invited to participate in a one-on-one interview. Nine students volunteered and all of them participated. The students were a mix of first-year and second-year students, had a variety of intended majors, and had varying levels of success in the course. Three had final course grades in the A range, three in the B range, two in the C range, and one withdrew from the course.

Interviews

The semi-structured, videotaped, one-on-one interviews were centered around mathematical tasks and were conducted near the end of the semester. The explicit goal of the interviews was to uncover student reasoning, rather than to teach mathematical content. The interview tasks for the data reported in this paper were centered around the "Car Problem." The first part of the Car Problem (see Figure 1) is adapted from Carlson's (1998) study. Students were presented with graphs of the speed of two cars that left from the same place and traveled forward in the same direction. They were asked to decide which car was ahead, which was traveling faster, and which was accelerating faster at $t = 2$.

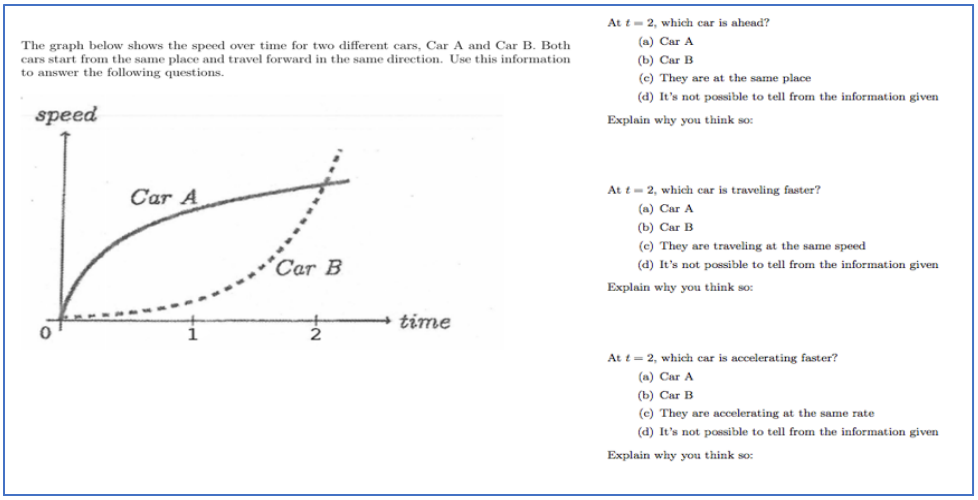

Figure 1. The first part of the "Car Problem."

In the second part, students were asked to decide which car had a greater average speed and to describe the relative position of the cars during certain time intervals (see Figure 2). These tasks were chosen because they addressed core introductory calculus concepts such as rate of change, average value, and accumulation. These tasks also did not include explicit functions to manipulate. While the intent of these tasks was to uncover students' conceptual ideas, the ways students approached the tasks and their verbal commentary during the interviews also gave strong insights into their epistemologies of mathematics.

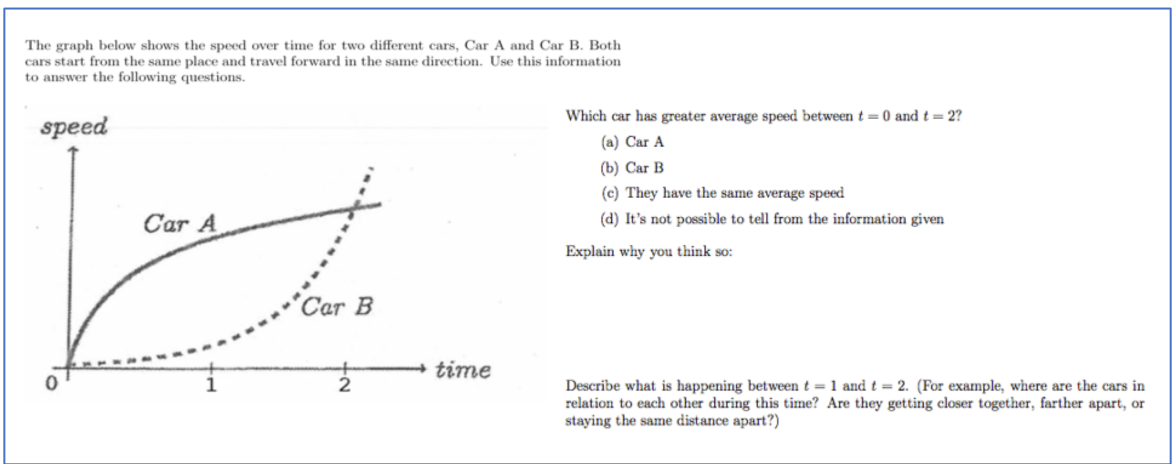

Figure 2. The second part of the "Car Problem."

Coding and Data Analysis

All nine interviews were fully transcribed and examined to identify moments that were evidence for students' beliefs about the nature of calculus specifically or mathematics generally. Some of these moments occurred when students spontaneously spoke about their beliefs while others occurred in the context of working on the interview tasks or responding to interviewer questions. I iteratively developed categories that balanced capturing detail about an individual student's beliefs with capturing similarities across individuals. The categories I developed in this analysis focus on factors that are readily observable in research interview settings. Table 1 shows the categories and codes in the framework used in this study. For example, if a student made a statement, comment, or question that showed evidence of what their apparent goal was, it was coded first into the "Apparent Goals" category and then either the "Correct Answer" or "Makes Sense" code. Note that the categories and codes are not mutually exclusive.

Table 1. Description and example of each code.

Code	Description	Example
Apparent Goals (what the participant was trying to do)		
Correct Answer	Apparent goal is to obtain a correct answer, regardless of the method by which it is obtained	"I would guess Car A 'cause frankly *the only thing I haven't look at in the graph yet* is area." – Mary [4:08]
Make Sense	Apparent goal is to make sense of the problem and/or arrive at an answer that feels satisfying	"But that, like *doesn't make sense* because it [Car A] is going faster the whole time." – Ash [8:35]
Trust (kinds of knowledge that the student viewed as valid)		
External Trust	Trusts external knowledge such as memorized formulae, facts from class, information from textbook, etc.	"I think it's C because *in the formula* you would only use the two points and those are the same." – Gloria [13:43]
Intuitive Trust	Trusts his/her own intuition	"I *feel like* there has to be an endpoint. Yeah, so it must be here." – Yuki [22:07]
Sources (type of intellectual sources students draw upon)		
External Sources	Drawing upon external sources such as formulas, symbols, memorized facts, etc.	"We're going over average values *in class now* so I'm gonna use that." – Lynn [6:29]
Internal Sources	Drawing upon internal sources such as conceptual reasoning, own understanding, intuition, etc.	"Well *if I'm thinking about the water*…you would just pour and pour and would go up faster and faster." – Nate [38:08]

While the set of six codes captures each individual's epistemologies of mathematics in more detail, collapsing the codes into two thematically similar code groups allows us to (a) more clearly examine similarities and differences in epistemologies between and across individuals, and (b) track large-scale shifts in the type of epistemological resources an individual used throughout different parts of the interview. The first code group is "Formal Resources" which includes Correct Answer, External Trust, and External Sources, indicated in green in Table 1. The second code group is "Intuitive Resources." which includes Make Sense, Intuitive Trust, and Internal Sources, indicated in orange in Table 1.

Results

Shifting and Varied Epistemologies

Students display multiple, seemingly contradictory epistemologies of mathematics. These ideas about the nature of mathematical knowledge appear to be dynamic and context-dependent. All nine participants in the study drew on elements (apparent goals, trust, and/or sources of knowledge) from both the Formal Resources and Intuitive Resources code groups while working on the different interview tasks. The Car Problem provides a clear example of students drawing on epistemological elements from both the Formal Resources and Intuitive Resources code groups across different question contexts. Each of the three question contexts within the Car Problem (position question, speed question, and acceleration question) were similar in structure, as they all asked about a characteristic of the data represented by the same problem setup and graphs, all had the same multiple-choice formatting, and all had the same answer choices. Comparing student responses to the three question contexts illustrates how each individual utilized different resources at different times. Table 2 displays the primary code group (Formal or Intuitive) for each participant while working on each question. Eight of the nine students used primarily Intuitive Resources for some questions and primarily Formal Resources for others. There was not a strong relationship between which question the student was working on and the type of resource used..

Table 2. Primary resource type used by students in the first part of the Car Problem.

Participant	Position Question	Speed Question	Acceleration Question
Ash	Intuitive	Intuitive	Formal
Gloria	Formal	Intuitive	Intuitive
Ian	Intuitive	Intuitive	Formal
Jane	Formal	Formal	Formal
Lynn	Intuitive	Formal	Formal
Mary	Formal → Intuitive	Formal	Formal → Intuitive
Nate	Formal → Intuitive	Intuitive	Intuitive → Formal
Sonia	Formal → Intuitive	Intuitive	Intuitive → Formal
Yuki	Intuitive → Formal	Intuitive	Intuitive → Formal

The arrow notation (→) denotes a significant shift in the primary resource type used within a question.

The case of Mary working on the Car Problem provides a case study of shifts in the type of epistemological resources she drew upon. Mary initially spent a total of two and a half minutes on all three questions in the first part of the Car Problem. She relied primarily on Formal Resources to arrive at her answers, including memorized-from-class ideas (e.g., "slope = velocity" and "speed is acceleration") and process of elimination ("well, the only thing I haven't used yet is area, so it's probably that.") Without prompting, she stated that she was unsure of whether her answers to the questions about the cars' relative positions, speeds, and accelerations were correct. She said "on a test, I'd just, like put down this answer and move on." She then asked if she could move on to the next part of the interview task. The interviewer responded by asking her to explain how she knew the answers she had written down. After this, Mary spent eighteen minutes reworking all three parts of the Car Problem. Eventually, she decided to label the axes with units (miles per hour on the vertical "speed" axis, and hours on the horizontal "time" axis) to figure out what the area and slope should represent. She stated that "slope is *y* over x" and calculated that miles per hour divided by hours would be miles per hour squared, which she determined was a type of unit that would represent acceleration. She said to find the area you would take "length times width," so it would be "miles per hour times hours, which is miles" and reasoned that the area under the curve would represent miles traveled. When asked to explain her thinking Mary spent more time on her work, drew on Intuitive Resources for the first time in the interview, and eventually corrected her erroneous initial responses based on her own reasoning that did not rely on memorized procedures. A possible explanation for this is that the interviewer pointing out the "explain why you think so" part of the question implied to Mary that "explaining why" is an epistemologically valid and valuable thing to do, and the kind of thinking needed to do it was a different kind of thinking than what she originally used.

Resolving (or Not) Conflicts Between Intuitive and Formal Resources

During the interviews, students often used both Formal Resources and Intuitive Resources while solving a problem. A clear example of this is students' work on the average value question in the second part of the Car Problem (see Figure 2). Of the eight students who worked on this problem, six (75%) used both Formal Resources and Intuitive Resources and verbalized an apparent conflict between the two approaches (see Table 3). Using Formal Resources led all six of these students to the conclusion that Car A and Car B would have the same average speed from $t = 0$ to $t = 2$. Conversely, using Intuitive Resources led all six students to the answer that Car A would have a higher average speed in this interval. All of these students then proceeded to select which resource type (and hence, which answer) they thought was correct. All three students who prioritized their Intuitive Resources ultimately answered that Car A had higher average speed (answer choice "A") while all three who prioritized Formal Resources concluded that Car A and Car B had the same average speed (answer choice "C").

Table 3. Resource type(s) used and answer selected by students on the average value part of the Car Problem.

Participant*	Resource type(s) used	How conflict between resources types was resolved, if applicable	Answer selected
Ash	Both	Formal	C
Gloria	Both	Formal	C
Ian	Both	Intuitive	A
Jane	Intuitive	N/A	A
Lynn	Both	Intuitive	A
Mary	Both	Formal	C
Nate	Both	Intuitive	A
Sonia	"Complete guess"	N/A	A

*Yuki did not work on the average value question due to time constraints.

Ian's work on this problem is an illustrative example, as his reasoning shared similarities with several other students and he articulated clearly the conflict between his intuition and use of formal mathematics. Parts of Ian's interview that were coded as Formal Resources are indicated in green text in the transcript below. Intuitive Resources are indicated in orange.

Ian: I'm trying to recall the formula for average speed, and right now I think it's the speed at time-2 and the speed at time-0... I mean, the speed at time-2 minus the speed at time-0, divided by 2 because time is 2. Well, based on that, I would say the average speed is the same. [circles the answer choice "(c) Car A and Car B have the same average speed"]. But intuitively, that's not how I think. Car A has higher speed because it has more area [below the curve].

Interviewer: Tell me more about both of those ideas. So one was a formula, and the other you said intuitively you think it should be Car A, but the formula tells you they're the same.

Ian: I know that the distance is speed times time. I don't know. I would say this [points to his writing of 'distance = speed · time'] is certain. The distance of a speed-time graph would be the area under the graph. So based on that, Car A, it would travel farther. If Car A traveled further, then it would make sense to say that it would have higher average speed over the time that it's been traveling, because that's the only way for it to travel further. So yeah, I guess just based on that reason, I can choose Car A. I don't know. [Ian erases his earlier choice of answer (c) and instead chooses "(a) Car A has greater average speed."]

Interviewer: What about the formula you had that told you they're the same?

Ian: This [pointing to the writing of 'distance = speed · time' is somehow here in my head. That formula was taught to me before somewhere. Yeah. But I trust my intuition more."

Ian abandons the formula in favor of his intuition, even though the formula was the first thing he attempted to use to solve the problem. He does not attempt to explore *why* the formula gave a different answer than his intuition or why it might not have been an appropriate formula to use in this case. Furthermore, his statement that the formula is "somehow here in my head" and the lack of attempt to use the meaning of the formula in thinking about this problem suggests that this piece of formal mathematical knowledge is not linked to his intuitive knowledge, at least in this case for this particular student. Furthermore, he does not *expect* that the two should be linked. Like Ian, none of the students who experienced conflict between formal mathematical knowledge and their own intuitive knowledge made any attempt to reconcile them. This suggests that students view these intellectual resources as quite separate and independent, rather than resources that could be useful in conjunction with each other.

Discussion

The main conclusion from this study is that many students employ varied epistemologies when doing mathematics that can sometimes be in tension. They may at times consciously or unconsciously suppress their own abilities to reason intuitively about mathematical phenomena because they do not believe that these intellectual resources are valuable when doing mathematics. For mathematics education research, this suggests that evidence of students' beliefs about mathematics gathered in one context (on a survey or an interview, for example) should not be interpreted as indicative of the full range of their epistemologies. For instruction, there is not necessarily a need to replace students' epistemological beliefs with different ones, but rather a need to supporting and reinforcing the productive beliefs that are already there. Last, noting that students' epistemologies of mathematics play a role in how they approach mathematical tasks gives instructors a potential opportunity to leverage shifts in epistemologies to support students' learning of calculus content.

This is a small sample that only included participants who volunteered to be interviewed. While it is possible that these findings are indicative of the kinds of epistemologies that some beginning calculus students hold, these results should not be interpreted as broad claims about calculus students in general. In addition, further research could explore how different instructional strategies in calculus courses influence students' epistemologies.

Evaluating the Quality of Instruction in Post-secondary Mathematics (EQIPM) is a video coding instrument that provides indicators of the quality of instruction in community college algebra. Following an extensive revision, and the coding of a set of 84 videos from 40 instructors, we report the results of a confirmatory factor analysis, that suggests that the instrument captures three distinct hypothesized dimensions of quality of instruction in community college algebra classes. Due to the nature of the instruction observed, the items in the instrument needed to be treated as categorical and some had to be removed from the analysis. We use the data to provide a first glimpse of the quality of algebra instruction that we found in this data set.

Keywords: Algebra, Instruction, Video Coding, Community Colleges

Quality of mathematics instruction matters for students' learning and motivation towards pursuing further studies in a particular discipline. Interestingly most research primarily documents the negative effects of poor quality of instruction on various aspects of students' experiences: learning, affect, beliefs, identity, perception of self, etc. (Maltese & Tai, 2011; Seymour, 2002; Watkins & Mazur, 2013). The interest in documenting classroom activity has been growing, because of mounting evidence that when 'active learning' is implemented in classrooms, students perform better (Freeman et al., 2014). Most of these reports, however, are not based on evidence collected from large-scale observations of classroom teaching. In part, this is because teaching is a complex practice that is also highly contextualized, not only by the content itself, but also by the available resources (e.g., textbooks that support inquiry, online sites), and the institutional features in which it occurs (teaching at an institution with selective admissions is different from teaching at a community college that is open access). In recent years, more scholars have been scrutinizing teaching practice with the goal of making claims regarding its connection to student learning. We contribute to this body of work, with an instrument that attends to instruction in algebra courses at community colleges. Our work builds on foundational contributions made to understand the quality of mathematics instruction in elementary and middle school settings and its connection to student achievement, and complements current work to describe the instruction needed to support faculty in teaching inquiry-oriented materials. We also posit that a reliable and valid method to fully describe how instruction occurs can bring to light the complexity of instructors' work in post-secondary settings and contribute to the development of faculty professional development opportunities that can be focused on the classroom interactions that matter for student learning (Bryk, Gomez, Grunow, & LeMahieu, 2015). As part of a larger project that investigates the connection between the quality of instruction and student learning in community college algebra courses, we have been working on an instrument, Evaluating Quality of Instruction in Postsecondary Mathematics

(EQIPM), that seeks to characterize instruction in community college algebra.* In this paper, we present the results of a confirmatory factor analysis that supports the hypothesized structure of quality of instruction that we envisioned. We note that at the time of our project there were no instruments that could reliably be used to ascertain quality of instruction in post-secondary settings, in particular at community colleges.

Theoretical Perspective

We assume that teaching and learning are phenomena that occur among people enacting different roles—those of instructor or student—aided by resources of different types (e.g., classroom environment, technology, knowledge) and constrained by specific institutional requirements (e.g., covering preset mathematical content, having periods of 50 minutes, see Chazan, Herbst, & Clark, 2016; Cohen, Raudenbush, & Ball, 2003). We focus on instruction, one of many activities that can be encompassed within teaching (Chazan, et al., 2016), and define it as the interactions that occur between instructors and students in concert with the mathematical content (Cohen et al., 2003). Such interactions are influenced by the environment in which they occur and change over time. The EQIPM instrument, designed with the goal of assessing the quality of the interactions defining instruction, specifically the Quality of Instructor-Student interaction, the Quality of Instructor-Content Interaction, and the Quality of Student-Content Interaction, supported by the quality of *Mathematical Errors and Imprecisions in Content or Language* that are present in a lesson. Figure 1 illustrates the theorized structure of the coding instrument by showing individual items within the three constructs. The items under *Segment features* help characterize the segment (i.e., Nature of Mathematics, Modes of instruction, Technology use). See the Appendix for the definition of the items

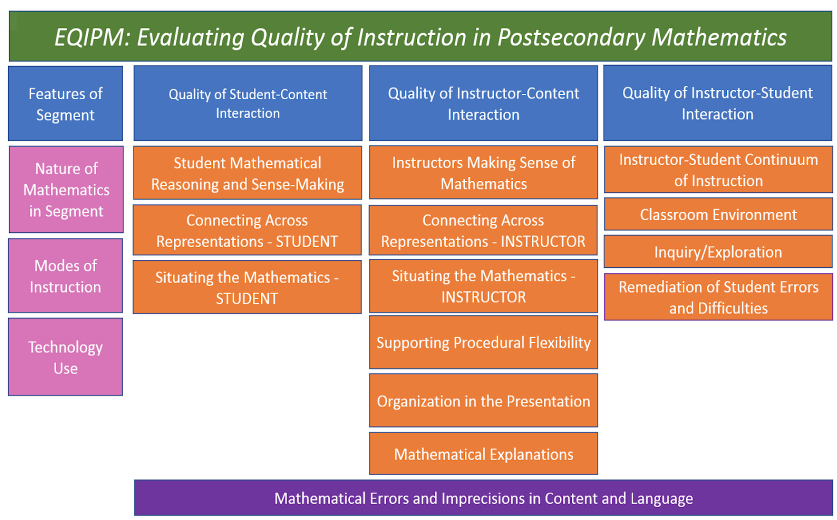

Figure 1. Dimensions and codes for the EQIPM instrument.

Methods

In the Fall 2017 semester we video-recorded 131 lessons in intermediate and college algebra classes from two different community colleges in each of three different states. The lessons ranged in duration between 45 and 150 minutes, and were taught by 40 different instructors (44 different unique courses video-recorded; 4 instructors taught 2 sections of a course). The lessons covered one of three topics: linear equations/functions, rational equations/functions, or exponential equations/functions. These topics were chosen because they offer us opportunities to

* Our instrument is different from another classroom observation tool, *Equity QUantified In Participation* (EQUIP) developed by Reinholz and Shah (2018) which assesses equitable participations in classrooms.

observe instruction on key mathematical concepts (e.g., transformations of functions; algebra of functions) and to attend to key ways of thinking about equations and functions (e.g., preservation of solutions after transformations; covariational reasoning), which are foundational algebraic ideas that support more advanced mathematical understanding (Breidenbach, Dubinsky, Hawks, & Nichols, 1992; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). The development of EQIPM was similar to the process used by Hill and colleagues (2008) and by Litke (2015). Their instruments describe and qualify instructional practices from video-recorded lessons by subdividing lessons into 7.5-minute segments and rating all segments within a lesson. For the analysis reported here, we coded 44 lessons of each of the unique courses video-recorded.

Using Version 4 of EQIPM (AI@CC Research Group, 2018), each 7.5-minute segment within a lesson was coded by one member of a team of 15 researchers using a rubric that defined the items. For each item, coders were asked to identify evidence that matched each item. If no evidence was found, coders entered a 0. If there was evidence, to support the item, the coders were asked to rate its quality on a 1 to 4 scale according to the rubric. In all items except one, a rating of 1 or 2 meant that the evidence in the segment weakly represented the description of high-quality for the item, whereas a rating of 3 or 4 meant that the evidence within the segment strongly represented the description of high-quality for the item. The item *Mathematical Errors and Imprecisions in Content and Language*, was rated in the reverse (a low rating was assigned for minor imprecisions and errors; a high rating was assigned for major imprecisions and errors). Each coder provided a justification for their rating. Each coder independently coded 3 to 4 consecutive segments of a lesson to minimize bias due to familiarity with the instructor or the lesson. Fourteen percent of segments were randomly chosen for double-coding by two coders. Each pair of coders held calibration meetings to discuss their ratings when one of the following situations arose: (1) when one rater assigned a 0 and the other rating was not 0 and (2) when the discrepancy between non-zero ratings by the coders was greater than one point. In each case a single rating was assigned after a discussion of the evidence. When it was difficult to decide, the coding was discussed in a meeting with all the coders.

Thirteen percent of segments (150 out of 1122) were removed from the data set before conducting the confirmatory factor analysis (CFA) because they were marked as having no mathematics taught in the segment. The variables in our model were continuously scored 0- to 4, but their distributions were not uniformly distributed, which is an assumption for typical CFA. For this reason, we decided to use ordinal CFA and reduced the rating scale into three ordinal categories. The 0 ratings remained as 0 to indicate no evidence; ratings of 1 or 2 were reclassified as a 1, to indicate low quality of instruction, and ratings of 3 or 4 were reclassified as a 2, to indicate high quality of instruction. The final sample included 972 segments, representing a balanced proportion of segments by course (intermediate algebra, n = 515 segments; college algebra, n = 457 segments) and diverse representation by topic (linear equations, n = 107 segments; rational equations, n = 283 segments; exponential equations n = 539 segments; and other topics, n = 43 segments).

We used our theoretical model that hypothesized that the items fell into 3-factors, *Student-Content Interaction, Instructor-Content Interaction, and Instructor-Student Interaction,* and tested the structure using confirmatory factor analysis (CFA). CFA is a statistical technique used to verify the factor structure of a set of observed variables, when there is a robust hypothetical model. Using modification indices (see below), that included removing problematic items, the model was adjusted until a properly fitting model was found. This process was based on commonly used criteria for CFA models (Hu & Bentler, 1999).

Preliminary Findings

We found that the 3-factor theoretical model was an adequate good fit to the data: CFI = 0.967, RMSEA = 0.039, SRMR = 0.079. The item *Mathematical Errors and Imprecisions in Content and Language* was excluded from the modeling, because, consistent with other studies, we hypothesized that the item would potentially load in all the factors. In addition we removed *Remediation of Student Errors and Difficulties* because its loadings (0.158) were below the level of acceptability. We added two modifications based on suggestions from modification indices which allowed the error variances between two pairs of variables to be correlated: *Student Connecting Across Representations* and *Instructor Connecting Across Representation* as well as *Instructor Connecting Across Representations* and *Inquiry/Exploration*. This model had both acceptable model fit indices and acceptable standardized factor loadings; we did not pursue further modifications. Our CFA model supported three meaningful factors using 12 of the 13 items (see Table 1). We found that two factors, *Student-Content Interactions* and *Instructor-Student Interactions* are positively correlated ($r = 0.981$, $p < 0.001$) whereas the other two are not (*Student Content Interactions – Instructor Content Interactions,* $r = 0.264$, *n.s.*; *Instructor-Content Interactions – Instructor Student Interactions,* $r = 0.231$, *n.s.*).

Table 1. Standardized Factor Loadings for the 3-Factor CFA Solution.

Construct	Item	Standard Estimate	SE
Factor 1: Student-Content Interaction			
	Student Mathematical Reasoning & Sense-Making	0.798	0.041
	Student Connecting Across Representations.	0.603	0.041
	Student Situating Mathematics	0.439	0.084
Factor 2: Instructor-Content Interaction			
	Instructor Sense-Making	0.791	0.059
	Instructor Connecting Across Representations	0.377	0.049
	Instructor Situating Mathematics	0.284	0.049
	Supporting Procedural Flexibility	0.256	0.054
	Organization in the Presentation	0.394	0.057
	Mathematical Explanations	0.397	0.051
Factor 3: Instructor-Student Interaction			
	Continuum of Instruction	0.874	0.047
	Classroom Environment	0.736	0.049
	Inquiry/Exploration	0.660	0.049

Discussion

Factor 1 seems to capture all three hypothesized items of **quality of student-content** in the second column of Figure 1 with reasonably strong loadings (factor loading greater than 0.6) for *Student Mathematical Reasoning and Sense-Making* and *Connecting Across Representation* and adequate loading (greater than 0.3) for *Students Situating Mathematics*. This item had 97% of segments rated as not present. *Students Situating Mathematics* contributes less to the quality of student-content interaction than the other two variables and relates less to the other two variables in this factor. Further discussion focused on refining this item may be warranted.

Factor 2 also appears to capture all six items hypothesized for **quality of instructor-content interaction** (third column of Figure 1); this factor has a wider range of loading. Only *Instructor Making Sense of Mathematics* has a reasonably strong loading. Three other items, *Instructor Connecting Across Representations*, *Organization in the Presentation*, and *Mathematical*

Explanations, have adequate loadings (greater than 0.3); two items, *Instructor Situating the Mathematics* and *Supporting Procedural Flexibility* have weak loadings. The weak loadings may speak directly about how instructors manage mathematical content attending to discrete topics rather than situating the topics within broader mathematical ideas (67% of 972 of the instances were rated 0, no evidence) and presenting mathematics with one efficient procedure rather than attending to flexibility (71% of 972 of the instances were rated 0, no evidence). These two items have limited contributions to the quality of instructor-content interaction at this time.

Finally, Factor 3 for **quality of instructor-student interaction**, embedded three of the four items under the fourth column of Figure 1 that were meant to address how students and the instructor were working together. The three items have reasonably strong loadings, all greater than 0.6. *Remediation of Student Errors and Difficulties* had to be removed from the analysis because of poor fit. One problem in rating this item stems from when instructors had opportunities to remediate, which occurred mainly during sessions in which students worked individually on problems at their desks. In many instances, it was difficult to ascertain what remediation was occurring, because it was unclear how the remediation was happening; thus, it was not possible to assess its quality. How instructors remediate errors and difficulties students have is crucial for high quality instruction, in particular in 1-1 interactions with the students. The item may need to be further refined to account for these cases.

These CFA results are encouraging. We will use the constructs to model student outcomes (percent grade in course), controlling for variables at the student and instructor level (demographics, beliefs, attitudes, prior knowledge) to determine if there is a difference in student performance that can be associated with high quality instruction. The next step would be to scale these individual variables into composite scores for use in further analysis.

Being able to identify three distinct factors that can be used to describe the quality of community college algebra instruction is promising for the field in that each of the constructs suggest specific areas for supporting the work of instructors in teaching community college algebra. These results also support previous research in K-12 that models learning via assessing the quality of instruction defined as the interactions between teacher, student, and content. The factors used will be included in the full model of our data to determine links between instructional qualities and student performance. Moreover, the instrument has substantial promise for the design of future professional development efforts with community college faculty that would promote high quality instruction.

Appendix: Definition of the Items

Student-Content Interaction
Student Mathematical Reasoning and Sense-Making: Assesses student utterances that showcase reasoning and sense-making about mathematical ideas
Connecting across Representations-STUDENT: Assesses the connections that students express within, between, and across representations of the same mathematical problems, ideas, and concepts
Situating the Mathematics-STUDENT: Assesses how students make connections to other aspects of the algebra curriculum, related topics, or the broader domain of mathematics, situating and motivating the current area under study within a broader context.
Instructor-Content Interaction
Instructors Making Sense of Mathematics: Assesses how instructors leverage known and new mathematical ideas or students' personal knowledge or experiences, in order to make meaning of the mathematics presented.
Connecting across Representations-INSTRUCTOR: Assesses the connections that instructors make within, between, and across representations of the same mathematical problems, ideas, and concepts
Situating the Mathematics-INSTRUCTOR: Assesses how instructors make connections to other aspects of the algebra curriculum, related topics, or the broader domain of mathematics, situating and motivating the current area under study within a broader context.
Supporting Procedural Flexibility: Assesses how instructors support the development of procedural flexibility, by identifying what procedure to apply and when and where to apply it.
Organization in the Presentation: Assesses how complete, detailed, and organized the instructor's presentation content is when outlining or describing the mathematics, or describing the steps used in a procedure.
Mathematical Explanations: Assesses how instructors provide mathematical reasons and justifications for why something is done.
Instructor-Student Interaction
Instructor-Student Continuum of Instruction: Assesses the degree to which either the instructor or the students contribute to the development of the mathematical ideas (abstract concepts, formulas, notation, definitions, concrete examples, pictorial examples, and rules/properties). It captures who is responsible for the development of those ideas.
Classroom Environment: Assesses how instructor and students create a respectful and open environment in their classroom and in which expectations for high quality mathematical work are the norm.
Inquiry / Exploration: Assesses the degree to which mathematics exploration and inquiry occurs
Remediation of Student Errors and Difficulties: Assesses remediation (either for the whole class or with individual/small groups) in which student misconceptions and difficulties with the content are addressed
Cross-Cutting Item
Mathematical Errors and Imprecisions in Content or Language: Assesses mathematically incorrect or problematic use of mathematical ideas, language, or notation.

Analyzing Collegiate Mathematics Observation Protocols: Attending to the Instructional Triangle and Inquiry-Based Mathematics Education Practices

Erica R. Miller	Kimberly C. Rogers	Sean P. Yee
Virginia Commonwealth University	Bowling Green State University	University of South Carolina

Typically, departments and universities evaluate and provide feedback to college mathematics instructors on their teaching by conducting classroom observations. When these observations are guided by an observation protocol, the protocol provides a particular lens that focuses the observer's attention on certain aspects of instruction. To understand the way in which mathematics departments are currently evaluating teaching, we investigated the structure, focus, and alignment with inquiry-based mathematics education practices of items on 25 observation protocols. The results suggest that protocols mainly include closed-response items that are evaluative, focus more on the instructor than the students or the content, and rarely attend to inquiry-based mathematics education practices. These results have implications for both those who develop observation protocols and those who use observation protocols as a measure of teaching practices. In particular, our study highlights the need for careful consideration to be taken when observations are used for performance measures.

Keywords: Classroom Observation Protocols, Instructional Triangle, Inquiry-Based Mathematics Education

At its core, a classroom observation protocol (OP) has an agenda. It guides the observer to explicitly attend to certain aspects of teaching, learning, and the classroom environment while disregarding others. To better understand the purpose of OPs and identify different aspects of teaching and learning they attend to, we analyzed OPs that were developed by and used "in house" in mathematics departments as well as OPs that were developed by education researchers and used more broadly. The purpose of this study is to inform our understanding of the current (explicit or implicit) stance that mathematics departments take on evaluating teaching in order to identify where progress must be made with observations and provide direction for teachers of undergraduate mathematics education. The following research questions guided our analysis.

RQ1. How are classroom observation protocols structured?
RQ2. On what aspects of instruction do classroom observation protocol items focus?
RQ3. To what extent do classroom observation protocol items attend to the four pillars of Inquiry-Based Mathematics Education (Laursen & Rasmussen, 2019)?

Literature Review

Classroom Observation Protocols

OPs are often used as a way to provide teachers with specific feedback and evaluations of their instructional methods and classroom practices. OPs may be designed as descriptive or evaluative instruments. The principal aim of descriptive OPs is to capture and describe what is happening in a class, whereas evaluative OPs measure (with ordinal, cardinal, or scalar measurements) the quality of a class against a theory of instructional quality. Moreover, OPs may also be holistic (encompassing the whole lesson) or segmented (separately rating shorter segments of the lesson). Segmented protocols usually capture structure, while holistic views can be more appropriate for capturing quality (Tatto, Burn, Menter, Mutton, & Thompson, 2018;

Tatto et al., in press). For example, a lengthy whole-class discussion may span several segments that are treated separately. A holistic protocol, on the other hand, might focus on how an error made early in a lesson is featured in the lesson closing, clearing up students' misconceptions.

Additionally, protocols will likely vary in the degree of structure, whether they require high or low inference by observers, and on what they focus observers' attention. Although much can be learned from a content-general OP (e.g., Classroom Assessment Scoring System, Mikami et al., 2011), specific indicators of mathematics teaching and learning are important for capturing quality of mathematics instruction. Multiple research projects (e.g., Joe et al., 2013; Mihaly et al., 2013) and reviews (Bostic et al., in press; Boston et al., 2015) synthesize the major OPs developed for teaching mathematics at the K-12 level. These reports provide the field with syntheses of measures for K-12 mathematics teaching, but there is a lack of overarching syntheses of protocols for measuring the quality of undergraduate mathematics instruction.

The Instructional Triangle

In order to analyze what aspects of instruction OPs focus on, we chose to use the instructional triangle framework. Cohen, Raudenbush, and Ball (2003) defined teaching as "what teachers do, say, and think with learners, concerning content, in particular organizations and other environments, in time" (p. 124). In their definition, four critical aspects of teaching become apparent: teachers, learners, content, and environments. Cohen et. al took these four aspects and situated them in a model that represents instruction as interaction (Figure 1). This model is often referred to as the instructional triangle, since it situates the teacher, learners, and content in direct interaction inside of environments.

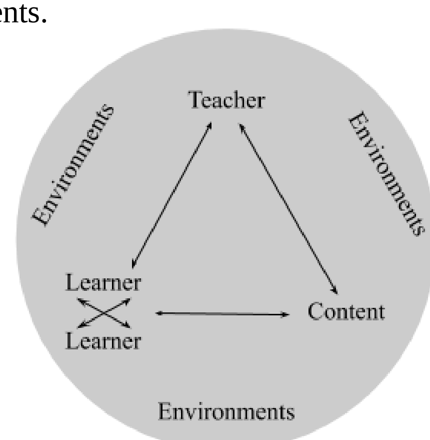

Figure 1. Cohen, Raudenbush, and Ball's (2003) instructional triangle.

Inquiry-Based Mathematics Education

Over the past two years, undergraduate mathematics educators in the U.S. have brought together the ideas of inquiry-based learning (Laursen, Hassi, Kogen, & Weston, 2014) and inquiry-oriented instruction (Rasmussen & Kwon, 2007) to align with international work in inquiry-based mathematics education (IBME, Laursen & Rasmussen, 2019). In Laursen and Rasmussen's seminal work, IBME does not try to claim its own scholarly territory, but collaboratively complement the use of inquiry for a more unified and robust model to aid undergraduate mathematics education. Drawing from secondary and collegiate views of inquiry about student engagement and student learning internationally, IBME prescribes four critical pillars for student learning (p. 138):

1. Students engage deeply with coherent and meaningful mathematics,

2. Students collaboratively process mathematical ideas,
3. Instructors inquire into student thinking, and
4. Instructors foster equity in their design and facilitation choices.

The intent of these four pillars is to "account for student learning and thus offer guidance to instructors seeking to develop their teaching practice" (Laursen & Rasmussen, 2019, p. 138). Therefore, these four pillars provide guidance towards evidence-based effective teaching strategies that align with the Mathematical Association of America's (2018) Instructional Practices Guide and offer a prescriptive model to look at teaching. This new model for teaching undergraduate mathematics education offers a student-centered focus on inquiry, but is this currently a measurement used by higher education? To answer this question, this study uses the IBME pillars as a tool to determine to what extent OPs already incorporate these pillars. As a result of this study, we aim to provide the field with a baseline to understand what mathematics departments attend to and focus on in OPs to aid in further study of growth in teaching undergraduate mathematics (Miller et al., 2018).

Methods

Data Collection

This study grew out of a session from the College Mathematics Instructor Development Source (CoMInDS) Workshop on Improving the Preparation of Graduate Students to Teach Undergraduate Mathematics at the University of Tennessee, Knoxville in 2019. Participants at the workshop came from universities across the U.S. and were involved with providing professional development for college mathematics instructors in their respective mathematics departments. During the workshop session, the organizers asked participants to upload OPs to a shared folder. A total of 25 OPs were uploaded by 14 individuals from 13 different universities, the majority of which were developed and used internally by individual mathematics departments (N = 17). However, participants also uploaded some OPs developed by universities (N = 3) and researchers (N = 5), which we also analyzed. Although the majority of OPs uploaded were for observing graduate students, some were designed for observing faculty members or instructors at large. Also, the majority of the OPs were specifically for observing mathematics classes (N = 19), but two were for observing STEM classrooms and four were for observing any classroom. Since this sample of OPs provided us with the opportunity to analyze department observation protocols that we normally would not have access to, we chose to focus on only these OPs for this study. In doing so, we aimed to understand the nature of the OPs that were identified by faculty who are invested in improving mathematics instruction in their departments.

Data Analysis

In order to answer our research questions, we chose to analyze the individual OP items along three main dimensions: structure, item focus, and attention to the four pillars of IBME (Laursen & Rasmussen, 2019). To analyze the structure, we first recorded the Item Type (Scalar, Checkbox, Numeric, or Open Response). As we began coding, we added additional structural codes to note if an item (b) had Additional Space for Comments even though it was a closed-response item, (c) was primarily used for Observation Record Keeping (e.g., observer name, date, number of students present), or (d) provided an opportunity for the Observee (to have a) Voice by leaving comments. For the second dimension, we analyzed if the item was Teacher-Focused, Student-Focused, Lesson/Content-Focused, or Classroom Logistics/Physical Environment-Focused. Although it was possible that an item may have attended to multiple aspects of instruction (e.g., both the teacher and students), we chose to only code for an aspect if it was the primary focus of the item. We also recognized that social or cultural environment was also sometimes a focused, but coded these items as either Teacher- or Student-Focused since they involved mostly human interactions. Finally, for the third dimension, we analyzed whether or not each item attended to Student Engagement, Student Collaboration, Instructor Inquiry, and Equity. We decided to apply a broad interpretation of what counted as Student Engagement and Equity. For example, we coded items that attended to whether or not the classroom environment was respectful as attending to Equity and included any item that mentioned student engagement, even if the item did not explicitly attend to whether or not "students engage deeply with coherent and meaningful mathematical tasks" (Laursen & Rasmussen, 2019, p. 138).

Table 1. Examples of Item Focus and IBME Pillar codes.

Example Item	Codes	Justification
The teacher used questioning strategies to encourage participation, check on skill development, and facilitate intellectual engagement and productive interaction with students about important science and mathematics content and concepts.	Teacher-Focused Student Engagement Instructor Inquiry	The item mentions student engagement, but is mainly focused on the teacher's classroom facilitation.
Interactions reflected collegial working relationships among students (e.g., students worked together productively and talked with each other about the lesson).	Student-Focused Student Collaboration	This item primarily focuses on evaluating how well students worked together during class.
The lesson was well organized and structured (e.g., the objectives of the lesson were clear to students, and the sequence of the lesson was structured to build understanding and maintain a sense of purpose).	Lesson/Content-Focused	Although the teacher directs and organizes the lesson, this item focuses primarily on evaluating the lesson and content.
The classroom is organized appropriately such that students can work in groups easily and get to lab materials as needed, and the teacher can move to each student or student group.	Classroom Logistics/Physical Environment-Focused	This item explicitly focuses on the physical (as opposed to social or cultural) environment of the classroom.

Results

In total, there were 656 items on the 25 OPs. However, this number includes 125 items that we categorized as Observation Record Keeping. Although some of these items recorded information that may be relevant to evaluating student engagement (e.g., number of students enrolled, number of students present, number of students tardy), we decided to categorize these items separately and focus only on the other 531 items in the OPs. In particular, all of the numbers and percentages we mention in the rest of the report are focused on only the 531 non-

Observation Record Keeping items. Due to space constraints, we cannot report our results for each individual OP. Instead, we group OPs by who developed them (departments, universities, or researchers) and compare across the groups. In Table 2, the percentages in each column are calculated based on the last row (Total Number of Items) in that column.

Table 2. Comparison group summary of code frequencies.

Code Categories	Department (N = 17)		University (N = 3)		Researcher (N = 5)		Total (N = 25)	
Item Type*								
Scalar-Categorical	84	(32%)	111	(87%)	33	(24%)	228	(43%)
Scalar-Continuous	6	(2%)	0	(0%)	30	(22%)	36	(7%)
Checkbox	40	(15%)	0	(0%)	26	(19%)	66	(12%)
Numeric	1	(0%)	0	(0%)	39	(28%)	40	(8%)
Open Response	135	(51%)	17	(13%)	9	(7%)	161	(30%)
Item Focus								
Teacher	161	(61%)	46	(36%)	63	(46%)	270	(51%)
Student	43	(16%)	14	(11%)	44	(32%)	101	(19%)
Lesson/Content	48	(18%)	48	(38%)	31	(23%)	127	(24%)
Classroom Logistics/ Physical Environment	20	(8%)	7	(5%)	11	(8%)	38	(7%)
IBME Pillar								
Student Engagement	45	(17%)	10	(8%)	56	(41%)	111	(21%)
Student Collaboration	15	(6%)	4	(3%)	19	(14%)	38	(7%)
Instructor Inquiry	18	(7%)	27	(21%)	33	(24%)	78	(15%)
Equity	18	(7%)	21	(16%)	15	(11%)	54	(10%)
Total Number of Items	266		128		137		531	

**Item Type is the only code group where category columns will add up to 100%, because every item was required to be categorized into a distinct item type. However, items could be coded with none, one, or multiple Item Focus and IBME Pillar codes, so these rows are not distinct and category columns do not total to 100%.*

The OPs contained between 7 and 93 items (N = 25, M = 21, SD = 17.68). Of the three comparison groups, department OPs tended to be the shortest; containing 7 to 36 items (N = 17, M = 16, SD = 9.26). Researcher OPs had the most consistent number of total items; containing 22 to 33 items (N = 5, M = 27, SD = 4.62). University OPs had a wide variance of total items (9, 27, and 93), although the longest OP did say that the observer should only pick 20 items to focus on. The majority of items on the OPs were either Scalar-Categorical (43%) or Open Response (30%). Looking across the comparison groups (Table 2), we noticed that department OPs had a much higher percentage of items coded as Open Response (51%) in comparison to university (13%) and researcher (7%) OPs. However, university OPs did not include Scalar-Continuous, Checkbox, or Numeric items, while researcher OPs had a more even distribution of the items that were closed-response.

In addition to looking at the total number of items and item types, we considered whether or not closed-response items had Additional Space for Comments to be left by the observer. On the one hand, researcher OPs had the highest percentage of closed-response items (93%) and the highest percentage of closed-response items that had Additional Space for Comments (68%); so they still had a balance of quantitative and qualitative feedback. Department OPs, on the other hand, only provided Additional Space for Comments 15% of the time and the three university OPs never included Additional Space for Comments. The final structure that we coded for is whether or not the OP contained items that provided the observee with an opportunity to leave feedback or comments, which we called Observee Voice. This was not a common code, but department OPs had the highest percentage of Observee Voice items (14%) in comparison to university (2%) and researcher (5%) OPs.

For RQ2, we coded for the four aspects of the instructional triangle: teacher, student, content, and environment. The majority of items across all protocols were Teacher Focused (51%) and few items were Classroom Logistics/Physical Environment Focused (7%). However, considering the three comparison groups, we see each group had a different focus. Department OPs had the highest percentage of Teacher Focused items (61%), while university OPs had the highest percentage of Content/Lesson Focused items (38%) and researcher OPs had the highest percentage of Student Focused items (32%). Moreover, university OPs had almost an even split of Teacher (36%) and Content/Lesson (38%) focused items and researcher OPs had more Teacher (46%) than Student (32%) focused items.

For RQ3, the final dimension we analyzed was whether or not items on OPs attended to the four pillars of IBME (Laursen & Rasmussen, 2019). Although the IBME Pillars were only recently identified, we hoped that many items would attend to them since these pillars are based on established best practices and recommendations in undergraduate mathematics education. However, we found that the minority of the items (42%) attended to the IBME pillars, and ironically this percentage drops to 36% if we consider only the OPs that were explicitly designed for observing mathematics classrooms. Of the four pillars, Student Engagement was attended to the most (21%) and Student Collaboration was attended to the least (7%). Out of three comparison groups, the researcher OPs had the highest percentages of items that attended to Student Engagement (41%), Student Collaboration (14%), and Instructor Inquiry (24%). Few of the items on university OPs attended to Student Engagement (8%) and even fewer attended to Student Collaboration (3%), but they did have a higher percentage of items that attended to Instructor Inquiry (21%) and the highest percentage of items that attended to Equity (16%). Finally, we found that items on department OPs sometimes attended to Student Engagement (17%), but rarely attended to Student Collaboration (6%), Teacher Inquiry (7%), or Equity (7%).

Discussion

From this analysis, we found that the majority of items included in OPs provided quantitative measures of instruction, which suggests that the majority of items analyzed were designed as evaluative measures, not descriptive. Given that OPs are often used to evaluate teaching, this result was not surprising, as quantitative data is often the primary way that performance is measured in academia (Yee, Deshler, Rogers, Petrulis, Potvin, & Sweeney, 2019). Many items focused primarily on the teacher, which may suggest that OPs still have a strong tendency to be teacher-focused as opposed to student-focused. Even though the majority (N = 19) of these OPs were developed specifically for observing mathematics classrooms, few of the items attend to the IBME pillars. This result may suggest that although the field of mathematics education has recognized the importance of student engagement, student collaboration, instructor inquiry, and equity, our evaluative methods have not.

One implication of our results is that OPs tend to be more evaluative than descriptive, which may lead to the introduction of bias or inconsistency in interpreting results. In particular, many of the Scalar items did not include descriptors for the categories or comparisons that were being made. Therefore, there is no way to judge whether or not observers are interpreting and rating items in the same way. This lack of descriptors is especially concerning given that OPs can be used as performance measures for academic raises, performance reviews, and promotion decisions. Additionally, although mathematics education research has described instruction as having three main components (teachers, students, and content), OPs often focus primarily on one or two of these components, which puts the instructional triangle off-balance. For instance, in Figure 2 we include a black triangle that represents an even split of items from an OP focusing on the teacher, students, and content. The triangle in red represents the department OPs, which focused mostly on the teacher and very little on the other aspects. The triangle in blue represents the university OPs, which split the focus on the teacher and content, but paid little attention to the students. Finally, the green triangle represents the researcher OPs, which did attend to instructors more than content, but were the closest to an even split among the three aspects of instruction. Ultimately, our results indicate that mathematics departments need to carefully consider redesigning their OPs to better align with current recommendations in order to realize the vision for IBME at the collegiate level.

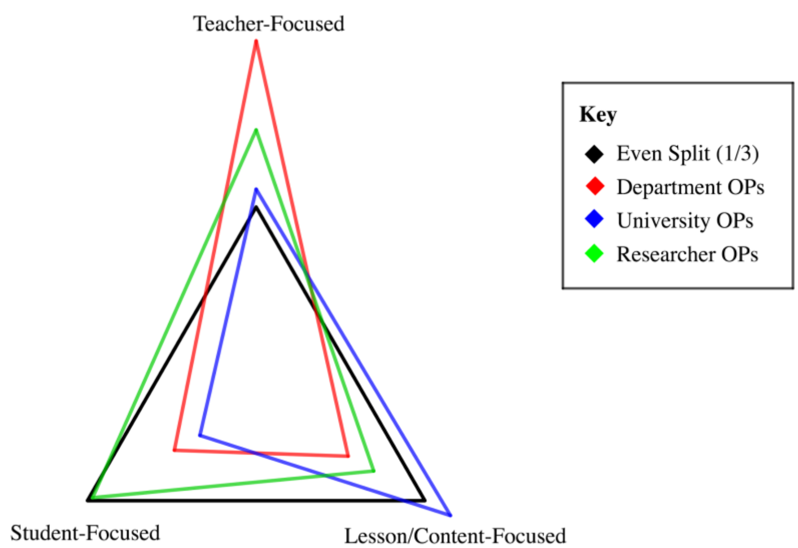

Figure 2. Distribution of Item Focus for each comparison group.

One limitation of our study is the limited sample size. In particular, we analyzed a small number of OPs developed for internal use by universities and those developed by researchers for external use. Future work could increase the sample size for these two categories to make a more robust comparison of the three groups, but this initial study provides us with an understanding of what is currently being used when observing collegiate instruction at 13 different universities. Additionally, all department OPs analyzed were shared by participants who chose to attend a workshop specifically focused on collegiate mathematics instruction. In particular, many workshop participants described their involvement in the development or revision of the department OPs that they shared. This background information means our sample of department OPs comes from individuals who have a vested interest in and commitment to improving and evaluating instruction at the undergraduate level, and therefore may be biased. However, this bias of educators who value and care about instruction shows how much more work is still needed as we see such low references to the IBME. This is not to suggest we cannot make progress, but rather the field needs to recognize where we are versus where we want to be.

Students' Understanding of Partial Derivatives

Thembinkosi P. Mkhatshwa
Miami University

This paper extends work in the area of quantitative reasoning at the undergraduate level, in addition to proposing a conceptual framework for interpreting partial derivatives in different contexts. Task-based interviews were used to examine third-semester calculus students' reasoning about partial derivatives in two tasks, one situated in a mathematics context (Alajmi, 2012) and the other in a diet and exercise context. Findings of this study indicate that interpreting partial derivatives, especially in the latter context, was problematic for a majority of the students. Overall, findings of this study suggest that student difficulties with interpreting partial derivatives in real-world contexts are similar to student difficulties with interpreting ordinary derivatives. Implications for calculus instruction are included.

Keywords: partial derivatives, quantitative reasoning, calculus

Research on student reasoning about several calculus topics at the undergraduate level is well documented. However, much of this research has focused on topics in univariate calculus and has not examined student reasoning about topics in multivariable calculus (e.g., Henderson & Britton, 2013; Rasmussen, Marrongelle, & Borba, 2014). Student reasoning about ordinary derivatives is one area that has received much attention in the research literature (e.g., Berry & Nyman, 2003; Habre & Abboud, 2006; Jones, 2017; Siyepu, 2013; Zandieh, 2000). An ordinary derivative (denoted by $\frac{d}{dx}$) describes how a real-valued function of a single independent variable changes with respect to the independent variable. A few studies have examined student reasoning about partial derivatives (cf., Martínez-Planell, Gaisman, & McGee, 2015; Thompson, Manogue, Roundy, & Mountcastle, 2012; Weber, 2012). A partial derivative (denoted by $\frac{\partial}{\partial x}$) describes how a real-valued function of two or more independent variables changes with respect to one of the independent variables by treating the other independent variable(s) as a constant.

In response to the scarcity of studies that have examined student reasoning about calculus topics in multivariable calculus, the current study reports on undergraduate students' reasoning about partial derivatives. Our study was guided by the following research question: What do calculus students' responses to application problems involving partial derivatives reveal about student understanding of partial derivatives? Partial derivatives are covered in every first course in multivariable calculus (commonly known as Calculus III) in the United States. Although we acknowledge that the ideas of ordinary and partial derivatives can be used in connection with complex functions as well, in the present study, we limit the use of these ideas to real-valued functions. In this study, the term "quantity" refers to a measurable attribute of an object (Thompson, 2011). Examples of quantities in this study include the weight (of a person-the object) and time spent on daily exercise.

Literature Review

Students' Understanding of Partial Derivatives

As previously noted, studies that have reported on student thinking about partial derivatives are scarce. Of the few available studies, Martínez-Planell et al. (2015) examined student understanding of several topics, including partial derivatives, in differential calculus of real-valued functions of two variables. The study participants were 26 science and engineering majors who had recently completed a multivariable calculus course. These researchers reported that approximating the value of a partial derivative at a point when given a real-valued function of two variables in tabular form was problematic for 10 students. In addition, determining the sign (positive, negative, zero) of a partial derivative at a point when given the graph of a real-valued function of two variables was difficult for several students. The present study provided opportunities for students to interpret positive and negative partial derivatives in different contexts. Martínez-Planell and colleagues posited that findings of their study show that students' misconceptions and difficulties with partial derivatives originate from a weak understanding of ordinary derivatives.

Thompson et al. (2012) found that students struggle to represent partial derivatives algebraically in a thermodynamics context, in addition to lacking an understanding of what it means to keep all (but one) independent variables of a real-valued function of several variables constant when calculating a partial derivative. Weber (2012) used a teaching experiment to assess and support student thinking about rates of change (partial derivatives) of real-valued functions of two variables. This researcher found that quantitative reasoning supported students' ability to generalize their understanding of rates of change of real-valued function of a single variable to that of real-valued valued functions of two variables. Weber argued that the results of his study created a need to investigate how mathematicians and mathematics educators think about rates of change (partial derivatives) of real-valued functions of two variables. In response to this argument, we examined how experts think about partial derivatives in different contexts. Details of this examination are provided in the next section-A Conceptual Framework for Partial Derivatives.

Students' Understanding of Ordinary Derivatives

Although the current study is focused on students' thinking about partial derivatives, it is important to discuss the research literature on students' understanding of ordinary derivatives for comparison. Specifically, we use the literature base on students' understanding of ordinary derivatives to identify trends in students' reasoning about ordinary derivatives that may be comparable to the results of the current study. There are two themes that emerge from the research that has looked at students' understanding of ordinary derivatives: (1) students' difficulties and misconceptions and (2) teaching interventions for developing students' understanding. Following is a discussion of these themes.

In the first theme, several studies have reported on students' difficulty to write ordinary derivatives in symbolic form (e.g., Klymchuk, Zverkova, & Sauerbier, 2010; Villegas, Castro, & Gutiérrez, 2009; White & Mitchelmore, 1996). Much research has reported on students' tendency to confuse ordinary derivatives ("rate quantities") with "amount quantities" when solving application problems that have real-world contexts (e.g., Mkhatshwa & Doerr, 2018; Mkhatshwa, 2019; Prince, Vigeant, & Nottis, 2012; Rasmussen & Marrongelle, 2006). For instance, Rasmussen and Marrongelle (2006) reported on a student who did not make a "distinction between rate of change in the amount of salt [a rate quantity] and amount of salt [an amount quantity]" (p. 408) in the context of a differential equations modeling activity. A related line of research shows that interpreting negative ordinary derivatives is problematic for undergraduate students (e.g., Beichner, 1994; Orton, 1983). Many studies have found that while ordinary derivatives are often well understood by students in kinematics contexts, making sense of ordinary derivatives in non-kinematics contexts is often difficult for students (e.g., Cetin, 2009; Ibrahim & Rebello, 2012).

In the second theme, research by Carlson, Larsen, and Lesh (2003) shows that the integration of a models and modeling perspective (Lesh & Doerr, 2003; Lesh & Zawojewski, 2007) in the teaching of calculus could lead to an improved student understanding of ordinary derivatives in real-world contexts. Other research has reported that using different modes of reasoning such as covariational reasoning and performing physical enactments of dynamic situations in calculus instruction enhances students' understanding of ordinary derivatives (e.g., Carlson, Jacobs, Coe, Larson, & Hsu, 2002). Berry and Nyman (2003) used technology in the form of motion detectors to help students develop robust understandings of ordinary derivatives in a kinematics context.

A Conceptual Framework for Interpreting Partial Derivatives

This framework explains how experts (mathematicians and mathematics educators) interpret partial derivatives in different contexts. In addition, the framework identifies things that experts pay attention to when interpreting partial derivatives. Precisely, the framework describes what it means to have a complete understanding of the concept of a partial derivative in calculus education. The framework emerged from analysis of three mathematics and one mathematics education professors' written responses to the two tasks shown in the methods section. Most of these experts had recently taught at least a section of multivariable calculus. At the time of the study and based on the Carnegie Classification of Institutions of Higher Education, two of the experts were affiliated with different mathematics departments in R1 institutions and the other two experts were affiliated with different mathematics departments in R2 institutions.

A thematic analysis of the experts' responses to questions about the meaning of the partial derivative in the aforementioned tasks revealed that depending on the context of the task, all the experts interpreted partial derivatives as "the slope of a tangent plane" in Task 1-a task with a mathematics context. Figure 1 illustrates how one of these experts interpreted the partial derivative in part b of Task 1 as the slope of a tangent plane. We state as a remark that one of the experts interpreted partial derivatives first as a "rate of change", and then as "the slope of a tangent

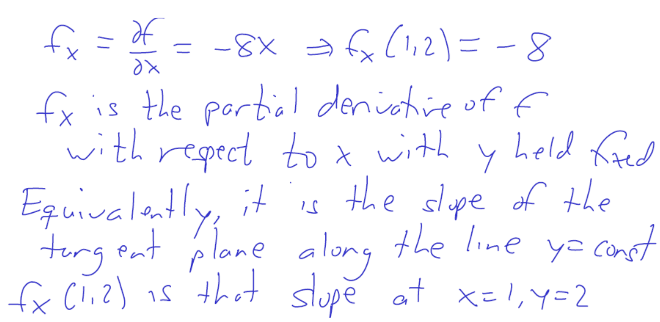

Figure 1. An expert's interpretation of the partial derivative as slope of the tangent plane.

plane" in Task 1. All the experts interpreted partial derivatives as a "rate" in Task 2-a task with a diet and exercise context. When interpreting partial derivatives in Task 2, all the experts consistently attended to three elements, namely constant and varying quantities, direction of change, and quantifying (Thompson, 1994d) the rate of change or slope. The following response to part b(i) of Task 2 written by one of the experts exemplifies the experts' attention to the aforementioned elements when interpreting partial derivatives in Task 2, in addition to interpreting a partial derivative as a rate:

> This is the <u>rate</u> [interpreting a partial derivative as a rate] that weight <u>increases</u> [attention to direction of change] with respect to calories consumed when calorie input is 2000 and with 15 minutes of exercise. So, <u>if my exercise stays constant</u> [attention to a constant quantity-time spent exercising] at 15 minutes a day, then <u>for every calorie that I consume</u> [attention to varying quantity-calories consumed] over 2000, I would expect my weight to increase by about <u>0.02</u> [quantifying rate of change] pounds.

When interpreting partial derivatives in Task 1, the experts only mentioned two elements, namely constant and varying quantities and quantifying the slope. This can be seen in one of the expert's response to part b of Task 1 shown in Figure 1.

Methods

This qualitative study used task-based interviews (Goldin, 2000) with 19 students. The interviews contained five tasks. In this paper, we report on how three students reasoned about two of the tasks, herein referred to as Task 1 and Task 2:

Task 1. Let $f(x,y) = 16 - 4x^2 - y^2$.

a. Calculate $f(1,2)$ and explain what it means.
b. Calculate $f_x(1,2)$ and explain what it means.
c. Calculate $f_y(1,2)$ and explain what it means.

Task 2. Suppose that your weight, w (in pounds), is a function of two variables:

$$w = f(c,n)$$

where c is the number of calories you consume daily and n is the number of minutes you exercise daily.

a. $f(2000, 15) = 175$.
   i. What does this tell you?
   ii. What are the units of the number 175?

b. $w_c(2000,15) = 0.02$.
   i. What does this tell you?
   ii. What are the units of the number 0.02?

c. $w_n(2000,15) = -0.025$.
   i. What does this tell you?
   ii. What are the units of the number -0.025?

The students worked through the tasks while the interviewer asked clarifying questions about their work. After a student concluded their work on a task, the interviewer asked the following questions about the task and the content of their solutions: (a) Have you seen a problem like this before? (b) What was the easiest part when solving this problem? (c) What was the challenging part when solving this problem? Two students acknowledged having seen a problem similar to Task 1 prior to participating in the study. All the students stated that they had not seen or solved problems similar to Task 2.

Setting and Participants

The study participants were three undergraduate students (pseudonyms Ava, Kim, and Cody) at a research university in the United States. At the time of the study, the students were enrolled in three sections of a traditional calculus III course taught by three different professors who had previously taught multiple sections of the course. Two sections were taught in spring 2018, and the other section was taught in spring 2019. The students were recruited via email using class rosters obtained from their calculus professors. In addition, the students were chosen based on their willingness and availability to participate in the study. The students were familiar with partial derivatives through course lectures and the course textbook (Stewart, 2016). We state as a remark that the students in this study had limited exposure to problems that involve interpreting partial derivatives in real-world contexts such as in Task 2 through classroom instruction and/or homework assignments. At the time of the study, two students were mathematics majors, and the other student was a statistics major. We note that this is a required course for mathematics, engineering, and physics majors, and that students outside the aforementioned disciplines rarely take this course as an elective. All the students were sophomores.

Data Collection and Analysis

Data for the study consisted of transcriptions of video-recordings of the task-based interviews and work written by the three students during each task-based interview session. Data analysis was done in two stages. In the first stage, we used a priori codes that were suggested by the conceptual framework discussed earlier. Specifically, we read through each interview transcript and coded instances where each student: (1) interpreted partial derivatives (e.g., as slopes or as rates of change), (2) identified (or did not) constant and varying quantities when interpreting partial derivatives, (3) commented (or did not) on direction of change when interpreting partial derivatives, and (4) quantified (or did not) the rates of change (ROCs) or slopes when interpreting partial derivatives. In addition to the a priori codes from the conceptual framework, we used three additional a priori codes, namely confusing quantities, easy part, and challenging part.

Confusing quantities. As noted earlier, several studies have reported on students' tendency to confuse rate quantities with amount quantities (e.g., Mkhatshwa, 2019; Rasmussen & Marrongelle, 2006). Since partial derivatives can be interpreted as rate quantities, we coded instances where students confused partial derivatives with amount quantities. For example, a student who assigned units of pounds instead of pounds per calorie to the partial derivative in part b (ii) of Task 2 was coded as having confused a rate quantity with an amount quantity.

Easiest part. This code was informed by one of the questions we asked students after completing each task: What was the easiest part when solving this problem? We coded instances where students reasoned about what came easy when solving each of the two tasks.

Challenging part. This code was informed by one of the questions we asked students after completing each task: What was the challenging part when solving this problem? We coded instances where students reasoned about what was difficult when solving each of the two tasks.

In the second stage of the analysis, we looked for patterns in each of the codes identified in the first stage of the analysis. These patterns included trends in the students' understandings, or difficulties they had in connection with each of the a priori codes identified in the first stage. The common understandings or difficulties in students' reasoning found in the second stage of our analysis provided answers to our research question.

Results

There are three findings, summarized in Table 1, from this study. First, all the students' interpretations of partial derivatives varied with the context of the tasks they were given. Cody interpreted the partial derivative $f_x(1,2) = -8$ as "the slope of the surface [$f(x, y) = 16 - 4x^2 - y^2$] in the x direction at (1,2)" in Task 1, and the partial derivative $w_c(2000,15) = 0.02$

as “the rate of change of one’s weight with respect to calorie consumption” in Task 2. Ava interpreted the partial derivative $f_x(1,2) = -8$ as “the slope of the tangent vector in the x direction at the point (1,2)” in Task 1, and the partial derivative $w_c(2000,15) = 0.02$ as weight gained “daily due to calorie intake” in Task 2. When asked about the units of the number 0.02, Ava said it would be in pounds, suggesting that she interpreted the rate quantity $w_c(2000,15) = 0.02$ with units of pounds per calorie as an amount quantity with units of pounds. Kim interpreted the partial derivative $f_x(1,2) = -8$ as “the derivative function evaluated at the point (1,2) with respect to x” in Task 1. When asked to elaborate on this, she said “if the function is a curve [pointing at the equation $f(x,y) = 16 - 4x^2 - y^2$ in Task 1], then the derivative is a line. She went on to say, “when you are evaluating it [pointing at the expression $f_x(1,2)$ in Task 1] at the point [(1, 2)], I think you get the value of the line, so the -8 [from $f_x(1,2) = -8$] is the value of the line.” When probed about the idea of a line, she said “from Calc I, when you take the derivative of a curve [pointing at the equation $f(x,y) = 16 - 4x^2 - y^2$ in Task 1], you get a line.” Kim interpreted the partial derivative $w_c(2000,15) = 0.02$ as “the average weight gain per day…with respect to calories.”

Table 1. Summary of results.

Student	Task	Interpretation of Partial Derivatives			Constant(s)	Variables	Direction of Change	Quantifying ROC/Slope /Other
		Slope	ROC	Other				
Ava	Task 1	x					x	x
	Task 2			x			x	x
Kim	Task 1			x				x
	Task 2			x			x	x
Cody	Task 1	x			x	x	x	x
	Task 2		x		x	x		x

Second, two students (Cody and Kim) did not comment on direction of change in at least one of the two tasks. For example, when asked to explain what $w_c(2000,15) = 0.02$ means in Task 2, Cody responded by saying “assuming one’s daily amount of exercise is held at 15 minutes, the rate of change of one’s weight with respect to daily calorie consumption at 2000 calories is 0.02 pounds per calorie.” In his response, Cody did not comment on direction of change in that he did not indicate whether or not the person’s weight will be increasing or decreasing. Cody is the only student who remarked on constant and varying quantities in the two tasks when interpreting partial derivatives. Specifically, Cody identified time spent on daily exercise as a constant quantity when he commented, “assuming one’s daily amount of exercise is held at 15 minutes,” in his interpretation of the partial derivative $w_c(2000,15) = 0.02$ in Task 2. It can be argued that he identified number of calories consumed per day as a varying quantity when he stated, “…the rate of change of one’s weight with respect to daily calorie consumption,” in his interpretation of the same partial derivative. All the students successfully quantified the ROC/Slope/other quantity they used as a numeric value for the partial derivatives they were asked to interpret, especially in Task 1 where these values were not given.

Third, all the students either identified calculating the output of a real-valued function of two variables such as the function in Task 1 as the easiest part when solving the two tasks, or interpreting the output of such functions. For example, when asked about the easiest part when solving Task 1, Ava commented, “finding the partial derivatives and plugging in the values of x and y [i.e., the point (1,2)] was the easiest part.” All the students stated that interpreting partial-derivatives in real-world contexts such as in the context of Task 2 was the hardest part when solving the two tasks. For example, in response to the question about the challenging part when solving the two problems, Cody said, “interpreting partial derivatives in real-world context.” He added, “we have not done problems like this in class.” The other students expressed similar sentiments about the opportunity they had to learn about partial derivatives in real-world contexts during course lectures.

Discussion and Conclusions

Overall, findings of this study indicate that students have a weak understanding of partial derivatives, especially when applied in real-world contexts. To some extent, the students’ difficulties with interpreting partial derivatives observed in this study reflect the opportunity they had to learn about applications of partial derivatives in real-world contexts through classroom instruction or homework assignments. As noted by one of the students (Cody) above, the students were not exposed to applications of partial derivatives in real-world contexts through classroom instruction. In fact, the presentation of partial derivatives during course lectures closely followed the presentation of partial derivatives in the course textbook (Stewart, 2016). We argue that there is a limited number of practice problems on interpreting partial derivatives in real-world contexts provided in the textbook. Specifically, the textbook (Stewart, 2016) contains a total of 114 practice problems, consisting of 9 examples in the expository section on partial derivatives and 105 exercises at the end of the aforementioned section. Of these practice problems, only 13% (i.e., 15 problems) involve interpreting partial derivatives in different contexts, namely physics, mathematics, biology, and economics.

Findings of several studies suggest that mathematics instructors often closely follow course textbooks in their presentation of content during course lectures (e.g., Alajmi, 2012; Begle, 1973; Kolovou, van den Heuvel-Panhuizen, & Bakker, 2009; Törnroos, 2005; Reys, Reys, & Chavez, 2004; Wijaya, van den Heuvel-Panhuzen, & Doorman, 2015). For instance, Reys et al. (2004) argued “that the choice of textbooks often determines what teachers will teach, how they will teach it, and how their students will learn” (p. 61). We recommend that calculus instructors supplement the examples and practice problems given in calculus textbooks to include more examples and exercises with applications of partial derivatives in different real-world contexts in order to maximize students’ opportunity to learn from such tasks which are rare in the course textbook used by the students in this study. In addition, calculus textbook authors need to include more examples and exercises on applications of partial derivatives in real-world contexts to help students gain a deeper understanding of partial derivatives. Future research might examine the opportunity to learn about partial derivatives provided by classroom instruction and calculus textbooks in the United States.

Partial derivatives have numerous applications in many fields of study such as in thermodynamics, electrostatics, and magnetostatics (Thompson et al., 2012). Future research might involve interviewing engineering instructors to determine the meanings/interpretations of the partial derivative (e.g., slope of a tangent plane or rate of change) they would want students to master upon completing a multivariable calculus course, and prior to enrolling in an engineering course such as electromagnetics for which knowledge of multivariable calculus is expected. One student (Ava) confused a partial derivative (a rate quantity) with an amount quantity in a diet and exercise context. Many studies have reported similar results in other real-world contexts (cf., Mkhatshwa, 2019; Rasmussen & Marrongelle, 2006).

Using RME to Support PSTs' Meanings for Quadratic Relationships

Quadratic relationships are an important topic in algebra through calculus. In this report, we describe how a task designed using Realistic Mathematics Education (RME) principles supported students in developing meanings for quadratic relationships via their covariational reasoning. After describing the task design and sequence, we present student activity highlighting shifts in their meanings before, during, and after a six-week teaching experiment. We highlight the role of interactions amongst students, task, and the teacher in supporting such shifts. We conclude with a discussion and areas of future research.

Keywords: Quadratic Relationships, Realistic Mathematics Education, Pre-Service Teachers, Covariational Reasoning

Quadratic relationships are an important topic in algebra through calculus. However, much of literature examining students' meanings for quadratic relationships point to misconceptions rather than accounts of students' developing productive meanings for quadratic relationships (e.g., Zaslavsky 1997; Lopez et al., 2016). The few studies (e.g., Ellis & Grinstead, 2008; Ellis 2011) providing accounts of students' developing productive meanings for quadratic relationships via their covariational reasoning examine the activity of middle and high school students. We build on this research by examining the possibility of engendering similar meanings in pre-service teachers (PSTs), which is an important population as their meanings are likely to impact their future students' meanings (Thompson, 2013; Thompson, 2016). In this report, we address the research question, "How can tasks designed using Realistic Mathematics Education (RME) design principles support students in developing meanings for quadratic relationships?"

Theoretical Perspective: Covariational Reasoning and Quadratic Growth

We ascribe to Thompson's (1994) characterization of quantitative reasoning as a person's analysis of situations into quantitative structures which include a network of quantities and quantitative relationships. Relevant to this report, quantitative reasoning can involve both numerical and non-numerical reasoning (Johnson, 2012), but the essence of quantitative reasoning is non-numerical, having more to do with the comprehension of quantities in a situation and how they relate to each other (Smith & Thompson, 2007).

Extending Thompson and colleague's characterization of quantitative reasoning, Carlson et al. (2002) defined *covariational reasoning* to be the "cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). They described five mental actions students may engage in when reasoning covariationally that allow for a fine-grained analysis of student activity. The mental actions include coordinating *direction of change* (area and height both increase; MA2), *amounts of change* (the *change* in area *increases* as height *increases in equal amounts*; MA3), and *rates of change* (area *increases at an increasing rate* with respect to height; MA4-5). Several researchers (e.g., Paoletti & Moore, 2018; Moore, 2014) have highlighted how engaging in these mental actions can support students in developing productive meanings for various secondary and post-secondary mathematical ideas.

Because our goal was to support students in developing meanings for quadratic relationships via their covariational reasoning, we first intended to support students in reasoning about the amounts of change of one quantity with respect to a second. After this, we hoped to support students in identifying the amounts of change of one quantity increase by a constant amount for equal changes in the second quantity, which is the defining characteristic of quadratic relationships (Ellis, 2011; Lobato et al., 2012). Ellis (2011) highlighted how middle-school students are capable of developing such understandings via their covariational reasoning. We were interested in examining the possibility of supporting PSTs developing similar meanings.

Realistic Mathematics Education: An Outline with Examples

RME is an instructional theory for mathematics (Van den Heuvel-Panhuizen & Drijvers, 2014) that aims to connect what students already know to what they do not know yet (Gravemeijer, 2008). RME focuses on opportunities for students to re-invent mathematics by organizing *experientially real* situations (Cobb et al., 2008; Gravemeijer, 2008); tasks are *experientially real* to students if they can engage in a personally meaningful mathematical activity and need not refer to some ‘real-world’ situation or context.

Horizontal mathematization refers to the process of a student engaging in and developing understandings for a constructed experientially real context. These initial *models of* (Linchevski & Williams, 1999) the situation(s) are specific to the context but should support students in developing informal strategies and representations that will be useful as they begin to generalize to other situations or contexts. After developing models of situations via horizontal mathematization, students can begin the process of elaborating and extending their informal mathematical activity, which is referred to as *vertical mathematization*. Gravemeijer and Doorman (1999) referred to vertical mathematization as “mathematizing one’s own mathematical activity” (p. 117), which may involve making a drawing, defining, or using conventional notations (Cobb et al., 2008). Vertical mathematization should result in a shift to *models for* a mathematical idea.

We designed the *Growing Triangle Task* (Figure 1 (a, top), https://ggbm.at/t6d63cun) with RME principles and our theoretical perspective in mind. In this task, we have students interact with a dynamic Geogebra applet showing an apparently smoothly growing scalene triangle with the intention of providing students an experientially real context to begin to mathematize. To support the students in attending to area and one other quantity (i.e. reason covariationally), we highlighted the base length of the triangle in pink. The base length grows (apparently) smoothly as the longer slider increases (apparently) smoothly. Further, with amounts of change (Carlson et al., 2002) in mind, we included a second smaller slider which allows students to increase the increment by which the pink base length increases (e.g., to larger equal chunks versus apparently smoothly). Finally, we provided students with several paper cut-out manipulatives (Figure 1(a, bottom)) including five triangles with equal changes in base length as well as trapezoidal cutouts that represent the amounts of change of area for equal increases in base length. We intended for these manipulatives both to support students in constructing an experientially real context and non-numerically examining how the amounts of change were changing (i.e. to support students in developing a *model of* the area growing such that it has a constant second difference).

(a) (b) (c)

Figure 1.(a) (top) Several screenshots of Growing Triangle Task and (bottom) Paper Manipulatives, (b) two graphs with three coordinate points used during in class session, and (c) a table of values task used during pre-interviews

After the PSTs had the opportunity to identify constant second differences in the growing triangle task, we presented them with several graphs representing imaginary length-volume situations, each with three coordinate points (see Figure 1(b) for examples) and the instructions "We know the **differences in the amounts of change of volume are constant** with respect to the length of a side. Complete each graph." Our goal in this activity is to support students in beginning the process of mathematizing their own mathematical activity.

After providing students with several opportunities to represent covarying quantities that had a constant second difference, we were interested in exploring the extent to which the students may identify such a relationship as quadratic. If they did not, we intended to define such a relationship as quadratic. Hence, we intended for the results of the students' vertical mathematization to be a *model for* quadratic relationships such that the defining characteristic was the amounts of amounts of change of one quantity being constant with respect to equal changes in the second quantity.

Methods, Data Corpus, and Analytical Perspective

In order to better understand PSTs developing meanings for quadratic (and other) relationships via their covariational reasoning, we conducted a six-week whole-class teaching experiment (Cobb et al., 2003). Prior to the teaching experiment, we conducted four task based clinical pre-interviews (Clement, 2000; Goldin, 2000) which allowed us to examine several PST's initial meanings for quadratic growth. We interviewed all four PSTs who volunteered for about 45 minutes. Additionally, we conducted post-interviews with two of these PSTs to examine shifts in each PST's meanings for quadratic growth.

The teaching experiment occurred in a course that was specifically for PSTs and covered both mathematics content and pedagogy. There were 19 PSTs enrolled in the course, each of whom had taken a calculus sequence and several additional advanced mathematics courses. Each session of the teaching experiment lasted 75-minutes, with the majority of time spent with students working in small groups on large whiteboards. After small group work, the course instructor (CI) led whole class discussions to present various groups' work and to summarize key concepts. We video-recorded one group during group work and captured all whole class interactions. Class content prior to the two sessions addressing quadratic growth included activities intended to support students in reasoning covariationally, including the Ferris Wheel Task (Moore & Carlson, 2012; Moore, 2014) and Power Tower (Moore et al., 2014).

To analyze the data, we adopted a social constructivist perspective (Vygotsky, 1978; Ernest, 1998). Principally, Vygotsky (1978) accepted that sense-making happens on an individual level but asserted the social interaction which initiated the individual's sense-making should not be ignored. As such, social constructivism does not propose to explain an individual's cognitive activity that occurs during the learning process but rather proposes to take the individual-in-social-action as a unit of analysis to better understand additional facets of the individual learning

(Cobb, 1994). Particular to this report, we are interested in examining the ways in which the interactions among the students, teachers, and tasks may have supported students developing more sophisticated meanings for quadratic growth.

With respect to student-to-teacher interactions, the teacher serves as a facilitator, or more knowledgeable other (MKO), in the learning process (Ernest, 1998; Vygotsky, 1978). As the teacher observes student activity, she is responsible for providing learning opportunities to students during classroom discourse (Bozkurt, 2017). Further, as the MKO, a mathematics teacher's responsibility includes enculturating students into a broader mathematical community (Cobb, 2007), including supporting students in developing meanings for ideas consistent with the larger community so they can be participants in this community.

Results

Results from the Pre-Clinical Interviews

During each of the four pre-interviews, none of the PSTs maintained meanings that supported her in identifying quadratic change when prompted to identify the relationships represented in a table. As an example, consider Jennifer's activity addressing the table in Figure 1(c). She first determined the slope between the first two and second two points to determine the relationship was non-linear. She then continued, "Not sure if this means anything but I'm pretty sure all the *y*'s are multiples of threes… and since they're rapidly increasing maybe it can be exponential growth." In this and the other cases, each PST's meanings did not support her in identifying quadratic growth from a table. Hence, each PST's meanings did not support them in identifying second difference to characterize a relationship as quadratic.

Results from the In-Class Teaching Sessions

The Growing Triangle Task: Horizontal Mathematization. Four weeks after the pre-interviews, the class instructor (CI) presented the whole class with the series of tasks around the Growing Triangle Task. He provided them a link to the task, and prompted them to "Sketch a graph representing how the green area of the triangle changes with respect to the base (in pink).". During all group work, we video-recorded Jennifer and Rebecca as they worked together with a teacher-researcher (TR) who was not the CI. The pair quickly identified the area as increasing as the pink base length increased (MA2). When the TR prompted them to consider how the amounts of change of area were changing for successive equal changes in base length, both PSTs quickly responded "by more" each time (MA3). Justifying their conclusion, and reasoning non-numerically, the PSTs pointed to the successive trapezoids (Figure 2(a)) and stated these represented the "area added" to make the next triangle. Attempting to support them in describing how the amounts of change were changing (i.e. examining second differences), the TR asked, "Are they [*pointing to the trapezoids*] increasing by more, less, or by the same amount?" Responding, Rebecca overlaid the trapezoids (Figure 2(b) and (c)), and again reasoning non-numerically, used her fingers to denote the amounts of change in area from one trapezoid to the next, and stated the trapezoids "are all increasing by the same [amount]." The TR, as the MKO, facilitated and provided students opportunities to reason covariationally about an experientially real situation and to identify the constant second difference with respect to base length. Hence, we infer the combination of a carefully designed task sequence along with a TR, provided Jennifer and Rebecca opportunities to develop more sophisticated meanings for quadratic relationships.

(a) (b) (c) (d) (e)

Figure 2. Trapezoids (a) one below the other (b) overlaid and (c) recreated showing equal amounts of change, (d) the table in the on-line homework, and (e) the student work during micro-teaching.

After each of the groups constructed and graphically represented the relationship between the growing triangle's area and base length, the CI led a whole class discussion summarizing important findings intending to support the students in horizontal mathematization. Specifically, he highlighted the amounts of change of area increased for successive increases in side length and that the amounts of amounts of change increased by the same amount. Further, he presented some groups' graphs, which accurately reflected this relationship prior to class time ending.

Addressing the second task: Beginning Vertical Mathematization. Intending to support the PSTs in starting the vertical mathematization process (i.e., beginning to formalize and generalize their activity), the CI began the next class by having PSTs determine new points in several graphs representing volume and length values as described above (e.g. Figure 1(b)). As part of this process, we intended for the students to have an opportunity to consider how to operationalize their non-numeric reasoning about constant second differences with the trapezoids (e.g. Figure 2(c)) to a situation with numeric values.

As the PSTs engaged with this task, they used numeric constant second differences to determine new points (i.e. further mathematize their own mathematical activity). Specifically, they made tables of values from the given points, identified equal changes in the Length values, and then identified first and second changes in the given Volume values. Based on the CI's observations, most groups used the constant second difference to determine the next first difference prior to determining the next volume value. We take such activity as indicative of the students beginning the process of vertical mathematization.

Although students were able to use the constant second differences, none of the students, often when prompted, made any conclusions regarding the type of relationship represented by the points. Hence, after engaging in a whole class discussion in which groups described how to find additional points from the given points, the CI, as MKO, attempted to enculturate the PSTs into the broader mathematical community by defining a relationship with a constant second difference as representing a quadratic relationship.

CI: [*after the students have described how to plot additional points and connected these points*] Have you ever seen things that looks like this before? Yes? No? What do they look like?

S1: [Inaudible] negative parabola?

CI: A negative parabola? Are the other two [*pointing to the graphs created for two other situations*] parabolas?

S2: Pieces.

CI: Could be pieces of parabolas?

S3: Half a parabola?

CI: And so I actually put those first two [*pointing to two graphs*] in there to see if someone commented on the general shape. If you are just looking at the first two [*graphs*], what could they be? Could be half parabolas or could they be anything else?

S4: Exponential?

CI: Could be something more exponentially? … So, it turns out, whenever the amounts of change, change constantly… basically you have +2, +2, +2 for that second difference… then the relationship is quadratic. That's what it means to be quadratic.
[*The CI then presented a slide defining "Whenever the* ***amounts of change*** *change constantly (i.e., we have a second constant difference), the relationship is* ***quadratic"***].

Whereas prior to this whole class interaction none of the PSTs identified the relationships as quadratic, and none of the four PSTs in the pre-interview identified a given relationship represented tabularly as quadratic, immediately after this classroom interaction there were indications students had begun to reorganize their meanings for quadratic relationships. Specifically, in an on-line homework due two weeks after this interaction, we asked the students to identify the type of relationships shown in Figure 2(d) (with options linear, quadratic, cubic, or not enough information). Ten of the 19 PSTs correctly identified the relationship as quadratic on their first attempt. An additional four PSTs correctly identified the relationship on their second attempt. We take this data to indicate many of the PSTs had engaged in vertical mathematization as they generalized properties of the relationship they inferred in the Growing Triangle Task (i.e. their horizontal mathematization) to quadratic relationships more generally, and began to understand constant second differences as a defining characteristic of quadratic relationships. Hence, we infer the classroom interactions (including among students, TR, CI, and the task) supported many students in developing more sophisticated meanings for quadratic growth.

Student activity after the Growing Triangle Task: Evidence of Vertical Mathematization. We present data from a later classroom session and from the post interviews to provide evidence of the lasting impact of shifts in the PST's meanings. Four weeks after the last in-class teaching session addressing quadratic relationships, most of the PSTs were working in groups pretending to be high school students as a pair of their peers were acting as teachers (i.e. micro-teaching). The 'students' were working on a task asking them to identify the number of distinct regions in the plane created as they added non-parallel lines, no three of which were collinear. Two of the PSTs (Sonya and Nina) were working together to create the table representing the number of lines (L) and regions (R). They created the table shown in Figure 2(e) then quickly moved to identifying first and second differences. Immediately after writing the '1' representing the second difference between the first differences 3 and 4, they said:

N: So our change, our change of our change is constant. So what does that mean?
S: [*interjecting*] It's a quadratic equation.
N: [*continuing*] It's a quadratic equation!

Both Sonya and Nina immediately identified a relationship with a constant second difference as quadratic. We take this as evidence that each student's meanings for quadratic growth at this point in the semester included this defining feature of quadratic change.

As additional examples, Jennifer and Rebecca each maintained meanings that supported her in determining if a relationship, represented tabularly, was quadratic in individual post interviews. When prompted with the table in Figure 3(a) and asked to find the relationship, Jennifer immediately mentioned she needed to find the first and second differences. As she was finding the first differences (in green) and second differences (in red), Jennifer stated, "It's a quadratic, uhhh… yes, quadratic. 'cause the amounts of amounts of change are the same. Quadratic!" Similarly, Rebecca quickly identified first and second differences (Figure 3(b)) to determine the relationship was quadratic.

Discussion, Implications, and Future Research

We described a series of tasks designed with RME principles in mind aimed at supporting PSTs' developing more sophisticated meanings for quadratic relationships via their numeric and non-numeric covariational reasoning. We described how the students constructed an experientially real situation, then began the process of horizontal mathematization as they reasoned non-numerically about amounts of change and constant second differences in the *Growing Triangle Task*. The students initially developed a model *of* a situation which the PSTs further mathematized as they addressed additional tasks. As shown in the later interactions, for many students, the initial model *of* the Growing Triangle transformed to a model *for* quadratic change, which is the result of vertical mathematization (Gravemeijer & Doorman, 1999; Linchevski & Williams, 1999). Hence, we add to the growing body of literature (Paoletti & Moore, 2018; Moore, 2014) showing ways PSTs can develop productive meanings for quadratic relationships via their covariational reasoning.

In this paper, we focused on the ways in which a carefully designed task can be implemented in a whole class setting by one or more MKOs to support PSTs in developing more productive meanings for quadratic relationships. These findings lead us to suggest several different areas for future research. First, a limitation of this study was that we conducted it with one class in one setting. Future researchers may be interested in using similar tasks with PSTs in other settings to examine the efficacy of this instructional sequence in these settings. Second, as we adopted a social constructivist lens, we do not make claims regarding the underlying reasons for the observed shifts in students reasoning (e.g., the mental operations that support students in achieving such shifts). Future researchers may be interested in using these or similar tasks as a means to explore PST's mental operations to develop models of such changes. Such research may support further task design, development, and implementation.

Finally, we note that our tasks are similar to those used by others (Ellis, 2011; Lobato et al., 2012) but that our tasks first supported PSTs identifying constant second differences non-numerically, which is the essence of quantitative reasoning (Smith & Thompson, 2007). We conjecture such reasoning may also be productive for middle or secondary students first learning about quadratic growth. We call for researchers to consider using tasks similar to those presented here as a means to further explore ways to support these students in developing foundational understandings of quadratic growth. Hence, we intend for these tasks and results to serve as a starting point for additional investigations into students of various levels developing foundational understandings of quadratic growth via their quantitative and covariational reasoning.

Quantitative Reasoning and Symbolization Activity: Do Individuals Expect Calculations and Expressions to Have Quantitative Significance?

Alan E. O'Bryan
Arizona State University

This paper describes ways of thinking students employ when they choose to use calculations or produce algebraic expressions to respond to mathematical tasks and their expectations regarding the meanings of what they produce. My findings suggest that students' reasoning in symbolization activity is often guided by perceptual features of tasks, such as the numbers explicitly given in prompts and key words students identify. I describe the construct "emergent symbolization" as a potentially productive way of thinking in symbolization activity based on synthesizing prior work and the results of this study. I close by making connections between similar work in analyzing students' ways of thinking about graphs and discussing how my work contributes to the common instructional goal of promoting connections between representations.

Keywords: quantitative reasoning, student thinking, mathematical representations

Math standards commonly include the goal that students make connections between representations of mathematical relationships. For example, The American Association of Two-Year Colleges (2018) standards state that "Students should be provided opportunities to represent and communicate mathematical ideas using multiple representations such as numerical, graphical, symbolic, and verbal" (p. 25). However, intending that students make such connections does not guarantee they occur. Whether a student is successful in recognizing what a representation conveys about how two quantities are related and changing together relies on such things as the ways of thinking she engages in and the connections she is positioned to make.

Moore and Thompson (2015) studied students' ways of thinking about graphs and described advances derived from taking seriously how students interpret the meaning of graphs. Their work highlights complexities in students' reasoning about one kind of representation (graphs) and suggests potential benefits for students who envision graphs as emerging from coordinating pairs of covarying quantities they have conceptualized for a given context. In this paper I report results from studying students' reasoning about symbolization activity (the production of mathematical expressions and formulas that use operations and algebra to represent relationships). My results suggest that a key component of students' fluency and flexibility in representing relationships algebraically is also the degree to which they conceptualize quantities and quantitative relationships in a situation and foreground their activity based on these conceptualizations.

It seems likely that students inclined to engage in quantitative reasoning (Thompson, 1990, 1993, 1994, 2011), with a focus on coordinating relationships between quantities including using variables and variable expressions to represent the values of quantities, are well-positioned to make productive connections between mathematical representations. However, testing this hypothesis, and understanding the mechanisms by which students successfully make connections between representations, requires continued empirical studies designed to recognize and articulate students' ways of thinking about representations. This paper contributes to that work.

Theoretical Perspective

Quantitative reasoning (Thompson, 1990, 1993, 1994, 2011) describes a way of reasoning involving identifying objects' measurable attributes (*quantities*) and conceptualizing relationships between quantities. *Quantification* is the process of deciding on a measurement system for producing quantities' values. Quantities exist within the mind of an individual, and thus when talking about quantities, quantitative relationships, quantification, and so on, I take the position of describing them from an individual's perspective (either actual or hypothetical). As a lens for considering students' meanings and reasoning, I use Thompson and Harel's (Thompson, Carlson, Byerley, & Hatfield, 2014) descriptions that are extensions and elaboration of Piaget's (2001) genetic epistemology. An individual's *meaning* for an idea describes the set of implications inherent to the scheme(s) triggered by an in-the-moment *understanding* of a context or stimulus. Meanings may be temporary or they may be stable over time. A *way of thinking* describes a pattern in how an individual uses certain meanings. Descriptions of students' ways of thinking are useful for characterizing mental processes essential for specific types of mathematical reasoning (e.g., quantitative reasoning, proportional reasoning).

Emergent Symbolization

In O'Bryan and Carlson (2016) we described our work with a teacher (Tracy) involving a professional development intervention, classroom observations, and clinical interviews. Our analysis suggested a set of expectations she developed about the meanings for the calculations she performed and algebraic representations she generated that she independently established as mathematical learning goals for her students. These expectations included explaining what quantity she intended to calculate (represent) before performing a calculation (writing an expression) and how the order in which calculations are performed or the order of operations used to evaluate expressions reflects details about how individuals conceptualize a situation.

I have since encapsulated aspects of my understanding of Tracy's expectations and ways of thinking into the construct *emergent symbolization (or emergent symbol meaning*) (O'Bryan, 2018). Emergent symbolization refers to actions motivated by one or more of the following expectations.

1. An expectation that performing calculations or generating expressions should reflect a quantification process for quantities that the individual conceptualizes.
2. An expectation that demonstrating calculations and producing expressions are attempts to communicate an individual's meanings. Thus, when given a set of calculations or expression/formula, we can hypothesize how the individual conceptualized a situation based on analyzing the products of their reasoning.
3. An expectation that the order of operations used to perform calculations, evaluate expressions, and solve equations "reflects the hierarchy of quantities within a conceptualized quantitative structure" (O'Bryan, 2018, p. 234).

I hypothesize that emergent symbolization is a potentially productive way of thinking for students and teachers and that targeting its development is a worthwhile instructional goal. Part of the important initial work in testing this hypothesis is describing nuances in how students reason about, and their expectations regarding, performing calculations or generating algebraic expressions in response to mathematical contexts and prompts.

Research Questions

Given that students develop stable ways of thinking over time, understanding nuances in these ways of thinking is important for educators and researchers. The work reported here focuses on results from considering two research questions.

1. When a student chooses to perform a series of calculations or generate an algebraic model to respond to a task, what does the student believe her work represents?

2. Do students' ways of thinking reflect an attempt to organize mathematical processes according to generalizations of quantitative relationships or is there a different set of expectations driving their mathematical activity?

Methods

During Spring 2018 seventy students enrolled in a precalculus course at a large public university in the United States using our research-based online materials (O'Bryan & Carlson, 2016). All students completed a pre-/post-test including multiple-choice items from the APCR and CCR exams (Madison, Carlson, Oehrtman, & Tallman, 2015) at the beginning and end of the course. In addition, I selected five students (Gina, Lisa, John, Marcus, and Shelby) for recorded clinical interviews (Clement, 2000) representing a wide range of majors and pre-test scores. I conducted interviews with each student at the beginning of the course and during the last month of the course using the same subset of questions from the pre-/post-test and the same interview protocols. During these interviews the multiple-choice options were hidden. I coded student responses to identify when students did or did not reference quantities, units, and quantitative relationships as a foundation for their calculations and symbolization activity.

Results

I share the following results from pre-/post tests and interviews, and to highlight common expectations and ways of thinking I observed. In this paper I am not focusing on shifts that may have resulted during the course, but rather on characterizing stable meanings and ways of thinking students exhibited.

Pre-Test and Pre-Interview Results

Students answered the Tomato Plant A task in Figure 1 on the test and during interviews. I chose this task to assess students' recognition of the need to update the reference quantity from one interval to the next (that is, update the answer to the question, "Percent of what?").

A tomato plant that is 4 inches tall when first planted in a garden grows by 50% each week during the first few weeks after it is planted. How tall is the tomato plant 2 weeks after it was planted?

a. 5 inches b. 6 inches c. 8 inches **d. 9 inches** e. 12 inches

Figure 1. The Tomato Plant A task (Madison et al., 2015).

On the pre-test, 54% of students selected the correct response. During interviews, three of the five students answered the question correctly, and all responses contained two similarities. First, all students focused on the amount to *add* each week and none of them described the relative size of the new height compared to the old height when explaining their reasoning. Second, all students described a percentage value as a number that results from moving a decimal place two positions rather than describing a measurement process. Of the two students who answered

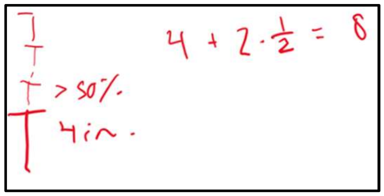

Figure 2. Marcus's work for the Tomato Plant A task.

incorrectly, Marcus' response proved interesting relative to later observations. See Figure 2.

Marcus's answer (8 inches) assumed that the weekly 50% increase was always based on the plant's initial height. But what is most interesting is the expression he used to represent his answer. Apart from being an incorrect statement (which he recognized), all five students utilized the structure "initial value + (change in independent value)(1-unit percent change as a decimal or fraction)" to create a general model in the Tomato Plant B task. See Figure 3.

> José plants a 7-inch tomato plant in his garden. The plant grows by about 13% per week for several months. Which formula represents the height h of the tomato plant (in inches) as a function of the time t in weeks since it was planted?
>
> a. $h = 7(0.13)^t$ b. $h = 7 + 1.13t$ c. $h = 7(1.13t)$ **d. $\underline{h = 7(1.13)^t}$** e. $h = 7 + 0.13t$

Figure 3. The Tomato Plant B task (Madison et al., 2015).

During the pre-test, 20% of students selected the correct answer, but <u>none</u> of the students interviewed provided the correct response. In their interview responses, all five students generated a formula equivalent to "$h = 7 + 0.13t$" where h is the tomato plant's height (in inches) and t is the elapsed time (in weeks) since the initial height measurement. The important observation here is not that students failed to provide (or select) the correct algebraic model. Rather, *the most important result is what their reasoning tells us about their expectations regarding the quantitative significance of the calculations they perform and the expressions they write.* Figure 4 shows Shelby's work in completing the Tomato Plant B task.

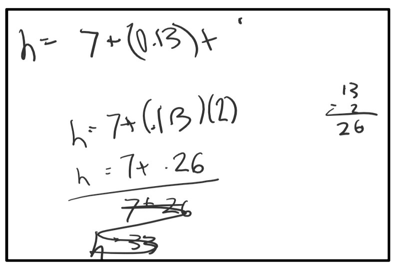

Figure 4. Shelby's work on the Tomato Plant B task.

Shelby: Okay so we're trying to find the height [*she underlines "height h" in the problem statement*] and then t is gonna be a variable [*she underlines "t in" in the problem statement*]. So height [*she writes "h="*] and then we start with seven [*she writes "7"*]. So we start at seven, so that's just gonna keep increasing [*she writes "+" after h = 7*] so and then put a plus. Um [*she writes "(0.13)t" after h=7+*]. Yeah, I'm gonna go with that.

At this point I asked Shelby to determine the plant's height after two weeks. She evaluated her formula but hesitated after writing "7+.26". She considered that maybe her answer was wrong and tried "7+26" based on moving the decimal two places as an alternative. She decided that "33" was too large, so her original answer must be correct and settled on "7.26" as her answer.

In Shelby's final answer we see a form similar to what appeared in Marcus's response to the Tomato Plant A task, and several aspects of her response appeared throughout interviews with all students. First, Shelby was not inclined to check the reasonableness of her solution without prompting. Second, she appeared to be using keywords to guide her work (such as "increase" means "add"). Third, her criteria for judging the accuracy of her solution was based on whether the values it produced seemed reasonable. None of the students explained how parts of their algebraic representations modeled relationships between quantities within the situation or explained the meaning of the term "0.13t"

Consistently in the Tomato Plant B task, as well as similar tasks such as modeling a bacteria colony doubling over set time intervals, students appeared to establish a goal and then create a mathematical representation as a literal translation of this goal from English. See Figure 5.

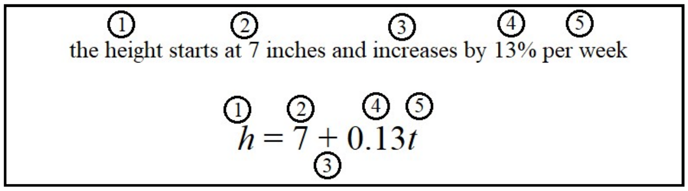

Figure 5. Students may produce the formula h = 7 + 0.13t as a literal translation of a goal statement written in English focusing on key words.

Supporting this idea is the consistent absence in students' responses of any numbers not explicitly stated in task prompts. For example, the correct model for the Tomato Plant B task requires using "1.13", and neither "1.13" nor "113%" appear in the prompt. Similarly, I observed students model a doubling-time situation with a function formula missing the number two when the prompt included the word "double" but did not include "2" in the prompt.

The students interviewed exhibited similar behaviors during symbolization activities throughout the course. Students rarely mentioned units when referencing numbers given in the problem text and rarely referenced the quantities being measured. In addition, students were not inclined to justify their answers unless prompted and, when I did prompt them, judged their models based on whether they produced numerical values the student deemed reasonable rather than referencing the structure of quantitative relationships the student conceptualized.

Post-Test and Post-Interview Results

All five students interviewed successfully completed the class, and all earned at least a "B" on the course final exam. Therefore, based on grades and exam performance, interviewees all met course requirements and objectives. However, data from the post-test, post-interviews, and analysis on students' interactions with course materials shows that the ways of thinking identified in the pre-test and pre-interviews was remarkably stable for many students.

Post-Results for Gina, Marcus, and Shelby. Gina, Marcus, and Shelby all continued to display many of the same ways of thinking during their post-interviews. All three had difficulty explaining how claims they made about features of one task or representation appeared in other tasks or representations and their reasoning often involved generating sets of potential answers then picking from among the results. For example, I asked Gina to determine the percent change from a price of $131 to $195. Gina first evaluated the difference "195 – 131 = 64". She then said, "I kinda remember how to do this" and used a calculator to compute "64/195 = 0.328", then "ans * 100 = 32.8", then "195/64 = 3.047", then "ans * 100 = 304.7", and finally "195/131 = 1.489". After reviewing these results she told me that the price increased by 32.8%. I asked her what that number was a measurement of (what quantities were being compared). Rather than answering my question, she computed "131/195 = 0.672" and said that her answer should have been "67%". "Sixty-seven percent of what?" I asked. She responded "131".

Analyzing these students' behavior during course lessons showed that all three tended to require high numbers of attempts to complete tasks in the lessons I examined. When their initial attempt was incorrect, they required seven or more attempts over one-third of the time, and nearly 20% of those instances they required 11 or more attempts before finally completing or abandoning tasks. For example, one lesson task asked students to determine a percent change from one value of a quantity to another value. The correct answer was 40%, but Shelby entered 140%. She then completed *19 additional attempts* in quick succession (240, 1.40, 139, 239, 299, 399, 499, 199, 240, 1.4, 39.9, 29.9, 49.9, 2, 200, 100, 140, 14, and 40) before finally entering the correct answer. In these instances the students were not coordinating their reasoning by first conceptualizing the quantities in a situation and the quantitative relationship they wanted to communicate and then considering how to represent or evaluate that relationship.

Finally, all three students tended to revert to the general form "$a + rt$" when completing tasks like Tomato Plant B. While Marcus and Shelby often caught themselves and modified their answers to exponential models, their continued challenges in justifying aspects of their models quantitatively suggest that this might be "pattern-matching" behavior rather than shifts in their expectations for the meaning and goals of generating algebraic representations.

The case of John and Lisa. Both John and Lisa exhibited shifts in describing the quantitative significance for the calculations they performed and the representations they generated. Since the focus of my paper is not on analyzing the results of a teaching intervention, I will not dwell on these changes beyond demonstrating some differences I observed in their reasoning and expectations during the post-test and post-interviews.

Figure 6 shows Lisa's work on the Tomato Plant B task during the post-interview.

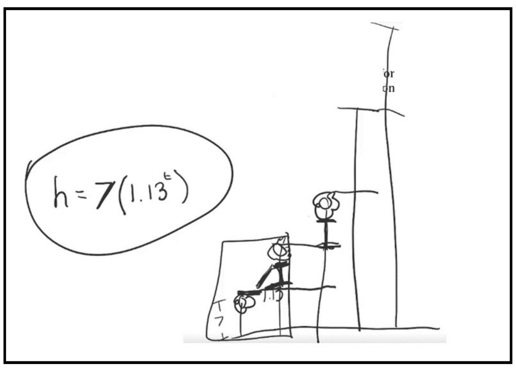

Figure 6. Lisa's work on the Tomato Plant B task (post-interview).

In justifying her work, Lisa provided a clear explanation for the meaning of each value in her model and supported her explanations with drawings where she elaborated on how she imagined the relationship between h and t, as modeled by the formula, also being modeled using diagrams.

An example from John's post-interview is also worth sharing. In the Tomato Plant A task John was the only student who spontaneously represented the plant height as an exponential expression rather than calculating the amount to add each week and performing addition. He wrote "$y = 4 \text{ x } (1.5)^2$" [*"x" representing multiplication*] as his answer and then determined that value with a calculator. In this process he first evaluated $(1.5)^2$ to get 2.25 and multiplied this by four. I asked him if 2.25 was an important number to understand or if it just represented an intermediate step in the calculation process. He explained that 2.25 represented the growth factor for a two-week change in time elapsed. This was an idea never mentioned by the other students I interviewed but seems important in terms of John's fluency with writing and explaining exponential models at the end of the course.

These examples hint at a connection between students' fluency with mathematical representations and the degree to which they expected these representations to reflect their conceptualization of relationships between quantities, at least in familiar contexts.

Discussion

Moore (2016) proposed the distinction between *operative thought* and *figurative thought* (Piaget, 2001; Steffe, 1991; Thompson, 1985) as a useful lens for understanding differences between students' ways of thinking about graphs. Figurative thought describes thought that relies on perceptions directly accessible during the reasoning process. One implication of a person limited to figurative reasoning within a context is the inability to extend beyond that context to organize his thinking relative to general relationships and connections to other contexts and ideas. Operative thought suggests a degree of control and coordination in the reasoning process that extends beyond perceptual features of a given context. An implication of operative thought is that the individual makes conscious decisions throughout his reasoning process and is aware of how work within one context connects to work in other contexts.

I see parallels in Moore's analysis with students' symbolization activity in the answers to my research questions. Students' symbolization activity was primarily driven by their assimilating interpretations of the tasks at hand to schemes where the resulting actions (performing specific calculations, generating algebraic representations, etc.) were not motivated by reflections on quantities, general relationships, or connections to other tasks. Their activity seemed subordinate to perceptual features of the tasks (such as the specific numbers given in a problem statement, their identification of key words, and perhaps even the structure of students' native language). The students whose ways of thinking did not shift during the course struggled to describe quantitative meanings for their calculations, often produced sets of potential responses and picked from among these choices rather than foregrounding their activities in conceptualizing the quantities' values and relationships they wanted to represent, and typically did not or could not make connections between tasks or between different representations.

Emergent symbolization is an example of operative thought "involv[ing] mental representations of actions and consideration of the consequences of those actions that allows students to make propitious decisions about next steps in their reasoning process and how those steps connect to conclusions already made" (O'Bryan, 2018, p. 315). My results do not prove that John and Lisa developed the full set of expectations that drive emergent symbolization reasoning (that would require a different study). They do show that students who were able to explain quantitative meanings for steps in their calculation processes and components of their mathematical expressions were also able to explain how aspects of their calculations or algebraic reasoning related to reasoning in other tasks and might also be represented in other forms.

Moore and Thompson (2015) argued that studying students' shape thinking is critical for providing perspective on how to foster students' connections between the variety of possible representations for mathematical relationships. It is important for "researchers to be clearer about what a graph represents to a student, and thus what students understand multiple representations to be representations of" (p. 784). This paper is an attempt to begin answering this call relative to students' symbolization activity with the long-term goal of better understanding how students see connections between mathematical representations. More work is needed to continue to flesh out the ways of thinking students employ in symbolization activity. I am particularly interested in examining students' symbolization activity in novel contexts to understand the potential implications of students' expectations regarding the models they generate and the meanings they identify in those models in less familiar contexts.

Development of Students' Shared Understanding in Guided Reinvention of a Formal Definition of the Limit - from Commognitive Perspective

Jungeun Park
University of Delaware

Jason Martin
University of Central Arkansas

Michael Oehrtman
Oklahoma State University

This paper examines the mechanism behind students' guided reinvention process of a formal definition of the limit of a sequence by looking at how students' shared understanding develops and what discursive rules enable such development using the commognitive approach focusing on the relationship between routines (discursive rules) and changes in endorsed narratives (shared understanding). A Calculus II instructor conducted a teaching experiment in which 11 students reinvented a formal definition of the limit starting from their initial statement about the sequence convergence, mainly including dynamic language such as "approaching." In our analysis, we identified the routines about the application of the definition in examples and non-examples, and the consistency between written and illustrated form of their definition, and the readers of the definition, and how those routines contributed to the changes in students' endorsed narratives about sequence convergence during the guided reinvention.

Introduction

Research has documented students' difficulty in understanding formal limit definitions and attempted to make these definitions more accessible to students through guided reinvention teaching experiments with pairs of students (Oehrtman, Swinyard, & Martin, 2014; Swinyard & Larsen, 2012). This study expands on this body of research by implementing a teaching experiment in class where the instructor asked groups of students to reinvent a formal definition of sequence convergence. Our goal was to examine the mechanism behind students' reinvention by looking at their interactions with instructor's prompts and other students' work in class through the lens of routines and endorsed narrative.

Theoretical Background

Guided Reinvention of a Formal Definition of Sequence Convergence

A typical formal definition for a limit with an illustration can be seen in Figure 1. Several studies have pointed out that this definition involves challenges involving multiple nested quantifiers such as the universally quantified ε, the index N depending ε, and absolute values, and inequalities, and developed instructional approaches that involve students' engagement with such challenges (e.g., Cory & Garofalo, 2011; Swinyard & Larsen, 2012). Some of such approaches have adopted a guided reinvention iterative refinement process (IRP, Oehrtman, Swinyard, & Martin, 2014) approach based on principles from Realistic Mathematics Education (Freudenthal, 1973) in which learners "come to regard the knowledge they acquire as their own private knowledge, knowledge for which they themselves are responsible" (Gravemeijer, 1999, p. 158). During an IRP in creating a sequence convergence definition, students write a definition, evaluate their definition against graphical examples of sequences converging to and not converging to a specified limit value, identify problems, discuss potential solutions, revise their definition, and then initiate another iteration (Oehrtman, Swinyard, & Martin, 2014). Within the IRP, *problems* are defined as conflicts raised by the students between their descriptions and illustrations for the limit versus their stated definition. Once students realize a problem, students discuss potential solutions and their definition eventually evolves to reflect adopted solutions.

During this process of realizing, engaging in, and resolving problems, students develop ownership over the process and product of the IRP.

A sequence $\{a_n\}$ has the **limit** L and we write

$$\lim_{n\to\infty} a_n = L \qquad \text{or} \qquad a_n \to L \text{ as } n \to \infty$$

if for every $\varepsilon > 0$ there is a corresponding integer N such that

$$\text{if} \qquad n > N \qquad \text{then} \qquad |a_n - L| < \varepsilon$$

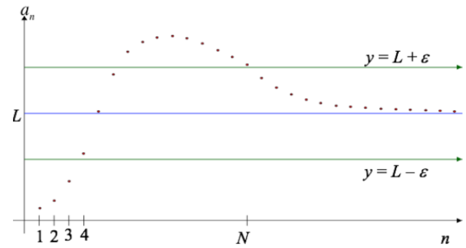

Figure 1: Example of formal sequence convergence definition (Stewart 2008, p. 677)

Endorsed Narratives and Routines

To examine the mechanism behind students' guided reinvention of a formal definition of the limit, we adopted endorsed narratives and routines from Sfard's (2008) commognitive approach. Sfard (2008) defined *endorsed narratives* in discourse as shared "descriptions of [mathematical] objects, of relations between objects, or of processes with or by objects," which the discourse community endorses as true (p. 134). Sfard (2008) defines a *mathematical object* as a collection of realizations sharing the same endorsed narratives and a *realization* as any perceptually tangible, visual or vocal, means of communicating a noun element of an endorsed narrative. In our analysis, we included modifiers of a noun element as realizations due to the important role that modifiers play in the quantification of such elements (e.g., one, any, and every attached to epsilon). Endorsed narratives are evidenced by students' adoption of the narrative as true and their rejection of any violations to the narrative that may get "called out" by the discursive community. During reinvention's IRP, what students create is not only written definitions, but also the problem/solution pairs that explain how the endorsed narratives contributing to the changes in their definition have evolved.

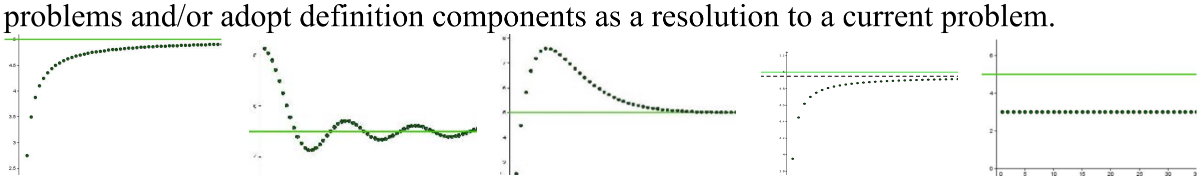
Routines refer to meta-discursive rules (i.e., metarules) that define repetitive discursive patterns in speakers' use of words and visuals, or while creating and endorsing narratives. Metarules are different from object-level rules; object-level rules "are narratives about regularities in the behaviour of objects in the discourse, whereas metarules define the patterns in the activity of" the people who share a discourse, "trying to produce and substantiate object level narratives," which is a form of endorsed narratives (Sfard, 2008, p. 201). This paper adopts this definition of routines as metarules that define, govern, and derive the repetitive discursive patterns, which enabled students' progress in reinventing a formal definition of the limit of a convergent sequence. According to Sfard (2008), there are three types of routines: certain courses of actions, metarules for when a certain course of actions are appropriate to apply, and metarules for when the application of the course of actions is concluded. For example, in a guided reinvention context, a students' course of action could be to engage the IRP – write a definition, test their definition against example and non-example graphs, find a problem and the solution, and revise their definition, and repeat this cycle again. Students could decide to apply this IRP course of action when the instructor asked for an illustration, or after revising their definition. Their course of action could be considered as concluded by the students when they explicitly express their satisfaction with their definition and stop going through revision process. Students could also decide that a course of action is concluded if they observe an instructor approving a change made in their definition or even if an instructor merely re-voices what students said, did, or wrote. Metarules are not specific to certain realizations, but determine certain discursive actions in multiple contexts. Since routines are metarules of discursive actions aiming to produce object-level rules, routines directly impact a generation of or changes in endorsed narratives (Sfard, 2008). Using routines and endorsed narratives as the theoretical lens, we address the following questions:

- What were the routines established during the guided reinvention? How were the routines initiated, established, and adopted by students?
- How did the endorsed narrative change during the guided reinvention? How did the routines support the changes in the endorsed narratives that afforded progress toward a formal definition of sequence convergence?

Research Design

The data for this study was collected from a second-semester calculus class at a medium-sized public university in the U.S., where the instructor conducted a guided reinvention teaching experiment with two groups of four students and one group of three students. The experiment was conducted over five class sessions that ranged from 50 to 75 minutes in length. Students had just completed sections on sequences, series, power series, and Taylor series using Stewart (2008). The activity of one group of four students was audio and video recorded. We refer to the videoed group as GTE, and the other two groups as G1 and G2. Another camera captured whole class interactions with the instructor. We will refer to individual students within GTE using pseudonyms: Becky, Jamie, Trevor, and Rachel. All their written work was collected and digitized.

The teaching experiment began when the instructor asked students to create example and non-example graphs of sequences converging to 5 (Figure 2). Following the creation of these graphs, the students were asked to create a formal definition for sequence convergence by completing statements like "$\lim_{n\to\infty} a_n = 5$ means that …" The students were encouraged to create a definition for sequence convergence to 5 that captured all of their example and excluded all of their non-example graphs. Following the prompt, the instructor guided groups through the IRP. Between the first three teaching experiment sessions, students completed homework by reflecting on their IRP progress during class and attempted individual definitions. The students prepped for the fourth and fifth sessions by viewing other groups' definitions to identify problems and/or adopt definition components as a resolution to a current problem.



Example A Example B Example G Non-example 5 Non-example 7

Figure 2: Selected graphs from 12 graphs used during the TE (Solid lines show 5).

We transcribed all recorded data, created lists of definitions written or verbally stated by individual GTE students or by GTE as a whole, and catalogued GTE's interactions with the instructor and with other groups, their problems, proposed solutions, and resulting changes to their definitions. Then, we focused on changes in their definitions and illustrations, and came up with their endorsed narratives which drove those changes. Then, we examined the interactions and discussions around those changes to identify the discursive patterns and the routines that govern them. Then, we examined how routines contributed in changes in students' endorsed narratives and definitions.

Results

Routines

In our data, the IRP is the course of action, and we were interested in the metarules that determine when this IRP is initiated and applied, and when it is considered as concluded by GTE and the whole class. In our analysis, we found four routines:

Routine 1. A definition should include all examples and exclude all non-examples.
Routine 2. Each component in a written definition should have a place on graphs.
Routine 3. Graphical observation and illustration of a written definition on graphs should be captured in the definition.
Routine 4. A written definition should make sense to everyone.

Routine 1 defines and derives the course of action, IRP, in which students consistently revise their definitions, test it against examples and non-examples, identifying the problems, and coming up with solutions, and iterating the cycle by revising their definition again. Routine 1 not only governs the initiation of an IRP, but also defines a closure for the IRP. We see such a closure when students are in-the-moment satisfied that their definition includes all examples and excludes all non-examples.

Routines 2 and 3 define and derive discursive patterns where students constantly moving back and forth between their written form of definitions and illustration of their definitions. Specifically, Routine 2 defines the discursive pattern of students placing the components in the written definition on example and non-example graphs. This was closely tied to the quantification of the components in the definition (e.g., the word “ultimately” in “ultimately approaching 5” was drawn on graphs). Routine 3 defines the discursive pattern of students examining if their illustration and their observation on example and non-example graphs are captured in their written definition. This was closely tied into the quantification and relationships their illustration reflects based on how and in what order they placed those components (e.g., students always drew ε first, and then identified *N*, but their written definition did not clearly state ε as an independent quantity).

Routine 4 defined and derived students’ discursive pattern of continuously revisiting their use of words and symbols in the definition. For example, in the beginning of the TE, the instructor used a third person to point out the problems with their definitions (e.g., “I could see a student who hadn't seen your definition before, and saying…terms go away from 5, and then they come back and then they go away and come back, that the terms in [example graph] B, the values of them, a_n, they don't always approach 5,” Instructor, Day 1), had groups of students critique each other’s definition by asking them to list problems and suggest solutions, and then groups were to address those critiques. This discursive pattern was identified multiple times in students’ utterances while they express concerns about how they use and relate the terms and symbols, which might not be clear to others (e.g., “The way they [the students in another group] are reading it is that the error bound is coming off the n_c… To us it doesn't say that, but to other people it does”, Rachel, Day 5).

In general, we found a trend that in the beginning of the guided reinvention, those discursive patterns were mainly initiated by the instructor, but as the guided reinvention progressed, those discursive patterns naturally occur within students’ discussion without the instructor being present, which shows that the students adopted the routines that govern those discursive patterns. When a discursive pattern occurred at least three times in students’ discussion without the instructors’ presence, we concluded that students adopted the routine.

Endorsed Narratives

We found four endorsed narratives that led to changes in GTE's definitions:

Endorsed Narrative 1. Dynamic language is insufficient.

Endorsed Narrative 2. Convergence behavior needs to be explained with relevant vertical distances and their relationships.

Endorsed Narrative 3. Convergence behavior involves designating a quantitative relationship between vertical distance and *n*.

Endorsed Narrative 4. Epsilon comes first.

For each endorsed narrative, multiple routines were involved. Due to the limited space, we will discuss the routines that were involved in the generation of Endorsed Narrative 1 in detail and provide a summary for the rest. Endorsed Narrative 1 was initiated with GTE students' problem with dynamic language such as "goes to" and "approaching" used with "terms," "errors," and "error bound" in their definition. Routine 1 was dominantly applied in students' discussion of potential solutions, but Routine 4 was also applied. They mainly used two graphs. Non-example 5 converges to a number less than 5, but still approach 5, and the limit of example B is 5 but its terms do not always approach 5. The inclusion of graph B and subsequent terms in graph B as "not approaching" and the exclusion of graph 5 and its terms "approaching," provided the impetus to produce conflict for the students between the students' use of "approaching" within their current definition and Routine 1. The following excerpt from Day 1 shows an example of one such conversation involving the problems initiated first by the instructor [1,3], and then by GTE students [4, 6, 11, 13], and GTE students' proposed solutions to the problems [2, 5, 6, 12, 14]. This excerpt also shows the GTE students' repeated narrative of rejection of related dynamic language coordinated with testing such language against the necessity of capturing graphs B as convergent ([4, 11,13]). Routine 4 was also applied first by the instructor pointing out this conflict using a third person [3], and then by the students when they were deciding the word for the distance between the terms and the limit as "error" or "distance" [7-10].

1 *Instructor*: They're [pointing to dots in Example B] not approaching, they're getting further away [Becky: nodding while pointing to the same part of Example B].

2 *Becky*: That's what the ultimately is for.

3 *Instructor*: I could see a student who hadn't seen your definition before saying … since you described it as terms go away from 5, and then they come back and then they go away and come back, that the terms in B, the values of them, a_n, they don't always approach 5…[going away]

4 *Jamie*: He is right, it's like not approaching 5 right here [pointing to Example B]

5 *Trevor*: So if we said something about the distance between a_n and 5, instead of approaches?... I know it goes further from here [showing distance with fingers on Example B where errors are increasing] but then ultimately there's never a distance that far away again. [pointing to a minimum value]

6 *Becky*: I mean that's kind of the idea that the error is decreasing

7 *Becky*: but we're not supposed to say that, right? Definitions?

8 *Jamie*: Cause I don't know if. So we're telling this to like dumb people, right?

9 *Rachel*: Yeah, people who don't understand.

10 *Jamie*: So we can't say error. We just have to say distance.

11 *Becky*: Well that's not true either cause the distance is increasing at the last point.

12 *Trevor*: It increases, increases right here [pointing to the 1st minimum], but it's never going to be further away than that. So ultimately, the distance is still getting shorter, so if ultimately worked for G then I feel like it should work for B.
13 *Becky*: I'm not sure if that's true either. Like this one is closer to 5 than that one [where the dots are going further away from 5]. And that's as n is increasing.
14 *Trevor*: [continuing his sentence] Period.

To resolve the initial conflict, GTE students introduced several new words to their definition. First, they considered the word "ultimately" ([2 ,5, 12]), but later stated that "ultimately" was not a solution as they came to realize a non-terminating pattern of terms "going away and coming back" again and again in Example B (e.g., Rachel: "It's still the same thing because the value is going away and it comes back and it goes away again and it comes back. Ultimately, obviously not cover that," Italics added, Day 2). The word "ultimately," later evolves to an n-value (equivalent to N in a formal definition, Figure 1) to rule out bad early behavior of the terms when Routine 2 was applied. Then, the distance between the term and 5 ([6, 11]) was considered and used with "ultimately," which Becky called an "error." With the observation of the behaviors of the terms in Example B ([5, 12]), which "increases, increases…but never going to be further away than" the first extreme value of the term ([12]), they also introduced the word, "period" as a solution ([14]). The "period" was used to establish an error bound dependent upon the maximum value of the terms within each oscillation of the sequence [13], which later they rejected by applying Routine 1 about the definition capturing all the example graphs because "not all of the graphs have periods" [Trevor, Day 1]. Although introducing those words did not directly resolve the conflict in Day 1 or 2, their realizations of those words evolves over time, and eventually used to resolve the conflict.

Endorsed Narrative 2 was supported by their problem about using the description about the location of the terms on graphs. For example, they used the "error bound" as "over minus under" [the vertical distance between consecutive terms: one above 5 and one below 5] to graph B, but found that this was a problem due to Routine 1 because this definition does not apply to all the terms of the sequence or other example graphs. As a solution, they decided to move toward comparing the vertical distance between the limit (5) and the term (a_n) (i.e., $|a_n–5|$) and the error bound as the distance between bounding lines (ε) around the limit. It should be noted that the instructor pointed out the conflict between their use of "error bound" as "over minus under" and how "error bound" is used in Lagrange Remainder formula, which students had seen in class. However, students' follow-up conversation did not address this conflict.

Endorsed Narrative 3 was initiated with GTE students' problem with using words describing the convergence based on the behavior of the dots on graphs rather than the quantitative relations. For example, with example G, GTE students used the word "ultimately" in their early definitions such as "a_n ultimately approach 5 as n increases" or "the distance between the terms of a_n and 5 is ultimately decreasing as n increases." By applying Routine 2, placing the components in the written definition on example and non-example graphs, GTE students located "ultimately" on graph G, and finally denoted the start of "ultimately" with a specific value N where error between a_n and the limit 5 is less than the error bound, $|a_n–5|<\varepsilon$, is satisfied for $n>N$ combined with Endorsed Narrative 2.

Endorsed Narrative 4 started with the problem of GTE students' illustrations of the definition on the graphs were inconsistent with their definition. For example, students were drawing the error bound, ε first, but their definition not capturing this process (e.g., GTE's definition 16. If $|a_n–5|\leq \varepsilon$ for any value of n, $n_c < n$ with error $\rightarrow 0$, then a_n converges to 5 (n_c = some n)). The instructor initiated the problem based on the Routine 3: the written definition should capture the illustration by asking "What did you always draw first?", and then "Do you feel like your definition…captures that?" multiple times. As a solution, GTE group first rearranged the statement "$|a_n–L|\leq$error bound" to read "error bound$\geq|a_n–L|$," and then added "within a given error bound". After receiving a critique from another group about the relationship between "error bound" and "n_c" (Problem: "Error bound for an n_c?" Suggested Solution" Should be error bound for $\{a_n\}$") to GTE's definition 18 (If error bound $\geq |a_n–5|$ for n_c being an n that all terms after n_c are within a necessary given error bound, then $\lim_{n\to\infty} a_n = 5$), GTE students applied Routine 4 (e.g., Rachel: "the way they're reading it [our definition] is that the error bound is coming off the n sub c…To us, it doesn't say that, but to other people it does"), and changed their definition by defining n_c based on the error bound given for the terms (GTE's Definition 21: $\lim_{n\to\infty} a_n = 5$ means that within a given error bound for a_n there is an n_c such that if $n>n_c$ then $|a_n–5|\leq$ the given error bound).

Discussion and Conclusions

Building on the body of research that examined students' epistemological development of a formal definition of the limit of a convergent sequence through guided reinvention, this study revealed what enabled such development. The results of this study provide the mechanism behind the guided reinvention with the analysis of what types of the routines were initiated by the instructors, how they were eventually adopted by students, and how those routines applied to students' problem/solution pairs which contributed to the changes in endorsed narratives, which led to the development of their definitions. In our results, students' adoption of the routines, and the problems as their own was key to development of their endorsed narratives and definitions. Specifically, when students realized the conflict between adopted routines and their definitions, they often identified it as a problem and attempted to solved it. However, when the conflict came from outside the routines that they adopted (e.g., the content covered in class), they did not realize it as a problem even if the instructor pointed out the conflict. This shows that what students have created through guided reinvention – adopted routines and shared endorsed narratives – had more weight than the instruction given in class.

Students' Interpretations of Expressions from Calculus Statements in the Graphical Register

Erika David Parr
Rhodes College

Graphs of real-valued functions figure prominently in the study of calculus. While the use of graphs in instruction has shown promise for supporting student thinking, previous research has also shown that students may interpret graphs in ways that differ from an instructor's intention. This study aimed to investigate how students interpret expressions from calculus statements in the graphical register. To this end, I conducted 150-minute clinical interviews with 13 undergraduate mathematics students who had completed a calculus course. In the interviews, students evaluated six calculus statements for various real-valued functions depicted in graphs in the Cartesian coordinate system. I describe the characteristics of four distinct interpretations of expressions from these statements in the graphical register that students used in this study, which I refer to as (1) nominal, (2) ordinal, (3) cardinal, and (4) magnitude. I discuss some implications of these findings for teaching and directions for future research.

Keywords: Students' Interpretations, Graphical Register, Graphs of Functions, Cartesian Coordinate System, Calculus

In the modern approach to the teaching of calculus, graphs of real-valued functions tend to figure prominently. Key results in calculus, such as the Intermediate Value Theorem (IVT) or the limit definition of a derivative are often illustrated with graphs as figures in textbooks and curricula (e.g., Stewart 2012). Calculus instructors, when surveyed, reported a significant portion of their assessments included graphical interpretations of central ideas of calculus (Burn & Mesa, 2015). The inclusion of such graphs in the teaching of calculus, by both instructors and in texts, is in line with initiatives to incorporate visual representations into mathematics curriculum (e.g., Arcavi, 2003). In fact, recent calculus curriculum reform efforts have often sought to leverage the power of technology to illustrate the coherence of Calculus concepts using animated graphs of functions (e.g., Active Calculus- Boelkins, Austin, & Schlicker, 2018; DIRACC-Thompson, Byerley, & Hatfield, 2013).

Graphs have been shown to afford students opportunities for reasoning about concepts in calculus (e.g., Kidron & Tall, 2015) and may even promote an understanding of key definitions and theorems in calculus (Roh & Lee, 2017). While graphs may provide a powerful support to students, they are only effective insofar as students interpret them in conventional ways. In fact, research has shown that students encounter a variety of issues when interpreting graphs of functions provided to them or those of their own construction (e.g., Bell & Janvier, 1981; Frank, 2016). Some students may conceive of graphs as static shapes on the page with certain properties due to that shape (Moore & Thompson, 2015). Other students may fail to conceive a point as a coordination of two pairs of values (Thompson & Carlson, 2017), and instead interpret points as designating a location in space, labeled as outputs of a function (David et al., 2019). Students' interpretations of graphs, when unconventional, may have far-reaching consequences at the undergraduate level. As Dawkins and Epperson (2014) found, the students who withdrew from Calculus classes typically lacked an understanding of graphical representations. In this study, I sought to extend the current work that has been done in understanding students' interpretation of graphs by addressing the following question: *How do undergraduate students interpret expressions from statements in calculus on graphs of functions in the Cartesian plane?*

Theoretical Perspective

For the purposes of this study, I adopt radical constructivism (Glasersfeld, 1995) as my guiding theoretical perspective. In this view, graphs do not inherently contain a certain set of information; rather, the way in which an observer might interpret them is subject to his or her action schemes, as well as where he or she places attention in his or her perceptual field (Glasersfeld, ibid). I also adopt the view that interpreting graphs is semiotic in nature, consistent with Duval (1999). By this, I mean that interpreting a graph involves cognitive activity of processing a system of symbols intended to represent certain mathematical properties. To distinguish between students' interpretations with expressions on graphs from their reasoning with numerical values, I also use Duval's (1999) language of *registers* and refer to the first as an interpretation in the *graphical register* and the second as an interpretation in the *numerical register*. In this study, I focus on students' interpretations of expressions in the graphical register of the Cartesian coordinate system, specifically.

Methods

As part of a larger study, I conducted 150-minute clinical interviews (Clement, 2000) with 13 undergraduate mathematics students from a large public university who had taken at least one calculus course. These students were selected from a group of 82 students who volunteered to be pre-screened using a survey. I analyzed students' responses to survey items and selected 13 students to interview, with a goal of optimizing the variety of students' interpretations of expressions in the graphical register. This participant selection was in line with the method of theoretical sampling (Corbin & Strauss, 2014; Emmel, 2013).

In the clinical interviews, the selected students were asked to evaluate six statements related to key definitions and theorems from calculus for a variety of real-valued functions, displayed as graphs in the Cartesian plane. These statements were written to be either true or false, depending on the function to which they referred. The six statements were related to the following calculus topics: (1) the Intermediate Value Theorem, (2) the definition of a strictly increasing function, (3) the definition of an injective function, (4) the definition of continuity at a point, (5) the difference quotient, and (6) the Mean Value Theorem. As the students explained their evaluation, I asked them to label the graph of the function for which they were evaluating the statement. The placement of these labels, as well as the student's words and gestures served as a basis for the model I began creating of the student's thinking as the interview progressed. I also asked the student follow-up questions as needed to refine this model, in response to the different possible responses from students.

The preliminary data analysis took place both during each interview as well as immediately following each interview. Once all the interviews have been conducted and initially analyzed, I began to re-analyze each interview, drawing on the patterns observed in the first round of analysis. The observed patterns, developed through a process of open coding (Corbin & Strauss, 2014), in turn developed into a set of codes that I used to re-analyze each interview. The nature of the development and use of these codes was cyclical. As more codes emerge from analyzing interviews, these codes were applied retroactively to previously analyzed interviews. The cycle was complete once no new codes were needed to characterize each student's thinking with each graph and statement pair relative to the research question. The final set of codes was used once more to re-analyze each interview to ensure consistency in coding and refine descriptions of each code as necessary.

Results

From the instances in which students operated with expressions in the graphical register with provided or self-drawn graphs, I observed four different ways in which students assigned and used these expressions, which I refer to as students' *interpretations* of expressions in the graphical register. The four ways of interpreting expressions in graphs I refer to as follows: (1) *nominal*, referring to the use of an expression as a label; (2) *ordinal*, referring to the use of an expression as indicative of an ordering; (3) *cardinal*, referring to the use of an expression as a count of some quantity; and (4) *magnitude*, referring to the use of an expression to indicate an amount of a quantity regardless of unit.

Nominal Interpretation of Expressions

Throughout the interviews, I observed some students in some instances place expressions on graphs to indicate a certain position within the graph, typically on an axis or along the trace of the graph of the function. These students then reasoned about these expressions as referring to these positions they identified in the graph. In doing so, they tended to allow only a single label to be ascribed to one position and used two different labels for two different positions in the graph. These students used such labels for comparison of the positions they had marked to see if these positions were the same or different, as a means of determining whether expressions were equal or unequal. In these cases, the students did not refer to the value of these expressions numerically, or as indicating a certain ordering, an amount of units, or a measurement, but purely as a label. When students reasoned about expressions as labels for positions on the graph in this way, I refer to their interpretation of expressions as *nominal*.

Micah, a student who had completed Advanced Calculus, was one such student who interpreted expressions nominally in the graphical register when explaining his evaluation of Statement 3 (For all real numbers c, d in (a, b), if $f(c) = f(d)$, then $c=d$.) with Graph 2. With this task, Micah used expressions as labels of positions, and then compared these positions as a way of comparing the expressions. Micah explained that in his counterexample labeled on the graph (Figure 1), "$f(c)$ does indeed equal $f(d)$, but c does not equal d. If they [c and d] were [equal], they would have to be the exact same point. So d would have to equal c (*writes in '=c' next to d on the x-axis*). They would both have to be here, but that's not true."

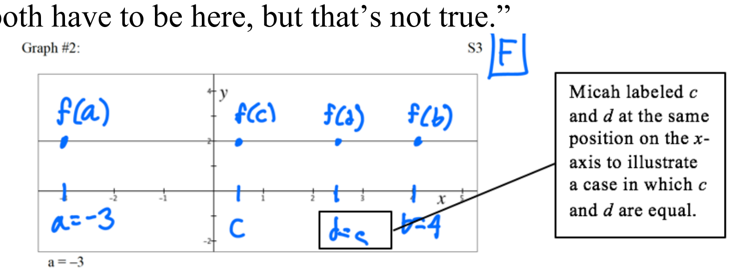

Figure 1. Micah's labels on Graph 2 when evaluating Statement 3.

Based on his explanation of his counterexample, which he labeled on the graph, Micah evaluated Statement 3 as false for the function shown in Graph 2. Micah claimed that for the $f(c)$ and $f(d)$ he chose, c and d were not equal to each other. The justification that he used to arrive at this claim was that c and d were in different positions along the x-axis. He confirmed that this was the reason for his conclusion by explaining that the only way for c and d to be considered equal would be for the two values to be located at "the exact same point." To show what he meant by being at "the exact same point," Micah used the label of "d=c" to indicate the case when these two expressions would be the same, i.e., when they would refer to the same position on the x-axis. In reasoning this way, Micah equated two expressions being placed on the same position on the x-axis with the expressions being equal to each other. For this reason, I categorized Micah's interpretation of the values c and d as nominal.

Ordinal Interpretation of Expressions

I observed other instances in which students ordered expressions by using a spatial relation of positions in the graph (i.e., a position is above/below a position, or a position is to the left of/to the right of another position). Students using this interpretation would label expressions at positions in the graph and then spatially relate these positions to each other to describe the order of the expressions. Often, students used this interpretation of expressions on the graph to claim that one expression was less than, equal to, or greater than another expression. Unlike students using a nominal interpretation of expressions, students interpreting expressions in this way described the *ordering* of expressions using the positions labeled in relation to each other on the graphs. I refer to this way of interpreting expressions on graphs as *ordinal*.

Jess, a student in a senior-level Topology course at the time of the interview, interpreted expressions on the graph through a spatial relation of positions when evaluating Statement 2 (For all real numbers c, d in (a, b), if $c < d$, then $f(c) < f(d)$.) for the function in Graph 1. Jess first labeled c and d on the x-axis, and then labeled the corresponding $f(c)$ and $f(d)$ on the y-axis (Figure 2). Jess claimed that the example of $f(c)$ and $f(d)$ she chose disproved Statement 2 because $f(c)$ was greater than $f(d)$. When I asked how she knew that $f(c)$ was greater than $f(d)$, she replied that "vertically [f of] c is higher than [f of] d."

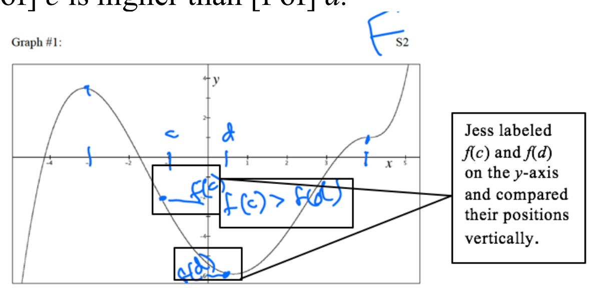

Figure 2. Jess' labels on Graph 1 when evaluating Statement 2.

With this task, Jess first identified the positions of $f(c)$ and $f(d)$ and labeled them on the y-axis. To make a comparison of $f(c)$ and $f(d)$, Jess compared the vertical orientation of these positions on the y-axis to each other. Specifically, Jess concluded that $f(c)$ was greater than $f(d)$ because the position labeled $f(c)$ was higher "vertically" on the graph than $f(d)$. In reasoning about the expressions in this way, Jess interpreted $f(d)$ as a relative reference point from which she compared the position of $f(c)$. By describing $f(c)$ as higher than $f(d)$, and thus, greater, Jess used a spatial ordering of these expressions. Jess made this visual comparison about the positions she had labeled as $f(c)$ and $f(d)$ to draw conclusions about the comparison of two expressions, rather than referring to numerical values of $f(c)$ and $f(d)$. For this reason, I classify her interpretation of expressions in the graphical register in this instance as ordinal.

Cardinal Interpretation of Expressions

I also observed some students interpreting expressions as numerical values measuring a portion of an axis or trace of the graph between two reference points. These students counted discrete units which they perceived or ascribed to portions of axes or traces of the graph to measure them. Some students counted the tick marks on the axes on the provided graphs as units to measure portions of the axes. In other cases, students ascribed units which were discrete points along the trace of the graph that they could count. Figure 3 illustrates ways students interpreting expressions in this way may have ascribed units and counted along a horizontal axis, a vertical axis, or the trace of the graph. I refer to this interpretation of expressions in the graphical register as a *cardinal* interpretation.

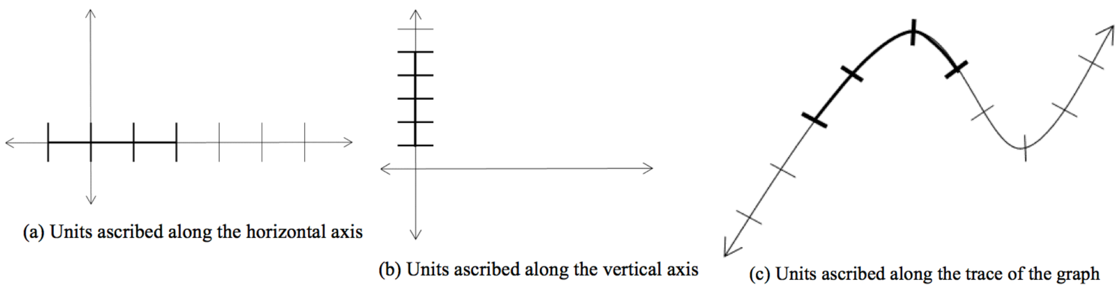

Figure3(a)-(c). Units ascribed and counted along a portion of an axis or graph–A key characteristic of a cardinal interpretation of expressions on graphs.

Annie, enrolled in a Calculus III course at the time of the interview, encountered the limitation of a cardinal interpretation of expressions in the graphical register when evaluating Statement 6. Annie interpret a difference in inputs as a count of units along the *x*-axis and also attempted to interpret a difference in outputs as a count of units along the graph. When working with Graph 1, Annie described her interpretation of the differences "*f*(*b*) – *f*(*a*)" and "*b*–*a*" in Statement 6 (There exists a real number *c* in (*a*, *b*) such that $f'(c) = \frac{f(b)-f(a)}{b-a}$). Figure 4 shows Annie's labels on Graph 1 when interpreting Statement 6.

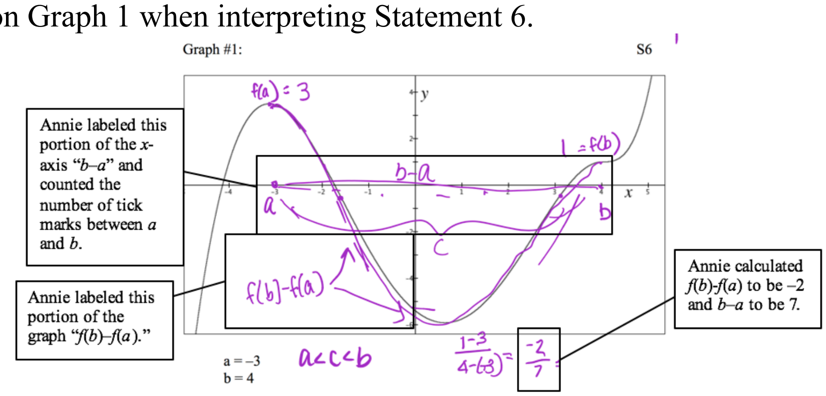

Figure 4. Annie's labels on Graph 1 with Statement 6, showing her labels of differences on the graph.

While working on this task, Annie spoke about the differences "*f*(*b*) – *f*(*a*)" and "*b*–*a*" in the statement as "changes in the values." When I asked her to represent those changes on the graph, Annie drew a line from *b* to *a* on the horizontal axis and claimed "this is *b*–*a*." She also traced over the graph from the point she had labeled *f*(*a*) to the point she had labeled *f*(*b*) and claimed "this whole thing is *f*(*b*) – *f*(*a*)." She described the values she calculated for the quotient in the statement, as –2/7. She explained this was related to slope and the "changes in *y* values over the changes in the *x* values," motioning to the portions of the graph she had marked off. She then explained that the changes in the *x* values were "all of these values between our *b* and *a* [*motioning over x-axis from a to b*], which is 7." When I asked about the meaning of 7 in reference to those values, Annie claimed "Well, there's 7 of them, like, in between, like if you were to count them out there's 7." As she said this, she tapped on the tick marks on the *x*-axis between *a*, labeled at –3, and *b* at 4. I then asked about her meaning for –2 in the graph, the value she calculated for "the change in *y*." Annie responded, "So, like, yeah we can get that 7 because there's like 7 real numbers in between that um but for this (*points to f(b)–f(a) label on graph*) it's not like there's –2 numbers in between (*long pause*) I don't know."

In this episode, Annie used a cardinal interpretation of the value of the difference "*b–a,*" which she calculated to be 7, as a count of units along a portion of the *x*-axis. Her words and motioning indicate that she was thinking of the *x*-axis as consisting of units which she could count. While Annie verbally claimed to be counting in units of "real numbers" between –3 and 4, she motioned to count the integer values located at the discrete tick marks along the *x*-axis. Because Annie's interpretation of a difference was a measurement of a portion of an axis between two reference points in additive units, I categorized Annie's interpretation of the expression as cardinal.

Annie's explanation of "$f(b) - f(a)$" indicated an attempt to interpret this difference on the graph in a similar manner, but was met with conflict. In this case, Annie interpreted $f(b)$ and $f(a)$ at positions on the trace of the graph. While she placed these output labels on the graph, Annie found the numerical values associated with these outputs by projecting the points to the *y*-axis, and calculated the difference to be –2. Annie was confused when trying to interpret $f(b) - f(a)$ similarly to her interpretation of *b–a* described above. Annie was trying to make sense of "a change in values" which she claimed to be –2 as related to a number of units, between the positions she labeled $f(a)$ and $f(b)$ on the graph. Annie had previously interpreted *b–a* in terms of additive units, which were represented by tick marks, and did not express any conflict in explaining the meaning of the numerical value of "7" in that instance. However, Annie was unable to reconcile her interpretation of $f(b) - f(a)$ on the graph with a negative value. Because she was attempting to think about the units additively along the graph, which she anticipated counting up from 0, a numerical value of –2 was a source of conflict. At the end of the episode, Annie was unable to say any more about what the "–2" meant in the graph beyond "the change in the values [$f(b)$ and $f(a)$]." Thus, Annie's cardinal interpretation of the expression of a difference on the graph was limited to whole number values.

Magnitude Interpretation of Expressions

Unlike the other interpretations, some students in some instances interpreted an expression as representing an amount of distance on a portion of a graph that could be measured from a fixed reference point on the graph. These students used distance or measurement language and labeled segments which they interpreted as having the length of the value to which they were referring. Students in these instances labeled expressions at the end of the portion of the graph with the specified length, or with a curly bracket to indicate a portion of the graph. Some students even expressed that the interpreted an expression as a directed distance, in which the sign of the numerical value of the expression indicated a direction between a starting and ending position on the graph. In these instances, I refer to these students as interpreting expressions as *magnitudes* on the graph.

Micah was one such student who conceived of expressions as distances from 0 along the axes when interpreting Statement 2. Micah claimed that the statement "may hold for some values of *c* and *d* but definitely not for all," drew a graph of a linear function, and labeled *c* and *d* on the *x*-axis and $f(c)$ and $f(d)$ on the graph (Figure 5). He explained that in his example, "*c* is less than *d* but $f(c)$ is not less than $f(d)$." When I asked him to further explain how he knew this, he replied "so *c* is less than *d* so I guess the distance here from 0 to *c* [*draws in horizontal curly bracket from the origin to c on x-axis*] is less than the distance from 0 to *d* [*draws in horizontal curly bracket from the origin to d on x-axis*]." To explain that $f(c)$ is not less than $f(d)$, he drew two vertical curly brackets on his graph, one from the origin to $f(c)$ on the *y*-axis, and one to the right of the point he labeled $f(d)$ from the origin up to this point. He explained, "then now $f(c)$ we're, we're doing vertically so this distance from 0 to $f(c)$ is …smaller than the distance from 0 to $f(d)$, because we go from 0 when we count."

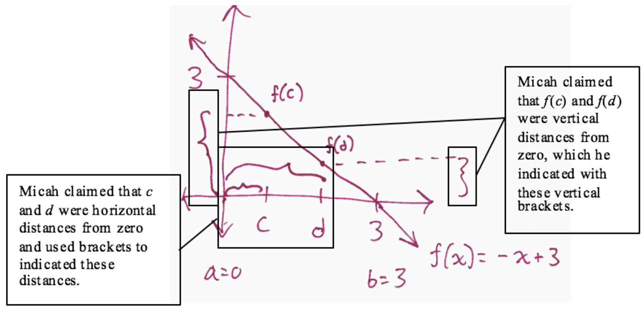

Figure 5. Micah's self-drawn graph to illustrate an example where he claimed Statement 2 was false, with distances marked as curly brackets.

To compare the pairs, c and d and $f(c)$ and $f(d)$, Micah compared the distances from 0 on their respective axes. In doing so, Micah revealed that he was reasoning about these expressions as magnitudes on the graph. Micah drew horizontal curly brackets from the origin, which he referenced as 0, to c and d, and explained that he was comparing the size of these distances to illustrate that c was less than d. Similarly, Micah drew in vertical curly brackets to compare the distances from 0 at the origin to $f(c)$ and 0 to $f(d)$. Although Micah mentioned the notion of counting when describing 0 as a reference point, Micah did not count by units when describing the distances in the graph. Instead, Micah compared the magnitudes of the distances, represented as segments on the graph. For Micah, comparing the value of pairs of inputs and outputs was connected to comparing distances from 0 in the direction of the axes on the graph. For this reason, I classified Micah's interpretation of expressions in the graphical register as magnitudes in this episode.

Discussion & Conclusion

The findings of this study characterize ways in which students may interpret expressions from mathematical statements in the graphical register. The findings reported in this study have implications for the teaching of calculus, specifically related to expressions involving differences. Many calculus theorems and definitions are stated using differences, which are illustrated as distances in the graphical register. In this study, the students who interpreted differences of expressions as cardinals on graphs did not at any time interpret these as magnitudes on graphs, and vice versa. One possible explanation for the mutual exclusion of the use of these interpretations is that students who used a cardinal interpretation of expressions may have had no other interpretation of expressions to draw on. If this is the case, students may benefit from opportunities to reason about magnitudes on graphs in their instruction. These reasoning opportunities ought to encourage students to conceive of measurements in the Cartesian plane as more than additive, possibly including fractional or irrational values rather than whole numbers.

Further research in this area may examine the role of each of the four interpretations of expressions in the graphical register identified in this study in other mathematical contexts or within various coordinate systems. Investigating how students interpret expressions in the graphical register in these various contexts may shed light on students' understanding of related concepts. Another direction for future research may be to develop interventions to support certain interpretations of expressions in graphs for contexts in calculus. For instance, interventions may be designed to support students in interpreting expressions as magnitudes, to develop their understanding of slope in the graphical register as a ratio of magnitudes.

Folding Back in the Arzelà-Ascoli Theorem

Zackery Reed
Oklahoma State University

Michael Oehrtman
Oklahoma State University

While learning is often characterized as a process of abstractions from robust understandings, students' reasoning in advanced contexts can be a more dynamic process of reflection across multiple layers of complex cognitive structures. To explore the ways that real analysis students' understandings of abstract mathematical concepts evolve in the context of multi-faceted proofs, we observed students' attempts to prove the Arzelà-Ascoli Theorem. We describe the understandings from which students built to engage in more complex reasoning and demonstrate their folding back (Pirie & Kieren, 1994) to facilitate the co-evolution of their foundational and advanced understandings.

Keywords: real analysis, metric spaces, formal mathematics, folding back

Introduction and Review of the Literature

As students learn mathematics in progressively more advanced settings, their understandings and ways of reasoning are supported by increasingly complex cognitive structures that rely on more basic understandings developed from earlier courses. This is especially true in abstract and formal mathematical settings such as real analysis and abstract algebra, specifically in courses beyond transition to proof or first semester introductions to advanced topics like algebra, analysis, or topology. To investigate students' co-evolution of both advanced and basic understandings of abstract and proof-based mathematics, we conducted a series of task-based clinical interviews (Hunting, 1997) with two pairs of students in the context of functional analysis. We report on the sessions wherein the students attempted a proof of the Arzelà-Ascoli Theorem, which required the coordination of multiple complex concepts in metric and function spaces. Observing their sense-making in this advanced setting allows us to characterize the complex nature of learning at an advanced level, attending to students' folding back (Pirie & Kieren, 1994; Gravemeijer et al., 2000) to not only support their understandings of advanced mathematics, but also to reinforce their understandings of the more basic concepts to which they folded. This results in a "thickening" (Pirie & Keiren, 1994) of their cognitive structures at multiple levels. While studies abound characterizing students' abstraction of knowledge at the undergraduate level (e.g., Cook, 2018; Gravemeijer & Doorman, 1999; Lockwood, Swinyard, & Caughman, 2015; Oehrtman, Swinyard, & Martin, 2014; Rasmussen, Zandieh, King, & Teppo, 2005; Zandieh & Rasmussen, 2010), much less has been documented about the role that folding back plays in students' progressive development of complex understandings, especially as students engage with formal mathematics.

We also explore ways that students understand key concepts in real analysis. While real analysis is a pillar of advanced mathematics, there are still few studies that explore students' reasoning about its fundamental topics. Real analysis has been utilized as a setting for inquiries into various tangential topics (Alcock & Weber, 2005; Lew et al., 2016; Weber, 2009; Troudt, Gulden, & Oehrtman, 2015; Zazkis, Weber, & Mejía-Ramos, 2016; Edwards & Ward, 2004; 2008) and basic concepts such as formal convergence (e.g. Adiredja, 2013; Cornu, 1991; Cottrill, Dubinsky, Nichols, Schwingendorf, Thomas, & Vidakovic, 1996; Gass, 1992; Oehrtman, Swinyard, & Martin, 2014; Roh, 2008; Swinyard, 2011; Swinyard & Larsen, 2012; Tall, 1992;

Tall & Vinner, 1981; Williams, 1991) have been more heavily investigated, yet few studies (Reed, 2017; 2018; 2019; Caglayan, 2018a; 2018b; Strand 2017) investigate students' understandings of key anlaytical topics.

Reed (2017) demonstrated the impact of a real analysis students' reversed quantification of real number convergence on his construction of pointwise function convergence. The student, Kyle, had adopted a domain-first perspective (Swinyard & Oehrtman, 2014) of real number convergence which he then abstracted to point-wise convergence of functions, stating that the error bound ϵ was a function of x and the index N, writing $\epsilon(x, N)$. Reed (2017) attributed this to his understanding of convergence being rooted in his internalization of the informal notation $\lim_{n\to\infty} f_n(x)$ rather than any attention to the implications from the definition's quantification. We build on this work to investigate the degree to which students draw from informal understandings to generate meaning for definitions with multiple quantifiers interacting with constrained sets within a definition. We thus address the following research question: *How do students leverage and develop relevant background knowledge in advanced proof activity.*

Theoretical Perspectives

We employ a radical constructivist (Glasersfeld, 1995) perspective to characterize students' understandings and infer aspects of their cognition by observing their utterances and mathematical activity. We specifically attend to the students' engagement in goal-oriented activity as indications of their understandings (in the sense of Thompson et al., 2014) of the analytical concepts relevant to the Arzelà-Ascoli Theorem. While we attend to their development of understandings in terms of their assimilations to schemes (Thompson et al., 2014), we also attend to other more broad aspects of their cognitive progression. Specifically, we pay special attention to the instances when students *fold back* (Pirie & Kieren, 1994), drawing from more concrete understandings to reinforce their developing advanced knowledge.

Folding Back

The theory of Realistic Mathematics Education (Gravemeijer, Cobb, Bowers, & Whitenack, 2000) characterizes students' engagement in activity and representation that progresses from concrete to abstract. Students' "models are initially tied to activity in specific settings and involve situation-specific imagery" (p. 243), but evolve along with their purpose to interpretations independent of situation-specific imagery, and ultimately to conventional mathematics independent of support from prior models and applicable "as an entity in its own right." Though Gravemeijer, et al. acknowledge their levels "of activity clearly involve a developmental progression," they note that activity may often "fold back" to prior levels.

> The construct of folding back was originally defined by Pirie and Kieren (1994) as activity, vital to growth of understanding, which reveals the non-unidirectional nature of coming to understand mathematics. When faced with a problem or question at any level, which is not immediately solvable, one needs to fold back to an inner level in order to extend one's current, inadequate understanding. This returned-to, inner level activity, however, is not identical to the original inner level actions; it is now informed and shaped by outer level interests and understandings. Continuing with our metaphor of folding, we can say that one now has a 'thicker' understanding at the returned-to level. This inner level action is part of a recursive reconstruction of knowledge, necessary to further build outer level knowing. (p. 173)

Underlying Mathematics

We focus on our subjects' attempts at constructing a proof of the Arzelà-Ascoli Theorem, specifically the version stating that a subset S of the continuous real-valued functions defined on a closed interval, $C([a,b],\mathbb{R})$, with the supremum metric is totally bounded if and only if it is equicontinuous and bounded. The supremum metric on this space is given by $d_{\sup}(f,g) = \sup_{x\in[a,b]}|f(x) - g(x)|$.

A set S in a metric space is bounded if there exists an element of the set $x \in S$ and a radius r such that $S \subset B_r(x)$. In the case of $(C([a,b],\mathbb{R}), d_{\sup})$, a bounded set is equivalent to a uniformly bounded collection of functions, i.e. a set S where there is an upper bound $M \in \mathbb{R}$ such that $|f(x)| \leq M$ for all $f \in S$ and $x \in [a,b]$.

A totally bounded set S is one such that for every $\epsilon > 0$, there exists a finite collection of points $\{x_i\} \subset S$ such that $S \subset \cup B_\epsilon(x_i)$. We call such a collection of ϵ-balls a finite covering of S.

An equicontinuous set of functions S is one such that for every $\epsilon > 0$, there exists $\delta > 0$ such that for all $f \in S$, if $|x - t|<\delta$ then $|f(x) - f(t)|<\epsilon$.

These properties of sets are often visually depicted in distinct meaningful ways. One common method is to represent the metric space as a region on the page with points inside the region representing elements of the space, as if the space were a subset of $\mathbb{R}^2$. An ϵ-neighborhood is then represented by a disk in the diagram. We call such a representation a generic metric space diagram. While such a representation emphasizes metric properties of the set, a function space represented in this way loses detail about the ways in which such a metric is measured, e.g., as a supremum of output differences for two functions across all input-values. A second common representation of a function space is to draw their graphs on a common set of axes. In this representation, an ϵ-neighborhood around a function can be thought of as a tube extending vertically above and below its graph, and any function whose graph lies completely inside this tube is thus in the ϵ-neighborhood. We call such a representation a graphical diagram. While this representation emphasizes the structure of functions and details about the ways that the metric is defined, it can obscure some of the general metric space properties, for example thinking of functions as elements rather than points. We were interested in the representations students would draw from to generate meaning in the context of proof-construction, and the impact of these choices on their reasoning.

Methods

The episodes we present were part of a larger collection of task-based interviews in which we investigated the ways that students engaged in sense-making in the context of real analysis. We recruited students from a two-semester, metric-space-focused advanced calculus sequence intended to prepare advanced undergraduate math majors (and graduate students with less background in analysis) for a graduate-level analysis sequence. The course covered sequence convergence in Euclidean spaces and general metric spaces with applications to basic function spaces, completeness and compactness, differentiation and integration in single and multiple variables, and differential forms.

Clinical Interviews

We recruited four students from the class to participate in a series of five task-based clinical interviews (Hunting, 1997) each lasting about 90-minutes. One pair of students were statistics graduate students preparing for real analysis, while the other two were masters-level mathematics students. In this report we discuss the results of the latter sessions with the two statistics students, Adisa and Fenfang (pseudonyms), wherein we observed the students attempting to prove the aforementioned version of the Arzelà-Ascoli theorem.

We frequently asked students to explain and justify arguments they made, describe how they understood ideas they were utilizing, and how they understood any visual representations they made. All interventions were exploratory in nature, meaning that we were interested in seeing how the students would reason with these tasks rather than trying to achieve a specific learning trajectory.

Data Analysis

Both researchers reviewed video recordings of all sessions to identify episodes that demonstrated the prior mathematical understandings the students drew from to construct arguments, the ways their understandings evolved, and instances of folding back. Author 1 made descriptive timestamps of the video records attending to the aforementioned criteria, and then both authors met to discuss the relevant episodes identified in the timestamps and to characterize themes that emerged throughout the sessions. The authors then returned to the videos to code relevant episodes according to the initial collection of emergent themes, analyzing students' folding back and further documenting their development of understandings. The authors then met again, resulting in an iterative process that continued until the researchers had identified and agreed on the major themes that emerged from the data, and also the students' in-the-moment understandings (Thompson et al., 2014).

Results

We now describe the ways that Adisa and Fenfang drew from the structures and representations of general metric spaces when reasoning about function spaces, and then in greater detail present a key moment of folding back for Adisa, wherein his understandings for function continuity and equicontinuity co-evolved through targeted graphical investigation.

Generic Metric Space Diagrams vs. Graphs

Early in their attempt to prove totally bounded implies bounded, Adisa and Fenfang looked up their textbook's definition of totally bounded. Reading off the phrase "A set $A \subset M$ is totally bounded if for each $\epsilon > 0$ there exists a finite covering of A by ϵ-neighborhoods," Adisa represented the function space $C([a, b], \mathbb{R})$ as a generic metric space with a square on the board and a covering represented by smaller overlapping circles. He commented that, "Every function we have is in one of these balls," while Fenfang stressed that the centers were functions. Adisa then began an inequality, $|f(x)| \leq |f(x) - f_i(x)| + |f_i(x)| \leq \epsilon + \ldots$ and left the remaining portion blank as they wrestled with how to work with bounding the values of $f_i(x)$. Unsure how to proceed, Adisa redrew their generic metric space diagram with center dots that he called $f_1, f_2, f_3, \ldots$ then stated, "I don't know why I keep drawing it this way. This is referring to sets." He erased the generic metric space diagram and redrew it as a graph of several functions with tubes around centers f_1, f_2, and f_3, saying "It's more like I enclose the function in an ϵ-tube."

Thus, Adisa began to interpret the general phrase of an ϵ-neighborhood as meaning an ϵ-ball for a set of points and an ϵ-tube for a set of functions, remaining adamant about this distinction throughout the interviews. His image of enclosing a function in an ϵ-tube on a graph conceptually entailed that the center of the neighborhood was a function, but in which nearby were points in $[a, b] \times \mathbb{R}$, rather than other functions in $C([a, b], \mathbb{R})$. Adisa described this both graphically and algebraically, saying "That's the problem. You can't relate these to together [points to metric space and graph diagrams]. Here [points to metric space diagram], you are just covering points. Here [points at several locations along a graph], you are covering a **sequence** of points, a formula line." Adisa's emphasis on always attending to, and representing, multiple x-values of a function rather than attending to functions as objects resulted in corresponding difficulty engaging in visual reasoning throughout the interviews.

While focusing singularly on the meaning of a totally bounded subset $\mathcal{E} \subset C([a,b],\mathbb{R})$, Adisa was able to conclude that any function $f \in \mathcal{E}$ would have to be in one of the ϵ-neighborhoods, and since ϵ-neighborhoods are ϵ-tubes graphically, that f should lie entirely in one of the ϵ-tubes. However, as Adisa focused on other tasks involving using the idea of a totally bounded set of functions, he would revert to reasoning about points being close to functions. In one episode, he began questioning, then asserting, that a covering of $\mathcal{E}$ meant that the ϵ-tubes only needed to cover $[a,b] \times [-M,M]$ so that a function might not be in any single ϵ-tube but cross through many, as long as its graph was covered. Adisa eventually resolved the conflicts arising from this reasoning by recalling that he had earlier decided that any function must lie entirely in one ϵ-tube, but without ever revisiting the reason why.

Fenfang, on the other hand consistently viewed the generic metric space diagrams precisely as generic images. She responded to Adisa's confusion by explaining,

> I think A is just a set. We don't need to think a set of what. It's like a general version. A is a set. If we only talk about a property of the set, we don't need to look at what is in the set. Like we learned in the first semester, we just look at the general version of a set of compact or complete or something. I think in the set can be function or something or point or whatever. But if we look at this specified question, should be reasonable in the ϵ-tube because in the set is a function. So how a function is to the other function is in the ϵ-tube. Here [points at set diagram] it's just a general version. Here [points at function inequalities] it's more special case.

Her ability to easily see the same things and translate between a generic metric space diagram and a graph supported flexible reasoning that required Adisa to fold back and reason through more carefully. For example, Adisa eventually had the insight into how to complete their inequality, recognizing that the collection of centers, f_i, were finite so that they could just consider a uniform bound for all of them. He, however, had to consistently reason about that bound pointwise for each function, $-M_i \leq f_i(x) \leq M_i$, then considering the maximum M_i while Fenfang was able to more efficiently characterize these bounds in terms of the sup metric on $C([a,b],\mathbb{R})$, saying for example "Each of the infinite functions [f] will be close to one of the finite functions [f_i]." This account of the interplay between their generic metric space representations and their graphical representations demonstrates the kinds of background images that were meaningful to each student, and the degree to which both students explicitly or implicitly drew from general structures to inform their reasoning in metric spaces. Moreover, this demonstrates the students' folding back to basic images, algebraic representations, and principles of general metric spaces to inform their argument construction.

Folding back to continuity

While attempting to prove that a uniformly bounded, equicontinuous collection of functions is totally bounded, Adisa and Fenfang first conjectured the role that boundedness played by representing functions graphically. This representation led the students to visually assess that the graphs restricted to $[a, b] \times [-M, M]$ would eventually be covered by finitely many ϵ-tubes. Their strategy then became to attempt successive adding of epsilon tubes in some type of boot-strapping manner until the entire collection of functions was covered. As the representation did not force them to distinguish between covering the points in $[a, b] \times [-M, M]$ from covering the space of functions, they did not recognize the difficulty introduced by vertical variation of the functions. Correspondingly, they observed that they could not conceive how equicontinuity played a role and that they needed to better understand this concept. Thus they intentionally engaged in a session of folding back to interpret this definition.

Adisa and Fenfang first turned to a graphical representation of equicontinuity in their textbook, attending to regions of "higher changes" in the graphs and the observation that for "every function in the set, the . . . output will be close if the input is close enough." They did not, however, relate this interpretation to the formal or logical structure of the definition. Since the diagram in the book was ambiguous in its representation, Author 2 suggested investigating the collection of functions, $\{x^n\}$ on $[0, 1]$, already familiar to the students. After drawing a few functions in this sequence, the students continued offering vague interpretations of amounts of vertical change corresponding to small changes in the domain, disconnected from the formal structure of the definition of equicontinuity. After a few moments of thinking about their graphs, Adisa expressed that he was "done" reasoning about the picture, and that he "understood" the written characterization of equicontinuity, but did not understand what a picture would look like. We infer that he saw a need to further develop his understanding of equicontinuity to incorporate into their current proposed way of arguing, but was unsure how to do so.

Author 2 then further engaged the students in connecting their imagery to the definition by specifying a value $\epsilon = 1/2$ and asking whether there was a δ such that, within that δ distance from $x = 1$, all outputs of the functions would be within $1/2$ of $f_n(1)$. The students affirmed that no such delta existed, and Adisa drew a graph in the sequence with large n and depicted the $\epsilon = 1/2$ as an epsilon tube around this function. He then demonstrated that picking a domain value close to 1 would result in an image distance of greater than $1/2$ from $f_n(1)$.

Drawing from visual analogy to the behavior of the set of $\{x^n\}$ near $x = 1$, Adisa then claimed there was no δ that would work for his single x^n with such a large value of n. However, when pressed whether his function was continuous he laughed nervously, confessed confusion over the discrepancy, and lamented that he could not revisit all of this more fully as an undergraduate. Author 2 then guided the students through graphically identifying a δ-neighborhood of $x = 1$ that would result in Adisa's x^n being within $\epsilon = 1/2$ of the output 1.

Author 2 then asked the students to find another function in the sequence for which their identified δ did not satisfy the constraints. Fenfang drew an appropriate function, corresponding to an even larger n-value, and Adisa remarked "Oh another one in between." Fenfang then suggested the presence of another δ corresponding to her new function, which then served as the basis for their developing a more robust understanding of equicontinuity. Both students then made comments suggesting an understanding that, for a given ϵ and point of continuity, each function had an associated δ because of continuity, but the set $\{x^n\}$ was not equicontinuous because further iterations of the sequence would require increasingly smaller δs, and no one δ would work for the entire sequence.

Adisa then restated the definition of equicontinuity, emphasizing aspects that were now made relevant for him "So if you can find *one* δ that works ***for all of them***, then you can say it's uniformly [equicontinuous]" (Adisa's emphases). While he previously had uttered those words when reading the written definition, we infer from his new emphases and the context of the discussion that he had developed a new (and thickened) understanding of equicontinuity. Specifically, Adisa (and Fenfang as well) understood that the role of the singular δ was associated with the continuity of each function in the collection.

Later, Adisa drew a different example of a function set that was not equicontinuous, and his description of the sequence attended to the variation in the δs associated with the uniform continuity of each function. The students' folding back facilitated both of their' development of two kinds of thicker understandings related to equicontinuity. First, the students could construct visual depictions of function collections that were not equicontinuous and could articulate the structural elements of those sets that resulted in this lack of equicontinuity. Second, the students developed a more robust understanding of the relationships between the variables within the definition, specifically the role that δ plays in establishing the uniformity of the equicontinuity.

Discussion and Concluding Remarks

Addressing our research question, we have documented Adisa and Fenfang's varied reliance on general metric space understandings and representations when reasoning about function spaces, and also demonstrated a key moment of folding back in the students' coordination of various complex ideas while proving in real analysis. Adisa and Fenfang had completed a proof-based advanced calculus course and were proficient in drawing from useful results and making sophisticated arguments at the formal level, but still benefited from engaging in more informal ways of reasoning to thicken their formal understandings. In these instances, it was the setting aside of more "advanced" concepts (such as equicontinuity) to spend time reinforcing the foundational understandings that contributed to their productive mathematical activity. While Adisa and Fenfang could productively reason with quantifiers, we also found that they were less proficient at attending to the implications of the quantifiers on the more complex set-based relationships occurring within definitions. Instead, they drew from concrete images such as the general metric image, the idea of an epsilon neighborhood, or a nonspecific relationship between vertical and horizontal changes in functions.

We have documented the phenomenon of folding back as a mechanism for learning in the midst of complex goal-oriented activity. Adisa's thickening of equicontinuity coincided with his development of a more robust understanding of function continuity, a concept he originally learned in undergraduate real analysis. These students' folding back represents a nonlinear development of understanding that has been underrepresented in characterizations of abstraction and generalization in more unidirectional terms.

We find it reasonable that many advanced mathematics students have developed complex understandings of important mathematical topics that are supported by more basic understandings that are not as robust as we would expect. Further investigation can explore ways to support students' learning in the presence of such understandings. Specifically, we are interested in examining how hypothetical learning trajectories and other constructs of design research can explicitly anticipate and support effective folding back. Attention to opportunities in proof-based courses for students to grapple with and coordinate various basic understandings meaningfully in their constructions of arguments could improve this natural co-evolution of foundational and more advanced mathematics.

How problem posing can impact student motivation: A case study

Paul Regier
The University of Oklahoma

This case study utilizes self-determination theory (Deci & Ryan, 2000) to explore the motivational development of three students who participated in problem posing as part of an introduction to proofs course. The experience of these students illustrates several ways in which problem posing can create new more integrated habits of motivational regulation. However, the differences of these cases highlight how students may benefit from experiencing problem posing in a way that makes explicit the purposes of student problem posing in relation to other educational goals. This research underscores the motivational benefits of making the connections between problem posing, problem solving, learning, and self-regulation more explicit earlier in students' mathematical education.

Keywords: problem posing, motivation, introduction to proof

In improving the teaching and learning of mathematics, there is need to understand the factors that promote the development of student motivation (Pantziara & Philippou, 2013). Savelsbergh et al. (2016) conducted meta-analysis of 65 independent math and science teaching experiments concluding that for the five types of teaching approaches considered (inquiry-based, context-based, computer-based, collaborative learning strategies, and extra-curricular activities), all demonstrated positive effects on general attitude and interest toward the subject. However, there was "little clarity about what interventions cause effects on what outcome, and under what conditions." (p. 159). The evidence in mathematics instruction was sparser, focusing primarily on classroom atmosphere and teacher behavior, with only one case studying problem posing.

While problem posing been suggested as a motivational tool in mathematics education (Hošpesová & Tichá, 2015), there is little research explaining *how* problem posing impacts the motivation of students studying mathematics. This paper contributes to the research on motivation in mathematics, firstly, by studying the types of motivational regulation experienced by students engaging in problem posing, and secondly, by exploring the ways in which problem posing appears to have supported their motivational development.

1. Literature Review

1.1. Problem posing

According to Silver (1994), problem posing refers to the generation of new mathematical problems as well as the re-formulation of given problems. Problem posing has been variously described as a "practice deeply embedded in the activity of problem-solving" (Brown & Walter, 1983), an important part of research mathematics (Silver, 1994), a means of learning mathematics (Kilpatrick, 1987), a means for fostering mathematical creativity (Silver, 1997), an integral part of mathematical exploration (Cifarelli & Cai, 2005), a formative assessment tool for instructors (Kwek, 2015), and an aspect of general mathematics instruction (NCTM, 1991). This paper focuses on this later aspect of problem posing and its use as it relates to teaching and learning mathematics. For this purpose, I consider student problem-posing as the activity of students authoring their own mathematical questions (Walkington, 2018).

There is a wide variation to the ways problem posing can be fostered (Silver, 1994; Stoyanova & Ellerton, 1996). Various techniques have been offered as to how to facilitate student problem posing in the classroom, including Brown and Walter's "what-if-not" strategy (1983) and personalization via student's writing their own story-problem (Winograd, 1990). Problem posing is also considered a natural part of inquiry-oriented instruction in teaching students to use self-questioning and self-regulatory techniques (Collins, 1986).

However, Cai, Hwang, Jiang, and Silber (2015) assert that, "Few researchers have tried to describe carefully the dynamics of classroom instruction where students are engaged in problem-posing activities" (p. 22). Cai et al. continue, "because classroom instruction is generally complex, with many salient features that can be investigated, researchers will need to identify those features that are most relevant for problem posing and which may be the most influenced by introduction of problem posing" (p. 23).

Problem posing has been described as a means of improving student disposition toward mathematics (Silver, 1997), of which motivation toward math is a significant aspect. Thus, a better understanding of the relationship between problem posing and student motivation may contribute toward answering the question offered by Cai et al. (2015), "what are the key features of effective problem-posing instruction in classrooms?" (p. 23).

1.2. Motivational Regulation

A central question in teaching is how to maintain or improve intrinsic motivation for learning (Valås & Søvik 1994). Motivation in education has been researched from many perspectives (Bern, 1972; Wigfield & Eccles, 2000). In particular, social learning theory (SLT; Bandura, 1982) and self-determination theory (SDT; Ryan & Deci, 2000) explain motivation as mediated by perceived competence, or self-efficacy. Both SLT and SDT provide valuable perspectives to understanding the impact of problem posing on motivation by highlighting the role of the internalization of standards or values that regulate activity.

While SLT focuses on *intrinsic interest*, or the predisposition or tendency to engage in an activity, SDT considers motivation in a slightly broader sense as "energy, direction, persistence and equifinality—all aspects of activation and intention" (Ryan & Deci, 2000, p. 69). This study utilizes this later perspective, taking the view that people are motivated or "moved to act by very different types of factors, with highly varied experiences and consequences." (p. 69). Rather than measuring students' interest toward mathematics, this project seeks to understand the broad reasons why students are motivated to act in relation to mathematics.

SDT also offers two theoretical perspectives that can guide the study of student motivation toward mathematics. Firstly, SDT characterizes extrinsic and intrinsic motivation not as binary variables, but on a continuum based on by perceived locus of causality (external vs. internal). This offers finer-grain analysis of student motivation than other motivational theories. Secondly, SDT (Ryan & Ryan, 2000) describes three psychological needs that foster the development of self-motivation – competence, autonomy, and relatedness.

1.2.1 SDT Continuum of Motivational Regulation. SDT describes three intermediate forms of "extrinsic" regulation between purely external and purely internal (intrinsic) regulation—introjected, identified, and integrated. These types of regulation vary by the degree to which an external regulators or reason for acting has been internalized (or "taken in") and subsequently integrated (accepted as one's own). In this way, *external regulation* describes behavior "performed to satisfy an external demand or reward contingency" (p. 72), *introjected regulation* describes behavior that results from "taking in a regulation but not fully accepting it as one's own" (p. 72) and is enforced through internal pressures, such as guilt, anxiety, or regulated self-esteem dynamics; *identified regulation* "reflects conscious valuing of a behavioral goal or regulation, such that the action is accepted or owned as personally important" (p. 72); and *integrated regulation* describes reasons for acting that are "fully assimilated to the self, which means they have been evaluated and brought into congruence with one's other values and needs" (p. 73). While integrated regulation shares many qualities with *intrinsic regulation*, or behaviors done for their "inherent satisfactions" (p. 72), they are still considered separate because integrated regulation refers to actions done "to attain separable [external] outcomes" (p. 73).

According to SDT, as one increasingly identifies with or takes ownership of a reason for acting, the perceived locus of causality (PLOC) for that action will increasingly stem from oneself. As external regulators are increasingly internalized and integrated, one experiences greater autonomy in action. In this way SDT explains the development of self-motivation from external regulation and introjected regulation to identified regulation and integrated regulation. Studies have shown that people demonstrating higher levels of identified and integrated regulation experience greater interest and enjoyment, exert greater effort, and utilize more positive coping styles (Ryan & Connel 1989).

1.2.2 Psychological needs that support self-motivation. SDT also describes three innate psychological needs—competence, autonomy, and relatedness—which are the basis for self-motivation. *Competence* refers to one's sense of their ability to do things successfully, which is described by SDT as facilitating intrinsic motivation. However, developing a sense of competence is not a sufficient condition for experiencing self-motivation; according to Deci and Ryan (2000), "people must not only experience competence or efficacy, they must also experience their behavior as self-determined." This need to maintain a sense of self-determination, or ability to take action, is referred to as *autonomy*. This is described in attributional terms as an "internal perceived locus of causality" (deCharms, 1968). Deci and Ryan further state that "this requires either immediate contextual supports for autonomy and competence or abiding inner resources (Reeve, 1996) that are typically the result of prior developmental supports for perceived autonomy and competence" (p. 70).

The third psychological need, *relatedness* refers to the need to maintain a secure, interpersonal relational base. Deci and Ryan (2000) describe that experiencing a sense of relatedness is critically important to internalization since the "primary reason people initially perform [externally motivated] actions is because the behaviors are prompted, modeled, or valued by significant others to whom they feel (or want to feel) attached or related" (p. 73).

1.3 Research Question

This paper studies the question: how does problem posing impact students' motivation for mathematics? To begin answering this question, this paper explores the following three sub-questions. In the context of students' experience of problem posing in an introduction to proofs course: RQ1-What types of regulation characterize a student's motivation for mathematics over time? RQ2-To what degree does a student attribute changes in motivational regulation to problem posing? RQ3-In what ways does problem posing appear to support a student's sense of competence, autonomy, relatedness in Discrete Mathematics?

2. Methods

This qualitative research project serves as an illustrative case study of students experience problem posing in an introduction-to-proofs course, taught in fall of 2017. Each class period of this course was observed and video-recorded by the author for prior research (Regier & Savic, 2019). The course was taught utilizing an inquiry-based teaching pedagogy (Laursen et al. 2014) which involved both student problem posing in class, as well as several assignments which provided explicit opportunities for problem posing out of class, collected as data.

Two students, given pseudonyms Fred and Frank, were recruited due to their participation in interviews in December 2017. Fred had taken a Calculus II the prior semester with the same instructor, Dr. F. A third student, Aaron, was recruited voluntarily from among the remaining students that agreed to be contacted for follow-up research. Each student had demonstrated active participation in class. At the end of the semester, Frank, Aaron, and Fred received grades of A, B, and C, respectively, and all indicated that they had worked hard and were proud of the grade they received.

Interviews were conducted in the spring of 2019 using a semi-structured interview methodology. Questions included “Why did you take Discrete Mathematics?”; “What motivated you in class?”; “What took away motivation?” Each student’s write-your-own test assignment was shown to students and used to ask questions about problem posing. Students were asked if and how problem posing impacted them in general, if and how it impacted their approach to Discrete Mathematics, as well as if and how it impacted their sense of competence, autonomy, and relatedness. Finally, students were asked to describe their motivation (for engaging in class, solving problems, and for posing new problems) since Discrete Mathematics.

Each interview was transcribed, removing phrases such as "like," "um," and "kind of" for clarity, and coded in a qualitative data analysis software package (NVivo) in three separate cycles as described below. The first cycle involved reading and coding each interview transcript for evidence of motivational regulation for *learning* and *doing* mathematics, as expressed in the student views concerning their engagement toward mathematics. This followed Hannula’s (2006) view that motivation “is observable only as it manifests itself in affect and cognition, for example as beliefs, values and emotional reactions” (p. 165). Then, anything coded for evidence of regulation was then sub-coded these into the five types of regulation detailed in **Section 1.2.1**. This utilized the student’s self-described locus of causality (PLOC) for acting and followed Ryan & Connel’s (1989) research perspective that "the status of variables as real causes or motives is not directly relevant," rather the “focus is more on how persons understand and describe their own purposes for acting and the relation of such purposes to a continuum of autonomy" (p. 750).

The second coding cycle involved coding for student experience of, or instructor support for, any of the three psyhcological needs—competence, autonomy, and relatedness—that serve as the basis for self-motivation (see **Section 2.2.2**). Because the sub-codes used for these first two cycles were previously defined by SDT, this coding style can be characterized as provisional coding (see Saldaña, 2013, p. 144).

The third cycle involved applying content-based codes for anything related to problem posing, that is, students authoring their own mathematical questions. These codes primarily fell into the following four categories: student’s own problem posing (in or out of class), peers’ problem posing (in or out of class), instructor (or teaching assistant) support for student problem posing, student support for others’ problem posing. This coding method can be described as structural coding (Saldaña, 2013, p. 84) since these codes served to categorize experiences involving problem posing for analysis across other codes.

Results

The three research questions (section 2.4) were explored through three respective steps of analysis. First, each students’ motivation development toward mathematics in and since Discrete Mathematics was summarized based off quotes coded for “regulatory style” (RQ1). Second, the degree to which each student attributed their level of (or a change in) regulatory style to problem posing (RQ2) was studied by looking at the intersection of coding for “problem posing” and “regulatory style.” Third, the degree to which problem posing appeared to have supported the integration of regulation (RQ3) was analyzed by considering the intersection of the codes “problem posing” and “support for self-motivation.” A summary of the results for RQ1-3 for each student are provided in Table 1 below. For space considerations, only brief segments of the analysis of Aaron's interview regarding RQ1 and RQ2 are provided below, with the coding for **regulatory style** given in **bold**.

Table 1. Summary of Results for Fred, Aaron, and Frank

Research Question	Fred	Aaron	Frank
1. What types of regulation characterize a student's motivation for mathematics over time?	Described consistent development from external to internal (identified and integrated) regulation for *doing* mathematics.	Described development from external to internal (identified and integrated) regulation for *doing* and *teaching* mathematics.	Described little change in regulation, appearing to be largely internally motivated from the start of college.
2. To what degree did a student attribute changes in regulation to problem posing?	Attributed this change in regulation, in part, to his *own* experience problem posing.	Connected problem posing with this change in regulation and with taking ownership of his own learning.	Did *not* attribute a change in regulation to problem posing.
3. In what ways does problem posing appear to support a student's sense of competence, autonomy, relatedness?	Described increased confidence for exams due to his own problem posing, an increased sense of autonomy in relation to his own problem posing and the instructor support for problem posing, and an increased sense of relatedness from his own and peers' problem posing.	Described gaining a sense of competence and being able to "choose where his learning went" from both his own problem posing and from the way class was set up in support of problem posing, and gaining a sense of relatedness from the problem posing of his peers.	Described problem posing as having little impact on his sense of competence, autonomy, and relatedness in class.

Aaron described at the beginning of the semester, having "**a big assignment for another class** one week," saying "I didn't apply myself in Dr. [F]'s class and that took a hit to my motivation in that class because I would go to class and **I'd feel like an idiot**." This was coded for **external regulation** since Aaron described another assignment as the reason for not participating, and **introjected regulation** since feeling "like an idiot" describes a self-esteem dynamic.

Later, Aaron described an experience of playing basketball at the gym and realizing he had an idea for a proof. He said "I pulled out my phone and **I started writing up a proof on it. It hit me just then. I was like, "hmm, oh." I just had to start writing notes and stuff on it."** Since solving the proof was important enough to him that he stopped playing basketball to start writing down his ideas for a proof, this was coded for **identified regulation**. Quotes like this contributed toward demonstrating a shift in Aaron's motivation (RQ1).

Aaron's interview further provided evidence that this shift in regulation was linked to his problem posing activity. When asked "what did you take from Discrete Math?" Aaron mentioned exploration several times, saying things such as, “I like how he gave us like things to explore before we ever covered content in math.” At this point I asked about his experience problem posing, to which Aaron commented on.

> *Aaron*: That’s one thing that I struggled with in that class because I hadn’t done that yet, but I feel I’ve kind of gotten better at it because [every] homework he had us ask two questions. It was always do this problem and ask two questions. A lot of times I was like, what the heck am I supposed to ask? **What I found myself doing a lot of the times is I would ask a question and then I would answer it myself.** I’d be like, I can’t put that question because I just answered it. So, it was actually like **I was learning by myself and learning [from] what *I thought* of rather than learning some kind of prescribed material.** I was thinking creatively and asking my own questions and answering them.

Aaron learning by himself from what he “thought of rather than learning some kind of prescribed material” was coded for **integrated regulation**, since this described his learning as stemming from himself. Since this was in association with Aaron’s experience asking questions on homework, this was considered evidence that a shift in regulation was linked to his problem posing activity (RQ2).

4. Discussion

Dr. F’s support of problem posing appeared to have increased Fred’s sense of relatedness through other students’ problem posing, which in turn contributed to his willingness to pose his own problems. The carrying out of those actions, i.e. problem posing, then provided opportunities for integration of regulation related to those actions. An example of such integration of regulation can be seen from Fred describing problem posing as part of the larger process of “learning” that mathematics is not replicated but created. Rather than “just plugging numbers basically and memorizing formulas and plugging in numbers” as Fred described his experience in primary and secondary school, Fred shifted toward seeing mathematics as “coming to your own setup and equation and solution on our own.”

Aaron also described how habits of thinking involving problem posing contributed to developing greater integrated regulation toward mathematics. Aaron described utilizing problem posing in his approach problems: “I try to break it into pieces I do understand and think about ‘what I do understand?’ and ‘how I can tackle the problem if I understand this bit of it or this bit of it?’” This perspective conveys how problem posing enabled Aaron to gain an internal orientation (PLOC) toward mathematics.

Aaron described problem as contributing to his confidence for mathematics and helping him “feel like a mathematician,” as well as his sense of being related to other students. At several points in the interview, he ascribed his change in motivation to his peers’ problem posing above his own problem posing experience. This demonstrates how the development of self-regulation is impacted by the social context in which students experience or engage in problem posing.

In contrast to Aaron and Fred, Frank described little change in motivational regulation in Discrete Mathematics. In fact, he described lower motivation for the problem posing assignments than for "very challenging math problems." While he recognized the value of problem posing, he did not perceive it as challenging enough to merit his effort. He said that, “unfortunately the downside of assignments that are this kind of open-ended and this free-form is that, really, you don’t have to push yourself more than you want to.”

SDT explains Frank’s behavior in that, without a sufficient level of perceived challenge, the problem posing tasks used failed to meet Frank’s need for developing a greater sense of competence toward mathematics. Ryan and Connel (1989) found that the identified and intrinsic regulation defined by SDT correlate with an intrinsic motivation component of a binary motivational model (Harter, 1981) called *mastery motivation*, characterized by an internal PLOC. It appears Frank was more self-motivated for challenge in mathematics than he was for exploration and self-discovery. SLT offers a further explanation of Frank's behavior by describing how "self-development is aided by a strong sense of self-efficacy to withstand failures, tempered with some uncertainty (construed in terms of the challenges of the task rather than fundamental doubts about one's capabilities) to spur preparatory acquisition of knowledge and skills" (Bandura, 1986, p. 394). Accordingly, Frank appeared to not judge the uncertainty of the problem posing tasks as useful to the acquisition of knowledge and skills.

In spite of being one of the most mathematically advanced students in the class (from an assessment standpoint), Frank said "I haven't developed the mathematical confidence to feel like my problems are valuable." In contrast to Fred and Aaron, Frank did not view himself as posing "valuable" mathematical questions. Why was Frank hesitant to see the value problem posing in the context of his class' learning, problem solving, and proof writing?

One explanation for this has been offered by Silver (1994) who described that, for students already successful under more directed instruction, "there may be little desire or motivation to alter the existing power relations in the classroom, or to alter the hierarchical assumptions underlying current conceptions of mathematical performance" (Silver, 1994, p. 25). Thus, for students like Frank, explicit discussion of the fundamental assumptions of how mathematical knowledge and skills are or can be obtained may be needed in order to promote views of problem posing as worthy of effort. Therefore, to benefit the most students possible, problem posing may need to be presented in a way that makes explicit the purposes of problem posing in relation to other educational goals. This also highlights the importance of framing problem posing and uncertainty as useful to the development of mathematical knowledge and skills.

5. Conclusion

This study confirms the use of problem posing as a motivational tool beyond simply connecting students to their own existing interests (Silver, 1994). Problem posing has the potential to create new more integrated habits of regulation. Aaron's experience demonstrates how by asking his own questions, by posing his own problems, he gained internal orientation to his own mathematical activity. As someone (student, instructor, researcher) poses problems that are increasingly internally obtained, they gain greater access to the resources within them, perhaps primarily, the motivation or energy to continue pursuing something new, difficult, and unknown.

One limitation of this research is that the results are based on students' self-reported reasons for acting, and thus, there may be bias in the explanation of their actions. However, the results for each student do appear internally consistent, and as the interviews were voluntary and over a year after their participation in Discrete Mathematics, there was little external reason to give biased responses. Another limitation of this paper is the lack of explicit characterization of instructor actions used to foster or promote student problem posing. Such a characterization would further the study of the impact of instructor actions for fostering problem posing on student development of self-motivation. There is a need for both an explicit characterization of the key features of problem-posing instruction (Cai et al., 2015) as well as the ways to measure teaching characterized by those features to be able to better study the impact of teaching to foster problem posing on student regulation toward mathematics. By better explaining the ways in which problem-posing can impact student regulation, this research can contribute toward allowing students to develop autonomy, ownership, and self-motivation for studying mathematics.

Varieties of Sameness: Instructors' Descriptions for Themselves and Students

Rachel Rupnow
Northern Illinois University

Group isomorphism and homomorphism are topics central to abstract algebra, yet research on instructors' views of these concepts is limited. This study examines two instructors' views of group isomorphism and homomorphism and how they drew on notions of sameness to describe them. Differences between instructors' descriptions in interviews and instruction are explored.

Keywords: Isomorphism, Homomorphism, Abstract Algebra, Instructional Practice

Experts have identified isomorphism and homomorphism as two of the central topics of Abstract Algebra (Melhuish, 2015). Although some research has been done on how students and mathematicians approach isomorphism, research on understandings of homomorphism is more limited. Furthermore, research on mathematicians and, specifically, instructors is limited. This paper focuses on two instructors' views of isomorphism and homomorphism and on differences in how they described these concepts in different settings.

Literature Review and Conceptual Framework

Previous work has examined conceptions of isomorphism more than homomorphism and largely from students' perspectives. Early studies focused on students' approaches to determining if groups were isomorphic. Dubinsky, Dautermann, Leron, and Zazkis (1994) indicated that students focused on cardinality of groups when looking for isomorphisms, but not whether the homomorphism property was satisfied. Leron, Hazzan, and Zazkis (1995) also noted students' tendency to check cardinalities, but their students tested other properties too. Weber and Alcock (2004) and Weber (2002) asked undergraduate and doctoral students to theorems related to isomorphism and to prove or disprove specific groups were isomorphic. While both doctoral and undergraduate students were able to prove simple propositions, doctoral students had continued success with more sophisticated propositions. Melhuish's (2018) replication study suggested doctoral students' success rested on their relational understanding of properties of isomorphism, though knowledge of properties and relational use of them could be distinct.

In isomorphism-focused studies, some research has been conducted on homomorphism. Nardi (2000) noted students' struggles in proving the Fundamental Homomorphism Theorem (FHT) stemmed from three major sources: an inability to recall definitions or a lack of understanding of definitions, poor conceptions of mapping, and not recognizing the purpose of sections of the proof. Much like the isomorphism context, Weber (2001) observed that despite undergraduates' ability to recall relevant theorems, they struggled to move past "definition unpacking" techniques when trying to prove theorems related to isomorphism and homomorphism, whereas doctoral students experienced success by invoking their holistic understanding of concepts. Melhuish, Lew, Hicks, and Kandasamy (2019) examined relationships between students' understanding of function and their abstract algebra knowledge, including understandings of isomorphism and homomorphism, by examining properties, metaphors, examples, representations, and different views of functions in abstract algebra.

Limited work has been conducted on mathematicians' views of isomorphism. Weber and Alcock (2004) noted algebraists' notions of isomorphism as meaning groups were "essentially the same" (p. 218) or that groups being isomorphic meant "one group was simply a re-labelling of the other group" (p. 218). However, non-algebraist instructors' views remain unknown.

A theoretical lens for analyzing mappings is the conceptual metaphor construct (e.g. Lakoff & Núñez, 1997). Conceptual metaphors utilize one's structured knowledge of a source domain to inform one's view of a related target domain. Because conceptual metaphors reveal the structure of thought, they are a natural lens for studying the abstract concepts of isomorphism and homomorphism. Conceptual metaphors have previously been used to examine students' reasoning about functions in algebra (Zandieh, et al., 2016; Rupnow, 2017). Zandieh et al. (2016) examined students' notions of function in linear algebra. Rupnow (2017) examined students' metaphorical expressions in the context of isomorphism. In this study, conceptual metaphors are used to frame responses to two research questions: (1) how did instructors draw on notions of sameness to describe isomorphism in interviews and instruction and (2) how did instructors draw on notions of sameness to describe homomorphism in interviews and instruction?

Methods

Data for this paper are drawn from classroom video and interviews of instructors. Classroom data was collected when isomorphism or homomorphism were discussed in class. Only segments focused on isomorphism or homomorphism were completely transcribed.

The participants were two faculty members teaching an introductory abstract algebra class. Instructor A used the Inquiry-Oriented Abstract Algebra (IOAA) materials in class. Instructor B used a mixture of lecture and activity days. Both had taught the course at least once before and taught isomorphism before homomorphism. Neither does research in algebra. Instructors were recruited at the beginning of the semester from that semester's abstract algebra teachers. Participants engaged in semi-structured interviews (Fylan, 2005) lasting roughly one hour each. The interview with each instructor occurred as they began teaching isomorphism and focused on definitions and descriptions of isomorphism and homomorphism, as well as their explanations when teaching. Interviews were audio and video recorded and any written work was collected.

The interviews and videos were transcribed and coded using thematic analysis (Braun & Clarke, 2006). This included multiple iterations of coding (Anfara, Brown, & Mangione, 2002); first, transcripts were open-coded for vivid, active words that could indicate conceptual metaphors; next, statements were viewed holistically for mathematical approaches being conveyed by statements; finally, codes were generated and refined by repeating the previous stages. These codes were influenced by Zandieh and colleagues' (2016) and Rupnow's (2017) work. Codes related to the formal definition and mapping also arose (Rupnow, 2019), but only codes related to sameness or combining sameness and mapping are reported here in Table 1.

Results

Results address isomorphism (research question 1) and then homomorphism (research question 2). Metaphor codes are abbreviated to generic sameness, same properties (isomorphism) or similar properties (homomorphism), matching, renaming (Instructor A) or relabeling (Instructor B), disembedding, and equivalence classes.

Isomorphism

Instructor A. Many examples of sameness language were invoked in both interview and classroom settings, though more variety appeared in class.

Interview setting. When discussing isomorphism, Instructor A often invoked generic sameness. Their initial description of isomorphism was: "When I think about groups, if they're isomorphic, it means that they are the same group just notated with different names or notated with a different operation, but that the groups are essentially the same." They went on to link this generic idea of sameness to the specific idea of finding a renaming function to demonstrate sameness: "I would verify that two things are the same by finding a renaming function, an isomorphism between the two groups. So I kind of feel like that is the test...."

Table 1. Metaphor code descriptions and examples.

Metaphor Code	Code Description	Example
An isomorphism/A homomorphism is a mapping between groups that are the same/similar.	Generic references to groups being the same or similar	"So going back to the two different groups of just things...you would have to have the same, like, relationship equivalencies between the one and the other group."
An isomorphism/A homomorphism is a mapping between groups with the same/similar properties.	Use of properties shared by isomorphic groups (e.g. size) or in a homomorphism (domain mapping to a range with the same or fewer elements)	"...they're two different sizes so there can't exist an isomorphism between them."
An isomorphism/A homomorphism is a matching.	Emphasizes aligning similar objects with each other	"I guess I would say [isomorphism]'s a correspondence that...matches like things with like things."
An isomorphism/A homomorphism is a renaming/relabeling.	Aligns similar elements while recognizing names are arbitrary	"If you just took these elements and attached these other labels instead of the labels you originally had and you get the same exact structure..."
An isomorphism/A homomorphism is a disembedding.	Extraction or highlighting of properties from domain to codomain	"A homomorphism is just a function that preserves the structure…not necessarily...all of the structures…Like the integers map to Z mod 2…, that could preserve the structure of…the evens and the odds, but it destroys a lot of the other properties of the integers."
A homomorphism is a mapping defined by equivalence classes.	Leverages shared structures of groups to find similar elements in the domain	"So my idea for the homomorphism is just taking it from Z mod 6 to Z mod 3 sort of directly so I mean like, theta of 4 mod 6 would equal 1 mod 6 because they'd both be 1 mod 3..."

When asked if they thought about isomorphism the same way they described it to students, they related their thinking about the formal definition to renaming again:

> I want them to get to the formal definition, but even then, I want them to understand the formal definition as like a renaming function. I feel like that was not at all obvious to me as a student. And so it was really hard to unpack...why this...seemingly arbitrary function would prove that two things were the same.

In addition to standard descriptions given to describe isomorphism, Instructor A related isomorphism to naming stuffed animals when asked how they would explain isomorphism to a child: “I might say…each of their stuffed animals has a name, but it would be the same bear even if I called it a different name....It’s the same bear if I call them Fred or Sam.” Comparing this intentional metaphor to their standard language for isomorphism, we see that the choice highlighted sameness once again. Specifically, they highlighted the arbitrariness of the name of the bear in keeping with the renaming metaphor.

Classroom setting. In teaching, Instructor A used sameness when defining isomorphism and when thinking about how to approach whether or not groups were isomorphic (e.g. “Always start these with…are they the same?”). Same properties language was also incorporated, especially when verifying groups were not isomorphic (e.g. different sizes implies not isomorphic).

Renaming language was only used when first presenting the formal definition as a colloquial way to understand the idea. However, matching was used often before the formal definition was given to reason about whether groups in Cayley tables were the “same” in some way:

> If I look at the same equation, those line up…and those should line up, but when I look at my equation, those don’t line up. On the mystery table, this equals D. So it’s like I can check the equation on the mystery table and D_6 and see if I get the same answers.

Note this matching language placed value on the specific results of computations, whereas the renaming language used names but focused more on underlying properties.

Summary. In both interview and classroom settings, Instructor A highlighted generic aspects of sameness as well as the specific idea of renaming. In class, matching and same properties language were added. Same properties were used to identify specific aspects that were or were not the same when addressing specific groups, which had not been a prompted activity in the interviews. Instructor A’s use of matching language often seemed to replace renaming in class.

Instructor B. Like Instructor A, many examples of sameness language were used in interview and classroom settings, but more variety appeared in class.

Interview setting. Instructor B used isomorphism language focused on general sameness as well as relabeling. When first asked about the words or phrases that came to mind to describe isomorphism, they provided three images: “structure-preserving map, equivalence of structures, relabeling of elements.” Matching was incorporated when considering how to describe isomorphism to a child: “It’s a correspondence that matches like things with like things.” When pressed for a preferred way of thinking about isomorphism, they wove together relabeling and sameness ideas with the formal definition:

> I really prefer to think of it as a relabeling so that…from an algebraic point of view, there’s really no difference between these structures, and so...if you just took these elements and attached these other labels instead of the labels you originally had…you get the same exact structure. So that’s the idea I try to get across more than...that you have a...bijective function that...preserves such and such operation.

They incorporated disembedding as well as general mapping and sameness language when expanding on what relabeling meant to them:

> The isomorphism itself can just sort of disappear to the background and you can...really just identify...these structures….And you could start talking about *the* cyclic group with n elements….And you don’t need to know...what cyclic group, you don’t need to…know that there could possibly be two different cyclic groups hanging around, and…a function mapping elements to another. You can just say, ‘Well, if...I had a different instance of a cyclic group with n elements, if I wanted to, I could just change those labels to these labels,’ and so really it’s the same underlying structure.

Of note, their concept of isomorphism was about a shared structure, allowing us to see the groups were *isomorphic*, as opposed to a focus on the function that connected them (*isomorphism*).

Classroom setting. In class, sameness was used to refer to groups being "essentially the same" on a number of occasions, especially when the definition was initially given. Same properties were used especially during the activity day when students were being prompted to look for properties that should hold in both groups if they were isomorphic. Relabeling was used numerous times to refer to the isomorphism being used to show groups were isomorphic and on the activity day, it was used to prompt approaches for students when working with discrete mappings. Matching was used a few times as students were prompted to look at which element was "matched up" with each element when creating a discrete mapping.

Summary. In both interview and classroom settings, Instructor B highlighted generic aspects of sameness as well as the specific ideas of matching and relabeling. In class, same properties language was added. Like Instructor A, same properties language was used to identify specific aspects that were or were not the same when addressing specific groups, which had not been a prompted activity in the interviews. In both interview and class contexts, Instructor B used relabeling language more than matching language.

Homomorphism

Instructor A. Although Instructor A often used sameness-related ways of thinking about homomorphism in the interview, they used these infrequently in the classroom setting.

Interview setting. Instructor A frequently spoke in terms of equivalence classes, specifically with a goal of addressing which elements were behaving in a similar way. For example, when initially describing homomorphism, they focused on equivalence classes as a way to identify which elements from the domain group were somehow the same:

> I think equivalence classes; like the idea that I could pick one representative for a set, and the homomorphism…gives me a way to think about what's equivalent.…Apply the same name to a group of things that are equivalent or collapsing a set into a single element…

Thus, for homomorphism, much like isomorphism, they viewed sameness as central to their understanding. However, in this case the sameness focused within groups, to see which elements acted in the same way, instead of globally identifying the two groups as being the same. When asked if their view of sameness in isomorphism and homomorphism was the same, they clarified:

> With isomorphism I mean this collection and the operation is the same as this collection and operation, and the only thing different about them is the names that I chose for the elements in operation… In homomorphism... I'm saying what things in my domain are the same under that mapping. So it's kind of like I take my domain, call everything the same, and then that collection of same things maps to a single element in the range.

When asked to describe a homomorphism to a ten-year-old, they struggled to find an adequate picture, but finally decided the 'class of same name' idea could be captured:

> So going back to stuffed animals…I could sort things into bears and dogs…, but the idea that it partitions the set, or that these are equal sizes…there it quickly falls apart with that collection of stuffed animals. But I could get at...that they function the same.

In this intentional analogy, we again see a focus on creating equivalence classes, much like the majority of the time spent discussing homomorphism. When asked if they thought about homomorphism in the same way they tried to relate it to students, they believed they spent more class time on the formal definition than ideas of sameness in class.

Classroom setting. Their perception of sameness language used in class given in the interview was relatively accurate. Equivalence classes were highlighted on the last day of the unit in the context of the FHT. While discussing this theorem, pictures were drawn on the board illustrating bands that would be mapped to specific places. The similar properties metaphor was added in class, but largely used indirectly as properties of homomorphisms were being derived. Most other discussion around homomorphism centered on formal definition language.

Summary. In the interviews, Instructor A's view of homomorphism focused on sameness, especially through equivalence classes. They emphasized a view of localized sameness, where elements that were the same in the domain would be collapsed to a single representative. This image was shared in class, but on the last day of the unit. Thus, most of the sameness language that infused the interview were absent until the final day of the unit.

Instructor B. Although Instructor B used some sameness-related language in the interview, notions of sameness were clearer in their teaching.

Interview setting. When discussing homomorphism, Instructor B initially used formal definition language. However, when asked to explain further, they contrasted their view of homomorphism with their view of isomorphism as a relabeling: "Since you...lose the bijectiveness, you sort of lose this…other way of thinking about it as just...being able to take an element here and then just attach the label that you were using over here instead of…the original label." After contrasting with isomorphism, they created an image focused on collapsing by mapping that fit the equivalence class type: "I guess you could sort of view it as threads condensing into a single...element in the codomain and...then those would become equivalence classes modulo the kernel of the map." In this description, a set of elements from the domain are mapped to a single element in the codomain. Each such set forms an equivalence class, and these sets all have the same size as the kernel, which is the equivalence class mapped to the identity.

When asked how they described homomorphism to students, they noted it shifted over the course of the semester. Initially they would focus on homomorphisms as isomorphisms without bijectivity. However, later in the semester, more details would emerge:

> When you look at the seven elements that get mapped to a particular element, then what we really have is this…equivalence class modulo the kernel, and then we can...if we mod out by the kernel, then we can take any one of those things as a...representative. So I think...by...the first isomorphism theorem [FHT], then I'm sort of describing to them what I'm thinking about when I think about a homomorphism.…Kind of don't really initially see how the... structure within the...domain group is reflected in the...co-domain whereas with isomorphism we...see that right away.

Note Instructor B would introduce the term homomorphism soon after introducing isomorphism, but because students did not have an understanding of quotient groups to draw upon, the initial motivation for homomorphism was showing it was distinct from isomorphism. However, this initial distinction shared with students was not Instructor B's structural view of homomorphism. Once students learned about quotient groups and could understand the FHT, the structural view of homomorphism would become accessible and part of instruction through equivalence classes.

Classroom setting. In class, the similar properties metaphor was used indirectly as different properties of homomorphism were derived and as the FHT was used to find all possible homomorphisms. Disembedding was used in the context of the FHT as a way to relate groups:

> If you've got a surjective homomorphism, then the range H essentially is already living inside of G somehow. All the information about H is already here, and in fact we can recover H purely in terms of G by taking the factor group of G mod the kernel.

Another way of saying this is if we have an onto homomorphism, then the structure of the range exists in the domain somehow and can be extracted through quotient groups. This metaphor was also used in practice as a template for finding all possible homomorphisms between groups. Equivalence classes were modeled through specific examples that used congruence as a potential homomorphism mapping. For example, the instructor showed a homomorphism existed from Z_6 to Z_3 by using congruence classes as the mapping, though the rationale for choosing this function was not stated. After the FHT was given, equivalence classes were suggested as the "big picture" takeaway: "the range of the homomorphism has to be a factor group of the original group."

Summary. Instructor B did not use generic sameness language to talk about homomorphism and used limited sameness-based language in the interview. Yet, sameness-based language was invoked through equivalence class and disembedding language. In class, equivalence class and disembedding language was used throughout the unit when structuring approaches to finding homomorphisms and to explain the FHT. Thus, despite not immediately recognizing sameness in their thinking about homomorphism, it still structured much of their teaching.

Discussion

Both instructors intentionally drew upon ideas of sameness to discuss isomorphism in interview and teaching contexts. These included calling isomorphic groups "essentially the same" and using renaming or relabeling to talk about how the isomorphism function showed sameness. In class settings, Instructor A used more matching, a less abstract version of renaming. This did not appear to be an intentional shift but could have been influenced by the instructional materials or a desire to give students a more concrete understanding of isomorphism.

For homomorphism, differences were more obvious between interview and class contexts. Instructor A provided a detailed view of localized sameness through equivalence classes in the interview but only used this imagery on the last day of the unit after introducing the FHT. Instructor B did not initially use sameness-based language to describe homomorphism in the interview but used equivalence classes to structure finding homomorphisms both before and after the FHT and used disembedding to interpret the FHT.

These shifts in language also highlight the difference in the conceptual difficulty of isomorphism and homomorphism. Whereas both instructors directly noted sameness was at the heart of their understanding of isomorphism, only Instructor A stated a sameness connection in homomorphism. Even then, it required further explanation to articulate what type of sameness was intended and how it could be distinguished from the stronger sameness of isomorphism.

Conclusions and Future Work

The instructors drew upon different ideas related to sameness to discuss both isomorphism and homomorphism. Instructors' views of isomorphism, including general ideas of sameness and renaming or relabeling, were similar to algebraists' recorded views (Weber & Alcock, 2004). However, it is unknown whether instructors who are not algebraists and trained algebraists have different views of the more conceptually difficult idea of homomorphism.

Of note, there were subtle shifts in language for isomorphism and homomorphism in the two contexts. The instructors' sameness language for homomorphism especially shifted in interview and classroom contexts. One instructor used extensive sameness language in the interview but only used such language on one class day. The other instructor struggled to give non-definition views of homomorphism in the interview but threaded sameness-based ideas throughout their teaching. This suggests that instructors may not always employ language reflecting their own understanding in the classroom; other instructors may not be able to articulate their understandings equally well in all contexts. Furthermore, this raises questions about what students take away from instructors' lessons: frequently used language or the last language used.

Metacognition in College Algebra: An Analysis of "Simple" Mistakes

Megan Ryals

San Diego State University

Students' characterizations of their errors have the potential to direct their future efforts in mathematics, both in and out of the classroom. This study investigates the errors made on one exam by three college algebra students who identified "simple mistakes" as the primary reason they were not satisfied with their test grade. We developed codes for the types of errors made and classified each as "simple" or "not simple." We then calculated the percentage of points lost due to simple mistakes for each of the three students. Results showed that for each student, approximately 20-40 percent of the errors made on this test could be classified as simple mistakes. We present hypotheses connecting the students' frustration to these results and provide directions for future research that may test these hypotheses and illuminate differences between student and instructor definitions of simple mistakes.

Keywords: Metacognition, College Algebra, Error Analysis, Simple Mistakes

Introduction

Math education research has largely focused on the cognitive dimension of learning, exploring students' understanding of specific concepts and the ways in which instruction can better serve students in their pursuit of mathematics learning. While incredibly important, this focus alone does not explain or assist with challenges that go beyond or precede understanding of the content. For students to learn most effectively and thoroughly, they must be able to assess their level of understanding accurately to know where to focus their studying. Metacognition, defined as "knowledge and cognition about cognitive phenomena" (Flavell, 1979, p. 906), is not a fixed trait, but rather knowledge that can be taught and expanded. It is possible for mathematics instructors to help students develop metacognitive knowledge and skills in the classroom (Donker, De Boer, Kostons, Ewijk, & van der Werf, 2014; Schneider & Artelt, 2010). Moreover, this is a worthwhile effort because of the link between metacognition and performance. Specifically, meta-analyses have shown that students with stronger metacognitive skills outperform their peers (Ohtani & Hisasaka, 2018; Schneider & Artelt, 2010). However, despite calls for efforts toward this end (Pintrich, 2002) little attention has been directed towards equipping mathematics instructors with methods to develop students' metacognition.

This paper discusses part of a larger study that examines the impact of metacognitive instruction for college algebra students. Here we classify the types of errors made by students who describe their primary reason for poor exam performance as making "simple," "careless," or "small" mistakes. We are motivated by our expectation that students' views of their errors may impact their mathematical confidence, their willingness to persist, and the ways in which they focus their study efforts in the future. Specifically for those students, we ask: How closely do students' perceptions of their mistakes align with their actual mistakes? To answer this question, we discovered the types of errors students made on a college algebra exam and then classified those errors as "simple" or "not simple." We then determined the proportion of lost points that could be attributed to “simple mistakes.” Finally, we considered whether, without simple mistakes, the students may have achieved their desired grades, and ultimately whether their disappointment with their performance could accurately be attributed to these kinds of error.

Review of Literature

Research of student metacognition has considered both knowledge and regulation of cognitive processes (Brown, 1978; Desoete & De Craene, 2019; Garofalo & Lester, 1985). Most have agreed it is difficult to completely distinguish metacognitive knowledge from self-regulation. Social cognitive theory now includes metacognitive processes, motivation, and self-efficacy as part of self-regulatory knowledge. Self-regulation skills can be taught and use of these skills improves student performance (Cook, Kennedy, & McGuire, 2013; Zimmerman, 2015).

Mathematics educators, focusing on metacognitive skills, recognize the key role of metacognitive monitoring processes in problem solving (Carlson & Bloom, 2005; Desoete, 2003; Goos & Galbraith, 1996; Schoenfeld, 1992; Silver, 1982). As Garofalo and Lester (1985) point out, others have studied “examining one’s own knowledge and thoughts” without using the term metacognition. They highlight Skemp’s “reflective intelligence” and Piaget’s “reflexive abstraction” as two key examples.

Some have begun trying to improve metacognitive function through in-class instruction, which is appropriate, as studies have fairly consistently shown a strong link between metacognition and performance (Pintrich, 2002; Zimmerman, 2002; Zimmerman, Moylan, Hudesman, White, & Flugman, 2011). The call to provide metacognitive instruction in context, rather than detached from mathematics, is not new (Lester, Garofalo & Kroll, 1989). Many students lack metacognitive awareness when they come to college (Pintrich, 2002) and could greatly benefit from metacognitive strategies being taught in the context of a specific course (McGuire, 2015; Tanner, 2012). Zhao, Wardeska, McGuire, and Cook (2014) report on a 55-minute introductory chemistry classroom intervention that presented to students the results of a learning strategies survey and introduced students to the Study Cycle developed by Frank Christ (1998). Similarly, Tanner (2012) devoted time in a biology course to instruction on planning, monitoring, and evaluating strategies. In math education, recent studies show the success of teaching students to use self-explanations in learning mathematics (Hodds, Alcock, & Inglis, 2014; Rittle-Johnson, Loehr, & Durkin, 2017). There have also been some attempts at teaching other various study skills in the college mathematics classroom (Taylor & Mander, 2003). The meta-analysis of Donker and colleagues (2014) found metacognitive knowledge instruction had an effect size of 0.66 in the field of mathematics.

Psychologists Kruger and Dunning (1999) note that people who are unskilled in a particular domain tend to overestimate their abilities in that domain; they attribute this miscalibration to a lack of metacognition. The Kruger-Dunning effect, or “meta-ignorance” suggests that students don’t know what they don’t know; thus, it is possible to label an error as a “simple mistake” when in fact the error was due, at least in part, to lack of conceptual understanding. A 2017 meta-review by Panadero, Jonsson, and Botella, shows that self-assessment contributes to self-regulated learning and self-efficacy. In order to improve student self-assessment, Zimmerman (2015) has called for more research on how self-regulatory knowledge can be included in all levels of instruction. Studies are needed to specifically look at the relationship between self-calibration and undergraduate mathematics performance and whether in-class metacognitive instruction can improve self-calibration and thereby improve performance.

We study student calibration by determining how closely students' prediction or assessment of their performance aligns with the actual errors they make on exams. Following the focus of math educators on the role of metacognition in problem solving, early error analysis classified errors according to the level of thinking used in Polya's (1945) four problem solving phases: understanding the problem, devising a plan, carrying out the plan, and checking the solution (Abdullah, Abidin, & Ali, 2015). Others have increased the breadth of error analysis to include mistakes made on typical high school problems (Zaslasky, 1987). These broad characterizations of errors led to more detailed analysis of errors for specific concepts from those as fundamental as slope to those as applied as optimization (Cho & Nagle, 2017; LaRue & Infante, 2015). We have built on and modified these error analysis techniques to focus on college algebra concepts.

Methods

This is part of a larger study about the impact of metacognitive instruction within the mathematics classroom. Twenty College Algebra students were identified as at-risk and enrolled in a support co-requisite course (co-course), which has traditionally been used to provide additional practice on content and an opportunity for students to ask questions in a smaller classroom setting. Attendance in the co-course was voluntary and the majority of students enrolled did not attend regularly. After exam one, approximately one day each week was devoted to activities designed to improve students' metacognition.

Seven students completed a Post-Exam Self-Assessment after exam one was returned and answered the question, "Are you happy with your score; why or why not?" Three students, whose exam one scores ranged from 51% to 71%, replied with some version of the statement "No, because I made lots of simple mistakes."

We analyzed all incorrect problems on exam one for these three students. Some exam questions were graded with partial credit based on student work and others were multiple choice. We analyzed graded exams where points lost for each error were clearly marked. We developed a coding scheme for the types of errors made. This was an iterative process of creating codes, discussing them among team members, revising and recoding. We did not restrict ourselves to an a priori list of codes, (Braun & Clarke, 2018; Braun & Clarke, 2006) but did refer to a list of error types on our exam analysis activity which students used to determine the reason for missing exam questions. This list included 13 reasons for errors such as "I made a copy error", "I could not remember the steps needed", "I made an arithmetic error," etc. We tested the coding system by individually coding exam questions for the three participants. In subsequent discussions, codes were added, combined and refined.

Once the list of codes was finalized, each error code was classified as "simple" or "not simple." We defined a "simple" error as one that could be made accidentally, would likely not be repeated, or violates a mathematical convention rather than a rule (i.e. not reducing coefficients). A "not simple" error arises from a lack of conceptual understanding. We do not know if this is how students define "simple" and "not simple" errors as this is beyond the scope of this study and is an area for future research. We note that in making decisions about things like convention, which may vary across different mathematical environments, we relied heavily on one author's knowledge of the course expectations. For example, many college algebra problems ask students to simplify their answer, and the definition of simplified may vary across classrooms.

Some errors were coded as "either" simple or not simple because of a lack of information about the student's thinking about written work. This led to results being reported as an interval rather than a fixed number. For example, students were not required to show work for multiple choice questions. For any multiple choice question with no work, the student could have simply bubbled in the wrong letter, a simple mistake, or had a conceptual misunderstanding, a not simple mistake. Therefore, multiple choice questions with no work were automatically coded as “either.” 8-14% of the missed points were on multiple choice problems with no work shown. For other problems, surrounding student work was sometimes used to determine the type of error. For example, if the student had performed a similar action correctly multiple other places, it was coded as a “simple” copy error. However, in the absence of evidence a student could perform a correct action, the error was coded as a “not simple” algebra error. In the future, interviews could be conducted to classify “either” errors as “simple” or “not simple.”

Once the codes were labeled as “simple” or “not simple,” an independent coder who was familiar with the course was presented with instructions for coding. The codes developed by the authors were listed as examples for the independent coder, but the independent coder was merely asked to classify each error as “simple” or “not simple.” Of 108 points lost between the three students, the authors classified 89 of those as either “simple” or “not simple.” The remaining 19 points were classified as “either.” For the 89 points not categorized as “either,” inter-rater reliability was 86.5%. The few instances of disagreement between the independent coder and the authors were balanced; that is, sometimes the authors classified an error as simple while the independent coder chose not simple, and in other cases it was reversed, so that the overall percentages of simple versus not simple were very similar.

Finally, we calculated metrics to determine how “simple” errors impacted student performance. Because any one problem may have contained multiple errors, the annotated graded exams were used to determine how many points were lost for each error and were coded accordingly. The percentage of missed points due to “simple” errors was then calculated. Additionally, the possible grade range without “simple” mistakes was calculated for each student and compared to their desired grade.

Results

The coding process ended with nine categories of errors, some of which were divided into subcategories. Tables 1 and 2 present these categories with student examples. We note that these categories emerged from analysis of a single exam; thus, the problem types examined were limited and we expect the categories would need to be expanded to be comprehensive even just for college algebra. Three of these categories were classified as “simple” and six as “not simple.”

The designations of these specific error types as “simple” or “not simple” are made specifically with college algebra coverage and expectations in mind. Errors designated as “not simple” for college algebra may be considered “simple’ for students in a higher level course. For example, a mistake in finding a common denominator when adding fractions involving variables would not be “simple” for college algebra as this is part of the course content for college algebra, but for a calculus student, such a mistake would likely be “simple.”

Table 1 provides examples of the six different types of errors classified as “not simple” mistakes. These errors were classified as “not simple” because there was an apparent lack of knowledge or understanding of college algebra or prerequisite content. We do not provide totals for the number of each type of error since we expect these results would depend significantly on the exam used and the problems given on the exam. Rather, we used these codes to classify each error as “simple” or “not simple” and report the percentages of each type for each student.

Table 1. Not Simple Error types

Not simple Error	Description	Selected Student Example
Formula	a) uses wrong formula for situation b) incorrectly memorized formula c) unaware a formula is needed d) incorrectly plugs into formula	b.  c. Misunderstanding	misunderstands question vocabulary, format, or instructions	Arithmetic to Algebra	unable to translate arithmetic ideas to situations with variables	Algebra (single step)	errors in factoring, distribution, exponent rules, like term collection, etc.	Algebra (process)	a) incorrect application of memorized multistep process (wrong situation) b) memorized process incorrectly displaying no comprehension of concept	a.  b. Gets stuck	a) no work shown b) started but abandoned problem	b. 
Errors of arithmetic, transcription, and convention were classified as "simple" mistakes. These are displayed in Table 2. In each of these types of errors, we recognize first that the simple mistake is not likely to be repeated, and in classifying student errors, we confirmed this when possible by considering the student's surrounding work. We also noted that these were mistakes that could easily be made by an expert who was limited by time and did not check over their work. That is, the mistake could be made by someone who had a complete conceptual understanding necessary to solve the given problem.

Table 2. Simple Error types

Simple Error	Description	Selected Student Example
Arithmetic	Mistake in one of four arithmetic operations	Transcription	Copy error not occurring as a pattern of misunderstanding	Convention	Answer is correct but does not adhere to conventions	
We found that between 20-40% of the lost points on Exam One for these students can be attributed to simple mistakes, such as a one-time arithmetic error or copying a formula or expression incorrectly. This percentage is somewhat small when viewed in light of how the participants were selected: all three participants identified simple mistakes as the reason they were unhappy with their grade. Table 3, below, shows the percent of simple errors for each participant and shows their potential grade in the absence of simple errors.

Table 3. Results by Student

Student	Exam Score (%)	Percent of errors that are "simple"	Grade without "simple" errors	Desired Grade
1	68	18.75-40.63	77.08-84.38	80
2	51	20.40-36.73	63.54-71.88	70
3	71	20.69-37.93	80.20-85.42	90-95*

*Student 3 was absent when the class was asked about desired grades. This is the student's predicted score rather than desired score.

For each student, approximately 20-40% of mistakes were due to simple errors. Student 1 could have made their desired grade of 80% and student 2 their desired grade of 70% if they had not made these "simple" mistakes. Therefore, it is possible students do not believe all (or even the majority) of their mistakes are simple, but only enough to make the difference between the grade they got and the grade they wanted.

However, we note that the majority of the students' errors were not simple, yet this is the type of error that these three students identified as preventing satisfaction with their grade. It is also possible that students define a simple error differently than we have defined it and that they would have classified a larger portion of their mistakes as simple.

Limitations and Future Research

Analysis was conducted solely with written student work. This required making assumptions about student thinking and what students did or did not know or understand. This led to uncertainty in our results and having to present the results as intervals. Future work would benefit from incorporating student interviews, conducted shortly after exams, to distinguish more clearly between cases of simple and not simple errors.

Additionally, our results are not generalizable due to the small number of participants and the restriction of analyzing a single exam in a single course. Subsequent studies may ask all students in multiple courses to estimate the percent of points lost on multiple exams due to simple mistakes. These studies should also collect and compare student and instructor definitions of simple mistakes; one or more may differ significantly from the definition used here. We suspect that some students define mistakes as simple if the error is easily identified and understood after looking at the solution.

Another area of future research is on the effect of classifying errors as “simple” on student motivation and study effort. Misclassifying an error as “simple” when it was due to a conceptual misunderstanding could result in overconfidence. Ferla, Valcke, and Schuyten (2010) showed that overconfidence causes decreased motivation to understand course material, which results in decreased study effort and poorer course performance.

We pose a final question: If student definitions of a simple mistake do align with our definition, why are these students seemingly more frustrated with their simple mistakes than their not simple mistakes? We suspect the reverse may be true for instructors, particularly since a decrease in not simple errors would be an indication of learning gains as opposed to test taking skills. Future research may assess the impact of addressing this issue directly with students. In particular, instruction in how to direct their studying efforts as well as self-assessment training may cause students to focus their attention more on their not simple errors and how they might prevent these errors on future exams.

Affective Pathways of Undergraduate Students While Engaged in Proof Construction Tasks

V. Rani Satyam
Virginia Commonwealth University

The transition to proof is a known point of struggle for many undergraduate mathematics majors. This work examines this difficult transition point from an affective lens, specifically students' affective pathways while working on proof construction tasks. A series of four semi-structured interviews were conducted with 11 undergraduate students enrolled in a transition to proof course, and affective pathways were studied using non-traditional instruments: an emotion word selection task and an emotion graph. Open coding and constant comparative methods were used to identify common affective pathways within the emotion words and graphs. These pathways reveal common student experiences while working on proofs, which may be used to fine tune external learning conditions to positively influence engagement and experience.

Keywords: Emotions, Beliefs, and Attitudes; Reasoning and Proof; Problem Solving; Methodological Tools

This transition to proof-based mathematics is known to be difficult for undergraduate students; students struggle with learning how to prove, as a shift from mostly computational to now problem-solving work involving writing arguments (Moore, 1994; Selden & Selden, 1987). In order to help students through this, there is a need to understand the student's experience. We know much about the mathematical struggles students encounter (Alcock & Weber, 2010; Harel & Sowder, 2007; Selden & Selden, 1987), but to fully examine experience, especially those factors that drive experience, we need to understand affectively what is happening to students as they engage in proving (Selden & Selden, 2013).

Affect may be defined as "the wide range of beliefs, feelings, and moods that are generally regarded as going beyond the domain of cognition" (McLeod, 1992, p. 576). Three major types of affect are beliefs, attitudes, and emotions (McLeod, 1992). As we have increasingly paid attention to affect over the years (Middleton, Jansen, & Goldin, 2017), it is clear that affect is an integral part of learning, especially problem solving (McLeod & Adams, 1989). In thinking about what parts of a student's affect are malleable, it may be emotions they are open to change, as they occur in-the-moment (Middleton, Jansen, & Goldin, 2017). By understanding the sequence of students' emotions, we can develop and fine-tune tasks and lesson sequences to foster opportunities for positive affective experiences.

The research question guiding this work is: What are the affective pathways undergraduate students experience when constructing proofs, while learning how to prove? The primary purpose of this work is to examine the affective pathways of undergraduates' emotions while proving. A secondary purpose is to test novel instruments for collecting data about affective pathways: selecting emotion word cards and graphing their emotions.

Background and Theoretical Frameworks

There are different perspectives from which to approach studying students' proving (Stylianides, Stylianides, & Weber, 2017). I take the perspective of proving *as a form of problem solving*. Students' tasks can also be broken into three categories of activity: constructing, reading, and presenting arguments (Mejía-Ramos & Inglis, 2009). This study focuses on the task of *constructing a proof* for a novel argument, where statements to be proven are new to the student and additionally designed to cause an impasse, drawing from the problem solving perspective. Research on proof construction is common in the field (Mejía-Ramos & Inglis, 2009), and I take an affective view on the activity.

Historically, affect has been conceptualized as separate from cognition. Three types of emotions often discussed in mathematics education literature, dating back to McLeod (1988), are beliefs, attitudes, and emotions. These can be compared along the dimensions of *magnitude, valence (positive or negative), duration, level of awareness*, and *level of control* (McLeod, 1988; Gómez-Chacón, 2000). Early research focused on attitudes (e.g. Higgins, 1970) and later years brought a focus on students' beliefs about math and the influence of said beliefs. Studies on emotion, however, are rarer. Emotions are more difficult to study as they are much shorter in duration and thus fleeting and hard to capture, compared to attitudes and beliefs which have been measured using large-scale questionnaires. Due to my focus on emotions, I focused on capturing *magnitude* and *valence*.

DeBellis and Goldin (2006) discussed the notion of an *affective pathway* as a sequence of feelings, e.g. *bewildered* to *frustrated* to *surprised* to *happy* over the course of working on a task. This framework explains how certain emotions can be positive or negative depending on where they lie in the pathway and what function they fulfill. For example, *frustration* is commonly seen as negative but it can also lead to searching for a better solution so it can serve a positive function. In other words, "negative" emotions can serve a positive purpose. As such, the goal is not to avoid negative emotions. The affective pathway is one strand of a larger *engagement structure* (Goldin, Epstein, Schorr, & Warner, 2011), which describes a student's pattern of engagement in the classroom.

It is vital to study affective pathways, as a piece of engagement structures, because they occur in-the-moment and so can be influenced by the teacher, task, environment, etc. (Middleton, Jansen, & Goldin, 2017). By understanding affective pathways better, we can more precisely and with more understanding fine-tune the external conditions that influence learning that are under our control. In-the-moment affective constructs, like affective pathways, are thereby a vehicle for student change. The purpose of this work is to identify students' affective pathways while constructing proofs.

Method

Participants, Context, & Data

A series of four semi-structured interviews were conducted with N=11 undergraduate students taking a transition to proof course at a large Midwestern university. In each interview, students were given two proof construction tasks to work on (see Figure 1 for example).

We say that two integers, x and y, have the same <u>parity</u> if both x and y are odd or both x and y are even. Prove the following statement: Suppose x and y are integers. If $x^2 - y^2$ is odd, then x and y do not have the same parity.

Figure 1. Proof task from 1st interview.

Two instruments served as stimuli for students to describe their experiences: an emotion word selection and an emotion graph task. Originally meant as stimuli, one larger goal of this study is to examine whether the data from these instruments can be analyzed on their own. Self-report was an appropriate method because a subject's perception of their experience is by definition their experience, in what they take forward from them, drawing from phenomenography (Marton, 1981). There were N = 88 graphs and word selections in total.

Emotion word selection. Participants were shown eleven cards with an emotion written on each. Five pairs of positive-negative and one neutral emotion word were chosen based on the literature about emotion and math to capture range: annoyed, curious, disappointed, surprised, sad, joyful, frustrated, satisfying, ashamed, proud, and indifferent. Participants were asked to select which (if any or other) words they experienced on each proof task.

Emotion graphs (adapted from Smith et al., 2017; McLeod, Craviotto, & Ortega, 1990). Each participant was given a blank graph, where the x-axis was time and the y-axis represented valence of emotion (positive and negative). Participants were asked to sketch how their emotions varied in intensity over the entirety of each proof task. The graph allowed for a temporal look at the ups and downs in emotion over the course of the experience. Graphing emotions is a technique that can be used to describe variations in students' emotional responses while solving a problem (McLeod, Craviotto, & Ortega, 1990). Participants were asked to mark on the horizontal axis and/or annotate their graph with short captions at the points where they felt emotions shift.

Data Analysis

To identify affective pathways, I used qualitative bottom-up methods, specifically forms of open coding and constant comparison, to find groupings of conceptually meaningful categories. For the emotion graphs, I first categorized graphs by their end behavior, which revealed how the task ended: six graphs ended with negative emotion, ten ended with baseline emotion, and 72 ended with positive emotion. I then used the following algorithm: First, I sorted graphs by Overall (monotonically) Positive, Overall Negative, Flat or little variation, and Other. I separated monotonic graphs, especially positive ones, because dips were likely to represent hardships and hence different experiences. Lastly, I looked within the Other category for meaningful patterns and found the Concave Down and Concave Up categories; the rest stayed categorized as Other.

While analyzing the word selection, the emotion words fell into one of three categories: Negative, Neutral, or Positive. Originally considered positive words, curious and surprised were in fact *off-balance states*; they could be spoken about positively or negatively, depending on the context and surrounding emotions. For these reasons, curious and surprised were categorized along with indifferent now as Neutral. Many participants naturally listed emotion words in the order in which they felt them, despite no prompting to list them this way. I coded the temporal order for the shifts in valence (positive/negative/neutral).

Negative	**Positive**	**Neutral**
annoyed		curious
disappointed		surprised
sad	joyful	indifferent
frustrated	satisfying	
ashamed	proud	

Figure 2. Positive, negative, and neutral emotion words.

Results

First, I share an example of a positive and negative affective pathway. These examples were chosen because they illustrated the pathways well, both in graph and words. Then, I report on the types of affective pathways found looking across all the entire dataset of graphs and words.

Example: Positive Affective Pathway

Positive affective pathways are characterized by a positive end behavior and tend to overall trend positive. Figure 3 shows an emotion graph that depicts a positive affective pathway.

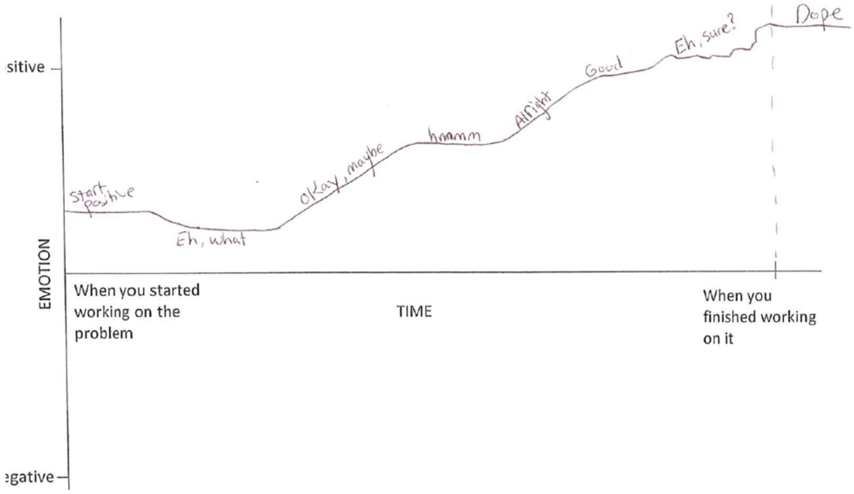

Figure 3. Leonhard's emotion graph for Interview 2, Task 2.

Leonhard chose the following emotions words, in this order: curious, befuddled (his choice), surprised, proud, satisfying, and joyful. One can see how the start behavior, dip, and then ensuing increases in his emotion graph match the order of his emotions: his annotations of "starting positive" may correspond to feeling curious, "eh, what" to feeling befuddled, and his annotations become increasingly positive of his work as do his emotions.

Example: Negative Affective Pathway

In contrast, a negative affective pathway typically ends with negative emotion and tends to overall trend negatively as the task goes on. The start behavior may be positive and there may be local peaks but the end behavior is always negative. Figure 4 is an emotion graph that depicts a negative affective pathway.

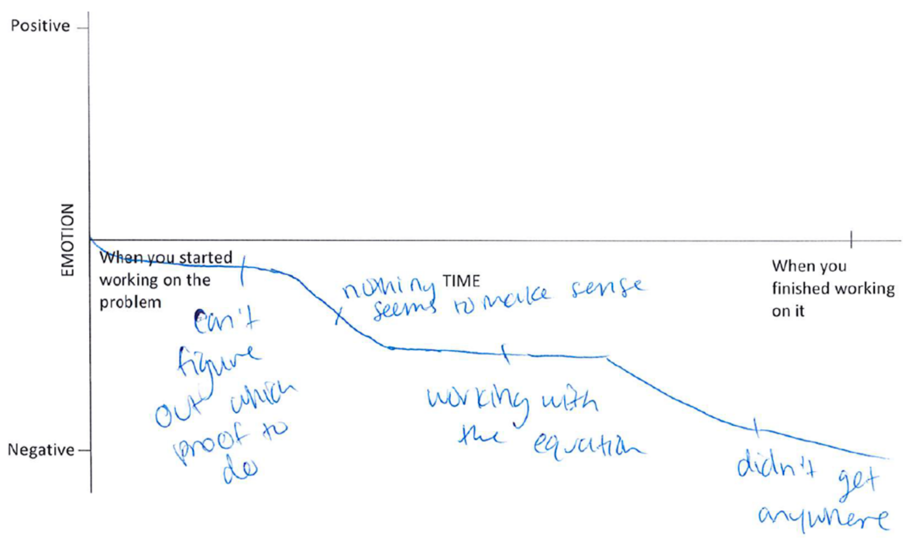

Figure 4. Gabriella's emotion graph for Interview 4, Task 2.

Gabriella started out at a neutral emotional level, based on her graph starting at y=0. Gabriella said she typically would approach proofs by looking for which proof method (direct proof, proof by contrapositive, proof by contradiction, etc.) to apply. Soon into the task, she didn't know which one to use. Based on this graph, we can see how not only were her emotions all negative after the start but also the magnitude of her negative emotions grew. There was a brief plateau as she was working with the equation given in the statement, but ultimately not coming to an answer felt extremely negative.

Gabriella's emotion words, chosen in this order, were curious, frustrated, annoyed, and sad. The feeling of curiosity is neutral, as it can in general be positive or negative depending on the context. Given that it was the first word she chose, the graph starting at the zero axis corroborates the idea of curiosity as neutral. From there, her string of negative emotions aligns with her graph showing increasingly negative feeling.

Having examined two examples of affective pathways via emotion graphs and words, we turn to analyzing the corpus of graphs and words to identify more complicated pathways.

Affective Pathways: Graphical Analysis

The emotion graphs reveal a number of different affective pathways, corresponding to different experiences while proving. Table 1 shows the affective pathways found within the emotion graphs. Of the 88 graphs, 39% were concave up, 18% were overall positive, 13% were overall negative, 10% were flat, 9% were concave down, and 11% fell into the Other category.

Table 1. Percentages are rounded.

Frequency Percentage of Affective Pathways via Emotion Graphs

Graph Behavior	Meaning	#	%
Overall Positive	Went well	16	18%
Overall Negative	Went badly	11	13%
Flat	No or little influence	9	10%
Concave Down	Started well, ended badly	8	9%
Concave Up	Overcame struggle	34	39%
Other	N/A	10	11%

Overall Positive, Overall Negative, and Flat graphs. Overall positive graphs represented experiences that went well, with no hardships to the extent that they negatively influenced emotions. These experiences may not be true problem solving, i.e. encountering a problem; these were experiences where the student was successful throughout. In comparison, overall negative graphs were where the problem solving experience went poorly, usually with the participant perceiving they did not know what to do or had not done it correctly.

Flat graphs were those where the participant drew a straight line, with little to no variation. Flat graphs showed experiences with little influence on and/or change in emotion, depending on if the graph were completely flat and above the x-axis because the problem felt easy or along the x-axis because the student was unsure the entire time.

Concave Up vs. Concave Down. Concave up and concave down match their mathematical namesakes: concave up graphs started at base-line or positive and had at least one dip but overall ended positively. These graphs suggested that the student overcame struggle(s). In comparison, concave down graphs were characterized by a high but then falling at the end. Concave down graphs were experiences that started well but where the student got stuck and could not resolve it. Based on the end behavior, concave up graphs tended to align with self-perceptions of success while concave down were with self-perceptions of failure.

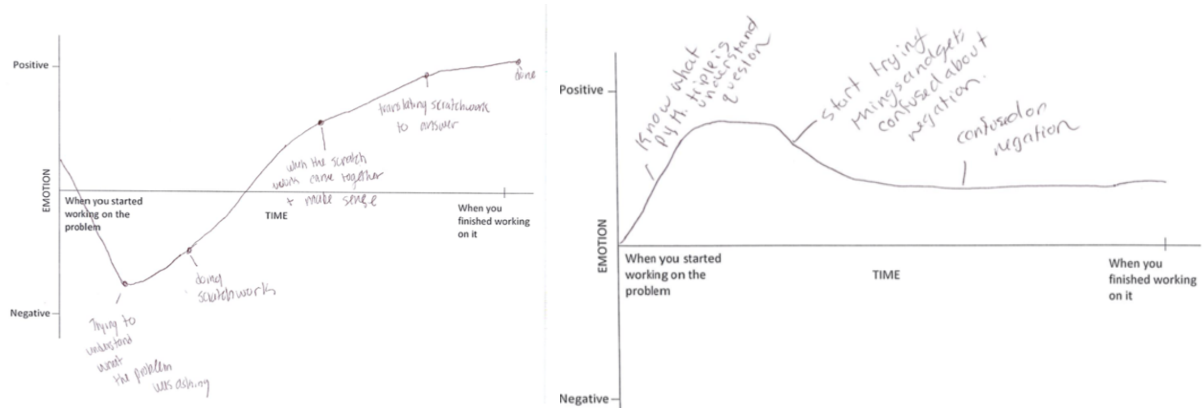

Figure 5. Examples of a Concave Up graph on left and Concave Down graph on right

Other. The Other category consisted of emotion graphs that did not fit the existing categories. The graphs had either of the following general patterns, shown in Figure 6.

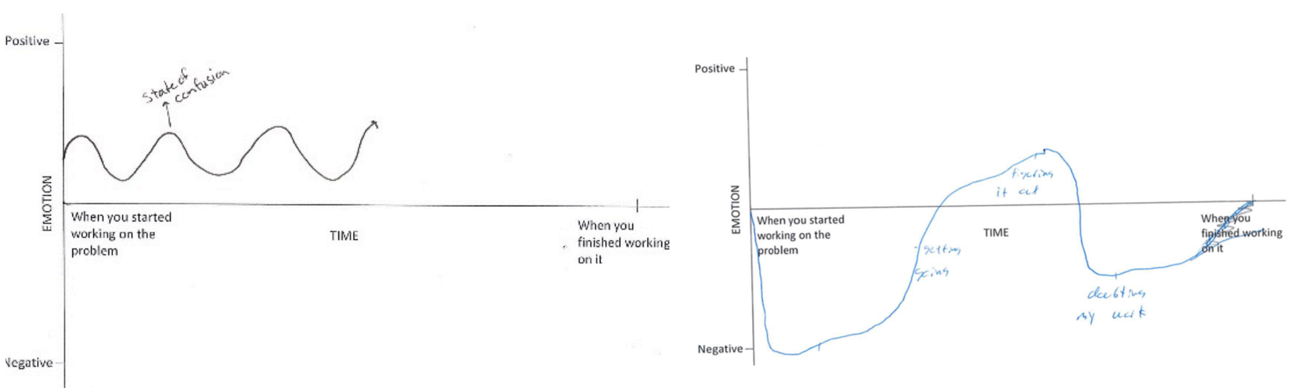

Figure 6. Examples of the Other category

Two emotion graphs reflected feeling confused (left graph of Figure 6). The rest had a number of peaks and falls (right graph of Figure 6), such that they could not be squarely *Concave Up* or *Concave Down*. These latter graphs reflect how proving (and problem solving in general) can bring about a number of emotional highs and lows for a student, in the space of a single task.

Affective Pathways: Word Analysis

There were more categories of affective pathways found in the emotion words, because they were a string of discrete items (in contrast to the continuous visual nature of graphs) and there was no maximum number of emotions. Table 2 lists the types of affective pathways of positive-negative-neutral emotions that occurred in the dataset with an example. This includes times where students did not explicitly say the emotions were in order of occurrence. This is a limitation, but I argue the order in which students stated them may be naturally revealing.

Table 2. + is positive, - is negative, N is neutral, ellipses (...) show additional emotion shifts, forward slash (/) indicates two emotions occurring simultaneously, and semicolon (;) indicates an emotion felt over the entirety.

Frequency and Percentage of Affective Pathways via Emotion Words, by Start and End Valence

Pathway	Description	#	%	Example Pathway
+	All Positive	11	13%	satisfying→joyful
-	All Negative	8	9%	confused
N	All Neutral	7	8%	indifferent
-/N...+/N	Emotions Rise	33	38%	overwhelmed/ashamed→curious→satisfying
+/N...-/N	Emotions Drop	14	16%	satisfying→curious→disappointed→indifferent
-...-	Negative Start & End	4	5%	nervous; ashamed→frustrated→indifferent→ disappointed
+...+	Positive Start & End	2	2%	satisfying→overwhelmed→surprised→annoyed →satisfying
N...N	Neutral Start & End	9	10%	curious→confused→surprised

The most common affective pathway was Emotions Rise (n=33, 38%). These experiences started out negative or neutral (curious/surprised/indifferent) and then ended well. These were likely true problem-solving experiences in that students likely did not know what to do at the start, in contrast to All Positive, where participants had positive emotions the entire way. The second most common affective pathway was Emotions Drop, (n=14, 16%) showing the opposite behavior, where the experience started well but then negative emotions occurred in the middle of the problem. These are instances where students experienced unexpected challenge and did not overcome them, perceiving their work to be wrong.

Discussion

These affective pathways illustrate the myriad of emotions that students experience while working on a proof. For some proof tasks, emotions are straightforwardly positive or negative. But more often than not, there were quite a few highs and lows over a problem as students searched for a solution, and these sharp transitions paint a detailed picture of students' mathematical experiences while proving. The emotion graphs provide a continuous portrait of the intensity and valence of students' emotions, while the emotion words give the nature of each emotion, as discretized by the individual. These tools together provide different information but can, if used carefully, be used to corroborate each other. One limitation is that the researcher searched for alignment; it may be beneficial to ask students themselves to align their words with their graphs, for validity. Future analyses will integrate graphs and words more closely.

Examining affective pathways contributes to understanding students' emotional responses to mathematics, specifically on proof tasks but also problem solving in general. By identifying common sequences of emotions, this work helps inform curriculum developers on how to design mathematical tasks and lesson sequences in order to foster opportunities for positive, satisfying mathematical experiences for all.

A Tale of Two Sides: Students' Feedback Preferences and Professor's Feedback Provisions

Nurul Schraeder
West Virginia University

David Miller
West Virginia University

The purpose of this study is to investigate students' engagement with and utilization of the proof feedback from their professor, and their feedback preferences. We interviewed seven participants about their general experience with feedback on proofs. We then continued interviewing four of these students periodically about the feedback they received on specific selected proofs to see how they interpreted the feedback they received and how they utilize the feedback when asked to revise their proof production. The results showed that the majority of participants had a strong preference towards explicit feedback and, in contrast, that professors provided primarily implicit feedback. Furthermore, we found that students did not read professors feedback when they received satisfactory grades on their proofs, they usually only utilized the feedback when working subsequent assignments or studying for exams, and they did not use the Professors' feedback to rewrite their proof production.

Keywords: feedback, proofs, implicit, explicit, revision.

It is well documented that undergraduate students have difficulty writing proofs (Weber, 2001; Moore, 1994; Sowder & Harel, 1998) and that proof-writing is a primary competence that mathematicians want students to learn in upper-level mathematics classes (Weber, 2004; Zorn, 2015). In order to help students to improve their proof writing, professors provide feedback on students' proofs with the goal that students will use the feedback to improve their proof writing (Byrne, Hanusch, Moore, & Fukawa-Connelly, 2018; Moore, 2016; Miller, Infante, & Weber, 2018). It is important to investigate professors' feedback on students' proofs because feedback can have a greater impact on students' understanding and writing of mathematical proofs than other instructional practices (Black & William, 1998; Henderson, Yerushalmi, Kuo, Heller, & Heller, 2004; Hattie & Timperley, 2007).

Byrne et al. (2018) found that many students do not use professors' feedback in any significant way, if they use the feedback at all. One reason that students may not use professors' feedback in any significant way (or altogether) may be because they (usually) are not required to address the feedback or revise their proofs once assignments are returned. While we would argue that feedback can aid students' proof-writing skills and proof comprehension, we do not know much about students' preference for proof feedback and the type of feedback professors' provide on students' proofs.

Conceptual Framework and Related Literature

Researchers in a variety of disciplines have found that professors' (corrective) feedback on students' assignments is an important component of teaching and learning in the university setting (e.g., Ackerman & Gross, 2010; Hattie & Timperley, 2007; Hounsell, 2003; Mulliner & Tucker, 2017). Van Beuningen, De Jong, and Kuiken (2008) defined corrective feedback as "the marking of students' error by the teacher" (p. 280). Multiple studies have classified feedback in a variety of categorizations (for example Carroll & Swain, 1993; Ellis, 2008; Lyster & Ranta, 1997; Van Beuningen et al., 2008; Vardi, 2008) and for brevity, we will only mention two of these categorizations. These two are the ones that we used to analyze feedback in this study.

Several authors have described a feedback classification according to the explicitness of the feedback: *explicit* and *implicit* feedback (i.e. Carroll and Swain, 1993; Ellis, Loewen, & Erlam, 2006, Kim & Mathes, 2001). *Implicit corrective feedback* is defined as feedback that has no overt indicator that an error has been committed, whereas *explicit corrective feedback* refers to the feedback with an overt indication of the errors (Ellis, Loewen, & Erlam, 2006). In other words, in terms of proof feedback, implicit corrective feedback is instructors' feedback on a student's proof production that does not provide a clear indication that an error has been committed and explicit corrective feedback would clearly indicate a proof production error.

Research findings on *implicit/explicit* feedback have either found that explicit feedback is more effective than implicit feedback or that there is no difference. For example, a number of studies in language acquisition found the superiority of explicit feedback compared to implicit feedback (Carroll & Swain, 1993; Ellis et al., 2006). Other studies found no difference between the effectiveness between *implicit* and *explicit* feedback (Kim & Mathes, 2001). In a meta-analysis from 33 studies of *explicit* and *implicit* feedback, Li (2010) found that *explicit* feedback is more effective on a short-term scale and *implicit* feedback is more effective on a long-term scale.

Several authors also have defined a feedback classification considering the presence of correction towards the error: *input-providing* and *output-prompting* feedback (i.e. Ellis, 2008; Adams, Nuevo, & Egi, 2011, Lyster, 2004). *Input-providing feedback* is defined as feedback that supplies the learner with the correct form (or model) of the error, and *output-prompting feedback* is feedback that does not supply a model (Adams, Nuevo, & Egi, 2011). Most "research on implicit versus explicit feedback has not taken into account the *output-input* dimensions of feedback" (Adams, Nuevo, & Egi, 2011, p.45).

Other studies have found that *output-prompting* feedback is more effective than *input-providing* feedback (Ammar, 2008; Ammar & Spada, 2006; Lyster, 2004; Lyster & Ranta, 1997; Sheen, 2004). Lyster and Ranta (1997) and Sheen (2004) state that *output-prompting* feedback will most usually spur students to respond to the feedback. Ammar (2008), Ammar and Spada (2006), and Lyster (2004) found that students who received *input-providing* feedback (in the form of *recast*) performed no differently from students who received no feedback. Finally, Lyster and Izquierdo (2009) found that both *input-providing* and *output-prompting* feedback are equally effective in the context of dyadic interaction.

Regarding students' preference of feedback, Kim and Mathes (2001), Nagata (1993), and Amrhein and Nassaji (2010) reported that students clearly prefer *explicit* feedback. Moreover, Amrhein and Nassaji (2010) also found not only students would prefer *explicit* feedback, but they also prefer *input-providing* feedback. In contrast, the students think that *implicit* and *output-prompting* feedback would not be useful for them. Amrhein and Nassaji (2010) mentioned

> The students also showed approval of having their errors explicitly marked and corrected with WCF (written corrective feedback) such as error correction with a comment and overt correction by the teacher [...]. Most students explained that a clue with no correction is not useful because students need more specific advice (p. 115).

Finally, no prior studies have investigated professors' feedback on students' proof production in undergraduate mathematics based on *implicit/explicit* or *input-providing/output-prompting* feedback. However, there have been a few studies that have examined professors grading of proofs (Byrne et al., 2018; Miller et al., 2018; Moore, 2016) and Byrne et al. (2018) also examined professors' feedback on proofs with regards to Lyster and Ranta (1997) classification. Byrne et al. (2018) found that students had a lot of difficulty describing normatively correct logic for the changes that professors were expecting students to make when implementing their feedback on proofs. That is, for the most part, students could use the professor's feedback to rework their proofs, but had great difficulty justifying why the change was imperative.

We focused on the combined feedback categorization (both implicit/explicit and input-providing/output-prompting) for several reasons. First, Byrne et al. (2018) found that students have better understanding towards the feedback when it is supplied with a correction (recast and explicit correction). This suggests that feedback in the form of *input-providing* is superior than *output-prompting* in terms of eliciting corrections from students during proof revision. Secondly, prior literature in language acquisition has shown that students prefer *explicit* feedback while teachers find that *implicit* feedback is more desirable (Amrhein and Nassaji, 2010). Finally, language acquisition studies have found that both explicit and output-prompting feedback is more effective than implicit and input-providing feedback, respectively.

Since professors spend a considerable amount of time and energy providing feedback on students' proof productions (Moore, 2016) and we believe that professors want students to learn from the feedback that they provided, it would be well worth the time, especially at a point in the undergraduate mathematics curriculum when students are first learning about proof, to find out if professors' feedback are supporting students as they learn to write and understand proofs. In this paper we investigate students' preference and utilization of professors' feedback and the types of feedback that professors provide while grading proofs in an introduction-to-proofs class. The research questions that guided our investigation are stated as follows:

Research Questions:

1. What are students' preferences for the proof feedback they receive from their professor?
2. How do students use their professors' proof feedback?
3. In terms of *implicit/explicit* and *input-providing/output-prompting*, what type of feedback do professors give on students' proof productions in an introduction-to-proof class and how does that compare with students' feedback preferences?

Methodology

Participants

Seven students in an introduction-to-proof class at a large state university in the United States consented to participate in this study during the Fall of 2018. All participants had completed at least the second semester of Calculus. We anonymized the data by referring to the first interviewed student as S1, the second as S2, and so on, and assigned a feminine pronoun for each student.

Material and Procedure

Each participant (S1 through S7) met with the first author and was videotaped and audiotaped for the first phase of the interview that asked participants semi-structured open-ended general interview questions about their views and use of feedback on proofs, such as: Why do you think professors write feedback on your assignment?, Do you think feedback is important?, Is there any type of feedback you prefer or not prefer?, How do you use feedback?.

For the second phase, four participants (S1 through S4) agreed to meet with the first author to further interview about their interpretations of the feedback on a few of their graded proofs. The selected participants for this phase varied in performance (from below to above average) for the first part of the semester in the course with content covered in three chapters on basic set theory, logic, and basic introduction to proofs (direct, contrapositive, and contradiction proof techniques). For each participant, the first author, in consultation with the second author, selected two to three proofs on homework and exams during the remaining portion of the course for which participants had been given numerous items of feedback from the professor and participants' proofs contained a number of errors. The interviews occurred periodically as the proof artifacts were identified by the authors. For each selected proof, the participants were then asked by the first author to review their proof, discuss each feedback item that they received and the professor's intentions for the feedback, and finally revise their proof, articulating their thoughts as they worked on their revisions. This process was repeated for one to two more proofs for each participant, totaling 11 participant interviews.

All participants' revision work and their verbal thoughts about their revision were recorded on a LiveScribe notebook and backed up using video and audio recordings. After the participants finished working on the revisions, participants were asked to describe their approach to revising their proof to get their overall thoughts on their revision work. Once the interview was completed, the first author rewrote the revised proof to anonymize the participants' written proofs and names, and then asked the professor of the course (second author) to provide feedback and regrade the proof. The interviewer asked the students for another revision only if the revision submitted received a grade of 70% or lower. In the case that the participants needed to revise their proof again, the first author only asked them to revise their proof to see if they would use the feedback. This was followed by asking the participants to describe their approach to revising their proof again.

Analysis

All interviews were transcribed. The authors engaged in thematic analysis (Braun & Clarke, 2006) in the following way. First, both authors individually read over all the transcribed data while identifying and highlighting passages that might be of theoretical interest concerning feedback. Both authors met to discuss and compare their findings and developed a list of phenomena for further investigation. Next, each author reread the transcripts again, searching for further participant comments related to each phenomena of interest; we then put these excerpts into a file of comments related to that phenomenon. Through this process, we developed criteria and descriptions of these themes. Finally, the authors individually went back through the data one last time to identify passages that would satisfy the criteria for each of these themes.

In addition, the professors' feedback was categorized using the *input-providing/output-prompting* and *implicit/explicit* categories. Each comment was classified with regards to the two properties: is a correction presented and is there an overt indication that an error had been committed. To code this, we followed these steps:

1. Did the professor provide the correct form in the comment? If so, then it is *input-providing* feedback; otherwise, it is *output-prompting* feedback.
2. Did the professors give an overt indication of the error? If yes, then it is *explicit* feedback; otherwise, it is *implicit* feedback.

After each author categorized all the feedback, they meet to compare their feedback categorizations and discussed each time they disagreed until they came to a consensus. The result of this categorization can be found on Table 1 in the results section.

Results

Students Engagement with Professors' Feedback

Disregard proof feedback when awarded satisfactory grades. The first finding was that the majority (5 out of 7) of the participants did not pay attention to the professor's feedback when they are satisfied with their grade, regardless of the feedback. For instance, S5 talked about the circumstance that she would ignore the feedback, "I guess when I got a hundred on it [a proof], I might not read it [the feedback] because I figured I did well." S4 also mentioned getting good grades and prioritizing importance were reasons not to look at feedback when she said, “If I've got a lot of papers back and my grade is pretty good and there are other papers that need more attention, I'll ignore the feedback on the better ones.” Finally, S1 remarked about not paying close attention to feedback on a good performance; she gave an indication of the possibility that she might look at it later even with a good grade, “If I get like high enough grade I'll probably just like brush it [the feedback] off and wait to look at it for later.” In contrast, a minority (2 of 7) of the participants claimed to read the feedback more regularly. For example, S2 asserted that “I always read it [the feedback], I'm not quite certain if I always if I always read into it what I should but I always I always try.”

This evidence suggests that the grade can be an indicator of how much students engage with professors’ feedback.

Students’ utilization of feedback for future reference. The second finding is that students generally do not use the feedback to revise their work. This was illustrated by S3 when she noted, “I just remember that [the feedback], I usually don't write anything on paper. I know it's probably a good thing to do but hmm, I don't know I just I just look at it and then put it up usually.” Only one (of seven) student, S7, claimed to use the feedback to revise the work when she explained, “let's practice studying rewriting the whole proof and then change the parts that he advised me to change.”

As part of this finding, we found that most students (5 out of 7) professed they used feedback to help them with their next assignments. For example, S3 voiced, “if I have a similar problem in another homework then I might go back and look what I missed previously but usually I just looked at it for 5 minutes or so and put it up.” Moreover, S6 also stated that she would use the feedback for reference on future assignments, declaring “like getting ready for a final or like a big test after like the little quizzes I like to look at those [previous work with feedback] and make sure like remember this little thing that you messed up on.”

However, one out of seven students, S7, claimed that she would fix the part she messed up by redoing the work. She stated,

> if I messed up like part of the proof, I feel like okay let's practice studying rewrite the whole proof and then change the parts that he advised me to change and see if after that it looks a little bit better and then go from there.

In summary, the participants, generally, do not find professors’ feedback to be a prompt for them to conduct a revision on their own. This suggests that revising proofs as a response to the feedback they received does not seem to be a norm among students. However, this data suggests that the feedback had an impact on students’ future assignments; they would use the feedback as a reference when proving a similar statement on homework and when studying for an exam.

Students Preferences on Proof Feedback

First, the majority (5 out of 7) of the participants preferred *explicit* feedback. For example, S1 mentioned that “I think the best feedback is just tell me straight up what's wrong in it [...] I mean not like this can be or this could be right, but I'd rather just get a straight yes-or-no answer.” However, she did not state any preference for input-providing or output-prompting feedback.

S2 described that good feedback needs to be *explicit*, but also in the form of an output-*prompting*. This is illustrated as S2 stated,

> good feedback *tells you what you did wrong* and usually *has a hint* of how you could improve it [...] because if it is more detailed, if it's spelling it out for us, we're not as likely to think about it as much.

The preference for an *explicit* feedback was also emphasized S3 when the interviewer asked about her preference on feedback with the answer of "I guess any feedback that tells you why, you know, the underlying reason as opposed to just putting an X.*"* S3 did not state any preference for either *input-providing/output-prompting* feedback.

S6 emphasized the need for *input-providing* feedback, but no preference for implicit or explicit feedback when she said,

> I like whenever they actually like write out what the right answer would have been, not just saying you should have done this but like I like to see the steps and kind of compare like what I might have been thinking and didn't put to what it should have actually looked like.

Overall, the participants showed a strong view towards their preference for *explicit* feedback and did not particularly express a preference for input-providing or output-prompting feedback.

The Professor's Proof Feedback

Table 1 below shows the result of the classification of the feedback of participants' proofs that we used according to *implicit/explicit* and *input-providing* (IP)/ *output-prompting* (OP) categorization. We see that the majority (70%) of the professor's feedback were classified as *implicit* feedback and almost all (89%) of the feedback were classified as *output-prompting*. Therefore, the professor generally did not give feedback that explained the errors in the students' written proof, nor did the professor fill in the details or outline how to correct the error.

Table 1 ***Feedback type distribution on each of students' proofs. Each number represents the number of the professor's comments that belong to the types.***

Feedback Type		S1-1	S1-2	S1-3	S2-1	S2-2	S2-3	S3-1	S3-2	S4-1	S4-2	Quantity & Percentage
IP	Implicit					1				1	2	4 (9.09%)
	Explicit			1								1 (2.27%)
OP	Implicit	4	3	2	9			3	4		2	27 (61.36%)
	Explicit	1	3	1	1	2	1	1		3	1	12 (27.27%)

Conclusion and Discussion

There are four important results from this study. First, students' engagement with feedback was affected by grades. We found that grades affected the way students perceive the feedback and that students would dismiss the feedback when their performance is satisfactory. One possible effective way to improve students' engagement with feedback is refraining from assigning the grades (Black and William, 1998; Jackson and Marks, 2016). Jackson and Marks (2016) found that grade-withholding resulted in a significant improvement in feedback utilization which resulted in improvement on students' achievement. We hypothesize that professors provide feedback on proofs even when they assign a high grade to help students improve and reinforce their proof-writing, and understanding the norms of proof-writing.

Second, we found that most of the participants preferred *explicit* feedback from the professor, which reinforces language acquisition students' preferences (Amrhein and Nassaii, 2010; Kim and Mathes, 2001; Nagata, 1993). We also found that 70% of professors feedback was *implicit* which reinforced research by Amrhein and Nassaji (2010). However, we were unable to obtain results for students' preference for *input-providing/output-prompting* feedback. Since we found that: 1) the majority of the professors feedback was *output-prompting*, 2) some participants expressed they preferred *input-providing* feedback while others preferred *output-prompting* feedback, and 3) participants did not vocally express complaints about their professors predominating *output-prompting* feedback during the interviews, we believe that students do not have strong preference about *input-providing/output-prompting* feedback

Third, generally, we found that students do not use feedback to revise their proofs on their own and, for the most part, referred to feedback when working on similar proofs on subsequent assignments or when studying for exams. We find this to be a very positive result and an excellent use of feedback since students were not asked to revise their proof after they were graded, and that students referred back to the feedback when they were working on proofs in subsequent homework, when studying for exams, or both. Students may benefit from addressing the feedback on their proofs, or with an opportunity to either revise their proof or implement the feedback to prove a similar statement.

Finally, students' preferences on feedback did not align with what the professor liked to provide in terms of explicit/implicit feedback. Most participants preferred explicit feedback, but 70% of the professor's feedback was implicit. To balance students' preferences on feedback and professors' provisions on feedback, professors may need to consider giving more explicit feedback so that students obtain an overt reason on why the proof is flawed or why a correction is needed.

We were not able to determine all students' preferences with respect to *input-providing* and *output-prompting* feedback, but we did notice that 89% of the professors' feedback was output-prompting feedback. Finally, with respect to the combination of these two feedbacks, we found that the majority (61%) of the professor's feedback was *implicit output-prompting* feedback. These findings are in line with Amrhein and Nassaji (2010) where they found that teachers valued feedback that is less explicit such as *clues* or *comments* with no corrections, because they believed it is important for students to know how to correct their errors, so they understand it better.

Limitations and Future Directions

The findings in this paper may not accurately represent the behavior of mathematics' professors in general since our data only comes from one professor. Another limitation for this study is every participant was not interviewed on the same problems since we needed student proofs that had numerous errors, and this varied for each participant. For future research, more careful attention should be given to proofs produced by the participants over the course of the study to find ones where most participants had numerous errors.

Future research on feedback with a larger number of professors is needed to further investigate our results. Other needed studies may focus on the type of feedback professors provide, the purpose for each type of feedback, what they want students to learn from their feedback, and how their purpose impacts what feedback they provide.

Students' Language about Basis and Change of Basis in a Quantum Mechanics Problem

Kaitlyn Stephens Serbin
Virginia Tech

Rebecah Storms
Virginia Tech

Megan Wawro
Virginia Tech

We explored how 12 quantum mechanics students from two universities discussed basis and change of basis as they performed probability tasks, one of which required a change of basis. We found that students' utterances referred to a person, a calculation, or a vector being in a basis, or a vector being written in a basis. Students discussed change of basis as changing the form of a vector, writing the vector in another form, making a vector become a new vector, and switching bases. We performed a discourse analysis on the situated meanings of students' phrases.

Keywords: linear algebra, basis, change of basis, quantum physics, discourse analysis

A course in linear algebra is commonly required for undergraduate physics students, given that several topics covered in linear algebra, such as vector and matrix manipulation, change of basis, normalization, and eigentheory are also addressed in physics courses, including quantum mechanics. Concepts included in both linear algebra and quantum mechanics courses are sometimes discussed and used differently in the two different contexts. One such example is that bases are typically orthonormal in quantum mechanics contexts (McIntyre, Manogue, & Tate, 2012), which is not the case in linear algebra generally. Furthermore, a change of basis in a quantum mechanics context may be performed differently than a change of basis in a linear algebra context, such as through formulaic substitution of commonly used bases rather than a change of basis matrix. Because instructors want students to have a cohesive understanding of basis and change of basis across these interdisciplinary contexts, it is useful to explore how students describe (change of) basis and perform calculations in a quantum mechanics context.

In this study, we explore how quantum mechanics students discuss linear algebra concepts in the context of two spin-½ system probability problems, the second of which required a change of basis. In particular, we explore how quantum mechanics students discuss basis and change of basis by conducting a discourse analysis of the situated, contextually-dependent meanings of their utterances that refer to basis and change of basis (Gee, 2005). Our research question is: how do students discuss basis and change of basis as they perform these tasks, and what are the meanings of students' utterances regarding basis and change of basis?

Literature Review

There is a growing body of literature related to student understanding of basis (e.g., Bagley & Rabin, 2016). Some studies described students' productive ways of intuitively reasoning about basis (Adiredja, Belanger-Rioux, & Zandieh, 2019; Adiredja & Zandieh, 2017; Zandieh, Adiredja, & Knapp, 2019). Adiredja and Zandieh (2017) investigated students' conceptual metaphors for basis. Students in their interview study described real-life examples of basis, including examples related to recipes, fashion outfit choices, Legos, marching band, and religious teachings. As students explained their examples, their verbs related to bases describing or generating a space, and their adjectives described bases as minimal, maximal, representative, essential, different, and non-redundant. Adiredja et al. (2019) described a class implementation of a task that prompted students to give real-life examples of basis and explain how they relate to the formal definition of basis. This task allowed students to connect their intuitive understanding of basis with formal mathematical language. Using the same task, Zandieh et al. (2019) found that their students often used real-life examples of basis that illustrated the roles of a basis as generating, structuring, and traveling, and the characteristics of a basis as different and essential.

Stewart and Thomas (2010) found that when students in their study reasoned about basis, they mainly focused on symbolic matrix manipulations such as row-reduction but often did not seem to understand how the calculations were related to finding a basis. In addition, the students often did not connect span and linear independence with basis as they created concept maps, nor did they attend to embodied conceptualizations of basis. Schlarmann (2013) found that two students focused on linear independence as they determined a basis for a particular subspace of $\mathbb{R}^3$ and on span as they verified their set actually formed a basis. We found few studies that focused on student understanding of change of basis. One exception is Hillel (2000), who found challenges students may face with the algebraic notion of change of basis; Hillel stated that students who understand a vector as a string of numbers may have difficulty may have difficulty understanding how one string of numbers can be equivalent to a different string of numbers.

Theoretical Framing

Spoken utterances have situated meanings; they take on specific interpretations in specific contexts relative to the culture of the people communicating (Gee, 2005). Situated meanings of phrases are negotiated through communicative social interaction, and they are assembled as people communicate in a given context based on their perception of that context. Language and context have a reflexive relationship in that the language used influences how people construe the context, and the context influences how people interpret the meaning of the language; discourse analysis involves exploring these relationships. In this study, we perform a discourse analysis of students' phrases referring to basis and change of basis within their problem-solving approaches to a quantum mechanics problem in an interview setting. We explore the situated meaning of students' utterances while considering the contexts in which the language was used.

Of particular interest to our study was that of Ochs, Gonzales, and Jacoby (1996), who performed a discourse analysis of physicists' utterances as they collaborated in a lab setting. They identified three main ways that physicists' technical parlance was grammatically constructed: 1) physicist-centered, 2) physics-centered, and 3) indeterminate. In physicist-centered constructions, the physicist is either an active agent who directly affects physical entities or an experiencer of those physical entities. Physics-centered constructions highlight the physics as being the subject of interest and consider relevant physical entities as either active or sentient in some fashion. Somewhere between these two concrete and more grammatically sensical constructions are the indeterminate constructions, which Ochs et al. found to be ubiquitous in physicists' utterances. These constructions are characterized by a personal pronominal subject completed by an inanimate predicate (i.e., a clause that grammatically should not apply to a personal pronoun), such as "when I come down I'm in the domain state." Ochs et al. supported the theory that the pronominal subjects here have a "blended identity composed of both the animate physicist and the inanimate physical entity" (p. 348); in other words, physicists used language that seemed to sympathize with the inanimate objects they were trying to understand, blurring their identity with that of the physical object.

Other studies recognized this kind of language in mathematicians' and students' utterances. As mathematicians describe concepts, they sometimes use talk, gestures, and diagrams "in ways that blur the distinction between the mathematical and physical world" (Sinclair & Tabaghi, 2010, p. 223), and mathematics and physics students sometimes use language that blur this distinction. Rasmussen (2001) exemplified a differential equations student who used language indicative of positioning himself as an actor in a direction field: "If I were unstable, I'd try to get stable as much as I could…if you're stable, you won't want to go away from that line" (p. 82). The student seemed to blur his own identity with that of a graphical solution to a differential equation. Gire and Manogue (2011) found that two quantum mechanics students used non-standard terminology in their explanations of operators. Although the students' indeterminate verbal constructions were not the study's focus, we noticed students made utterances, such as "when you measure something you are acting on it… you act on that state which changes the state" (p. 4), in which they seemed to blend their identities with that of an operator. This language may seem informal, but students' identification with a physics entity has been shown to be productive way of making sense of physics concepts (Scherr, Close, Close, & Vokos, 2012).

Methods

Semi-structured interviews (Bernard, 1988) were conducted with 12 quantum physics students; eight were in a junior-level course at a large public research university in the northwest US, and four were in a senior-level course at a medium public research university in the northeast US. Both courses used McIntyre et al. (2012) as the main text. The interview aimed to elicit evidence of student understanding of linear algebra concepts used in quantum mechanics. In this study, we analyze the students' responses to the questions in Figure 1. A relevant follow-up question was: "How do you see this problem relating to basis or change of basis?"

Consider the quantum state vector $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$.

a) Calculate the probabilities that the spin component is up or down along the *z*-axis.
b) Calculate the probabilities that the spin component is up or down along the *y*-axis.

Figure 1. The interview questions analyzed in this paper.

The data collected include video recordings and transcripts of the interviews and copies of student work. For each student, all mentions of basis and change of basis in the interview transcripts were extracted. Based on these excerpts, we performed a grounded theory analysis of how students talked about basis and change of basis (Strauss & Corbin, 1998). We performed multiple rounds of coding, in which we produced in vivo codes, used the constant-comparative method to identify similarities among the codes across all the transcripts, and grouped codes together to create axial codes that identified the different ways in which students tended to talk about basis and change of basis. These codes are discussed in the results section.

Some student utterances that we coded, such as "we're in the *z*-basis," seemed to have ambiguous meanings, yet we assumed these utterances were sensible to the speaker. Because many of these phrases were ubiquitous throughout the interview transcripts, we assumed the meanings of these phrases are culturally shared among these quantum mechanics students. We examined the situated meanings (Gee, 2005) of students' utterances regarding basis and change of basis to unpack what the students likely meant in these utterances. We inferred the utterances' meanings by considering the context in which they were spoken. Finally, we used Ochs et al.'s (1996) characterization of indeterminate grammatical constructions to guide our interpretation of the meanings of the students' utterances that referred to a person being in a basis.

Brief Physics Background and Literature

Quantum mechanical systems and all knowable information about them are represented mathematically by normalized kets, symbolized in Dirac notation as $|\psi\rangle$. Kets mathematically behave like vectors, and a ket's complex conjugate transpose, called a bra, is symbolized as $\langle\psi|$. Spin is a measure of a particle's intrinsic angular momentum and is represented mathematically by an operator such as $\hat{S}_z$ (where the z indicates the particle's axis of rotation). In a spin-½ system, there are two possible results for the S_z measurement: $\pm\frac{\hbar}{2}$; they correspond to $|+\rangle$ and $|-\rangle$, which comprise a set of orthonormal basis vectors called the S_z basis. Any quantum state $|\psi\rangle$ is a linear combination of them: $|\psi\rangle = a|+\rangle + b|-\rangle$ with corresponding bra $\langle\psi| = a^*\langle+| + b^*\langle-|$.

Interview question (a) asks students to determine the probability of obtaining $\frac{\hbar}{2}$ or $\frac{-\hbar}{2}$ in a measurement of the observable S_z on a system in state $|\psi\rangle$. This is calculated by $P_\pm = |\langle\pm|\psi\rangle|^2$, where $\langle\pm|\psi\rangle$ is an inner product between one of the basis kets and psi. Because $|\psi\rangle$ is written as a linear combination of the two vectors that comprise the z-basis, solving this problem requires no change of basis. The analogous information can be determined for other axes of rotation, such as y. To complete question (b), a change of basis is involved because the given state vector $|\psi\rangle$ is written in terms of the z-basis but the prompt asks for the probability that the spin component is up along the y-axis. The two main approaches are to either change $|\psi\rangle$ to be written in terms of the y-basis (denoted $|\pm\rangle_y$), or change the y-basis vectors to be written in terms of the z-basis. In either change of basis approach, one would need to utilize the relations $|\pm\rangle_y = \frac{1}{\sqrt{2}}|+\rangle \pm \frac{i}{\sqrt{2}}|-\rangle$.

Some studies have investigated student understanding of probability in quantum mechanics contexts (e.g., Close, Schiber, Close, & Donnelly, 2013; Passante, Sadaghiani, Pollock, & Schermerhorn, 2018; Wan, Emigh, & Shaffer, 2019), but we have not found any studies that specifically focus on students' understanding of basis or change of basis within physics contexts.

Results

We present our results in three sections. We first describe the codes of how students talked about basis and the meanings of students' utterances associated with the codes. Then we present the codes of how students talked about change of basis and the meanings of those utterances. We conclude with a description of how one student talked about (change of) basis in various ways.

Meanings of Students' Utterances Involving Entities "In a Basis"

We examined the situated meanings (Gee, 2005) of students' utterances that contained the phrase "in a basis" as they appeared in the students' responses to the interview questions. In this subsection, we describe the ways in which students talked about entities being "in a basis" and discuss the situated meanings of those utterances, given the context in which they were spoken.

A person is in a basis. When students used phrases such as "we are in a basis," we coded the object of focus in the student's language as a person. According to Ochs et al. (1996), the phrases can be understood as indeterminate grammatical constructions that use a personal pronoun subject with a predicate involving the experience of an inanimate object. In these phrases, it may seem linguistically unclear what entity the pronouns I, you, and we refer to. These phrases do not seem to literally mean that the speaker is in the basis, so we explore other meanings.

Five students spoke utterances that were coded as referring to a person being in a basis. Two of them, A6 and A25, made these utterances as they began question (a). A6 explained, "So, because we're in the *z*-basis, I already know that the probabilities- my plus *z* is going to be the square of the norm of my first component." A25 claimed, "So we are in the *z*, we are in the *z*-basis, so this makes this pretty easy." In both instances, the students referred to "we" as being in a basis as part of their justification for why they could perform the "easy" procedure of squaring the norm of the coefficients. A6 and A25's utterances of "we are in the *z*-basis" seem to mean that they interpret the problem to involve vectors that are all expressed in terms of the *z*-basis.

A6 and A8 used phrases that were coded as a person being in a basis as they justified the change of basis procedure they performed for question (b) in Figure 1. When the interviewer asked A6 if she thought about basis for this problem, she claimed that the change of basis was the first step and said, "you can't do anything until you're in the same basis." In her utterance, it seems that a person being in a basis was a condition necessary for an inner product calculation to be performed. A6 seemed to blend her identity (Ochs et al., 1996) with that of a basis vector. Here, "you" in "you're in the same basis" figuratively refers to basis vectors. Given the context of this utterance, the phrase referring to "you" being in a basis seems to mean ${}_{y}\langle +|$ and $|\psi\rangle$ are expressed in terms of the same basis, which allows one to calculate the inner product.

A calculation is in a basis. Two students' (A21 and A8) utterances were coded as having an object of focus as a calculation when talking about basis. They used phrases such as "we do this in a basis" or "we are working in a basis." These phrases seemed ambiguous, so we explored what the students' utterances mean within the context of the interview task setting. We look at A21 as an example. After A21 correctly computed the probability in question (b), he explained how expressing $|+\rangle_y$ in terms of the z-basis allowed him to make assumptions about the inner products $\langle +|-\rangle$ and $\langle -|+\rangle$ being 0 (because the basis vectors are orthogonal). Then he claimed,

> But if I were to do this in the y-basis…if I were to just like write this out as like let's say y plus, but against all of this [points to $|\psi\rangle$], then I can't make any assumptions about that [orthogonality], so I don't really know how to calculate that in bra ket language.

A21's phrase "if I were to do this in the *y*-basis" referred to calculating the inner product of ${}_{y}\langle +|$ and $|\psi\rangle$, and it implied a basis can be a context in which calculations can be performed.

A vector is in a basis. Every student referred to a vector as being in a basis, but the implied meanings were varied. One meaning of the phrase "a vector is in a basis" is that the vector is an element of a set of basis vectors (e.g., A6's utterance, "I mean I can just call this a plus *y* [referring to $|+\rangle_y$], in the y basis"). Another meaning of the phrase "a vector is in a basis" is that a vector is expressed in terms of basis vectors. For example, A6 claimed, "I needed plus *y* [$||+\rangle_y$] in the *z*-basis, because [$|\psi\rangle$] was in the *z*-basis." In this case, neither of the vectors $|+\rangle_y$ or $|\psi\rangle$ are actually elements of the z-basis. Therefore, A6's utterance can be interpreted as her needing $|+\rangle_y$ to be a linear combination of *z*-basis vectors because $|\psi\rangle$ is a linear combination of *z*-basis vectors. Most students' utterances about a vector being in a basis seemed to have this meaning.

Some of the students used language consistent with a vector being in a basis when they explained the task setting or as they justified their choice of using a certain strategy for performing the task. For instance, as A21 justified his change of basis, he explained, "Yeah okay, so if I wanna compute this [pointing to $\left|(\frac{1}{\sqrt{2}}\langle +| - \frac{i}{\sqrt{2}}\langle -|)|\psi\rangle\right|^2$]... I wanna be able to read off those coefficients really easily and do this in bra-ket notation if these are in the same uh basis." By "these," A21 seemed to be referring to the vectors in the inner product each being a linear combination of basis vectors from the same basis. Vectors being in the same basis seemed to be a condition allowing him to perform inner products using bra-ket notation.

A vector is written in a basis. Six students spoke utterances that referred to a vector being written in a basis. Some used this language as they justified the need for a change of basis. C5 said, "If I'm doing the inner product of the positive *y* [$|+\rangle_y$] with that [pointing to $|\psi\rangle$], I need that to be written in the *z*-basis or to do those inner products to be nice." C5's phrase "I need that to be written in the *z*-basis" means that he needs $|+\rangle_y$ to be written as a linear combination of *z*-basis vectors. Some students referred to a vector being written in a basis as they described the result of the change of basis. For instance, A32 claimed, "that's the quick thing we can see is that now this is, this is written in the *z*-basis." When A32 claimed a vector is "written in the *z*-basis," he seemed to mean that a vector is written symbolically as a linear combination of basis vectors.

Meanings of Students' Utterances Involving Change of Basis

Utterances relating to change of basis were identified by verbs indicating some form of alteration of the basis or a vector. These phrases fell into distinct categories:

A) Phrases in which the verb's connotation deems its object (the vector) as concrete or (figuratively) tangible, and the verb implies a change in that physical form
B) Phrases in which the verb's usage alters its object (the vector) titularly
C) Phrases in which the verb relates two distinct objects, both of which are vectors
D) Phrases in which the verb's object is the basis itself.

Category A. A student's phrase was coded in category A if the student used language which indicated the vector was "change[d]", "convert[ed]", or in some other way altered as a result of the basis change. Six students used this type of language, such as "I *changed this* from the *y* basis to the *z* basis" (A6), "I could've *turned this* into the y basis" (A11), and "I'm going to *convert the y plus or minus bra* into the z basis" (A30). These phrases follow the language structure for category A. Due to the connotation of verbs used in this category, we propose that these students see the vector as having a physical form, and the change-of-basis process alters the vector's physical form. Of particular note is that without exception, students refer to the vector being changed into a basis, not another vector. These phrases seem to mean that the vector is being changed to be in terms of a different basis, rather than the vector actually changing into a basis.

Category B. A student's phrase was coded in category B if the student used language which indicated an explicit titular change in the vector; for example, C3 said "So, from that you just rewrite it like that, and that's essentially changing the basis of plus y into the z basis." From this statement, we infer that C3 sees what might be considered the "name" of the vector (i.e., the coefficients of the basis kets) changing to be the result of the change of basis. The most common verbs used in this category were "rewrite" and "express"; the objects of these verbs were always vectors, never bases. The meanings of these phrases can be taken somewhat literally because the verb's relationship to its object is clear from the verb's inherent meaning. For example, the verb "rewrite" creates a setting in which the vector is being altered into something of the same form.

Category C. A student's phrase was coded in category C if the student used language which indicated that the pre-change of basis and post-change of basis vectors were two distinct vectors. Unlike category A, this language does not imply that the post-change of basis vector is the pre-change of basis vector with some alterations, but rather implies that the post-change vector is a different vector entirely. Only one student, A8, used phrases coded in this category. In each instance, he said something to the effect of, "we can represent our φ going to the φ' in the y-basis." Of particular interest in this phrase is that A8 gave the pre- and post-change of basis vectors two different names, indicating that, to him, the two vectors are objectively distinct.

Category D. A student's phrase was coded in category D if the student used language which positioned the basis, not the vector undergoing the change, as the object of the verb. Only A13 made utterances that were coded in this category, with utterances such as "switch the basis" and "change your *y*-basis to your *z*-basis." These utterances seem to have a literal meaning.

Example of a Student's Utterances Regarding Basis and Change of Basis

A8 talked about basis in a variety of ways as he reasoned through the interview questions. As he engaged in question (a), his utterances exemplified three of our "in a basis" meanings:

> Because *this is written in z*, oh and this along the *z* axis, so because this is written along the *z* axis, I'm assuming that *we're working in the z basis*...Then you do plus with, norm squared of plus with psi, and by the same rule I talked about earlier … you get 4/13 and 9/13. So you literally just square the components if you want it like that…It's super

simple *if you're working in the basis that you're in.*

By "this is written in *z*," A8 seems to mean the vector is written in terms of the *z*-basis. Given this fact and that the problem asked for the probability that the spin component of the state vector was up along the *z*-axis, he assumed "we're working in the *z*-basis." Here his language seemed to position the *z*-basis as a context for performing the probability calculation. By "we're working in the *z*-basis," he seems to mean every vector involved in the inner product was expressed in terms of the *z*-basis. This justified his procedure choice of squaring coefficients because he knew that having every vector in terms of the same *z*-basis lets him take advantage of the orthogonality of the basis vectors. After performing this procedure, he said, "It's super simple if you're working in the basis that you're in." He refers to "you" as working in the basis and "you" as being in a basis. He seems to mean that the computation is simple if the vectors involved are in terms of the same basis. As A8 worked on question (b), he described two methods for changing basis:

> So… one [method] is to *put this vector in some φ' that's in the y basis,* and then just do y plus phi prime y cause it makes calculations, and it follows the same rules as this. Um, the other possibility is to do, is to *take the spin up y and go to whatever it is in the z, in the z basis,* cause we have *this in the z basis*. Um, they're both equivalent.

A8's utterances seemed to refer to change of basis as changing the vector ($|\psi\rangle$ or $|+\rangle$) into another vector ($|\psi'\rangle_y$ or $\frac{1}{\sqrt{2}}(|+\rangle + i\,|-\rangle)$). He referred to the post-change of basis vector as a different vector than the original (i.e., Category C) and referred to the result of the change of basis as a vector that is in a basis. Later, in detailing how he thought about basis in this problem, he said, "[Y]ou can't actually perform this calculation *when you're … in the different bases*." He again used "you" being in a basis as a situation in which one can perform the calculation. Overall, A8 referred to a vector being written in a basis or a person working in a basis as he explained the problem situation, he referred to a vector being in a basis as the result of the change of basis, and he referred to a person being in a basis when he justified his procedure.

Conclusion

In this study, we explored the ways in which quantum mechanics students discussed basis and change of basis as they performed probability tasks, of which one required a change of basis. The students' utterances referred to a person, calculation, or vector being in a basis, or a vector being written in a basis. Students talked about change of basis as changing the form of a vector, writing the vector in another way, making a vector to become a new vector, and switching bases.

We examined the situated meanings (Gee, 2005) of students' utterances that referred to basis and change of basis to unpack what the students meant. Even though phrases, such as "we're in a basis," may seem ambiguous, these phrases make sense to the speaker. The meanings of these utterances are socially constructed and contextually dependent. "Words have different specific meanings in different contexts of use…The meanings of words are also integrally linked to and vary across different social and cultural groups" (Gee, 2005, p. 53). The meanings of those utterances are likely shared among members of the quantum physics students' culture. Understanding the context of students' utterances helped us gain insight into their meanings. Future research can explore ways in which students socially construct meaning for something to be "in a basis" and can investigate how instructors' utterances influence the phrases students use.

The Decision to use Inquiry-Oriented Instruction: Why Don't Beliefs Align with Practice?

Mollee Shultz
University of Michigan

Patricio Herbst
University of Michigan

In this study of inquiry-oriented instruction (IOI), we explore the relationship between beliefs, professional obligations, and inquiry-oriented practice among college mathematics instructors. Professional obligations consist of the responsibilities that instructors have towards various stakeholders, including the institution, the individual students, mathematics as a discipline, and society (Herbst & Chazan, 2012). Past studies have reported inconsistencies between beliefs and practice; professional obligations may help explain why instructors cannot always realize IOI practices in the classroom. We operationalize these constructs in a set of surveys and use structural equation modeling to explore the hypothesized relationships.

Keywords: Inquiry-Oriented Instruction, Professional Obligations, Decision-making, Beliefs

Across the nation, students are required to take introductory mathematics courses as part of their undergraduate degree for STEM and other fields. More than 60% of students intending to complete a STEM degree end up switching to a different major or not completing a degree, with many of these students citing uninspiring, unwelcoming mathematics courses as the reason for their departure (PCAST, 2012). There have been widespread calls for mathematics faculty to use evidence-based teaching methods that include more active learning for the sake of student retention (PCAST, 2012), more authentic understanding (Johnson, Caughman, Fredericks, & Gibson, 2013), and more equitable outcomes (Laursen, Hassi, Kogan, & Weston, 2014). We use the term *inquiry-oriented instruction* (IOI) in this study to describe any or all instructional practices aimed to increase the students' engagement, with the goal of discovering what inquiry-oriented practices are reportedly being used and why. In this study, we expand upon the work done with the INQUiry-oriented Instructional REview (INQUIRE) instrument (Shultz & Herbst, 2019) to name what practices are being used by undergraduate mathematics instructors, and investigate possible reasons why those practices are being used.

Literature and Framing

We review the literature on the connection, or lack thereof, between beliefs and practice. The studies motivate the theoretical framework because we pose that there are rational justifications why instructors do not always enact their beliefs. Beliefs have been studied because of their central role in guiding judgements and decision-making (Bandura, 1986; Philipp, 2007). Though links have been found between teacher beliefs and teacher practice, researchers have also found inconsistencies between beliefs and practice. For example, Wijaya, van den Heuvel-Panhuizen, & Doorman (2015) found that junior high school teachers in Indonesia reported in questionnaires that they found context-based tasks beneficial for students, but observations revealed the teachers did not implement them. Raymond (1997) followed an elementary teacher and found that her practices were consistent with her beliefs about mathematics content, but not about mathematics pedagogy. DeFranco & McGivney-Burelle (2001) observed 22 graduate teaching assistants in a mathematics department throughout enrollment in a mathematics pedagogy course and found that, though their written journal reflections demonstrated that they adopted a new set of beliefs, their classroom practices did not change.

Instead of accusing instructors of being unmotivated to change, we agree with Leatham's (2006) notion that "teachers are inherently sensible rather than inconsistent beings" (p. 92) and pose that instructors must attend to social and contextual factors. Sztajn (2003) illustrated this phenomenon by studying two teachers with similar beliefs about mathematics but differences in instruction. The two teachers taught in separate contexts, and Sztajn (2003) could only explain the differences in instruction once she considered the contexts in which they were teaching and their broader beliefs about children, society, and education. Skott (2001) studied a teacher who believed that mathematics learning happened best when he could engage students in an unobtrusive manner but was prevented from always enacting this belief due to conflicting priorities such as building students' confidence and managing the classroom. While he wanted to support students to work and investigate mathematics independently, such as by not offering too much scaffolding and not evaluating student responses by letting them find out if their suggestions are correct on their own, he sometimes used direct instruction due to the classroom environment. Engeln and colleagues (2013) found that while the 917 teachers from 12 countries all had, on average, positive attitudes towards inquiry-based learning, the implementation varied more widely country to country. This suggests that the implementation was less dependent on individual beliefs than it was on contextual and cultural factors.

Practical Rationality

Herbst and Chazan (2011, 2012) proposed the framework of *practical rationality* to describe the ways that practicing teachers make decisions based on both social and individual resources which is useful to account for the environment in which the relationships among teachers, students, and content exist. This theory of decision-making provides a lens for how teachers account for and rationalize their decisions, rather than explaining the cognitive processes involved in making the decision. Herbst & Chazan (2011) hypothesize that a source of justifications for decisions in institutional environments where mathematics instructors work come from four *professional obligations* that mathematics teachers must respond to as professionals: towards creating a socially and culturally appropriate environment for students to share space and resources in a class (interpersonal), representing the discipline of mathematics appropriately (disciplinary), respecting institutions such as the department, school, or state in matters including curriculum, assessment, and policy (institutional), and to treating individual students as persons with unique assets and needs (individual). The obligations correspond to various stakeholders in the educational system, namely the community, mathematics as a field, the institution, and the students, respectively (Herbst & Chazan, 2012). The theory provides a lens to address the "multiple and sometimes conflicting educational priorities" (Skott, 2001, p. 18) that arise in the practice of teaching.

We are interested in factors that can explain instructors' use of IOI practices, and the framework of beliefs with practical rationality can help balance the individual and social factors that go into making those decisions. The following questions guide our study:

1. Is there a relationship between the beliefs of instructors and inquiry-oriented practices in college mathematics instruction?
2. If so, do professional obligations help explain the relationship between beliefs and inquiry-oriented practices in college mathematics instruction? If so, how?

Methods

Data Collection

We administered four self-report instruments to collect data for this study: inquiry-oriented instruction review (INQUIRE), professional obligations (PROSE), beliefs (Clark and colleagues, 2014), and a background survey. Self-report surveys are widely used and researchers have found ways to argue for their validity. Hayward, Weston, & Laursen (2018) found that self-report surveys were trustworthy when used to describe what is happening in instruction, in comparison to observation protocols designed to measure the same happenings. Similarly, Desimone, Smith, and Frisvold (2010) found that there were only small differences between student reports of teacher behavior and teacher's self-reports, that disappeared when controlling for background variables.

We collected data from a national sample with participants representing 94 different mathematics departments across 37 states, plus Washington, D.C. We compiled a comprehensive list[1] of Research I and Research II mathematics department emails, along with a handful of high-ranking liberal arts colleges. Participants qualified for the study if they had at minimum one year's teaching experience, including tenure or tenure-track faculty, adjunct faculty, and graduate student instructors. There were 252 finishers of the INQUIRE instrument, and 194 participants that completed all instruments in the study[2].

The INQUIRE instrument was designed using different practices found in the literature on IOI, and organized around the interactions represented in the instructional triangle (Cohen, Raudenbush, & Ball, 2003; Shultz & Herbst, 2019). The practices measured by the instrument are organized and defined in Table 1. Each practice is measured by at least three items. Instructors were asked to consider a typical day in a lower-division course and respond to questions on a Likert-type frequency scale from 1-Never to 6-Multiple times each class.

The PROSE instrument was a four-part multimedia questionnaire created using the Lesson*Sketch* platform (www.lessonsketch.org). Each part of the questionnaire consisted of fifteen to eighteen scenarios that featured an undergraduate college mathematics classroom where an instructor chose to act on behalf of one of the professional obligations. Participants were then shown a statement about the instructor's action (e.g. "The teacher should stick to the mathematics at hand, rather than take class time to make connections to other mathematical ideas.") that they respond to on a 6-point Likert-type scale from strongly disagree to strongly agree.

For the beliefs instrument we used all published items from Clark and colleagues (2014). They developed a survey on a six-point scale from 1-Strongly disagree to 6-Strongly agree. Their study included an exploratory factor analysis that yielded three main factors consisting of 21 items grouping into the following three categories: Allowance for student struggle with problems (TASSP), teaching modeling for incremental mastery (TMIM), and awareness of students' mathematical dispositions (TASMD). Their items were tested with 259 upper-elementary and

---

[1] The list was compiled from an original list acquired by Pablo Mejía-Ramos of Rutgers University and updated by the GRIP lab.

[2] The INQUIRE instrument had a flawed implementation: In Qualtrics, if a user responded to the question, "How often do you ask students to revise a definition?" with "1-Never", they were skipped past the remaining sections of the survey (all student-student and teacher-content questions) due to an error in the survey logic. Of the original 252 finishers, 143 chose "1-Never". We recovered data for 85 participants, who retook the rest of the instrument. There are 58 participants that did not retake it.

184 middle-grade mathematics teachers. To keep the text of our results as transparent as possible, we use the names *Struggle, Model, and Awareness,* in place of the acronyms TASSP, TMIM, and TASMD, respectively. Though college mathematics instructors may have different beliefs than K-12 teachers, we expected that the general factor structure would still hold.

Table 1: Definitions and organization of constructs measured by the INQUIRE instrument

Triangle Relationship	**Constructs**	**Description**
Student-Content	Open problems	Posing problems that either have multiple solutions or multiple nontrivial ways of arriving at a solution
	Constructing/Critiquing	Posing tasks that ask students to create or critique conjectures or claims
	Proving	Using previously established results to construct formal arguments for mathematical claims
Teacher-Student	Interactive lecture	Instructing to the full class while asking for feedback from students, asking questions of students, and having students engage with the mathematics
	Hinting without telling	Guiding a student to work productively without directly telling the student a correct way to proceed
Student-Student	Group work	Creating an environment where students work together on mathematical tasks or problems
	Student Presentations	Having a student or students present completed or in-progress work to the class

We chose this instrument because of its alignment with common categorizations of mathematics teacher beliefs on teaching and learning and because we hypothesized categories of struggle, model, and awareness would predict inquiry-oriented practices. We suspected that the belief that students should struggle would predict more frequent use of inquiry practices, while belief that teachers should model to help students incrementally master techniques would predict less inquiry-oriented practices. Instructors that interact with their students more through active learning strategies like group work, or hinting without telling, might perceive themselves as more aware of their students' dispositions. Finally, all participants took a background information instrument that collected basic information such as years of teaching experience, status in the department, general research interests, and type of institution.

Data Analysis

We explore the relationships between constructs using a structural equation model (SEM). SEM refers to a family of related techniques, including factor analysis and structural regression modeling (Kline, 2016). It is a causal inference method that takes qualitative hypotheses and questions about causal relationships and outputs numerical estimates of hypothesized effects (Kline, 2016). An advantage of using SEM over ordinary least squares regression (OLS) is that OLS assumes each item contributes equally to a given construct, while

SEM considers that not all items have the same amount of error. Once the dimensionality of each instrument was established using factor analyses in MPlus, we checked the internal consistency of each factor by calculating Cronbach's alpha and mean inter-item correlations in Stata.

Results

Reliability and Validity

We conducted confirmatory factor analyses for each instrument to confirm that items grouped as hypothesized. The reliability statistics for each item grouping are shown in Table 2. Most groupings had satisfactory reliability statistics, following the guidelines of inter-item correlations (IICs) between .15 and .50 (Clark & Watson, 1995) and alpha scores above .7 (Kline, 2016). Kline (1999) noted that for some psychological constructs, lower alpha scores can be appropriate due to the diverse nature of what is being captured.

Table 2: Inter-item correlations and alpha statistics for items in each construct included in our models

Instrument	Constructs	IIC	α
INQUIRE	Constructing/Critiquing	.48	.90
	Proving	.45	.87
	Solving open problems	.38	.71
	Interactive Lecture	.25	.62
	Hinting without telling	.38	.65
	Group work	.58	.90
	Presentations	.54	.87
Beliefs	Struggle	.38	.75
	Model	.31	.76
	Awareness	.42	.74
PROSE	Individual	.19	.74
	Interpersonal	.26	.86
	Disciplinary	.25	.85
	Institutional	.18	.66

We created a structural equation model for each targeted practice of the INQUIRE instrument. We separated them into individual models because the study is aimed to investigate how beliefs and obligation predict specific practices rather than how practices are related to each other. Following the recommendation by Little, Cunningham, Shahar, and Widaman (2002), we used parcels after exploring the dimensionality of the items to be parceled. Using parcels, or aggregated groups of items, as indicators for latent constructs has the advantages of being more likely to fulfill the distribution assumptions inherent in SEM, and creating a model with fewer free parameters so that the sample size is sufficient (Little et al., 2002). All seven models had satisfactory fit statistics (CFI>=.91, TLI>=.90, RMSEA<=.05). These fit statistics show that beliefs and professional obligations are reasonable indicators for modeling the inquiry-oriented practices that instructors choose to implement.

Predicting Inquiry-Oriented Practices

Professional obligations significantly predicted five of seven inquiry-oriented instructional practices: the use of open problems, having students work with each other in group work, having students make presentations, inviting students to construct and critique work, and using interactive lecture. We illustrate only three models here due to space limitations (see Table 3).

The instructors use these three practices more or less than their beliefs alone would indicate. We found that professional obligations could be in direct opposition with the actions that their avowed beliefs would recommend.

Table 3: Structural equation models showing how beliefs and professional obligations predict inquiry-oriented practices of including group work, presentations, and open problems, coefficients are STDYX standardized

		Group Work		**Presentations**		**Open Problems**	
Instrument	Latent construct	Loading	SE	Loading	SE	Loading	SE
Beliefs	Struggle	.46**	.17	.63***	.18	.36*	.17
	Model	-.04	.19	.31	.20	-.18	.19
	Awareness	.27**	.10	.15	.11	.32***	.10
Professional Obligations	Individual	.28*	.14	.64***	.14	.42**	.16
	Interpersonal	-.01	.16	.04	.17	-.21	.17
	Disciplinary	-.13	.17	-.53**	.18	-.25	.18
	Institution	.28*	.11	.21†	.12	.37**	.12

† p≤0.10, *p≤0.05, **p≤=.01, ***p≤.001

Choosing to have students participate in *group work* with their peers was significantly predicted by the belief that students should be allowed to struggle (ß=.46, p<.01), awareness of students' mathematical dispositions (ß=.27, p<.01), the individual obligation (ß=.28, p<.05), and the institutional obligation (ß=.28, p<.05). If an instructor held more of the two belief constructs, they would be more likely to use group work. If an instructor tended to recognize the individual and institutional obligations, they would be even more likely to use group work. The individual obligation makes sense, because the type of patience and empathy required to attend to individual students' needs is also necessary for attending to individuals as they engage with group work. We are not certain why recognition of the institutional obligation was positive, as we hypothesized compliance with institutional policies would predict less inquiry-oriented practices.

Having students give *presentations* was significantly predicted by the belief that students should be allowed to struggle (ß=.63, p<.001), the individual obligation (ß=.64, p<.001), and the disciplinary obligation (ß=-.53, p<.01). While the individual obligation is in line with the belief that students should be allowed to struggle, the disciplinary obligation is in direct opposition with it in predicting the practice of having students present their work. Many of the high-loading items in the instrument measuring the disciplinary obligation had to do with correcting student work or choosing to highlight more elegant mathematical work. So an instructor who believes student presentations are beneficial still might not use them due to recognizing the disciplinary obligation, wanting to expose students to accurate or elegant mathematical work.

Presenting students with *open problems* to solve was significantly predicted by the belief that students should be allowed to struggle (ß=.36, p<.05), awareness of students' mathematical dispositions (ß=.32, p<.01)., the individual obligation (ß=.42, p<.01) and the institutional obligation (ß=.37, p<.01). The two beliefs have positive coefficients, indicating that if an instructor holds more of those beliefs, they are more likely to give students open problems. Recognition of the individual obligation and intuitional obligation could be used to understand why even more instructors use open problems than just their beliefs would indicate.

Beliefs played a significant role predicting the constructs of *proving,* and *hinting without telling,* and professional obligations did not hold a significant relationship with either of them. We conjecture that these two practices are not as distinct from more typical forms of instruction, e.g., they can be done within a lecture format without changing anything in the curriculum or lesson plan. The comparatively small deviation from typical instruction might explain why recognition of various professional obligations do not have a significant impact on the decision to use them or not.

Discussion

While policymakers might be frustrated that their research-based recommendations are seemingly ignored, a consideration of the complex environments within which instructors operate may help them understand why that happens. Our results indicate that beliefs often do not align with practice because there are other environmental and social factors, as modeled here by professional obligations. For example, even if instructors are convinced that having more peer interaction with group work would create the most learning opportunities, they might decide to have more whole-class discussions for the sake of individual students or exposing students to all the content within the scheduled time. Having students give presentations might align with an instructor's desire to have students experience struggle, but not enough to risk that the discipline of mathematics would be represented poorly.

Conversely, our results give insights into which practices might be more feasible to implement: including open problems, having students work in groups, including more opportunities to prove, and hinting without telling. As professional obligations were not significant negative predictors of these practices, if instructors are convinced these practices are beneficial, they might be more inclined to act on it. For the practices that are not as feasible, our results have implications for the types of professional development or policy changes that might accompany an initiative to include more IOI. For example, if a department wanted instructors to include more student presentations, they might hold workshops that emphasize how to do so in a way that would allow students to help each other represent the mathematics accurately. While the results suggest that the disciplinary obligation acts as a constraint on enacting beliefs, the recognition of the institutional and individual obligations works in tandem with beliefs for the use of student presentations. Departments might leverage instructors' individual and institutioanl obligations to encourage the use of such practices.

This study offers a conceptual framework for understanding instructors' decisions and a methodology (SEM) to operationalize it. For future work, we would like to expand the lens from the instructor perspective to gauge the impact of each individual practice on students' experiences. If instructors choose to not use student presentations due to their individual obligation, what if we were able to give them data about how it impacts the student experience? What if we could give instructors data about how to best implement inquiry-oriented practices in ways that would build students' confidence instead of potentially embarrass them? We hypothesize that additional data on the student experience with particular aspects of IOI, rather than IOI as a whole, would be useful information for both instructors and researchers.

“What Happened to the Vector?”
Felix’s Emerging Conception of Translations

Janet G. Sipes
Arizona State University

Felix initially used a metaphor in considering translations between algebraic representations of systems during an individual clinical interview. I investigated the mathematical underpinnings for his metaphor by asking him to perform translations in the vector space register. That investigation precipitated a discussion where Felix developed mathematical understanding for a translation between the vector space register and the linear systems register. My analysis is based on the Theory of Quantitative Systems which I developed as a result of my study of Duval’s Theory of Semiotic Representation Registers (1999, 2006, 2017).

Keywords: systems of linear equations, registers of representation, supporting students’ learning, metaphor, structure sense, teaching experiments

Introduction: Study Specifics

Herein I report on part of my dissertation study (Sipes, 2019) entitled *Undergraduate Students’ Conceptions of Multiple Analytic Representations of Systems (of Equations)*. For the study I conducted semi-structured individual clinical interviews which I video recorded and analyzed. The content of this report is based on my interview with Felix, a university student enrolled in a junior-level applied linear algebra course.

The theoretical lens for my analysis was a theory I developed, the Theory of Quantitative Systems, which was motivated by Duval’s (1999, 2006, 2017) Theory of Semiotic Representation Registers. (Note that in addition to this contributed report, I have submitted a theoretical report delineating my theory.) Briefly, in my theory I declare that mathematical systems such as matrix algebras, the algebra of real numbers, and vector spaces fit Duval’s definition of registers of representation (systems of notation with specific symbols and rules). Translations of algebraic expressions within the same register are referred to as treatments, while translations of algebraic expressions between differing registers are referred to as conversions. Duval hypothesized that two sources of incomprehension in mathematics are: 1) the kind of cognition required to perform treatments and how it contrasts with 2) the kind of cognition required to perform conversions.

The need for attending to notational distinctions in linear algebra was documented by Hillel (2000), Pavlopoulou (1994), and Artigue, Chartier, & Orier (2000). Hillel (2000) studied video-recorded sessions of lecturers teaching on the topic of eigenvectors and eigenvalues. He noted that the experts moved fluidly between various representations, giving little notice to the nuances of notation and meaning. Using “graphical”, “symbolic”, and “tabular” as categories of registers of representation, Pavlopoulou’s (1994) dissertation study, experimental in design, allowed her to obtain important and convincing results in linear algebra (Artigue, Chartier, & Orier, 2000). Artigue et al. (2000) called for investigations that would check the consistency of Pavlopoulou’s results in contexts that are richer and more complex. I am aware of only one such follow-up study; Sandoval & Possani (2016) considered students’ conceptions of vectors and planes in $\mathbb{R}^3$. While their study centered strongly on the geometric, I focus on the algebraic.

My semi-structured interview with Felix unfolded in such a way that I could address two questions. First, I set out to address the question “What is the nature of Felix’s understanding of vector space operations?" Next, I considered "How might I influence Felix's thinking about changes in register?" In terms of the Theory of Quantitative Systems (TQS) and the Theory of Semiotic Representation Registers (Duval, 1999, 2006, 2017), the first question is about Felix's work with treatments. In terms of the theories, the second question addresses Felix's work with a conversion. Each question is addressed following a discussion of Felix's initial use of metaphor in our interactions.

The task that I had Felix consider was comparing and contrasting various representations that may come up in solving a system of linear equations. Ten students who participated in individual video- and audio-recorded clinical interviews were initially asked to compare and contrast the first three representations shown in Figure 1. Next, I presented participants with the fourth representation shown in Figure 1 and asked them to comment further. I refer to the representations, from left to right, as the augmented matrix, the matrix equation, the vector equation, and the linear system.

$$\left[\begin{array}{cc|c} 1 & 2 & 7 \\ 4 & -1 & 1 \end{array}\right] \qquad \begin{bmatrix} 1 & 2 \\ 4 & -1 \end{bmatrix}\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 7 \\ 1 \end{bmatrix} \qquad x\begin{bmatrix} 1 \\ 4 \end{bmatrix} + y\begin{bmatrix} 2 \\ -1 \end{bmatrix} = \begin{bmatrix} 7 \\ 1 \end{bmatrix} \qquad \begin{cases} x + 2y = 7 \\ 4x - y = 1 \end{cases}$$

Figure 1. Four representations of system.

Felix's Metaphor

Felix largely described the various representations in terms of how they appear on paper. For instance, he described the augmented matrix as "before *x* and *y* is placed". He described the matrix equation as "where it was before we multiply it" (referring to the linear system that results from performing matrix multiplication). He described the vector equation as "showing" multiplication not element-by-element, but column-by-column. In addition, Felix described the representations in terms of "columns", "individual pieces", and "one piece". He was apparently describing the coefficient vectors in the vector equation as "columns", the individual coefficients as in the augmented matrix as "pieces", and the coefficient matrix in the matrix equation as "one thing". In other words, Felix acknowledged various units in the representations. In addition to his visual descriptions, he referenced various actions involved in translating between representations, and those actions were not particularly mathematical. In at least four instances, Felix referred to the action of "cutting". Other actions he mentioned were "gluing", "throwing", "tilting", and "multiplying downwards".

Overall, Felix described the various representations in terms of differing units (sub-pieces of algebraic expressions) that get put together in various ways. I would say that Felix was using a *cut-and-paste metaphor* for translating between representations. That is, he seemed to group symbols into different pieces, some larger and some smaller, while describing the action of translation in terms of rearrangement. This regrouping and rearranging of units might be referred to as imagistic (Clement, 1994) since Felix seemed to act (mentally) on the representations using dynamic imagery. In other words, Felix used dynamic imagery as a means to account for what happens between the source representation and the target representation. The cut-and-paste metaphor allowed Felix to view the translations as transparent, where the target representation is obvious from the source representation, given his mental activities. With his cut-and-paste metaphor, Felix seemed to be rearranging various units (pieces) of notation without much consideration of the mathematics. That is, I questioned whether Felix had good *structure sense*, which I take as the parsing of algebraic notation into appropriate mathematical units. (Structure sense is an area of interest for me; I use the term differently than it is used in existing literature.)

Felix gave some indications of mathematical foundations for his cutting and pasting by frequently referring to multiplying and using mathematically correct terminology like “vector”, “columns”, and “element”. However, while I was conducting the interview, I was uncertain about what mathematics might or might not underlie his metaphor. Opportunities that allowed me to address my uncertainty presented themselves. As a result, I was able to investigate the mathematical underpinnings for his cut-and-paste metaphor in two ways. First, I set out to investigate his understanding of vector space operations. Next, I worked to influence his thinking about a change in register.

Felix’s Developing Conceptions

While Felix did not initially attend to mathematical rigor in his descriptions of the various translations, I got the impression that reflection and deep thinking were mathematical practices for him. For instance, he mentioned that his experience of being introduced to row reduction left him with the impression that it was an entirely new topic. In trying to make sense of the morass of calculations involved in row reduction, he was able to tie the process back to the elimination method he had learned earlier in his schooling. In time he came to see row reduction as an extension of the elimination method.

Another instance that seemed particularly insightful was Felix’s comparison between coordinate systems and the four representations shown in Figure 1. He compared the four representations, which he viewed as representative of a linear system (the last representation in Figure 1) to using polar coordinates instead of Cartesian ones; he seemed have in mind how varying systems of notation can be used to indicate the same thing. The two instances I have described along with my overall experience of our interview suggested to me that Felix could provide potentially valuable insights into students’ thinking about vector space operations and changes of register. I followed up on my impression as described in the next two sections.

Working with Treatments (Considering Vector Space Operations)

Possibly, the four representations under consideration were so obviously transparent (visually similar) to Felix that it did not occur to him to describe the translations in terms of mathematics. In the moment of the interview, his descriptions did not make it apparent that he was doing more than visually manipulating the symbols. I was able to get a more complete picture of Felix’s conceptions by discussing the vector space operations of scalar multiplication and vector addition. (Our latter interactions support that transparency and visual symbol manipulation were, in all likelihood, both parts of Felix’s conception.) Of the first three representations in Figure 1, Felix stated: “This way (pointing to the augmented matrix) you can solve with row-reduced echelon form. And this one (pointing to the matrix equation), if it’s invertible, we can just do an inverse matrix. And for this one (pointing to vector equation)…” (long pause) “… I don’t think I know of a way to solve it with this notation”. I saw Felix’s admission as a perfect opportunity to divert from my interview protocol.

I asked Felix to solve the system using the vector equation (the third representation in Figure 1) after he expressed doubt in his ability to do so. (I take his admission as evidence that, to some extent, he had previously been engaging in visual symbol manipulation rooted in his cut-and-paste metaphor.) I asked Felix, “If x is a scalar, how do you multiply it by the vector?” Felix responded, “Just multiply by each element”. The written work he produced upon answering appears in line 2 of Figure 2. Note that I felt it might be necessary to described x as a scalar in case Felix had a surface view of x as a variable without attributing to it the additional role of scalar within a vector space; further, the possibility existed that Felix had only seen scalars that were real numbers.

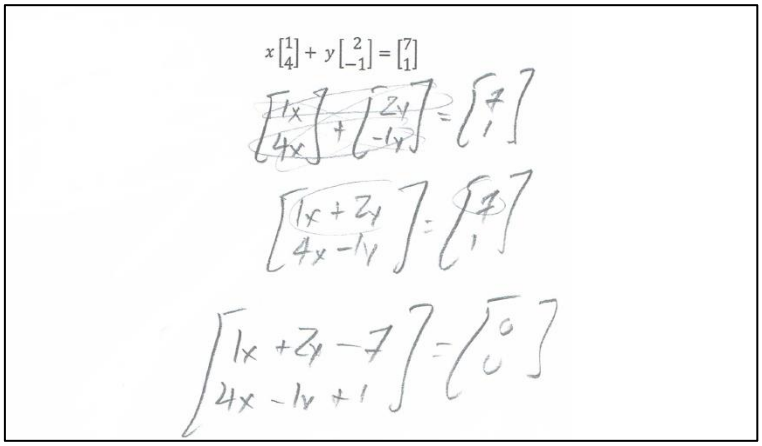

Figure 2. Felix's Written Work.

Next, I framed Felix's written result in line 2 of Figure 2 as the sum of two vectors. I pointed to the left-hand side of the equation in line 2 of Figure 2, and asked, "How do you add two vectors?" Felix stated, "So just add the corresponding elements." Then he mumbled and wrote line 3 of Figure 2. My expectation was that Felix would next write a system of equations; however, he did not. Rather, he stated, "You could even go as far as like…go one step further." He then mumbled while writing line 4 of Figure 2. In terms of my and Duval's theories, Felix performed a treatment in the vector space register rather than performing, as I expected, a conversion between the vector space register and the linear systems register. His work in line 4 is evidence of a propensity to continue working in the same register rather than changing registers. An open question is if students in general exhibit such an inclination to perform treatments rather than conversions. Sandoval & Possani (2016) found some such evidence.

In summary I set out to investigate Felix's understanding to address what I saw as a less-than-impressive display of formal mathematics in his cut-and-paste metaphor. To be clear, I see Felix's metaphor as an enlightening and potentially productive as a way of thinking. However, in the moment that I was conducting the interview, his descriptions were confusing mixtures inconsistent with other profound statements he had made. What I found was that with framing in terms of mathematical terminology and ideas that Felix connected to, mathematical underpinnings that were absent in his metaphorical descriptions were revealed. Specifically, I framed the problem by suggesting that *x* is a scalar and that the result of the scalar multiplication is the sum of two vectors. Further, I encouraged Felix with a statement and a question: "You know how to multiply by a scalar" and "How do you add two vectors?" Felix accurately described and enacted the vector space operations of scalar multiplication and vector addition. In other words, Felix was able to perform a series of treatments in the vector space register as shown in Figure 2. This suggests that, while Felix's descriptions tended to be metaphorical and imagistic, his conceptions were not without mathematical foundations.

Supporting a Conversion Mathematically

My expectation was that Felix would write a system of equations from line 3 of his written work (Figure 2). Since he performed a treatment in the vector space register instead, I took the opportunity to investigate if he could develop a mathematically logical foundation for the translation from the vector register to the linear systems register. I note that Felix was interested in, and therefore able to, engage in the conversation. Not all interview participants (10 students) seemed interested in investigating and developing connections. However, Felix's interest in making connections had become apparent during our interview as evidenced by the explanations he often constructed for himself. Recall, for instance, his connection between row reduction and the elimination method, and his comparison of the representations shown in Figure 1 to Cartesian versus polar coordinates. My attempt to influence his thinking is documented in our dialogue shown in Figure 3.

When I suggested (line 1, Figure 3) to Felix that some people go directly from what he wrote in line 3 of Figure 2 to writing a system of equations, Felix acknowledged that the translation "seems kind of weird" (line 6, Figure 3) since "we're just kind of getting rid of the vector". While I described the translation as getting "rid of the brackets" (line 7, Figure 3), Felix spoke in terms of getting "rid of the vector" (lines 6 and 8, Figure 3). I assumed that his coursework had required him to enact the translation, so I saw Felix's statement that the translation was "weird" as evidence that he had become uncomfortable with the "disappearing vector" approach. Additional evidence of his discomfort/curiosity is supported by his subsequent enthusiastic reaction, asking a question in three ways (line 8, Figure 3): "Why did you get rid of the vector? What happened to the vector? Why is the vector not there anymore?"

1	*Interviewer*:	So some people go from this (pointing to line 3 of Figure 2) straight to writing a system, which we have written here somewhere.
2	*Felix*:	Yeah, like this. (pointing back to the systems representation on some of his earlier work.)
3	*Interviewer*:	Why can I write a system from this? (pointing to line 3 of Figure 2) When I multiply these out, I should be getting matrices, right? Or these are actually vectors? Do you see those as vectors? (I tend to think in terms of matrices, but Felix had been calling them vectors.)
4	*Felix*:	Um-hmm.
5	*Interviewer*:	How can I go from having a vector to having a system? How can I explain that mathematically?
6	*Felix*:	Yeah, trying to explain it from just looking at this (pointing to line 3 of Figure 2) seems kind of weird because we're just kind of getting rid of the vector.
7	*Interviewer*:	You just get rid of the brackets, right?
8	*Felix*:	Yeah, you just get rid of the vector. But then the question comes up, why did you get rid of the vector? What happened to the vector? Why is the vector not there anymore?
9	*Interviewer*:	(I laugh.) Yeah, that's my question!
10	*Felix*:	Yeah!
11	*Interviewer*:	What if you think about it as a matrix rather than a vector? Does that help any?
12	*Interviewer*:	What makes two matrices equal? How do you know two matrices are equal?
13	*Felix*:	If the corresponding elements equal to each other.
14	*Felix*:	So this would equal that!
15	*Felix*:	Yeah, but that IS the definition of a matrix, and if they know how to identify if they are the same.
16	*Interviewer*:	What does matrix equality mean?
17	*Felix*:	Yeah, *matrix equality*.

Figure 3. A dialogue about a change in register.

Next, I asked Felix if thinking in terms of matrices would help resolve the issue (line 11, Figure 3). I then followed up by asking, “What makes two matrices equal?” (line 12, Figure 3). I did this since I supposed that he might be more familiar with the tenets of matrix algebra than with the tenets of vector spaces. Specifically, I thought the idea of “matrix equality” might be a more familiar idea than that of “vector equality”. Felix responded, “If the corresponding elements equal to each other” (line 13, Figure 3). At that point Felix seemed to have an epiphany. In an animated way, he circled the first entry of each of the vectors/matrices as shown in line 3 of Figure 4. While circling the top two components, he stated “So this would equal that!”(line 14, Figure 3). Next, Felix extended his written work by drawing an arrow from line 3 and writing the first equation of the system as shown in the final line of Figure 4.

Felix had apparently realized that the equations for the linear system result from equating corresponding elements of the matrices (vectors). In his next statement, Felix seemed to be describing the essence of matrix equality (line 15, Figure 3): “but that IS the definition of a matrix, and if they know how to identify if they are the same”. I gave Felix a name for his description by asking (line 16, Figure 3): “What does matrix equality mean?” He latched onto the terminology, stating “Yeah, *matrix equality*.”

$$x\begin{bmatrix}1\\4\end{bmatrix} + y\begin{bmatrix}2\\-1\end{bmatrix} = \begin{bmatrix}7\\1\end{bmatrix}$$

$$\begin{bmatrix}1x\\4x\end{bmatrix} + \begin{bmatrix}2y\\-1y\end{bmatrix} = \begin{bmatrix}7\\1\end{bmatrix}$$

$$\begin{bmatrix}1x+2y\\4x-1y\end{bmatrix} = \begin{bmatrix}7\\1\end{bmatrix}$$

$$\begin{bmatrix}1x+2y-7\\4x-1y+1\end{bmatrix} = \begin{bmatrix}0\\0\end{bmatrix}$$

$$1x+2y=7$$

Figure 4. Felix’s Addendum to His Written Work

As a result of my influence, Felix seemed to have constructed mathematical support for the conversion from the vector register to the linear systems register. In other words, Felix became able to mathematically justify why a system of equations can be extracted from a representation involving only vectors (or matrices depending on one’s perspective/language). I assert that for Felix, an unreflected, taken-for-granted step in a solution process had become a translation rooted in mathematical logic.

A Note on Methodology. I would describe my work with Felix on the change in register as an impromptu, mini teaching experiment. By *impromptu*, I mean I acted on an opportunity that presented itself during the clinical interview and took a diversion away from my intended interview trajectory, a practice encouraged by Hunting (1997). I use *teaching experiment* in the sense that Steffe & Thompson (2000) prescribed; I tend to think of these experiments as being individual and/or small group (not whole class experiments) and cognitive in nature. Steffe and Thompson elaborated the idea of a teaching experiment as a living methodology; the experiment may occur over several sessions with adaptions taking place between sessions. Such a teaching experiment involves a great deal of thinking and planning to conduct a conceptual analysis of a math concept prior to the development of an experimental teaching sequence. The process includes considering how to influence the student's thinking in productive ways, and the researcher must be adaptive both within and between sessions when the student responds in ways that are not expected. Clearly, my work with Felix occurred within a single session. While I did not have a formal conceptual analysis and experimental instructional sequence written out, I had ones in mind from several years of repetitively teaching multiple sections of College Algebra. I believe recognizing the opportunities that presented themselves in my interview with Felix was only possible given my prior experience with teaching students to solve systems using matrices.

As I see it, the appeal the of teaching experiment methodology is that inherent in it are pedagogical suggestions. While documenting students' thought processes through individual clinical interviews is a productive undertaking in itself, pedagogical recommendations can only be hypothesized subsequent to the investigation. In contrast, the teaching experiment, puts on display a pedagogical approach that data from interviews supports as productive, unproductive, or needs improvement.

Conclusions

Students mathematical conceptions may not be mathematically rigorous for a variety of reasons. While students may use visual techniques, heuristics, metaphors, and rehearsed algorithms, experts can mathematically support such approaches when they recognize that students are using them. This is what I did with Felix in two distinct ways.

Initially, Felix accounted for translations primarily by using dynamic imagery which I have designated the *cut-and-paste metaphor*. With support, however, he was able to voice his knowledge of vector space operations and to carry them out. Further, a change of register that he had seemingly taken for granted prior to our interview became a matter of importance for him. With support Felix was able to construct mathematical justification for the conversion and resolve the conflict he encountered.

Since I have argued that teaching experiments have direct pedagogical implications, I will say a bit more about my interaction with Felix. I believe I did three key things to support Felix's mathematical realization. First, I drew his attention to the change in register (line 5, Figure 3). Apparently, he had not previously acknowledged it, but I sensed that he might be capable of considering the distinction. Next, I changed my language to match his language (lines 3 and 5, Figure 3). I was thinking in terms of matrices; but he was speaking in terms of vectors. Third, I attempted to help him shift from his vector perspective to my matrix perspective (line 11, Figure 3), believing that my language might enlighten him in ways that his language did not. The key, I believe, was in navigating between the student's language and conception (acknowledging where he was) and attempting to steer him to what I believed might be a more productive perspective based on my experience of teaching students about matrices. As a result of my influence, Felix seemed to have constructed mathematical support for the conversion from the vector register to the linear systems register.

I make one additional note that Felix is an existence proof that students can have their interest piqued in such things as changes in register. I found other instances of students attending to differences in register in my larger study of university students enrolled in a junior-level applied linear algebra course.

Linear Algebra Thinking in the Embodied, Symbolic and Formal Worlds: Students' Reasoning behind Preferring certain Worlds

Sepideh Stewart
University of Oklahoma

Jonathan Epstein
University of Oklahoma

To understand linear algebra concepts, one needs to be familiar in many different modes of thinking. Mathematicians often move between these modes of thinking fluently and expect that students will pick up the main ideas along the way. Yet, a majority of students do not have the cognitive framework to perform the move that is so natural to mathematicians. Employing Tall's (2013) three-world model, in this research a set of linear algebra tasks were given to students in order to encourage them to move between Tall's embodied, symbolic and formal worlds of mathematical thinking. Our working hypothesize is that by creating opportunities to move between the worlds, students may be exposed to multiple modes of thinking which results in richer conceptual understanding. The results of a survey revealed that a majority of students preferred the symbolic world. Their reasoning for their choices will be discussed.

Keywords: linear algebra, embodied, symbolic, formal

Introduction

Hillel (1997, p. 232), outlined three types of languages in linear algebra: "The language of the general theory (vector spaces, subspaces, dimension, operators, kernels, etc.); The language of the more specific theory of R^n (n-tuples, matrices, rank, solutions of the system of equations, etc.); The geometric language of 2- and 3- space (directed line segments, points, lines, planes and geometric transformations)". He believed that these languages are interchangeable, but are not equivalent. In Hillel's (1997, p. 233) views "knowing when a particular language is used metaphorically, how the different levels of description are related, and when one is more appropriate than the others is a major source of difficulty for students". Dreyfus (1991, p. 32) believed that, "one needs the possibility to switch from one representation to another one, whenever the other one is more efficient for the next step one wants to take… Teaching and learning this process of switching is not easy because the structure is a very complex one." Duval (2006) believed that students' difficulties with comprehending mathematical ideas is due to their lack of flexibility between moving between registers, as most students do not have the cognitive structure to perform the switch that is available to the expert. In his views, "changing representation register is the threshold of mathematical comprehension for learners at each stage of the curriculum" (p. 128). To understand the nature of movements between modes of thinking of a group of linear algebra students in this study we employed Tall's (2013) three worlds of embodied, symbolic and formal mathematical thinking.

Theoretical Background

Tall (2010) defined the worlds as follows: The embodied world is based on "our operation as biological creatures, with gestures that convey meaning, perception of objects that recognise properties and patterns...and other forms of figures and diagrams" (p. 22). Embodiment can also be perceived as giving body to an abstract idea. The symbolic world is based on practicing sequences of actions which can be achieved effortlessly and accurately as operations that can be expressed as manipulable symbols. The formal world is based on “lists of axioms expressed formally through sequences of theorems proved deductively with the intention of building a coherent formal knowledge structure” (p. 22).

Using Tall’s model, Stewart, Thompson and Brady (2017) investigated a mathematician’s (and co-author) movements between Tall’s worlds while teaching algebraic topology. In this study, the instructor reported that students experienced the most difficulty in moving from the embodied world into the formal world. Believing the struggle would stimulate mathematical growth in his students, this instructor “refused to give students proofs that were pre-packaged. More specifically, he wanted to provide students with intuitions and pictures that would help them understand the conceptual nature of the proof and ultimately lead them to it” (p. 2262).

Although, moving between the worlds is a natural part of doing mathematics for many mathematicians, our studies suggest that many students are not as eager to move. For example, Stewart, Troup and Plaxco (2019a) created a model of instruction to investigate a linear algebra instructor’s movements between Tall’s (2013) three worlds of mathematical thinking. The study revealed that despite instructor’s intentions in moving the class between the worlds, his students were reluctant to move. In a case study, Hannah, Stewart and Thomas (2014) found that a majority of first-year linear algebra students preferred to stay in the symbolic world. Other studies in linear algebra have considered the relationship between formal and other approaches and have demonstrated that developing teaching approaches that promote formal ideas is valuable. For example, Wawro, Sweeney, and Rabin (2011) considered students’ concept images of the notion of subspace and found that students made use of geometric, algebraic and metaphoric ideas to make sense of the formal definition. Zandieh, Wawro, and Rasmussen (2017) analysed data of students engaging in symbolizing a variety of linear algebra tasks in classroom. In a study by Stewart (2018), nine linear algebra tasks were created to encourage the learners to move inside and in between the three worlds. The creation of suitable tasks is one of the crucial aspects of helping students to move between different modes of thinking.

In this paper, we will investigate, students’ reasoning in moving between Tall’s worlds via a survey after doing a task designed by the instructor in class. The research questions guiding this study were: (a) Which was the most comfortable world for students and why? (b) What were some of the factors causing the students to move between Tall’s worlds, if any?

Method

As part of a larger study (Stewart, Epstein, & Troup, 2019b), this research involves an introductory linear algebra class at a Southwestern research university. There were 38 students, mostly engineering majors in their second or third years of study, and the instructor was a mathematician specializing in differential geometry. This paper focuses on a period of approximately one week following the first midterm exam, which covered matrix algebra, linear systems, Gaussian elimination. During the first class period following the exam, Tall’s (2013) Three Worlds were presented by the instructor. This involved a description of each world followed by a representative piece of mathematics, and a diagram, taken from Tall’s (2013) book demonstrating how the worlds are not necessarily disjoint, but instead weave together creating mathematics as we know it. In order to see what effect empowering the students with knowledge of Tall’s worlds would have they were given an activity which offers the opportunity to inhabit or move among all three worlds. We describe this activity now.

The activity explores the connection between the number of solutions to a linear system, the configuration of the lines or planes determined by the system, and the reduced row echelon form of the system's associated augmented matrix. In the first part of the activity (see Figures 1a and 1b), students are provided with a GeoGebra file which displays a linear system with two

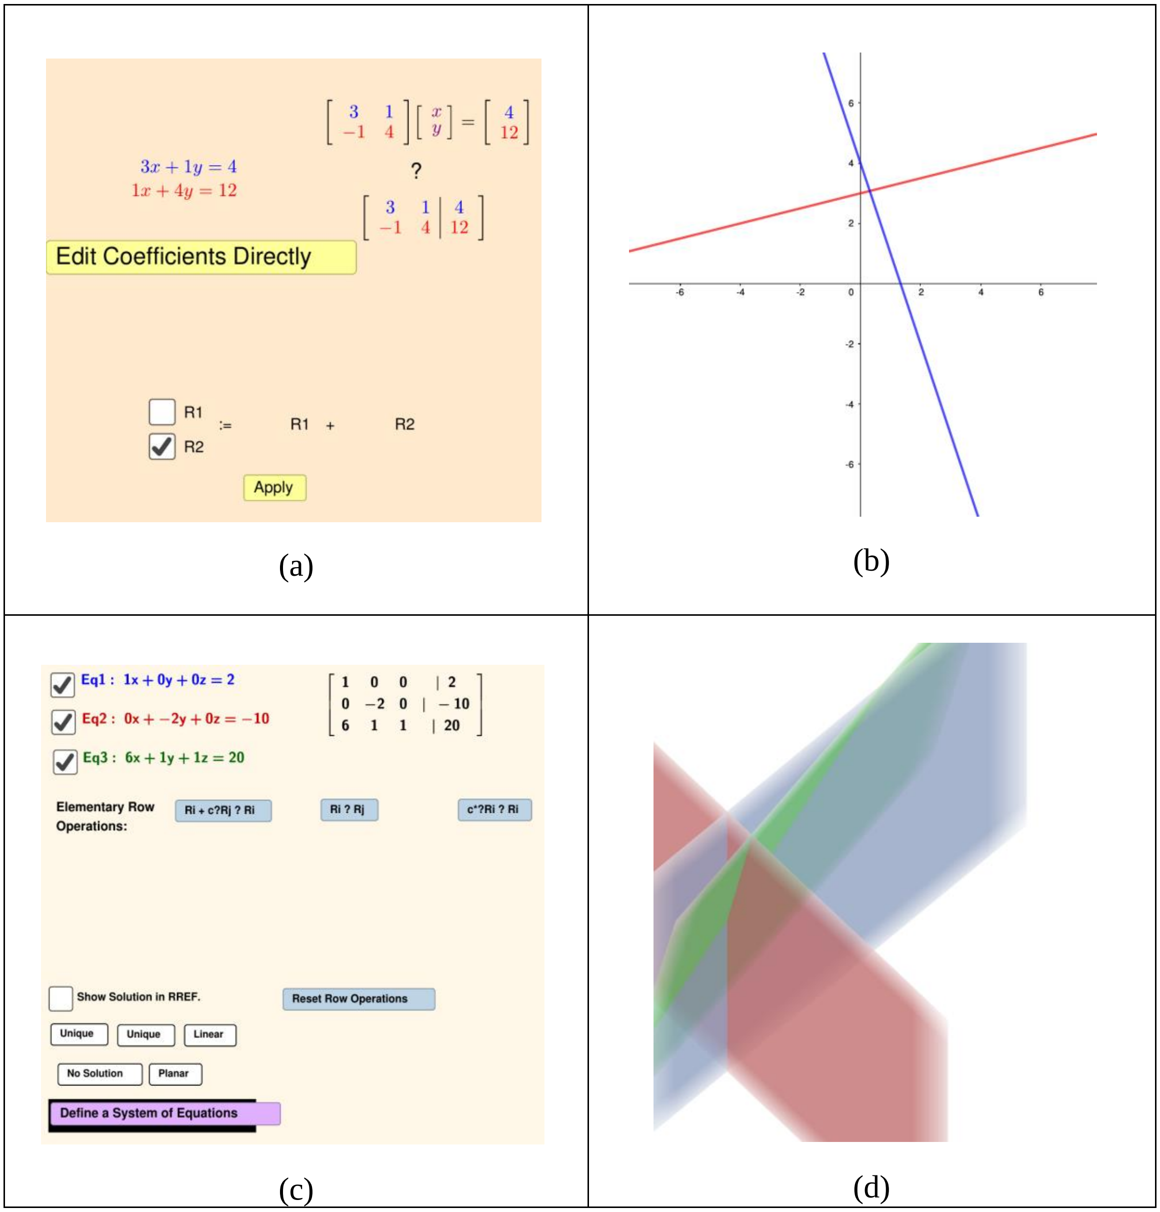

Figure 1. Geogebra tasks.

unknowns and two equations in three ways (as a linear system, in matrix algebraic notation, and as an augmented matrix), while also displaying the two lines determined by the system on the right-hand side. The worksheet also allows one to apply row operations to the system, immediately updating all the notations and graphics. After familiarizing themselves with the GeoGebra file, the activity asks the students:

1. Use Gaussian elimination to solve the system. For each step in the process:
    a. decide what row operation is needed;
    b. express the row operation in our notation;
    c. perform the row operation to the system in the GeoGebra worksheet;
    d. and sketch the graphs of the equations that result.
2. Imagine that the graphs from each step are frames in a movie (like a flip-book). What remains constant throughout the movie? What changes throughout the movie?

In the second part of the activity, the students use a similar GeoGebra file (by James Factor) to explore the effect of Gaussian elimination on linear systems with three unknowns. The interface for applying row operations is shown on the left-hand side in Figure 1c, while the three planes determined by the systems are shown graphically on the right-hand side in Figure 1d (by James Factor). For four systems $\mathbf{A}x = \mathbf{b}$, the students are asked to "examine the graphs of the planes and deduce the reduced row echelon form of the augmented matrix $[\mathbf{A}|\mathbf{b}]$. As in class, use the symbols 0, 1, $*$ to express your answers. If necessary, use row operations to help determine your answers."

While working through this activity students can choose to inhabit any of the three worlds, or move between them. The symbolic world is available via the algorithmic procedures of Gaussian elimination and row reduction. The graphical component of the activity, provided by GeoGebra, gives access to the embodied world. Lastly, the questions regarding abstract reduced row echelon forms allow students to inhabit the formal world by systematizing observations and making general statements about entire classes of linear systems. The following week a survey was administered. The survey questions were: Q1: With your understanding of the definition of the three worlds, which of the worlds (possibly more than one) were you inhabiting while working on Worksheet 8 last week? Q2: Which of the worlds are you most comfortable inhabiting? Why?

In this study the research team converted the worksheet results into Excel spreadsheets to expedite an open coding (Strauss & Corbin, 1998) and sorting the data to search for themes after coding. The analysis of the survey from 15 students who agreed to take part in this study is discussed.

Results

The data was coded according to which worlds were indicated by the students. If a response indicated that one world was primarily inhabited while a another was secondary, it was coded for both of the worlds, etc. For each of the six possible combinations of worlds and for each of the two survey questions, Table 1 shows how many responses indicated that combination.

Table 1. The codes.

Tall's (2013)Worlds	Survey Question 1	Survey Question 2
Embodied (E)	0	2
Symbolic (S)	2	10
Formal (F)	0	0
ES	7	3
EF	2	0
SF	2	0
ESF	2	0

In response to the first survey question, we observed that S2 predominantly commented on the embodied world aspect of the activity, but also remarked on the symbolic facets of the task. Whereas, S9 felt that she or he originally was in the symbolic world and then was forced to go into the embodied world.

S2: Mostly the Embodied world. Using the Geogebra software we could physically see how the concepts we were analyzing manifested themselves as manipulable intersecting lines. There was also an element of the symbolic world involved as we manipulated the equations using the elementary operations.

S9: I think I was in the symbolic world because we were given matrices. I think I was then forced into the embodied world by comparing the matrices with the corresponding visuals.

On the other hand, S11 was completely content to carry on in the symbolic realm, despite the fact that the visual aspects of the task could have potentially added to her or his knowledge.

S11: While working on worksheet #8, I was inhabiting mostly the symbolic world, bordering on the embolic and formal world. My mind is more computationally driven, so I started immediately manipulating the matrix into reduced row echelon form. I occasionally checked the graphs on the right to see what was going on in the embolic world. Then after completing my computation, I took a step back at the big picture, how what I was doing computationally could be formalized for all dimensions beyond R^2 and R^3.

Interestingly, both S5 and S14 did not make any comments about the embodied aspects of the task. S14 was only concerned with the symbolic parts of the task, however in general felt more comfortable in the embodied world.

S5: I think worksheet 8 is based on the symbolic. Yes, there are axioms and laws to follow while working on the worksheet, but the work is pretty cut and dry and does not need much interpretation.

S14: 1 seemed to be more in the symbolic while 2 was also symbolic knowing the terminology would have been more in the formal. The symbolic was due to the following of the steps and the formal was just due to needing to know what the gaussian elimination.

Inhabiting in the Symbolic World

We noted that, many students in this study preferred the symbolic world. Their justifications for favoring this world included comments such as: “very interesting way of looking at things mathematically” (S1), “makes sense and follows a concrete and fathomable set of rules” (S2). Three students referred to their past experiences and argued that: “where most of my recent math education has been focused” (S6), “Ever since I was little, the symbolic world was easier to relate the number” (S8), and “because in a long time I was study in that way. When I was in China they do the practicing sequences of actions a lot” (S13). Another student pointed out that: “it is far more intuitive than the formal world” (S9). One student went as far as saying that: “In the symbolic world, I can clearly and effectively express my ideas through symbols that are agreed upon and understood by the mathematical community” (S4). It seems that these students desired working in this world based on their past experiences and the fact that their view of mathematics could mainly include calculations and following rules. Furthermore, since students can be successful in manipulating the symbols, there is no need to consider other ways of tackling a problem. For example, the following students call the formal world harsh and believe that maybe the embodied world would be somewhat limiting, and more complex ideas are difficult to express in this world.

S1: The embodied is almost meaningless without some structure, and the formal is a bit harsh, at least mentally.
S4: Mathematical concepts can quickly run out of space in the embodied world.
S15: The embodied world is relatively straightforward, but more complex ideas are very difficult to express in this form.

Inhabiting in the Embodied World

Only two students expressed their tendencies for the embodies world and strikingly linked that to understanding. S14 also acknowledged a need for knowing more formal understanding as well.

S7: I personally am a very visual learner so I am most comfortable inhabiting the embodied world because it shows information in the form of figures, diagrams, and other visual aspects. The embodied world is easier for me to understand.
S14: I am more comfortable with the embodied form. I am more of a visual person that needs to see how an equation relates to real life situations or at least many examples so I can understand what something means. I know I need more of a formal understanding because I am taking flight controls next semester in which will rely heavily in the formal.

Inhabiting in the Embodied and Symbolic Worlds

The results also revealed two students' willingness to dwell in both embodied and symbolic worlds simultaneously. S3 admits that she or he is *still* living in these worlds. The main rational for this is the need to have a picture and the fact that the formal world is too abstract.

S3: I am still in embodied and symbolic world. I would say formal world would be too abstract for me to have a picture on my mind. Embodied is easier because it is fun and real. Symbolic can help manipulate the embodied.
S12: I am by far the most comfortable with the embodied and symbolic worlds. I am a very visual learner, and I struggle with taking abstract ideas and applying them to new situations. I learn best by repetition, which lends itself to both the embodied and symbolic worlds.

Discussion and Concluding Remarks

As the researchers were seeking to understand how and why students move between Tall's worlds (2013), they decided to empower the students by giving them the three-world framework and terminology in class. The activity presented them with a situation in which they could inhabit and move between the worlds, and their reflections are a window onto how they viewed themselves operating within the three-world framework. To the extent that mathematicians operate in all three worlds, what inhibited or promoted simultaneous inhabitation of the three worlds? In line with our previous findings (Hannah et al., 2014), most students remained primarily in the symbolic world during the activity and stated that they are most comfortable there. However, several students gave illuminating reasons. The finiteness of the embodied world present obviously limitations, when the goal of the mathematics is to create general statements or theorems. On the other hand, it is difficult to articulate those general statements without a fluency in the use of symbols. Hence the student preference for the symbolic world may be caused not only by the ease of rote symbolic manipulations, but also by the fact that the symbolic world plays a role in the other two. In Tall's views, "As mathematical ideas progress into more sophisticated levels, the balance between embodiment and symbolism changes" (2013, p. 408). He also adds that "Over the longer term, embodied strategies may give insightful meaning at various stages of development, but as the mathematics becomes more complicated, symbolic strategies offer greater power and precision" (p. 407).

This study suggests a way of encouraging more organic movement between the worlds. By investing time preparing the students to express embodied notions and to articulate general statements in symbols, this natural barrier to moving from the embodied and formal worlds to the symbolic could be diminished. We also believe that once students arrive to a new world, in order to mathematically grow they need to be supported and nurtured.

Acknowledgements

We would like to thank Jonathan Troup and David McKnight for their tremendous contributions to this project.

Reasoning Covariationally about Constant Rate of Change: The Case of Samantha

Michael Tallman
Oklahoma State University

John Weaver
Oklahoma State University

We present the results of a teaching experiment designed to foster a pre-service secondary teacher's construction of a scheme for constant rate of change through engendering reflecting and reflected abstractions. Although the research participant developed a productive conception of rate of change as an interiorized ratio, images of chunky continuous covariation imposed an obstacle to her ability to reason efficiently across a variety of contexts. The participant's rate of change scheme was grounded in reflected abstraction, which enabled her to become consciously aware of its essential aspects and to appreciate its applicability across a variety of contexts.

Keywords: Algebraic thinking, Reflected abstraction, Pedagogical content knowledge

Introduction

We previously reported the results of a study that examined the effect of a pre-service secondary teacher (Samantha) having constructed a scheme for constant rate of change grounded in reflecting and reflected abstractions (Tallman & Weaver, 2018). Specifically, we concluded that the conscious awareness of mental actions and conceptual operations constituting Samantha's scheme for constant rate of change—which resulted from having engaged in reflected abstraction—had positive implications for her image of effective teaching and for the pedagogical actions she envisioned enacting to conform to this image. The central findings of Tallman and Weaver (2018) challenge the assumption that *pedagogical content knowledge* (Shulman, 1986, 1987) is a synthesis of knowledge of content and knowledge of pedagogy (Depaepe, Verschaffel, & Kelchtermans, 2013). Tallman and Weaver did not, however, document the specific features of the mathematical intervention that enabled Samantha to construct a scheme for constant rate of change implicative in her instructional goals and supportive of her pedagogical approach. Such is the focus of this paper.

We present the results of a teaching experiment designed to foster Samantha's construction of a scheme for constant rate of change through engendering *reflecting* and *reflected abstractions* (Piaget, 2001). Our objective in doing so is to clarify how mathematics faculty at the undergraduate level might support pre- and in-service teachers' construction of mathematical schemes that enable effective pedagogies, rather than to maintain the traditional practice of teaching content and pedagogy separately with the expectation that these distinct knowledge domains will unify in the context of practice to support effective instruction.

Theoretical Background

Piaget proposed abstraction as the mechanism of scheme construction and refinement and distinguished five varieties: *empirical*, *pseudo-empirical*, *reflecting*, *reflected*, and *meta-reflection* (Piaget, 2001). We summarize only *pseudo-empirical*, *reflecting*, and *reflected abstraction* because of their unique role in the construction and refinement of mathematical schemes and because these three types of abstraction served as design principles and analytical constructs for our teaching experiment.

Pseudo-empirical abstraction occurs when a subject abstracts properties of objects that have been modified by or created through the subject's actions and enriched by the properties drawn from their coordination (Piaget, 1977). In pseudo-empirical abstraction, the subject does not disassociate the action from the object nor the object from the action. What the subject abstracts, then, is not simply a property of the object (as in empirical abstraction) nor the action that produces or modifies the object, as in reflecting abstraction (see below), but a property of the object that is produced by and which, crucially, *represents* the action of the subject.

Reflecting abstraction involves the subject's reconstruction on a higher cognitive level of the coordination of actions from a lower level, and results in the development of *logico-mathematical knowledge*, or schemes at the level of *operative thought*. Reflecting abstraction is thus an abstraction of actions and occurs in three phases: (1) the *differentiation* of a sequence of actions from the effect of employing them, (2) the *projection* of the differentiated action sequence from the level of activity to the level of representation, or the reflected level, and (3) the *reorganization* that occurs on the level of representation of the projected actions (Piaget, 2001). Once a subject differentiates actions from their effect and coordinates them, she is prepared to project these coordinated actions to the reflected level where they are organized into cognitive structures, or schemes.

Reflected abstraction involves operating on the internalized actions that result from prior reflecting abstractions, which results in a coherence of actions and operations accompanied by conscious awareness. It is the act of deliberately operating on the actions and operations that result from prior reflecting abstractions that engenders such cognizance. As a result of the awareness of internalized actions that occurs as a byproduct of reflected abstraction, the subject's ability to purposefully assimilate new experiences to the reflected level provides evidence that she has engaged in reflected abstraction.

Methods

We conducted a teaching experiment (Steffe & Thompson, 2000) to construct a model of Samantha's scheme for constant rate of change and to characterize the evolution of this scheme as she engaged in instructional experiences designed to promote reflecting and reflected abstractions. The fundamental goal of a teaching experiment is to construct a model of another's mathematical realities that is viable with the researcher's interpretation of students' observable behaviors. In the context of a teaching experiment, the schemes that students construct through spontaneous development are brought forth through exploratory teaching, and it is the responsibility of the researcher to discern how students modify their cognitive schemes as they experience specific teaching actions.

Our teaching experiment occurred during Samantha's student teaching semester while she was enrolled at a large university in the Midwestern United States. Samantha participated in eight teaching episodes that each lasted between 60 and 105 minutes. Samantha also attempted problems between teaching episodes and discussed her solutions during the following interview. All teaching episodes were video recorded and selectively transcribed. Members of the research team met between teaching episodes to discuss provisional hypotheses about the current state and development of Samantha's scheme for constant rate of change and to modify tasks for subsequent teaching episodes.

We employed grounded theory procedures (Corbin & Strauss, 2008; Strauss & Corbin, 1990) to analyze the teaching experiment data. Specifically, we began by performing an iteration of open coding to identify instances in which Samantha revealed characteristics of her meanings for constant rate of change and associated ideas (e.g., slope). We then conducted an iteration of axial coding to construct and refine categories of episodes identified with particular codes from the initial open coding. For each category, we articulated the conceptual operations that appeared to inform Samantha's language and actions. Finally, we identified shifts in the meanings Samantha demonstrated and described the instructional actions that appeared to occasion these shifts.

Conceptual Analysis of Constant Rate of Change

In this section, we briefly describe the particular conception of constant rate of change we designed our teaching experiment to support. This conception, together with our image of the actions and abstractions required for its construction, constitutes our central research hypothesis.

A mature rate of change scheme relies upon productive conceptualizations of ratio, rate, and continuous variation. A *ratio* is a multiplicative comparison of the measures of two constant (non-varying) quantities while a *rate* defines a proportional relationship between varying quantities' measures (Thompson & Thompson, 1992). Constructing a rate therefore involves images of *smooth continuous variation* (Thompson & Carlson, 2017), as well as the expectation that as two quantities covary, multiplicative comparisons of their measures remain invariant. A rate is a reflectively abstracted constant ratio (Thompson & Thompson, 1992, p. 7). As such, its construction involves internalizing the coordinated actions entailed in multiplicatively comparing the measures of continuously covarying quantities. *Rate of change* is a quantification of two covarying quantities and results from a multiplicative comparison of changes in the quantities' measures. The rate of change is constant if these changes are proportional. Conceptualizing changes in quantities' measures as quantities themselves involves a *quantitative operation* (Thompson, 1990) with attention to a point of reference (Joshua et al., 2015).

Thompson and Thompson (1992) describe four levels in the development of students' ratio/rate schemes:

> The first level, *ratio*, is characterized by children's comparison of two taken-as-unchanging quantities according to the criterion "as many times as." The second level, *internalized ratio*, is characterized by children's construction of co-varying accumulations of quantities, where the accrual of the quantities occurs additively, but there is no conceptual relationship between ratio of accumulated quantities at iteration x and the ratio of accumulated quantities at iteration $x + 1$. The third level, *interiorized ratio*, is characterized by children's construction of co-varying amounts of quantities, where the amounts vary additively but with the anticipation that the ratio of the accumulations does not change. The fourth level, *rate*, is characterized by children's conception of constant ratio variation as being a single quantity—the multiplicative variation of a pair of quantities as a measure of a single attribute. A *rate* is a reflectively-abstracted conception of constant ratio variation. (Thompson & Thompson, 1992, p. 7-8)

What distinguishes these levels in the development of students' ratio/rate schemes is how they conceptualize the variation of quantities upon which they operate to construct the ratio/rate. In other words, these levels reflect various levels of sophistication in students' *covariational reasoning* (Carlson et al., 2002; Thompson & Carlson, 2017).

Results

Teaching Episode 1: Transition from *Internalized Ratio* to *Interiorized Ratio*

We began the first teaching episode by engaging Samantha in a series of tasks situated in the following context: "While training for a triathlon Clara rides her bike on a long, straight road at a constant rate. She passes under a stoplight while riding." To discern how Samantha conceptualized the covariation of Clara's distance from the stoplight and the amount of time elapsed since she passed the stoplight, we asked her to describe how these quantities vary together.

> *Interviewer*: How are those two quantities—the distance that she is from the stoplight and the amount of time elapsed since she passed the stoplight—how are those two quantities changing together?
>
> *Samantha*: Um, as more time passes she's getting farther from the stoplight.
>
> *Interviewer*: … Could you be more specific?
>
> *Samantha*: … Since she's going a constant rate she'd go the same distance for each change in time. … So if she goes an hour she goes the same amount of miles that she goes the next hour.

Samantha's response reveals her conception of constant rate of change as a correspondence of additive changes in accumulated distance and elapsed time. This meaning for rate is consistent with Thompson and Thompson's (1992) second level (*internalized ratio*) in the development of students' ratio/rate schemes. Samantha appeared to have dissociated elapsed time as an independently varying quantity, but remained focused on discrete accumulations of distance that correspond to one-unit accruals of elapsed time.

We later asked Samantha to describe what it means to say that Clara rode her bike at a constant speed of 12 miles per hour. Her response further supports our claim that chunks of accumulated distance corresponding to one-unit of elapsed time were dominant in her initial meaning for rate:

> Every hour, she goes 12 miles. … You go 12 miles in an hour and then like you're going multiples of 12 I guess for every hour. So you'd take 12 times one, 12 times two. So it'd be 12 times x … where x would be your time in hours.

To perturb Samantha's understanding of speed as a distance and time as a ratio, and to begin to support her conception of an invariant multiplicative relationship between continuously covarying quantities, we prompted her to consider the amount of time it would take Clara to ride 25 miles if she rides at a constant speed of 10 miles per hour. Since the solution is not a whole number of hours, Samantha was positioned to (pseudo-empirically) abstract a constant multiplicative relationship between accumulated distance and elapsed time. She correctly determined that it would take Clara 2.5 hours to travel 25 miles if riding at a constant speed of 10 miles per hour. Samantha justified the 0.5 hour required for Clara to travel the final 5 miles as follows: "If you're assuming that she's goes the same speed the whole time, then you have– a whole hour will take 10 (miles) so since she's going the same speed then a half an hour will take five." Samantha's response suggests an initial step towards the generalization that if Clara travels a fraction of the distance she rides in one hour, it takes that same fraction of an hour, thus revealing a transition towards a conception of rate as an *interiorized ratio*.

We subsequently asked Samantha to determine the amount of time it would take Clara to travel 17 miles if she rides at a constant speed of 13 miles per hour. Her immediate response was to divide 17 by 13, which appeared to have been motivated by a pseudo-empirical abstraction from her activity on the previous task. Although Samantha struggled for several minutes to formulate a coherent explanation for why division is the appropriate operation, aspects of her five-minute response revealed her tentative understanding that a fractional part of a time unit corresponds to the same fractional part of the distance traveled in that time unit (and vice versa).

Samantha's response to a subsequent task ("How long does it take Clara to ride 5 miles from the stoplight if she rides at a constant speed of 9 miles per hour?") further demonstrated her reasoning in a way compatible with Thompson and Thompson's (1992) description of an interiorized ratio. She drew a line segment to represent an elapsed time of one hour and partitioned this line segment into nine pieces that represent consecutive changes in distance of one mile (see Figure 1). This image itself represents Samantha's understanding that one mile (being 1/9th of the distance Clara travels in one hour) corresponds to an elapsed time of 1/9th of an hour. She explained, "There should be nine of them (miles) in an hour. … say she goes five (miles), that's five out of the nine miles, and so since I broke my bar up into ninths, then I have five out of nine of an hour." It is noteworthy that Samantha's solution relied upon having partitioned one hour into the number of miles Clara travels in an hour.

Figure 1. Uniform partition of one hour into one-mile accumulations of distance.

To support Samantha's understanding that the correspondence of fractional parts of a time unit and equivalent fractional parts of the distance traveled in that time unit does not require having first imagined a uniform partition of an hour (where the number of partitions is determined by the number of miles Clara travels in an hour), we directed her focus to Clara's accumulated distance as a whole and prompted her to multiplicatively compare this distance with the corresponding fractional part of an hour. Specifically, we asked, "Five miles is what fraction of the number of miles Clara travels in one hour?" We intended this question to promote her realization that this multiplicative comparison exists without having to construct a uniform partition of one-unit of elapsed time—an understanding essential to constructing a general rate of change scheme to which Samantha might assimilate subsequent tasks. In essence, we attempted to support Samantha's anticipation that *any* distance from the stoplight is some fraction of the distance Clara travels in one unit of time, and that it therefore takes Clara that same fraction of one time-unit to travel that distance. After struggling for several minutes to formulate a response to the question we posed (and various restatements of it) Samantha finally admitted, "I don't understand." The difficulty she experienced stemmed from her conception of the variation of accumulated distance and elapsed time as occurring in chunks (i.e., as changing discretely by intervals of fixed magnitude), a way of thinking Thompson and Carlson (2017) reify as *chunky continuous covariation* (p. 435). We demonstrate how Samantha's chunky continuous covariational reasoning persisted throughout the remainder of the teaching experiment and illustrate its effects on the development of her understanding of rate of change below.

Teaching Episodes 2-5: Solidification of *Interiorized Ratio*

Samantha independently reexamined the tasks from the first teaching episode prior to the second. The second teaching episode began with Samantha describing what she had been thinking about since the conclusion of the prior interview. She read aloud a sentence she wrote to summarize the relationship between accumulated distance and elapsed time for an object traveling at a constant speed: "The fraction (or multiple) of the distance traveled in one hour is the amount of time it takes to go a given distance." Samantha independently applied this understanding to work through the tasks from the first teaching episode, and was ultimately surprised by its general applicability.

After having summarized her activity between the first and second teaching episodes, Samantha responded to the task, "Suppose Clara rides her bike at a constant speed of 16 miles per hour. How far is Clara from the stoplight 0.38 hour after she passed the stoplight?" Samantha reasoned that since Clara rode for 0.38 of an hour, she traveled 0.38 of the distance she would have traveled in an hour, or 0.38 times 16. Her solution to this problem, and several others like it, demonstrates that Samantha had conceptualized rate as an interiorized ratio. We later asked Samantha to consider the following task:

> A swimming pool that is only partially full has 10,800 gallons of water. Water is added to the swimming pool 10:00 AM at a constant rate of 24 gallons per minute. Let Δt represent any change in the number of minutes elapsed while the pool is being filled and let Δv represent the corresponding change in the number of gallons of water in the pool. Write an equation that expresses the relationship between Δt and Δv.

Samantha wrote the equations "$\Delta v = 24(\Delta t)$" and "$\Delta t = {}^{1}/_{24}(\Delta v)$" to express the relationship between Δt and Δv. To justify these equations, Samantha explained, "Since it's 24 gallons per minute, any number of minutes that I'm given, I would multiply that by 24 because I have change in *t* of them, and that would give me the number of gallons in the pool." Samantha's response—as with many others that preceded it—suggest that her conception of rate was grounded in a correspondence of discrete accumulations in covarying quantities' measures, as opposed to being based on images of smooth continuous covariation constrained by a proportional relationship.

We prompted Samantha to explain how her the second equation above expresses the relationship between the change in time elapsed since water started being added to the pool and the corresponding change in the volume of water in the pool. She replied,

> This is the hard part. I mean for every one minute you get 24 gallons, so if you take any chunk of the gallons added, it doesn't matter which chunk you take since 10:00 AM—you could choose 10:30 to 11:00, you know—then you would multiply that by 1/24. It's hard to figure out exactly how you would get there though. … So, in this one (*pointing to the equation* "$\Delta v = 24(\Delta t)$) it's like 24 gallons per minute and for however many minutes, and so that gives you your chunk of gallons, so since you have that then you know that your time would then have to be 1/24$^{\text{th}}$ of the gallons, the chunk of gallons, change in time I guess would be. I'm thinking of them as chunks in my mind. Like that's how I'm visualizing them. Then change in volume as like a chunk. I don't know why.

Samantha's statement and prior activity indicate that she pseudo-empirically abstracted from previous tasks the multiplicative relationship between a whole-number of minutes elapsed and the corresponding number of gallons of water added to the pool. She then made a generalizing assimilation of this relationship to non-integer values of elapsed time and inverted the proportionality constant to describe the reciprocal relation between Δt and Δv. There was no evidence that Samantha conceptualized Δt and Δv as quantities that covary smoothly and continuously. We therefore suspect that Samantha had not constructed a *rate* as Thompson and Thompson (1992) described it—as a reflectively abstracted constant ratio. Her conception of rate was instead the product of a pseudo-empirically abstracted constant ratio, which explains the tenuousness of her conception of the proportional relationship between Δt and Δv.

Teaching Episodes 6-8: Engendering Reflected Abstraction

In the final three teaching episodes, we asked Samantha to compare and contrast the reasoning required to solve various pairs of tasks from the instructional sequence that guided the teaching experiment. Our intention was to engender reflected abstraction by prompting Samantha to perform mental operations on the products of her prior reflecting abstractions. Continually reenacting, comparing, and contrasting her prior reasoning necessarily brought her conceptual activity into conscious awareness and resulted in her rate of change scheme becoming progressively coherent and refined. We share one illustrative example.

During the sixth teaching episode, we prompted Samantha to compare and contrast the reasoning required to solve the following two tasks:

1. While training for a triathlon Clara rides her bike on a long, straight road at a constant rate. She passes under a stoplight while riding. How long does it take Clara to ride 17 miles from the stoplight if she rides at a constant speed of 13 miles per hour?
2. A swimming pool that is only partially full has 10,800 gallons of water. Water is added to the swimming pool 10:00AM at a constant rate of 24 gallons per minute. How long will it take to add 1,725 gallons of water to the pool?

Discussing the meaning of rate of change that might enable students to solve these two problems, Samantha explained,

> I think they have to think about for any, like, (*long pause*) for any change in one quantity, how that relates to the other quantity. They need to think about, um, just because your change in distance is, you know, 13 times as large as your change in time, also thinking about it works the other way too. Your change in time also has a relationship to your change in distance. It's $1/13^{\text{th}}$. … Like being able to go both directions.

We asked Samantha to express her point in the general context of "a varies at a rate of r with respect to b." She clarified,

> They would need to understand that it varying at a constant rate means that like any change in a is going to be r times as large as the change in b. … They have to think the change in a is r times as large as the change in b or change in b is $1/r^{\text{th}}$ the change in a. … They have to be able to think about both of those.

Discussion

Although Samantha ultimately developed a productive conception of rate of change as an interiorized ratio, and thus was able to coordinate corresponding fractional changes in covarying quantities' measures, images of chunky continuous covariation (Thompson & Carlson, 2017) imposed an obstacle to her ability to reason efficiently across a variety of contexts. Still, Samantha demonstrated a sophisticated conception of rate of change that enabled her to reason productively about an assortment of novel tasks. Additionally, Samantha became consciously aware of essential aspects of her scheme for constant rate of change by engaging in reflected abstractions, which contributed to her recognition and appreciation of the general applicability of the meaning she had constructed. Our results suggest two important implications for the content preparation of pre-service secondary teachers at the undergraduate level: (1) images of smooth continuous covariation are fundamental to a mature rate of change scheme, and possibly other mathematical ideas where the covariation of two (or more) quantities is constrained by multiplicative relationships; and (2) engaging in reflected abstraction is essential for supporting pre-service teachers' construction of coherent and refined mathematical schemes, and should thus be a central principle of instructional design for content courses serving prospective secondary teachers.

The Role of Lines and Points in the Construction of Emergent Shape Thinking

Halil I. Tasova
University of Georgia

Biyao Liang
University of Georgia

Kevin C. Moore
University of Georgia

In this study, we focus on a student's meanings for lines and points in the context of graphing covarying quantities. Specifically, we illustrate a student conceiving a line as representing a direction of movement of a dot on a coordinate plane. Consequently, the student did not conceive a dot moving in the coordinate plane as leaving a trace of infinitely many points; similarly, points on a line did not exist until they were physically and visually plotted. We conclude that the student's meanings for lines and points had a significant impact on his graphing activities, in particular, on his construction of emergent shape thinking.

Keywords: Graphical Shape Thinking, Quantitative and Covariational Reasoning

Graphing is critical for understanding various ideas in mathematics (Kaput, 2008; Leinhardt, Zaslavsky, & Stein, 1990; Thompson & Carlson, 2017). Despite its importance, students experience a number of challenges in interpreting and making sense of graphs that may affect their learning of many topics in algebra and calculus (e.g., Clement, 1989; Leinhardt et al., 1990; Moore & Thompson, 2015). In addressing those challenges and difficulties, a number of researchers have suggested that quantitative and covariational reasoning is productive for students' construction of graphing meanings (e.g., Carlson, 1998; Frank, 2017; Johnson, McClintock, & Hornbein, 2017; Saldanha & Thompson, 1998; Thompson, Hatfield, Yoon, Joshua & Byerley, 2017). Specifically, some researchers (e.g., Frank, 2017, 2018; Moore & Thompson, 2015) have emphasized that a productive meaning for a graph is conceiving it as an emergent trace of points that unite two covarying quantities' magnitudes and/or values (i.e., *emergent shape thinking*). In this paper, we contribute to extant theorization of emergent shape thinking by demonstrating how a student's meanings for lines and points influenced his construction of emergent shape thinking. In particular, the student's meaning for a line as indicating a direction of movement of a dot was a contraindication of him conceiving of a graph as an emergent trace of a point, and an implication of his meaning for a line is that it constrained him from thinking of a line as consisting of infinitely many points.

It is worth noting that, in this study, we situated students' learning about quantities' relationships within contexts emphasizing the quantities' *magnitudes* independent of numerical *values*. By a quantity's magnitude, we mean the general sense of the quantitative size of an object's measurable attribute (e.g., length), whereas, by quantity's value, we mean the result of measuring that attribute. Researchers have argued that reasoning with quantities' magnitudes supports students in understanding quantities' covariational relationships (Liang, Stevens, Tasova, & Moore, 2018; Thompson, Carlson, Byerley, & Hatfield, 2014).

Background

Emergent Shape Thinking

Moore and Thompson (2015) introduced the notion of *emergent shape thinking* to describe a person who envisions a graph "*simultaneously* as what is made (a trace) and how it is made (covariation)" (p. 785). This conception involves (1) representing two inter-dependent quantities' magnitudes and/or values varying on each axis of a coordinate system, (2) forming a multiplicative object (Saldanha & Thompson, 1998; Thompson, 2011; Thompson et al., 2017) by uniting those two quantities' magnitudes or values as a single object, and (3) assimilating the process of a multiplicative object moving within the plane in ways invariant with the two covarying quantities as generating a graph, or conceiving a given graph as an emergent record of all instantiated moments of the simultaneous coordination of two covarying quantities. In this study, we report on a student who demonstrated compelling evidence of the first two elements of emergent shape thinking that are listed above; however, demonstrated a contraindication of the third element of emergent shape thinking due to his meanings for points and lines.

Students' understanding of points on a line

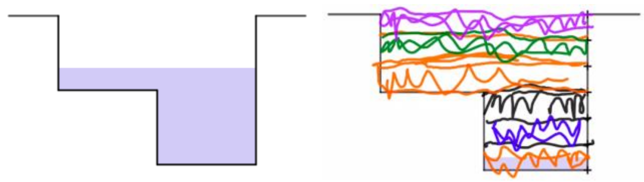
Researchers (e.g., Kerslake, 1981; Mansfield, 1985) have investigated how students conceived points and lines in the context of graphing. They have revealed that students (especially secondary level students) tend to "see" points on a line only if they are visually marked on a graph. For example, Manfield (1985) reported that some secondary and undergraduate students did not perceive points in between two marked points on a line, and some students only perceived endpoints of a straight line on a paper or points on the vertices of a zigzag line. These authors also reported on students who believed no line has points until they are placed on the line. Similarly, Kerslake (1981) reported that about 89% of secondary students (N=1798) did not conceive of infinitely many points on a line. When asked how many points are on a straight line that goes through three points, several students answered "three" or the number of places where the line and a coordinate grid intersect. Although there were some students being aware that there were many points (e.g., "lots" or "hundreds" p. 123) on a line, Kerslake reported that their conception was still constrained "by the physical constraints of actually drawing the points" (p. 123). For example, a student said there are points "as many as there is room for" on the line in between two points plotted (p. 123). In this study, we found a student whose meanings for points on a line was similar to that of the students reported by these aforementioned researchers. We contribute to these findings by discussing how such meanings constrained his construction of emergent shape thinking.

Method

We conducted a semester-long teaching experiment (Steffe & Thompson, 2000) with four secondary students. In the teaching experiment, we aimed to investigate the mental actions involved in the students' conceiving situations quantitatively and representing particular quantitative relationships on number lines and coordinate systems. In this paper, we focus on one of the four students, Zane, since his meanings for the lines and points were consistent and clearly described by him throughout the teaching experiment. We believe it is important to document his ways of thinking in order to add nuances to our models of students' thinking in a graphing activity in terms of emergent shape thinking.

Zane participated in 16 one-hour long videotaped teaching experiment sessions over the course of seven weeks. The first author was the teacher-researcher (TR), and the second author served as the witness-researcher (WR). Before conducting the teaching experiment, the TR developed an initial sequence of tasks by considering particular design principles focused on graphing covarying quantities (e.g., Frank, 2017; Moore & Thompson, 2015; Thompson & Carlson, 2017). The TR revised and implemented those tasks based on on-going inferences and analysis of Zane's thinking. Each task was designed with a dynamic geometry software and displayed on a tablet device. We recorded all sessions using two video cameras to capture Zane's work and his gestures and a screen recorder to capture Zane's activities on the tablet device. We transcribed the video and digitized Zane's written work for both on-going and retrospective conceptual analyses (Thompson, 2008). Our analysis relied on the generative and axial methods (Corbin & Strauss, 2008), and it was guided by an attempt to developing working models of Zane's thinking based on his observable and audible behaviors.

In this paper, we report data from Zane's activity in the Swimming Pool Task adapted from Swan (1985). We presented Zane a dynamic diagram of a pool (see Figure 1a), where he could fill or drain the pool by dragging a point on a given slider. We designed the task to support Zane in reasoning with the inter-dependence relationship between two continuously co-varying quantities: amount of water (AoW) and depth of water (DoW) in the pool.



(a) (b)

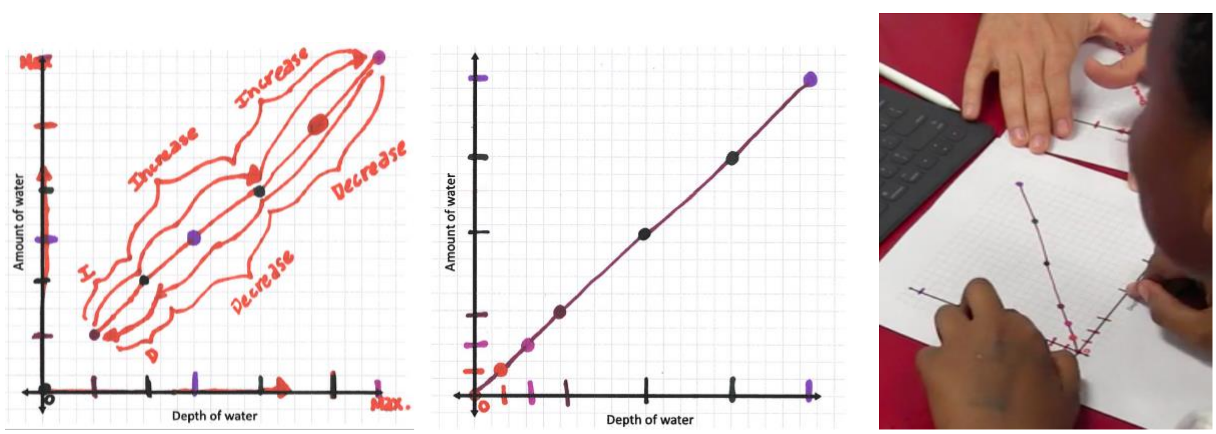
Figure 1.(a) A diagram of the pool (b) illustration of Zane's partitioning activity.

Analysis and Findings

In this section, we illustrate Zane's meanings for his graphs, including the tick marks, points, and lines as he perceived on the graphs. Then, we discuss how these meanings influence his assimilation of what we perceive to be an emergent trace of a point.

Zane's construction and interpretation of his displayed graphs

We asked Zane to sketch a graph that shows the relationship between AoW and DoW as the pool fills up. Zane started with drawing tick marks on each axis and plotting points corresponding to two related tick marks (see his color-coded points and tick marks in Figure 2a and 2b), then he connected those points with line segments. He initially constructed Figure 2a and adjusted his graph to Figure 2b to represent bigger increments at the top half of the pool. He also drew arrows to show "increase" and "decrease" in both quantities (Figure 2a).



(a) (b) (c)

Figure 2. (a) Zane's first draft, (b) Zane's second draft, and (c) Zane moving his fingers on axes.

Meanings for tick marks. When questioned about his tick marks, Zane referred to the quantity's magnitude by drawing a line segment from the origin to the tick mark on the axis. He also used his fingers to simulate the quantities' variation as the TR played the animation to fill the empty pool. He initially placed his left and right index fingers at the origin saying "I started from zero" and then moved his left index finger up along the vertical and his right index finger to the right along the horizontal axis (Figure 2c). While he was moving his fingers, we inferred that he wanted to make sure both fingers hit each corresponding tick marks at the same time so as to match AoW and DoW as he perceived in the animation.

In order to determine if Zane perceived quantities' magnitudes *in between* his tick marks, the TR asked him if he moved his fingers by jumping from one tick mark to another. He responded that he moved his fingers continuously and described an intermediate state:

> Because, I mean, on the thing [*pointing to the pool in Figure 1b*], it is not like very jumping up [*moving up his finger very fast from the bottom of the pool*]. It is really just, like, because the water can be [*pointing to the orange shaded area at the bottom of the pool, Figure 1b*] also a half of it too [*pointing to the water level in Figure 1b*].

In summary, we infer that Zane could simultaneously coordinate both quantities' variations on the Cartesian coordinate system. He conceived of the distance from each finger to the origin as representing the magnitude of AoW or DoW, and he could keep track of the two quantities' variations simultaneously and continuously, including intermediate states between tick marks.

Meanings for points. As the conversation continued, the TR tried to gain insights into the extent to which he coordinated those tick marks on the axes to construct meaning of points on the graph. The TR asked Zane to show the point on his graph that shows the AoW and DoW when the pool is full. Zane first pointed to the far right and top purple tick marks on each axis (see Figure 2b, also see his gesture illustrated in Figure 3a), and then, he pointed to the corresponding purple point on the plane (see Figure 2b). His actions showed that he could associate these two tick marks on each axis to the point on the plane. Then the TR asked him to move his fingers correspondingly on each axis as we played the animation. The following excerpt demonstrates his activity:

TR: I am gonna take out water. You are gonna

Zane: Go down [*moving his right and left index finger to the left and down, along the horizontal and vertical axis respectively. Then, he put his finger back in their original position at the very end tick marks on each axis, see Figure 3a*].

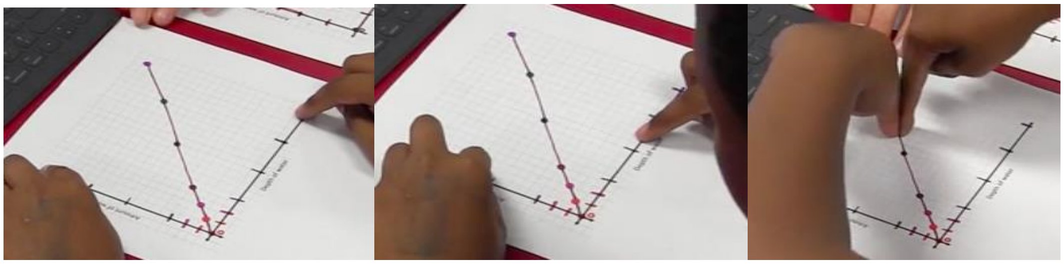
TR: Yes. But, when you do this, you gotta imagine what happens to this point [*pointing to the corresponding point*] ... when I start changing, you are gonna move your fingers and imagine what happens to the corresponding point.

Zane: [*We played the animation and Zane moved his left and right index fingers smoothly on each axis to the left and down, respectively. The TR stopped the animation where the water level is within the area that are shaded in green [see Figure 1b], and he immediately stopped moving his both fingers, see Figure 3b*].

TR: Okay. Where is the corresponding point?

Zane: [He *simultaneously moved his left index finger to the right horizontally and right index finger up vertically, and stopped when the two fingers met; see Figure 3c*] like right here. [*Then he plotted a point on his graph and added two corresponding tick marks on each axis*].

We interpreted that Zane was able to conceive of a point on the plane as a multiplicative object that simultaneously unites the two quantities' variations. Later, he described a point moving up and down along the line as representing *both* quantities' increases and decreases at the same time, saying "the dot represents both." That is, he held in mind two quantities associated with a point and imagined variation of the two quantities as the point moved.



(a) (b) (c)

Figure 3. (a) the location of Zane's fingers before the animation started, (b) the place where Zane stopped, and (c) Zane pointing to the corresponding point where both fingers met.

Meanings for lines. When questioned why he connected the points with lines, Zane responded that the line shows "where the dots go." Additionally, he said, "it also helps to person who comes in, they will understand that the line is probably moving down and up." We infer that Zane conceived of a line on the coordinate plane as showing a path of movement of a dot in either direction. We hypothesized that this meaning for a line might be related to his meaning constructed outside a graphing context prior to the study. Therefore, the TR drew a straight line on a blank paper and asked him how he would define a line. He responded, "a point, hmm, something that goes and never stops." The TR followed up, "What is that goes and never stops?" After an eight-second pause, he said "hmm, from a start point [*placed his right index finger on the left end side of the line*] to an end point [*moves his finger to the right end side of the line*]. We inferred that Zane conceived a line as describing how an object moves from one location to another, and this was compatible with his understanding of lines in the graphical context.

Based on this inference, the WR hypothesized that he might not conceive of a line as consisting of infinitely many points. To test this hypothesis, the WR asked him, "how many points do we need to plot in order to fully describe what is going on here?" Zane added three additional points on each segment between the points that he originally plotted on his graph (see Figure 2b) and said "24". The WR then asked him to compare two graphs, a graph with 24 dots plotted and another graph that includes a line, and discuss how they were similar or different. He replied "wait, did the person who has the line also have 24 points too?" We inferred from his activity that, for him, a line with dots and a line without dots are different graphs and the dots are critical components that convey additional information to a line.

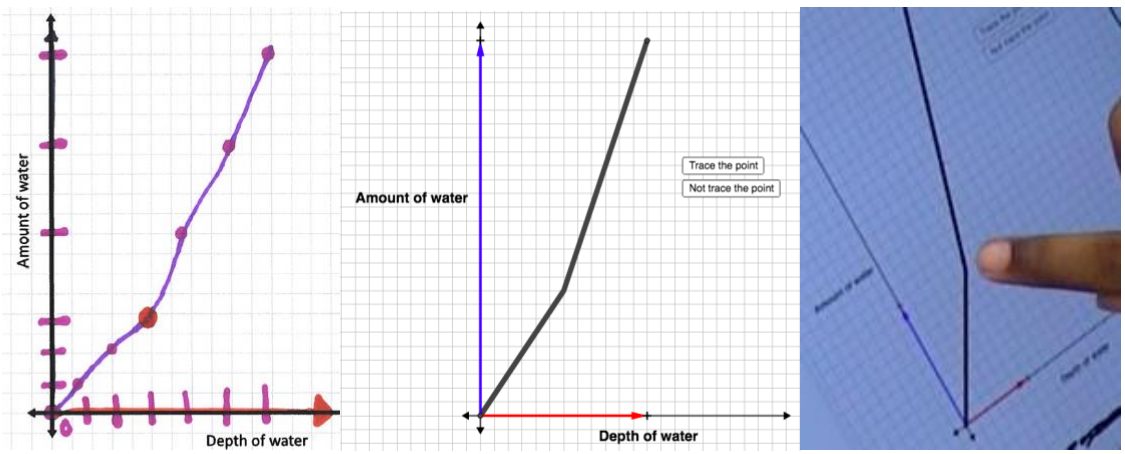
As an additional evidence, when asked whether his graph (see Figure 4a) shows every single moment of how the two quantities vary in the situation, Zane said no because in order to show it, you need to plot an additional point. We infer that, for Zane, lines do not have points until they are visually plotted. He needed to physically plot additional points to represent moments in between two available points, even if there is a line connecting them. That is, he did not conceive of his line as showing these extra moments. In the next section, we demonstrate that such meaning for a line played a role in his construction and interpretation of what we perceived to be in-progress trace.

Zane's Interpretations of an Emergent Trace

Given these interpretations of Zane's meanings for tick marks, lines, and points, the TR hypothesized that he likely did not interpret his prior finger activity (Figure 2c and Figure 3) as generating infinitely many coordinate points. To test this hypothesis, the TR showed him an animation on an tablet device (see https://youtu.be/97EOENUM_co) and asked: "is this trace [*Figure 4b*] showing us the relationship between depth of water and amount of water for this pool?" He replied "no" and struggled to make sense of what the animation was showing, which suggested that he did not perceive the animation as a simulation of his prior graphing activity on paper.

The WR asked Zane whether those dots[1] on his paper (see Figure 4a) are "part of the line on the computer." Zane replied, "there is only one dot," pointing to the animating dot that produced the trace (see his gesture in Figure 4c). When asked "is there any other dots on this graph?" he shook his head. Moreover, he interpreted his graph (Figure 4a) as having more dots than the one produced in the animation (Figure 4b), commenting that mine is better because "mine have more dots".

Zane also claimed that he could not construct his graph in the same way as the animation did due to physical constraints of human, saying, "well, I cannot do that, because, like, can you do dots and dots [*tapping his right index finger very fast along his graph shown in Figure 4a*] and trace it?" This is an additional contraindication that he conceived of graphing a line as a way to represent infinitely many points.



(a) (b) (c)

Figure 4. (a) Zane's last draft and (b) an instance of the animation, and (c) Zane pointing to the "only" point on the trace.

In summary, despite his success in the finger activity and being able to conceive of a point as a multiplicative object, Zane assimilated his activity as well as the animation as one dot moving along a line path instead of one dot generating infinitely many points by leaving a trace. We claimed that his meaning for a line as describing a direction of movement (as opposed to consisting of infinitely many points) played a critical role in his construction and constrained him from conceiving a graph as an emergent, in-progress trace (i.e., the third component of emergent shape thinking).

Discussion

Moore and Thompson (2015) and Frank (2017, 2018) emphasized the important role of forming a multiplicative object in students' development of emergent shape thinking. What we have found in this study is that multiplicative object is a necessary but not sufficient condition

[1] We use the word *dot* instead of *point* when we have evidence of Zane referring to a visual circular object that is plotted on the plane, but do not have explicit evidence of him holding the two quantities *in mind* (i.e., conceiving a multiplicative objective) at the moment. By using the word "dot", we are also genuine to Zane's language in this activity.

for emergent shape thinking. We found that Zane constructed a meaning for individual points as multiplicative objects, and he could do the finger tool activity (i.e., moving index fingers on each axis) smoothly to represent continuous, simultaneous co-variation of two quantities. However, he interpreted his activity of connecting points on his graph as representing a direction of movement of one point from one location to another; hence he did not imagine a segment or a line as including infinitely many points and representing every moment of the quantities' covariation. In turn, he did not perceive an emergent trace generated by a continuously moving point as a line. Thus, we claim that Zane's meanings for lines and points constrained him from developing a meaning of graphs consistent with emergent shape thinking (i.e., a graph as an emergent trace of points). Given the results provided by this study and other researchers (e.g., Manfield, 1985; Kerslake, 1981) regarding students' understanding of lines and points, it is important that we take into account students' meanings for lines and points constructed in other contexts and consider how those meanings may influence students' construction of graphing meanings.

Although we report on findings from a secondary student, the implication of this study is important for both the secondary and the undergraduate mathematics education community. We are drawing on the construct, emergent shape thinking, that was initially developed from undergraduate students. The results of this study regarding a secondary student's meanings afford us a better understanding of students' graphing activity, including their construction of emergent shape thinking. Prior researchers (e.g., Frank, 2017) have reported on students' difficulty with constructing an emergent meaning for graphs, and the case of Zane suggests that one source of such difficulty can be students' meanings for lines and points in general. If students conceived of a line as showing *one* point's movement, it would be difficult for them to assimilate a line graph as an emergent trace that includes *infinitely many* points, despite being able to conceiving each point as a representation of two quantities' magnitudes (and/or values) at a particular moment. Consequently, they would need to physically plot points to show quantities' magnitudes (and/or values) at any specified moments (i.e., a pointwise meaning for a graph). Thus, we conjecture that meanings for lines and points consistent with Zane's might help explain students' difficulties with constructing and representing smooth and continuous images of covariation in graphical contexts (Castillo-Garsow, Johnson, & Moore, 2013).

Our analysis supports the affordance of Castillo-Garsow's (2012) distinction between "a problem situation, the method used to solve it, and the reasoning that derives or selects that method" (p. 56) when characterizing students' covariational reasoning. Zane conceptualized two quantities' covariation continuously regarding the pool situation; however, he used a discrete method (i.e., plotting points) when constructing his graph due to a constrain implied by his meanings of lines. We argue that it is important for researchers to be aware of such a discrepancy and be aware that a pointwise graph activity (i.e., plotting the points first, and then connecting them) does not necessarily imply that their images of quantities' covariation is discrete, and vice versa. When characterizing students' covariational reasoning, it is important for us to take into account students' activities and reasoning in various context (e.g., situations, graphs in different coordinate systems, and number lines) before we make claims about their covariational reasoning. We believe identifying this inconsistency and its causes can allow us to better advance students' understandings of graphs.

You Don't Want to Come Into a Broken System: Critical and Dominant Perspectives for Increasing Diversity in STEM among Undergraduate Mathematics Program Stakeholders

Rachel Tremaine
Colorado State University

Jessica Hagman
Colorado State University

Matthew Voigt
San Diego State University

Jessica Gehrtz
University of Georgia

As attention grows towards the disparities between majority groups and underrepresented minorities within undergraduate STEM education, there is a need for understanding where different university stakeholders stand on the subject of increasing diversity. This paper aims to juxtapose categorizations of stakeholder motivations and dominant and critical perspectives to propose a framework for analyzing stakeholder attitudes and informing increasingly productive conversations on eliminating inequity in STEM fields.

Keywords: Diversity, Equity, STEM, critical perspective, dominant perspective

The STEM achievement and enrollment disparities between populations based on gender, race, ethnicity, and class are well documented; so well documented, in fact, that we choose to take this shared knowledge as fact and do not provide documentation, treating this as a claim that does not necessitate warrant. We instead focus on the varying ways that communities and individuals respond to this shared knowledge, both in how they make sense of this knowledge within their own frameworks and what they propose to do with this knowledge. Mathematics, and specifically calculus, is an integral component of all math-intensive STEM degrees, and has been repeatedly shown to contribute to the disparities in STEM (Chen, 2005; Ellis, Fosdick, & Rasmussen, 2016; Hagman, 2019). In this paper, we focus on how different stakeholders involved in the precalculus and calculus programs that serve math-intensive STEM programs make sense of the lack of diversity in STEM and the role of precalculus and calculus programs in that disparity.

A recent national conversation among calculus coordinators and math department chairs from 56 research-focused mathematics departments indicates that this population is aware of the need to attend to diversity, equity, and inclusion within their precalculus and calculus programs, but currently rely on university-level programs to support a diverse student population (Apkarian et al., 2019). While these university-level programs can be a very important support for students from historically marginalized populations, it is also important for there to be an integration of academic and social supports (Tinto, 1997); in other words, it is important for mathematics departments to explicitly take ownership of issues related to diversity, equity, and inclusion and integrate attention to these principles into their precalculus and calculus programs (Hagman, 2019). It is also important to recognize where various stakeholders within the mathematics programs (such as coordinators, chairs, instructors, and students) currently are in their own understanding of issues of diversity, equity, and inclusion so that we can "meet them where they are" to support growth. Together, these motivations lead us to our research question: *What are the implicit and explicit motivations of various stakeholders at the university for why it is important to attend to diversity in STEM education?*

Theoretical Framing

To begin to understand various stakeholders' views regarding diversity, equity, and inclusion in undergraduate mathematics, we draw heavily on an analysis conducted by Basile and Lopez (2015) in which they explore the motivations for increasing diversity in STEM articulated by different STEM policy documents. They performed this analysis using a critical race theory lens, which enabled the authors to be especially attuned to the underlying and potentially subversive components of these documents; in other words, rather than taking any argument for an increase in diversity in STEM as good, the authors critique the motivations articulated, allowing for a more nuanced (and honest) discussion of why and how various stakeholders argue for attention to students of color (the primary population attended to in their study). We both narrow and extend this analysis by exploring the motivations articulated by various stakeholders related to a precalculus and calculus program at one institution for attending to diversity in STEM.

Basile and Lopez's (2015) analysis provides an essential starting place for our analysis by critically considering the different motivations articulated in policy documents for increasing diversity in STEM. Basile and Lopez identify three motivational categories as instrumental in distinguishing why individuals and organizations see value in changing representation in STEM: *economic benefit to state*, referencing the goal of supporting the United States to be globally competitive; *diverse perspective as a benefit to STEM enterprise*, referencing the different perspective that diverse populations bring to the STEM disciplines; and S*TEM experience as a direct benefit to Students of Color,* referencing the benefit to students of experiencing the joy of learning the knowledge and skills of STEM.

Data Collection

The data used in this analysis was collected as part of the Progress through Calculus (PtC) grant, spanning multiple universities and many individuals within those universities. For this analysis, we used purposeful sampling to identify three samples of data from a highly selective private university, herein referred to as Dunshire University. At Dunshire, we identified a local liaison familiar with PtC who could connect us to individuals and groups that were involved with diversity-in-STEM related initiatives on campus, as well as individuals who identified with historically underrepresented groups in STEM fields.

Our data collection consisted of individual interviews and focus groups. The three interviews we chose from this process were selected not only due to the different university stakeholders they represent (students, faculty, and administrators), but also because we felt they exemplified adaptations of Basile and Lopez's categories within a collegiate context. In order to gain insight into student perspectives on increased diversity, we identified a student group on campus focused on fostering inclusivity and providing feedback on university actions, and invited members of that student group, which we will refer to as the Diverse Student Organization (DSO), to participate in a focus group. We followed a similar focus group structure for faculty members involved in an on-campus program designed to increase persistence of undergraduate underrepresented minority students through faculty mentorship. We will refer to these individuals as Faculty Education Mentors (FEM). In addition, we conducted an individual interview with the advisor of DSO, who is considered an administrative director at Dunshire.

In addition to asking each interviewee about their role on campus and their own interactions with diverse populations in a collegiate setting, we asked them about the need to increase diversity in STEM and their reasoning regarding why such an increase was necessary. During our interviews, we left the meaning of the term "diversity in STEM[1]" up to the interpretation of each interviewee, allowing the interviewees to dictate the populations to which they wanted to attend according to their own personal and professional experiences. While this was intended to allow everyone an entry point into the discussion, we recognize that it also limits the amount of discussion regarding the experiences of individuals within STEM and has the potential to enact essentialism within our own work.

Thematic Analysis

After collecting the interview data and transcribing the interviews, we conducted a multiphase thematic analysis (Braun & Clark, 2006) to understand the motivations of various undergraduate mathematics program stakeholders for attending to diversity. The results of this analysis are twofold: first, a data driven theoretical framing for perspectives on diversity in STEM in a university context, and second, the application of this framing on our three interviews giving insight into the perspectives of different stakeholders.

First Level Analysis

In the first phase of our analysis, we conducted a deductive analysis drawing on Basile and Lopez's (2015) three motivations, while also inductively using the data to inform adaptations and expansions of these motivations. Our adaptations of these categories encapsulate what each category might look like when primarily applied to the reasoning of university stakeholders as well as what was actually shared by the interviewees. This resulted in four first level themes, the first three which parallel the original three categories, and then a fourth which emerged from the data, as summarized in Table 1.

We adapted Basile & Lopez's "economic benefit to the state" code to "financial or cultural benefit to the university." While Basile & Lopez analyzed policy documents in which stakeholders would have been primarily concerned with the economic welfare of the nation on a broad scale, a university setting yields more concern regarding specific university funding and reputation. We added a cultural component after recognizing the consistency of stakeholders desiring not only a quantitative university benefit, but a qualitative benefit to the overall university culture as well. This theme is referred to as "*Cultural or financial benefit to the University*." Incorporating Basile and Lopez's assertion that motivation can come from a desire to provide diverse perspectives to existing questions within STEM fields, "diverse perspectives as a benefit to STEM" remains relevant in a university context as underrepresented minority (URM) students will become the primary contributors to their selected STEM industry as they graduate. This category acknowledges the unique contributions of URM students, faculty, and administrators to the fields they support through both economic and entrepreneurial contributions. Diverse perspectives are extremely valuable when addressing current questions posed in the STEM community, and when posing new questions that may not have been previously considered by STEM contributors. This theme is referred to as "*Economic and entrepreneurial benefit to the STEM enterprise*." While Basile & Lopez's third category

---

[1] While putting forth these questions, we used terms such as "underrepresented" and "minority/ies", which Basile & Lopez identify as fairly generalizing and, "while potentially appearing to be inclusive, [are] an example of racial essentialism" (p. 532). We recognize that these terms have the capacity to disregard individual experience and perspective, especially considering the broadness in spectrum of the experiences of individuals of differing race, gender, sexual orientation, cultural background, or disability status and the intersectionality that may occur amongst those identities.

discusses the direct benefit to students, the primary assertion in their categorization was that "all individuals deserve to experience the joy of learning STEM and benefit from the knowledge and skills, especially groups that have been traditionally excluded" (p. 544). We have broadened the category to include any motivator that has a direct and positive impact on the college experience or long-term outcome for a STEM student of a traditionally underrepresented identity. This theme is referred to as "*Direct benefit to underrepresented minority students in STEM fields*." Through our analysis, there emerged only one additional motivation that was not captured by the above three categories. Several of the interviewees cited benefits that related to the broader population of individuals for whom an increase in diversity in a college setting might be beneficial by way of influence, connections, or availability of opportunities. The two major populations mentioned by our data were the families of underrepresented minority students, and overall minority communities, and this theme is referred to as "*Societal and economic benefit to underrepresented minority families and communities as a whole*."

Table 1. *Descriptions of first level themes.*

Theme Category	**Description:** *Representation in STEM should be increased due to the:*
Cultural or financial benefit to the University	Cultural or economic benefit for the university at which individuals of underrepresented minorities are involved, whether as students, faculty, administrators, or volunteers.
Economic and entrepreneurial benefit to the STEM enterprise	Economic benefit it creates for the industries into which those individuals will enter as members of the workforce, through URM contributions to existing or difficult questions, or as URM participation allows for new questions and broader population inclusion.
Direct benefit to underrepresented minority students in STEM fields	Direct benefits - social, economic, and personal - that it fosters for the students pursuing those STEM fields at a university level.
Societal and economic benefit to underrepresented minority families and communities as a whole	Increased positive outcomes it creates for disadvantaged URM communities and families by way of increased income, a broader spectrum of opportunity, and general quality of life.

Second Level Analysis

After all four members of the research team agreed on the first level themes and their application to the three transcripts, we revisited the coded segments and recognized that there was nuance within the segments that was not captured through the first level themes. To help us make sense of this nuance, we revisited literature that explicitly addresses different perspectives on equity within mathematics education. We found Martin's (2003) paper discussing the rhetoric related to the concept of "mathematics for all" and Gutiérrez's (2009) paper defining equity along a critical and dominant perspective as particularly relevant to our data, and synthesized these perspectives to create our second level themes.

Martin (2003) conducted a critical analysis of the language used within mathematics education researchers and practitioners related to equity, which is well aligned with Basile and Lopez's analysis of the language related to equity used within STEM policy documents. Martin distinguishes between a top-down perspective and a community-up perspective. The top-down perspective on equity is driven by those in power (policy makers, researchers, administrators, teachers) and draws heavily on the idea that equity in mathematics education will be achieved when achievement gaps between white students and students of color are eliminated. This perspective frequently draws on “mathematics for all” language. Martin emphasizes that this is a worthy goal, but cannot be the only goal. He contrasts this approach with a community-up perspective, which is driven by the voices and needs of students, parents, and communities of color, and is viewed as a process rather than a finite goal:

> the second conceptualization of equity—as a process—highlights the fact that the necessary hard work will be ongoing and even when gains are made, a high degree of vigilance will be necessary to ensure that needs of marginalized students are attended to and that our definitions of equity are responsive to who these students are, where they come from, and where they want to go in life (p. 14).

Martin’s distinctions provide a link between the analysis of policy documents and a more theoretical grounding of equity in mathematics education provided by Gutiérrez. Gutiérrez (2009) defines equity in mathematics education along two axes, the dominant axis and the critical axis. The dominant axis entails attention to access to mathematics education and how this affects achievement. Discussions of equity from the dominant axis frequently attend to differences in access and achievement between white students and students of color, and focus on supporting students of color to “play the game”, working within the existing systems to achieve goals set forth by stakeholders with power in the discipline. This axis is contrasted with the critical perspective on equity, which attends to people’s identities and how these identities affect power. Discussions of equity from the critical axis emphasizes ways to support students to “change the game” and critically reflect on and challenge the entity of mathematics. Gutiérrez emphasizes that both dimensions are necessary to achieve equity in mathematics education. We note that both Martin and Gutiérrez emphasized that discussions on “mathematics for all” and attention to removing access and achievement gaps are not inherently bad; instead, these are important components of discussions related to equity when combined with discussions that attend to the experiences of the students in these systems and an awareness that these systems themselves create and sustain the inequities we are seeking to dismantle.

While these frameworks are explicitly about equity in mathematics education, and our emphasis is on motivations for increasing diversity in STEM, we view them as compatible. One way to view discussions of increasing diversity in STEM is through a STEM for all/increased access and achievement lens. Another way to view these discussions is by examining and questioning the system that has created these disparities. These distinctions, informed by Martin (2003) and Gutiérrez (2009), lead to our two second level themes, in which we use Gutiérrez’s language of dominant versus critical.

The *dominant perspective*, in working toward eliminating inequity in STEM, does so by operating within the current structure of the STEM enterprise. When applied to a university setting, it asks students, faculty, and administrators to alter their practices in a way such that they work toward ‘success’ definitions that have already been set out by the STEM status-quo, such as ensuring better grades for students, increasing access to research opportunities, or applying their knowledge by working to solve questions that are already being asked by the STEM community. In contrast, the *critical perspective* frames change as an increase in identity leading to an increase in power for the marginalized group in question. The critical perspective shifts focus from how to obtain better outcomes within the current STEM system to how eliminating inequity can redefine and challenge the STEM system, resulting in comprehensive, wide-spread change to STEM as an entity, whether that be through asking previously unconsidered questions, changing common perceptions of who can be successful within STEM, or creating differentiated spaces for marginalized populations in a newly defined STEM atmosphere. It interrogates what STEM can be by recognizing that the definition of the field itself is fluid and thus can be challenged and molded by diverse perspectives.

Reasons given by stakeholders for increasing diversity in STEM

This framework allows us to examine not only the reasons for increasing diversity from the perspective of different stakeholders, but also how to frame an argument that pushes the field and reframes the argument from a student/community-focused perspective. In answer to our research question, we share the integration of our first and second level coding and provide sample examples from our data set. In Table 2, we share the overlay between our first and second level codes, driven by our data and the literature and theory described previously. To help exemplify the interaction between these layers and highlight the difference of dominant versus critical perspective within them, we examine how these differences show up in data related to the benefit to the STEM enterprise. The first example we highlight comes from a student participating in DSO, in which they explain how a more diverse population can solve tasks set forth in the current STEM environment better than a homogeneous group:

> *DSO Student:* I've read reviews where, like [professional] groups are working on like just problem solving tasks and the more diversified group is the one who usually does the best just because they have different perspectives…. So it's just interesting that people who think differently are from different backgrounds just overall do better on tasks.

A contrasting example of a critical perspective on the benefit to the STEM enterprise comes from the advisor of DSO, who shares the examples of advances in videography and cinematography by now knowing how to film black skin by utilizing blue lighting:

> *Advisor of DSO:* That means that there had to be people of color to know, to come in and say no this is how you do this or had to discover that and broaden awareness and you know make it more widely acceptable, like, this is how you do this ...there's lots of things that students- that people can benefit from by being able to have a seat at the table because things can be made with not someone else in mind but with everyone in mind.

Table 2. *Integration of first and second level codes.*

	Dominant Perspective	**Critical Perspective**
Economic and entrepreneurial benefit to the STEM enterprise	Bringing in diverse perspectives will help solve existing problems and answer questions that already exist in STEM industries.	Bringing in diverse perspectives changes what STEM asks and what it can solve, and alters the methodology of solving STEM-focused problems by making that methodology more inclusive.
Cultural or financial benefit to the University	Increasing diversity provides more representation in faculty and students, which helps with recruitment and allocates more pre-existing resources to diverse populations on campus.	Increasing diversity will culturally shift STEM environments at the university and is needed to address systemic hiring inequalities.

Direct benefits to students in STEM fields	Increasing diversity provides role models and helps other students by increasing representation and creating spaces within existing systems that are inclusive.	Increasing diversity creates a more positive identity for students in STEM fields, and thus increases their power within the discipline.
Societal and economic benefit to families and communities as a whole	Increasing diversity fosters success for traditionally underrepresented groups within society's existing structures.	Increasing diversity recognizes and challenges the way underrepresented minority communities and families and their motivations and attitudes about STEM are perceived.

Discussion

Our work has synthesized a categorical analysis of STEM policy documents with theoretical perspectives on equity within mathematics education, yielding a framework from which to situate perspectives on increasing diversity among math stakeholders within a broader theoretical field. Our framework enables detailed themes to be identified in terms of where certain stakeholders may stand regarding their motivation to increase diversity, as well as an idea of how best to format productive discussions that center around the need to increase diversity.

An example of how this application might take place may be through a trend that we as a research team noticed when analyzing this smaller data set. Within our transcribed focus group with the Faculty Educational Mentors, we noticed that they, as faculty, typically communicate through a dominant perspective. We conjecture that this is due in part to the fact that the faculty *are within* the system, and so can advocate for improving the system related to diversity, equity, and inclusion, but it may be too far outside the scope of their lived experiences to recognize a need to change the system that they have been successful within. By applying this framing to various stakeholders' perspectives, we can begin to identify which arguments are more comfortable or natural for various groups, and then can seek ways to connect with them at those levels and also use the framing to help further their thinking into other realms. For example, it may be beneficial to support faculty who come from a dominant perspective regarding benefits for students to engage in those benefits from the critical perspective, or perhaps it is more beneficial to remain within the dominant perspective but broaden the reach of the perceived benefits to additional first level categories. More research needs to be done to understand which approach is most constructive, for whom and for what goals.

We cannot dismiss the fact that STEM can be a very empowering system for students from marginalized populations, and so only working to dismantle this system does not honor those students and their achievements. So, just as only coming from a dominant perspective is alone not enough, only coming from a critical perspective has the potential to devalue the benefits of the current STEM system to a diverse population of students. By developing a framework that takes both the dominant and critical perspective into account and applies them to four major categories of motivation, we hope to further the quality and depth of discussions and actions taken to increase diversity in STEM education by undergraduate mathematics program stakeholders.

Fostering students' mathematical creativity necessitates certain instructional actions - one of which is designing and implementing tasks that foster creativity. Drawing on the literature on mathematical creativity, we describe existing research-based features of tasks for eliciting student creativity, or creativity-based tasks, and provide suggestions for implementation of such tasks. Based on these features, we analyzed two instructors' first experiences designing and implementing creativity-based tasks in Calculus I. Both instructors' frequent use of the multiple-solutions feature suggests that this feature could be an entry-point for designing and implementing creativity-based tasks for other instructors seeking to foster creativity.

Keywords: Calculus, creativity-based tasks, mathematical creativity, task design

The importance of mathematical creativity in mathematics and mathematics courses is documented in numerous research studies, policy and curriculum-standard documents (e.g., Borwein, Liljedahl, & Zhai, 2014; CUPM, 2015; Levenson, 2013; Moore-Russo & Demler, 2018; NSB, 2010; Silver, 1997; Sriraman, 2009; Tang et al., 2017; Zazkis, & Holton, 2009). Askew (2013) points out that "[c]alls for creativity within mathematics and science teaching and learning are not new, but having them enshrined in mandated curricula is relatively recent" (p. 169). For example, in its latest guidelines for majors in mathematical sciences, the Mathematical Association of America's Committee on the Undergraduate Program in Mathematics (CUPM) states that "these major programs should include activities designed to promote students' progress in learning to approach mathematical problems with curiosity and *creativity* [emphasis added] and persist in the face of difficulties" (Schumacher & Siegel, 2015, p. 10). In this paper, we focus on mathematical creativity in Calculus I, a course that is commonly offered for majors in these mathematical sciences programs.

Students' experiences in Calculus I play a critical role in their persistence in science, technology, engineering, and mathematics (STEM) programs (Rasmussen et al., 2019). The lack of or limited exposure to class materials (e.g., tasks, homework problems, exam questions) that promote conceptual discussions is one of the reasons reported by Calculus I students for switching out of a STEM major (Johnson, Ellis, & Rasmussen, 2014). In fact, a textbook analysis (Lithner, 2004) concluding that 70% of Calculus exercises at the end of the section were about mimicking previously done examples of the same section is one indication to students' limited exposure to conceptual ideas. Though there are Calculus reform projects that address this particular issue by advocating for new curriculum materials for more conceptual discussions (see Bressoud et al., n.d.), we believe it is still a priority to explicitly value and foster students' mathematical creativity in Calculus I classes. In particular, we argue for the creation and implementation of tasks that are designed not only for conceptual understanding but also for enhancing students' mathematical creativity. In this paper, we discuss research-based features of tasks that promote mathematical creativity and their potential implementation. Additionally, we share analysis of two instructors' uses of these features in the design and implementation of the tasks in their Calculus I classes.

Theoretical Perspective and Background Literature

In our work, we define mathematical creativity as a process of offering new solutions or insights that are unexpected for the student with respect to their mathematics background or the problems they have seen before (Liljedahl & Sriraman, 2006; Savic et al., 2017). This process-oriented definition (Pelczer & Rodriguez, 2011), in contrast to examining final products (Runco & Jaeger, 2012) of those processes, provides a dynamic view of creativity rather than a static one. We focus on valued mathematical actions (Cuoco, Goldenberg, & Mark, 1996; Schoenfeld, 1992) such as taking risks and making connections that can lead to creativity in mathematics (Karakok et al., 2015; Leikin, 2009). Our definition also encompasses creativity relative to the student versus creativity relative to the field of mathematics (Beghetto & Kaufman, 2013; Leikin, 2009). Finally, this particular definition identifies creativity specific to the domain of mathematics rather than domain-general creativity (Baer, 1998).

Fostering students' mathematical creativity, as we define it, necessitates certain instructional actions that are encapsulated by Sriraman's (2005) five theoretical principles. The *Gestalt principle* discusses the importance of giving time to allow incubation to occur (Hadamard, 1945). The *Aesthetic principle* highlights explicitly valuing the beauty and uniqueness of solutions or methods. The *Free-market* and *Scholarly principles* emphasize creating a safe environment where students can present and defend their work, and allowing students to build off one another's work, respectively. The fifth principle, *Uncertainty*, focuses on tolerating ambiguity and knowing that it is acceptable to not know a solution. Levenson (2011) provides empirical support for these principles and adds "choosing appropriate tasks" (Levenson, 2013, p. 273) as one of the roles of teachers for the promotion of creativity.

We conjecture that intentionally implemented tasks designed to align with Sriraman's principles have the potential to enhance mathematical creativity. For example, a task that is aligned with the Gestalt principle needs to be challenging enough for students that they would need time to incubate. An intentional implementation of such a task that demonstrates the Scholarly principle would include an instructor giving students the opportunities to discuss their approaches and build off of one another's work; all the while, students' mathematical creativity is at the forefront of such discussions.

Task design

We adopt Henningsen and Stein's (1997) definition of a mathematical task as ‘‘a classroom activity, the purpose of which is to focus students' attention on a particular mathematical concept, idea, or skill'' (p. 528). For a task to promote creativity, it needs to have additional features that provide students opportunities to push their mathematical processes toward new solutions or insights that are unexpected for them. For practical reasons, we use the term *creativity-based tasks* to describe such tasks.

We situate our discussion of creativity-based tasks and task design within two perspectives of creativity: *Developmental* and *Problem Solving and Expertise-Based* perspectives (Kozbelt, Beghetto, & Runco, 2010). The *Developmental* perspective posits that creativity develops over time (i.e., process-orientation) in an environment where students are provided authentic tasks and opportunities to interact with others. The *Problem Solving and Expertise-Based* perspective emphasizes problem-solving processes, heuristics, and tasks, underscoring the use of tasks to challenge students' thinking processes and provide opportunities to solve problems in various ways. A key component of our work is developing tasks that would allow such processes. We base these tasks on Skemp's (1976) relational understanding framework and Lithner's (2008) creative mathematically-founded reasoning. As relational understanding relates to students' development of conceptual structures, a creativity-based task promotes both making connections between concepts and taking risks by students to become independent thinkers. Additionally, creative mathematically-founded reasoning involves novel (with respect to students) mathematical arguments. It is noted by Boesen, Lithner, and Plam (2010) that students use creative mathematically-founded reasoning to solve unfamiliar, nonroutine tasks. In this sense, creativity-based tasks can be viewed as unfamiliar and non-routine.

Features of Creativity-Based Tasks

"Recall and apply" tasks are important in developing procedural fluency in Calculus I, but to foster mathematical creativity, instructors need to design tasks that require "evaluating mathematical statements; example generation (constructing an instance); analyzing reasoning; conjecturing; generalizing; visualization; using definitions" (Breen & O'Shea, 2011, p.87). Tasks with these features can promote conceptual discussions and making connections between seemingly different ideas and concepts.

Silver (1997) discusses the importance of the interplay between problem posing and problem solving to creativity and states "[i]t is in this interplay of formulating, attempting to solve, reformulating, and eventually solving a problem that one sees creative activity" (p. 76). We believe it is important for tasks to engage students in problem posing and problem solving not only in order to promote creativity but also to enable "teachers and students to become subjects of the educational process by overcoming authoritarianism and an alienating intellectualism" (Freire, 1999, p. 8). The need for posing problems can be facilitated by assigning tasks that are ill-defined, ambiguous, or open-ended. Kwon et al. (2006) define an incomplete or an open-ended problem as "a problem which does not define clearly what the question asks for, therefore allowing many possible solutions" (p. 52). Thus, another feature of a creativity-based task is providing opportunities for students to pose problems and questions, then to seek answers to these problems and questions (Haylock, 1997; Silver 1997). Experts describe the ability to identify key research questions as part of their creative work (e.g., Hadamard, 1945; Mansfield & Busse, 1981).

Relating to many possible solutions, Leikin (2013) defines a multiple-solution task as one that "explicitly requires students to solve a mathematical problem in different ways" (p. 388) where different solutions are determined by: "(a) different representations of some mathematical concepts involved in the task, (b) different properties (definitions or theorems) of mathematical objects within a particular field, or (c) different properties of a mathematical object in different fields" (Leikin, 2013, p. 388). Thus, multiple-solution tasks can also promote utilizing other representations (verbal, symbolic, gestures) as well as connecting certain aspects of different representations in a way that fosters deeper mathematical thinking. Multiple-solution tasks not only value students' individual approaches, but they also allow for originality and novelty in using certain standard or less standard tricks.

Examples

One of the tasks that we designed for Calculus I, the *Circle Task* poses the questions "Is there anything in real-life that is a perfect circle? How do you know if you have a perfect circle?" This task involves the mathematical concepts of infinitesimals, (possibly) limits, integrals, and arc length. As a creativity-based task, its open-ended nature provides opportunities for students to take risks in exploring novel ideas and to make conceptual connections to fundamental aspects of Calculus.

As another example, we modified a typical "find the limit" question to "Consider the limit $\lim_{x \to 1} \frac{\sqrt{x}-1}{x-1}$. Evaluate the limit in as many ways as possible." We designed this *Limit Task* as a creativity-based task that involves the mathematical concepts of limits and derivatives. By asking students to evaluate the limit in more than one way, students are pushed to think of a solution beyond one that they are mathematically inclined to provide. As the question did not specify how students are to approach the problem (algebraically, graphically, using a table, etc), the task carries the open-ended feature. The task fosters making connections between various concepts as students could view this limit as a slope of the tangent line, which could be computed by the derivative at 1.

Task Implementation

Stein, Grover and Henningsen (1996) noticed that tasks that were designed to be cognitively demanding (e.g., involving conjecturing, justifying, generalizing) became less demanding because they "became routinized, either through students' pressing the teacher to reduce task ambiguity and complexity by specifying explicit procedures or steps to perform or by teachers' taking over the challenging aspects of the task" (p. 479). That is to say, the implementation of a task plays a crucial role in fostering creativity.

To mitigate the possibility of a reduction in cognitive demand, we suggest using Sriraman's (2005) five principles as guidelines for implementing creativity-based tasks. To bridge theory and practice, the authors (Cilli-Turner et al., 2019) investigated one teacher's actions with the five principles and suggested numerous teacher actions stemming from these principles to potentially foster students' mathematical creativity. Building on the results from (Cilli-Turner et al., 2019), we suggest that when implementing an open-ended task such as the Circle Task, instructors could assuage students' discomfort in task ambiguity (Uncertainty) by assuring students that multiple solutions exist. The instructors can also provide additional time for students to incubate (Gestalt) on what it means to have a perfect circle and a real-life circle. Following this incubation, instructors can give students opportunities to present their findings (Free Market and Scholarly). Similarly, the Limit Task affords different possible implementations because it has a "call-back" feature where instructors can use it progressively at various points throughout the semester as new material is covered, deepening students' incubation period (Gestalt). Aside from (re)using this task while covering graphs, limits, and derivatives, the task can be revisited after covering L'Hospital's Rule by asking students to find the limit in four different ways and giving students opportunities to share (Free Market and Scholarly) these different ways. Instructors can facilitate the Aesthetic principle by valuing the novelty of using the trick of factoring linear terms in this limit.

Research Methods

As part of a larger research study that explores mathematical creativity in Calculus I classes, our research team designed the two creativity-based tasks: the Circle Task and Limit Task. These two tasks and their features were shared with two instructors, Jo Parker and Juniper Travers (pseudonymous), at a South-Midwest regional university who participated in the larger study. Prior to the start of the 'research' semester, we had 2 two-hour online professional development (PD) sessions with a two-day break between the sessions. At these sessions, we introduced some goals of the research project, features of creativity-based tasks, and the Limit Task. The sessions also included discussions on various ways to explicitly value and foster mathematical creativity and implement creativity-based tasks. The two instructors designed a task or modified an existing one to include some creativity-fostering features. To provide extended support, the online PD continued on a weekly basis throughout the semester for an hour to support participants' instructional practices that explicitly foster mathematical creativity and task design. We facilitated open-ended discussions concerning how to assess student work on creativity-based tasks. Both instructors were asked to implement the Limit and Circle tasks in their Calculus I classes and also to develop and implement at least four other creativity-based tasks.

In this paper, we share results from our preliminary analysis of collected data to address the research question: What features do instructors use in their creativity-based task design and implementation processes? We collected instructors' creativity-based tasks, their journal entries for the PD in which they reflected on their design and implementation processes, their classroom video-recording of the days on which these tasks were used in class, and their Calculus I material from previous teaching experiences. At the end of the semester, we conducted semi-structured interviews that included questions regarding their tasks and task design processes. Instructors' tasks, journal entries, and interview transcripts were analyzed with a deductive approach using task features as codes (Patton, 2002).

These codes or features (in *italic*) were: *open-ended*; allows *multiple solutions, multiple representations, different approaches leading to one answer, posing problems and questions;* promotes *making connections between different concepts, evaluation/justification, generalization making, incubation;* allows for *originality/novelty, conjecturing, use of a trick or a less standard algorithm*, and *uncertainty*.

Analysis

We analyzed the tasks that instructors used as creativity-based tasks in their courses. Some of these tasks were only one problem in a longer activity sheet or an assignment set. The implementation of these tasks varied from task to task and instructor to instructor. We observed that both instructors most frequently used the "multiple solutions" feature in their tasks. These multiple-solution tasks also afforded multiple representations (algebraic, symbolic, graphical). For example, Juniper developed this extrema task:

(a) Sketch or write the equation of a function for which the 2nd derivative test is inconclusive at $x = 1$. Provide justification as to how you know the 2nd derivative test fails.

(b) What would be a next step for finding extrema if the 2nd derivative fails?

We coded this task as a *multiple-solution* task that could afford *multiple representations* (algebraic and/or graphical). This task also included features such as requiring students' *originality* in creating such a function, promoting *uncertainty* as students might need to try few possibilities before they find a function that works. We coded the task as one that fosters students' *evaluation* skills as it required them to justify if the test fails. We coded Part (b) of the task as *an open-ended* question where the instructor did not provide specific directions to students.

Similarly, Jo's task on integration "Find a non-trigonometric function f and domain $[a, b]$ such that $\int_a^b f(x)dx = 0$" was coded as a task that has *multiple solutions* and *multiple representations* (algebraic and/or graphical). It was also coded as a task requiring students' *originality* in creating such a function and promoting *uncertainty* as students might need to try a few possibilities before they find a function that works. As a contrast to the extrema task, we did not code this task as an open-ended one because the question instructed students to find such a function, and hence students knew, before tackling the task, that there will be at least one. If the task was phrased "Is there a non-trigonometric function…? If so, find at least one (or two)" then it would have carried the open-ended feature.

In many of Jo's creativity-based tasks, she asked for creation of a function that satisfies (or does not satisfy) certain criteria. With this structure, the most common feature Jo utilized was *multiple solutions* affording *multiple representations*. The *open-ended* feature was utilized on fewer occasions. The feature of *different approaches leading to one answer* was also utilized but minimally. Most of Jo's tasks fostered *making connections between different ideas and concepts* and promoted Sriraman's *uncertainty* principle.

One of the most noticeable changes between materials from her previous Calculus teaching to the 'research' semester was the adaptation of creativity-based tasks on her final exam review sheet. On the final review sheet in the previous semester, we coded 15 questions as "*routine*" exercises in Calculus I as they resembled the typical exercises. On the other hand, the final review sheet for the research semester had five "non-routine" creativity-based tasks with the following combination of features: *multiple solutions* and *representations*, *open-ended*, and *different approaches*. The tasks also fostered *making connections between different concepts* and aligned with the *uncertainty* principle. She also added a creativity-based task on her final exam.

Juniper's creativity-based tasks were developed for each of the following content areas: limits, continuity, relative extrema, absolute extrema, and integration. Many of these tasks asked to create a function that satisfies (or does not satisfy) certain criteria, which were similar to tasks developed by Jo. With this structure, we noticed that Juniper utilized *multiple-solution* tasks affording *multiple representations* most frequently. The *open-ended* feature was also used frequently. Juniper included tasks that required students to *pose problems and questions*. There were questions on tasks that explicitly asked students to *evaluate* or justify their answers or approaches. It was noticeable that her final exam did not include any of her creativity-based tasks and it was very similar to her final exams from previous semesters. However, she did use a creativity-based task on Exam 2.

Participants' journal entries were also coded for features of tasks. For example, Jo Parker implemented the Circle task as a writing assignment. In her teaching reflection journal, she stated that she wanted to "provide students with the opportunity to practice written communication skills while also gaining experience in answering a more open-ended mathematical question. I told the students that there was not a single correct answer to the prompt…" In this reflection, it seems that Jo Parker embraces the *open-ended* feature of this task to facilitate an additional mathematical process, written mathematical communication skill. Juniper's reflections hinted that she wanted to emphasize *incubation* in her implementation of tasks. She assigned students to work on some of the tasks outside of class and asked them to bring their work to the next class for discussion.

We also triangulated our coding of participants' tasks and journal entries with their interview transcripts. When asked "was there any particular feature that was most important to you when you were designing or thinking about these tasks," Jo referred to the features of *multiple solutions* and *posing questions*. In her implementation of her task in which she asked students to explore the conditions for which Rolle's theorem holds, she was happily surprised that even after students submitted their answers, they were posing questions and discussing ideas with each other in class. Referring to the Limit task, she said, "I love the fact that you can approach it in many different ways…I think the traditional way that students think of it is multiply by the conjugate. But, I mean they can factor in it. I mean it's just a little trick…I think it's cute. It's a little bit outside the box but it's still within their realm of knowledge.”

On the other hand, Juniper referred to the extrema task as a memorable task, stating that “[it] sticks out in my mind because that's where I actually saw [students] construct another concept that we haven't gotten to yet. So that it's like a huge leap where creativity had taken them further in mathematics content.” The most common task feature she stated was justification because, “[it] is always important in my mind. They can come up with an answer, but they have to be able to explain… I think underlying all of it was ‘do these questions really highlight the underlying mathematical concepts?” Although this was coded for *evaluation/justification* elsewhere in her tasks, the *multiple solutions* feature was coded most often in Juniper’s tasks. It could be that in her implementation of these tasks, she provided additional questions during discussions that facilitated this feature of evaluating and justifying.

Discussion

Raising instructors’ awareness of mathematical creativity and advocating for change in our pedagogies to promote creativity are the driving purposes of this project. This change can be initiated with small adjustments in task design. The results of our initial analysis of data demonstrate these adjustments made by two instructors. As noted in the analysis, the multiple solutions feature was most commonly used in tasks designed by the instructors. This result mirrors Levenson’s (2013) findings that many of her participants advocated for the use of multi-solution tasks. Levenson further noted that the collection of tasks that were chosen by five instructors who thought these tasks fostered mathematical creativity had fewer open-ended tasks and no problem-posing tasks. Our results indicate a similarity, which we believe is due to the fact that this project was the first time for our participants to set out to explicitly value creativity in their classroom; hence there seems to be a limited attempt to having open-ended and problem-posing tasks. Though Levenson (2013) highlights the importance of open-ended tasks and problem-posing tasks claiming that they “may afford additional opportunities for developing students’ mathematical creativity and it is important to raise teachers’ awareness to the variety of tasks which may serve this purpose” (p. 288).

An intentional selection or creation of tasks that have multiple solutions or that can be approached in different ways seem to be a feasible entry point into fostering mathematical creativity. Allowing students to pose problems, generate examples, make conjectures, and so forth, are other ways to direct students’ thought processes towards creative mathematically-founded reasoning (Lithner, 2008). According to Beghetto (2017), instructors can alter their tasks slightly, such as asking students to come up with their own approaches, or substantially by asking students pose their own problems and ways of solving those problems.

According to Sriraman, teaching practices that are aligned with the five principles have the potential of fostering students’ creativity. In our analysis of creativity-based tasks, we noticed that the Gestalt and Uncertainty principles can be viewed as features of such tasks. However, we claim that the Free Market, Scholarly, and Aesthetic principles are important aspects of the implementation of such tasks that can further promote students’ creativity. In fact, these aspects of implementations differentiate creativity-based tasks from non-routine tasks. We plan to investigate this claim in future research to study potential implementations that complement creativity-based tasks in fostering students’ creativity.

Factors That Influence Graduate Student Instructors' Pedagogical Empathy

Karina Uhing
University of Nebraska–Lincoln

Interpersonal relationships are central to the teaching and learning of mathematics. One way that teachers relate to their students is by experiencing empathy for them. In this study, I explore the phenomenon of pedagogical empathy, which is defined as empathy that influences teaching practices. Specifically, I examine how graduate student instructors (GSIs) conceptualize empathy as it relates to the teaching and learning of mathematics and identify factors that influence this pedagogical empathy. The findings presented in this paper emerged from interviews with 11 GSIs in which they answered questions designed to elicit their thoughts about empathy. The participants provided complex and diverse notions of how empathy relates to teaching mathematics. Conclusions drawn from this paper may help inform professional development efforts targeted at novice and experienced instructors at the post-secondary level.

Keywords: Empathy, Graduate student instructors, Professional development

Interpersonal relationships are central in the teaching and learning of mathematics. One way that teachers relate to their students is by experiencing empathy for them (Cooper, 2011). This empathy is often situated at the intersection of teacher and student affect and has the potential to influence teaching practices; yet, little research has been conducted in this area (Zembylas, 2007). Exploring how empathy influences teaching can lead to a deeper understanding of teaching practices and have far reaching implications for the broader education community.

This study aims to explore how graduate student instructors (GSIs) conceptualize empathy as it relates to the teaching and learning of mathematics. The conclusions drawn from this study will add to the emerging body of literature about GSIs' knowledge, beliefs, and teaching practices (e.g., Speer, Murphy, & Gutmann, 2009). In addition, this research can be used to inform professional development efforts for both novice and experienced instructors.

Theoretical Perspective

Empathy is a nuanced concept. Researchers have described empathy in various ways and have developed different characterizations depending on the context in which empathy is referenced (Cuff, Brown, Taylor, & Howat, 2016). It is therefore important to provide a working definition of empathy as it relates to the context of teaching. Drawing on the work of Cooper (2002, 2004, 2011), I define empathy as "a highly complex phenomenon, closely associated with moral development, which develops over time and with frequency of interaction and which is highly dependent on the actors and the context of the interaction" (Cooper, 2004, p. 12). In this paper, I use the term *pedagogical empathy* to refer to the empathy that a teacher experiences for a student or group of students. I further propose that pedagogical empathy has the potential to influence teaching decisions and involves how teachers use their understanding of students' perspectives and experiences to inform the actions they take in the classroom.

The findings presented in this paper also draw on Zembylas's (2007) framework, which establishes a connection between pedagogical content knowledge and emotional knowledge. Zembylas (2007) contends that "teacher knowledge is a form of knowledge ecology—a system consisting of many sources and forms of knowledge in a symbiotic relationship" including "content knowledge, pedagogical knowledge, curriculum knowledge, knowledge of learners, emotional knowledge, knowledge of educational values and goals and so on" (p. 356). Specifically, Zembylas (2007) narrows in on emotional knowledge and defines the construct of emotional ecology to explain the relationship between emotional knowledge and pedagogical content knowledge. Building on his work, I conceptualize pedagogical empathy as a filter that connects pedagogical content knowledge and emotional knowledge. The findings presented in this paper describe three factors that are critical in the development of this connection.

Purpose

This paper stems from a larger study that explores the ways in which pedagogical empathy might influence teaching practices. As a first step, it is important to consider how instructors conceptualize empathy and identify factors that have the potential to influence pedagogical empathy. Thus, this paper focuses on the following research question: *What factors might influence the ways in which mathematics GSIs experience empathy for their students?*

GSIs are an important and unique population to study because they are not only instructors of undergraduate mathematics courses, but also students in graduate mathematics courses. Having these simultaneous roles may make it more likely for GSIs to experience pedagogical empathy for their students as they may have recently had similar or shared experiences as students themselves, an important factor that has been shown to be associated with empathy in other contexts (Eklund, Andersson-Stråberg, & Hansen, 2009). Leaders of GSI professional development can use insights from this study to help GSIs reflect on their experiences and increase their awareness of pedagogical empathy.

Methods

Eleven mathematics GSIs at a large Midwestern university participated in this study. Each GSI was the instructor of record for a precalculus course, although they had varying levels of teaching experience. None were international GSIs. Participants selected their own pseudonyms, which are used below. Data were collected during the summer and fall of 2018 through multiple interviews and classroom observations of the GSIs. The findings in this paper emerged primarily from analysis of the initial interviews, which were designed to explore how GSIs conceptualize empathy. Participants were initially asked to write down their definition of empathy as it relates to teaching mathematics and provide an illustrative example. Participants then discussed their definitions and responded to questions such as: "Where do you think empathy comes from?" and "Is it necessary for math teachers to have empathy for their students?"

Interviews were transcribed and analyzed using MAXQDA. Since pedagogical empathy is a novel theoretical construct, inductive coding was initially used to generate a set of preliminary conceptual codes relating to how GSIs conceptualize empathy within the context of teaching and learning mathematics (Miles, Huberman, & Saldaña, 2014). Each interview was tagged using these preliminary codes, and each coded segment was summarized. These segments were then sorted using pattern coding (Miles, Huberman, & Saldaña, 2014). During this process, the conceptual codes were refined and further developed into themes. Finally, these themes were organized into two categories that relate to how the participants described their experiences with empathy within the context of teaching and learning mathematics.

Findings

Two main categories of themes emerged from coding the initial interviews: drivers of pedagogical empathy and conditions related to the enactment of pedagogical empathy. The themes that fall under these categories highlight elements that have the potential to influence how GSIs experience pedagogical empathy. Due to space considerations, only the drivers of pedagogical empathy are described in this paper. Table 1 provides an overview of the drivers along with a short summary of each theme and a representative quote from a participant.

Table 1. Drivers of Pedagogical Empathy

Theme	Summary	Representative Quote
Past Experiences	Drawing on past experiences as a way to empathize with students	*"I think I draw from those experiences, my own personal experiences as a student to kind of guide me in how I should interact with my own students."* - Oliver
Context of Mathematics	Considering how the disciplinary context of mathematics might impact pedagogical empathy	*"Students come in from a lot of backgrounds, many in which they're taught to hate math or to think of themselves as bad at math."* - Mark
Non-mathematical Factors	Experiencing empathy for students in ways that go beyond the scope of teaching and learning mathematics	*"People have come up to me with problems about their life, just in general, and you have to be able to relate to that also, which isn't necessarily math-related."* - Bill

Drivers of Pedagogical Empathy

During analysis, several drivers emerged. These drivers appear to motivate pedagogical empathy and can be grouped into three main themes: personal experiences, the context of mathematics, and non-mathematical factors. Specifically, GSIs discussed the importance of drawing on personal experiences, considering the disciplinary context of mathematics, and accounting for non-mathematical factors when experiencing pedagogical empathy for students. These themes illustrate how pedagogical empathy can be influenced by different factors and are described in depth below.

Drawing on personal experiences. All of the participants discussed how experiencing empathy for students can be impacted by past personal experiences. In some cases, these experiences helped GSIs relate to their students and were seen as a way to empathize with students. In other cases, GSIs saw having a lack of similar past personal experiences as a potential barrier to experiencing empathy for their students. A few GSIs also reflected on how they had developed empathy over time by learning from their experiences as both teachers and students.

Oliver was one of the GSIs who discussed relating to his students by drawing on his past experiences as an undergraduate student. He recalled being in a physics class and constantly needing to use sine and cosine, even though he "barely understood what they meant at the time." He went on to explain how "this moment created something" that he could reflect back on and use when trying to empathize with his students. Oliver also gave a specific example of how his experiences as a student have influenced his teaching practices:

> I think often I don't click with instructors that don't have this [empathy]. I feel like certain instructors, they get frustrated. I feel like there's a sense of frustration with you when you don't understand something quickly, and I've never been the person to learn things really quickly. So I think I draw from those experiences, my own personal

> experiences as a student to kind of guide me in how I should interact with my own students and how not to be frustrated with their slowness or their inability to comprehend something that maybe seems trivial to me.

Amanda was another GSI who talked about understanding what it feels like to be a student who is struggling with something. When asked where empathy might come from, she reflected on her experiences as a first-year graduate student. In particular, Amanda said that she remembered how it felt to be "sitting in a classroom listening to a lecture and have no idea what's going on," and that sometimes she will see that same look of confusion in her students' eyes. Amanda went on to say that her empathy comes from wanting students "to understand that they can get to an understanding of the material," and that she does not "want anybody to leave a classroom thinking that they're bad at math."

While some GSIs found it relatively easy to connect with students in their precalculus courses, others discussed how their life experiences might be dissimilar to those students, making it harder to empathize with them. In particular, Jack talked about how it is easier to empathize with situations that are more "proximal" and how it "takes skill to empathize with people who are further away from you in life experience." He explained how it might be difficult for some GSIs to empathize with their students:

> I do think it's probably harder for people to empathize with students who take the lower math courses. There are a lot of experiential barriers between someone who's in graduate school in mathematics teaching an Intermediate Algebra student. So I do think that it is more difficult in that situation for the instructor to empathize.

Jack also discussed how it was easier for him to empathize with his students in a Calculus II course that he had recently taught because it was easier to "simulate the student's emotions" and "detect what then needs to be done."

Beth expressed similar thoughts about why it might be difficult for GSIs to experience empathy for their students: "From my experience with other grad students teaching courses, for some of them, they didn't struggle with it. They don't see a reason why their students are struggling with it." She went on to explain that sometimes it is difficult for her to figure out how to explain something to a student because "it's hard to come up with those sorts of reasonings for very basic things," and that GSIs who are teaching lower level math courses "might struggle more because it's been a long time since they've seen it and they think it's easy."

A few of the GSIs with more teaching experience discussed their belief that empathy could be improved over time because of their past experiences with teaching. Specifically, Mark discussed how he was less cognizant of what his students were experiencing when he first started teaching:

> I think it's fair to say I was less empathetic, less aware of my students' feelings the first few semesters I was teaching than I am now because I just didn't realize...the extent to which people did actually come in dreading these math classes, and it's not because they're like lazy or something, but just because they've been taught to hate them.

Mark also talked about how one can develop empathy by recognizing "something that you've seen a lot in other students." Likewise, Aaron discussed not having had similar experiences to many of his students and developing empathy by being exposed to people's stories, reading articles, and absorbing information about people's college lives.

Joe was another GSI who talked about empathy as a skill that comes from "training and practice." He also explained how teachers might "start" in different places when it comes to experiencing empathy:

> I think a lot of empathy comes from practice, but I think also I'd say people don't start in the same place. Like some people, the first class they ever teach, they're like really good at empathizing with students, and some people don't get that and maybe I'm guessing some people never develop that and some people develop that while they go on and practice more and work at it, if they work at it.

In the past, Joe had been "less empathetic to students who didn't really care about their math class" because he had always liked math and thought it was interesting. He discussed trying to "contextualize" that for himself by thinking about having to take a driving course, which he did not enjoy. After making this connection between his own experiences and his students' experiences, Joe described being more aware of how his students might feel and trying to use this newfound understanding in his interactions with them.

Considering the disciplinary context of mathematics. In addition to discussing how empathy can be influenced by past experiences, several participants reflected on how the disciplinary context of mathematics might impact pedagogical empathy. Many GSIs talked about how students might feel or think about mathematics, often linking back to cultural stereotypes and students' prior experiences with mathematics. Participants also acknowledged that teachers and students could hold opposing beliefs about mathematics and that it is important to consider these different perspectives as they have the potential to influence how teachers empathize with their students.

A few GSIs discussed how students might feel or think about mathematics and the resulting impact that might have on their experience in the course. Aaron brought up empathizing with a student in his class who he described as "hesitant" and "scared." He talked about "trying to think of ways to figure out more about how this student is feeling about math" and how he could "bring her more confidence while she approaches problem solving." Another participant, Mark, emphasized the importance of knowing that "students come in from a lot of backgrounds, many in which they're taught to hate math or to think of themselves as bad at math" and suggested that in order to "reach all students" instructors need to consider students' perspectives of mathematics as a discipline.

In addition to considering student perspectives of mathematics, a few of the GSIs discussed their own perspectives and experiences with mathematics. Beth talked about how one of her goals as a teacher is to get her students to "appreciate math and appreciate that they can do it" because she wants them to feel the way that she feels about mathematics. She went on to explain how this view impacts her teaching:

> I think if you close yourself off from how your students are feeling and just like this is the material I need to teach and I'm going to teach this material at this pace regardless of how my students are learning, you're going to cut a lot of people off from learning math and actually wanting to pursue it. I don't know. I mean people think I'm crazy for wanting to do math, and I want more people to think, "oh I could do this. I could go on to Calc 3 if I wanted to or even further than that."

Mark also brought up his history with mathematics, although he discussed having mixed feelings about it: "I did go through a few years in high school where I didn't like my math classes, but even then I didn't really feel like I disliked math. I just disliked the math class because it was boring." He went on to share how Calculus had changed his perspective and how that influenced his view of the course as an instructor:

> Calculus, for me, had been just such a joyful class. It was sort of like what reignited my interest in math, reminded me that math class was a cool thing. So when I was teaching it

> the first semester, it didn't really even occur to me that my students could legitimately be worried about this and frightened about this.

Other GSIs openly discussed their negative experiences with math. Aaron explained how he shares a personal story with his students to tell them about his "perspective on the culture of math and how there's a fear-based culture of math in many cases." Aaron's story involves being a student in an undergraduate math class where he was handed a sheet of problems to solve:

> I didn't know how to even start any of them because I hadn't taken the necessary class prerequisites. So I was just sitting there waiting, not really able to do anything, and the professor stood in front of me and just started staring at me, at my blank sheet of paper for like five minutes. He finally broke the silence by asking, "Do you understand?" And it made me feel really bad.

By sharing this story with his students, Aaron hopes that they will be able to recognize and acknowledge their own fears and anxieties about math and can better relate to him as an instructor.

Accounting for non-mathematical factors. While many participants talked about how the context of mathematics influences empathy, several of them discussed how instructors are likely to experience empathy for their students in ways that go beyond the scope of teaching and learning mathematics. Many GSIs addressed this fact by acknowledging that students' experiences outside of the classroom can profoundly affect their learning and emphasized that it is important for instructors to consider non-mathematical factors when dealing with certain situations.

Bill brought up these nonacademic factors during his interview and suggested that part of being a teacher is empathizing with students outside of the classroom:

> There's also parts of it that aren't even about math, right, that are…I mean even just in the couple of years that I've been teaching, people have come up to me with problems about their life, just in general, and you have to be able to relate to that also, which isn't necessarily math-related. I guess you have to be able to be empathetic, have empathy for students even outside of an academic setting.

Other GSIs echoed this sentiment. Mark talked about all of the "stuff students are going through, inside and outside of our classrooms that affects their ability to learn and get something out of the class." Similarly, Henry mentioned being aware of and understanding that there might be lots of different reasons why a student may not be doing well in a class: "It might be something to do with their understanding of the material...[or] with how hard they're working. It might be something completely outside of those things involving the student's life, and keeping that in mind is probably beneficial."

Aaron also discussed the importance of understanding and relating to what students are going through outside of the classroom. Specifically, he noted the importance of considering a student's "history in a "holistic sense" and "conditions like what their schedule looks like, whether they have a supportive family environment or a demanding family environment, whether they have a commute to school that's long, all of these sorts of things." He went on to say that it is necessary for teachers to be aware of these external pressures and have an understanding of "how they impact the student's learning outcomes."

Another GSI, Jane, talked about teaching first-year college students who might be adjusting to a new environment: "you're empathetic to the fact that they just got to college and that they're not only taking your course, but they're transitioning into this new experience, these new classes that are way different than their high school classes." She also clarified that experiencing pedagogical empathy in this way is "more general" and not "necessarily specific to math" but still important, especially for students in their first year of college.

Discussion

The data presented above highlight several factors that have the potential to influence how GSIs experience pedagogical empathy for their students. While these factors can greatly impact interactions between instructors and students, instructors often have little to no control over many of them. In this section, I discuss how the three emergent themes address my research question and pose further questions worth investigating in this area of research.

As illustrated by the findings, past personal experiences can support or hinder the ways in which GSIs experience pedagogical empathy for their students. Seeing similarities between your own personal experiences and those of a student can make it easier to empathize with that student, while lacking similar experiences might make it more difficult. This result brings up questions related to equity: Are GSIs more likely to experience empathy for students with whom they more closely identify? Could this tendency lead to inequitable teaching practices? Are there ways to identify and avoid this occurrence? If so, how can professional development be structured to acknowledge this fact and expand GSIs' perspectives to include a broader awareness of student experiences?

Another question prompted by these findings is whether GSIs might be able to transfer their experiences from one context to another in order to empathize with students. One GSI, Joe, was able to "contextualize" what his students might feel by recalling his experience of taking a driving course that he did not enjoy. Joe's story suggests that this transfer of empathy might be possible. Thus, leaders of GSI professional development should design activities that encourage GSIs to reflect on their past experiences as *both* teachers and students in a variety of contexts. Engaging in this reflection might help GSIs better understand how to leverage past experiences—which may or may not be related to mathematics—in order to empathize with a wider range of students in more equitable ways.

In addition to past experiences, mathematics itself can be a driving influence of pedagogical empathy. As Mark (and other GSIs) acknowledged, students "come from a lot of backgrounds, many in which they're taught to hate math or to think of themselves as bad at math." Experiencing pedagogical empathy can increase GSIs' awareness of these different backgrounds and help them understand how their students might feel towards mathematics. If GSIs are aware of these negative perceptions or fixed mindsets, they can then take steps to reframe them and encourage their students to view mathematics in a more positive light.

Finally, it is important to recognize that empathy can be elicited in ways that are beyond the scope of teaching and learning mathematics. As many of the GSIs noted, students deal with a variety of issues in their daily lives, and their experiences outside of the classroom can influence the learning that happens in the classroom. Pedagogical empathy can help instructors understand the challenges that students may be facing and better attend to individual student needs.

Many facets of pedagogical empathy remain unexplored. Further research is needed to better understand the concept of pedagogical empathy and its connections to different types of knowledge that inform teaching decisions. This work sheds light on a few of its motivating drivers and provides insights for leaders of GSI professional development to consider. By encouraging GSIs to reflect on both their own and their students' experiences, leaders of professional development can increase GSIs' awareness of pedagogical empathy and help them identify different ways to relate to their students, thus supporting their growth as undergraduate mathematics instructors.
