ISSN: 2474-9346

Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) returned to Boston, Massachusetts for its twenty-fourth annual Conference on Research in Undergraduate Mathematics Education from February 24 - February 26, 2022.

The program included plenary addresses by Dr. Paul Dawkins, and Dr. Karen Keene, and the presentation of 145 contributed, preliminary, and theoretical research reports and 75 posters. The conference was organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in the field of undergraduate mathematics education, each of which underwent a rigorous review by two or more reviewers:

- Contributed Research Reports describe completed research studies
- Preliminary Research Reports describe ongoing research projects in early stages of analysis
- Theoretical Research Reports describe new theoretical perspectives for research
- Posters are 1-page summaries of work that was presented in poster format

The conference was hosted by the Wheelock College at Boston University. Many members of the RUME community volunteered to review submissions before the conference and during the review of the conference papers. We sincerely appreciate all of their hard work by the 152 reviewers. We wish to acknowledge the conference program committee for their substantial contributions to RUME and our institutions. Without their support, the conference would not exist.

This was also the first year the RUME Conference was held in a hybrid format. The conference was simultaneously accessible in person and online using GatherTown. There were 397 registrants in total. Of these, 208 attended in-person and 189 attended virtually.

Finally, we wish to express our deep appreciation for Wheelock College and Boston University. Their support enabled us to have our conference and continually support our community.

Counterexamples and Refutations in Undergraduate Mathematics

Lara Alcock
Loughborough University, UK

Nina Attridge
University of Portsmouth, UK

How do undergraduate mathematics students interpret refutations? We investigated this question by asking participants to 1) decide whether statements are true or false and provide refutations, 2) evaluate counterexamples and 'correct versions' of the statements as valid or invalid refutations, and 3) judge which potential refutations are better, explaining why. We report a study in which 173 undergraduate mathematics students completed this task. Results reveal that participants did largely understand the logic of counterexamples but did not reliably understand the broader logic of refutations.

Keywords: Counterexample, Refutation, Conditional Statement, Logic, Undergraduate

Introduction

Logical reasoning is core to mathematics. It is promoted officially in educational policy and guidance documents (e.g., DfE, 2014; NCTM, 2000), it is addressed explicitly in undergraduate introduction-to-proof courses (e.g., Hammack, 2013), and its development is considered in depth in studies in undergraduate mathematics education (e.g., Hub & Dawkins, 2018; Yopp et al., 2020). Moreover, logic and content knowledge are interlinked. Some teaching sequences rely upon students using reasoning skills to construct content knowledge (e.g., Dawkins & Cook, 2017), and there is evidence that intensive mathematical study at age 16-18 develops abstract logical reasoning skills (Attridge & Inglis, 2013).

But what of situations in which content knowledge interferes with logical reasoning? Understanding logical statements is difficult (Dawkins, 2017; Evans, Handley, Neilens & Over, 2007), and even relatively simple situations can mislead students into using familiar content knowledge without considering all relevant logical possibilities (Dawkins & Cook, 2017; Epp, 2003). The study reported here addresses this issue from a novel angle. Its design is based on observation of real analysis students' responses to questions asking them to state whether statements were true or false and, for each that they declared false, to justify their answer with a counterexample or a brief reason. One such statement, for which results are reported here, was

$\forall\, a, b \in \mathbb{R}, |a+b| < |a| + |b|$.

We might anticipate that some students would incorrectly answer *true* because the statement 'looks like' one that appears in the course, so inattentive students might fail to notice the difference and declare it true without considering possible counterexamples. Or students might search for counterexamples, but fail to find any due to insufficiently developed example spaces (Goldenberg & Mason, 2008) or insufficient checking that a relevant example really has the required properties (Edwards & Alcock, 2010). In the real analysis course, some students did indeed give incorrect *true* responses. However, many also gave correct *false* responses accompanied by invalid refutations. The following was common for the statement above.

FALSE. Reason: It should be $\forall\, a, b \in \mathbb{R}, |a+b| \le |a| + |b|$.

The provided reason can be considered a 'correct version' of the original statement. But it does not refute the original. This illustrates the possibility of interference between content knowledge and logical reasoning, but the mechanism, as discussed below, is not obvious.

Theoretical Background

Perhaps, to explain invalid refutations like that above, accessibility is key. If correct versions come readily to mind for students confronted with similar but false statements, they might write those down as refutations and think no further. This would be consistent with phenomena observed in research around dual-process thinking in mathematical situations (e.g. Evans & Stanovich, 2013). Alternatively, perhaps accessibility is key in that counterexamples do *not* come to mind. Students' *example spaces* take time and effort to develop (Watson & Mason, 2005), and reasoning about concepts is often skewed by early or familiar examples (Zazkis, Liljedahl & Chernoff, 2008). This might make counterexamples relatively inaccessible, especially where concepts are or poorly explored (Sinclair, Watson, Zazkis & Mason, 2011; Zazkis & Chernoff, 2008). If accessibility is key, we would predict that on seeing appropriate counterexamples, some students would recognise them as such and switch answers accordingly.

It might be, however, that invalid refutations arise from explicit value judgements. Perhaps students who give correct-version reasons do think about the logic of their answers—even generating counterexamples—but nevertheless judge correct-version reasons to be better. This might occur if students' mathematical epistemologies are not well developed: some might believe that mathematics is primarily about dutiful recitation of correct answers (Muis, 2004). Alternatively, students might think about the logic of their answers but fail to arrive at valid conclusions. Extensive research has shown that people in general do not reason in normatively correct ways (e.g., Evans, Handley, Neilens & Over, 2007), and that mathematics students typically perform better but far from perfectly (Attridge, Doritou & Inglis, 2015; Attridge & Inglis, 2013). If explicit value judgements are key, we would predict that if presented with appropriate counterexamples, some students would stick with correct-version reasons as better.

The study presented here investigated these possibilities using a three-stage instrument. Undergraduate mathematics students were presented with three items and asked to give initial true/false and counterexample/reason responses. Then, for each item, they were asked to evaluate the validity of both a counterexample and correct-version reason, and subsequently to decide which of the two is the better response, explaining their decision. The outcomes have pedagogical relevance: instructors must understand the origin of this phenomenon in order to intervene in a way that connects with student thinking. They also have theoretical relevance: we know that mathematical and logical reasoning are linked (Inglis & Attridge, 2016), but we know little about how reasoning does or could develop alongside content knowledge in the logically demanding world of early proof-based mathematics (Dawkins & Cook, 2017; Lee, 2017).

Method

Our study used a specially constructed true/false instrument, completed by students in a lecture in a real analysis course that covered sequences, real numbers, and series. Approximately two thirds of the large class (more than 200 students) were first-year students registered for a UK mathematics degree; they spent 75-100% of their study time on mathematics. The remainder were second-year students on joint-degree programmes involving approximately 50% mathematics. All had high but (usually) not elite prior mathematical attainment.

The instrument used the three items:

- $\forall\, a, b \in \mathbb{R}, |a+b| < |a| + |b|$.
- If $x < 3$ then $1/x > 1/3$.
- A sequence (a_n) is increasing if and only if $\forall n \in \mathbb{N}$, $a_{n+2} \geq a_n$.

For the first, *absolute value item*, the obvious correction is to the triangle inequality, which involves correcting the conclusion. Providing a counterexample requires two numbers. The second, *reciprocal item* invites correcting the premise by ruling out cases where $x < 0$. It is simpler than the first in that providing a counterexample requires just one number. The third, *sequence item* invites correction to the definition of *increasing*, which in the course was given as 'A sequence (a_n) is increasing if and only if $\forall n \in \mathbb{N}$, $a_{n+1} \geq a_n$'. Because all sequences that satisfy this definition also satisfy $\forall n \in \mathbb{N}$, $a_{n+2} \geq a_n$, a counterexample must not be increasing and is nontrivial to construct because it cannot be drawn from the sequences that, for most students, would be considered prototypically non-increasing (Alcock & Simpson, 2017).

The true/false instrument contained four pages. On the *initial response* page, participants were presented with all three items and the prompt 'Answer TRUE or FALSE to each question. For those that are FALSE, give a counterexample or a brief reason'. On each remaining page, participants saw one item again, together with a possible counterexample response and a possible correct-version reason. As shown in the sample page in Figure 1, they were asked to evaluate each response by ticking boxes, then state which answer they thought better and why.

Evaluation of Answers to Question 1 1

$\forall a, b \in \mathbb{R}$, $|a+b| < |a| + |b|$.

Below are some examples of typical answers. Tick one circle to show how you would evaluate each answer.

1. FALSE 1.2
   Counterexample: If $a = 1$ and $b = 6$ then $|a+b| = 7$ and $|a| + |b| = 7$.

   ◯ The answer is correct and the counterexample is valid.

   ◯ The answer is correct but the counterexample is not valid.

   ◯ The answer is incorrect.

2. FALSE 1.3
   Reason: It should be '$\forall a, b \in \mathbb{R}$, $|a+b| \leq |a| + |b|$'.

   ◯ The answer is correct and the reason is valid.

   ◯ The answer is correct but the reason is not valid.

   ◯ The answer is incorrect.

3. Which answer is better and why? 1.4

Figure 1: Evaluation and forced-choice page for the absolute value item (in original layout); the small-font numbers to the right label which item is which to facilitate analysis of the randomised-order versions.

We constructed six versions of instrument with different permutations of the three items. For each evaluation page in each version, multiple copies were created in which the orders of the counterexample and correct-version reason were randomised. The instrument was distributed on individual paper copies. The front page contained informed consent information, explaining the purpose of the study and the way in which the data would be used. Participants were given 15 minutes in week 3 of the course to complete their versions of the instrument; 173 agreed that their data could be used. We report here on the initial, evaluation and forced choice responses.

Results

Initial Responses

The initial responses were classified according to whether participants stated *true* or *false*, and qualitative analysis revealed several categories of counterexample/reason. The categories (and short codes) are shown below, with illustrative responses from the absolute value item.

- CEX: Single correct counterexample.

  'False. $a=5$, $b=6$, $|a+b|=|a|+|b| \rightarrow |5+6|=11$, $|5|+|6|=11$.'

- CEXG: Correctly specified general class of counterexamples.

  'False. If a and b are both positive, $|a+b|=|a|+|b|$.'

- CEXI: Single incorrect/incomplete counterexample.

  (Participant simply wrote the symbol '$\leq$' without numbers.)

- CVR: Correct-version reason.

  'False. $\forall\, a, b \in \mathbb{R}$, $|a+b| \leq |a| + |b|$.'

- CVRI: Incorrect correct-version reason.

  'False as $\forall\, a, b \in \mathbb{R}$, $|a+b| = |a| + |b|$.'

- E: Alternative form of explanation.

  'False. Arguments can be equivalent/equal, not stated.'

- EI: Incorrect alternative form of explanation.

  'False. Counterexample: $(a+b)^2 \nless a^2 + b^2$, $a^2 + 2ab + b^2 < a^2 + b^2$.'

- T: True.
- O: Other (blank, incomplete, or inconsistent responses like 'true' with a counterexample).

Regarding the CEX and CEXG classifications, we note that some authors value general classes over single correct counterexamples due to their power to provide insight into why a claim is false beyond 'exceptions' (Giannakoulias, Mastorides, Potari & Zacharides, 2010) and to their consequent relationship to mathematical theory building (Yopp, 2017; Zeybek, 2016). Here our focus is on simple refutation, but we respect the distinction in these descriptive results.

Table 1 documents the distributions of initial responses. For all items, about one fifth of the 173 participants answered *true* (not the same participants each time: 19 answered *true* twice and none answered *true* three times). For *false* responses, justifications that were incorrect on their own terms (with an 'I' in the code) were uncommon, though more appeared for the sequence item. Beyond this, distributions across the three items differed considerably. The reciprocal item was the 'easiest' to respond to in a normatively correct way: 119 participants provided only counterexamples and a further nine included valid counterexamples. Thus 74% of participants gave a counterexample for this item, and 95% of those who correctly answered *false* included a counterexample. This shows that, of those not tripped into answering 'true', a majority understood the logic of counterexamples well enough to provide these in some circumstances (cf. Stylianides & Al Murani, 2010). For the absolute value and sequence items, however, the data clearly document the observed reasoning problem. For these items, correct-version reasons formed the entire response for 43 (25%) and 72 (42%) of participants respectively.

Table 1: Initial responses summarized by type for the absolute value, reciprocal and sequence items. Responses involving extra explanation are included with the main type except where they occurred separately.

	CEX	CEXG	CEXG+CEX	CEXG+CEXI	CEXI	CEX+CVR	CEXG+CVR	CEX+CEG+CVR	CEXG+CVRI	CVR	CVR+CEXI	CVRI	E	EI	T	O
Abs	50	9	2		1	18	8			43		4	1	1	34	2
Rec	64	29	26		1	3	4	1	1	5					38	1
Seq	23	1		1	8	12				72	3	3	6		35	9

Evaluation Responses

Almost all participants who erroneously said *true* at the initial response stage recognised their mistake during the evaluation stage and accepted at least one suggested *false* answer as correct. The striking feature of the evaluation data was that the majority of those who had correctly answered *false* neither stuck with their initial response type nor switched. Instead, they accepted *both* the counterexample and the correct-version reason as valid. This is captured in Table 2 where, for each sub-table, the shaded cell highlights the number and percentage of normatively correct responses: counterexample valid and correct-version reason invalid. For all items, this combination was much less frequent than accepting both as valid.

Table 2: Counts of validity judgements for the evaluation responses. CV=answer evaluated as correct and counterexample/reason as valid, CI=answer evaluated as correct and counterexample/reason as invalid, I=answer evaluated as incorrect. Blank or unreadable responses mean that one participant is omitted for each question.

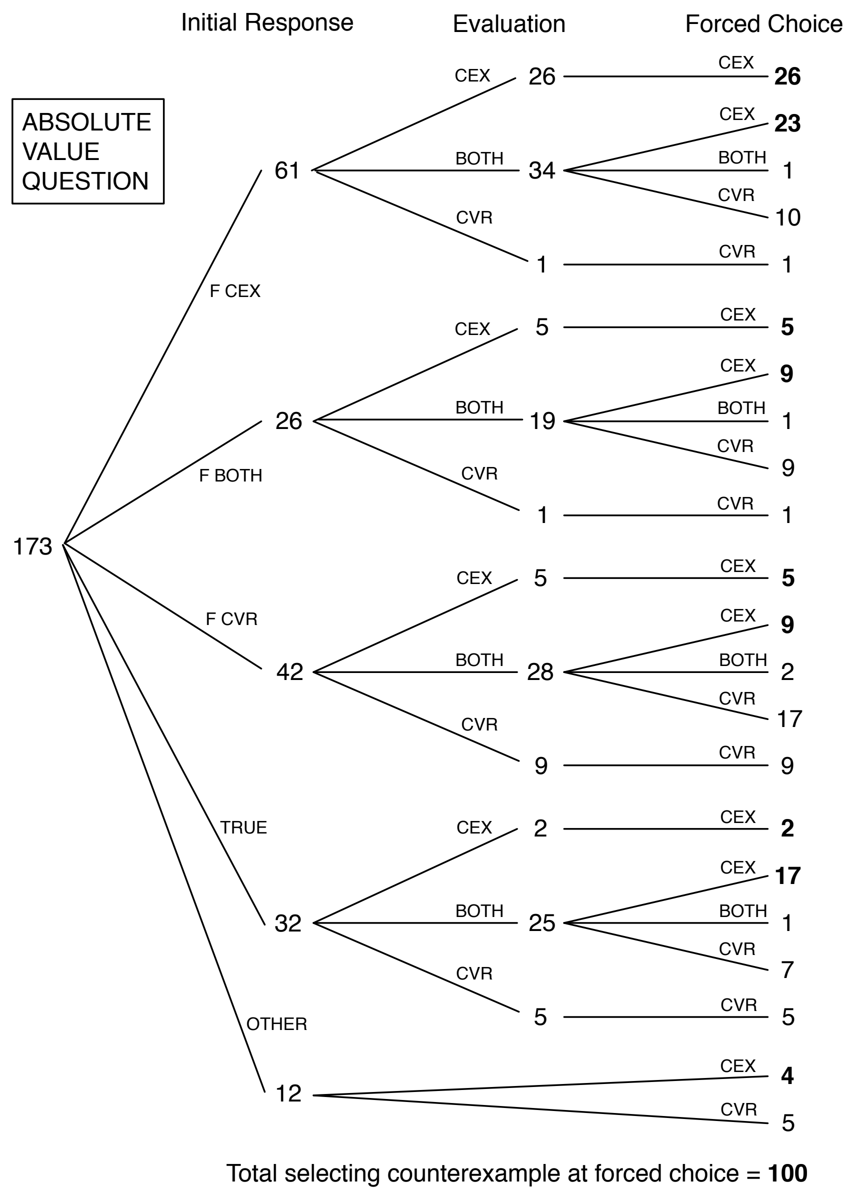
			Counterexample		
			CV	CI	I
Absolute value	Correct-version reason	CV	114 (66%)	12 (7%)	5 (3%)
		CI	36 (21%)	2 (1%)	0 (0%)
		I	2 (1%)	0	1 (1%)
			Counterexample		
			CV	CI	I
Reciprocal	Correct-version reason	CV	119 (69%)	6 (3%)	0 (0%)
		CI	44 (26%)	0 (0%)	0 (0%)
		I	2 (1%)	0 (0%)	1 (1%)
			Counterexample		
			CV	CI	I
Sequence	Correct-version reason	CV	95 (55%)	15 (9%)	13 (8%)
		CI	33 (19%)	2 (1%)	1 (1%)
		I	4 (2%)	5 (3%)	4 (2%)

Thus, only a small minority of participants rejected the counterexamples, indicating that they understood these to be valid refutations. But, for each item, only around one fifth to one quarter of participants rejected the correct-version reason. This means that participants largely did not interpret the broader logic of refutations in a normatively correct way.

Forced Choice Responses

The above result renders the forced-choice responses of particular interest: when asked to choose, which would participants judge better? Responses for the absolute value item are summarised in the tree diagram in Figure 2. To render these readable, initial response categories are combined so that F CEX includes all *false* responses with valid counterexample-only justifications, F BOTH includes all *false* responses with valid counterexamples and correct-version reasons, and F CVR includes all correct-version-reason-only responses.

Figure 2: Tree diagram showing contingent responses for the sequence item. Numbers differ slightly from those in Table 1 because, for example, a participant might have given a counterexample at the initial stage but introduced an inconsistency later, and thus be classed as 'other' here.



Responses for the reciprocal and sequence items were broadly similar and, in theoretical terms, these findings cannot be explained by the accessibility account alone. When offered counterexamples, some participants who initially gave correct-version reasons switched, but more did not. Moreover, some participants switched from counterexamples to correct-version reasons and, for all three items, close to half judged the reason better when forced to choose. This suggests that value judgements account at least partly for students' responses; it does not appear that the result of reflective thought is necessarily a mathematically valid answer.

We conclude these results with a by-participant perspective. Table 3 shows the distributions of participants according to scores out of three for the number of initial counterexample responses (initial score), the number of evaluations only the counterexample judged valid (evaluation score) and the number of counterexamples selected at forced choice (choice score). This confirms a lack of simple interpretations: a majority of participants gave and accepted counterexamples and judged them better some but not all of the time. This indicates that for most, valid reasoning was possible but not reliable (cf. Dawkins & Cook, 2017; Epp, 2003).

Table 3: Distributions of initial, evaluation and choice scores out of three.

	0	1	2	3	Mean (SD)
Initial Score	23	69	62	19	1.45 (0.86)
	13.3%	39.9%	35.8%	11%	48.2%
Evaluation Score	104	35	16	18	0.70 (1.01)
	60.1%	20.2%	9.2%	10.4%	23.3%
Choice Score	33	36	44	60	1.76 (1.13)
	19.1%	20.8%	25.4%	34.7%	58.6%

Discussion

This study investigated reasoning about refutations in undergraduate mathematics. For all three items in our instrument's initial response stage, a large majority of participants correctly answered *false*. However, for the absolute value and sequence items, substantial minorities justified *false* answers only with correct-version reasons. In the evaluation stage, participants who had answered *true* recognised their mistakes, and very few rejected counterexamples as invalid refutations. However, a majority also accepted correct-version reasons as refutations, indicating that they did not understand their logical inadequacy. By-participant analysis confirmed that most participants gave normatively valid responses in some but not all cases.

Methodologically, we acknowledge that a survey provides limited insight into what students 'really think'. Our instrument provided information on both spontaneous reasoning and more considered reflection in response to structured prompts but, if pushed in an interview setting, some students might change their minds or reveal thinking that was not captured on paper (cf. Stylianides & Al Murani, 2010). We also acknowledge that our instrument's instruction that a *false* response should be accompanied by 'a counterexample or a brief reason' implicitly condones justifications of both types, and might have influenced some participants toward or away from providing counterexamples. It would be interesting to compare responses to versions of the instrument that ask specifically for counterexamples and generally for justifications.

In the meantime, our findings shed light on student understanding of refutations as an aspect of logical reasoning, and lend larger-scale support to arguments (e.g. Dawkins & Cook, 2017; Hub & Dawkins, 2018; Ko & Knuth, 2013) that students specialising in mathematics might benefit from interventions designed to help them interpret issues of logic in normatively valid ways and consistently across mathematical content.

The Synchronous Online Environment as a Mediator of Collective Proving Activity

Tenchita Alzaga Elizondo
Portland State University

Technological tools can transform how students interact not only with each other but also with the mathematics itself. This study investigates how students in a synchronous remote Introduction-to-Proof course operationalize the technological tools available to them to engage in collective proving activity. I identify several utilization schemes students developed for these tools and describe how students coordinated them and their impact on the role of proof.

Keywords: Proof, Computer Mediation, Instrumental Genesis, Collaborative Learning

Technology fundamentally changes the way students interact by acting as a mediator (Vygotsky, 1962), impacting not only interactions between students but also the process of developing knowledge through those interactions (Borba & Villarreal, 2006). Consequently, mathematics courses offered remotely present new challenges as well as opportunities for students to learn collaboratively with one another. This is only magnified in proof-based courses which traditionally do not engage students in collaborative work.

The impact technological tools can have on student learning has been investigated by various scholars. Stahl (2006) found that shared online whiteboards can provide students with a consistent reference to their work and Clark et al. (2007) discussed how they support students during argumentation. When it comes to collaborative writing, Zhou et al. (2012) found that technological tools that like Google Docs can support students in developing a shared meaning, providing a rich learning experience. Lastly, Öner, (2008) noted that dynamic technology can promote a doing perspective of math that focuses on the process rather than the result.

While this literature is very insightful, very little of it is in the context of proof and if it is, it is primarily related to geometrical proofs (e.g., Fukawa-Connelly & Silverman, 2015; Öner, 2008). This study hopes to build on this literature by addressing how technological tools can impact students' collective proving activity in a remote Introduction-to-Proof course.

Theoretical Perspective

Instrumental Genesis

In order to study how the remote learning environment impacts students' collective proving process, this study will draw on Instrumental Genesis Theory (Lonchamp, 2012; Rabardel & Bourmaud, 2003). This theory describes a relationship between artifacts and their users, and the impact of that relationship on cognition.

An *instrument* is differentiated from an artifact through a process called *instrumental genesis.* Béguin and Rabardel (2000) define an instrument as made up of the physical structures of the artifact and what is referred to as a *utilization scheme* which is a cognitive structure that designates a method for using an artifact (Carvalho et al., 2019; Lonchamp, 2012). It is only when an artifact is paired with a utilization schemes that it becomes an instrument (Rabardel & Bourmaud, 2003). The process of instrumental genesis contains two sub-processes. First, *instrumentalization* is oriented toward the artifact and describes the process of exploiting the properties of an artifact either temporarily or permanently (Carvalho et al., 2019; Lonchamp, 2012). Alternatively, *instrumentation* is oriented toward the subject and describes the development and evolution of utilization schemes (Lonchamp, 2012). In classroom settings, instrumentation is specifically focused on the practices students develop to create an instrument in support of knowledge-building activities (Hakkarainen, 2009). This study will be particularly focused on the students' instrumentation process as it focuses on how students learn to use the artifacts available to them to work with their peers on proving activities.

Students in remote environments have access to multiple artifacts which can both support each other and complete similar tasks. Together, these artifacts make up an *instrument system* (Rabardel & Bourmaud, 2003). In courses where students meet for short periods of time (like synchronous online courses) the instructor has an important responsibility in preparing the system (Lonchamp, 2012). When preparing for a course, the instructor develops initial utilization schemes that shape the artifacts for the students, students then develop additional and personal (to themselves and their group) utilization schemes. Development of these schemes with accompanying goal-directed activity, will be the focus of this study.

Proof as Problem-Solving

In this study, the students' proving activity is viewed as a form of problem-solving. Scholars with this view work to "understand the skills, competencies, and dispositions that students need to produce adequate performance on proof related activities" (Styliandes et al., 2017, p. 239). Carlson and Bloom (2005) developed a *Multidimensional Problem-Solving* framework that identifies problem-solving phases and attributes that impact each phase. For this study I draw specially on the problem-solving phases to describe the structure of students' proving process. There are four major phases in Carlson and Bloom's problem-solving cycle. *Orienting* involves taking actions to develop an understanding of the problem situation through behaviors like sense making, organizing, and constructing. *Planning* involves developing a strategy for how to approach the problem. Savic (2015) noted that this can happen at a local level (e.g., identifying warrants for individual lines) or at a global level (e.g., choosing a proof framework). Carlson and Bloom identified a sub-cycle that occurs during this phase, a conjecturing cycle where students: a) *conjecture* an approach to the problem, b) *imagine* how that approach would play out, and c) *evaluate* that approach. This cycle is repeated until a plan has been established. After planning, students *execute* their strategy that was developed in the planning phase. Lastly, *checking* involves verifying the accuracy and adequacy of the executed strategy. Like the planning phase, this can happen at a local or global level. As students work through these phases, they either *cycle forward* when an executed solution is deemed valid, or *cycle back* when an approach needs to be reworked.

This study is focused on understanding how students operationalize the remote learning environment to engage in collective proving and the impact of that operationalization on their collective proving activity. In particular, I will use these theories to help me answer: *How do students operationalize the remote environment to engage in the collective proving process? How does that operationalization impact their engagement with the mathematics itself?*

Methods

Data Collection

The data for this preliminary analysis is from a university Introduction-to-Proofs course that was part of a larger, ongoing NSF-funded project (ASPIRE in Math, DUE #1916490) that is developing Introduction-to-Proof curricula and accompanying instructor support materials. This course was taught remotely with 14 students and met synchronously over Zoom for 10 weeks, three times a week for an hour and five minutes each day. For each day of the class, screen recordings were used to capture the entirety of the students' activity both in breakout rooms and whole class. Moreover, the screen recordings were used to capture simultaneous use of the different modalities each day (e.g., Google Docs and Zoom).

This study focuses on three students' collective work during one day of this course. The, three students Abigail, Alison, and Justin, worked together to collectively write a proof of what the class called the Sudoku Property of group Cayley tables. This refers to the fact that for each row and column of a Cayley table, every group element appears exactly once (i.e., it exists and is unique). The instrument system was made up Google Docs and Zoom. The instructor had prepared the Google Docs before class by including the task with instructions for the students.

Data Analysis

Analysis for this study drew on Powell et al.'s (2003) methodology for studying video data. The first stage of this plan is identifying *critical episodes* that are significant to the research agenda. The episode described above was identified as a *critical episode* since from an initial impression, it seemed that the technological artifacts played an important role in students' ability to work together. A multimodal transcript (Hoffman, 2018) was created using the video data to capture all student interactions as accurately as possible. The transcript was then analyzed using Carlson and Bloom's (2005) problem-solving framework and Instrumental Genesis. Coding of different problem-solving phases involved identifying the problem-solving phase a student's action belonged to relative to the group's collective problem-solving. To capture the students' instrumentation process, each time the students used a technological artifact I answered the questions: 1) What is the goal of using the artifact? 2) How did the student(s) use the artifact?

Once the multimodal transcript was created and coded, I conducted dual thematic analyses on the Instrumental Genesis coding (Braun & Clarke, 2006). First, to identify themes for students' goal directed activities (using my answers to the first question) then, to identify themes for the utilization schemes for each goal directed activity (using my answers to the second question). This dual thematic analysis resulted in the identification of different goal directed activities and associated utilization scheme(s). I then went back to the transcript and video to analyze how the students' instrumentation process impacted their collective proving process by coordinating the students' instrumentation process with the different problem-solving phases. Moreover, identified how the instrumentation processes impacted the kind of proving activity the students engaged in and how the instrumentation processes supported (or hindered) the collective activity. From this, I created descriptions of the role of students' instrumentation processes in their collective proving process.

Results

Students' Different Instrumentation Processes

I identified seven sub-goals that students developed toward the general goal of engaging in collective proving activity, five of which corresponded to a specific problem-solving (P-S) phase (see Table 1). In what follows I discuss how the students coordinated some of these schemes and how this coordination aided in them writing collectively.

Table 1: Identified themes of students use of technology to engage in collective work

P-S Phase	*Goal-directed Activity*	*Artifact*	*Utilization Scheme*
Orienting Phase	Understand Task	Zoom	• Discuss Goals with Peers
		Google Doc	• Read from or Add Information to Worksheet about the Task
Planning Phase	Communicate Idea	Zoom	• Verbally Share Ideas
		Google Doc	• Write Out Proposed Idea • Use Cursor to Reference
	Evaluate Peers' Idea	Zoom	• Listen to Peers' Ideas • Read Peers' Chat
		Google Doc	• Read Peer's Written Proposed Idea • Identify What Peer is Referencing
Execution Phase	Create Team Solution to Task	Zoom	• Verbally Dictate Answer
		Google Doc	• Add on to Existing Text (*repurposing/adapting*) • Write Full Answer
Checking Phase	Check Team Solution to Task	Zoom	• Verbally Share Concern or Acceptance
		Google Doc	• Read Full Answer
Throughout	Update Workspace	Google Doc	• Delete Unnecessary or Irrelevant Text • Update Visual Aids
	Receive Instructor Feedback	Zoom	• Ask Instructor Questions Verbally • Move to Whole Class Discussion
		Google Doc	• Read Instructor Comments

Coordinating between instruments. Several of the students' instrumentation processes involved developing utilization schemes for one artifact that relied on the utilization scheme for the other. Specifically, the students coordinated the textual affordances of the Google Doc with the verbal affordances of Zoom in two ways. First, during the planning phase, the students used the Google Doc to aid in *communicating and evaluating an idea.* Consider the following two students who discussed why a group element must show up at least once in a Cayley table.

Alison: …Once an element shows up once, it can't show up again. So, it has to be filled by a different one. An empty space. Are you following my train of thought? […] Here, I'm gonna write it out and then then read and tell me what you think. (Alison writes in google doc "We already proved that each symmetry can show up at most one time in each row. So, if B appears once, it cannot show up again….")

Abigail: (as Alison is typing) Oh, yeah, that makes sense. Because there's only like, Okay, if it's a six-by-six table, then and you place one. And then you can't place it again. So, you have to pick another one from the five remaining.

Even though Alison wrote down almost exactly what she said out loud, to Alison the Google Doc was an instrument that could better help her communicate her ideas. For Abigail, the writing on the Google Doc acted as a visual mediator, providing additional insights to Alison's approach.

The second way this coordination was observed was by students visually referencing existing text with their cursor during their verbal communication. For instance, when discussing further justifications that their proof needed, two students had the following conversation:

Alison: Should we regroup it too?

Justin: Probably at **that point**. Do we use two steps somewhere?

Alison: Maybe associativity **right here**.

As seen in Figure 1a and Figure 1b, Alison's cursor was visible to the everyone viewing the Google Doc. At this point, the group had established the utilization scheme of using the cursor as an indicator of where in the document the cursor's owner (i.e., the student's) attention was. With just the placement of the cursor, Justin knew where in the proof Alison's attention was when he suggested they regroup "at that point" and Alison knew that her cursor would indicate to Justin what she meant by "right here". Students would also highlight the text to visually reference parts of their document. This coordination allowed the students to use indexical terms (e.g., this one, that one, here) in such a way that avoided ambiguity during conversation.

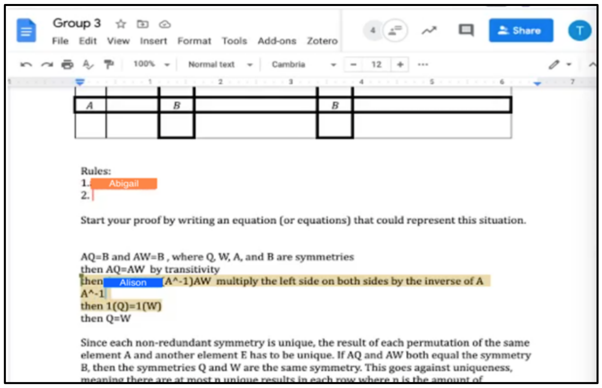

Figure 1a. Alison's cursor identifying "that point"

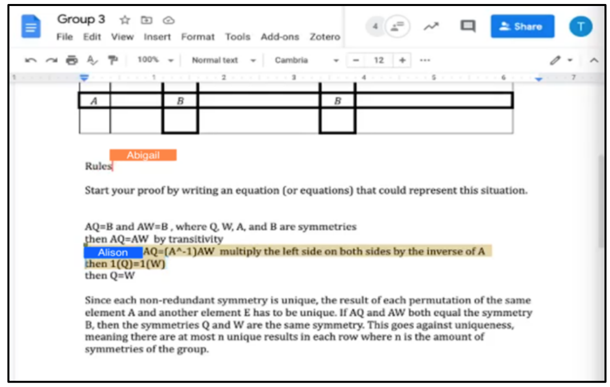

Figure 1b. Alison's cursor identifying "right here"

Writing collectively. The students in this study developed various utilization schemes to achieve the goal of *creating a team solution.* Engaging collectively in the execution phase of the problem-solving process often involved different people executing different parts of the task. For instance, Figure 2 shows the group's completed proof of the uniqueness of group elements in a Cayley table that was written among all members. The different colors represent different student contributions, showing how the proof writing was carried out by all students.

While at times the group engaged in collective writing by writing simultaneously, a particularly interesting use of the instrument system was the students' schemes to repurpose and adapt existing text. As was discussed earlier, students' schemes of communicating ideas involved writing text down in the Google Doc as an aid to their verbal communication. This syntactic communication scheme supported the development of a repurposing scheme in which students repurposed text originally serving a communicative function so that it was now serving a final solution function. This scheme was often utilized without any explicit comments from the students and instead the text was implicitly identified as serving this new function when students moved on to the execution phase. For example, consider the proof in Figure 2, the lines "AQ=B and AW=B, so AQ=AW, then Q=W" were originally written by two students to communicate

AQ=B and AW=B , where Q, W, A, and B are symmetries
then AQ=AW by transitivity
then $A^{-1}AQ=A^{-1}AW$ multiply the left side on both sides by the inverse of A
then $(A^{-1}A)Q=(A^{-1}A)W$ by rule 1
then 1Q=1W by rule 3
then Q=W by rule 2

Since each non-redundant symmetry is unique, the result of each permutation of the same element A and another element E has to be unique. If AQ and AW both equal the symmetry B, then the symmetries Q and W are the same symmetry. This goes against uniqueness, meaning there are at most n unique results in each row where n is the amount of symmetries of the group.

Figure 2. Proof written collectively with different colors representing different student contributions

their ideas about how the proof by contradiction should work during the planning phase. This exact text was then built on and slightly edited during the group's execution phase and makes up an important part of the final solution. By employing the repurposing scheme, students opened up the pool of ideas to include more than just contributions during the execution phase.

The Instrumentation of Proof

Students' instrumentation of the technological artifacts (i.e., Zoom and Google Docs) transformed the role that the proof played in their collective activity. Beyond being a document that represented a complete, formal argument, a proof became an evolving artifact that represented the sharing of ideas and their dynamic argumentation during the proving process. The students developed several utilization schemes that leveraging this feature transforming the proof into an instrument.

Due to the students repurposing and adaptation schemes, their proof was encoded with the group's discussions. Using their referencing scheme, the students developed a utilization scheme to use the proof to *engage in argumentation* with each other. For example, consider the case when a group of students were discussing why their current proof proved that an element appears at most once in each row of a Cayley table:

Justin: Because they have to be the same thing. Because we're- that shows that Q and W equal each other.

Abigail: Yeah, it does the same thing as being, like like R equals R (writes R=R in the Google Doc), we wouldn't even have that because those are the same symmetry. You know what I mean? So, these are like the identical symmetry (highlights R=R and then W=Q). And so, it wouldn't be one of the like, one's on the outside of the table…

By writing *R=R* and then immediately highlighting *W=Q*, Abigail is doing more than just referencing to bring attention to the very last line of the proof. Instead, she is relying on the last line to communicate the argument from the full proof: if an element B shows up twice in a row *A* then there must exist two elements *W* and *Q* in the header row that are equal to each other.

In addition to the proof acting as an instrument to communicate ideas, the students' instrumentation processes transformed the proof into an instrument that represents their evolving argument. Specifically, the students developed a utilization scheme of using the proof as a *record of their current understanding*. The students' proving process involved multiple iterations of

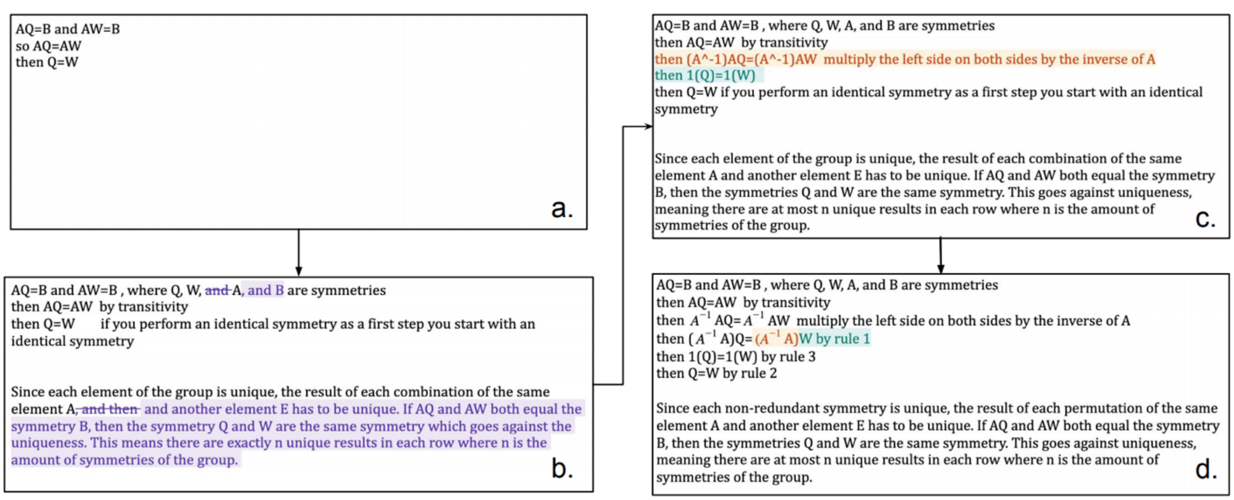

Figure 3. Evolution of the Students' Proof

proposing and evaluating warrants for different parts of the overall argument; often including simultaneous executing and checking cycles. Throughout these cycles the students employed several utilization schemes for the technological artifacts in such a way that their written proof was continuously updated and thus, evolved as their argumentation evolved. To model this evolution, consider Figures 3 which represents a few steps in how the group's proof evolved as they engaged in several problem-solving cycles.

Discussion

These results show that students use and operationalize the instrument system of the remote environment in many ways to engage in collective proving activity. Moreover, through an instrumental genesis lens, we can see how students can successfully transform artifacts into collaborative instruments.

Students used multiple instruments in a complimentary way to help organize their collective activity around a common task (e.g., writing on the Google Doc to supplement a verbal explanation). Not only did this dual scheme enrich students' communications to one another, but it also enriched their abilities to understand and listen to one another. Scholars have noted that due to the many moving parts of the remote environment, successful coordination of instruments can play an important role in developing a collective understanding (e.g., Çakir et al., 2009; Stahl, 2006). The students in this study also developed schemes that leveraged this coordination to create a collective solution. Their repurposing schemes allowed their communication to be embedded into their final work and the editing features of the Google doc allowed for easy and simultaneous editing to occur among the students. Together these schemes supported the creation of a collective proof that reflected the ideas of each individual.

The students' instrumentation of the technological artifacts resulted in the instrumentation of their proof. Due the various utilization schemes applied to the Google Docs and Zoom, the students' proof became an evolving artifact that represented the sharing of ideas and their dynamic argumentation during the proving process. As such, the proof was utilized to communicate with one another and to record their evolving understanding of the argument. CSCL literature on students' use of Dynamic Geometry Systems often emphasizes how students' use of these artifacts results in an emphasis on the process of *doing* math rather than on the final product (Öner, 2008). Results from this study show evidence of an analogous view of math when it comes to proving activity. This evolving feature of proof can support students in seeing proving as a process that involves first, second, etc. attempts, where ideas are proposed, executed, and refined. If proof is viewed as a dynamic object and not as a final document full of formal (and perhaps foreign) language, it might become more accessible and inviting to students.

This study presented a case of how one group of students successfully navigated and leveraged the remote environment to engage in collective proving activity and how that impacted their proving process and their conception of proof overall. Future work is needed to further explore these results further and how students can be supported to leverage technological tools in a productive way.

Developmental Math Students' Perceptions of (Re)learning Outcomes: The Value of Algebra All Over Again

Kristen Amman
Rutgers University

Juan Pablo Mejía Ramos
Rutgers University

We report findings from an exploratory study on developmental mathematics students' perceived experience re-learning content they had already studied in middle- or high-school. Our findings suggest that these experiences may be largely shaped by students' expected and perceived learning outcomes associated with that content. Rather than describing the mathematical concepts learned, students focused on the additional value of the Intermediate Algebra course when describing their expectations and perceptions learning about a topic they had seen before in previous algebra courses. We describe how six of those learning outcomes depended on students' confidence in their previous understanding of the content to be relearned, and how those learning outcomes influence students' modes of engagement during (and emotional reactions to) their relearning experience.

Keywords: developmental mathematics, relearning, confidence

Developmental (or remedial) education courses are commonly offered at U.S. colleges and universities for students that are deemed underprepared for "college-level" work in mathematics, reading, or writing. Traditional developmental courses are often nestled within a sequence, meaning that a student needs to pass multiple courses before enrolling in a credit-bearing course of the same subject. The Conference Board of the Mathematical Sciences Survey (CBMSS) found that in Fall 2015 approximately 41% of all two-year college and 11% of all four-year college and university mathematics and statistics enrollment was in developmental courses. Despite this sizable enrollment, only an estimated 50% of students beginning at public two-year institutions and 58% of students beginning at public 4-year institutions pass or earn some credit for all the developmental mathematics courses (DMC) they attempt to take (Chen, 2016). Reasons for these failure rates have been proposed at various levels, but most research has thus far focused on entry and exit problems with the developmental course sequence such as placement and attrition (e.g. Bahr, 2008a; Bahr 2012a; Bailey, Jeong & Cho, 2010). These studies give us a broad sense of the paths students take to credit-bearing courses, but leave the reasons for rates of attrition, passing, and graduation obscured with a "black box" of teaching and learning in DMC (Grubb, 2001). In order to address the black box problem in developmental mathematics reform, more research needs to be done that characterizes student experiences in developmental mathematics programs and identifies aspects that appear to be critical to the formation of end-of-course outcomes over time. This exploratory study began to fill this gap in the literature by describing student experiences with content through the theoretical lens of *relearning*, or the experience of trying to learn about something one has already tried to learn about before.[1]

[1]A brief report of these results appears in the proceedings for the 43rd Meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education.

Literature Review

Student experiences in DMC involve significant amounts of time learning about content students have seen before, either from a previous K-12 mathematics course or from a previously-attempted DMC (Ngo & Velasquez, 2020; Fay, 2020). Stigler, Givvin and Thompson (2010) summarize student experiences in DMC as being, "presented the same material in the same way yet again" (p. 4). In their study of 306 first year students placed into intermediate algebra at California State University, Benken, Ramirez, Li, and Wetendorf (2015) found that 60% of these students had taken courses beyond Algebra II in high school. Likewise, Ngo (2020) investigated the percentage of college students who take "redundant" math courses, or courses whose content is either at the same or lower level than their highest completed math course in high school (or lower than what they would be predicted to pass given their results on a 12th grade math assessment). He found that while roughly 20 percent of all college students take redundant math courses, that percentage increases to roughly 40 percent when looking at developmental math students specifically. Taken together, these studies indicate that the experience of learning about content one has seen before (possibly even to some level of mastery) occurs more frequently for developmental mathematics students than students enrolled in other math courses in college. For students enrolled in a multi-course sequence or for the large proportion of students who fail DMCs, this repeated interaction with content seen before occurs more often.

This similarity to content seen before across multiple timepoints is a point of concern for developmental math educators due to the high numbers of students who are recommended to take developmental mathematics courses who fail to complete them because they never enroll in the final course in the first place (Bahr, 2008a; Bailey, Jeong & Cho, 2010). Accordingly, the past 10 years has seen an influx in the adoption of new forms of developmental mathematics experiences throughout colleges and universities other than the traditional, sequential, semester-long experiences. These reforms change the amount of time students spend in remedial courses, but nevertheless involve the underlying phenomenon of learning about content seen before. Across traditional and reform-oriented DMC, studies of effectiveness have thus far relied on end-of-semester outcomes such as student passing rates and graduation rates. However, the over-reliance on this method of evaluation combined with the lack of information about student experiences in DMC has made it difficult for researchers and practitioners to understand the reasons for these outcomes and apply them to other contexts. In order to address this issue, researchers have been called to open up the "black box" of instruction in DMC (Grubb, 2001; Sitomer et al., 2012; Mesa, Wladis & Watkins, 2014), particularly when it comes to student experiences with content. Although such research is limited, the research that does exist suggests that students' past experiences with content influence their current experience each time that content is re-encountered (Sitomer, 2014; Zientek et al., 2013; Givvin, Stigler, & Thompson, 2011). However, currently no such studies have been conducted in service of describing what it is like for students to learn about content they have seen before, despite the defining role of this phenomenon in developmental math classes. The purpose of this study is to begin to fill this gap by characterizing student experiences with content they have tried to learn about before, an experience we define below as "relearning".

Theoretical Framework: Relearning

At the most basic level, we define relearning as requiring three things: some (mathematical) content, a "time 1" (T1) representing a past occurrence when an individual has tried to learn about that content, and a "time 2" (T2) representing the most recent time an individual has tried to learn about that same content again. While the content at T1 and T2 need not be identical, it does need to cross a threshold of similarity such that the content learning goals at T2 are essentially the same as those at T1. Although the name *relearning* appears to suggest some degree of mastery of content at T1, we make no such assumption in our conceptualization. As argued previously, although it may not be the case that absolutely every piece of content a student encounters in DMC has been seen before, it is likely that most of the content is familiar. Further, by nature of their design, the learning goals of DMC are identical to those of middle and high school algebra courses considered prerequisites for undergraduate mathematics instruction. Given the scarcity of research on student experiences with this phenomenon in DMC, we turned to what research does exist that in some way considered developmental mathematics student experiences with content in order to begin to structure our investigation. In order to incorporate a focus on the influence of students' past experience with that same content, we additionally anchored our analysis in variables that have proven useful in research from cognitive psychology on the influence of past experiences on perception in interaction (Kleinschmidt & Jaeger, 2015).

First, in two papers on community college developmental mathematics students, Stigler, Givvin, and Thompson (2010) and Givvin, Stigler, and Thompson (2011) suggested that repeated exposure to instruction that associates learning mathematics with rote memorization may explain data indicating that developmental mathematics students' procedural knowledge is disconnected from actual mathematical concepts, resulting in minimal ability to evaluate the validity of their answers. Second, in their research on 169 developmental classes in 20 community colleges, Grubb and Gabriner (2013) provided an account that pushed back on the idea that student experiences would be homogenous. Instead, they proposed that there were five different types of developmental mathematics students according to their "learning needs". The two that focus on student relationships to content are "brush up" students (deemed only to need a quick reminder of content) and students with insufficient basic academic studying skills, which leaves them with an understanding of content that is just good enough to pass, but not good enough to retain concepts beyond a final exam. While the later is reminiscent of Givvin, Stigler, and Thompson's hypothesis, the former presents another possibility. The other categories (students who have been misplaced, students with learning disabilities, and students with mental health issues) are less relevant to our focus on relationships to content, but nevertheless highlight the important role that affective states and attitudes towards the course on student experiences. Finally, Cox and Dougherty (2019) described types of student experiences from their interviews with 25 pre-algebra students across four sections of a developmental math course at a community college. The resulting categories were defined by either the expected or perceived impact of the course on students' relationship to the content they had seen before. In a notable departure from the results of the previous studies, some students characterized their experience as wanting to deeply understand the reasoning behind their use of procedures in a way that they had not done before (although, it was relatively uncommon for students to feel this had been accomplished by the end of the course). Others indicated that the course was useful in "refreshing" their memory, similar to the "brush up" students described previously. However, unlike Grubb and Gabriner, Cox and Dougherty described student perceptions of their own experiences rather than instructor's perceptions of students, and thus were able to identify variation within the "brush up" student category in terms of affective disposition (e.g., while some students were satisfied with the function of the course as a 'refresher', others found 'reviewing' to be a waste of time given their prior experience).

The convergence of these results suggested that the question of what students get out of a DMC in terms of their relationship to the content might be a defining experiential feature because it is unique to this type of mathematics course. Given the previously-noted possible variation in this type of experience in terms of engagement and affective disposition as well as the lack of theory that would allow for a targeted investigation of this concept, we turned to research in cognitive psychology on the influence of past experiences on perception (Kleinschmidt & Jaeger, 2015) for further guidance. In particular, the variables of perceived *similarity* of experience and *relevance* of the prior experience in the new situation were variables that seemed to characterize how individuals perceive and approach scenarios they have been in before. With these variables as well as methods of engagement and affective disposition in mind, we set out to explore how developmental mathematics students experience relearning content they had seen in previous algebra courses. In particular, we focused on the following questions addressing two aspects of that experience: how similar do students think the content of DMCs are to that of their school algebra courses, and how relevant do they perceive their current knowledge of algebra to be in their success in DMCs?

Methods

This was a multiple-case study in which three students enrolled in an Intermediate Algebra course at a four-year public university in the Spring 2020 semester participated in one-hour, semi-structured interviews before and after learning about a topic they indicated they had seen before (Equations of a Line and Polynomials) in a previous algebra class. Each student also participated in one follow up interview in the Fall 2020 semester. Simon and Zena were students of Instructor A, had never previously taken an algebra course in college, and were an 18-year-old first year student and a 19-year-old second year student at the time of the study, respectively. Valeria was a student of Instructor B, had previously taken three algebra courses in college, and was a 20-year-old third year student at the time of the study. Both Instructor A and B were recommended by the head of the department for their quality of instruction, and as many participants as possible were recruited through an online survey. All course meetings in which these topics were covered were conducted in person, prior to the switch to online instruction due to the Covid-19 pandemic. Each of these meetings were observed and recorded with the first author taking fieldnotes on participant behaviors and problems worked on during class. In interview 1, students were asked to describe their history learning about the topic, confidence in their current understanding, and to predict what the experience of learning about the topic again would be like. In interview 2, after the topic had been taught, students were asked to describe what it was like to learn about the topic again, including how predictions aligned with what occurred. Discussions were anchored in problems gathered from field notes or student work as often as possible. A detailed discussion of the instructor interviews and student follow-up interviews is beyond the scope of this report. The results reported here focus on student interviews from the Spring 2020 semester. Interviews were transcribed and analyzed using a modified thematic analysis. While data collection was guided by some theoretical propositions, the novelty of the research called for a more exploratory approach. Thus, coding proceeded in five stages beginning with in vivo coding (Creswell, 2007) and progressing to a modified thematic analysis (Braun & Clarke, 2012) as familiarity with the dataset increased.

Results

Due to space constraints, we report results around one variable central to our findings on student experiences: learning outcomes, or the resultant relationship between a student and material they have seen before at the end of a relearning experience. This is not a grade or an indication of passing/failing but instead an answer the question: what was the value of this learning experience in terms of students' understanding of content this time around? Across Interview 1 and 2, students described six types of learning outcomes (Table 1).

Table 1. Students' expected/perceived learning outcomes when relearning algebra content seen before.

Outcome	Definition	Example
Gain a Deeper Understanding	Students see previously-learned material in a new way and use this shift in perspective to gain a "deeper" understanding than they did before.	Zena, Interview 2: I think [in high school] I definitely just memorized it short term for the exam or class and now I actually understand what I'm solving for and what I'm trying to do with the equations.
Confirm my Understanding	Students already know the content and verify that their existing understanding is adequate.	Simon, Interview 1: We're just learning what I already know. It takes a load off the class cause you just know what's gonna happen and so it's kind of fun to be able to [solve problems] while he's explaining.
Jog my Memory	Students refresh their memory of material they have forgotten due to matters unrelated to inadequate prior understanding such as time. After the class is completed, they do not require further practice.	Valeria, Interview 1: It will be like a refresher. Cause I took it already and like I said, I'm bad with names of things, so I don't really know what it looks like, but once we're doing it in class I'll know what to do.
Reconstruct my Memory with Guidance	Students are guided through a reconstruction of their memory of previously-learned material and avoid remembering things "incorrectly". After the class is completed, they require further practice.	Zena, Interview 1: If I'm trying to remember what I first learned I could get confused easily with what I vaguely remember and what I don't; so I just want a concrete 'this is how I should do it'…and I think that would help me understand faster.
Fix Past Mistakes	Students identify and address inadequate understandings of course material gained from past experiences.	Zena, Interview 2: When I have to make my own linear model, what I have trouble with is corresponding the x and y with the variables they give…I think I've gotten better at it in this class just because he really kind of breaks down why we're doing it.
Accept what I Don't Understand	Students acknowledge that they hold inadequate understanding of course material gained from past experiences, but see themselves as being unable to address it.	Valeria, Interview 1: I just can't get it. [Word problems don't] make sense to me at all, and I try, like I've been watching videos and all that stuff, but I still won't get it at all.

While the codes are not ordered hierarchically, they were each associated with a degree of confidence in the student's perception of their current understanding of the relearned material. *Confirm my Understanding*, for example, was associated with a high degree of confidence in a student's perception of their understanding of the relearned material, thus allowing them to simply confirm that their current understanding is adequate. On the other and, the learning outcome *Reconstruct my Memory with Guidance* was associated with a lower degree of confidence, as students who mentioned this outcome felt that they understood the material enough to partially rely on memory, but not well enough to do so without significant assistance from an instructor. Some of these outcomes, as with *Jog my Memory* are reminiscent of prior conceptualizations of the value of developmental math courses (i.e., Grubb and Gabriner's (2013) brush up students, Cox and Dougherty's (2019) refreshing). Others, such as *Confirm my Understanding* and *Accept what I Don't Understand* are novel. Each of these outcomes were informed by students' pasts, and represent a multitude of frames through which they could interpret their experiences. Importantly, discussions of their expected and perceived learning outcomes were associated with particular methods of engagement with re-learned material and affective dispositions while relearning. Differences in engagement and affect were frequently observed across the same learning outcome. For example, although all three students noted *Confirm my Understanding* as a learning outcome, Simon and Valeria associated this outcome with not paying attention during class, whereas Zena did not describe engaging in this behavior.

This variation in engagement and affect for each learning outcome was even observed for the same student across Interview 1 and 2. For example, Simon described the experience associated with *Confirm my Understanding* as "kind of fun" in Interview 1, and as boring in Interview 2. Due to the exploratory nature of this study, it remains an open and critical question about the extent to which students' degrees of experience with re-learning informed their dispositions towards the learning outcomes as well as the types of learning outcomes they perceived as viable. Student descriptions of their experience with re-learning also shifted both from Interview 1 to Interview 2 when discussing the same topic (from expected to perceived learning outcomes), and within the same interview when discussing different aspects of a topic. Because each of these interviews centered around one unit (3-4 classes), this meant that students were describing different learning outcomes for different problems, subsections, and problem-solving strategies within one unit as well as different learning outcomes from those that they expected going into the lesson. For example, in Interview 2, Valeria described different anticipated learning outcomes for sub-topics within the polynomials unit. With many subtopics in the unit that involved adding or multiplying polynomial expressions, Valeria found herself frustrated with the experience of learning about content that she already understood (confirm my understanding) to the point where she saw little value in paying attention during class.

Valeria: Polynomials is just like, a thing to me like I honestly could care less. So when I know, I know. I'm like, I'm kind of getting lazy with this, cause this is like the third time of taking this class. But usually, I don't know, in class I just, I don't like it cause of the time.

Interviewer: Cause it takes so long, you mean?

Valeria: Well like the class period and cause she explains like every little thing sometimes. Like she's like 'what's 3 times 2?' like we all, we all should know that, so there's no point in asking it. But she does that sometimes.

Interviewer: And when you said like the stuff that you know, you know. Can you say more what you mean by that?

Valeria: Like if, like when she starts doing examples and I do them on my own and get the right answers, like maybe she'll do five and I get the first three right then I'm like I don't really need to pay attention any more. So then I'll just either like daze off or like go on my phone to be honest.

However, for other sub-topics that she found more difficult, Valeria's experience seemed to be dominated by avoidance behaviors and anxiety gained from her past history with algebra. For example, when discussing factoring techniques she remarked, "If [a polynomial] has a number in front of the x^2 one, then I'll usually just sit there and just stare at it, but if it doesn't then I can usually just do it...I think it just scares me or something. It just like scares me." In a follow up interview, Valeria went on to suggest that her difficulties with this type of factoring, both conceptual and emotional, could only be resolved if she had learned about them in a different way the first time they were introduced (*Accept what I Don't Understand*). As Valeria's case illustrates, due to their previous experience with algebra, developmental mathematics students are frequently making judgments about what they expect to get out of their re-learning experience often based only on perceived similarity of content (to what they've seen before) and their confidence in understanding the material at that time. Interestingly, she saw her experience with *Accept what I Don't Understand* as similar to *Confirm my Understanding*, given that both outcomes were motivated by her unwillingness to engage with course content. This suggests that the relationships between these learning outcomes would be a worthwhile pursuit for future investigations in this domain.

Conclusions

Given that some learning outcomes may be more or less desirable than others, the results provided here may be useful to DMC instructors seeking to understand the potential impacts of their pedagogy on student understanding, and how this may vary from other courses in which students are learning new mathematics for the first time. The fact that student perceptions of their learning outcomes shifted not only by topic within an interview, but across interviews as they gained more information casts doubt on literature that attempts to classify students as one particular type, or as having one type of learning need. Given the exploratory nature of this study, we would encourage future inquiry into the types of learning outcomes across various DMC contexts: both topic-by-topic and considering course experiences more holistically. It may be the case that DMC as well as other courses that involve relearning may be designed in ways that encourage or discourage particular learning outcomes from being achieved. A mathematics department looking to evaluate the effectiveness of a DMC could ask: what learning outcomes are desirable for us in these courses? Beyond setting expectations for the content students should be learning in these courses, instructors of courses that contain relearning experiences need to ask: what relationship to this content could a student build in this course given the type of instructional support and content engagement I am providing? Practically, the language of learning outcomes also may provide more specific information about not only what students learned while in the course, but *how* they approached the task of relearning in order to achieve that outcome. Having language that can go beyond 'a review' could facilitate more meaningful conversations with students that result in setting more appropriate expectations for their learning experience. Additionally, the notion of "fixing" one's past mistakes shares similarities to findings from Dibbs (2019) who investigated the experiences of undergraduates retaking calculus courses, another type of relearning experience. The extent to which the findings described here might be relevant to other such contexts is an area for future inquiry.

Vector spaces are often taught with an axiomatic focus, but this has been shown to rely on knowledge many students have not yet developed. In this paper, we examine two students' conceptual resources for reasoning about null spaces drawing on data from a paired teaching experiment. The task sequence is set in the context of a school with one-directional hallways. Students' informal reasoning about paths that leave the room populations unchanged supported more formal reasoning about null spaces. We found that one student used context-based resources (such as 'loops' in hallway) to reason about null spaces, while the other student drew largely on previously formalized mathematical resources (e.g. free variables, linear dependence). The use of formal resources sometimes required recontextualization, which may function to constrain student sense-making or afford opportunities for broadening students' formal prior knowledge.

Keywords: linear algebra, subspaces, null spaces, conceptual resources

Axiomatic treatments of vector spaces are thought to be often inaccessible to students because they unify and formalize many ideas that many students have not yet developed (Dorier, 2000; Grenier-Boley, 2014). In their genetic decomposition of vector spaces, Parraguez and Oktaç (2010) identified the binary operations of scalar multiplication and vector addition, as well as the closure of sets under linear combinations of these operations, as the critical constructs for consideration in regard to students' learning about vector spaces. We thus argue that subspaces function as a more accessible entry point for supporting students' learning about vector spaces.

Given the increasingly important role of linear algebra in real world applications, more work is needed to support students in developing robust conceptualizations for subspaces, and particularly null spaces, given their applicability to a wide range of closed systems problems. In this paper, we examine data from an instructional sequence on subspaces whose design is informed by the principles of Realistic Mathematics Education (RME; van den Heuvel-Panhuizen & Drijvers, 2020). In particular, we address the research question: What are students' conceptual resources for reasoning about null spaces in the context of an RME-based instructional sequence focused on subspaces?

Literature and Theory

A limited number of studies target students' early reasoning about vector spaces, subspaces, and especially null and/or column spaces (Stewart et al., 2019). Two recent exceptions in the area of subspaces are the work of Wawro et al. (2011) and Caglayan (2019). Wawro et al. (2011) documented 8 undergraduate students' concept images for subspaces in relation to how they reasoned about the concept definition -- identifying geometric and algebraic interpretations, and the critical role of reasoning about a subspace as a part of a whole for making sense of the formal textbook definition presented to students. Caglayan (2019) interviewed 14 undergraduate math majors who had recently taken linear algebra, asking them to use a digital geometry system

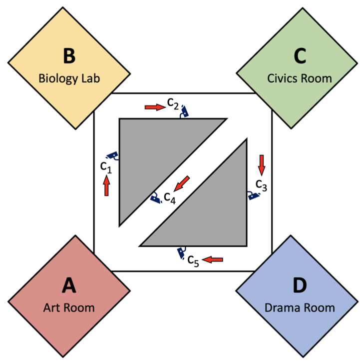
(Matlab) to classify 57 subsets of 7 different vector spaces as subspaces or not -- particularly highlighting ways in which students used the zero vector to show the set was not closed. These studies and others (e.g. Açikyildiz & Kösa, 2021; Dogan, 2018) highlight the potential value of geometry for introducing ideas related to vector spaces. Our study differs as we examine an experientially real context for engaging students in reasoning about ideas related to subspaces and null spaces, but do not leverage the geometry of two and three dimensional space.

We draw on diSessa's (2018) Knowledge in Pieces (KiP) view of learning and cognition, which is influenced heavily by constructivist and cognitivist traditions. We value this as a lens to theorize conceptual resources (Taber, 2008) and adopt anti-deficit views of students and their learning (Adiredja, 2019). KiP emphasizes the complex, continuously shifting, and contextually-bound nature of knowledge, where learning involves reconfiguration of "naive" knowledge into more normative understandings (diSessa, 2018). For example, the notion that 'multiplication makes bigger' is a concept that is considered normatively correct in some contexts (numbers larger than 1) and not others. It is a "small knowledge structure" that can either be cast as an unuseful idea from a deficit perspective or a useful idea that can be more explicitly contextualized and reconfigured to reflect broader and more normatively accepted understandings.

Study Context

This work was conducted as part of a broader research project focused on developing a series of research-based linear algebra materials. These materials were developed in alignment with RME principles of experientially real starting points, guidance from an instructional figure, and the critical role of model-of, model-for shifts in students' mathematical activity (Van den Heuvel-Panhuizen & Drijvers, 2020). In this manuscript, we leverage a KiP lens for examining students' mathematical activity. To our knowledge, KiP frameworks have not been heavily leveraged in the literature to analyze student reasoning in RME-inspired task sequences and we believe coordinating these perspectives may provide a meaningful contribution to the field.

In its current form, the sequence consists of three core tasks. In this manuscript, we focus our analysis on students' reasoning in the context of the second and third tasks. Our team's approach to subspaces was organized around the notion that subspaces are non-empty subsets of vector spaces that are closed under linear combinations. To support students' development of meaning in relation to this notion, we leverage the scenario of one-way hallways during a pandemic (Plaxco et al, 2021). The hallway scenario can be viewed as a coordination between two sets of quantities: the number of people who pass through each of the one-way hallways as observed by cameras and the change in the population of each classroom that occurs during a period of observation (Figure 1a). For example, assuming people do not linger in the hallway, if 3 people pass by Camera 1 and Camera 2 during a class changeover, then the net change of the number of people in the Biology Lab is zero. This induces a mapping of the set of n-tuples encoding of the number of people passing by the camera in each hallway ("*camera vectors*"; in the West Wing, vectors of the form $\langle c_1, c_2, c_3, c_4, c_5 \rangle$) to the set of m-tuples showing the net change in each room's population over the period of hallway observations ("*room change vectors*"; in the West Wing, vectors of the form $\langle \Delta A, \Delta B, \Delta C, \Delta D \rangle = \langle c_4 + c_5 - c_1, c_1 - c_2, c_2 - c_3 - c_4, c_3 - c_5 \rangle$). In Tasks 1 and 2, students are asked to represent journeys of students walking through halls using camera vectors, reason about the relationships between the *camera vectors* and the *room change vectors* within the problem context, and reflect on and make generalizations based on their reasoning. These activities are focused on supporting students to reason about the set of camera vectors that do not change the populations of the rooms (which corresponds to the null space of the matrix that maps camera vectors to room change vectors). This activity culminates in the students representing the problem context using a matrix transformation. During the third task, students are asked to reason about a new wing of the school (the East Wing; Figure 1b) based on a given matrix, rather than a given hallway diagram.



(a)

$$M = \begin{pmatrix} -1 & 0 & 0 & 0 & -1 & 1 & 1 \\ 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -1 & 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 & 1 & 0 & 0 \end{pmatrix}$$

Participants, Data Sources, and Methods of Analysis

The study had two white male participants (who we refer to with pseudonyms Drew and Carson) at a predominantly minority public post-secondary institution in the Southeastern U.S. Drew and Carson were the only two volunteers satisfying the study constraints of their age being 18 and older and having taken an inquiry-oriented linear algebra course based on the IOLA curriculum. Both students had earned an "A" in the course. Our data sources for this analysis consist of video-recordings of a four-day paired teaching experiment (Steffe & Thompson, 2000), as well as any inscriptions created by participants or the teacher-researcher.

The paired-teaching experiment (PTE) consisted of four, 90-minute sessions. Each session was conducted and recorded on Microsoft teams and included two research team members. One was the teacher-researcher across all sessions; the other collected field notes and asked clarifying questions. Students were asked to think aloud and respond to questions regarding their work. Student work was captured by having students upload work, hold up their work to the screen, or work on a shared whiteboard. The research team debriefed after each interview session, noting mathematically significant aspects of student reasoning that emerged in the interview.

To identify students' conceptual resources for reasoning about null spaces, our team began by first assigning two team members to review each session of the PTE and note themes in students' mathematical reasoning that related to ideas about topics related to null spaces (including linear combinations of vectors, span, linear transformations, and solutions to homogeneous systems of linear equations as well as their applications in the problem context.) In this analysis, we focus on the final two days of the teaching experiment, when the definition of null spaces was formally introduced to students in relation to their prior work, and they were asked to extend their reasoning to a new context (one-directional hallways in relation to room locations in the East Wing of the high school, with information inscribed in a matrix rather than a map). Based on team members' notes, videos were selectively transcribed, and we identified two broad themes that functioned as conceptual resources for reasoning about null spaces: closed loop reasoning and RREF reasoning.

Findings

Though the data presented in this analysis comes from the final day of the PTE, it is important to note that students developed important ways of reasoning about camera vectors, room change vectors, and relationships between them on the previous days. Namely, the students described the sets of camera vectors corresponding to possible paths a single person or 5 people could take from room A to room C, and from room C to room C. They identified the former sets as not closed under linear combinations, and they identified the latter sets as being closed under linear combinations (with vectors in these latter sets earning the designation of "closed loop" vectors). See Plaxco et al. (2021) for more detail on this. The students agreed that closed loop vectors left room populations unchanged and identified ways of expressing the relationship between camera vectors and room population change vectors. In this section, we highlight how closed loop reasoning emerged as the core conceptual resource for one student across a pair of questions, whereas linear dependence and RREF reasoning emerged as the core conceptual resource for the other student. (Though interviewed as a pair, the students rarely engaged in one another's reasoning so for clarity we discuss their reasoning in ways that are largely separate.)

Closed Loops as a Context-based Conceptual Resource

Early on the fourth day of the PTE, both students were then given the equation in Figure 2 and asked to interpret what it meant "for that four-tuple on the right-hand-side to be all zeros." Almost without hesitation, Drew responded, "there is no net change in the room population after all movement is complete" indicating a fluency between the two contexts of hallway movement and the matrix equation. The students were then asked if the set S of vectors **c** in R^5 such that A**c**=**0** (in correspondence with the matrix equation shown in Figure 2) is a subspace of R^5 (with the reminder that this would mean that if we sum of any two vectors in S the result must also be in S, and if we scale a vector in S the result must also be in S).

$$\begin{bmatrix} -1 & 0 & 0 & 1 & 1 \\ 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & -1 & -1 & 0 \\ 0 & 0 & 1 & 0 & -1 \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \\ c_5 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

Figure 2. Matrix equation given to students to reason about the null space

Drew initially argued that the sum of two vectors in S would be in S by stating "yes, because they both equal zero." Drew later elaborated:

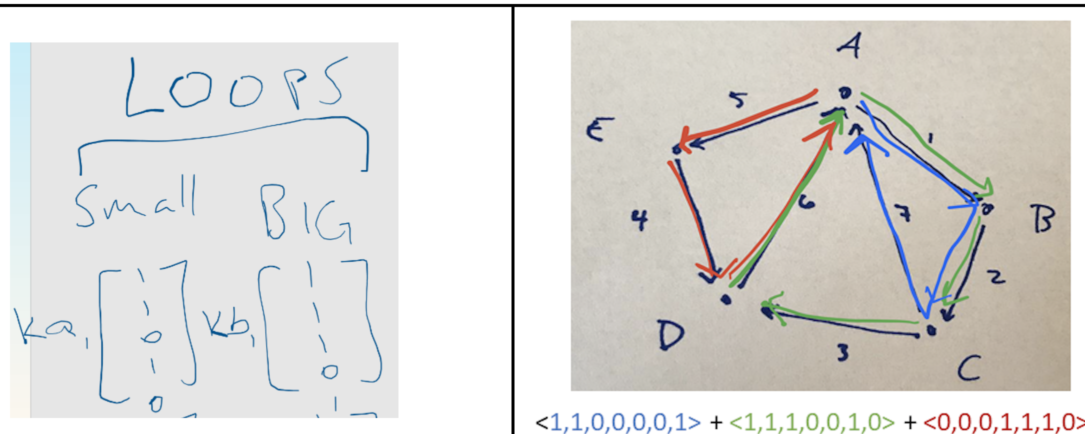
Drew: "Since both vectors are going to be equal to zero, the subspace will cover zero, so zero plus zero will still be in the subspace."

Interviewer: Are you saying that the camera vector has to be zero?

Drew: No, because they're both equal to zero after multiplying by the matrix. That's what we're saying… In order to get back to zero, we need to have a bunch of loops. That's how we get zero. If we keep adding more loops matter what and we just add the vectors of the loops together and we multiply it by that, it would still be zero, would it not? This is the way I'm seeing it. I'm saying 'cause like the way we get zeros is we just add a bunch of loops together. Uh, we just have a bunch of loops there and they're just constantly repeating. So if we had another vector, it's just another, butt ton of loops. We'd just have more loops which will get back to zero. The way I'm seeing it.

Drew later connected to the students' prior work describing paths from C to C:

> … it's like the linear combination that we did a while back, I think it's probably day one where it was like, like the big loops in the small loops and you could have as many of them as you wanted if you just continuously add more and more loops to it. It's still going to get you back to the same point. So, as long as we have loops like that one and the other one. It would, it would basically just be two different scalars… multiplied by those loops. And, that would be the combination of the vectors that we're adding together.



(a) Instructor's inscription of West Wing loops | *(b) Drew's East Wing map and loop vectors*

Figure 3. Inscriptions related to Drew's closed loop reasoning

As Drew spoke, the interviewer made the inscription shown in Figure 3a, as these corresponded to what students had described as the big and small loops on prior days of the PTE. The interviewer prompted, "if you just combine these two vectors together…." and Drew responded that we would "just have more loops." When asked by the interviewer if "more loops is also just a solution to this equation here," Drew again reverted to his hallway reasoning, "yeah, because they're just looping around." Drew similarly extended this line of reasoning when asked about scalar multiplication, saying in reference to figure 3a that, "if you multiply a_1 and b_1 by like ten each, it's just more loops."

When later presented with the matrix M in Figure 1b and asked to describe all the possible hallway flows that leave the number of students in each room unchanged, Drew generated the map shown in Figure 3b -- which is an appropriate translation of the matrix back into a hallway diagram -- and correctly identified three closed loop vectors (which mathematically speaking are a basis for the null space of the matrix M).

Drew's use of closed loops (or closed loop vectors) as a conceptual resource was characterized by four core ideas around which his reasoning was largely organized:

1. Closed loops are paths from a room back to itself
2. Closed loops leave room populations fixed
3. Linear combinations of closed loops are closed loops
4. Closed loop vectors are solutions to homogeneous equations

The first three ideas were developed on prior days of the PTE as indicated by Drew in his comments. However, Drew also connected these ideas to the matrix equation presented in Figure 3 - initially by connecting the zero vector on the right hand side of the equation to unchanging room populations, and then by further connecting these unchanging room populations to "closed loop" camera vectors (which sum and scale to closed loop vectors when scaling by non-negative integers). We argue that in this way, Drew's closed loop reasoning, as characterized and contextualized by this set of ideas, functioned as a robust conceptual resource for reasoning about null spaces in the hallways task sequence.

Multiple Solutions, Linear Dependence, and RREF as Formalized Conceptual Resources

In contrast with Drew, Carson did not leverage closed loops as a central conceptual resource in his reasoning on the tasks presented on the final day of the PTE. Rather, he drew heavily on more formal ideas from the linear algebra class but found that the hallways task setting required contextual reinterpretation of these ideas in ways that were not always straightforward.

When asked to reason about closure of the set S in relation to Figure 2, Carson did not immediately engage in the question set forth by the interviewer (namely, whether any two vectors that satisfy the given homogeneous equation would sum to a vector that also satisfies the homogeneous equation). Rather, he focused on interpreting the matrix equation, inquiring "So we're trying to solve the homogeneous equation, right?" After the interviewer restates his previous prompt (presumably to get Carson to focus on the closure aspect of the question), Carson continued. "There's a free variable, correct? … which means there is more than one solution to the homogeneous equation." Several minutes later, Carson seemed to continue this line of thought, saying "I have a question. If it wasn't linearly dependent, I don't think you'd be able to do it, be able to do loops and stuff. Is that correct?" The interviewer agreed that if the column vectors didn't form a linearly dependent set, then the only solution would be the trivial solution. The following exchange ensued.

Interviewer: Ok. So if those column vectors are linearly independent, then the loops would be what?

Drew: They wouldn't exist. They would be null, they wouldn't actually exist. They would get you a homogeneous answer.

Interviewer: Right. So the only way to get the classrooms to not change?

Drew: Would be to replace the c vector with zeros.

Interviewer: So what does that mean about student movement?

Carson: No one moves.

This episode highlights Carson's ideas about solutions to the homogeneous equations, free variables indicating multiple solutions, and linear dependence being important for the ability to "do loops." He then correctly reinterprets the trivial solution to the homogeneous vector equation to mean that no one moves in the hallway context.

When Carson is asked to find the hallways flows that leave room populations unchanged for the matrix shown in Figure 1b, he suggests "since it's dependent, find something that makes two of them zero. I make it, two of them, zero I guess? Try to find out the homogenous solution cause it wants to be unchanged… You could solve it using reduced row-echelon form is one way." Carson then used Maple to row reduce the matrix M. The conversation then turned to Drew's map (as discussed above) before the interviewer asked how Drew's loop vectors related to Carson's row reduced matrix. Drew argued that if you multiplied his vectors by Carson's matrix (excluding the final column of zeros), it should give you the zero vector, and verified it does. Carson commented that he “thought it would because it gives an absolute answer every single time. That’s why I like matrices. They give exact answers every time.” When asked if Drew’s closed loop vectors might be extracted from Carson RREF, Carson’s initial reaction was:

> It’s basically the idea of, there’s a free variable, right? So you could use any scalar to get to any other location that you wanted to by using scalars and adding them together. This is the part where I kind of get confused. I did all the steps, I just don’t know, I know each of these are column vectors that equal zero, zero, zero.

We interpret this comment to reflect Carson’s effort to brainstorm information he can glean from row-reduced matrices: the presence of free variables, information about span (e.g. places you can “get to”) -- but indicating that the connection between his row-reduced matrix and Drew’s closed loop vectors was not obvious.

We argue that Carson’s use of multiple solutions, linear dependence, and row reduction as conceptual resource was characterized by three core ideas around which his reasoning was largely organized:

1. Free variables indicate multiple solutions
2. Linear dependence is needed for (closed) loops
3. Row reducing matrices gives exact answers

Carson productively leveraged the first two ideas to reason about some aspects of null spaces, but the final p-prim did not provide sufficient detail to extract the desired camera vectors. Potentially complicating this issue is the fact that, in cases with infinitely many solutions, row reduction produces solution sets with free variables that can presumably range through all real numbers -- yet the hallways problem context requires limiting to solutions in which all entries are non-negative integers.

Discussion

The contextually developed conceptual resources organized around the idea of closed loops provided a productive entry point for several aspects of reasoning about null spaces (e.g. specifying elements, reasoning about closure, and identifying a basis), and both students had ideas related to closed loops. Previously formalized mathematical resources also offered useful insights into some aspects of null spaces, but were more useful in connecting to the hallways context at some times (e.g. connecting multiple solutions to linear dependence and closed loops) than at others (trying to extract camera vectors that leave room populations unchanged based on the RREF of a given matrix).

Short-duration and long-duration professional development workshops on inquiry-based learning (IBL) were designed to increase participants' capacity to teach using IBL methods. This study used a sample of 66 participants in short-duration workshops (one day or less) and 199 from long-duration workshops (four days plus ongoing support) held from 2016-2019 to investigate the role of workshop duration in increasing IBL capacity, and in fostering uptake of IBL teaching practices. After participating in professional development, both short-duration and long-duration workshop participants reported comparable levels of IBL capacity–meaning the beliefs, knowledge and skills that prepare them to use IBL. However, short-duration workshop participants implemented IBL teaching practices less intensively than long-duration participants. These findings support the use of both short-duration and long-duration professional development as a means to increase instructors' capacity to use IBL and their adoption of IBL teaching practices.

Keywords: Inquiry-based learning, Professional development, Workshops, Teaching

Introduction

Research-based instructional strategies (RBIS) have been shown to promote student learning and academic success in US undergraduate STEM education (Freeman et al., 2014; Ruiz-Primo, 2011). In undergraduate math contexts, a form of RBIS, inquiry-based learning (IBL), has been associated with positive student outcomes (Kogan & Laursen, 2014). However, use of RBIS by undergraduate STEM instructors is not common; approximately 20% use RBIS extensively (Stains et al., 2018; Eagan, 2016).

Prior research has shown that teaching-focused professional development (PD) can increase STEM college instructors' use of RBIS, including those of undergraduate mathematics instructors using IBL (Archie et al., 2021; Benabentos et al., 2020; Chasteen & Chattergoon, 2020; Manduca et al., 2017; Bathgate et al., 2019). The focus of these studies were long-duration PD experiences (e.g. multi-day workshops), rather than single instance "one-off" experiences. Duration has been identified as a "critical feature" of professional development (Viskupic et al., 2019), and research on PD in higher education settings has consistently demonstrated that PD is effective when it occurs over extended periods of time (Desimone, 2009; Allen et al., 2011; Ebert-May et al., 2015; Garet et al., 2001; Pelch & McConnell 2016; Postareff et al., 2007; Wilson, 2013). A review of PD in higher education found that PD that takes place over an extended period of time results in more changes in instructor teaching practices than one-time PD activities (Stes et al., 2010). However, this review contained few studies focused on short duration, one-time events.

K-12 contexts also have shown similar findings. For example, Supovitz and Turner (2000) found that 40 hours or more of PD participation was needed to make a detectable impact on teachers' use of inquiry-based teaching practices. Other studies suggest ideas about teaching and teaching practices change over time, rather than from "one-shot" workshops (Loucks-Horsley et al., 2009; Postareff et al., 2007). However, Kennedy's 1999 review of PD indicated that PD content was more strongly related to participant outcomes than duration. Given the costs of professional development for facilitation, participant support, and travel, it is important for providers and funders of PD to know what features of PD generate measurable impact on teaching practice and, by inference, on students' experiences and success in courses where research-based teaching is applied.

While research indicates that long-duration PD is effective in generating change to teacher practice, few studies have shown that short-duration workshops were less effective in doing this, thus more research is necessary to determine the importance of duration, among other variables, in PD. This study addresses this gap by investigating the outcomes of short-duration IBL workshops for undergraduate math instructors. In this study, we compare short workshop findings to those from long workshops that have already been shown to be effective in increasing math instructors' capacity to use IBL and to increase their use of IBL methods (Archie et al.; 2021). Specifically, this study sought to answer the following research questions:

RQ1: Do short-duration workshop participants report the same gains and levels of IBL capacity (attitudes, knowledge, and skill) as long-duration workshop participants?

RQ2: Do short-duration workshop participants implement and use IBL teaching practices to the same degree as long-duration workshop participants?

IBL workshop description

Long-duration workshops are an established, research-supported method of professional development for instructors to learn to use IBL. Participants travelled to workshops that occurred over four consecutive days, utilized consistent content and format, and featured ongoing support from workshop leaders and peers following the workshop (see Hayward & Laursen, 2018; Yoshinobu et al., 2021 for a full description of the long duration workshops). Long-duration workshops have been shown to increase participants' capacity to use IBL methods and subsequently, increase their use of IBL teaching practices (Archie et al., 2021).

Short-duration workshops were designed to complement long-duration workshops. Both models serve as professional development opportunities for mathematics instructors to learn about IBL and increase participants' capacity to use IBL teaching methods. Short workshops were intended to provide an introduction to IBL, while the long-duration workshops provided a deeper, implementation-focused experience. In both long and short workshops, leaders modeled IBL techniques through their facilitation. For example, leaders asked participants to engage in Think-Pair-Share activities to help participants understand how to use this technique in their own classrooms. Short and long-duration workshops were planned and led by the same cadre of trained workshop facilitators, working within a single, coordinated project grounded in PD literature, sharing a broad philosophy of IBL (Laursen & Rasmussen, 2019), and drawing on their training and experiences with long workshops to develop short workshops. Evaluation data show that both long and short workshops received very high ratings of participant satisfaction.

Between 2017 and 2020, the project supported 26 short workshops reaching at least 500 participants. The workshops were between 1-8 hours in length and were held at various institutions across the country, including two- and four-year colleges and sessions held at professional development conferences of the MAA and AMATYC. Short workshop content was non-standardized and varied by audience and facilitator preference, but most workshops provided a general introduction to IBL. A few workshops emphasized enhancing specific skills, such as assessment techniques, facilitating discussions, and generating classroom materials, and one centered on a particular audience, instructors of pre-service elementary teachers. The primary goals of the short workshops were to: increase awareness of IBL methods, enhance component skills of IBL, recruit new audiences of faculty into IBL teaching, reach departments or groups not yet active in IBL, and offer an "on-ramp" to IBL practice.

Methods

Data collection

Long-duration workshop participants completed a pre-workshop survey about one month before their workshop, a post-workshop survey immediately after, and a follow-up survey about 18 months later. Of 293 long-duration workshop participants from 2016-2019, 291 (99%) completed the pre-workshop survey, 275 (94%) completed the post-workshop survey and 199 (68%) completed the follow-up survey.

Short-duration workshop participants completed a brief post-workshop survey immediately following the workshop. In all, 328 post-survey responses were collected from an estimated 470 participants from 24 workshops, for an overall response rate of 70%. A more extensive follow-up survey about IBL implementation was sent in late 2020 to all participants who provided contact information when they attended a short-duration workshop from 2017-2020 (n = 270). Sixty-six follow-up survey responses were collected for a response rate of 25%. While the response to the post-survey was high (70%) and likely representative of the workshop population, the follow-up survey had a lower response rate (25%) and cannot be considered representative. Moreover, the follow-up was sent to all workshop participants in late 2020, so the time between workshop attendance and follow-up varied, ranging up to 3 years. Given this response rate, the high reports of IBL implementation in particular may be skewed due to non-response bias where the follow-up survey respondents may be those who were most interested or enthusiastic about IBL.

Measures

Measures of IBL capacity were used to answer RQ1 and are indicators of short-term outcomes resulting from workshop participation. Measures of IBL capacity include participants' attitude about IBL, their knowledge of IBL, and their skill using IBL. Short- and long-duration workshops used identical measures of IBL capacity attitude, knowledge, and skills on follow-up surveys and on long workshop pre and post surveys. As a measure of IBL attitude we asked "To what extent do you believe inquiry strategies are an effective learning method?" and was measured on a four-point scale (1 = Don't know, 2= Not very effective, 3= Somewhat effective, 4 = Highly effective). IBL knowledge and skill were measured with similar separate measures asking "How would you rank your current level of knowledge/skill in inquiry-based teaching" with both items sharing the same four-point response options (1=None, 2=A little, 3=Some, and 4=A lot). Thus, we can directly compare levels on these items at the follow-up timeframe and can compute gains for long workshop participants by comparing rankings across timepoints.

Since short workshop participants did not take a pre-survey, we instead asked them to rate their perceived gains in IBL attitude, knowledge, and skills on the post-workshop survey using a five-point scale (1= A lot less, 2= Less, 3=About the same, 4= A little more, 5= A lot more).

To answer RQ2, we directly measured short and long workshop participants' self-reported implementation of IBL and, as an indirect measure of implementation, their self-reported teaching practices. On short and long workshop follow-up surveys, we asked respondents to self-report their implementation of IBL methods by asking “Have you implemented an IBL course since the workshop?” with four response options: “No; Not a fully IBL course, but applied some approaches; Yes, one IBL course; Yes, more than one IBL course.”

Separately, we asked long workshop participants on the pre-workshop survey, and both short and long workshop participants on a follow-up survey, to indicate their frequency of use of 11 teaching practices using the following scale: 1= never, 2= once or twice during the term, 3= about once a month, 4= about twice a month, 5= weekly, 6= more than once a week, or 7= every class. As described in Hayward et. al (2016), five of these 11 teaching practices are classified as ‘core IBL’ practices because they characterize all variations of IBL that were emphasized in workshops: decreased use of instructor activities, including lecture and instructor problem-solving on the board, and increased use of student activities, especially student presentations of their own work and student discussion in small groups or as a whole class.

Data analysis

To answer RQ1 we computed frequencies of short workshop participants who reported gains in IBL attitude, knowledge, and skills in the post-workshop survey. For comparative purposes, we computed frequencies of the long-duration workshop participants who reported gains in IBL attitude, knowledge, and skills from pre-workshop and post-workshop surveys. We also calculated means of IBL attitudes, knowledge, and skill of short and long workshop participants from their respective follow-up surveys. We conducted an independent samples t-test to check for differences in follow-up survey IBL capacity measures by workshop duration.

To answer RQ2 we computed IBL intensity scores for each instructor based on their self-reported frequencies of the five core IBL teaching practices as follows: IBL intensity= student group work + student presentation + class discussion – lecture – instructor solving problems. IBL intensity scores were computed at the follow-up time point for both short- and long-duration workshop participants. We conducted an independent samples t-test to check for differences in intensity of use of IBL teaching practices by workshop duration.

Results

To answer RQ1, we compared both the proportion of reported *gains* in IBL capacity measures, and the final *levels* of IBL capacity, by workshop duration. First, as shown in Figure 1, a majority of both short and long duration workshop participants reported gains in all three IBL capacity measures (attitude, knowledge, skill). Since we measured and calculated gains differently across workshop types, it was not appropriate to make direct statistical comparisons of gains in IBL capacity. However, it is evident that the relative gains in capacity (attitude, skill, and knowledge), are the same for both short and long workshops; that is, the greatest gains are in IBL knowledge, followed by less extensive gains in skill and IBL attitude.

Also addressing RQ1, we conducted an independent samples t-test to check for differences in mean IBL capacity reported by workshop participants in respective follow-up surveys. While *gains* measures differ, the measure of final *levels* is the same in surveys sent to both long and short workshop groups. Descriptively, short workshop participants reported lower mean IBL capacity than did long workshop participants (Table 1). However, the only statistically significant difference in the individual indicators that make up IBL capacity was in IBL attitudes, and the effect size indicates that this difference was minimal. We found no statistically significant differences in either IBL knowledge or skill by workshop duration.

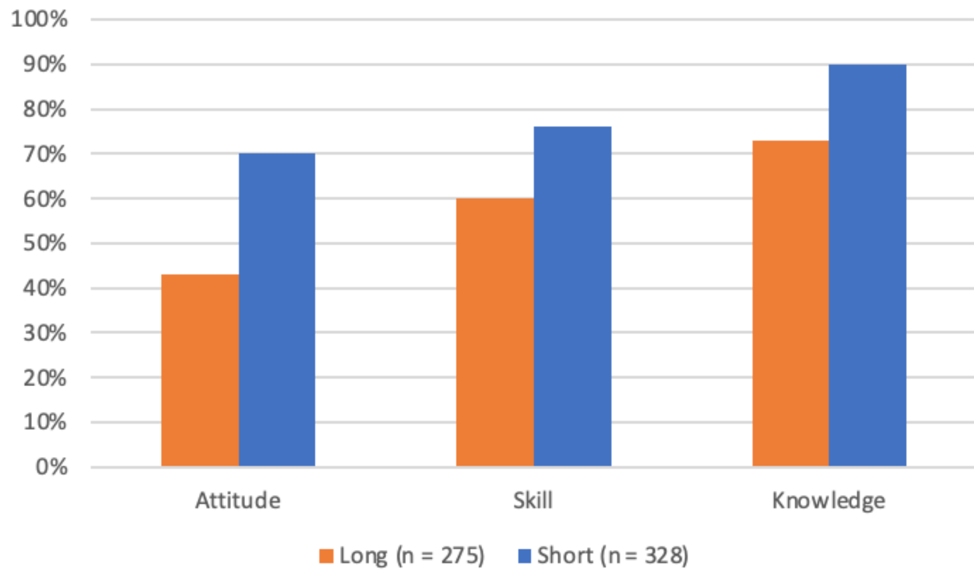

Figure 1. Proportion of workshop participants who reported gains in IBL capacity measures by workshop duration

Table 1.
t-test of mean IBL capacity follow-up measures by workshop duration

	Short workshop (n = 53)		Long workshop (n = 189)				
IBL Capacity	*M*	*SD*	*M*	*SD*	*t* (df = 240)	*p*	*d*
Attitude	**3.59**	0.50	**3.71**	0.51	-2.96	0.003	0.23
Knowledge	**2.96**	0.65	**3.24**	0.61	-1.54	0.126	0.46
Skill	**2.64**	0.74	**2.80**	0.64	-1.49	0.137	0.24

Note: *d* = cohen's *d* and is a measure of effect size.

To answer RQ2, we compared the proportions of participants who implemented IBL methods, by workshop duration. The measures used were identical for both survey groups. As shown in Table 2, we found that a higher proportion of short workshop participants (19%) did not implement IBL than long-duration workshop participants (5%). A greater proportion of long workshop participants (29%) reported implementing IBL in one fully IBL course than did short duration workshop participants (13%).

Table 2.
Proportion of workshop participants who implemented IBL methods by workshop duration

	Workshop duration	
IBL implementation	Short (n = 62)	Long (n = 199)
No	19.%*	5%*
Not a fully IBL course, but have applied some IBL approaches	53%	44%
Yes, one fully IBL course	13%*	29%*
Yes, more than one fully IBL course	15%	22%

* short and long workshop proportions differ at $p \leq 0.05$

RQ2 was also answered by comparing participants' intensity of use of IBL teaching practices after participating in their respective short or long workshops. An independent samples t-test indicated that average intensity scores after long workshops (M = 7.87, SD = 5.44) were significantly higher, (t(226) = 2.71, p = 0.007), than the IBL intensity scores after short workshops (M = 5.43, SD = 4.37. The effect size (C*ohen's d* = 0.46) indicated a moderate difference in the use of IBL teaching practices between long and short workshop participants.

Discussion

Both the long workshops and short workshops were designed to increase participants' capacity to use IBL teaching methods, and our findings suggest that short and long workshops may be effective in doing so. This study provided the opportunity to compare workshops that are driven by a shared philosophy and led by the same facilitators, but with different durations. However, the limited sample of short-workshop follow-up survey respondents (discussed in detail in the final section) provides a sense of the *possible* outcomes from short-duration workshops, while the robust sample of long-duration workshop participants provides a *generalization* of typical outcomes from the long-duration workshops. Therefore, direct comparisons of short and long workshops should be interpreted with caution.

Both short and long workshop participants reported the same pattern of gains in the three individual IBL capacity measures. The lowest gains by both groups were in IBL attitude; participants self-selected to participate and thus many participants already had a positive attitude about IBL, so their gains were small. Both short and long workshop participants reported higher gains in IBL knowledge than in skill. This is a logical finding considering that skills take time and practice to develop. Overall, both workshops seem to be improving participants' capacity or readiness to use IBL methods in a consistent way.

The lack of statistical and/or meaningful differences in follow-up measures of IBL capacity by workshop duration were unexpected and are inconsistent with prior research which has shown that long duration PD is more strongly related to outcomes than short duration PD (Stes et al., 2010). We expected that, in short workshops, the limited time participants had to acquire IBL knowledge and skill would translate into lower gains in IBL capacity than from long workshops. This finding is likely due to the small, and likely biased, sample of short workshop participants who completed a follow-up survey.

Findings related to RQ2 indicated that short duration workshop participants implemented IBL teaching practices to a lesser degree than long workshop participants. About 20% of short workshop participants who responded to the survey implemented no IBL teaching practices, and a greater proportion of long workshop participants implemented one course they considered to be fully IBL. Follow-up reports of IBL intensity also showed that short workshop participants used particular IBL methods less intensively. These findings are consistent with prior research, which has shown that long duration PD is positively associated with changes in teaching practices (Stes et al., 2010). These findings were expected given that the long workshops were implementation-focused: they used a consistent structure designed to meet implementers' needs and allowed participants work time to plan their own IBL course. Long duration workshop participants committed to four days, so they had a prior high level of commitment to implement IBL. Short workshops were less focused on implementation; rather, they sought to create broader awareness of IBL. Short workshops also required less participant commitment to implement IBL in their teaching and did not allow time for participants to plan how to implement IBL in their teaching.

Limitations and conclusion

While some aspects of these findings seem to support the efficacy of short workshops, several limiting factors of this research must be considered in interpreting these findings. The relatively small sample size from participants in short workshops (n = 66) is likely biased. Those short workshop participants who implemented IBL may have been more likely to respond to a follow-up survey than those who did not. Thus, the short workshop findings represent a best-case scenario for outcomes. They suggest that some participants respond to the workshops by implementing IBL methods in their own classrooms, but these findings should not be considered to be representative of all workshop participants.

While we measured pre-workshop and follow-up IBL capacity and teaching practices, we did not collect corresponding measures for short-duration workshop participants (Archie et al., 2021). Since short-duration workshop participants were not required to pre-register, we were unable to administer a pre-workshop survey. This prevented us from knowing participants' initial levels of IBL capacity and their teaching practices before attending a workshop. Without this data, we can't be certain about how much short workshop participants gained and the degree to which their teaching practices changed. Although we can't know the outcomes for all participants of short workshops, these results suggest that for some participants, short workshops may be an effective way to build IBL capacity. Others have suggested that starting with less intense implementations and building over time may lead to more widespread adoption, a process known as "phased inquiry" (Yarnall & Fusco, 2014) or "trialability" (Rogers, 2003); one interpretation of the findings is that short workshop participants are moving through this process. Thus, short workshops may have served in some respects as an effective "on-ramp" for instructors as they work towards full adoption of IBL teaching methods, while the long workshops led to greater measured change in teaching practice. Because duration is a basic PD design parameter that in turn affords or constrains other choices about content and engagement, these findings are important for PD providers and funders to consider as they make decisions about where to invest their effort and funds.

Comparing Student Strategies in Vector Unknown and the Magic Carpet Ride Task

Jeremy Bernier
Arizona State University

Michelle Zandieh
Arizona State University

We present findings from a study analyzing and comparing the strategies participants deployed in playing the game Vector Unknown and completing the Magic Carpet Ride task. Both the game and task are designed to give students an introduction to basic concepts about vectors needed for success in linear algebra. We found that participants used a diverse array of strategies, tending to favor algebraic approaches to the Magic Carpet Ride task. We also found that participants tended to try the same strategies in both tasks, but did not usually follow through with the same strategy in both contexts. These findings have implications for instructors considering using one or both tasks in their linear algebra class.

Keywords: linear algebra, game-based learning, inquiry-oriented instruction

Game-based learning (GBL) has proven to be a popular approach in STEM education and STEM education research (Klopfer & Thompson, 2020). However, much of the research into GBL in mathematics education has been focused on K-12 and especially K-8 education (Byun & Joung, 2018). One of the few games developed specifically for undergraduate mathematics instruction is Vector Unknown (VU; Mauntel et al., 2021), an adaptation of the Magic Carpet Ride (MCR) task from the Inquiry-Oriented Linear Algebra (IOLA) curriculum (Wawro, Zandieh, et al., 2013). VU, like the MCR task, is designed to give players an introduction to basic concepts about vectors needed for success in linear algebra. While the goals of both tasks overlap, the differences between them may lead to differences in the kinds of thinking students engage in when playing VU or solving the MCR task. This could be important to instructors deciding how they might use either or both in their own instruction. To begin to explore these differences, we present findings from a qualitative interview study with the following research questions:

RQ 1: What strategies do students deploy in solving the Magic Carpet Ride task and in playing levels in the Vector Unknown game?

RQ 2: What patterns are apparent in the use of strategies across tasks?

Context and Background

Literature Review

The idea that games and puzzles are environments where people engage in mathematical thinking is not new. Puzzles like Sudoku and games like Chess and Go have been the objects of study for mathematicians over the years (Silva, 2011). Moreover, the use of video games for the teaching and learning of STEM topics has been a popular application of GBL given their computational nature, their ability to simulate complex situations, and the active engagement they demand (Klopfer & Thompson, 2020). Vector Unknown is one of the few video games that have specifically been developed for undergraduate linear algebra (Mauntel et al., 2021).

Drawing from K-12 literature on GBL in mathematics education, there are clear indications of potential positive outcomes for student learning. In their meta-analysis on GBL research in K-12 math education, Byun and Joung (2018) computed an average effect size of d = 0.37 from quantitative studies, indicating a small-to-moderate-sized positive effect on math learning outcomes. Even so, some quantitative (Beserra et al., 2014) and mixed method studies (Ke, 2008) comparing games to similar non-game active learning opportunities have found that games may not always offer additional advantage over other active learning activities in terms of learning outcomes. While the VU game (Mauntel et al., 2021, Mauntel et al., 2020, Mauntel et al., 2019) and the MCR task (Wawro et al., 2012; Wawro, Rasmussen, et al., 2013) have each been the subject of several publications, no work thus far has compared student thinking in these tasks.

The Tasks

To properly contextualize the remainder of this paper, we present a brief summary of the two tasks being compared in this study below.

Magic Carpet Ride. The MCR task used in this study comes from the IOLA curriculum (Wawro et al., 2012; Wawro, Zandieh, et al., 2013) and is designed as a “day one” task as part of a larger “Magic Carpet Ride” unit that introduces concepts related to vectors, span, and linear (in)dependence. The day one MCR task asks students to determine if they can reach Old Man Gauss’s cabin at the point (107, 64) using two forms of transportation represented by vectors <3, 1> and <1, 2>. The next task in the unit asks students to consider whether there are “some locations that [Old Man Gauss] can hide and you cannot reach him with these two modes of transportation.” This task was used as a follow-up in some of the interviews as time allowed.

Vector Unknown. In VU, each level randomly generates a goal position (represented by a basket) and two pairs of vectors that are scalar multiples of each other (so one possible set of vectors is <-3, 2>, <-9, 6>, <1, 3>, and <2, 6>). Players then use any two of those vectors and integer scalars to get a rabbit from the origin to the goal. In this study, the current first three levels were used for the interviews. All participants played Levels One and Two, which work the same except for the Predictive Path feature. In Level One, as players choose their vectors and scalars, a Predictive Path line shows them where the rabbit will move when they hit “Go;” this feature is absent from Level Two. Level Three includes the Predictive Path and has an added component of a player first needing to get to three keys on the map and *then* go to the goal position. Completing Level Three usually requires the player to move from a location other than the origin after gathering some or all of the keys. See Figure 1 for an illustration of the game.

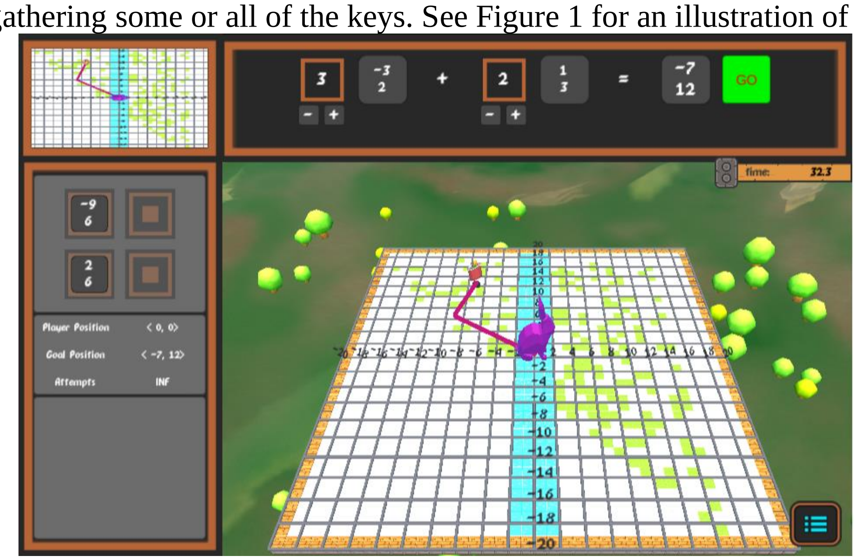

Figure 1. Gameplay of Vector Unknown.

Conceptual Framework

In answering our research questions, “strategy” needed to be operationalized. Because the purpose of this research was to compare two specific tasks, and because both of those tasks have published material to draw from, we used past work to develop a conceptual framework to operationalize strategy. This framework was based primarily on one developed with VU (Mauntel et al., 2021), supplemented by student sample work from the MCR task (Wawro et al., 2012; Wawro, Zandieh, et al., 2013), and further modified during the analysis process. Figures 2, 3, and 4 outline the conceptual framework.

Strategy	Mauntel et al. Description	Adaptations / Notes
Guess and Check	Player presses buttons while attending to how the vector equation changes or to how the geometric Predictive Path changes.	Name changed from “Button Pushing” to “Guess and Check,” to also include trying random scalars in the MCR task.
Quadrant-based Reasoning	Player chooses a vector to match the signs/quadrant of the goal position, references the direction of the Predicted Path or a quadrant on the graph to make sense of the direction of a vector, or understands vectors as slopes.	Slope-based strategies are the most common way this appears in the MCR task, as both the goal and given vectors have the same signs/quadrant.
Focus on one Coordinate	Player reduces the aim of the goal to one coordinate and attempts to reach that one coordinate.	In MCR, this occurs when the participant focuses on the North or East direction, one at a time.
Focus on one Vector	Player focuses on getting as close to the goal as possible with one vector and then utilizes another vector to reach the goal and/or alternates between the two.	In MCR, this occurs when the participant focuses on one of the modes of transport at a time.

Figure 2. Conceptual framework, part 1.

In past work with VU, Mauntel et al. (2021) used an iterative approach which sorted the strategies players used into four categories: Button-Pushing, Quadrant-based Reasoning, Focus on one Coordinate, and Focus on one Vector (see Figure 2). Additionally, each strategy participants used was classified as either Numeric or Geometric (see Figure 3), depending on whether the participant was relying on the numeric data (like the vector equation) or visual data (such as the predictive path) to solve the problem.

Strategy Type	Descriptors for Strategy Type
Numeric	Using arithmetic to solve or check a possible solution Referring to the vector equation (VU) or numeric values of vectors/goal
Algebraic	Setting up a system of equations Creating an equation for a line Creating symbols for unknowns
Geometric	Interpreting graphical information Drawing vectors or lines on a graph Using the Predictive Path (VU)

Figure 3. Conceptual framework, part 2.

Our review of student sample work for the MCR task (from Wawro et al., 2012 and Wawro, Zandieh, et al., 2013) lead to three adjustments to the framework. As a minor change, we renamed “Button-Pushing” to “Guess and Check.” More substantially, we noticed that algebraic solution strategies – strategies involving written equations with unknowns or variables – were more prominent in the MCR student sample work than in the VU research. To address this, we first added a fifth strategy: “System of Equations,” (see Figure 4), to specifically categorize the use of a system of linear equations. Second, Algebraic strategies were separated out from Numeric and Geometric as a third category for any strategy where the participant employed an algebraic equation or expression to attempt to solve the problem (see Figure 3).

Strategy	**Description**	**Basis for Addition**
System of Equations	Player creates a system of equations with two unknowns and then solves it to solve the problem.	Review of MCR student sample work (Wawro, Zandieh, et al., 2013).
Linearly Independent Vector Selection	Player chooses two vectors based on which pairs of vectors are scalar multiples of each other.	Strategy observed during analysis that did not fit into existing conceptual framework.

Figure 4. Conceptual framework, part 3 (new strategies).

Finally, the conceptual framework was further revised during the analysis process. In particular, an additional novel solution strategy for VU of “Linearly Independent Vector Selection” was noted. This strategy will be described and explored in the findings section.

Methods

Data Collection

The participants for this study were five students recruited from a third-semester calculus course at a large public university in the southwestern United States. All five students who indicated interest in the study participated in task-based interviews. For the purposes of this study, no demographic data were collected. As such, all participants will be referred to with the gender-neutral pronoun ‘they’ and pseudonyms generated from a list of gender-neutral names (Van Fleet & Atwater, 1997). Participants were asked if they had ever taken a college-level linear algebra course, and only one participant (Chris) said they had.

Interviews were conducted via Zoom due to the COVID-19 pandemic. The components of these interviews focused on in the analysis presented here consisted of two approximately 30-minute task portions for each of the MCR and VU tasks. In these interviews, the interviewer primarily described the tasks to be completed and did not typically interrupt the participant’s solving process, unless they had not spoken for a long time or were nearing the end of the allotted time. The order of the task portions varied from interview to interview. Figure 5 lists the participants by pseudonym and shows the order they completed the two tasks in.

Participant	Rikaine	Pat	Terry	Auren	Chris
First Task	VU	VU	MCR	MCR	MCR
Second Task	MCR	MCR	VU	VU	VU

Figure 5. Participants and task order.

Data Analysis

The conceptual framework outlined earlier in this paper was applied as a codebook. The two authors developed the conceptual framework over a sequence of meetings, settling on the approach as described above. Then, the lead author coded the transcript by identifying each time a participant applied or attempted to apply one of the strategies outlined in that framework. Further, a student's strategy was stratified based on whether they were applying Numeric, Algebraic, or Geometric versions of that strategy. Once identified, the strategies used by each participant were collected together and reviewed for accuracy and clarity before identifying which strategies best characterized the participant's solving process for each respective task. For MCR, this meant identifying which strategy was ultimately used to arrive at a solution, if any. For VU, where participants completed multiple levels, this meant identifying which strategy was used most frequently to arrive at solutions.

Findings

Our findings are oriented around our two research questions. Given space limitations, the first subsection addresses the first research question by summarizing the strategies students deployed in the MCR task and VU. The second subsection focuses on the novel strategy of Linearly Independent Vector Selection, as previous literature (Mauntel et al., 2021; Wawro et al., 2012) showcases detailed examples of the other strategies. Then, the two subsequent subsections address the second research question, by articulating two notable patterns apparent in the strategies used: the relative prevalence of Algebraic, Geometric, and Numeric strategies and the repetition of strategies across the tasks.

RQ 1 – Overall Distribution of Strategies

To begin to address RQ 1, we use Figure 6 to visually provide a summary of the diverse set of strategies that were used by the sample of participants. Within each box, an A, G, or N represents that the participant used an Algebraic, Geometric, or Numeric instantiation of that strategy, respectively. Bolded letters indicate the strategies that best characterized their performance on that task as defined in the Data Analysis section above.

Participant	Rikaine		Pat		Terry		Auren		Chris	
Task	VU	MCR	VU	MCR	MCR	VU	MCR	VU	MCR	VU
Guess and Check	G	N	G			G				
Quadrant-based Reasoning	G, N	**G, N**			A, N	**G, N**		**N, G**		
Focus on one Coordinate			**G, N**	N			N			N, G
Focus on one Vector	**G, N**	N	N		N					
System of Equations				**A**			**A**		**A**	**A**
Linearly Independent Vector Selection	N		N					N		N

Figure 6. Summary of strategies used by each participant

RQ 1 - Linearly Independent Vector Selection

As mentioned in the conceptual framework, a novel strategy for VU was observed in the analysis process. In four of the interviews, participants chose vectors based on the observation that some of the vectors were scalar multiples of each other. This strategy is perhaps best summarized by Chris's explanation [the vectors referred to are in square brackets]:

Chris: So what I'm thinking is that we can, uh, look for. First, identify any same vectors, any vectors that are linearly dependent, and I can already tell that the top right one [<-1, 5>] here and the bottom left one [<-2, 10>] here are linearly dependent, so they're the same vector, and then the also the other ones, the top left [<1, 1>] and bottom right [<-9, -9>] are linearly dependent so they're the same vector so that means that I can just use these top two as those are the only truly independent vectors available to me.

As Chris was the only participant who had taken linear algebra previously, they were the only participant to describe this strategy in terms of linear independence. Other participants typically only noted that pairs of vectors were scalar multiples of each other, such as in this excerpt from Rikaine:

Rikaine: Um and then, since these are, since these point in the same direction, I'm only really considering this one [<-3, -1>]. Just because I can scale it up to <-9, -3> if I need to.

This strategy is only implementable in VU (notice it is only present in VU columns, bottom row of Figure 6), as MCR has only two choices for modes of transport. Another notable aspect of this strategy was that, in two of the four cases where participants made use of this fact, this only occurred after additional interviewer questioning led them to observe that there were always pairs of vectors which were scalar multiples of each other. Thus, only one player (Rikaine) made an observation and selected vectors in this way without prior prompting or prior linear algebra experience.

RQ 2 - Algebraic, Geometric, and Numeric Strategies

Across participants, Geometric and Numeric instantiations of strategies were both common for VU (see the VU columns on Figure 6). Often, Geometric thinking was more apparent when the level had the Predictive Path feature. Only Chris used an Algebraic solution in VU. After completing the first level using a Focus on One Coordinate Strategy, and toying around with strategies in the second level, Chris reluctantly decided to pursue an Algebraic solution:

Chris: Ehhh, I wanted to avoid the algebra, but I think I'm going to have to use the algebra [laughs]. Going back to the method, okay setting up a two-by-two matrix.

They made this choice after having already solved the MCR task using a system of equations and an augmented matrix and having previously taken linear algebra at the college level.

On the other hand, MCR was mostly solved with Algebraic strategies, with Rikaine solving it primarily Numerically and Terry being unable to complete the task in the time allotted. This is not to say that Geometric thinking did not appear at all in solving the task – all of the participants drew a graph at some point. Some did so to set up their coordinate system and/or to visualize the problem, while a few did so after interviewer prompting to illustrate their solution. In these cases, however, drawing the graph was not directly linked to any of the solution strategies in our conceptual framework, and participants did not use these graphs as tools throughout the problem solving process.

RQ 2 - Repetition of Strategies

Most of the participants would at least attempt the same strategy in both the MCR task and VU. This can be seen by comparing the MCR and VU columns for each participant in Figure 6. For example, in the following excerpts, Pat attempts to apply the Focus on one Coordinate strategy first in VU and then in MCR:

Pat [During VU]: How to get to -7 with my x.…That [mousing over <-1, 3>] will at least get me to negative seven x.

Pat [During MCR]: I wonder if it's better to get to 64 first. So if it's 32 hours by magic carpet, that's the point (32, 64). Which would arrive me at the y, the y, the y value of his house.

In each case, Pat attempts to match one of the coordinates first. However, while they carried this strategy through to completion with VU, they ultimately chose to solve the MCR task with a

System of Equations. The only participant who did not at least attempt the same broad strategy across both environments was Auren. They relatively quickly settled on using a System of Equations on the MCR task, which they completed first. When they played VU, they did not ever consider this strategy, preferring instead to use Quadrant-based Reasoning.

Discussion

The findings above reflect the different affordances for students that VU and the MCR task offer. The fact that participants tended to try the same strategy for both tasks but did not tend to complete both tasks with the same strategy particularly supports this conclusion. This suggests that the two tasks are different enough that students may decide a strategy that worked in VU is not the best strategy for the MCR task, thus engaging them in different ways of thinking.

Two clear ways VU differs from the MCR task are in the offloading of computation and the limited magnitude of goal positions. Because the vector equation at the top of VU automatically updates whenever you change a scalar, it offloads computational work. The addition of the Predictive Path in some levels offloads even more work, as it allows the player to see both the Numeric value of the result and the path it takes on the coordinate plane to get there. In addition, goal positions have their x and y coordinates each somewhere between -20 and 20. This means that the goal position is relatively small in magnitude, particularly when compared to the goal position of the MCR task, (107, 64). These differences in features may be related to the differences in how students use Algebraic, Numeric, and Geometric thinking across the two tasks. Because the MCR task involves working with larger numbers, and because all computation and graphing is left to the student, students may be more inclined to think algebraically to avoid having to do a lot of computations or draw a precise graph. Conversely, because VU handles many computations for the player, asks the player to work with smaller numbers, and shows the player information on an already-made graph, it can be easier to engage in Numeric and Geometric thinking while solving this task. While each individual task may better support different kinds of student thinking, using them in conjunction with one another may support students using all three of these kinds of thinking.

Another difference is that players have a surplus of vectors to choose from in VU, with the four vectors available consisting of two pairs of vectors that are scalar multiples of each other. Thus, students not only have choice in what vectors they use, they also may be able to make observations about linear independence and dependence through playing levels of the game. We saw this with the strategy of Linearly Independent Vector Selection. In comparison, the first task in the MCR unit only includes two linearly independent vectors. However, the rest of the MCR unit does lead students toward considerations of linear independence and dependence. In addition, simply having students play VU may not automatically lead to students having any insight about linear independence. We can see this in the fact that three of the students who used this strategy only did so after additional interviewer questions. This suggests an important caveat: it is not just the design but also the implementation of the tasks that matters. Instructors who subtly or not-so-subtly prompt students to look closer at the vectors that are available to them may be able to scaffold these kinds of observations for students.

Students' Written Homework Responses using Digital Games in Inquiry-Oriented Linear Algebra

Zac Bettersworth
Arizona State University

Kaki Smith
Arizona State University

Michelle Zandieh
Arizona State University

In this report, we characterize seven of twenty-five students' responses to a single written homework assignment from the Spring 2021 academic semester. The homework was designed to incorporate the Vector Unknown 2D digital game to investigate how students answered questions about span and linear independence after playing various levels of the game. We present our modification of the roles and characteristics framework of Zandieh et al. (2019), our identification of students' grammatical use of game language and math language, as well as the results of analyzing students' homework responses using our framework.

Keywords: Linear Algebra, Inquiry-Oriented Instruction, Game-Based Learning

The teaching and learning of linear algebra are important due to their prevalence in many STEM disciplines. One of the goals of our team was to develop a sequence of game-based written homework assignments that paralleled the course progression of the Inquiry-Oriented Linear Algebra (IOLA) curriculum (Wawro, Zandieh, et al., 2013) for use in any linear algebra classroom. Here we build on past research stemming from the IOLA curriculum that uses Realistic Mathematics Education (RME) constructs to inform the design of curricular materials by iterating research, design, and implementation (Gravemeijer, 1999; Wawro, Rasmussen, et al., 2012).

Figure 1. Two screenshots of the Vector Unknown game for Level 3 (left) and Level 4 (right).

Vector Unknown (VU) introduces novice linear algebra learners to beginning topics such as linear combinations of vectors and span. Players move a bunny through a level to collect baskets and keys by dragging vectors and setting scalar values to create linear combination equations as seen in Figure 1. VU draws heavily on the use of the travel metaphor that is leveraged in the IOLA curriculum during the Magic Carpet Ride (MCR) task sequence (Plaxco & Wawro, 2015; Wawro et al., 2012). We extend the use of VU by augmenting its instructional use with a set of homework assignments. Since this was our first attempt at designing this set of game-based homework, we wanted to understand how our students thought about span and linear (in)dependence after playing several levels of VU. To accomplish our goal, we analyzed students' responses and gameplay screenshots from their second written homework assignment.

Research question: How did students use the Vector Unknown 2D game in their responses to questions about span and linear independence in their written homework?

Background Literature and Theoretical Perspective

Stewart, Andrews-Larsen, and Zandieh (2019) provided a thorough overview of the current state of the research literature on the teaching and learning of Linear Algebra ideas. Stewart and colleagues synthesized 54 research articles across various themes, including span and linear (in)dependence, that are relevant concepts within most Linear Algebra curricula. We use the literature review of Stewart et al. to inform our own.

Span and Linear (In)dependence

Plaxco and Wawro (2015) determined that travel is a consistent metaphor that students use to reason about span in the context of the IOLA curriculum. Adiredja and Zandieh investigated students' everyday examples of basis using an anti-deficit perspective (Adiredja & Zandieh, 2017; 2020). Extending their initial framework for students' example generation, Zandieh et al. (2019) determined that travel was a ubiquitous metaphor for the notion of basis even though the students had never encountered the IOLA curriculum. There have been several studies that analyzed how students think about linear (in)dependence: Ertekin et al. (2010) discussed student thinking about linear independence and dependence in geometric contexts, Hannah et al. (2013; 2016) and Stewart and Thompson (2010) made connections between students' embodied ways of reasoning about linear independence and dependence even when the students were unable to produce a formal definition. Rasmussen et al. (2015) analyzed video data to investigate students' progressive mathematization of examples of linearly (in)dependent vectors in $\mathbb{R}^2$ and $\mathbb{R}^3$.

Most relevant to our work is a similar study by Dogan-Dunlap (2010) who analyzed students' homework responses with an online module to learn more about the various ways students think about linear (in)dependence. When using the geometric web module, students' responses were characterized by Dogan-Dunlap across 17 categories, 11 of which were geometric. It could be the case that using manipulatives and educational video games support students in forming geometric interpretations of span and linear (in)dependence. However, no study has considered how students think about span and linear independence by analyzing students' written homework responses after playing a research-designed video game.

Game-Based Learning

The research team that developed the game VU incorporated Game-based learning (GBL) research as a lens to better understand the instructional affordances and limitations of using video games for teaching mathematical ideas (Coleman & Money, 2020; Gresalfi & Barnes, 2016). There has not been a lot of research leveraging games within higher-level mathematics courses. As such, our research adds to the burgeoning area of GBL within the IOLA curriculum (Mauntel et al., 2021). Digital Game-Based Learning (DGBL) has gained popularity in the K-12 literature over the past 20 years, "...DGBL in mathematics education can be regarded as the use of digital games within the context of learning mathematics," (Byun & Joung, 2018, p. 114). Other researchers within the IOLA research group have investigated the development of students' gameplay strategies using VU (Mauntel, Levine, et al., 2020; Mauntel et al., 2021). We agree that playing a well-designed video game does not imply students are mathematizing anything, "...a young child counting blocks, may...be experiencing mathematical play; whereas a middle school student who is being forced to play a very well-designed mathematics game in the classroom may not," (Williams-Pierce, 2019, p. 592). We view our design of written homework as a structured set of questions intended to support students in forming and testing conjectures about the game to engage in mathematical play while playing VU.

Roles and Characteristics of Basis Vectors Framework

We view the framework of Zandieh, Adiredja, and Knapp (2019) as viable to analyze the spontaneous game examples given by students in their written homework. Zandieh et al. built upon their previous framework of *roles* and *characteristics* codes to understand how students thought about basis through everyday example generation. Zandieh and colleagues used *roles* codes to describe the role that a set of basis vectors has relative to the ambient vector space. Zandieh and colleagues' *characteristics* codes described important conditions of a set of vectors. We did not explicitly ask students to generate examples using VU on their written homework. However, students' spontaneous use of game examples included descriptions of the roles and characteristics of the list of vectors given to the player in VU. We later elaborate on our alteration of the roles and characteristics of basis vectors framework of Zandieh, Adiredja, and Knapp (2019).

Methods

We designed a single written homework assignment to be used in the third author's IOLA class during the Fall 2020 semester. After reviewing student responses and meeting weekly, we refined the single homework assignment and wrote four new assignments during the Spring 2021 semester. Out of the forty-two students enrolled in the third author's IOLA class during Spring 2021, we collected the written homework responses of about twenty-five students (not every student completed each assignment). We analyzed the responses of seven out of the twenty-five students that submitted the second homework assignment due to their use of spontaneous game examples from VU in their response to the first question pictured in Fig. 2: Adrian (chose not to identify), Kieran (chose not to identify), Brooks (White man), Michael (White man), Jing (Asian/Asian American man), Tanner (White man), and Aahan (Asian/Asian American man).

The second homework was written with two mathematical concepts in mind: span and linear (in)dependence. In both the first and second written homework assignment, we explicitly used the word span, though we did not explicitly mention linear (in)dependence in either assignment. Students had encountered the IOLA lessons covering both ideas (Magic Carpet Task and Return to Home Task) by the time they received the second written homework assignment. Students were asked to play Levels 3, 4, and 5 on the hard difficulty of VU multiple times. Level 3 of VU includes four game objects (collect three virtual keys then travel to the location of the lock), Level 4 includes three collinear baskets where the line passes through the origin, and Level 5 includes three collinear baskets where the line of the baskets does not pass through the origin.

5.) (2 points) If you remove one of the vectors from your list in number 3) would the span of this new list be the same as what you marked in number 4)? Explain why or why not. Include in your answer whether it matters which vector you removed.
7.) (Extra Credit) Reflect on the similarities and differences between your answers in the Level 4 column and the Level 5 column. Make connections between as many of the boxes on your answer sheet as you want to receive up to 5 possible extra credit points.

Figure 2. Statement of the problems Q1 and Q2 from the second written homework

We conducted our first pass at data analysis of the second homework by open-coding every student's responses to each question to characterize the nature of the data and identify trends and themes (Strauss & Corbin, 1990). During this initial pass, we noted some students appeared to make connections between their understanding of span, linear independence and the explanations of their gameplay. While there were some selected response questions in the homework, we focused on the free response questions to better characterize students' connections. The framework of Zandieh et al. (2019) proved useful once we determined the subset of seven students who provided explanations using gameplay examples. To focus on how the students were using the game to reason about Linear Algebra concepts, we used the code *game language* to focus on pieces of the data where this might occur. An excerpt was originally coded as *game language* if the excerpt mentioned the student's actual gameplay, mechanics of the game, features of the game, or limitations of the game. For example, Adrian discussed increasing the distance traveled by the bunny in game language as opposed to saying something about increasing the value of the scalar multiple of said vector:

> "Therefore, it would likely only affect the first **movement** by increasing the distance **traveled** by the **bunny** in those two directions," -Adrian.

After determining the seven students that used game language to respond to Level 3 Question 5 (Q1), we used our modified framework of Zandieh et al. (2019) to code the seven students' responses to Q1 and Level 4 and 5 Question 7 (Q2) using our span and independence codes framework pictured in Figure 3. We will now focus our discussion primarily on the responses of the seven students who used game language in their responses to Q1.

Findings

Our findings include (1) students' mixed use of game and math language when responding to Q1 and Q2, (2) our modification of the Zandieh et al. (2019) basis framework, and (3) the results of using our frameworks to analyze students' responses to Q1 and Q2. In Figure 3, we present our span and independence framework. For each code, a portion of a students' response is given as an example to the reader. In Figure 4, we present the results of coding each student's response to Q1 and Q2 using our modified framework. In the column for students' responses to Q2, we separate the codes using semicolons if the student broke their response into paragraphs or sections.

Students' use of Game Language and Math Language After we determined some students responded to the homework using spontaneous examples from their gameplay, we wanted to know how some students used game examples in their open-ended homework responses to Q1 (25 responses) and Q2 (19 responses). We created various lists of words that would fall under *game language* usage (e.g. "bunny", "baskets", "route") and *math language* usage (e.g. "span", "plane", "magnitude"). We added a *mixed language* category for words that could be considered relevant to the game, but weren't always used to refer to one of the elements of the game (e.g. "vector", "line", "scalar"). We coded the second homework assignment itself and every students' responses to Q1 and Q2 at a word-for-word grain of analysis using our lists. We wanted to know if any students used *game language* when responding to Q1. We thought it would be interesting if a student responded primarily in game language to Q1, which was phrased primarily in mixed and math language. While many students' responses to Q1 involved math and mixed language use (69 instances of math language across 23 responses; 86 instances of mixed language across 22 responses), our seven research subjects were the only ones who responded to Q1 using game language. Out of the twenty-five responses to Q1, there were only 18 instances of game language across 7 out of the 25 responses. The data presented here is from the written responses to Q1 and Q2 of these seven students.

The Span and Independence Framework Zandieh et al. (2019) used *roles* codes to describe students' examples relative to how the basis vectors relate to the ambient vector space. In our modification of their framework, we instead use *span* codes to characterize students' descriptions of how vectors or objects relate to the span of said vector set. Further, Zandieh and colleagues used *characteristics* codes to describe students' examples based on the conditions that a set of basis vectors has. We instead use *independence* codes to characterize students' descriptions of the conditions of a set of vectors or objects. We view our use of *span* and *independence* codes as highly overlapping with the use of *roles* and *characteristics* codes. We present a description of the *span* and *independence* codes in Figure 3 with some short examples. Figure 3 is altered from the framework used by Zandieh et al. (2019) with the addition of our own restricting code, modification of three codes, and exclusion of two codes. There are some codes in Figure 3 whose names have been changed to better describe our data (i.e., restricting, redundancy, and sameness). If we did not find evidence of a particular code in our students' written responses, we did not include it in Figure 3 (i.e., systematic and structuring).

Span Codes	Information	Independence	Information
Generating (Gen)	Creating a line or plane through combining vectors or game objects. E.g., The spans being used **form** a plane; you could **form** a plane using the 4 vectors provided	Minimal (Min)	The set being the smallest or having the least number of vectors to fulfill the role in space. E.g., to accomplish the task with **smallest number of vectors**
Covering (Cov)	Filling or encompassing the space. E.g., The span must be a plane because all vector combinations **lie within** a certain range	Redundancy (Redun)	Having extraneous objects in the set. E.g., If one of the two vectors was **removed**, it likely **wouldn't have made much of a difference**
Traveling (Trav)	Moving (themselves or the bunny) through the game space or along a path. E.g., you can **reach** anywhere within R2 with no problem.	Sameness (Same)	Vectors in the set or objects related to the vectors (direction, parallel lines, etc.) are the same. E.g., The vectors <-1,5> and <-3,15> **represent the same line**
Restricting (Restr)	Certain conditions keep the span of a set of vectors from having a higher or lower dimension. E.g., There is also no z point in the vectors allowing 3D traversal, **limiting** it to a plane	Essential (Ess)	The critical importance of including a vector in the set or using a vector while playing the game. E.g., Two [vectors] **were needed** instead of one

Figure 3. Table altered from Zandieh et al. (2019)

Results from Span and Independence Coding We used our modified *span* and *independence* codes as a codebook to produce the set of codes for each student's response to Q1 and Q2 as shown in Figure 4. Looking across columns it can be shown that Q1 and Q2 elicited different sorts of responses from our research subjects. For example, there are far more uses of the essential code for Q2 than Q1. Looking across the rows of Figure 4, it can be seen that students emphasized different aspects of the roles or characteristics of the set of travel vectors provided in Levels 3 through 5 in VU.

Student Name	Q1: Level 3 Question 5 Response	Q2: Level 4/5 Question 7 Response
Adrian	Redun, Same, Trav	Ess, Gen, Ess, Trav; Trav, Ess, Trav; Trav
Kieran	Restr, Trav, Redun	Gen; Restr, Cov; Cov, Ess
Brooks	Cov, Trav, Restr	Trav, Min; Ess, Trav, Redun, Ess, Restr
Michael	Trav, Cov	Ess, Gen; Ess, Trav, Cov
Jing	Redun, Trav, Same	Ess, Cov, Ess, Same; Min, Gen, Ess, Trav; Gen, Cov, Same, Trav; Gen, Ess, Trav, Ess, Gen, Min, Trav, Gen, Same
Tanner	Restr, Trav, Gen	Gen; Gen, Ess
Aahan	Same, Trav, Redun, Trav	No response

Figure 4. The results of coding students' responses to Q1 and Q2

To demonstrate how we distinguished between students' responses using game language, consider the following portion of Adrian's response. For clarity, game language will be *italicized*, math language will be underlined, and mixed language will be *both* italicized and underlined.

> "Therefore, in order to reach all of the *goals*, the *bunny* needed to use a *vector* to get into *position* before using a second *vector* to *follow* the *linear* *path* towards each of the *goals*," -Adrian.

This excerpt was chosen to show a response that primarily used *game language*. Adrian claimed that an additional vector was needed from the perspective of the bunny, which was an indicator of *game language*. Further, to reach the goals (i.e., the baskets), Adrian claimed the bunny needed to first "get into position" to collect the baskets in Level 5. This need to "get into position" was related to the setup for Level 5 of VU (i.e., the line of the baskets did not pass through the origin).

To demonstrate how we used our *span* and *independence* codes, consider the following portion of Jing's response. For clarity, each indication of a *span* or *independence* code will be **bolded**. We coded Jing's response as Trav, Ess, Gen:

> "In level 5, I need to **reach** (Trav) the point of the line and that will **need an extra vector** (Ess) to make it happen, and it will **form** (Gen) a plane," -Jing.

This excerpt was chosen to show a common pairing of codes, *essential* and *traveling* as well as a response given primarily in *math language*. The reader may note the similarity in this portion of Adrian and Jing's responses to Q2 about their Level 5 gameplay in that both excerpts consist of an *essential* and *traveling* pairing of codes.

Discussion and Conclusion

We begin our discussion by first comparing students' span and independence codes across their responses to Q1 and Q2, pictured in Figure 4. We will also discuss trends in pairings of codes that emerged in students' responses similarly to the work of Zandieh et al. (2019).

In Figure 4, we found that we had assigned more students the *generating* code in Q2 than Q1. It may be the case that asking students to compare the span of their vector list in Level 4 and Level 5 led to more examples indicative of creating and forming lines and planes. This makes sense based on the way we asked Q1. Our emphasis was on having students mentally compare the span of their vector list in Level 3 and then comparing that to the span of a new vector list with one fewer vector. Students were assigned the *redundancy* code more times in their responses to Q1 than Q2. Since students were thinking about whether the span of their initial vector set was different than the span of the new vector set (with one fewer vector), this may have contributed to students' responses being characteristic of having extraneous objects in their imagined vector set. We see far fewer *sameness* and *redundancy* codes in general across students' responses to Q2, which also makes some sense. Instead of being asked about the effects of adding or removing a vector from a particular set, students were instead asked about whether the span of the set of vectors they used to win the level was a line (Level 4) or a plane (Level 5).

The *essential* and *traveling* code pairing was the most common pairing in students' responses to the Q2 which asked the students to compare Level 4 and 5. The major difference in these two levels is whether the baskets lie along a line that goes through the origin (Level 4) or not (Level 5). In the *essential/traveling* pairing, students were describing the need for an extra vector to "get to" the line or "detour" to the line containing the baskets in Level 5. The inclusion of the "offset" vector in Level 5 changed the span of the set of vectors needed to win Level 4 from a line to a plane (five out of the seven correctly answered this question). Students' use of gameplay language to compare Levels 4 and 5 may be indicative of the students' explicating an intuitive need for an offset vector, while still working towards more formal mathematization.

It is interesting that many students' intuitive notion about traveling on the offset vector, as indicated by the prevalence of the essential and traveling code pairing, did not appear to translate to more formal mathematization when writing the parametric equation for the line of the baskets in Level 5. It may be that thinking about "traveling to the line of the baskets" is a useful travel metaphor to support students' in transitioning towards more formal ways of reasoning. For example, we view the need to first travel to the line of baskets before collecting them as an informal way of reasoning that foreshadows a transition towards symbolizing the parametric vector equation for the line of the baskets in Level 5. Students were asked to write the vector equation for the line of the baskets on their homework, but only Michael, out of our seven research subjects, produced an equation of the form we had in mind (i.e., $\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 3 \\ 2 \end{bmatrix} + a\begin{bmatrix} 1 \\ 2 \end{bmatrix}$).

Our results add to the body of knowledge about student thinking about span and linear (in)dependence in the context of the IOLA curriculum. Specifically, our contribution is through incorporating the use of a research-designed game and written homework assignments to support students in thinking about the notions of span and linear independence while playing the game. The results of this study demonstrate the ability of the VU game, when accompanied with a written homework assignment, to evoke different ways of thinking about span and linear independence in an experientially real context. We see this as an extension of some of the other work using VU in the context of IOLA (Mauntel et al., 2021).

Further, some students adopted the perspective of the bunny when responding to the homework questions. Students adopting the perspective of the bunny seems to be related to Serbin, Wawro, and Storms' notions of *physics-centered* and *physicist-centered* grammatical constructions (Serbin, Wawro, & Storms, 2021). For example, a student may give an explanation that includes a description of a person within the span of a set of vectors (*physicist-centered*). We conjecture that students' use of *game language* may be connected to *physicist-centered* language, and *math language* use may be extremely similar to the notion of *physics-centered* grammar. Future work may investigate the nature of students' use of *game language* in conjunction with students' use of "bunny-centered" language when discussing their responses to the written homework.

Since we collected all five written homework assignments as data from every student in the third author's IOLA classroom during the Spring 2021 semester, we intend to expand our current analysis across all five homework assignments. Further, we intend to use the results of this study to motivate further revision of the game-based written homework assignments in the context of the IOLA curriculum.

Limitations and Acknowledgements

We acknowledge that this data was collected from a single IOLA course at a large University in the United States. This likely impacted the data we collected. The hope would be to eventually scale these homework assignments to more institutions using the IOLA curriculum as motivation to incorporate the Vector Unknown 2D and 3D game into their classroom.

In this paper, we present an empirical study examining challenges undergraduate mathematics students (N=73) encounter when engaging in programming-based mathematics inquiry projects, and how they handle these challenges. Results suggest that a majority of students find the programming or the programming of mathematics the most challenging aspect of their engagement, for different reasons. Also, with more experience engaging in such projects, it seems students may become more able to handle their challenges in an independent manner (e.g., through reviewing concepts, persevering, or planning).

Keywords: Computing; Math Inquiry; Challenges; Student Learning; Instrumental Genesis.

There has been a growing interest in studying and implementing innovative approaches in undergraduate mathematics, such as inquiry-based mathematics education (Artigue & Blomhøj, 2013; Laursen & Rasmussen, 2019), in which students are invited to engage in the practices of professional mathematicians. There is also a recent push to integrate computer programming – or more broadly, computational thinking – in different subject areas and at all levels of education (Guzdial, 2019; Wiebe et al., 2020; Wing, 2014); though the potential of integrating programming in mathematics learning has been known for a long time (diSessa, 2018; Papert, 1980), including at the undergraduate level (e.g., Leron & Dubinsky, 1995; Wilensky, 1995). In particular, programming can support a certain inquiry-based approach, where students engage in computational practices used by some professional mathematicians (Weintrop et al., 2016).

Some undergraduate mathematics curricula have integrated programming in this sense. For example, at Carroll College in the United States, mathematics majors use programming as a problem-solving tool throughout their mandatory coursework (calculus, linear algebra, modelling, abstract algebra, etc.) and may eventually apply their programming skills in senior projects or theses (Cline et al., 2020). Another example, in the Canadian context, is a sequence of three courses called Mathematics Integrated with Computers and Applications (MICA), which have been implemented at Brock University since 2001. Throughout these courses, students engage in a sequence of 14 projects (including end-of-course projects on student selected topics), in which they design, program, and use interactive computer environments to investigate mathematics concepts, conjectures, theorems, or real-world situations (Buteau et al., 2015).

In their recent “Call for Research that Explores Relationships between Computing and Mathematical Thinking and Activity,” to the international RUME community, Lockwood and Mørken (2021) argue that “serious consideration of machine-based computing [including programming] is largely absent from much of our research in undergraduate mathematics education” (p. 2). They suggest that much more needs to be investigated, “including identifying and exploring potential benefits, affordances, challenges, and problematic issues” (ibid.). They also point out that the various approaches to integrating computing in university mathematics classrooms should provide opportunities for research. In our 5-year research study, we address the above gap, using the opportunity provided by the natural MICA environment. In particular, we examine the teaching and learning of using programming for engaging in pure or applied mathematical inquiry. As part of our study, we seek to better understand the challenges students face during their learning, which we see as potentially providing insights for implementation. In this paper, we present some initial findings addressing the following research questions: What challenges do undergraduate mathematics students encounter when engaging in programming-based mathematics inquiry projects? How do students explain their challenges? How do they handle their challenges? Are there any differences among different demographics of students?

Theoretical Framework

In our work, we frame students' engagement in programming-based mathematics inquiry projects using a development-process model (dp-model, Figure 1) proposed by Buteau and Muller (2010). According to the model, students' engagement involves different steps, which arise in a dynamic, non-linear fashion. For example, at Step 3, students design and program an "object" (or interactive environment) they will use for their inquiry, and this may occur in a cyclic manner with Step 4 (verification and validation of the programmed math). This model was developed through an analysis of MICA projects, a literature review (Marshall & Buteau, 2014), and analyses of student data (Buteau, Gueudet, et al. 2019). It has also been argued to align with the programming-based practices mathematicians use to conduct research – i.e., inquiry (Buteau, Gueudet, et al. 2019; based on Broley, 2015). Balt and Buteau (2020) provide a 5-minute video illustrating the model in the context of two selected pure and applied student inquiry projects.

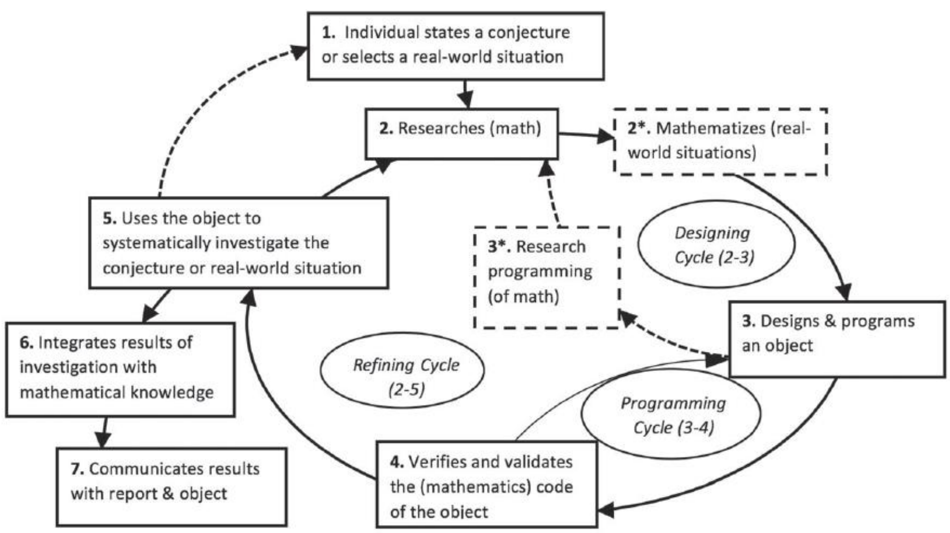

Figure 1. A model of students' engagement in mathematics inquiry projects (Buteau, Gueudet, et al., 2019, p. 6).

We further frame students' learning in the above model using the instrumental approach (Rabardel, 1995, 2002), whereby programming is an artefact (a human product) that may be transformed into a meaningful instrument (e.g., for conducting mathematical inquiry). This transformation – called instrumental genesis – involves the development of schemes (Vergnaud, 1998), including stable strategies (and principles underlying strategies) that enable the student to effectively achieve a goal (e.g., articulating a mathematical process in a programming language, as part of step 3 in the dp-model; Buteau, Gueudet, et al., 2019). In our case, a student's instrumental genesis involves the development of a web of schemes (Buteau et al., 2020), i.e., interrelated schemes found at different steps of the dp-model.

Instrumental genesis is a complex process that can be challenging for students (Laborde, 2002). In our research, we have been documenting individual students' instrumental geneses through the sequence of inquiry projects offered in the MICA courses mentioned above, including mentioning some challenges that arose for those few individuals, in certain projects (Buteau, Gueudet, et al., 2019; Buteau, Muller, et al., 2019; Gueudet et al., 2020). In this paper, we move away from this in-depth approach and move to a wider student population to examine, more systematically, challenges (i.e., aspects of students' engagement that appear to cause the most issues, in terms of schemes, steps from the dp-model, or more general elements), and how students mostly handle these challenges (i.e., to move their mathematical inquiry forward).

Methods

As mentioned above, we work in the context of a sequence of three programming-based mathematics courses, MICA I-II-III, offered at Brock University, which engage mathematics majors and future mathematics teachers in 14 inquiry mathematics projects. Our study is part of a larger five-year naturalistic (i.e., not design-based) research aiming at understanding how students learn to use programming for authentic mathematical investigations, if and how their use is sustained over time, and how instructors support that learning.

As part of Years 2-4 of this research, all MICA students were invited to respond to an online questionnaire (~12-15 minutes long) at the end of their course (MICA I, II, or III). Participation was voluntary. Table 1 shows some relevant demographic information for the 73 participants. The questionnaire contained different sections: demographics; confidence in programming (for mathematics investigations); usefulness of programming; etc. In this paper, we focus on the questions asking 'what' students found most challenging in MICA projects, 'why', and 'how' they mostly handled it. Participants provided short written responses to each question.

Table 1. Information about participants that will be used in this paper.

Demographics				
Gender	MICA I	MICA II	MICA III	**Total**
Female	25	14	9	**48**
Male	14	7	4	**25**
Total	**39**	**21**	**13**	**73**

Each 'what', 'why', and 'how' response was coded, first individually (among 2-5 coders), and then through consolidation (which led to lists of 'codes'). Codes for the 'what' question were first grouped into 'themes'. Since each participant's responses to the 'why' and 'how' questions elaborated on their 'what' response, these codes were sorted first into groups by the 'what' themes, and then codes in each group were looked at and grouped into themes. This thematic regrouping was consolidated by 2 coders. Finally, we created different graphical representations of the frequency distribution of the results, including in relation to different demographic groups. We then interpreted our results using the theoretical frame elaborated in the previous section.

Since participation was voluntary, we cannot claim that our sample is representative of all MICA students. This is a limitation of our study.

Results

We present selected results in four sections aligning with our four research questions.

What students find most challenging

Our analysis led to eight themes, with distribution across participants given in Figure 2.

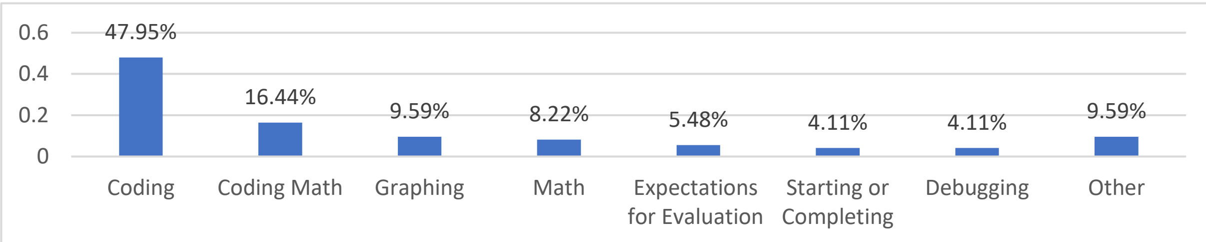

Figure 2. What participants (N=73) found most challenging about the MICA inquiry projects.

The part of the programming-based mathematics inquiry that most participants found most challenging was *coding* (e.g., "anything that requires a loop, an array, or long segments of code"), followed by *coding mathematical processes, including translating mathematics to code* (e.g., "making the computer do the math"). Both of these relate to students' (engagement with the) activity in steps 3-4 of the dp-model (i.e., the programming cycle). The other most challenging parts were mentioned in smaller proportion (at most 10%). Some are related to the programming cycle, such as *graphing and graphics*[1] (e.g., "getting graphs and picture boxes to do things") and *debugging* (e.g., "overcoming a roadblock or mistake in the coding"), making the issues at the programming cycle the most dominant ones (78% in total). All other challenges appear to relate to more general aspects of students' engagement (i.e., not necessarily related to a specific step in the dp-model): the *mathematics* (e.g., "understanding the math components"), *starting or completing the inquiry projects* (e.g., "at the beginning and setting up the program"), *expectations for evaluation* (e.g., "understanding what the professor expects"), and *other responses* such as "the imaginative process."

When reviewing participants' responses to both the 'what' and 'why' questions, we find that some of the latter challenges may be related to several steps in the dp-model. For example, the student mentioning the imaginative process explained: "I've always struggled with feeling confident in my own ideas ... coming up with my own conjecture …[was] the hardest for me," which we associate to step 1. Another student in the "other" theme specified: "I had a hard time understanding the content of the course in terms of how to apply my program to the questions asked of me," which we associate to step 5. And a student included in "math" said: "I found the written reports to be the most challenging … it just seemed to require more in depth thinking, rather than just knowing the math and programming it," which we associate to steps 6-7.

Why students find 'coding' and 'coding of mathematical processes' to be most challenging

We now consider the reasons behind the two greatest challenges reported by the highest proportions of participants. Our analysis of 46 participants' responses led to 11 themes, which can be categorized according to 4 different aspects of instrumental genesis.

The most dominant reason (32.6%) was *struggling with knowing what to do while coding, or starting or getting stuck with coding* (e.g., "I find it difficult to start as sometimes I don't know how to approach the math in a programming sense"). We infer that these students were

[1] Programming graphs in VB.Net requires coding a change of coordinate system.

struggling to mobilize or develop certain schemes (e.g., for articulating a math process in the programming language). Another reason, *struggling with making efficient code* (6.5%), also points to struggling to develop a certain scheme (e.g., "It's one thing to get the code to do what you want, it's another to get it to do that as efficiently as possible"). Thus, 39.1% of participants seem to suggest the development of certain schemes as causing the 'coding (math)' challenge.

Some reasons (with proportions totaling 36.9%) relate more to the nature of instrumental genesis: a process that takes time, effort, and confidence. This includes *coding (math) is new* (15.2%, the second most common reason), *needing more guidance* (10.9%, e.g., "I am expected to know commands and what to write with only being taught the basics"), *not being confident in coding* (6.5%, e.g., "I am not totally confident as a programmer"), and *needing more time* (4.3%, e.g., "It's a hard concept to understand in a short amount of time").

Two reasons (totaling 19.5%) point to the nature of the artefact (in this case, programming). This includes the third most common reason, *coding is finicky or picky* (13%, e.g., "one small thing can throw the whole code off") and *struggling to understand how a program works* (6.5%, e.g., "I really struggle to visualize how the program handles these codes and tend not to understand … how it is getting to the answer").

Finally, two reasons (totaling 8.6%) concern the nature of the mathematics: *finding it difficult to think computationally* (4.3%, e.g., "It generally takes a difficult path to go through the math and make it work") and *struggling with coding complicated or brand-new math* (4.3%, e.g., "some of the math is complicated enough on paper let alone telling a computer how to do it").

How students mostly handle what they find to be most challenging

Looking at how all 73 participants said they handled their most challenging part of their inquiry projects, 9 themes were found (summarized in Figure 3, left).

53.4% of participants indicated *seeking help from the instructor, teaching assistants (TAs), and/or peers* (e.g., "Asking as many questions, and getting as much help from the TA/Instructor as possible"; "I speak with peers and the professor in order to get on the right track").

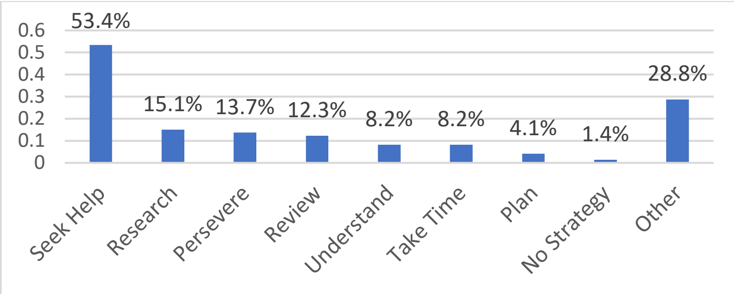
Some other strategies (with proportions totaling 35.6%) include ways of independently gaining the knowledge required to address the challenge: *researching beyond my lecture material* (e.g., "Using the textbook and online sources to self-teach"), *reviewing my (previous) lecture material* (e.g., "sit down with my lecture notes and review them"), and *seeking a deeper understanding* (e.g., "just trying to understand the topics more deeply").

Two other strategies (totaling 21.9%) are associated with taking the time needed to adapt or develop one's schemes for the given situation: *persevering* (e.g., "Just testing new ideas until one works") and *taking my time* (e.g., "I took things one step at a time").

One strategy is specific to 'coding (math)' (4.1%): *planning before coding* (e.g., "trying to structure out some sort of design before writing programs"), which we infer as students developing part of a scheme for articulating a (math) process in the programming language.

A very small proportion (1.4%) indicated having *no strategy* (e.g., "I haven't [handled it]").

There were also 28.8% of *other strategies* mentioned, such as "I've been handling it by staying on top of my academics." Many of these could be connected through a larger category of *working through it on my own*, as could most of the themes in Figure 3, left (excluding *seeking help* and *no strategy*). We thus regrouped students according to their ability to work independently on programming-based mathematics inquiry, as summarized in Figure 3, right: 32.9% of students mostly *just seek help from others*, 38.4% mostly *just work through it on their own*, 23.3% *do both*, and 5.5% mostly *just struggle and/or have no strategy*. We interpret students using a strategy including working through it on their own (61.7%) as suggesting that they may be "further along" in their instrumental genesis or more able to facilitate it themselves.



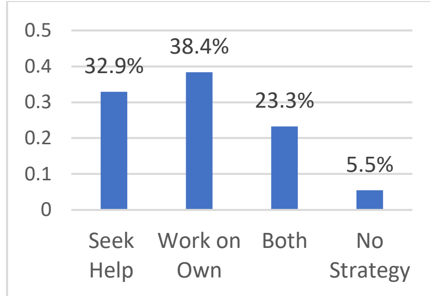


Figure 3. How participants (N=73) mostly handled their most challenging part of the MICA inquiry projects.

Some demographic comparisons in the 'what' and the 'how'

Finally, we present some results considering different demographic categories: year of study (MICA I vs. 'upper MICA,' i.e., MICA II or III) and gender (female vs. male).

When comparing MICA I and upper MICA participants, we found no clear difference in what was found to be the most challenging part of the inquiry projects. As for the way they mostly handled challenges, a greater proportion of MICA I participants indicated solely seeking help (38.5% vs. 26.5%), while a greater proportion of upper MICA participants indicated solely working through it on their own (47.1% vs. 30.8%); and a similar proportion of MICA I and upper MICA participants indicated utilizing both strategies. This may suggest that upper MICA students are more comfortable working independently in programming-based mathematics inquiry projects and they may be further along in their instrumental genesis.

There also seems to be no clear difference between what females and males find most challenging about MICA inquiry projects, except maybe for a slightly larger proportion of females pointing to the coding of mathematics (21% vs. 8%). Female and male participants also reported similar strategies for handling their most challenging part, in terms of solely working through it on their own or seeking help, though female students appear to do both slightly more (27% vs. 16%) and male students may be more likely to have no strategy (12% vs 2%).

Discussion

With this paper, we seek to answer Lockwood and Mørken's (2021) call for research by starting to examine the challenges students face when computing (including programming) is integrated in undergraduate math education, specifically in the context of mathematics inquiry.

In our study, student participants indicated in greatest proportion (~3/4) that the most challenging part of their inquiry is related to what we call "the programming cycle," which involves the design and creation of a program for the purposes of the inquiry, including the intertwined processes of translating mathematical processes into algorithms and validating the programmed mathematics. This aligns with work in computing education that has documented the many difficulties and misconceptions that novice programmers may have (Qian & Lehman, 2017): e.g., "their lack of well-established strategies and patterns often leads to various challenges in planning, writing, and debugging programs" (p. 6). The participants in our study pointed to different factors that may be contributing to their "coding (math)" challenge: not only the inadequacy of their current patterns of doing (which we framed in terms of schemes), but also the nature of the process required to develop such patterns (e.g., it takes time; Laborde, 2002). Participants also pointed to the nature of programming as a tool and the mathematics involved in their programming-based mathematics inquiry. It is possible that the "newness" of this experience is underlying participants' responses, in which case we may expect different results in the future if students start learning programming in STEM subjects from a young age (cf. Wiebe et al., 2020). We note, nevertheless, that students gaining fluency in programming need not imply their fluency in using programming to conduct mathematical inquiry (Buteau et al., 2019). Moreover, the latter will always be inherently challenging: "the inquiry process develops as interplay between known and unknown in situations where some individual or group of individuals is *faced with a challenge*" (Artigue & Blomhøj, 2013, p. 798-799, our emphasis).

Work in computing education emphasizes that challenges may inhibit students' ability to learn and make progress (Qian & Lehman, 2017). In contrast, our study found that just because a student finds something "most challenging" does not mean that they struggle: participants described several strategies for handling their challenges, with only a few suggesting that they had no strategy. The high proportion of students indicating that they "seek help" aligns with principles of inquiry-based mathematics education. Laursen and Rasmussen (2019) identify four pillars of such an approach, which highlight the importance of students collaboratively processing mathematical ideas and instructors facilitating students' thinking in equitable manners (e.g., encouraging students to explain their ideas and ask for others' explanations and help). Importantly, this also aligns with how most professional mathematicians do their work: i.e., in cooperation, collaboration, or consultation with one another (e.g., Bass, 2011; Burton, 2004). This said, our study also found that students seem to develop more independent strategies as they progress in the MICA courses. We conjecture that students may be learning when to collaborate and when to work on their own. One limitation of the current study is that we did not distinguish between "seeking help" and "collaboration." Moreover, we only considered how students *mostly* face their *most* challenging part of their inquiry. Looking more into students' interactions with peers, instructors, and other resources could be an interesting direction for future work.

In their call for research, Lockwood and Mørken (2021) mention equity issues as one of four key research foci for the RUME community investigating computing, concluding that a potential downside to integrating computing in undergraduate mathematics is that it could perpetuate inequities in certain populations. Indeed, research in computing education has highlighted the greater challenges typically faced by female undergraduates (e.g., Margolis & Fisher, 2003). The small differences we observed among female and male participants seem to be promising and is consistent with some of our past work (Buteau et al., 2014). It is possible that this is connected to the inquiry approach taken in MICA courses. For instance, Laursen and Rasmussen (2019) indicate that "current studies show that inquiry classrooms can level the playing field for women … and argue why this may occur … but also show that this is not automatic" (p. 138). Looking further into which aspects of the MICA environment may support equitable outcomes could be another pertinent direction for future work.

Overall, our study seems to suggest that the teaching approach in the MICA courses may positively support students in learning to engage in programming-based mathematics inquiry. To think about implications for teaching, we need to examine more closely the teaching that the students actually receive. In particular, there is the question of what instructors can do to best support their students in handling their challenges.

Acknowledgments

This work is funded by the Social Sciences and Humanities Research Council of Canada (#435-2017-0367) and received ethics clearance (REB #17-088). We thank all our research assistants, in particular Nina Krajisnik and Kelsea Balt, for their work on the questionnaire data.

In this naturalistic study, we examine students' learning as they engage in programming for mathematics investigations through a project-based approach. We focus on undergraduate mathematics students' (N=41) engagement in a sequence of 14 programming-based math investigation projects, with data primarily collected through online questionnaires. Results suggest that students learn the most when they engage in projects they are passionate about. Results also provide empirical evidence supporting the effectiveness of a project-based approach by demonstrating the potential richness of students' learning in projects (e.g., learning general ways of doing and succeeding, in addition to specific mathematical knowledge).

Keywords: project-based learning, computing, student learning, mathematics investigation, operational and predicative knowledge

There are different approaches to integrating programming – or more broadly, computing – in undergraduate mathematics education, including: as a required skill (e.g., a computer science course requirement), within specific courses (e.g., modeling, numerical analysis), or through a more integrated approach (e.g., throughout a program or in a sequence of specially-designed courses). For instance, a survey of 46 mathematics departments in the U.K. found that 89% of undergraduate mathematics programs teach programming to all students, most commonly in numerical analysis or statistics (Sangwin & O'Toole, 2017). In comparison, at Manchester Metropolitan University in the U.K. (Lynch, 2020), University of Oslo in Norway (Malthe-Sørenssen et al., 2015), and Carroll College in the United States (Cline et al., 2020), programming is integrated across the undergraduate mathematics curriculum as a learning and/or problem-solving tool. In the Canadian context, Brock University's Department of Mathematics and Statistics has integrated programming since 2001 in a sequence of three specially designed project-based courses called Mathematics Integrated with Computers and Applications (MICA) I, II, and III (Buteau, Muller, & Ralph, 2015).

In a recent "Call for Research that Explores Relationships between Computing and Mathematical Thinking and Activity in RUME," Lockwood and Mørken (2021) suggest that different approaches provide "opportunities for systematically studying different ways for [the] integration [of computing] to occur" (p. 6). They point out, in particular: "there are an increasing number of examples of meaningfully-integrated programs across the world, and *the RUME community can explore what kinds of programs are effective and why*" (ibid., our emphasis). Four potential research foci are identified by the researchers, one of which is teaching. On page 7 of the call, potential research questions are proposed, including (our emphasis):

1. How should computing be introduced and taught in postsecondary mathematics classrooms and how might we design *effective tasks and curricular materials* to integrate computing into postsecondary mathematics classrooms?
2. What are *effective (or ineffective) program, department, and institution-level models* for integrating computing into mathematics classrooms?

The study we present is connected to the above call for research and potential questions.

We focus on the effectiveness of a particular kind of task and program model: those that are situated within or based on projects. There are some studies reporting on the effectiveness of project-based learning (PBL) in post-secondary STEM courses (Ralph, 2015; e.g., in chemistry courses that incorporate the use of computerized models, Barak & Dori, 2005). Nevertheless, a literature review on PBL in K-20 mathematics education (Jacques, 2017) highlights a lack of research and mixed results on the topic, concluding that “we cannot say at this time if PBL is or is not an effective approach” (p. 431).

In our 5-year research, we are interested in examining the effectiveness of teaching and learning environments such as in the MICA courses mentioned above. These courses use a PBL approach, engaging math majors and future math teachers in a sequence of 14 programming-based mathematics investigation projects (see Table 1 in Buteau, Muller, & Ralph, 2015 for examples of the 14 projects). Previous work has reported on the potential effectiveness of this sequence, based on task analyses and reflections from a few students (cf. Buteau et al., 2016). In this paper, we further investigate the (comparative) effectiveness of the MICA projects, as reported by a larger group (N=41) of students, based on their responses to a questionnaire.

Theoretical Framework

The origins of PBL can be traced to first century philosophers such as Aristotle, who believed that humans mainly learn by doing. More recently, theorists connected to the establishment of PBL (e.g., John Dewey) were inspired by an apparent gap between what students learn in school and the skills and attitudes they need to succeed in a constantly changing world. Building on Dewey’s work, Kilpatrick (1921) defined a “project” as any unit of experience dominated by a purpose, which guides its process and drives its attainment. Other researchers have since provided a more elaborated definition, suggesting that projects should: (a) include complex tasks based on challenging questions or problems that involve students in design, problem-solving, decision making, or investigative activities; (b) give students the opportunity to work relatively autonomously over extended periods of time; and (c) culminate in realistic products or presentations (Jones, et al., 1997; Thomas, et al.,1999). Several other defining features of PBL can be found in the literature: e.g., (d) authentic content and assessment; and (e) teacher facilitation but not direction (Moursund, 1999).

The constructionist paradigm (Papert & Harel, 1991) embodies a particular kind of PBL approach in which students consciously and actively engage in constructing (e.g., through programming) tangible and shareable objects. Resnick’s (2014) “4 P’s” – projects, peers, passion, and play – describe some of the key instructional elements that can support an effective constructionist approach. He argues, for instance, that “when people work on projects they care about [i.e., that they are passionate about], they work longer and harder, persist in the face of challenges, and learn more in the process” (ibid., p. 1).

Though not explicitly intended, the MICA courses have been found to be intrinsically constructionist (Buteau, Muller, & Marshall, 2015). Also, the courses align with the features of PBL described above: MICA “projects” involve students in using programming for authentic pure and applied mathematics investigations ((a)/(d)); which are worked on autonomously, that is, facilitated rather than directed by instructors ((b)/(e)); and which culminate in useful computer environments and realistic project reports (c). Recall that the sequence of 14 MICA projects occurs over 3 courses: MICA I (Projects 1-4), MICA II (Projects 5-9), and MICA III (Projects 10-14). It is important to note that the last project in each course differs from the rest in that students can select a topic that interests them (all other projects concern topics that are specified by the instructor of the course). For instance, mathematics majors may decide to construct a program for investigating a problem or an area of research they find interesting; in a similar vein, mathematics teacher candidates may decide to program a “learning object” (Muller et al., 2009), i.e., a step-by-step guided learning of a school math concept, which may be relevant to their future profession (see Brock University, n.d., for some example projects). Inspired by Resnick (2014), we call these end-of-term projects “passion projects.”

In this paper, we look at the “effectiveness” of projects in a PBL approach in terms of “student learning.” Since our work focuses on a certain kind of PBL – where students are learning to use a particular digital tool (a programming language) – we further frame “student learning” using the notion of instrumental genesis (Guin et al., 2005; as described in Buteau et al., 2019). In mathematics education, instrumental genesis has been conceptualized as a complex process involving the intertwinement of learning techniques for using a digital tool and learning specific mathematics concepts (Artigue, 2002). For instance, the second MICA project in the sequence prompts students to implement an RSA algorithm to encode and decode messages. Students typically learn how to use functions and modules in order to program the algorithm, and they also learn the specific mathematics concepts underlying RSA encryption (e.g., modular arithmetic, Euclid’s algorithm for finding the greatest common divisor, finding powers and inverses in Z_n, …). To elaborate further on these two kinds of learning, Vergnaud (2009) offers a conceptualization of knowledge that distinguishes between operational knowledge (which provides means to do and succeed) and predicative knowledge (which consists of means to express ideas in words or symbols). Although both types of knowledge may be involved in PBL, early proponents of the approach seemed to be trying to shift from the focus of math education on predicative knowledge, to also include an appropriate emphasis on operational knowledge.

In light of the above theoretical framework, we pose two research questions:

1. What kind of programming-based math investigation projects are most effective?
2. In what ways are they effective (e.g., what kind of knowledge is learned)?

In this paper, we address these questions from the student’s point of view.

Methodology

The study we present is part of a larger 5-year (2017-22) iterative design research focusing on the learning and teaching of programming for authentic pure and applied math investigations. This is a naturalistic research contextualized in the MICA courses, which are semester-long mathematics courses including 2-hour lectures and 2-hour labs each week. Part of the research closely follows some MICA students over the MICA I, II, and III courses, using individual semi-structured interviews related to their engagement in each of the 14 programming-based mathematics projects (P1, …, P14), as well as their lab reflections and project reports. To complement this in-depth study of individual students’ learning, in each MICA course students are invited to voluntarily participate in pre and post anonymous[1] questionnaires.

The questionnaire data has been collected so far in Years 2-4 of the research. Questions in the pre-questionnaire differ from those in the post- since the latter invites students to reflect on their learning during the course. The questionnaires feature several sections, such as participants’ demographics and participants’ perceptions of: the importance/usefulness of digital technology (including programming), their own knowledge/confidence level in programming, what it means to learn/do math, and the course (the assignments, the teaching, and their learning).

[1] Students who participate in the in-depth study are not anonymous.

This paper focuses on a post-questionnaire question that contains two parts. In the first part, participants are asked to indicate which project they learned the most from, from all the projects in the MICA courses they had taken (for instance, a MICA II participant could select one project from either MICA I or II, i.e., from among P1 to P9). In the second part, participants are then asked to select a reason for the project they chose. Options are provided and participants can choose more than one option if they wish. The possible options are: (a) I learned a lot of new math; (b) I learned a real-world math application that really speaks to me; (c) I completed it all by myself without help; (d) It was challenging but I finally understood it; (e) I had to use new programming concepts or skills; (f) I discovered something I did not expect; and (g) Other.

41 students responded to the above question (24 from MICA I, 5 from MICA II, 12 from MICA III), which is not necessarily representative of the entire MICA student population (a limitation of our study). Responses were analysed using comparative bar charts and frequency tables. The first part of the questionnaire question was key to answering our first research question: When a participant indicated the project they learned the most from, we interpreted this as the "most effective" project from that participant's point of view, and we reflected on the kinds of projects that were selected. This reflection was further supported by the second part of the questionnaire question (students' reasons for their selected project), which was also key to answering our second research question (concerning the ways in which the projects are effective). As part of our analysis, we regrouped the above reasons into two categories based on whether they were indicative of learning predicative or operational knowledge (as defined in our Theoretical Framework). In the predicative knowledge category, we include (a), (b), and (f), which we see as reflecting project-specific learning of math concepts. In the operational knowledge category, we include (c), (d), and (e), which we see as reflecting learning of more general ways of doing and succeeding in using programming for math investigation. We note that each of the "Other" responses were reviewed to determine if they could be categorized as any of (a)-(f) (in which case they were recategorized and frequencies were adjusted accordingly).

Results and Discussion

We organize our results and discussion according to our two research questions.

The Most Effective Projects

Table 1 shows which programming-based mathematics investigation projects from among the sequence of 14 that participants selected as the ones they learned the most from. Note that we distinguish what we called "passion projects" with the notation "PP."

Table 1. The projects participants said they learned the most from.

Course	P1	P2	P3	PP4	P5	P6	P7	P8	PP9	P10	P11	P12	P13	PP14
MICA I	1	10	5	8	-	-	-	-	-	-	-	-	-	-
MICA II	0	0	0	1	0	0	0	1	3	-	-	-	-	-
MICA III	0	1	0	2	0	0	0	1	2	0	1	0	1	4
Total	**1**	**11**	**5**	**11**	**0**	**0**	**0**	**2**	**5**	**0**	**1**	**0**	**1**	**4**

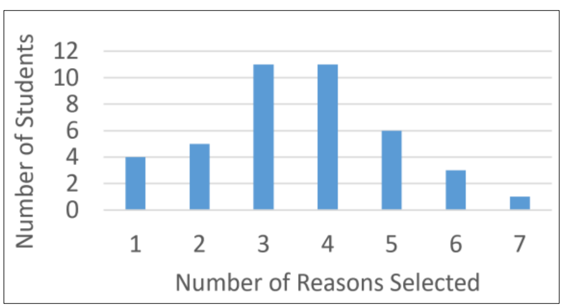
We observe that students selected a variety of projects. Some concern pure mathematics (P1: conjectures about primes or hailstone sequences, P3: a discrete dynamical system, or P11: simulations related to Bertrand's paradox), while others concern applied mathematics (P2: RSA encryption, P8: battle simulations, or P13: randomness of DNA sequences). Some have a higher ceiling in terms of potential for discovery and investigation (e.g., P1, where students are invited to choose or formulate a mathematical conjecture to explore, vs. P2, where students apply the RSA method to encrypt and decrypt messages). Some projects also differ in the degree to which they are scaffolded by instructors (e.g., P2, where students are guided through some steps to construct their program, vs. PPs, where students must determine the design and use of their programs). Finally, the projects chosen by participants show up at different moments in the sequence (e.g., a MICA III participant selected P2, which occurs towards the beginning of the sequence; another selected P13, which occurs towards the end).

Among the projects that were selected, nearly half (20/41) were PPs, in which students choose the topic of their investigations. This provides empirical evidence in support of certain constructionist claims: e.g., that students learn best when they are working on projects that are meaningful to them (Papert, 1980), i.e., on topics that they are passionate about (Resnick, 2014). We also note that about half of the participants who selected PPs indicated their passion project from MICA I, evidencing the low-floor-high-ceiling affordance of programming for mathematics learning (Gadanidis, 2017): already in their first year, with minimal programming background, these students said that they engaged in meaningful learning in such a project.

When looking at MICA I participants only, P2 was the most selected (41.7%), even over the MICA I final project (PP4; 33.3%). At first, this seems to be a rather surprising result, for example, due to P2's lower ceiling in terms of potential for discovery and investigation (Buteau et al., 2018), especially when compared to PPs. We discuss this result more in the next section.

The Ways in Which the Projects are Effective

In selecting the reasons for the project they learned the most from, participants had the option to select more than one reason. Figure 1 shows the number of reasons selected by participants (left) and the percentage of participants who selected the different possible reasons (right).



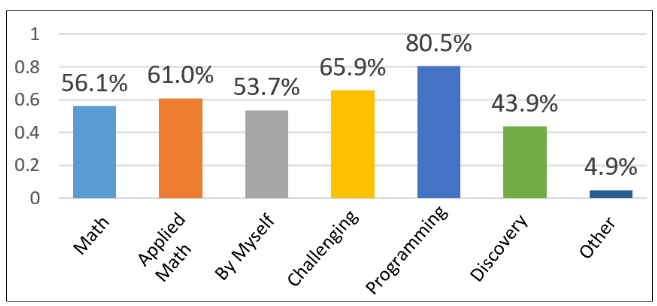


Figure 1. Number of reasons selected (left) and percentages of participants (N=41) selecting each reason (right).

A high percentage of participants (78%) selected at least 3 reasons. This highlights the richness of the students' learning experiences in their chosen projects.

"I had to use new programming concepts or skills" was selected by the highest percentage of students (80.5%). This shows that as students engage in these projects, they typically encounter avenues where in addition to applying their prior knowledge in programming, they also have to use new knowledge to create their program and complete their projects. Further, as seen in Figure 1 (right), at least half of participants selected that they persevered in the face of challenges (65.9%), learned a real-world math application that spoke to them (61.0%), learned lots of new math (56.1%), or completed the projects by themselves without help (53.7%). Also, close to half (43.9%) said they discovered something they did not expect. We argue that the prevalence of these different reasons, as well as the selection of multiple reasons mentioned above, provides evidence in support of the effectiveness of a PBL approach.

Only 2 students (4.9%) gave "Other" reasons for why they benefitted the most from the projects they chose (both of which were PPs). One student said, in addition to (a), (b), and (d): "I was paired with a cool partner and we worked well together." The other, who had designed and programmed a learning object, said, in addition to (c) and (e): "How to create a lesson plan which incorporates programming to teach mathematics to grade 9 students." These responses are linked to two characteristics of effective constructionist learning, as highlighted by Resnick (2014): the former to "peers" and the latter to "passion." It is notable that these two participants felt the need to specify these additional reasons for the effectiveness of their chosen projects.

As mentioned above, PPs and P2 were the most commonly selected projects by the participants. Participants' reasons for selecting these are depicted in Figure 2.

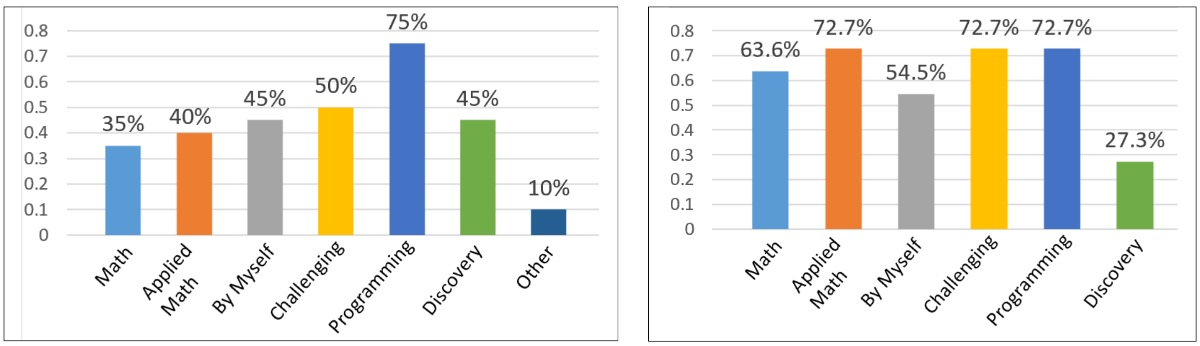

Figure 2. Percentages of participants who selected each reason for PPs (left; N=20) and P2 (right; N=11).

When just looking at PPs (Figure 2, left), we note that only two responses were selected by at least 50% of participants: "I had to use new programming concepts and skills" (75%) and "It was challenging but I finally understood it" (50%). In the case of PPs, students select their mathematics topic, which can naturally lead to new demanding needs in terms of the programming (as opposed to just using the programming learned during prior MICA projects). These results suggest that students' learning experiences in PPs may be more pointed.

In comparison, 5 reasons were selected by at least 50% of participants who chose P2, suggesting that P2 provides an opportunity for students to experience multiple facets of learning. This is likely linked to the position of P2 in the sequence of 14 MICA projects. For most students, P2 is the first project where they must program a more elaborate mathematical process, in addition to using new programming concepts and skills. This represents a steep learning curve for students: overcoming it, possibly almost all by themselves, would constitute a major accomplishment. The fact that students indicate learning a real-world application that speaks to them is not surprising: P2 concerns RSA encryption, a topic that relates to the digital world in which the students live. Interestingly, the other reason ("I discovered something I did not expect") was selected by less than 30% of participants, which seems to indicate that the low ceiling for discovery in P2 (as speculated in Buteau et al., 2018) is reflected in students' perceptions. We also point out that students coming from high school may not be used to investigating conjectures: therefore, after a more unsettling experience with P1, students may feel more comfortable with a more directed project like P2, where they can follow instructions and easily see the progress of their engagement. Anecdotally speaking, we have heard many other students state that P2 was a particularly memorable project.

Operational and predicative knowledge. In this subsection, we report on the kind of knowledge students indicated they learned in their chosen projects, based on our regrouping of reasons discussed in the Methodology. Table 2 summarizes the results.

Table 2. The kind of knowledge students learned in their chosen projects.

Projects	Operational & Predicative	Only Operational	Only Predicative
All	30	8	3
PP	13	5	2
P2	9	2	0

It appears that over 70% of participants learned both operational and predicative knowledge in the project they learned the most from. This reflects the different kinds of knowledge required in using programming for mathematics like mathematicians do (Broley, 2015). Also, over 90% of participants indicated learning operational knowledge. This aligns with proponents of PBL (e.g., Kilpatrick, 1921), who talk about the approach as an attempt to engage students in learning the general processes and attitudes involved in (mathematical) problem solving, in addition to learning specific (math) content. One could wonder about the 7.3% of participants who indicated learning solely predicative knowledge in the project they learned the most from. We note that these three participants were future math teachers. Two selected PPs, which could have been a learning object connected to their future career. If they did it in pairs, it is possible that the participant did not lead the coding of the object, and thus did not feel as though they gained operational knowledge.

Results for P2 in Table 2 align with the above results. In comparison, Table 2 offers a different perspective on the richness of learning experiences in PPs. Despite only a few reasons being identified by high percentages of participants (Figure 1), Table 2 suggests that many (65%) gained both operational and predicative knowledge.

Conclusion

In this paper, we answered Lockwood and Mørken's (2021) call for research by exploring the effectiveness of one approach to integrating computing in undergraduate mathematics: namely, PBL, as defined by general work in education (e.g., Jones, et al., 1997; Moursund, 1999; Thomas, et al.,1999) and the constructionist paradigm (e.g., Papert, 1980; Resnick, 2014). One main contribution of our study is that it addresses the gap of empirical evidence related to the effectiveness of such an approach (e.g., reporting on the different kinds of learning that may occur in programming-based mathematics investigation projects).

Our study was based on student (N=41) responses to an online questionnaire and was exploratory in nature. The theoretical framework and results inspire us to refine our questionnaire: in particular, to rework the reasons that students can choose to explain the project they learned the most from. There seem to be some reasons that could be revised (e.g., 'I learned a real-world math application that really spoke to me' could be divided into 'I learned a real-world math application' and 'I learned something that really spoke to me'). There also seems to be other reasons that are important to include (e.g., 'I worked with others'). As part of our larger 5-year research, we also have interview data, which could support us in digging deeper into the effectiveness of these projects and the types of learning that are involved (e.g., the more pointed yet significant learning that may be happening in passion projects, the rich learning in P2, or the combined learning of operational and predicative knowledge across the project sequence).

Formative Assessment in a Gateway Quantitative Reasoning Course

Deependra Budhathoki
Ohio University

Gregory D. Foley
Ohio University

Quantitative reasoning is an individual's ability to understand quantitative information in context, represent and model such information, solve real-world problems using mathematical and statistical knowledge, and communicate ideas using quantitative arguments. Using formative assessment practices in a QR course allows students to develop their QR competencies and demonstrate their learning. In this study, we explored whether and to what extent Quantitative Reasoning instructors implement formative assessment and examined their experiences and perceptions of using formative assessment. Herein we report on the formative assessment practices of six instructors who taught Quantitative Reasoning courses at public universities and public community colleges in Ohio during spring 2020. We analyzed the instructor's course syllabus and conducted a semistructured interview with each instructor. The results show that the instructors exhibited various formative assessment practices with a wide range of weights.

Keywords: Quantitative reasoning, formative assessment, projects, student presentations, feedback.

Quantitative reasoning (QR) is an individual's ability to understand and use numbers in context. It is associated with a person's critical understanding of quantitative information and sense-making in context (Elrod, 2014; Meyer & Dwyer, 2005; Wilder, 2012). Central to QR is the ability to think deeply and critically about real-world phenomena and link them to relevant mathematics and statistics, as suggested by Figure 1 (Foley & Wachira, 2021).

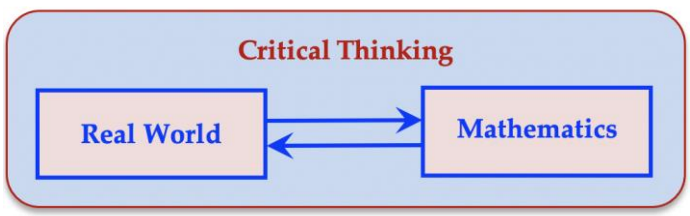

Figure 1. A model of student engagement in Quantitative Reasoning.

An introductory postsecondary (i.e., gateway) QR course aims to prepare students to solve problems in everyday and professional contexts. It includes some nontraditional mathematical goals, like thinking critically about quantitative information and contexts, collaborating with peers to solve real-world problems, and communicating orally and in writing using quantitative arguments (Mathematical Association of America [MAA], 1996; Stump, 2017). Policy documents and professional opinions suggest that instructors should use teaching and assessment approaches that support students to build QR competencies such as interpretation, representation, calculation, analysis/synthesis, assumptions, and communication (American Association of Colleges and Universities [AAC&U], 2009; Boersma et al., 2011).

Assessment in a mathematics course has no value if it does not measure appropriate goals (Steen, 1997). Lutsky (2008) and the MAA (1996) recommend that QR assessments include projects involving real-world tasks and student presentations; these assessments provide opportunities for students to solve problems and construct associated knowledge and skills. Learning via such assessments can provide constructivist and collaborative opportunities for students, with which they can lead themselves and their peers toward academic and non-academic success (Harwood, 2018; Thomas, 2000; Virtue & Hinnant-Crawford, 2019). Unlike traditional assessments—such as quizzes, tests, and exams—these recommended assessment strategies for QR may provide valid measures of the desired QR student learning outcomes of interpretation, representation, calculation, analysis/synthesis, assumptions, and communication.

However, a problem exists in that not all instructors of gateway mathematics are familiar with the sort of recommended assessments that use authentic situations and tasks to measure students' QR skills. Many instructors are still unclear about the most appropriate practices for assessing students' learning in a QR course (Wallace et al., 2009). Most of the assessments used to measure students' QR skills are traditional summative examinations or even multiple-choice tests administered on a computer (Boersma et al., 2011; Roohr et al., 2014). However, such practices do not match the suggestions for periodic and continuous assessments and feedback practices aligned to the desired student learning outcomes, suggested by the National Research Council (NRC, 2001) and Tunstall (2019). Thus, a major challenge in implementing gateway QR courses is aligning learning goals and assessments (Bae et al., 2019; Shavelson, 2008).

Compared to course development and instruction, fewer research studies and policy documents discuss the assessment of students' learning in a QR course (Madison, 2014; Sikorskii et al., 2011; Wright & Howard, 2015). Existing research publications that discuss assessment practices in such a course mainly focus on ensuring the reliability and validity of tests (Boersma et al., 2011; Taylor, 2009). Ward et al. (2011) found that (a) QR assessment practices vary widely across the institutions, (b) the majority of QR assessment initiatives were conducted at small universities and colleges, and (c) midsize and large universities generally lacked such empirical research on assessment of gateway QR courses.

Formative Assessment

Formative assessment is the diagnostic use of assessment during ongoing instruction (Boston, 2002). A key aspect of such assessment is timely feedback to instructors and students about their current practices to make immediate changes to improve student learning. Formative assessment is something instructors do *with* and *for* students to advance student learning (Heritage, 2010). Moreover, it *informs* instructors about the effectiveness of their current practices to use this information as needed to support student learning (Black et al., 2003; Ogange et al., 2018). Spector et al. (2016) explained that a formative assessment emphasizes *forming* judgments about students' progress, affecting the subsequent flow of instruction and learning. The NRC (2001) described a subsequent modification of teaching to promote student learning as the purpose for any formative assessment. Therefore, improved instructor and student practices are the chief aims of a formative assessment (Spiller, 2009).

Formative assessment is a lever for a paradigm shift in pedagogical practices and the effective delivery of instruction (Ogange et al., 2018). In addition to promoting student learning, it promotes democratic practices by valuing student thinking, putting forward their ideas, and challenging others' reasoning. Therefore, it is one of the effective methods of encouraging student engagement and achievement (Spector et al., 2016).

After their extensive research project, Black et al. (2003) reported four central formative assessment practices: *questioning, feedback, formative use of summative tests,* and *peer- and assessment by students*. Questioning is a process in which instructors pose questions to an individual student or a group of students, listen to their responses, and continue by either providing appropriate feedback or probing follow-up questions. Feedback consists of information about students' current levels of achievement and suggestions for improvement.

Formative use of summative tests can take several forms, including the use of student responses on tests to change instruction in the subsequent unit. Peer- and self-assessment are the practices in which students assess their peers and their own learning to determine whether the learning aligns with the course goals and develop reflective understanding; these practices give students the power to evaluate self and others' knowledge, make appropriate decisions, and enhance individual and interpersonal learning (Noonan & Duncan, 2005).

Formative Assessment and QR Learning

It is difficult to assess the QR competencies of interpretation, representation, calculation, analysis/synthesis, assumptions, and communication using only traditional summative quizzes, tests, and exams. Moreover, these high-level skills are new to most college freshmen, and they need support and feedback to develop these QR competencies. Hence, formative assessment is a natural fit for a gateway QR course. Sundre (2003) stresses linking and implementing QR assessment and instruction simultaneously, explaining that such practices enhance QR teaching quality. Moreover, Shavelson (2008), Spector et al. (2016), and Wilder (2012) suggest using formative approaches such as regular and periodic assessment accompanied by detailed feedback to enhance student engagement in QR activities and their consequent achievement. In addition, such practices improve the instructor's choice of learning activities. Reflecting on the information obtained through such assessments, QR instructors can determine students' needs and attitudes in time to make the necessary adjustments to provide learning experiences for students that address course goals (MAA, 1996).

Students' collaboration and communication are common characteristics of QR learning and formative assessment. Consistent with QR student learning outcomes, several formative assessment practices, like peer-and self-assessment, require students to work together to solve real-world tasks and develop abilities to work together as they need in their everyday life. In addition, such formative practices even involve students sharing their thinking and ideas in oral and written forms, arguing with evaluative arguments, and providing appropriate feedback to improve their mutual learning. Also, a formative assessment constitutes frequent dialogues between instructors and students and among students, which can help teachers and students articulate the course goals, address issues related to measuring students' communication skills, and reduce other challenges they face during QR assessment (Boersma et al., 2011). Moreover, formative assessment practices influence students' beliefs and motivations toward understanding and building their explaining, interpreting, and reasoning (MAA, 2018; Spector et al., 2016).

The purpose of this study was to explore instructors' preparedness and practices of using formative assessment in undergraduate-level Quantitative Reasoning courses. We examined the instructors' preparedness before they started teaching QR for the first time and their preparation before each class. Similarly, we explored their formative assessment practices by collecting and analyzing data about the nature, types, and frequencies of assessments and how they use such assignments to improve student learning. The findings of this study will be significant to novice and experienced instructors in planning, contextualizing, and implementing formative assessment in their QR teaching and enriching their student learning. Also, these results contribute to narrowing the research gap in the field with the ability to be transferable to other mathematics courses of equivalent level and in similar settings.

Data Collection

We employed a multiple case study design in this investigation. We defined our cases as the instructors who taught at least a QR course in the public community colleges and universities and their regional campuses in Ohio during the Spring of 2020. Then we employed purposeful selection to recruit 6 QR instructors (3 male and 3 female) teaching at least one section of QR at two public universities and three public community colleges in Ohio (2 participants taught at the same community college). Among the 6 instructors, 5 instructors taught the Ohio Department of Higher Education (ODHE) (2015) approved QR course that their QR course was transferable across other institutions in Ohio. The instructors had a wide range of experience teaching undergraduate-level mathematics between 9 and 30 years. Their experiences in QR ranged between one semester and three years. Also, one instructor worked as a QR coordinator at her institution during data collection, while another instructor had experience developing a QR course in his past institution.

The first author (Budhathoki) collected data by analyzing QR course syllabi and conducting semistructured qualitative virtual interviews with the instructors. In advance of each interview, he studied the instructor's course syllabus to explore their plans to implement the project(s) during the semester, know the weights provided to such project(s) to determine student grades, and prepare a guide for the interview. He used the findings of the syllabus analysis to supplement as well as to triangulate the assessment practices shared by the instructors. The interviews with the instructors focused on investigating the instructors' rationales for choosing their assessments and the ways they implement the assessments. Budhathoki even focused on confirming whether and to what extent the instructor implemented assessments differently than stated in the syllabus.

We employed the cross-case analysis to examine themes to explore commonalities and differences in the instructors' actions, activities, and processes assessment implementation (Cruzes et al., 2015; Stake, 2006). For this, we first analyzed each instructor's project practices separately and then organized their assessment practices into six categories: (a) student projects and oral presentations; (b) attendance, participation, and student collaboration; (c) homework and other written assignments; (d) quizzes and in-class assignments; (e) periodic tests and exams; and (f) final exam. Among these six categories, we considered the first two categories of assessments—projects and oral presentations; and attendance, participation, and collaboration—to be innovative practices as these assessments are not typical to an undergraduate-level mathematics course. For this, we relied on the fact that instructors mostly use quizzes, tests, and exams in other similar-level mathematics courses. We grouped the last four categories—homework and written assignments, quizzes and in-class assignments, periodic tests, and final exams—to be traditional approaches to assessing student learning. These assessments have been typical in undergraduate mathematics courses in the United States for many decades. Then, we categorized the instructors into two groups: (a) Group A consisted of the instructors who provided more than 40% weights to innovative assessments, and (b) Group B consisted of the instructors who provided lesser weights to innovative assessments. Then, we sought *literal replication* by comparing formative assessment implementation of the instructors of the same group and *theoretical replication* by comparing that of instructors across the groups (Yin, 2018).

Findings and Discussion

We discovered a great deal of variation across the instructors' approaches to assessing student learning and assigning grades. On average, the instructors gave 32.3% of the student grades through these two innovative types of assessments and set 67.6% of the student course grade the traditional these types of evaluations. Table 1 shows the frequency and average weights of different categories of assessments used by the instructors.

Table 1. Assessment Frequency & Weights Used by All 6 Instructors

Assessment Categories	Number of Instructors	Number per Category	Weight Range	Average Weight
Projects & oral presentations	6	1–3	4–45%	19.8%
Attendance, participation, & collaboration	6	N/A	5–20%	12.5%
Homework & written assignments	6	4–10	10–20%	17.3%
Quizzes & in-class assignments	4	2–10	7–30%	10.3%
Periodic tests	4	2–3	30–60%	26.7%
Final exam	4	1	10–25%	13.3%

Similarly, Table 2 shows each instructor's weights to each assessment category. Four (3males, 1 female) among the 6 instructors relied on traditional approaches to determine student learning and assign grades. These 4 instructors assigned 70–85% of student grades, with an average of 77.75%, through traditional assessments, mainly periodic tests, and final exams. On average, they assigned more than half of the student grades, 56.2%, through these assessment categories. Despite the prominent callouts for enhancing and assessing QR students' learning by allowing them to work on authentic projects to solve real-world problems using their mathematics and statistics knowledge, the four instructors slightly emphasized projects and students' oral presentations. Each instructor just employed one project during the semester, and on average, they assigned only 8.5% student grades through projects and oral presentations. It seems like these 4 instructors included projects as their assessment to meet the ODHE (2015) requirements. These instructors argued that students do not have enough confidence in math to do projects and make presentations. Only 1 of these 4 instructors had student presentations as part of their projects. They gave reasons for that, including time consumption and students' readiness. Instructor 1 explained his reason for not having student presentations by saying, "my students' confidence level in terms of their perception of their level and ability in mathematics is very low. And then, you compound public speaking on top of it, which is again something they don't feel very confident about."

Table 2. Weights to Various Assessment Categories Provided by All 6 Instructors

Assessment Categories	Instructors					
	1	2	3	4	5	6
Projects & oral presentations	10%	10%	10%	4%	45%	40%
Attendance, participation, & collaboration	15%	20%	5%	15%	15%	5%
Homework & written assignments	20%	20%	18%	16%	20%	10%
Quizzes & in-class assignments	5%	0%	7%	0%	20%	30%
Periodic tests	30%	30%	60%	40%	0%	0%
Final exam	20%	20%	0%	25%	0%	15%

On the contrary, the other 2 instructors (both female) substantially employed innovative assessments to measure student learning and assign grades. In Table 2, we have represented these 2 instructors as Instructor 5 and Instructor 6, who allocated 52.5% of student grades through innovative assessments. Both the instructors emphasized their projects and oral presentations among their assessment categories. Both of these 2 instructors employed three projects during the spring of 2020 to assign 40–45% student grades. After projects and oral presentations, both of these instructors gave more weight to quizzes and in-class assignments, which they employed almost every weekend to collect information about student learning. These instructors used the information from their quizzes and in-class assignments to make instructional decisions about whether they needed to discuss the concept further, clarify students' misconceptions, and rediscuss the significant ideas. For example, Instructor 6 explained the purpose of her chapter quizzes, "see how they understand the material in general." She also further explained that it is her chapter quizzes from where she gets information about student knowledge and provides feedback after then. Likewise, Instructor 5 mentioned that she used her quizzes and in-class assignments to check if the students had understood the content and, if not, rediscuss the material. She said, "If there are lots of questions or people having trouble with a certain idea, stopping and saying, let's clarify what the issue is and how can we fix it." She also mentioned reteaching and reevaluating if found. On average, they assigned 25% of student grades through quizzes and in-class assignments, which contributed to 25% of students' grades on average.

There was also a great deal of variation among the instructors' approaches to assess student learning and assign grades. Specifically, there were variations between the assessments employed by the instructors of the two different groups. The six instructors had three out of six assessment categories in common. However, for the discussion and analysis, we collapsed the last three assessment categories used above—(d) quizzes and in-class assignments; (e) periodic tests; and (f) the final exam—into the single category (d) quizzes, tests, and final exam in Figure 2. That resulted in two categories in both the traditional group and the innovative group of assessments. Figure 2 shows the comparison of average weights that the instructors from the two groups assigned to different categories.

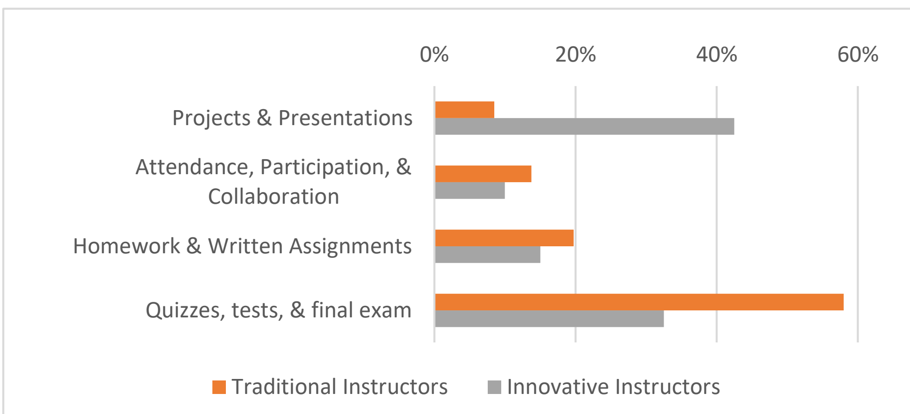

Figure 2. Comparison of Average Weights Assigned by Traditional and Innovative Instructors to Different Categories of Assessments'

The 6 instructors had varying practices of and perceptions about giving feedback to students. Though all 6 instructors claimed to provide feedback on student work, they primarily relied on written feedback indicating mistakes in student work, suggesting alternative ideas, and sometimes writing positive remarks for outstanding jobs. Even some instructors in the traditional group claimed that they provided feedback by posting solutions of homework and tests in their learning management system. All 6 instructors did not systematically practice giving oral feedback on student work. Nevertheless, the 2 instructors in the innovative give mentioned giving oral comments after student presentations but admitted that they still need to work much on their oral feedback practices. Also, only the 2 instructors in the innovative group and 1 instructor in the traditional group had some basic peer-assessment activities. All 6 instructors undermined the learning opportunities that students can get by evaluating their and peers' work. In addition, only the instructors in the innovative group let students redo their work by incorporating instructors' feedback. Likewise, only two instructors in the innovative group believed that providing feedback and allowing students to improve their work after receiving feedback helped students improve their performance and enhance their understanding. However, one of the instructors from the traditional group argued that feedback was helpful only for some students and only during some early weeks of the semester. Similarly, the instructors did not have similar perceptions about giving feedback.

The instructors had variations within the categories that were common to them. In Table 2, it is evident that they had only three common categories: (a) projects and oral presentations and (b) attendance, participation, and collaboration. They varied mainly in their frequency of a particular category, nature of student engagement, and afterward activities. For example, despite the project being common, some instructors required students to collect data and solve real-world situations. In contrast, some other instructors made students solve the worksheet's problems. Such variations remained both across and within the traditional assessment group and innovative assessment group. Variations in the implementation provided different learning opportunities for their students.

Conclusion

This study concluded that the instructors had a lot of variation in their categories of assessments and the ways they implemented their assessments. Though all six instructors had two innovative assessments in common—(a) projects and presentations and (b) attendance, participation, and collaboration—the variations in their implementations provided varying learning opportunities to students. Seeing altogether, the instructors primarily relied on traditional assessments such as homework, quizzes, and exams, with 67.6% of the weight going to these assessments to determine student grades.

Not all instructors implement their assessments to identify student learning gaps, improve their instructional practices, and provide support to enhance student learning. Despite loud callouts for student collaboration and communication in a QR course, the instructors did not orchestrate adequate opportunities for students to learn by working together and sharing ideas. Likewise, lacking communicative options limited students to develop evaluative arguments using quantitative information critical thinking. Providing students with oral feedback is valuable and powerful (Michael-Chrysanthou & Gagatsis, 2014). However, not all instructors had positive perceptions about giving feedback and giving opportunities for students to redo their work by incorporating instructor feedback.

Instructors' practices were imbalanced regarding student attendance, participation, and collaboration assessment. All six instructors used this category, but surprisingly the instructors in the traditional group provided more weight to this category than their counterparts in the innovative group. However, none of the six instructors had clear rubrics to assess these student learning attributes, and they primarily relied on their subjective evaluation.

Suggestions for Future Research

This study was conducted over a short period, including a reasonably small number of instructors. Plus, the instructor represented only a few higher education institutions. Thus, we strongly emphasize some future studies in this issue, including more instructors representing other institutions, and collecting data through other means, such as class observations. Reports from such a study may help policymakers and novice and experienced QR instructors successfully implement projects to develop students' QR competencies and support students for their academic and non-academic successes.

Comparing STEM Majors, Practicing and Prospective Secondary Teachers' Feedback on Mathematical Arguments: Towards Validating MKT-Proof

Rebecca Butler
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Sharon McCrone
University of New Hampshire

Mathematical Knowledge for Teaching Proof (MKT-P) has been recognized as an important component of fostering student engagement with mathematical reasoning and proof. This study is one component of a larger study aimed at exploring the nature of MKT-P. The present study examines qualitative differences in feedback given by STEM majors, in-service and pre-service secondary mathematics teachers on hypothetical students' arguments. The results explicate key distinctions in the feedback provided by these groups, indicating that this is a learnable skill. Feedback is cast as a component of MKT-P, making the results of this study significant empirical support for the construct of MKT-P as a type of knowledge that is unique to teachers.

Keywords: Secondary Teachers, Mathematical Knowledge for Teaching Proof, Feedback

Calls for students to experience deeper engagement with mathematical proof and reasoning across a variety of levels have been long standing (Nardi & Knuth, 2017; NGA & CCSSO, 2010; NCTM, 2009, 2014; Stylianides, Stylianides, & Weber, 2017). In order for this aim to be realized, mathematics teachers must be equipped with a substantial knowledge, both subject matter and pedagogical. The present study is part of a larger, NSF-funded research project, which studied how Mathematical Knowledge for Teaching Proof (MKT-P) of prospective secondary teachers (PSTs) evolves as a result of participating in a specially designed capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020). The course design and the assessment instruments draw on the MKT-P theoretical framework proposed by Buchbinder & McCrone (2020), which we describe below. At the same time, the project seeks to understand the nature of (MKT-P) empirically; specifically, whether this knowledge is unique to teachers and if it is learnable. To explore these questions, we compared the performance of STEM majors, in-service teachers, and prospective secondary teachers on an instrument designed to assess MKT-P (Buchbinder & McCrone, 2021). This examination of groups with distinct mathematical and pedagogical backgrounds aims to draw out the ways in which MKT-P is unique to teachers. Distinctions in performance of the practicing teachers with respect to individuals with little teaching experience or extensive theoretical knowledge of teaching, but strong knowledge of proof-specific subject matter, could reveal the components of MKT-P, which are unique to teachers (Krauss, Baumert, & Blum, 2008).

The study reported herein analyzes a particular aspect of the MKT-P - the ability to provide instructional feedback on student mathematical work. A set of items on the MKT-P instrument asked participants to provide hypothetical students with feedback on their mathematical arguments. This feedback was quantitively assessed in the larger study through a coding scheme concerned with correctness and mathematical richness of responses (Buchbinder, McCrone & Capozzoli, Butler, in preparation). As we coded these responses, we noticed significant qualitative differences between the feedback provided by the three groups, which could not be captured by the existing scheme. The current study provides in-depth exploration of the differences that caught our attention in the larger study. The research questions are:

1) How does the feedback to a hypothetical student on mathematical arguments compare across three groups of participants: practicing teachers, STEM majors, and PSTs.

2) How does the feedback of PSTs change before and after participation in the capstone course?

Background and Literature Review

In this study, providing feedback on students' arguments is taken as one practice specific to Mathematical Knowledge for Teaching Proof (MKT-P). Inspired by research on the notion of MKT-P (e.g., Corleis, Schwarz, Kaiser, & Leung, 2008; Lessig, 2016; Lin et al., 2011; Steele & Rogers 2012; Stylianides 2011), Buchbinder and McCrone (2020) proposed an MKT-P framework, which consist of three domains: knowledge of the logical aspects of proof (KLAP), knowledge of content and students (KCS-P), and knowledge of content and teaching (KCT-P). KLAP encompasses subject matter knowledge related to the mathematical content of proof, such as knowledge of definitions, proof types, and proof validity. KCS-P describes knowledge about student perceptions of various proof related concepts including knowledge of common difficulties or misconceptions. KCT-P is knowledge of pedagogical praxis specific to facilitating student engagement with reasoning and proof and encompasses such skills as design of classroom activities, the making of instructional moves, and the ability to provide students with productive feedback on their proof related activities.

Feedback is commonly described as "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding" (Hattie & Timperley, 2007, p.81). Extensive research across populations and disciplines has explored the ways in which various characteristics of feedback are related to student achievement (e.g., length, timing, positive or negative nature, and format) (Shute, 2008). Recent work in mathematics education builds on these established relationships between feedback and student learning by focusing on feedback as a teaching practice.

Kastberg et al. (2016) found that mathematics PSTs tend to center their feedback on the performance of the task, processes involved in completing the task, and personal evaluations with more attention to correct than incorrect responses. This finding is echoed by Crespo (2002) who found that PSTs tended to focus their feedback on the process and correctness of student responses, with PSTs supplying students with correct solutions in the case of incorrect responses and issuing praise in the case of correct responses. Over the course of a mathematics methods course, Crespo (2002) found that PSTs shifted the focus of their praise toward the process students used to obtain their answers and shifted the focus of their critiques toward probing student processes via questions and offering guidance toward correct solutions. These shifts are also evidenced by Santos & Pinto (2010) who tracked the changes in written feedback given to secondary students by a single teacher over the first two years of her teaching. They found that the focus of her feedback shifted away from the task and toward the student, errors were corrected less often, symbolic feedback was given less often, the nature shifted from stating facts toward leading clues, and length of feedback increased. Bleiler et. al. (2014) analyzed feedback given by PSTs on sample student proof strategies, finding that PSTs tend to critique student work for use of specific cases over general mathematical representations. Overall, the literature indicates that feedback is a practice which teachers develop over time with this development centered on shifts from product to process and from telling to guiding. This supports our assumption that providing feedback on student mathematical arguments is a particular task of teaching specific to classroom situations involving reasoning and proof; in other words, an element of MKT-P. Comparing feedback across groups with comparable mathematical knowledge but different pedagogical background can provide empirical support for this assumption and illuminate the nature of MKT-P.

Methods

Participants and the Study Setting

Three groups of participants were involved in this study; 17 in-service secondary mathematics teachers, 22 university STEM students, and nine PSTs involved in the capstone course *Mathematical Reasoning and Proof for Secondary Teachers*. The in-service mathematics teachers (11 female and 6 male) had teaching experience ranging between 2 to 25 years ($\bar{x}$ = 12.18, *SD* = 8.26). The teachers were recruited via presentations given at departmental meetings and were compensated for their participation with a $35 ex gratia payment.

The STEM majors and PSTs came from the same 4-year university. The STEM students, mostly computer science and mathematics, second year majors, were enrolled in a mandatory mathematical proof course. The course instructors reviewed the MKT-P questionnaire and confirmed that the students should have all the relevant proof knowledge included in it. The students who volunteered to participate in the study received a small extra credit in the course.

All but one of the PSTs enrolled in the capstone course were in their final year of their secondary mathematics education program, so they had completed the majority of their mathematical coursework, including the same Mathematical Proof course as the STEM majors, as well as two courses specific to mathematics pedagogy. While these latter courses did require some classroom observations, the participants had no personal experience with teaching.

The capstone course (taught by the second author of this paper) intended to enhance PSTs' MKT-P by helping the PSTs to connect their university-level knowledge of mathematical reasoning and proof with secondary school teaching (Buchbinder, McCrone, 2018; 2020). The course was comprised of four modules, each devoted to a particular proof theme: (1) direct proof and argument evaluation, (2) conditional statements, (3) role of examples in proving and (4) indirect reasoning. In each module, the PSTs refreshed their subject matter knowledge of the proof theme and subsequently examined common student (mis)conceptions of the topic. Next, they applied this knowledge by planning and teaching a lesson on that proof theme at a local school. They recorded their lessons using 360 video cameras and wrote a reflection report on their teaching (Buchbinder, Brisard, Butler, McCrone, in press).

Instruments

The MKT-P questionnaire contained 29 items designed to evoke participants' knowledge in each of the three domains of MKT-P. Ten questions were devoted to measuring KLAP, eleven to KCS-P, and eight to KCT-P. The content of the questions spanned the four proof-themes of the capstone course (direct proof, conditional statements, role of examples in proving, and indirect reasoning) framed across a range of topics in the secondary curriculum: number and operations, geometry, algebra and functions. The KCT-P items, which are the focus of this study, consisted of two parts: identifying errors in a sample student's argument and providing feedback to the student, with attention to both the strong and weak points of their work (Figure 1). This type of question requires participants to translate their proof-specific mathematical knowledge into the pedagogical practice of communicating with a student in a way that is productive for their learning. Hence these questions are appropriate for assessing KCT-P. By examining KCT-P items qualitatively, we hoped to detail the differences among the groups of participants, which we noticed in the larger study.

13. Mr. Briggs asked his students to prove the following statement: ***The sum of any two rational numbers is a rational number.***

a) **Paula's solution**:
Suppose r and s are rational numbers. Since r is a rational number, it can be written as a fraction. Similarly, s is a rational number, so it can be written as a fraction by definition of rational number. But the sum of two fractions is a fraction, and a rational number is a fraction, it follows that $r + s$ is a rational number. ■

i) Identify errors (if any) in the student's argument. If none, write "no errors".
ii) Provide feedback to the student, highlighting strengths and weaknesses of their argument.

Figure 1: Sample KCT-P item

Data Collection and Analytic Techniques

The same MKT-P instrument was administered to all three groups. The in-service teachers were given two weeks to complete the questionnaire in an on-line format. The STEM majors completed the paper-and-pencil questionnaire near the end of the course. The questionnaire took 1.5 – 2 hours to complete. The PSTs completed the MKT-P questionnaire *twice*; at the beginning of the course (as an ungraded assignment) and at the end of the course as a final exam.

The feedback provided by participants on KCT-P items was first analyzed for mathematical correctness and pedagogical depth, e.g., whether a student receiving this feedback would be able to improve their mathematical work. Through this analysis, detailed in Buchbinder et. al. (in preparation), we noticed stark differences in the three groups' feedback, which our coding scheme was not capturing. Consequently, we re-coded all data using a newly devised a coding scheme, along four dimensions. First, we counted the sheer *amount of words* in the feedback. Second, we analyzed the *perspective* - to whom the participants addressed their responses. Addressing a student directly (e.g., "you are on the right track") was coded as 1, using the collective "we" (e.g., "think what we are trying to show") was coded as 2, and referring to the student in the third person, was coded as 3. The third dimension was the presence of *questions* in the feedback. Lastly, since participants were asked to highlight both positive and negative aspects of the student's work, we analyzed the content of the feedback for complimentary and critical feedback. We used open coding and the constant comparative method (Strauss & Corbin, 1994) to identify recurring themes (Table 1). The unit of analysis was the appearance of a code in a given response, so occasionally multiple codes were assigned to a given response. Two researchers coded the data individually with initial Kappa agreement of 0.67 (moderate) for compliments and 0.53 (weak) for critiques. All disagreements were discussed and reconciled.

Table 1. Coding scheme for the content of the feedback

Code and Description	Examples
Empty Providing feedback which is devoid of substance beyond recognition of correctness	*Compliment*: Good proof *Critique*: Not proven enough
General Mathematical Comment A general statement about the mathematics of the student's work or describing work in a neutral manner	*Compliment*: Strength: showed multiple examples showing its true *Critique*: An example does not prove so a counterexample is needed.
Student Mathematical Work An explicit connection to the student's work is made in the feedback	*Compliment*: Molly had a great idea to show how the fractions add together to make a new fraction and used the closure property to argue details about the integers.

	Critique: Nicole only uses one example to argue that the statement is true.
Student Understanding Feedback gauges what the student knows or does not know	*Compliment*: You show your strong understanding of what a rational number is and how to use variables to generalize a situation. *Critique*: Calvin lacks an understanding in conjecture which is good to know for the teacher.
Mathematical Value Centered on some mathematical value (brevity/clarity), mathematical writing, or argument structure	*Compliment*: I like that the student attempted to use algebra in a general case to prove it *Critique*: Try to write it more in the 3rd person
Directing Solution The participant tells the student how to correct their work, either through suggestion or direct explanation	*Compliment*: N/A *Critique*: Nicole needs to use variables to show that the statement holds true for all rational numbers

Results

Although the *number of words* in the feedback does not give insight to its substance, it gives a broad sense of the participant's willingness to take seriously the hypothetical student and the mathematics of the problem. The groups showed notable differences in the mean number of words, with teachers averaging 37.43 words per response and STEM majors averaging 27.18 words per response. The PSTs'-Pre[1] feedback was initially closer to the length of the STEM majors', averaging 29.33 words per response; however, PSTs-Post surpassed the teachers averaging 48.69 words per response. This gain could be attributed to the high-stakes nature of the post-questionnaire, but it is nevertheless a valuable indication of engagement.

The groups also differed with respect to *perspective* in which they framed their responses. The teachers had an average perspective rating of 1.87 while the STEM majors had an average rating of 2.29. This means that teachers more often framed their feedback as an address to the student while STEM majors tended to talk about the student or to the collective. The PSTs-Pre aligned with the STEM majors, with an average rating of 2.54, which slightly lowered upon their second attempt to an average of 2.17 (for PSTs-Post). This shift indicates that PSTs began to address students directly in their feedback more often, but still less frequently as the teachers.

Participant's responses were also analyzed for the presence of questions, although these only appeared in about 25% of the data: across all groups, only 74 responses contained some form of question. Of these, 13 (17.6%) were generated by STEM majors and 37 (50%) by teachers, meaning that teachers tended to pose questions to the hypothetical students more frequently than the STEM majors did. The PSTs-Pre posed 9 questions as a group, and 15 questions on the Post, representing 12.2% and 20.2% of all questions in the data set respectively. Yet again, the PSTs-Pre performance on the questionnaire resembles that of the STEM majors, while the PSTs-Post performance shifted toward the teachers' performance.

Whenever possible, the content of the feedback was analyzed for the presence of compliments and /or critiques on student arguments. Complimentary feedback appeared in 62% of STEM majors' responses, 64% of teachers' responses, 73% of the PSTs'-Pre, and 91% of the PSTs'-Post responses. Figure 2 shows the frequency of each *compliment* type (detailed in Table 1) as a proportion of the complimentary feedback from each group to facilitate cross-group comparison.

[1] For ease of communication, we refer to the pre-course data as "PSTs-Pre" and the post-course data as "PSTs-Post"

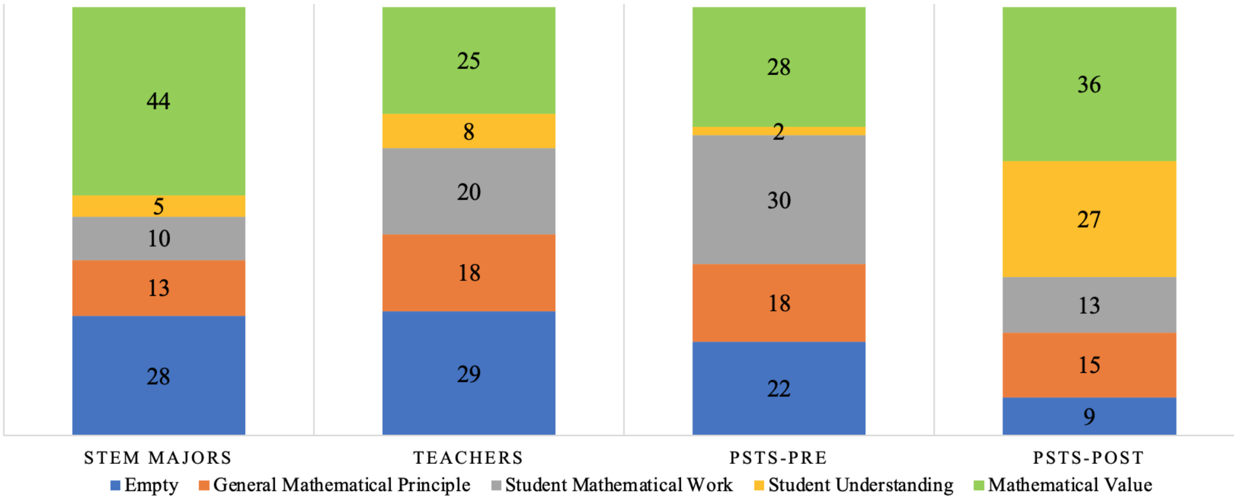

Figure 2: Distribution of compliment types by group (in percent of total complimentary feedback in each group)

Figure 2 shows that the only category for which all groups displayed similar proportions (within 5% of one another) is that of general mathematical principles. Among the notable differences between the groups is the drop in empty compliments of PSTs-Pre to PSTs-Post. While all other groups had similar proportions of empty praises (within 7%), PSTs-Post gave such feedback less frequently, with only 9% of their compliments considered empty. PSTs-Post also showed a large drop (17%) in complimenting student mathematical work, while dramatically increasing their complements of student understanding (2% to 27%). Both teachers and STEM majors showed low rates of such feedback (5% and 8% respectively) making this category a distinguishing feature of the PSTs'-Post complimentary feedback. PSTs also slightly increased their compliments of mathematical values from 28% to 36%. While PSTs-Pre were closer to the teachers on this category (25%), the PSTs-Post fell between the teachers and the STEM majors (44%).

Feedback of a *critical nature* was more frequent than complimentary feedback for both STEM majors and teachers, appearing in 86% of STEM majors' responses, 84% of teacher responses. 68% of PSTs-Pre and 89% of PSTs-Post feedback contained some sort of critique.

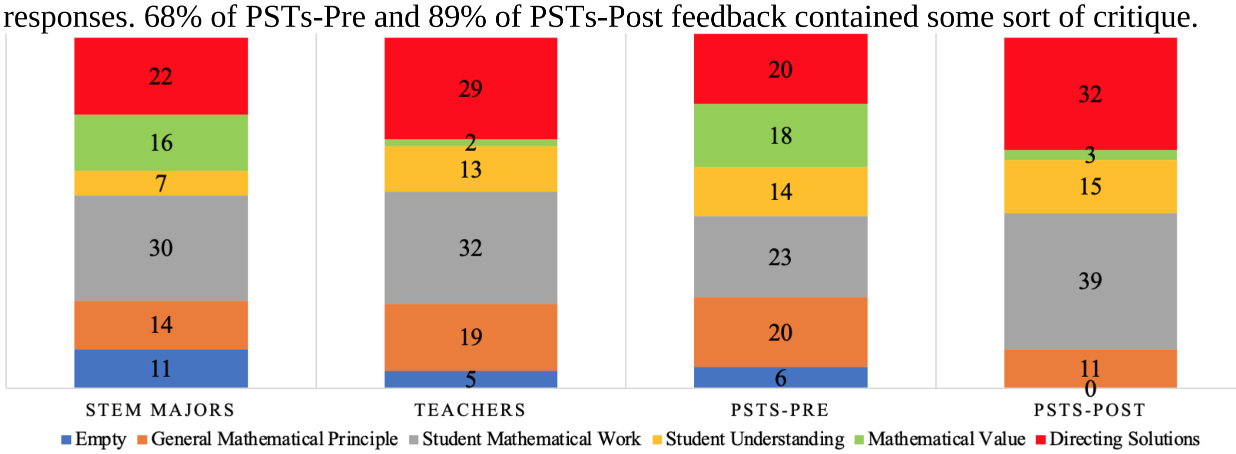

Figure 3: Distribution of critique types by group (in percent out of total critical feedback in each group)

Figure 3 shows the distribution of critical feedback categories for each group in percent of total critical feedback in each group. Compared to Figure 2, each group provided empty critiques less often than empty compliments, with such critiques being entirely absent for PSTs-Post. This indicates that the critiques provided by all groups are substantive and contain more information regarding the nuances of student's arguments. The types of critiques vary by group. Notably, PSTs increased their critiques of student mathematical work and directing solutions. PSTs-Post decreased their focus on general mathematical principles and mathematical values compared to PSTs-Pre. This indicates shifts toward specific aspects of existing student work and revisionary work rather than making general comments. The increase in directing solutions and decrease in mathematical values mark a shift toward the critique profile of the teachers while the decrease in general mathematical principles marks a shift toward the critique profile of the STEM majors.

Discussion

The two research questions of this study asked about qualitative differences in the feedback given by the groups and changes in PSTs feedback before and after the capstone course. Significant differences were found through these comparisons. Teachers tended to provide longer feedback, address the student directly, and frequently posed questions. STEM majors tended to write shorter responses in the third person. Content wise, teachers' feedback tended to focus on the particularities of student work while STEM majors focused on the mathematical conventions and qualities of mathematical writing. Considered holistically, the feedback provided by the PSTs-Pre is qualitatively close to that of the STEM majors, while PSTs-Post feedback is qualitatively close to that of the teachers. This is primarily evident in the shift toward longer feedback addressed to the student and inclusion of questions. It is also evident in the shift of critical feedback toward *directing solutions* and away from critiquing *mathematical values*.

These shifts in the PSTs feedback are consistent with the existing literature exploring PST feedback. PSTs in this study tended to provide complimentary feedback frequently, concurring with Kastberg et al. (2016) and Crespo (2002) that PSTs tend to focus on the correctness of responses. This study also echoes the trend in which PSTs write longer feedback focused on processes as they gain experience teaching (Santos & Pinto, 2010). The literature is furthered by this study as it compares the work of PSTs to both experienced teachers and STEM majors, revealing aspects of feedback specific to teachers and providing insight to their development.

While limited by small sample sized and the high-stakes nature of the PSTs post assessment, the results of this study elucidate MKT-P as a construct; namely, these qualitative distinctions contribute to the empirical validation of this theoretical construct. By drawing out the differences in feedback provided by groups with varying mathematical and pedagogical backgrounds, this study illustrates that there is an underlying difference in the MKT-P of these groups, thereby lending credibility to the construct as something which is both unique to teachers and learnable.

This connection of feedback to MKT-P also carries implications for teacher education. While the course that the PSTs of this study were enrolled in was not specifically aimed at cultivating specific feedback practices, changes in PST feedback were evidenced after taking this course. These changes along with the substantial differences in teachers' and STEM majors' feedback indicate that giving feedback is a learnable practice. By consciously attending to the development of MKT-P in PSTs, teacher preparation programs can better equip their participants to evaluate student work regarding proof and communicate their thoughts about this work back to the student in meaningful ways.

This paper explores how one mathematics major, Amelia, perceived and used a diverse set of resources to address specific challenges and learn mathematics through three semesters of proof-based course work. Drawing on data from interviews, homework logs, and classroom observations, we trace how shifts in her available resources shaped the actions she took to maintain personally meaningful mathematical reasoning and learning. Specifically, we highlight the ways that available resources shaped her mathematical agency and autonomy, as we have defined these constructs. These results have implications for further investigation of the resources available to support students' transition to competent proof work.

Keywords: transition to proof, resource use, student agency, student autonomy, authority

In the U.S. context, the transition in collegiate mathematics from computationally-focused introductory coursework to proof-intensive upper-level coursework substantially changes what is expected of students and their mathematical work—both their reasoning and written products Moore, 1994; Holton, 2001; Winsløw et al, 2018). The shift from being a consumer of mathematical algorithms and arguments to a producer or author of mathematical proofs is a nontrivial one, both in how one sees oneself and how one understands the nature of the discipline of mathematics (Selden, 2012). Such an epistemological shift has implications for what students believe about the role of instruction, the kinds of experiences and resources that mathematics class should provide them with, and the ways that they should organize their learning activity, both in class and out of class (Brousseau, 1997). For students who were previously successful in computational mathematics course, upper-division proof-based courses can be quite jarring as they grapple with how to adapt their prior ways of effectively studying and learning mathematics to the new requirements of proof-intensive mathematics courses. The broad aims of our research project are to better understand how undergraduate students construe the opportunities to engage in mathematical reasoning, both in and outside of their mathematics courses, and how these opportunities support (or not) their development as capable sense-makers and proof writers.

In this paper, we focus on a particular issue that is intertwined in the experience of undergraduate students: the role of external resources in students' developing reasoning processes. One way to see students' productive entry into proof work is that in the face of challenges, they consult with perceived mathematical authorities (teachers, texts, internet resources, peers) as appropriate and needed, while retaining their own central role in developing arguments and writing proofs. This paper explores how one mathematics major, Amelia, perceived and used external resources (social, material, and digital) to learn mathematics through three semesters of proof-based course work. We trace how shifts in her available resources shaped the actions she took relative to her mathematical reasoning and learning in her courses. Building upon prior work, we characterize the interplay between opportunities for sense-making and students' actions in terms of agency, autonomy, and authority.

Conceptual Framing

We understand agency as the self-defined space of action that students perceive in any given situation—a space where actors see some actions as possible/permitted and others as risky, costly, or even impossible. In conceptualizing agency, we follow Ahearn (2001) in linguistic anthropology, Bourdieu and Wacquant (1992) in sociology, Calabrese-Barton & Tan (2010) in education in not separating students' actions from the larger social and institutional structures that afford and constrain them. That is, we understand agency, not in terms of students' actions per se, but as their felt capacity to take action in the contexts where they do mathematical work, in or out of the classroom. Conceptualizing agency in this way is consistent with our orientation to understand how students experience the transition to proof, by centering their judgments and sense of what is possible.

> **Mathematical Agency:** The felt capacity to take action in the face of challenges related to mathematical work. This capacity is jointly shaped by contextual norms and resources in specific courses and students' narratives about their views of mathematics, their future in it, their learning processes, their selves relative to authorities.

Students see mathematical authority as residing in their instructors and the solutions they provide, some of their peers, textbooks, and internet sites.

In analyzing the actions that students take, we have been informed by Piaget's notion of intellectual autonomy (Piaget & Inhelder, 1969) where an important facet of an action is whether it is deemed sensible and owned by the actor (intellectually autonomous action) or whether she is dependent on some external authority to validate the action. We depart from Piaget's perspective in our focus on the more or less autonomous character of actions, not individual students.

> **Mathematical Autonomy:** A quality of actions, that reflects the student's active resistance to endorsing, following, or replicating the reasoning of mathematical authorities (e.g., texts, internet sources, instructors, peers), without engaging in sufficient sense-making to make that reasoning their own.

Specifically, we see students' acting more autonomously when they use resources judiciously and locally to resolve specific snags or obstacles in reasoning. That is, our view of more autonomous mathematical actions is not that they preclude students' engagement of resources, but that their use is bounded and subject to the overall goal of making personal sense of mathematics. Acting autonomously precludes the abdication of control for one's reasoning to another.

Grounded in these definitions we pursue the following research question: How do students exercise mathematical agency and display mathematical autonomy in the transition to mathematical proof and subsequent proof-based mathematics courses?

Methods

We observed classroom activity for two semesters of a multi-section introduction to proof course (ITP) and recruited student participants from multiple sections. During that semester, participants completed a baseline interview early in the semester, weekly homework logs, and a task-based interview later in the semester. The baseline interview focused on understanding their experience in mathematics prior to the ITP course and in its early weeks. One of the foci of the later task-based interview was to understand their view of the course, its challenges, and their learning in it. After completing the ITP course, we conducted interviews at the end of each of their subsequent proof-intensive mathematics courses.

We applied our conceptualization of agency and autonomy to these data sources for a small number of our participants, by coding for: challenges, actions taken, and felt capacity, while attending to the opportunities for action provided by courses and the resources that students engaged. During this process, one student's data, Amelia, appeared to shed light on how students' agency can change and in turn how that agency, as felt capacity to act, affects the autonomy of their actions. We analyzed Amelia's experience across her mathematics courses with respect to her work both in and out of class. Memos were constructed of patterns that occurred across time or distinct changes in her agency and autonomy. This work led to a pattern of resources being a key part in her narrative with respect to autonomy and agency both within and outside of the classroom. These were then used to begin to understand how STEM majors exercise agency and display autonomy during mathematical reasoning processes in their ITP and subsequent courses.

Amelia's Transition to Proof Work

Amelia was a junior mathematics major who ultimately planned to become a high school mathematics teacher. We began working with Amelia during her ITP course. She came to her major late after switching from another field and was working through her mathematics degree requirements to finish in four years, so that her fifth year would focus on student teaching. Amelia took four proof-based courses after her ITP course and in that time, her university shifted from in-person to online instruction in response to the COVID pandemic, as depicted in Figure 1. Our analysis focuses on two distinct portions of her transition to proof work: finding and using out of class resources and searching for resources to compensate for lectures she found unproductive.

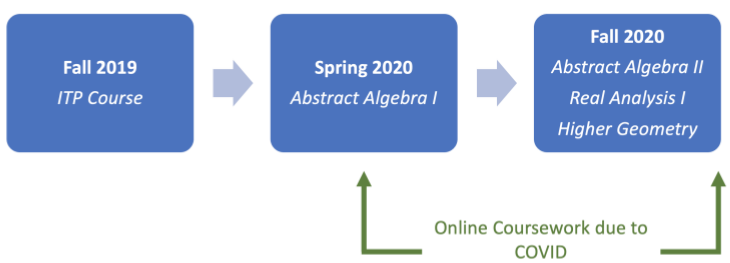

Figure 1. The progression of Amelia's mathematics proof-based courses from Fall 2019 to Fall 2020. The figure denotes when classes switched online (mid-semester), an important contextual shift, via the green arrows.

In her data corpus, we located four main types of resources: people, notes, solution keys, and the university's mathematics learning center (MLC), that she used across the observed semesters. We highlight that notes appear within both parts of our analysis; hers were initially produced in class (as most students do), but Amelia also adapted note-taking as an out of class activity. In each of the following sections, we summarize the narrative she relayed to us relative to opportunities and resources, and then discuss how these informed our analysis of students' agency and autonomy in challenging proof work. In Amelia's transition to proof-based mathematics, shifts in her sense and use of resources were especially apparent.

Finding and Using Out of Class Resources

Amelia's father, an engineer, was a central resource in her mathematical experience prior to her entry intro proof work. During her calculus courses Amelia would call him for help such as writing out the mathematics or explaining different topics. This dynamic began to shift in her ITP course. Initially he hedged his aid by stating he could not "help [her] with any of the fancy words, but this is how you do it" and expressed that he would not have succeeded in the ITP course since he generally cared more about the answer than the process that produced it. As the class progressed, she still reached out and he helped form negations or contrapositives, but ultimately, he remarked that he had 'overestimated' his abilities. Her father could no longer be her 'trump card' in mathematics. Despite the ITP experience, she reached out during abstract algebra I, but to no avail, as she had surpassed him in mathematics.

Once Amelia recognized that she had exceeded her father's expertise in mathematics, she began to explore other helpful out of class resources. She visited the MLC as one potential source; she logged in her (minimal) required hours, but overall found the resource of limited value relative to her homework practice.

Amelia: Sometimes it was just because I was like, busy and the only time I could go is on Wednesdays. And then like other times, it was I was understanding it. I didn't need to go. And then sometimes I just was too lazy to go.

Interviewer: Was it also too early because you, like you said you started homework Tuesday, Wednesday. So you sometimes started homework later than that?

Amelia: Yeah. So sometimes I like hadn't gotten around [to going] because I didn't want to go if I didn't have questions that I was going in with. Like I wanted to have like started the homework and found a spot where I got stuck or like a problem that wasn't in the notes or something like that.

Further, Amelia stated she was more likely to seek out help when she felt confident; when she was not confident in her approach proof tasks, she would put away her work and did not share it. But her central resource was her notes. When she worked on homework, her approach was to, "go through my notes. Because usually it's something that's in the notes recently. And I use my notes on my homework. I never do homework without… I don't think I'd get through it if I did it without the notes." Amelia did not describe her note-taking process, so we don't know her own sense of that process or how close to the instructor's written presentation they were.

Once Amelia completed her ITP course, the MLC was no longer available as it was not staffed for more advanced courses. Due to this change and others, she expressed frustration over lack of resources to her father:

> I was talking to my dad about this that it makes me feel like now I'm like alone on an island of like just, because the only other person I can ask about like, but it's just, she's not in my [abstract algebra I] class. She's not taking that right now. So it's like that class I feel like yes, I have gotten my contact information of other people, but there's no like MLC to go to or like, I don't really want to go to his office hours…That does not help me.

Amelia also reached out to a peer from her ITP course in a different section, but this possible resource was not fruitful as the two sections covered different topics. Ultimately, she was able to get the number of another student in her section, and she would text him sparingly if she was stuck on a part of a problem. During this course, the instructor provided solutions for homework and practice exams, and she used them to compare against her work and for exam review.

She started her abstract algebra II course not knowing anyone, but by the end of the semester she had made a friend. They were taking in multiple courses together and "would kind of compare notes on homework, and if [they] were struggling on a problem or something”. When they collaborated, their typical questions were, ‘Did you do this homework problem? I'm really confused on it. Or something like that, and then either we both be confused… or, Yeah, I did that one. Here's how I did it. Or like, I used this theorem, or whatever.’ Despite establishing this productive relationship with her peer, Amelia was frustrated by the lack of solutions for tasks on practice exams and review sheets. The instructor never uploaded solutions, which deviated from her prior courses, and she remarked that “If I am going to practice this, how do I know that I am getting it right? Because I don’t want to practice it wrong.” She appreciated prior instructors who uploaded them so she could compare her work, but she had now lost access to this out of class resource.

Interpretation Relative to Agency and Autonomy

Amelia’s transition to proof-based mathematics was oriented by the fact that she worked through her high school and early collegiate courses with a strong mathematical authority: her father. But during her ITP course and after, he could no longer serve as a mathematical authority and social resource; Amelia faced the fact that she surpassed him in mathematics. This was dual loss: he was both someone whom she could comfortably interact with about mathematics and was also able to declare whether she is right or wrong. This loss of a resource resulted in a decrement to her agency, as she no longer has the same felt capacity. In her previous courses, she did not always call her father but knew that she *could* call him if she was stuck or was uncertain. In response to this loss, she worked to find resources where she could comfortably discuss mathematics, but also indicated that she felt more comfortable when an authority (e.g., an instructor’s solution key) validated her reasoning and written work.

With respect to solution keys, she remained engaged in her sense making process and completed problem sets by herself, a pattern of actions we see as substantially autonomous. Although her deference to the solution keys for judging whether her solutions were ‘right’ or not suggested a pattern of less autonomous action. We see a similar pattern in her views and use of the MLC. One reason why she found it less beneficial than she hoped was that she wanted to work through problems and hit “stuck points” before turning to the MLC—paralleling her work with her father. This response to the resource of the MLC shows her resistance to replicating the thought processes of others. Instead, she wanted to engage in her own sense making and use resources judicially to resolve stuck-points in her own reasoning—an indication of substantial autonomy in her actions. Amelia sought out others to discuss the mathematics throughout her transition, and one of her highest points of frustration was when she felt that she was “alone on an island.” She reached out to peers in her sections, some of whom she knew were other sections. Although some of these attempts to secure social resources were not fruitful, she was successful with some, particularly in abstract algebra II. Overall, she tried to make decisions and take actions that maintained her level of agency by locating and using a variety of resources. Some actions were more autonomous than others, but overall, she retained, rather than abdicated, her control over her reasoning in her proof-based courses.

Responding to the Increasing Barrenness of Lecture

Amelia attended and actively engaged in her ITP course by asking questions of her peers during group work and of her instructor during segments of lecture. During one observed class session, the class worked on a problem where the TA gave a hint, but after working on the problem Amelia called the TA over because she did not understand a part of the resulting proof. As they worked together, they realized the hint’s algebra was incorrect. Amelia explained the problem to the class so her peers could also fix their algebra. Overall, she engaged in lectures with questions, discussed possible solutions with her peers, and remained focused on making her own sense during class.

Reflecting on abstract algebra I course, Amelia relayed she no longer asked questions in class, partially because the instructor "never left a space for questions to be asked." She added,

> I feel like maybe it's because I just didn't feel as comfortable [asking questions], because when people did ask questions, they would ask a question I would have too, but I wouldn't feel satisfied by the response. Like it didn't help much. So then it kind of was like, Why should I ask my own questions?

Her dissatisfaction with the instructor's responses to questions was one reason why she became more broadly unsatisfied by the lectures. Lectures were almost "word for word from the notes," so she "didn't really get much more from [the instructor]" than reading his notes, other than having someone audibly read them. Dissatisfaction and loss of motivation led her to decide to not synchronously attend lectures (after the shift to online instruction), as she judged this was not a productive use of her time. She continued this pattern of work for the duration of the semester, taking her own notes rather than attending lecture, although she reported that she fell behind towards the end.

In her proof-based geometry class, she listened during lecture rather than copying everything down. Her instructor posted her notes online, allowing Amelia to take notes on them at a later time and then use them as a resource for her homework. She did not take notes during class in her abstract algebra II course.

> But I wouldn't really take many notes during lecture, because a lot of them were very, very similar, to the same examples to what were in the book, is what I started to notice kind of like a couple of weeks in… I would more listen and then copy the notes from the textbook and then use those to help me on the homework So, it kind of felt like... it didn't feel like I was on my own and I was teaching myself, but I was doing those things outside of class, instead of having group discussion, or doing things in groups.

Amelia did attend the synchronous lectures in that course, even when they were not very helpful, because they kept her on track. She noted that if she treated it like an asynchronous course and viewed the lecture later, she would fall behind. In both the geometry and algebra classes she did not ask questions, feeling that the instructor wanted to just move ahead with the content. This dissuaded her from asking, even though upon reflection she felt she should have.

Interpretation Relative to Agency and Autonomy

In Amelia's responses to her courses, we see that she adapted to the interactive emptiness of lecture, in a manner roughly paralleling her adjustment to the loss of her father as a mathematical authority. Specifically, her change in question asking in classes subsequent to her ITP course highlights a key portion of the relationship between agency and autonomy. In her ITP course, she felt that questions were not only encouraged but were ultimately helpful for her mathematical understanding. She reported positive experiences in how her questions were received and answered, both with regards to instructors and peers, allowing her to make effective sense during class. Her comfort with question asking was highlighted in her narrative of not taking a hint at face value even though it was provided by the TA, a mathematical authority. She had the felt capacity to engage in the classroom, and more specifically engage in her personal sensemaking since she had opportunities that aided her in this process. In later classes, her felt dissatisfaction with answers to her questions indicated her continuing focus on personal sensemaking. If she had simply written out the lecture notes during class without processing the meaning or challenging the validity, this practice would indicate less autonomy. Instead, she interacted with the material enough to realize that she needed a different explanation, as she did not have a personal understanding of the topic, leading her to look for other resources.

When reflecting on question-asking in her abstract algebra II, she noted that she should have asked questions. It was not that she did not have questions, rather she felt the space during lecture did not permit this action. Her felt capacity thereby constrained the potential autonomy of her actions. She looked for alternate pathways and support but found even the lectures themselves unhelpful. She exercised her agency by producing and using her notes on her own time, and these became a reliable resource for completing homework and studying—while also seeking productive interactions outside of class. For Amelia, this process of notetaking felt more as if she were having a mathematical discussion, paralleling her search for resources other than her father, with whom she could have these discussions. Her engagement with the textbook and the process of creating her notes substituted in part for the opportunities provided by her prior ITP groupwork. Even though Amelia had not necessarily started with the same felt capacity that she was accustomed to, or was critical for her mathematics learning process, she worked to find other substitutions for her in-class experience thereby increasing her agency.

Conclusion and Future Work

We have used this case of an undergraduate major's transition to proof-based mathematics to illustrate the importance of longitudinal inquiry to understand such transitions and the central role of activity outside of the classroom in them. Conceptually, we have shown how analytic attention to course opportunities (or their absence) and different types of resources can be used to characterize changes in students' mathematical agency and autonomy. Our focus on agency, autonomy, and authority allows insight into how students experience the transition to proof-intensive mathematics courses and why their experiences play out the way they do, something that tracking grades, subsequent course taking, and major/minor completion cannot explain.

The particularities of the case are evident. Many students' transition to proof will not be oriented by the presence and retreat of a mathematical authority like Amelia's father. Further, Amelia's notetaking became a productive practice and resulted in a resource for her where it might not for others. But even in its particularity the case suggests ways to support students in addressing similar challenges in their proof-based coursework at many universities. In identifying these possibilities, we draw on the experience of other project participants, majors and minors whose transitions to proof-based mathematics have shown similar patterns to Amelia's experience as well as clear differences. One design option simply takes seriously the felt barrenness of lecture and to experiment with openings for interaction. Dissatisfaction with lecture as unproductive for learning is not isolated to Amelia as literature questions the modality of lecture both with respect to students' learning and their experiences (Freeman et al., 2014; Laursen et al., 2014, Lew et al., 2016, Prince, 2004). Another design consideration not only encourages collaboration but allots some classroom time for students to find peers for productive work outside the classroom. More generally, it may well be productive to devote class time to a discussion of the range of resources and how to use them—to support rather than undermine students' mathematically autonomous action.

Challenges in Mentoring Mathematical Biology Model Construction: Quantification and Context

Carlos William Castillo-Garsow
Eastern Washington University

The researcher observed a group of undergraduate students and faculty mentors collaborating in the development of a model for a student chosen topic in epidemiology. Results suggest that both students and mentors struggled with key understandings necessary to develop the model. Students struggled with conceiving of their compartment model as relating quantities, and mentors struggled with tracking and attending to the biological constraints of the problem the students chose.

Keywords: Ordinary differential equations, mathematical modeling, model construction, student-led projects, quantification

Choosing quantities and their relationships is a critical part of successfully approaching a mathematical model. Equations and graphs in word problem and modeling contexts represent relationships between quantities and their rates of change. However, the notion of quantity receives little focus in the teaching school mathematics (Smith & Thompson, 2007; Thompson, 2008, 2011). Thompson describes quantification as the process of conceptualizing of an attribute of an object as having a measure. Understanding how students and mathematicians imagine and interpret quantities is critical to understanding the process of model development.

Research in mathematical modeling and quantification typically focuses on students working pre-chosen tasks (Bliss et. al., 2006; Gravemijer, 1994; Goldin, 1997; Lesh & Doerr, 2003; Thompson, 2011; Steffe and Thompson 2000). Sometimes these tasks are quite open, and students go through cycles of model development; however, in assigning a task to students, there are constraints placed on students as part of intentionally guiding the students' conceptual development (ibid). It has been argued in the past that these constraints limit students' experiences in developing their own research questions (Castillo-Garsow, 2014; Castillo-Garsow & Castillo-Chavez, 2015). Furthermore, pre-chosen tasks place teachers or teacher-researchers in a dominant role where the teacher has an opportunity to learn and know everything there is to know about the problem. So these pre-chosen tasks rarely highlight difficulties in modeling or mentoring modeling that a teacher would experience.

For example, Camacho et al. (2003) found that choosing one's own project and research question creates situations in which students take the lead in researching topics far outside a mentors' area of expertise, essentially reducing the mentor to a role of consultant rather than leader. Mentors provide mathematical expertise, guiding students by suggesting appropriate tools and techniques. However, students take the lead in these projects, providing the background that defines the problem from subject area research and personal experience (Castillo-Garsow & Castillo-Chavez, 2015). These role reversals in which students are the experts are important sources of motivation and self-efficacy. Choosing a topic that mentors know less about allow students to participate and contribute in ways other than mathematical performance (Rubel, 2017), which is an area in which students cannot compete with mentors (Camacho et. al 2003; Castillo-Garsow & Castillo-Chavez, 2015).

This perspective creates a dichotomy of two ways in which difficulties with quantification can occur: understanding the background context but having difficulty mathematizing, or having an expert understanding of the mathematical tools for modeling, but having difficulty understanding and connecting those tools to the background context due to inexperience with the context itself. Quantification research typically focuses on the former, but rarely focuses on the latter. This study focuses on both. As students and mentors interacted with each other, this paper identifies challenges that arose in quantification for both students and mentors as they collaborated to construct a model in a student-led project.

Methods

This study occurred in the fifth week of an eight-week summer REU in mathematical biology. Prior to this study, the students had taken a three-and-a-half-week course consisting of lecture, computer lab work, and textbook exercises in dynamical systems. Following this course work, students self-recruited into groups of three to five, and chose a topic of interest. During the fifth week, students made daily presentations on their topic to a panel of faculty and graduate mentors who provided feedback. In the final three weeks of the program, students completed the analysis of their model and wrote a technical report on their project. Four groups of students chose to participate in the study, and this a case study from one of those groups. Analysis of the other groups can be found elsewhere (Castillo-Garsow, 2021, 2022).

The group of students in this study was formed of five undergraduate students who chose to construct a model for controlling a disease that can be treated but not cured. The students working on this project eventually developed their work into a published journal article, the citation for which is omitted for privacy. The students made six presentations over six days to a panel of faculty and graduate mentors who provided feedback to the students. Each proposal presentation was video and audio recorded, and the audio recordings were transcribed. Transcripts were open coded (Corbin & Strauss, 2014), and from that coding, themes emerged that identified and explained the primary areas of conflict between mentors and students. The results here are a case study of those transcripts, focusing on creating a narrative of those conflicts (Flyvbjerg, 2006). The purpose of this case study is to identify challenges than mentors and students may encounter while collaborating on a student-led applied mathematics project, both to inform mentors and to inspire future research.

Results

The groups' research question was focusing on the cost effectiveness of treating individuals with mild symptoms of a disease, compared to the current practice of only treating patients in the severe symptom stage. These mild symptoms occurred in many different diseases, meaning that treating individuals with mild symptoms would result in treating many individuals who did not have the disease of interest with medication for the wrong disease. The students proposed studying this question with a system of ordinary differential equations (ODE model).

Student Challenge: Quantity vs. Category

In the students' first attempt at constructing a disease model (Figure 1), the students classified individuals only by their symptoms. The category I_1 therefore contained both individuals who had the disease of study, and individuals who had the same symptoms of a difference disease. Students imagined that individuals who did not have the disease of study would return to S, while individuals who did have the disease of study would progress to I_2 or L. Describing this model, a student said: "After presenting mild symptoms, those mild symptoms go away, then they go back to the susceptible class. Only those who have [the disease] proceed to a progression to the severe symptoms, which are only for [the disease]."

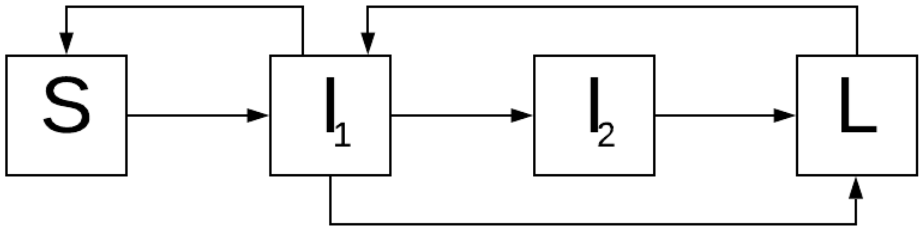

Figure 1: A simplified flow diagram of the disease group's first model. Box S represents susceptibles, I_1 represents individuals with mild disease symptoms from several diseases.. I_2 represents individuals with severe symptoms unique to the disease of study. L represents asymptomatic individuals.

However, in an ODE model, these variables only track a number of individuals. I_1 would necessarily be a numerical quantity of a number of individuals with mild symptoms, meaning that information about who does or does not really have the disease of study could not be stored in this information structure. Students may have made this mistake because they were imagining tracking individuals moving through the categories S, I_1, I_2, and L; rather than imagining S, I_1, I_2, and L as simple numbers of people. In other words, the students were not conceiving of S, I_1, I_2, and L as the values of quantities that could be measured (Thompson, 2011).

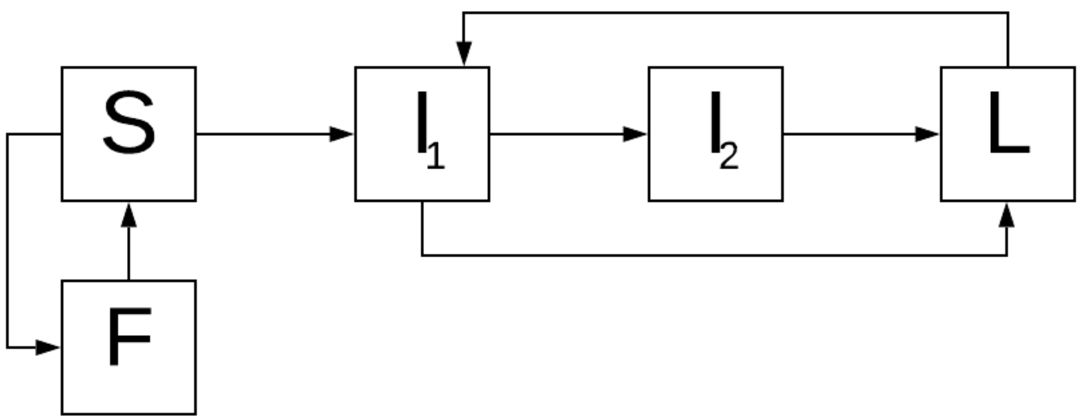

Figure 2. Students' second model, showing an F compartment for individuals falsely diagnosed with the disease of study. The students' fourth and fifth models also had a similar compartment forming a closed loop with S.

Mentors provided feedback on this model informing them that they needed a separate compartment for individuals who did not have the disease "I think you're going to need a separate class for those people" (day 3) and "There's no way to do this without a separate compartment" (day 3). But at this time, mentors did not explain that tracking individuals was not possible in an ODE, or that S, I_1, I_2, and L were numbers. Students responded by creating a compartment F for individuals falsely diagnosed with the disease of study (Figure 2), but this was changed again in the third version (Figure 3).

In the students' third version of the model (Figure 3), they repeated their categorization mistake with a new compartment. Here students imagined that all individuals exhibiting symptoms would receive the same treatment, so all treated individuals were placed in a single compartment. Again, the students imagined that from this compartment, individuals who did not have the disease of study would return to S, and individuals who did have the disease would advance to L, and that the model would somehow keep track of which individuals were which. This resulted in a model with a path from susceptible to asymptomatically infected passing only through treatment – implying that it was possible for treatment itself to cause infection. This time, mentors addressed problems with tracking individuals. As one mentor put it:

> You can't do that because if a person who doesn't have the illness and a person who does have the illness, and they go to the same thing. What you're doing after that is you're saying, both people who don't have it and do have it can now become [asymptomatic]. (Mentor, day 5)

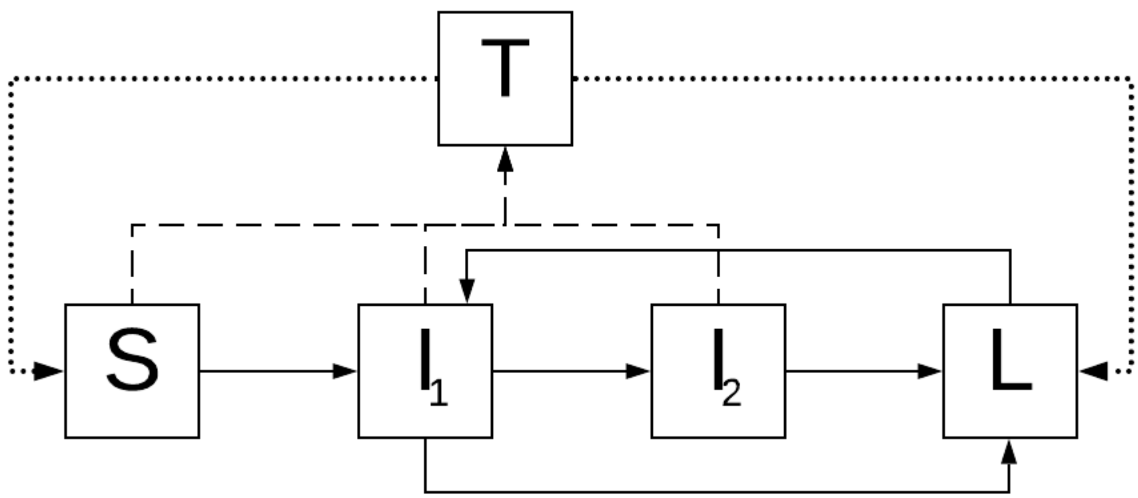

Figure 3. A simplified flow diagram of the disease group's third model, with an added T compartment for treated individuals. Dashed lines represent individuals moving into treatment. Dotted lines represent individuals moving out of treatment.

Another perspective here is that students may have been adopting the point of view of a physician-observer, rather than the point of view of the disease itself. Students wanted to lump all the mild symptoms into a single category because all mild symptoms look alike. Similarly, they wanted to lump all treated individuals together because they all were receiving the same treatment. However, from the point of view of the disease, individuals in these categories had very different diseases, and therefore needed to be tracked separately. In either case, I_1 and T did not represent numerical quantities.

Mentoring Challenge: Dynamics over the research question.

Because students were tracking the cost-effectiveness of treatments that had a risk of being wasted on individuals with another disease, the students needed a way to track the number of falsely diagnosed individuals. These falsely diagnosed individuals would add to the cost without controlling the disease. The students included a compartment, F, for this in their second, fourth, and fifth models (Figure 2).

This F compartment was isolated from the rest of the model in that the variable F did not appear in equations for I_1, I_2, or L. Because this compartment did not affect disease dynamics, mentors objected to its inclusion as unnecessary, and frequently forgot that the compartment was needed to answer the research question of cost. Examples include: "If you only consider dynamics, F compartment does nothing" (day 3) and "You asked the question how to treat early treatment for [the disease]. That part [F] has nothing to do with [the disease]. Why do you have to include this here?" (day 6).

Mentoring Challenge: Testing vs. diagnosis

In the disease model, a key component of the cost was the risk of treating other diseases. This risk was increased because no available test that could distinguish mild symptoms of this disease from mild symptoms of other diseases. The tests that did exist could only be used during severe symptoms, when testing was unnecessary because the symptoms were characteristic. The students frequently stated that there was no test, or that testing was only possible in the I_2 severe stage. However, mentors frequently assumed that there was testing or screening occurring in I_1. See the following excerpt from day 3:

Student: The current test that we have now, there is no way to test if you have [the] disease. There's absolutely no way. The only way you test it if you go here [I_2] and you have a lesion here to take samples

Mentor: The cost of this testing, and the patient, the I_1. The same test?

Student: There's no testing for I_1 in that.

Confusion about testing continued through day 5, where mentors continued to ask questions and suggest changes to the model that involved "testing" or "screening" individuals in I_1. For example, on day 5, suggesting changes to the third model (Figure 3) by incorporating screening: "So then you screen that [S] and once you screen that you put it here [I_1], [you] do not go here [T]." At least some of the confusion arose from students frequently referring to falsely diagnosed individuals as a "false positive," suggesting the presence of a test.

Discussion

Previous research from the project showed that mentoring had the most impact on students' decisions when the mentors focused on asking questions about the biological background, and making suggestions about the mathematics (Castillo-Garsow, 2021). That result is consistent with perspectives found in literature on these student-led projects, which describe students as having topic context expertise, while mentors have mathematical expertise (Camacho et al, 2013; Castillo-Garsow & Castillo-Chavez, 2015). Effective mentoring of a student-led project involves respecting the respective expertise of both students and mentors. This project shows an alternate perspective on the same phenomenon. Here, the challenges in model development arose from students struggling to adopt a mathematical perspective on the problem, while mentors struggled to understand the biological context.

The students in this project had a strong understanding of the biology, but had difficulty communicating that understanding to the mentors. The mentors had difficulty with setting aside their preconceived ideas of what the biology of this disease would be and imagined that testing and treatment occurred in ways that they were more familiar with. Mentors also struggled to attend to contextual concerns – such as cost – over mathematical concerns, such as the dynamical behavior of the model itself.

The students also struggled with quantification. They imagined the modeling process as the story of individuals moving through categories, and/or the perspectives of observers of those individuals. However, writing a mathematical model requires imagining not just individuals, but also numbers of individuals. The students' repeated difficulties in making the transition from category to quantity resulted in errors in the base structure of the model and the corresponding mathematical equations. Mentors initially responded by only correcting the surface level mistake. It was only after the mistake was repeated in a new way that mentors addressed the foundations of ODE model construction with students, specifically the principle that individuals did not have histories that could be tracked through compartments. Here the necessary mentoring expertise was in mathematics in understanding the assumptions and limitations of an ODE model, but also in pedagogical content knowledge by forming a model of the students' interpretation of the model and addressing individual tracking.

Conclusion

The results here add to the literature on student-led projects in mathematical biology modeling. The results of this paper suggest that the reversal of roles described in previous literature (Camacho et al. 2013; Castillo-Garsow & Castillo-Chavez, 2015) is not only sufficient for a successful project (Castillo-Garsow, 2021), but also necessary. In this example, difficulties in model construction came from participants operating outside of their areas of expertise. Students struggled with mathematical concepts, and mentors struggled with biological concepts. However, this struggle outside of ones area of expertise should not be avoided. Rather it was mutual teaching between students and mentors that enabled the participants to collaborate and develop a successful model that was eventually published.

The results of this research also suggest that more research is needed in the ways that mathematicians come to understand or struggle to understand scientific concepts as part of mathematical quantification. Quantification research cannot only address the mathematization of well understood scientific contexts, but must also explore how a developing understanding of the context influences the conceptualization of quantities and the development of quantitative relationships. In particular, further study of mathematics experts developing models of unfamiliar scientific problems would greatly add to our understanding of quantification.

Challenges in Mentoring Mathematical Biology Model Construction: Mechanisms and Listening

Carlos William Castillo-Garsow
Eastern Washington University

The researcher observed the project proposal week of an undergraduate research program in applied mathematics, where students took the lead in choosing a topic and developing their own research question. Results from the stories of two of the groups suggest that students struggled with identifying mechanisms that would inform the development of their research question and model, while mentors struggled with allowing students to direct the project and presentations.

Keywords: Mathematical biology, mathematical modeling, mechanism, research question, student-led project

Mathematics as it is taught in secondary and post-secondary classes differs greatly from mathematics as it is practiced by professionals (Lewis & Powell, 2017). Mathematics as it is taught in undergraduate classes is also divorced from the immediate needs of partner disciplines in the sciences, humanities, and social sciences (Ganter & Barker, 2004; Ganter & Haver, 2011). Reports from industry and professional societies repeatedly emphasize the importance of professional skills in communication, collaboration, problem solving, mathematical modeling, and creativity on top of a solid foundation of procedural skills and coherent mathematical understandings (Bliss et. al., 2016; Casner-Lotto & Barrington, 2006; Ganter & Barker, 2004; Ganter & Haver, 2011).

The skill of interest to this report is a skill for STEM and non-STEM described undergraduate mathematics classes described by Bliss et. al. (2016) as "Distilling a large ill-defined problem into a tractable question," which I will simply call "developing a research question." Smith, Haarer, and Confrey (1997) found that graduate students in applied mathematics struggle with developing research questions and mathematical models that are too applied and mathematically intractable, or are too mathematical with little application.

Camacho, Kribs-Zaleta, and Wirkus (2003) found that choosing one's own project and research question creates situations in which students' take the lead in researching topics far outside a mentors' area of expertise, essentially reducing the mentor to a role of consultant rather than leader. And these unique situations create opportunities to identify key components of soft-skills such as developing a research question. Encouraging students to follow their interests and positioning students as experts is also an equity directed practice that engages students with high level questions where students can participate and succeed in more ways than just performance, and students are engaged in contexts that connect with and respect their own experiences (Aguirre, 2013; Castillo-Garsow & Castillo-Chavez 2020; Goffney et al, 2018; Rubel, 2017).

This study follows two groups of undergraduate students who developed a topic of their own interest into a research question and accompanying mathematical model. Because the students in this project work in close collaboration with both graduate and undergraduate mentors, we have an opportunity to see how mathematicians at different stages of their career view the task of developing a research question and accompanying model. The purpose of this paper is to identify challenges than mentors and students may encounter while collaborating on a student led applied mathematics project, both to inform mentors and to inspire future research.

These two groups were selected for discussion due to a common theme in the results. A recurring idea that students encountered in constructing their projects was mechanisms. Although the meaning of “mechanism” remains debated in the scientific community (Craver & Taber, 2015; Hunt et al., 2018), the term mechanism comes from the idea of describing the function of a machine that would replicate a hypothesized scientific process (Craver & Taber, 2015). For our purposes, a mechanism is an interaction between biological parts that could explain an observed behavior, and is precise enough to suggest a mathematical relationship.

Methods

This study occurred in the fifth week of an eight-week summer research experience for undergraduates (REU) in mathematical biology. Prior to this study, the students had taken a three-and-a-half-week course consisting of lecture, computer lab work, and textbook exercises in dynamical systems. Following this course work, students self-recruited into groups of three to five, and chose a topic of interest. During the fifth week, students made daily presentations on their topic to a panel of faculty and graduate mentors who provided feedback. In the final three weeks of the program, students completed the analysis of their model and wrote a technical report on their project. Four groups of students chose to participate in the study, and this a case study from two of those groups. Analysis of the other groups can be found elsewhere (Castillo-Garsow, 2021, 2022).

The two groups in this study were formed of four undergraduate students each. One group wanted to study the relationship between eating disorders and the menstrual cycle (menstrual group). The other group was interested in developing a spatial simulation of tumor growth (tumor group). Both groups completed a technical report that was reviewed by the mentors. Neither group has published their research in a peer-reviewed journal by the time this paper was written. Both groups presented over six days to a panel of faculty and graduate mentors who provided feedback to the students. The menstrual group presented once per day. The tumor group gave seven presentations over the six days, with two presentations on day five. Each presentation was video and audio recorded, and the recordings were transcribed. Transcripts were open coded (Corbin & Strauss, 2014), and themes emerged that identified and explained the primary areas of conflict in goals between mentors and students. The results here are a case study of those transcripts, focusing on creating a narrative of those conflicts (Flyvbjerg, 2006).

Results

Menstrual Cycle Model

The menstrual group was interested in studying the interactions between eating disorders and disruptions to the menstrual cycle. They identified a mediating hormone: leptin, that affected both appetite and the secretion of hormones related to the menstrual cycle (Figure 1). However, the group’s final model did not include any leptin or eating disorders, focusing only on modeling the menstrual cycle.

Mentoring Challenge: Following the students’ lead. Students in this group were extremely consistent about their interests and research question. Their research question changed very little over the six day period, from “Tracking eating disorders through hormonal irregularities in the menstrual cycle” (day 1) to “what is leptin's effect on the induction of the menstrual cycle?” (day 6). However, mentors expressed concern that this research question would lead to a model complex enough to have interesting dynamics: “You cut from [leptin] because that only can impact to the forward. You do not have anything feedback.” (day 2). Eventually, mentors simply forbade students to work on leptin and appetite. “This is your model, only focus on this one, no leptin yet… then, if there is time, you go adding the leptin.” (day 6).

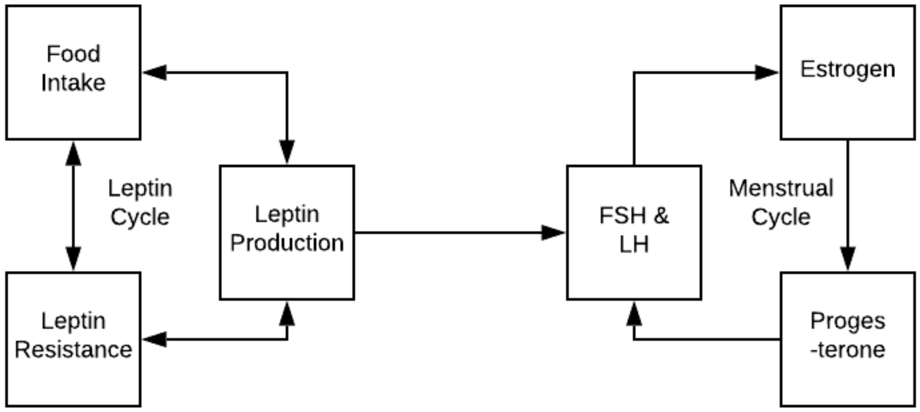

Figure 1. Leptin influences both eating habits and the release of hormones involved in the menstrual cycle.

This problem occurred because the students struggled to explain the mechanisms and relationships that they were interested in when describing their research question. Fundamentally their biological context had two feedback cycles: a cycle in which eating habits and leptin influence each other, and the cycle of hormones that regulate menstruation (Figure 1). What students were interested in studying was really the dynamics of eating disorders (Figure 2).

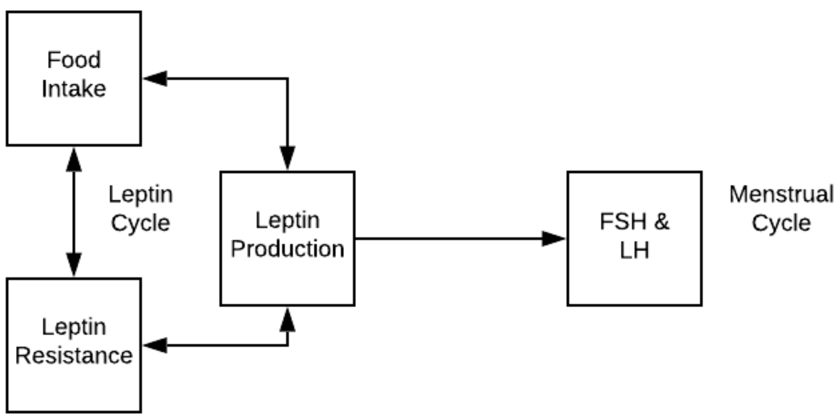

Figure 2. Representations of the part of the problem that held the students' interest.

The mentors had three objections. First was that there were other regulatory processes that influenced the hormones FSH and LH (Figure 1), and that made isolating these hormones from the entire menstrual cycle difficult. Second is that students focused early on leptin early on, and simplified their message to "We're studying the effect of leptin on the induction of the menstrual cycle." This created in the mentors an understanding that students were interested in studying a problem more like Figure 3. This led to the last objection: In both Figures 1 and 3, the effect of Leptin is only feed-forward. There was no obvious impact of the menstrual cycle on leptin production, meaning that leptin could be reduced to a simple input function in a menstrual cycle model, and didn't need to be studied dynamically.

Additionally, with the students found and presented prior modeling research on the menstrual cycle, and mentors, encouraged the students to dive deeper into these models, giving the project a greater and greater appearance of being about the menstrual cycle over time. The mentors did also make recommendations for prior modeling research on leptin, but as the mentors focused more and more on menstruation, opportunities to present leptin research didn't occur.

The students could likely have completed a successful project studying only the leptin cycle that would have been more in line with their interests. However, due to the problems in communication, the mentors steered the group towards a successful project studying only the menstrual cycle.

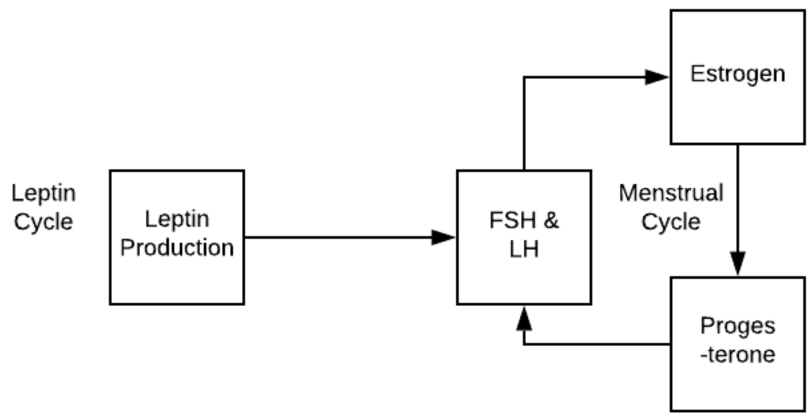

Figure 3. A depiction of a mentor's understanding of the menstrual cycle group's problem.

Student Challenge: Behavior vs. Mechanism. The menstrual group's communication difficulties were exacerbated by their confusion over biological behavior and mechanism. Students would answer questions about mechanisms with answers about biological behaviors. See this excerpt from day 2:

Mentor The levels of FHS and LH, how do they change?

Student: Here's a phase here called the follicular phase and that's where there's follicles that the FSH-- when the secretion of FSH happens, they create follicles that create granules that create the LH. Once the LH is there, these two hormones are able to mature the whole egg for release into the fallopian tube.

In this excerpt, the mentor is asking about mechanisms: asking the students to explain interactions that cause concentrations of FSH and LH to go up and down, or impact the rates at which these concentrations go up and down. The student responds not with an explanation of how FSH and LH change (a mechanism), but instead with an explanation of what FSH and LH do, how they impact the body (a behavior).

The idea of a mechanisms as a biological interaction that defines mathematical expressions is a relatively nuanced idea, and at least one mentor found it unsurprising that students struggled with this idea:

*Student***:** Can I ask a question? You're saying we're not understanding what is the mechanism. Honestly, I don't know what exactly that means in terms of mathematics I'm not sure what that means. Can you explain that to me?

Mentor: This is a very beautiful question that you're asking actually many of us are understanding in a different way also. That's why it will help you when you will draw that flowchart. We will precisely say, "Oh this is what we mean by saying mechanics." [The mentors] are using words like feedback which is almost the same thing as mechanism. Some people use different words for the same concept.

With feedback, students improved at describing mechanisms, “Estrogen at low concentrations has a decreasing effect on LH. The higher concentrations of estrogen, LH seems to have this peak at higher concentrations of estrogen” (day 3); however, they continued to struggle with this distinction and described biological behaviors when mechanisms were asked for: “FSH is entered through the ovaries through the capillaries.” (day 3).

The Tumor Model

Student Challenge: Finding a research question. The tumor group was interested in simulating the growth of a tumor in the lungs using a spatial model. However, with this focus on methodology, the students in the group struggled to find a research question. Over seven presentations and five days, the group proposed several different research questions, including studying the effect of a treatment strategy, studying attacks between cells, studying competition between cells for nutrients or space, or studying the internal processes of a cancerous cell in the lung. Finally with the encouragement of mentors who provide prior modeling research, the students settled on studying a tumor’s chemical defense against the immune system. What remained largely consistent for the group was the choice of topic: tumor growth in the lungs, and the choice of methodology: a two dimensional spatial simulation. The students were a group with a chosen topic and methodology in search of a problem.

Student Challenge: Mechanism vs. model. Part of the reason for the students’ difficulty in identifying a research question was that they struggled to understand the biology in terms of mechanisms of interaction. In contrast with the menstrual cycle group, which described biological behaviors instead of mechanisms, the tumor model frequently described abstract modeling concepts instead of mechanisms.

The core of the tumor model’s struggle was defining the concept of “fitness” in terms of mechanisms. The group wanted to explore a hypothesis that cells could sense the fitness of neighboring cells and induce apoptosis in neighboring cells that were less fit. However, the group struggled with explaining mechanisms that would determine which cells would win in an interaction cells. The could not identify what process a cell was sensing in a neighboring cell, how that process was being sensed, or what determined whether an attempt to induce apoptosis would be successful.

Definitions of fitness given by the students included “an ability of the cell to thrive in a given environment” (day 1), the growth rate of a cell (day 2), a change in the equilibrium of the tissue (day 2), “how normal the cell is” (day 2), “the length of a cell’s cycle” (day 2), “the rate of protein synthesis” (day 2), and the number of cells that a cell divided into (day 2). Several of these ideas, such as “ability of a cell to thrive” or “how normal a cell” is were based on abstract concepts that a modeler might define a measure for, but that a cell would not be able to sense. Others, such as the number of cells a cell divided into, required access to information that the cell could not react to for the fitness sensing hypothesis, because the replication would have already completed. Some of these ideas, such as the rate of protein synthesis, provided potential explanations for what a neighboring cell might be sensing, but students did not follow up on these ideas. Students also answered questions about this fitness sensing process with modeling rules and assumptions, such as: “We wanted to do a spatial model using a grid… If the neighbor cells will have more fitness, it would be able to occupy their space.” (day 2).

One complete mechanistic explanation that the students provided was that a cell would sense a nearby cell’s preparation to divide and release a toxin, and that tumor cells were more fit because they were resistant to the toxin. However, this explanation was not consistent with the hypothesis that neighboring cells sensed “fitness,” as the fitness mechanism occurred after the cell released its toxin, instead of the toxin being released in response to what the cell sensed.

Ultimately students abandoned the fitness sensing hypothesis, and instead built their research question on a previously published model for the interaction between the immune system an tumor growth, focusing on the ability of tumor cells to inhibit the maturation of immune cells by releasing a chemical. The students retained the interest in spatial models and cancer modeling by focusing on the local effects of the chemical release on interactions between tumor cell and immune cell pairs.

Mentor Challenge: Letting students explain at their own pace. Once the students settled on a research question, they developed a spatial continuous time Markov-chain model to simulate the tumor growth. However, the students were not familiar with this terminology, and instead explained the model as a cellular automaton. “We're going to model this with a stochastic cellular automata where our events are going to be discreet and the time of the transmission between the pair of events is going to be continuous.” (day 5 presentation 1). The students had an outline in mind, where they would introduce the idea of a stochastic cellular automata, then random time between events, the list of possible events, examples of these events, and then finally introduce equations for how the probabilities of events were calculated. However, the students were quickly thrown off script.

One mentor focused on the idea of cellular automaton and imagined a simulation driven by simple rules, similar to Conway’s Game of Life. This mentor expected a slide of rules that would be explained all at once. The students felt their simulation was much more complex, and wanted to explain rules and interactions one at a time. This created in mentors the impression that students did not understand the rules that governed their simulation: “Please go learn about Conway's Game of Life and then this will make it much clearer” (day 5 presentation 1), “If T encounters this condition it does this. If T encounters this condition, you do this. You have to work all this out otherwise you're not going to be able to do it.” (day 5 presentation 1). The students were called back for a second presentation on the same day.

In the second presentation, the students maintained a similar structure. Introducing the random time between events before moving to a list of events. “We consider continuous-time Poisson process, the events on the wheel and the waiting time between events are continuous, distributed as exponential” (day 5, presentation 2). The main difference in the presentation was that as one student discussed each event on their slides, another student wrote the equation for the probability of the event on the whiteboard. Mentors were much more receptive in this second presentation, offering direct feedback on the equations and identifying the methodology as a “standard continuous time Markov chain” (day 5, presentation 2). In total, the first presentation lasted almost 42 minutes, while the second presentation was completed in under 10 minutes.

One factor that may have contributed to the mentors’ responses to the first presentation is concern about time. Mentors had previously expressed concern about the short time frame left to complete the project “Remember you have three weeks” (day 4), and this presentation on day 5 was supposed to be the second to last presentation, meaning the mentors had only one more opportunity to review the students’ model as a whole group. The time pressure may have contributed to the mentors’ anxiety about students not having a model or not presenting the model efficiently, leading mentors to take more control of the presentation than was helpful.

Discussion

Both groups of students struggled to understand the modeling concept of a mechanism. The menstrual cycle group identified biological behaviors – such as the maturation of a follicle, or the release of a hormone – rather than identifying causes of those behaviors. They also struggled with identifying mathematical quantities such as the concentration of a hormone, describing instead qualitative behaviors. The tumor group also struggled with identifying mechanisms, although rather than focus on biological behaviors, the tumor group identified abstract constructs such as fitness, and struggled with connecting those modeling concepts to biological behaviors such as sensing the concentration of a particular protein.

While the students struggled with identifying mechanisms, the mentors struggled with letting students take charge. In the case of the menstrual group, concerns about the potential for the project to generate interesting dynamics caused mentors to encourage students to move away from their interest in eating disorders to focus more on the menstrual cycle. In the case of the tumor group, taking charge of the research question was necessary. The students’ focus was primarily on methodology (a spatial simulation of cancer), and they struggled with identifying a problem that would match that methodology while providing innovative insights. Where mentors struggled with the tumor group was letting students take control of the presentation and present the tumor model in a way that made sense to the students. This may have been due to anxiety about the remaining time, or difficulty trusting in the students’ ability to construct a model.

These anxieties are not unique to faculty. For example, Smith et. al. (2021) found that pre-service teachers of mathematics also struggled with anxiety related to trusting students with open ended projects: concerns that students would be capable of completing the project, and anxiety about letting go of control of the classroom. Similarly, the mentors felt anxiety about the tumor group’s ability to construct a model in the one day remaining and took control of the presentation on day 5. In the menstrual group, anxiety about student’s ability to construct an interesting model also led mentors to take some control away from the group, but in a more subtle way.

Although neither group completed the project that the students initially envisioned, both groups successfully completed a project related to their initial idea. And the students in both groups expressed satisfaction and pride in their projects when they were complete.

Conclusion

The students in this study had stated interests in topics, and the mentors were concerned with ensuring that students could complete a scientifically significant project within the time limit. In both cases, students struggled to explain the mechanisms of their projects to mentors, and this led mentors to take more control over the direction of the projects. Understanding and identifying mechanisms is a key challenge in mathematical biology (Reed, 2004), and scientists continue to debate the precise meaning of the term (Craver & Taber, 2015; Hunt et al., 2018). More research is needed in the area of how scientists, mathematicians, engineers, and students understand mechanisms differently.

How do students think about inverses across contexts? Theory-building via a standalone literature review

The topic of inverse is one of the most ubiquitous and important in the K-16 mathematics curriculum. We observe that the literature base on inverses is substantial yet context-specific and therefore compartmentalized. In other words, though much research examines students' reasoning with inverses within algebraic contexts, it is currently unclear what might be involved in productively reasoning with inverses across algebraic contexts. To address this issue, we employed a theory-building methodology for systematic, standalone literature reviews to develop a conceptual analysis for inverses across contexts. Our findings include the explicit description and illustration of three cross-context ways of thinking about inverse: inverse as an undoing, inverse as a manipulation of the original element, and inverse as a coordination of the binary operation, identity, and set.

Keywords: inverses, ways of thinking, conceptual analysis, standalone literature review

Introduction

Few topics are as ubiquitous throughout the K-16 mathematics curriculum – and, indeed, in mathematics itself – as inverses. Inverses are initially treated at the elementary level in the context of basic arithmetic operations (in the form of subtraction/additive inverses and division/multiplicative inverses) and eventually manifest in a variety of forms at the secondary level as students engage with the real numbers, functions, and matrices. Undergraduate mathematics majors encounter inverse across a broad spectrum of additional contexts, such as modular arithmetic and symmetries of planar polygons. Students' activity with inverses has generally been well-documented, yet much of what is known concerns only to how students reason *within* specific contexts and thus in its current form provides limited insight into how students might reason with inverses *across* algebraic contexts. Thus, in this study we seek answers to the following research question: what ways of thinking are necessary for reasoning productively with inverses across contexts? To answer this question, in this study we bring coherence to the extensive (yet largely context-specific and, hence, disconnected) literature base on inverses by employing a theory-building methodology for systematic, standalone literature reviews (Wolfswinkel et al., 2011). The theory we develop takes the form of a *conceptual analysis* (Thompson, 2008) in which we explicitly describe and illustrate three cross-context ways of thinking about inverse: *inverse as an undoing*, *inverse as a manipulation of the original element*, and *inverse as a coordination of the binary operation, identity, and set*.

Background

Fink (2014) characterized a standalone literature review as a "systematic, explicit, and reproducible method for identifying, evaluating, and synthesizing the existing body of completed and recorded work produced by researchers, scholars, and practitioners" (p. 3). The word *standalone* is used to distinguish such reviews from those found in typical research articles, which usually do not explicate their inclusion criteria or offer a substantial enough contribution without being paired with the study for which they provide context. Standalone literature reviews, on the other hand, provide explicit search parameters and inclusion criteria, clear descriptions of the analytical techniques, and produce a substantial contribution to the field without collecting any new primary data. The nature of these contributions can vary: while such reviews are often conducted to establish a certain threshold of evidence in favor of a particular policy, strategy, or intervention, they can also serve as a means by which to build theory – that is, to develop "a framework for positioning [future] research endeavors" (Okoli, 2015, p. 3). Wolfswinkel and colleagues (2011) argued that such an approach can help researchers to "extract the full theoretical value out of a well-chosen set of published articles" (p. 2).

Before proceeding, we note that the kinds of research questions we are asking are often associated with methodologies that involve direct interactions with students, such as task-based clinical interviews (e.g. Goldin, 2000) and teaching experiments (e.g. Steffe & Thompson, 2000). This raises a natural question: why answer these questions by conducting a systematic, standalone literature review instead of these more conventional methodologies? First, we propose that the full theoretical value of the inverses literature is currently not being realized: inverses are ubiquitous in the literature, yet nearly all of this literature focuses on students' reasoning *within* particular algebraic contexts and thus there is no coherent, overarching theoretical perspective for analyzing students' reasoning with inverses *across* algebraic contexts. Conducting a standalone literature review therefore offers a rich opportunity to "extract the full theoretical value" from the context-specific inverses literature to develop a coherent cross-context theory. Second, the kind of theory we aim to develop in this study (e.g. a cross-context conceptual analysis of inverse) is an essential tool that informs the conduct of teaching experiments and task-based interviews, yet, as we have noted, no such theory currently exists. Thus, we see the development of a conceptual analysis using a standalone literature review methodology as a precursor to – and not a replacement of – more conventional methodologies involving direct interactions with students.

Theoretical Perspective

Conceptual Analysis

The theory that we develop will take the form of a *conceptual analysis*. A conceptual analysis is an explicit description of "what students might understand when they know a particular idea in various ways" (Thompson, 2008, p. 57). The conceptual analysis we develop in this paper explicitly describes ways of thinking "that might be propitious for students' mathematical learning" (Thompson, 2008, p. 60). Specifically, we are interested in identifying and explicating ways of thinking about inverse that can support productive reasoning with inverse across algebraic contexts. A conceptual analysis can also serve as an integral component of what diSessa and Cobb (2004) call a *domain-specific instructional theory*, informing the selection of productive ways of thinking targeted in learning trajectories and also providing a mechanism with which to analyze and build upon students' thinking along that trajectory (e.g. Simon & Tzur, 2004).

Ways of Understanding and Ways of Thinking

We view students' reasoning in terms of Harel's (2008) *ways of understanding* and *ways of thinking*. These constructs afford a way to distinguish between and characterize students' mathematical thinking at various levels. Ways of understanding are the cognitive products of a mental act – that is, the explanations, descriptions, and procedures that one utilizes in response to a specific scenario. Ways of thinking, on the other hand, are broader perspectives and habits of mind that can be utilized to reason about a variety of scenarios and tasks. These can be inferred by identifying "common cognitive characteristics among [a] multitude of products of each act" (Harel, 2008, p. 497). That is, researchers infer ways of thinking by examining the common characteristics that manifest amongst students' ways of understanding. Though Harel did not set a specific number of times in which one must observe such common characteristics, we infer from his use of 'multitude of products' that such characteristics should be observed across at least two ways of understanding in at least two different contexts.

These constructs provide a clear, tractable way to characterize and illuminate key elements of students' reasoning about inverses. As ways of understanding are the explanations, descriptions, and procedures that one uses in *specific* scenarios, we therefore consider the explanations, descriptions, and procedures that a person associates with inverse within a *specific* algebraic context to comprise that person's ways of understanding inverse. A way of thinking about inverse is therefore inherently more general (and not specific to a single context) because it involves common elements observed in students' ways of understanding in a multitude of algebraic contexts. In this way, ways of understanding characterize elements of students' reasoning about inverses *within* an algebraic contexts while ways of thinking provide the desired insight into what is involved in reasoning productively with inverses *across* algebraic contexts.

The current study involves analyzing the descriptions, explanations, and procedures related to inverse exhibited in published research articles across the K-16 mathematics curriculum. Typically, ways of thinking and ways of understanding are constructs used to explain the mathematical activity of an individual – a way of thinking is characterized by patterns in that individual's reasoning. The current study, however, involves identifying commonalities exhibited across the ways of understanding of multiple (perhaps many) individuals. To resolve this issue, we employ Thompson's (2002) notion of an *epistemic student*, which is a mental depiction of a hypothetical student that a researcher develops in order to explain her mathematical activity. Thompson (2002) notes that "images of this type allow us to propose ways of thinking that are not specific to any one person" (p. 195). Thus, in order to thematically organize and identify common characteristics amongst the ways of understanding inverse that appear in the literature, we do so by imagining that these ways of understanding were exhibited by a particular epistemic student.

Methods

We follow Wolfswinkel and colleagues' (2011) 5-stage process for conducting standalone, theory-building literature reviews. Our procedures are summarized in Table 1.

Table 1. Summary of data collection and analysis procedures and results

Stage		General descriptions outlined by Wolfswinkel and colleagues (2011)	Summary of procedures
Data collection	1	*Define* the search parameters and outlets	Google scholar search for "inverse" in 7 high-quality mathematics education journals
	2	*Search* for relevant articles using the procedures outlined in Stage 1	Executing the search parameters yielded 895 potentially relevant articles

	3	*Select* relevant papers that resulted from the search in Stage 2	We *included* articles in which "inverse" was mentioned (a) on at least 30% of the pages in the article, and (b) at least 10 times total. We *excluded* articles in which "inverse" was used primarily in the context of logic, functional variation, and probability. This resulted in 53 relevant articles.
Data analysis	4	*Analyze* the papers that are selected in Stage 3 in order to develop a theory	Conducted a *thematic analysis* (Braun & Clarke, 2006) of all 53 papers in the sample to identify, describe, and illustrate ways of thinking about inverse
	5	*Present* the categories of the theory that emerged in Stage 4	Related the cross-context ways of thinking and associated themes to research questions and selected vivid excerpts to illustrate these ideas in the paper

In Stage 1 (Define), we used Google Scholar's "advanced search" feature to search for the word "inverse" in each of the 7 journals that were consistently rated as being of "high" or "very high" quality by both of the most recent assessments of journal quality (Toerner & Arzarello, 2012; Williams & Leatham, 2017): *Journal for Research in Mathematics Education*, *Educational Studies in Mathematics*, *ZDM*, *Journal of Mathematical Behavior*, *Journal of Mathematics Teacher Education*, *For the Learning of Mathematics*, and *Mathematical Thinking and Learning*. Stage 2 (*Search*) produced a list of 895 potentially relevant articles. In Stage 3 (select), we selected papers in which (a) the percentage of pages in the article containing the word "inverse" is at least 30%, and (b) the word "inverse" is mentioned at least 10 times. These criteria narrowed the list to 61 articles. We then recorded the algebraic context(s) in which inverses were discussed for each, removing in the process 8 articles invoking a meaning of inverse that we deemed irrelevant for our purposes (e.g. the inverse of a conditional statement in logic, inverse variation of quantities, and inverse probabilities). Our final sample of 53 articles is listed in a special section ('Bibliography of the 53 Articles in Our Sample') after the references.

For Stage 4 (Analyze) and Stage 5 (Present), we used *thematic analysis* (Braun & Clarke, 2006) to analyze of all 53 papers in the sample. Thematic analysis aims to develop theory by "systematically identifying, organizing, and offering insight into patterns of meaning (themes) across a data set" (Braun & Clarke, 2006, p. 57). This aligned with the overarching goal of our literature review: to develop a coherent, unifying theory that shines light on themes related to students' reasoning with inverses that are present but perhaps obscured due to the context-specific and fragmented nature of the inverses literature. It also aligned with our theoretical perspective: common themes observed across ways of understanding within particular contexts would emerge as the definitive characteristics of the desired cross-context ways of thinking about inverse.

Results

Inverse as an Undoing

Inverse as an undoing is a way of thinking about inverses in which "inverse is associated with an operation that cancels the previous operation and 'returns to the starting point'" (Zazkis & Kontorovich, 2016, p. 107). We highlight two definitive characteristics:

- *Characteristic U1*: inverse is viewed as an operation (or a sequence of operations)
- *Characteristic U2*: the operation (or sequence of operations) is applied to undo or cancel the effects of the original operation

The following excerpts illustrate various ways of understanding exhibited by students that we associate with *inverse as an undoing* within particular contexts (specified via the set and relevant binary operation):

- *Real numbers*: "The unknown was multiplied by 4 and then 17 was added. I can undo it by first subtracting 17 and then dividing by 4, thus the unknown is 15" (Selter et al., 2012, p. 403).
- *Functions*: "If I were to put 5 into $f(x)$ I would get 8, I would then show them that if I put 8 in $f^{-1}(x)$ then I would get the number I started with originally" (Weber et al., 2020, p. 14).
- *Linear transformations*: "You're pretty much transforming [the vector] into something else, and the inverse really just transforming to, or transforming it back to what it originally was" (Bagley, Rasmussen, & Zandieh, 2015, p. 40).
- *Symmetries of regular polygons*: "**Jessica:** Because any time you go clockwise and then counterclockwise, you're just going back to your spot. The same spot that you started with. **Sandra:** That's a good observation. … you're going to end up with nothing. So they're all just canceling, these four moves are just basically canceling each other out" (Larsen, 2009, p. 124).

Inverse as an undoing is compatible with the notion of *inversion*, a construct from the K-8 literature that involves "recognizing that adding and then subtracting the same number (or vice versa) leaves any initial number unchanged" (Baroody & Lai, 2007, p. 131). For example, "a child might induce that adding 1 to any (small) collection can be undone by taking 1 away" (p. 132). Notice that this description focuses on the relationship between the *operations* of addition and subtraction (Characteristic U1) and, specifically, how addition "can be undone" by subtraction (Characteristic U2).

Inverse as a Manipulation of the Original Element

Inverse as a manipulation of the original element is a way of thinking in which inverse is associated with a procedure by which a given element can be manipulated into its inverse element. This way of thinking is consistent with the observations of researchers that some students might understand inverse exclusively in terms of the application of inverse *procedures* (e.g. Paoletti et al., 2018; Wasserman, 2017). We identified two definitive characteristics:

- *Characteristic M1:* inverse is viewed as an *element*;
- *Characteristic M2:* inverse is associated with a procedure by which a given element is manipulated into its inverse element.

Examples of ways of understanding that we associated with this way of thinking are included below; selected illustrations that we associated with this procedure are shown in Table 2.

- *Real numbers*: Additive inverses can be found via "a unary function requiring a single input (the 'opposite of x' denoted by -x)" (McGowen & Tall, 2013, p. 529) – this function involves multiplying the original element by -1.
- *Real numbers*: "'flipping' the numerator and denominator of a fraction creates an inverse element to an original fraction" (Zazkis & Mamolo, 2011, p. 12).
- *Functions*: "We rewrite the […] relation which represents the inverse function of the given function, as $y = (x-3)/2$, by which we mean switching the variable x with the variable y in the equation which was found, after solving it in terms of *y*" (Pinto & Schubring, 2018, p. 901).

Table 2: Illustrations of procedures associated with *inverse as a manipulation*

Matrices (multiplication)	Complex numbers (addition)	Modular arithmetic (addition mod 99)
 (Kazunga & Bansilal, 2020, p. 349)	 (McGowen & Tall, 2013, p. 530)	 (Simpson & Stehlikova, 2006, p. 359)

Inverse as a Coordination of the Binary Operation, Identity, and Set

Inverse as a coordination of the binary operation, identity, and set is a way of thinking in which inverse is viewed as a relationship between a pair of elements of the set in question, the relevant binary operation, and the relevant identity element – specifically, that the combination of an element and its inverse element via the relevant binary operation yields the relevant identity element. We define it via the following three characteristics:

- *Characteristic C1* (binary operation): inverse is viewed in terms of as relationship between elements and their image with respect to the relevant binary operation
- *Characteristic C2* (identity): involves an explicit awareness that the two elements that combine (with the relevant binary operation) to yield the identity element are inverses if and only if their combination yields the relevant identity element
- *Characteristic C3* (set): attends to the fact that both an element and its inverse element are elements of the set in question

The following excerpts are representative of ways of understanding exhibited by students that we associate with *inverse as a coordination* (see also Table 3, which includes images of students' inscriptions that illustrate similar ways of understanding):

- *Real numbers (addition)*: "So we need to actually add 8 in order to do that. […] when you have a number and its additive inverse. When you add those together we get the additive identity zero. So we actually created a zero pair here" (Clay, Silverman, Fisher, 2012, p. 769).
- *Functions (composition)*: "If you're composing functions and you compose the function with its inverse, […] it produces the identity function. So you plug in '*a*' to that

composition, then you get out '*a*'. So we know that functions are a group (pause) and the identity function serves as the identity for that group, composition being the binary operation" (Wasserman, 2017, p. 189).

Table 3: Illustrations of student inscriptions associated with *inverse as a coordination*

Matrices	Symmetries of regular polygons	Modular arithmetic (modulo 99)
$\begin{bmatrix} 1 & 0 \\ 1 & -2 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ \frac{1}{2} & -\frac{1}{2} \end{bmatrix}=\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ (Bagley et al., 2015, p. 42)	~~If~~ For every move A, if ~~A·B=B·A then~~ A·B=B·A=I, then B is the inverse of A written A^{-1}. Every move has an inverse. (Larsen, 2009, p. 125)	$4 \oplus 95 = 99$ (Simpson & Stehlikova, 2006, p. 359)

Consider, for example, the excerpt above concerning the compositional inverse of a function. Characteristic C1 is readily observable, as the student explicitly mentions composition several times (e.g. "composing functions", "composing the function with its inverse," "composition being the binary operation"). The same is true for Characteristic C2, as the student explicitly identifies that a function composed with its inverse function "produces the identity function." Characteristic C3 is observable but perhaps less explicit: the student refers to "composing *functions*," suggesting that, when he refers to composing "the function with its inverse," he is aware that the inverse is also a function (and therefore a member of the same *set*).

Discussion

The primary contribution of this study is the conceptual analysis of inverse, which provides detailed descriptions of three ways of thinking about inverse: *inverse as an undoing*, *inverse as a manipulation of the original element*, and *inverse as a coordination of the binary operation, identity, and set*. The fact that it can be used to describe the nature of students' reasoning about inverses across contexts makes it – to our knowledge – the only one of its kind in the literature. In addition to venturing ways of thinking that can support productive reasoning with inverses, we note that this framework takes a key step towards bringing coherence to the inverses literature. Though space constraints have prevented us from exploring these ways of thinking in greater detail, here we shall simply note our primary claim: all three of these ways of thinking play a key role in supporting productive reasoning with inverses across algebraic contexts. Though this claim (which, we acknowledge, is not directly addressed in this short report) is supported by the literature, the theoretical nature of its derivation leaves two possibilities for empirical refinement and extension. The first is simply testing (and perhaps refining) this claim using methodologies that involve direct interactions with students. The second involves investigating how students might be supported in developing these three ways of thinking using, for example, the teaching experiment methodology.

We would also like to call attention to the standalone literature review methodology and its value. In the current study, this methodology enabled us to unearth valuable insights about the nature of reasoning about inverses that were indeed already documented in the literature (in some cases very well so) but were far from being widely recognized. More generally, we suspect that the inverses literature is not unique in being fractured and compartmentalized. We therefore see the methodology we employed in this study as a mechanism that researchers can use to combat this issue, particularly in cognitive research as a means of developing an initial conceptual analysis prior to conducting task-based interview or teaching experiments.

Observing Intellectual Need in Online Instructional Tasks

Douglas L. Corey

Michael Tallman
Oklahoma State University

The idea of intellectual need, which proposes that learning is the result of students wrestling with a problem that is unsolvable by their current knowledge, has been used in instructional design for many years. However, prior research has not described a way to empirically determine whether, and to what extent, students' experience intellectual need. In this paper, we present a methodology to identify students' intellectual need and also report the results of a study that investigated students' reactions to intellectual need-provoking tasks in first-semester calculus classes.

Keywords: Intellectual Need, Instructional Videos, Flipped Pedagogy

Problem solving has long been viewed as both an essential source and product of mathematical learning. However, Fuller, Rabin, and Harel (2011) characterize much of students' engagement with mathematics as "problem-free" in the sense that the mathematical "problems" students encounter can ordinarily be completed by applying skills and understandings previously developed, and thus are better characterized as "exercises." In contrast, "problem-laden" activity originates in and is sustained by students' construction of a problem in such a way that they (1) recognize their current knowledge structures as insufficient to solve the problem, and (2) construct an image of the understandings that would enable them to progress towards a solution. To address this issue, Harel (1998) proposed the *necessity principle*: "For students to learn what we intend to teach them, they must have a need for it, where 'need' refers to intellectual need" (p. 501). Although the construct of intellectual need has been widely applied in instructional design (e.g., Harel, 2013b; Koichu, 2012; Caglayan, 2015; Foster & de Villers, 2015) and analysis (e.g., Rabin, Fuller, & Harel, 2013; Zazkis & Kontorovich, 2016), prior research has not developed methods for empirically identifying students' experiences of intellectual need.

The goal of this paper is to explore the possibility of explicitly identifying students' self-reported experiences of intellectual need and to examine related factors that might be associated with these experiences. In addition, we seek to explore the relationships between students' experiences of intellectual need and their learning from instructional videos that were designed to present solutions to intellectual need-provoking [IN-P] tasks and to explicate the understandings and ways of reasoning required to construct these solutions.

Theoretical Framework

The concept of intellectual need is situated within an elaborate theoretical framework called *DNR-based instruction in mathematics* (Harel, 2008a) and is informed by two key theoretical premises: the *Knowing Premise* and the *Knowing-Knowledge Linkage Premise*. The Knowing Premise states, "Knowing is a developmental process that proceeds through a continual tension between assimilation and accommodation, directed toward a (temporary) equilibrium" (Harel, 2008b, p. 894). Relatedly, the Knowing-Knowledge Linkage Premise states, "Any piece of knowledge humans know is an outcome of their resolution of a problematic situation" (Harel, 2008b, p. 894). The Knowing and Knowing-Knowledge premises derive from Piaget's (1971) genetic epistemology and von Glasersfeld's (1995) radical constructivism.

Informed by the Knowing and Knowing-Knowledge Linkage Premises, Harel (2013b) describes intellectual need as the perceived need to resolve “a perturbational state resulting from an individual’s encounter with a situation that is incompatible with, or presents a problem that is unsolvable by, his or her current knowledge” (p. 122). This perturbation is rooted in the individual’s experience within the discipline and is based on “the learner’s discernment of how and why a particular piece of knowledge came to be” (Harel, 2013a, p. 8).

Intellectual need is distinct from *psychological need*, which is the motivation a student experiences to initially engage in the process of solving a problem (Harel, 2008). Harel (2013b) suggests that psychological need is often linked to students’ perceived obligation to participate in school, to increase social or economic status, or to advance societal goals. In particular, a student’s perception of how interesting or enjoyable they find the context could influence their motivation for engaging and persevering in solving the problem.

There is little discussion in the research literature of what might constitute evidence for students’ experiences of intellectual need. In most research, claims of students experiencing intellectual need have been associated with students’ expressions or activity that indicates puzzlement or curiosity. However, the data-collection protocols used in these studies did not appear to explicitly interrogate students’ experiences of these psychological states or the assimilations that occasioned them.

For this study, we operationalize intellectual need by using the colloquial ideas of puzzlement and curiosity. That is, we can ask students whether they felt curious or were left wondering about something as they engaged in a task or problem context. We also distinguish these feelings vis-a-vis the intellectual content of the task from the student’s interest in the underlying context—that is, an aspect of their psychological need for engaging in the task.

Research Questions

The goal of our study is to identify instances in which students experience intellectual need and some factors that are related to this experience, as well as their learning from the associated instructional videos. Thus, our research questions are:

1. How much variation of students’ intellectual need is there between video sets (i.e., collections of instructional videos, pre/post-video questions, and related material for topics in first-semester calculus)?
2. Are different instructors associated with different rates of students’ intellectual need?
3. Does trying an intellectual need-provoking [IN-P] task and/or watching a student problem-solving video lead to a higher rate of intellectual need?
4. Does a student’s mathematical background knowledge predict their experience of intellectual need?
5. Is there a relationship between psychological need and intellectual need?
6. Is there a relationship between students’ intellectual need and their learning from the associated collection of instructional videos?

Methodology

Our methodology addresses three issues: First, we needed a way to potentially provoke students’ intellectual need. Second, we needed a way to adapt these provocations to an online environment. Third, we needed a way to identify students’ experiences of intellectual need.

Provoking Intellectual Need: Task Construction

We needed to engage students in tasks that had the potential to provoke intellectual need. For each mathematical topic we investigated we examined the epistemology of the underlying concepts and procedures, the curriculum in which the concepts were embedded, and the research literature about the likely background knowledge of the students who would be enrolled in the class. Then, we collaboratively designed a problem for which the target concept was required to arrive at a solution and that provided an opportunity for a student to experience a perturbational state while working on the task or watching the associated student problem-solving video (described below). We also endeavored to situate the problem within a context that, we felt, might be interesting to the student population.

Adapting to an Online Environment: Student Problem-Solving Videos

We hypothesized that simply viewing and trying to solve a task might not lead a student to experience perturbation. In particular, we thought it might be possible for students to not realize that their initial way of thinking about a problem might be inadequate. Thus, we sought a way to help students identify shortcomings in their solution methods or reasoning about the tasks. To do this, we designed a "student problem-solving video" to accompany each IN-P task. In each video, a pair of actors posed as calculus students and attempted to solve the task. These videos were loosely scripted so that the actors demonstrated a variety of compelling ways of thinking about the task and concept that incorporated common student (mis)conceptions about the concept. The videos were presented to the students after they had attempted the IN-P task.

Identifying Intellectual and Psychological Need

After interrogating the concept of intellectual need, we felt that the terms "curiosity" and "wonder" were closely related descriptors. After attempting the IN-P task and watching the student problem-solving video, the students were asked the following two questions:

1. The task you just worked on dealt with the context of [context—e.g., "the speed of a baseball"]. In your honest opinion, how interesting/enjoyable was this context?
2. When you were working on this task, were there any parts where you genuinely were curious or were left wondering about something? If so, please state them in the box below; if not, please leave the box empty.

The first question was designed to enable students to self-identify an experience of psychological need; the second question was designed to enable students to self-identify an experience of intellectual need. Throughout the results, when we refer to a student experiencing an intellectual or psychological need, we mean that they responded "yes" to the corresponding question above.

Materials, Participants & Methods

Materials

We designed a set of 1-3 instructional videos for each of 30 target concepts in introductory calculus; each set of videos included a solution to one of the IN-P tasks and some additional explanation of the underlying concept. We also created a collection of multiple-choice and computational problems to be solved prior to and after watching the instructional videos, an IN-P task, and a student problem-solving video. For each video set, each student was randomly assigned to either try the IN-P task or not and to see the student problem-solving video or not.

Participants

The participants in the study were 2,733 students who were enrolled in first-semester calculus classes at one of 18 universities during the fall, 2018 and spring, 2019 semesters. The universities included both public and private institutions, ranging in size from just over 3,000 to over 35,000 students, from all regions of the United States and one institution in Indonesia. The institutions included small, private colleges through large, research-focused universities.

One member of the research team was the calculus course coordinator at their institution (a large, public university in the South-Central United States; we will refer to this as the Coordinated Institution) and incorporated a subset of the video sets into the curriculum during both the fall, 2018 and spring, 2019 semesters, for a total of 15 instructors coordinated sections. The other 18 instructors (33 instructors total) were voluntarily participating in the project research, and each selected a subset of the video sets to incorporate into their curriculum.

Statistical Design

We coded students as experiencing intellectual need if they responded "yes" to the question described in the methodology and experiencing psychological need if they indicated they found the context "somewhat" or "very" interesting. We measured students' background knowledge by the percent of pre-video questions they answered correctly, and coded students as having learned from the instructional videos if their score on the post-video questions was higher than on the pre-video questions.

Due to the nested and cross-nested nature of our data, we used Hierarchical Linear Models (Raudenbush & Bryk, 2002) to perform our statistical analysis. We use two models to answer our research questions: one with intellectual need as the outcome, and one indicating growth from pre-video questions to post-video questions as an outcome. Since both of our outcome variables were measured as a 1 or 0, the regression at the lowest level is a GLM model using logistic regression. The predictor variables in our models included whether or not the student saw the IN-P task; whether the IN-P task was computationally focused or not; the student's score on the pre-video questions, the number of the video set in the semester, whether a student watch the student problem-solving video; whether or not the student was at the large, coordinated institution; and, for the learning model, the student's response to the intellectual need question. Due to space constraints, we report results for only a subset of these variables. The models were run with about 26,000 online lessons, 1550 students, 25 instructors, 14 institutions, on 30 topics. This data set was smaller than the original dataset due to missing data, or small number of students in some classes/institutions.

Results

Unconditional Model for Intellectual Need

We ran unconditional mixed models to understand the variation at the student, instructor, and video set levels. We found that a typical student working on a typical video set from a typical instructor would experience an intellectual need in 4.5% of the video sets. However, different students have different rates at which they report experiencing an intellectual need: students 1 standard deviation less than the mean only report experiencing an intellectual need on 1.3% of the video sets and students 1 SD above the mean report it at 14.5%. There is similarly large variation between instructors (1.4% to 13.5%), and this increases to (0.4% to 35%) for two standard deviations. This means that some teachers rarely have average students (in a typical lesson) who report experiencing an intellectual need, while at the other end, some teachers have average students reporting an intellectual need on about a third of the video sets.

Because most institutions in our data set are represented by a single instructor, it is difficult to tease apart variation due to instructor and variation due to institution, curriculum, or pedagogy. To address this, we ran an unconditional model using only the data of the coordinated institution and found that the standard deviation at the instructor level was only 10% less than at the other institutions. The variation across video sets is less than between teachers or between students in a class, but the two standard-deviation range is 2% to 9.6%. This shows that some lessons are nearly 5 times more likely to generate an intellectual need than others. At the coordinated institution, the standard deviation across video sets was 20% lower.

Conditional Model for Intellectual Need

The results of the conditional mixed model with intellectual need as an outcome are displayed in Table 1. The asterisks indicate the level of statistical significance (i.e., * designates the result was significant at the p=0.05 level; ** indicates significance at the p=0.01 level; and *** at the p=0.001 level). The coefficients are given in log-odds. The percentages for the coefficients are marginal percentages given a unit increase in the variable from the model intercept, with all other variables equal to zero. The percentages are not additive like in a linear regression model, and the effect of a variable could be larger or smaller than the listed percentage depending on the values of other variables.

Variable	IN Outcome Coefficient	Marginal Percentages
Intercept	-2.12***	10.7%
IN-P Task (*IT*)	-0.294***	-2.5%
Problem-Solving Video (*V*)	-0.553***	-4.2%
*IT***V*	0.532***	6.3%
Psychological Need	0.382**	4.3%
Pre-Test Score	0.768**	9.9% per SD
Lesson Order	-0.044***	-0.4% per lesson
Coordinated Institution	-1.35***	-7.7%

Table 1. Results of the conditional mixed model for intellectual need.

We summarize these results below:

- Both the effects of trying the IN-P task and watching the video are, individually, negative. However, the effects are not additive, and there is a significant interaction term between the two predictors. Thus, students who both saw the IN-P task and the student problem-solving video were more likely to report experiencing an intellectual need than students that only saw the video.
- Typical students are about 40% more likely to report a self-reported IN if they report experiencing a psychological need.
- Students with above average pre-video achievement scores (1 SD above average), are almost twice as likely to report having an intellectual need.
- The rate at which students reported having an intellectual need decreased, on average, across the semester. Lessons near the beginning of the semester had a rate of 16.9%, while lessons near the end had an average rate of 6.9%, for students with zeros on all other variables.

Models for Learning

The unconditional Learning model shows that a typical student would improve from their pre-video to post-video score on 42.4% of the typical video sets. The conditional model for Learning shows that there is a significant positive association between experiencing intellectual need and learning. Typical students show evidence of learning on about 7% more lessons if they experience an intellectual need, an increase of about 23% (from the average/intercept of 29.9% up to 36.8% of lessons) over students that do not experience an intellectual need.

Discussion

Methodological Contributions

One significant contribution of this study is the methods and methodology to empirically identify students' experiences of intellectual need. This included developing tasks to provoke intellectual need, videos related to each task to help students recognize the need, and survey questions—administered at the point where we thought students might be experiencing disequilibrium—to enable students to report feelings of psychological and intellectual need.

There are several potential shortcomings of the methodology. We don't know whether "curiosity" and "wonderment" are the most appropriate terms to identify intellectual need, and students' self-identification might be inaccurate. Students might have been reluctant to respond affirmatively to the intellectual need question because doing so would require them to write additional information, this is supported by the significance of the Lesson Order predictor. Finally, we don't know the extent to which intellectual need can be provoked by a single task, even when the task is accompanied with a student problem-solving video. Instructor interaction and intervention might be essential to moving students into a state of disequilibrium, and our methods might have been insufficient to actually provoke genuine intellectual need.

Factors that Affect Intellectual Need

Overall, there was a relatively low rate of students reporting an experience of intellectual need. However, instructors—and, implicitly, the ways they incorporate the video sets into their instruction—are associated with different rates of intellectual need. Taken together, the results suggest that the instructor variation in our model is due mainly to differences in instructors, rather than other institutional factors. Thus, there is a complex interaction between pedagogy, curriculum, and students' interaction with the out-of-class learning materials, and this interaction needs to be studied in more detail.

Students were much more likely to experience intellectual need in response to some video sets than others. This means that some mathematical topics, tasks, or problem-solving videos were more effective at helping students experience and identify a state of disequilibrium. The relationship between video set content and intellectual need warrants further investigation.

There was a significant relationship between students' experiencing intellectual and psychological need. One explanation for this result is that there is a significant cognitive or emotional overlap between the two types of need, and that it is important to consider problem context when constructing an IN-P task. Alternatively, it could be that there is an overlap between our operationalizations of the two concepts, making it difficult for students to accurately distinguish between them.

Students who had more extensive background knowledge for a task were more likely to experience an intellectual need than other students. One explanation for this result is that students need a certain level of knowledge about the background mathematical concepts to engage in the IN-P task in the intended way. Alternatively, students might need the background knowledge to *identify* their experience as one of intellectual need. Both explanations suggest that IN-P tasks need to be carefully tailored to particular student knowledge and characteristics in order to provoke intellectual need.

Beyond the students' own background knowledge and other characteristics, it appears that the ways in which we structure the video-watching process can impact the students' experience of intellectual need. Students who (only) tried the IN-P task or (only) watched the student problem-solving video were less likely to experience intellectual need. However, for students who watched the problem-solving video, those who also tried IN-P task were more likely to experience intellectual need. This result suggests that merely provoking intellectual need is not a straightforward process, and that it would be useful for educators to have a framework to support the design and implementation of IN-P tasks.

Relationship between Intellectual Need and Learning

There is an association between a student experiencing intellectual need and demonstrating learning from the instructional videos. This result aligns well with the theory of intellectual need, which posits this relationship between need and learning. However, our measures of learning were relatively unsophisticated, and it is possible that we didn't accurately assess the depth or sophistication of students' learning. Furthermore, learning is often intended to take place over an extended period of time, rather than across a handful of short instructional videos, so we might not have adequately measured the intended constructs.

Conclusion

This study makes a significant methodological contribution to the design and evaluation of learning environments and materials. Our methodology and methods provide a first step into empirically identifying students' experiences of intellectual need and connecting those experiences to their learning. Our results also shed light on some of the factors that might impact students' experiences of intellectual need and how these factors influence learning. The relationship between intellectual need, learning, structuring the students' experience of the video sets, the students' background knowledge, and the instructor's pedagogy is complex. Taken together, these results highlight the importance of continuing to study intellectual need and to create a framework for helping instructors design and implement intellectual need-provoking tasks.

Goals for Student Learning among Mathematics Graduate Student Instructors (MGSIs)

Jen Crooks Monastra
University of South Carolina

Sean Yee
University of South Carolina

This study focuses on novice Mathematics Graduate Student Instructors (MGSIs), defined as graduate students who are full instructors of record for the first time. In this semester-long qualitative multiple-case study, researchers examined three MGSIs' goals for student learning with respect to their teaching decisions and planning. Findings indicated four dominant goals that were expressed in their first semesters within the classroom. This study found that novice MGSIs are capable of reflecting on and discussing their goals for student learning. Understanding how MGSIs build on these goals can provide useful avenues for professional development of early-career instructors.

Keywords: Teaching Assistants, Graduate Student Instructors, Goals for Student Learning, Professional Development, Teacher Education

Graduate students are often involved in teaching undergraduates through a variety of roles including grading, leading labs, facilitating discussion groups, recitation sessions, or serving as instructors of record. Although graduate students can have many teaching-related responsibilities, 35% teach their own classes as instructor of record (Belnap & Allred, 2009). This can equate to 17% to 21% of mathematics courses at doctoral institutions (Blair, Kirkman, & Maxwell, 2013), which influences a significant number of undergraduate students nationally. Many graduate students will continue teaching as they aspire to careers in higher education and accept positions in educational settings (Golbeck, Barr, & Rose, 2016). This study focuses on mathematics graduate student instructors (MGSIs). A MGSI is a mathematics graduate student who is serving as full instructor of record for an undergraduate mathematics course, meaning they are responsible for presenting the material, assessing student learning, and assigning final course grades. MGSIs are commonly assigned to teach mathematics service courses (non-mathematics major dominated courses), despite being students themselves, having limited teaching experiences, and limited access to professional development (Speer, Gutmann & Murphy, 2005; Deshler, Hauk, & Speer, 2015; Ellis, 2014). They face challenges when learning to teach that include balancing teaching with their own coursework or research, awareness of low status of teaching at a research university, difficulties getting and interpreting feedback, working with undergraduates who bring negative mathematical experiences to their classrooms, and anxiety in dealing with these challenges (Hauk et al, 2009). There is little research *from the MGSI perspective* to assist with the design of supports to help MGSIs develop as instructors, and little is known about how MGSIs experience learning to teach or implement teaching methods (Belnap & Allred, 2009).

MGSIs' teaching practices are important as calls for changing instruction in higher education settings have been growing (CBMS, 2016; PCAST, 2012). Saxe & Braddy (2015) summarized the recommendations as calls to "move away from the use of traditional lecture as the sole instructional delivery method in undergraduate mathematics courses" and to "seek to more actively engage students than we have in the past" (p.19). These calls for improving instruction have been grounded in research on improving student learning, which suggests teaching methods (such as active learning) can improve undergraduate STEM students' learning opportunities and help decrease failure rates (Freeman et al., 2014). However, studies related to collegiate instructors teaching practices are limited (Speer, Smith & Horvath, 2010).

To address this research gap, a larger semester-long study explored how MGSIs understand their teaching and their efforts to incorporate active learning methods when teaching an undergraduate course for the first time, by examining reasons they gave for making pedagogical decisions and identifying their perceived challenges[1]. It aimed to understand MGSIs' planning, conceptualized as a "set of basic psychological processes in which a person visualizes the future, inventories means and ends, and constructs a framework to guide his or her future actions" (Clark & Peterson, 1986, p.260). The larger study sought to address the research question: During their first semester teaching a new undergraduate mathematics course, how do MGSIs plan (design and reflect) and implement their plans, with a focus on their goals for student learning? To address this broad question, four sub-questions were created. Due to space limitations, this paper focuses on findings to only the first sub-question: *What goals do MGSIs aim to achieve for student learning?*

Theoretical Framework

Schoenfeld's goal-oriented decision-making theory informed the design of this study. The theory's main claim is that "people's decision making in well-practiced, knowledge-intensive domains can be fully characterized as a function of their orientations, resources, and goals" (Schoenfeld, 2011a, p.182). According to this theory, an individual's orientations (beliefs, dispositions, tastes, and preferences) help shape their goals, which are "the things that people consciously or unconsciously set out to achieve" (Schoenfeld, 2011b, p.459). Resources, which include teacher's knowledge, skills and physical materials, are used to achieve goals. Teachers often have multiple, different levels of goals operating at the same time. Goals can be broad overarching content or social goals, or they can be specific to a lesson or problem. When goals are overarching, they are a key aspect of curriculum design (Wiggins & McTighe, 2005) and are described in various standards (NCTM, 2000; NCTM, 2014; Blair, 2006). In this study, goals were defined as "a complex mixture of academic aims: factual, conceptual, procedural, dispositional, and expert-performance-based" (Wiggins & McTighe, 2005, p.58) as this best aligned with how MGSIs discussed their aims when designing and reflecting on their curriculum and instruction.

Methods

Methodological Approach

This study used a qualitative multiple-case study methodology, defined as "an empirical method that investigates a contemporary phenomenon (the "case") in depth and within its real-world context, especially when the boundaries between phenomenon and context may not be clearly evident" (Yin, 2018, p.15). Case study was appropriate for these research questions because the study looked at understanding MGSIs' thinking and decision making about teaching in the context of actual classroom experiences and could provide a more complete picture of MGSIs' planning and interactive teaching throughout a full semester. The research design provided ample reflection time and space for MGSIs to describe their goals and decisions. The site, course, timeframe, and participants themselves defined the bounds of this case (Yin, 2018). This case is comprised of MGSIs teaching precalculus, an undergraduate service course in the

[1] Supported by the University of South Carolina SPARC Grant (2020-2021)

mathematics department, as part of their teaching assistantship during fall 2019 at a large research university in the southeastern part of the United States.

Participants

All MGSIs teaching precalculus in fall 2019 were invited to participate in this study. Three male MGSIs in their early twenties who were in their second year of graduate school volunteered to participate and were given pseudonyms. Chen was an international graduate student and the other two, Willie and Patrick, were domestic graduate students. All were enrolled in a one-credit, year-long pedagogy course and were supported by peer mentors. Focusing on novice or less experienced instructors is important as universities continually use new MGSIs to provide instruction to undergraduates.

Data Collection

This study followed three MGSIs through their first semester of teaching precalculus. MGSIs were interviewed at the beginning of the semester to understand their prior teaching experiences and beliefs about teaching and student learning. They were asked to select three lessons throughout the semester, roughly one each month, where they planned to seek student engagement. These lessons were observed and video-recorded, lesson plans were collected, and the lessons were followed by a semi-structured interview (50-100 minutes) that explored the MGSIs' goals for student learning, planning and lesson design, and perceived challenges. Other forms of data included weekly journal entries (responding to 3-6 prompts), participant observations from a methods course for MGSIs, their course assignments, and interviews with their peer mentors. At the end of the semester, MGSIs participated in a focus group seeking to gain insight into their overall perspective on teaching the course for student learning.

Data Analysis

Dramaturgical coding which "attunes the researcher to the qualities, perspectives, and drives of the participant" (Saldaña, 2016, p.146) and is useful for exploring underlying psychological constructs was chosen as the coding scheme. Saldaña (2016) describes six types of codes that can be used for dramaturgical coding: objectives, conflicts, tactics, attitudes, emotions, and subtexts. Analysis of a pilot study suggested the emotion and subtext codes were not useful for answering the research questions, thus they were omitted from later analysis. Dramaturgical coding identified objectives defined as motives in the form of action verbs. In this study, objectives often referred to what the MGSI wanted students to know, be or do, although instructor objectives were also identified. To answer the research question, goals of MGSIs were identified through thematic coding of the objective codes. Conflicts or obstacles confronted by the participant-actor that prevent them from achieving the objective were coded to allow for analysis of the obstacles or challenges MGSIs perceived in their planning or teaching. Tactics or strategies used by the participant-actor to deal with conflicts and obstacles and to achieve objectives provided insight into elements of lesson design and classroom practices MGSIs selected and utilized in their classrooms. Finally, attitudes of the participant-actor towards setting, others, and the conflict included much of the MGSIs orientations about teaching and learning. A fifth category called influences was added to capture references to external influences on MGSIs planning.

Memos were written during data collection and throughout data analysis (Saldaña, 2016) to document the data collection and analysis process, reflect on interviews, note connections and questions, contemplate next steps in the research process, and summarize discussions between authors. All interviews were transcribed using Temi, a transcription software program, and cleaned by the first author. Seven data sources were coded for each MGSI: their semester-long journal, three lesson interviews, the background interview, and two written assignments from a pedagogy course. All coding was done in Dedoose and coding proceeded one MGSI at a time so that each instructor could be studied individually before making comparisons across cases. Codes were hierarchical; each code was placed under the dramaturgical categories of objectives, tactics, conflicts, attitudes, or influences (level 1). Objective codes included categories for student learning, students, and teachers (level 2). These goals were also coded at more detail (level 3) and sometimes used in vivo codes (Saldaña, 2016), such as "recognize and use appropriate tools". Code mapping (Saldaña, 2016), a technique to organize data and improve trustworthiness of findings during analysis, was employed after coding the first piece of data (Chen's journal), and again after coding the data from each MGSI. Quotes from categories at levels 2 and 3 were reviewed to confirm quotes described the same concept. The codes were listed, compared, and organized into categories by rearranging or combining similar codes. The codes were then condensed into themes. Generating themes was not a linear process; rather it involved sorting and comparing codes and considering how categories related to one another. As MGSIs expressed many common goals for student learning, findings are reported only through cross-case analysis. The first researcher coded and discussed codes and themes with the second researcher to reach agreement on all codes and themes.

Findings

Although MGSIs work towards many types of goals over a semester, the themes presented below were the most salient goals that MGSIs discussed while preparing for and reflecting on teaching precalculus. These goals related to what MGSIs aim to help students learn and were shared among all MGSIs in this study. MGSIs shared goals for student learning centered on student reasoning, understanding and sense making, developing productive dispositions as learners of mathematics (NRC, 2001), and procedural skills. However, what Saldaña (2016) termed the super objective, "the overall or ultimate goal of the participant" (p.148), focused on preparing students for their future. As each goal was expressed by all MGSIs, their data is presented together to illustrate the pervasiveness of the goal throughout the data set and among MGSIs. Analysis identified four goals for student learning as the most prominent goals in three novice MGSIs' planning. Table 1 summarizes the findings of this study.

Table 1: Summary of Goals and Aspects of the Goals

Goals	Aspects of Goals
Goal 1: Prepare Students for their Future	(1) Coursework; (2) STEM Careers; (3) Personal Study Skills
Goal 2: Develop Reasoning, Sense Making and Understanding	(1) Understanding Why: Deriving or Proving; (2) Sense Making and Developing Intuition; (3) Applying or Connecting Concepts, Facts or Procedures
Goal 3: Develop Productive Dispositions	(1) Enjoy Mathematics and/or Precalculus Class; (2) Build Self-efficacy; (3) View Mathematics as Useful; (4) Willing to Persevere
Goal 4: Develop Procedural Skills	(1) Content Skills to Solve Standard Problems; (2) Recognize and Use Appropriate Tools; (3) Know or Memorize Facts

Goal 1: Prepare Students for their Future

MGSIs frequently spoke about preparing their students for the future, which primarily related to future coursework or career-related skills. All journals contained multiple references and similar phrases to Patrick's journal, where he stated, "my main goal is to prepare these students for calculus," and all MGSIs directly identified this goal in their background interviews. This goal was continuously shared throughout the semester as the clear overarching goal MGSIs held relative to their students. In addition, MGSIs also kept in mind their students' STEM career aspirations. MGSIs' desires to prepare their students included both seeking to help students achieve their career goals and be competent workers in their STEM fields. As Willie remarked during the focus group, "we are trying to prepare them for their life," and knowing precalculus material will be important for students to obtain and keep their jobs. MGSIs noted the importance of their students correctly using mathematics in their future careers for projects that can have real life consequences. As Willie stated, "These kind of kids [STEM majors], they need to know it…[because] in the future, they are going to be using this" in their careers.

Another way in which MGSIs spoke of preparing students was in developing personal work habits and study skills. Less frequently mentioned than the career focused types of preparation, this category included learning how to learn, taking ownership of the learning process, and feeling personal satisfaction or pride in hard work, which are transferable to learning in areas outside of mathematics. Chen shared in the focus group how students' experiences of studying precalculus were important for undergraduates in ways beyond the mathematical content. He explained,

> It's not just like they have to know the material for calculus, but they still have to know *how to learn* the material… It's not just like math is math. Like you also need to learn the skill for learning like new knowledge.

Some of the focus on preparing students may be due to the course they were assigned to teach. For these MGSIs, the precalculus course was the prerequisite for calculus. Teaching precalculus thus became about student preparation and MGSIs' desire for their students to be prepared and successful in their future coursework.

Goal 2: Help Students Develop Mathematical Reasoning, Sense Making and Understanding

The most frequently coded objective for student learning related to students' mathematical reasoning abilities. MGSIs described this goal in many ways, including wanting students to conceptually understand or make sense of mathematics, to apply and connect concepts or ideas, to derive, prove, generalize or conjecture about formulas or theorems, and develop intuition. MGSIs discussed these ideas in a connected, overlapping manner. MGSIs frequently discussed wanting students to understand why theorems or formulas were true. Willie had designed a discovery jigsaw activity about quadratic functions. He explained in the interview,

> They all knew the quadratic formula. So my goal was to not explicitly say, you're finding the quadratic formula. It was for them to derive and say, oh look, it's the quadratic formula! [And have] the epiphany, the whoa! Like what you do when you get a proof and you spent forever doing and then you finally get there.

He reiterated during another interview, "Figuring out where it comes from, I think is pretty important because it gives you that more conceptual knowledge. You found it! Now you know how to do it again instead of me telling you how to find it." MGSIs were aiming to provide opportunities for students to develop mathematical understanding and reasoning skills.

MGSIs also aimed for students to understand and make meaning of mathematical definitions and terms. Chen reflected on his lesson about asymptotes, recalling "I hope they can relate that [where the function is undefined] to the vertical asymptote and the graph and where the problem happened." MGSIs often expressed a desire for their students to be able to apply previous material to the current lesson, to apply current concepts in the future, and to connect mathematical concepts. In another interview, Chen described how he asked students to make connections between the unit circle and the graphs of sine and cosine functions. "If they have to produce this graph, hopefully they can try to recall, to use this unit circle to graph. Again, it's a connection." Connecting the unit circle to the graph of a trigonometric function reflects Chen's aim to help students build connections between mathematics concepts.

Part of encouraging students to make sense of ideas seemed to relate to helping develop what MGSIs sometimes called students' intuition or their ability to think mathematically or creatively. In an interview, Patrick's reflected on what he wanted students to learn from working together to verify trigonometric identities. He discussed how students need to develop "that intuition of where to go or what to do next" and hoped that allowing students to work together in groups would help them build intuition. These quotes illustrate various ways in which MGSIs shared goals for students to develop understanding of mathematical ideas, make sense of mathematics and reason mathematically.

Goal 3: Help Students Develop Productive Dispositions

All MGSIs expressed affective goals for their students related to how students viewed themselves as learners of mathematics and how they understand the field of mathematics. This category included MGSIs' goals for students to enjoy and take interest in mathematics or their precalculus course, to build students self-efficacy, for students to appreciate the usefulness of mathematics, and develop a willingness to work on problems and persevere in solving them.

MGSIs wanted their students to hold positive views towards mathematics. As Willie stated in the focus group, "That's something I want to hear. Someone was like, yeah, I think I enjoy math now." In an interview, Patrick also explained he incorporated a jigsaw activity because "math is not just supposed to be something that you have to do. Math is not supposed to be a chore. So maybe these types of activities will make them more interested in or motivated [to learn mathematics]". Building students' self-efficacy was also a consistent goal for Patrick who stated in the background interview,

> One goal I might have is to sort of change that opinion of some students. You're not bad at math. Math is just a skill. As you practice it, like any other skill, you're going to get better at it.

Through their teaching, MGSIs hoped to improve students' attitudes towards mathematics and build their confidence in their ability to learn and do mathematics.

Additionally, MGSIs wanted their students to recognize ways mathematics contributes to daily life and be willing to persevere when solving problems. Chen wrote in his journal, "I hope to tell my students why they need to learn math...I hope my students appreciate the use of mathematics more." MGSIs also understood that for students to solve mathematical problems, they must be willing to try different ideas and not become discouraged or give up when the first idea is not successful. During the focus group, Chen discussed helping students develop perseverance. He explained, "I want to show them that it's okay to be wrong, like it's fine. Just use another ratio or another number, because the idea of trying is really helpful…especially when they haven't seen the pattern yet." The manner in which MGSIs discussed their goals to build students' confidence and desires for students to enjoy mathematics, hold positive views of mathematics, and be willing to persevere, aligns well with the notion of developing productive dispositions meaning "the tendency to see sense in mathematics, to perceive it as both useful and worthwhile, to believe that steady effort in learning mathematics pays off, and to see oneself as an effective learner and doer of mathematics" (NRC, 2001, p.131).

Goal 4: Help Students Develop Procedural Skills

Finally, MGSIs also aimed to develop their students' ability to execute various mathematical procedures. Common for mathematics courses at this level, MGSIs stated much of the course includes objectives for students to solve, compute, manipulate or simplify, which often amount to replicating or following procedures. As Chen stated in an interview,

> It's like by the end of the day, the goal for the lecture is for them to be able to solve [a triangle] using the law of sine. They don't have to actually know where it comes from. It would help with their intuition, but it doesn't like align with the goal that I want to reach [that students can solve triangles].

All MGSIs at some point described procedural skills as tools and stated in interviews their goal for students to "recognize and use appropriate tools." Willie explained in an interview that he wanted students to see completing the square as much as possible "because it's a good tool. You'll see it all the time and they definitely see it in calculus." MGSIs did not only want students to be able to execute procedures but also apply them appropriately.

Discussion

Goals were central to the theory, data collection and analysis in this study. A pilot study analysis suggested MGSIs thought about student learning as well as their own hopes and aims to facilitate learning. Schoenfeld (2011a) suggests teachers pursue multiple goals at different levels or sizes and those goals can be conscious or unconscious. Some goals, such as the super objective of preparing students for their future, were clear and conscious in all MGSIs' minds from the start to the end of the study. Other goals emerged or were discussed and identified more clearly as the semester progressed. MGSIs' awareness of and ability to speak about some goals increased throughout the semester. Findings described overarching cognitive or affective goals as they best explained MGSIs' planning on a larger scale and related to reasons MGSIs gave for planning or teaching decisions. All goals described in this paper became conscious goals at some point during the study and were confirmed by participants who reviewed a draft of the study's findings. These goals were remarkably consistent across the multiple cases of MGSIs, thus may provide a fertile starting point for professional development to support new MGSIs (Ellis, 2014).

This study illustrates new avenues of filling in the aforementioned research gap around MGSIs' goals for student learning. Although Schoenfeld's theoretical framework (2011a) asserts goals are shaped by orientations, it does not discuss the formation of goals. This study's use of dramaturgical analysis found that some MGSIs' goals for student learning were molded and shaped by their early impressions of teaching. For example, knowing their students needed to complete the calculus sequence, put added pressure on MGSIs as they recognized the importance of the course for their students' future success (Goal 1). This weaving of goals for student learning and lesson designs calls for the novice MGSI's voice when generating thoughtful, meaningful, and MGSI-centered professional development.

Analysis of a Mathematical Modeling Assessment

Jennifer A. Czocher
Texas State University

Robert Sigley
Texas State University

Sindura Subanemy Kularajan
Texas State University

Elizabeth Roan
Texas State University

In this paper we use multiple statistical approaches, including classical test theory (CTT), item response theory (IRT), and principal component analysis (PCA) to understand item behaviours, scale properties, and dimensionality of a developing multiple choice assessment of mathematical modeling competencies designed for tertiary STEM majors. We share analyses and inferences, making recommendations for the field in pursuing such assessments.

Keywords: mathematical modeling, assessments, differential equations

Mathematical modeling is an important skill for students at all levels of mathematics, in part because it can be a vehicle for learning further mathematics and partly because of the capacity of real world problems to motivate students to pursue and persist in STEM fields. As scholarly and pedagogical interest increases in teaching with (or through) mathematical modeling, so increase stakeholder interests in assessing growth in modeling skills. Many assessments for mathematical modeling knowledge and skills have been independently created, however the majority serve a local need and are based on ad hoc constructions or small-scale studies of student work (Frejd, 2013). At the same time, there have been increasing calls for instruments in mathematics education research to undergo evidence-based validity assessments (see, for example Melhuish & Hicks, 2019). The rationale is that documenting properties of tests and test-takers can aid the field in synthesizing, and thus building upon an abundance of research results. Within this context, we have been developing an assessment for evaluating interventions that aim to improve tertiary students' modeling skills. To facilitate scholarship in this area, the instrument is intended to support research designs based in a pre/post measurement paradigm. Thus, the project goal has been to develop two parallel forms of an assessment appropriate to targeting modeling skills of tertiary students. The purpose of the present study was to learn about the psychometric properties of the items and the scales. We ask and answer the research question: What are the psychometric properties of the instrument and do the items behave as intended?

Conceptual and Assessment Frameworks

We adopt a synthesis of instrument development frameworks (2014) as a set of validity criteria advanced as part of the *Validity Evidence for Measurement in Mathematics Education* project. Melhuish and Hicks (2019) recently applied the standards to concept inventories in mathematics education, demonstrating the approach to be viable for research assessments. They make a case that validity of an instrument should reflect empirical evidence to support its (1) content validity, (2) response process validity, (3) relations to other measures, and (4) internal structure. Content validity is established through expert evaluations and literature-informed item development. Seeking evidence of response process validity ensures that both items and distractors tap into students' reasoning patterns. Typically, evidence for response process validity is sought through direct student feedback on the items. Checking relations to other measures can mean calibrating the instrument against other assessments of the same content or instruments assessing distinct constructs. Finally, internal structure validity involves checks on dimensionality, internal consistency, and other psychometric properties for the items and scale. These evidence-based validity criteria guide our instrument development process. In this paper, we briefly summarize development and validity efforts for criteria (1)-(3) which are published elsewhere (Czocher et al., 2020; Czocher et al., 2021) and report on (4).

Integral to establishing content validity, operationalized here as construct validity, we adopt a cognitive view of mathematical modeling as a process consisting in multiple inter-related, idiosyncratic phases (Blum & Leiß, 2007; Kaiser, 2017). We define modeling as the process of rendering a non-mathematical problem about a real-world phenomenon of interest as a well-posed mathematical problem to be solved. The process involves modeling competencies like *understanding* (specifying a problem), *structuring* (identifying relevant and irrelevant factors), *mathematizing* (articulating mathematical relations among quantities), *working mathematically* (solving), *interpreting* and *validating* (checking the model represents the situation and addresses the real-world problem). We developed a pool of 118 multiple choice questions (MCQs) belonging to 9 real-world scenarios based in research reports on students' thinking during modeling and pedagogical materials. We sought scenarios that treated issues prevalent in society, involved situations in the sciences where differential equations might be used, or were suggested by informal interviews with STEM professors. Mathematics content ranged from arithmetic to algebra, to calculus, and to systems of ordinary differential equations. We chose a multiple-choice format to facilitate creating two parallel forms that could support pre/post-test research designs intending to measure gains in competencies. Across multiple rounds of field testing, we solicited feedback from an expert panel of mathematicians and mathematics educators as to the accuracy of the mathematical content and the extent to which items targeted intended competencies. We implemented revisions, culling items that failed to be correct or sensible.

To establish response process validity (Czocher et al., 2020; Czocher et al., 2021), we carried out three rounds of field testing: feasibility, difficulty and distractors, and discrimination. In the feasibility round, we solicited feedback on the items from a group of 12 STEM undergraduates, asking them to evaluate the items, scenarios, and response options for authenticity, sensibility, and rationale for selecting distractors. In the difficulty round, we administered the 63 most promising items on two forms to 35 and 43 STEM undergraduates, respectively. We kept items with difficulty $0.20 < p < 0.70$ and restructured or culled items that did not perform well. We also analysed distractor efficacy, ensuring that each distractor was selected by at least 5% of respondents. In the discrimination round, 30 remaining items were sorted onto two forms and administered to a sample of 25 secondary and 289 post-secondary students participating in an international modeling challenge focusing on applying differential equations (see below for details). The mean item difficulties were $p = 0.39$ and $p = 0.41$ for the two forms. An independent sample t-test ($t = -0.811, df = 144, p = 0.419$) confirmed no significant difference in mean score across the forms and Levene's test ($F = 0.412, p = 0.522$) confirmed equal variances. A set of point-biserial correlations were computed to identify high- and low-discriminating items. We estimated reliability of the two forms using Revelle's Omega Total (ω_T) as a measure of internal consistency, which is appropriate where multiple dimensions (e.g., mathematics content, modeling context, target competence, reading comprehension, item format, native English proficiency) contribute to predicting the construct of interest and when individual items measure the latent construct with differing degrees of precision (Raykov, 1997; Revelle & Zinbarg, 2008). The two forms had $\omega_T = 0.67$ and $\omega_T = 0.63$, respectively, approaching acceptable estimate of reliability 0.7.

To study relations to other measures, we investigated correlations between the instruments measure of modeling competencies and a related instrument's measure of self-efficacy to carry out those competencies (Czocher et al., 2021). In the spirit of Hackett and Betz (1989) and (Bandura, 2006), the Modeling Self-Efficacy (MSE) instrument uses a 0-100 rating scale to measure an "individual's perceived capacity to carry out the interrelated activities that make up mathematical modeling" ((Czocher et al., 2019, p. 13). Of the 314 students who took the MCQ in the discrimination round, 144 also took the MSE. For these students, we found that modeling self-efficacy was a highly significant predictor of modeling competency, as measured by these two instruments. We interpret the strong positive association between modeling competency and modeling self-efficacy as evidence of relation validity; since we expect a positive correlation between mathematics self-efficacy and performance.

We report on efforts to equate two parallel forms and investigate internal structure validity. To this end, we conducted a round of testing two forms using Rasch analysis. We selected Rasch analysis because it produces item difficulty estimates and person ability scores, allowing examination of the scale along both item and ability variables. Non-identical forms can then be equated by anchoring the difficulties of common items to the same values on a common scale. Rasch analysis produces Wright maps which can be interpreted to explain participants' test scores score in the context of the questions that appear on our instrument (Boone, 2016)

Methods

Based on results from previous rounds of testing, we constructed two forms, Ruby and Sapphire, each with 20 items and with 11 of those items common to the two forms. Construction used Classical Test Theory to balance the total (anticipated) difficulty of the forms and content coverage in terms of competencies targeted. In total, each form had 3 understanding, 5 structuring, 5 mathematizing, 2 interpreting, and 5 validating items. The expected mean item difficulties for Ruby and Sapphire were $p = 0.472$ and Sapphire $p = 0.475$, respectively. We administered the forms to a sample of secondary and post-secondary STEM students participating in an international mathematical modeling challenge focusing on using differential equations to solve real-world problems. The challenge took place remotely during the COVID-19 pandemic at the end of Autumn 2020 semester, depressing participation in the data collection. In total, 89 students responded to the items (see Table 1 for demographics), and some response sets were incomplete (detailed below). Additionally, >90% reported typically earning B's or higher in both their mathematics and major classes.

Table 1 Participant demographics

Male	64%	Science	21.3%	Diff Eq	81.8%
Female	33.7%	Mathematics	46.1%	No Diff Eq	18.2%
Non-binary	2.3%	Engineering	25.8%		
		Other	6.7%		

We first performed a classical item analysis to check that all items had positive item-total correlations. Item difficulties were calibrated for each form using a Rasch model. Item and person fit statistics and residuals were calculated to check model-fit assumptions and conduct dimensionality analysis, respectively. We identified items with fit statistics outside of the 0.5 to 1.5 range or exhibiting appreciable item-pair residual correlations (Yen's $Q_3 > 0.2$). Item-pairs with higher residual correlations were examined for patterns in their relationships. We excluded mis-fitting items and persons and re-calibrated the remaining dataset to the Rasch model. Due to small subgroup size (e.g., type of school, major) a Differential Item Functioning (DIF) analysis to assess potential bias was not feasible.

Given all of the assumptions below, which equation **best** models growth for a population?

1. The birth rate is proportional to the population.
2. There are sufficient resources for the population to thrive.
3. Members die of unnatural causes, like murders.
4. Unnatural deaths are proportional to the number of two-party interactions.
5. k_1 and k_2 are proportionality constants.

a. $\frac{dP}{dt} = k_1 P - k_2 \frac{P^2}{2}$

b. $\frac{\mathrm{dP}}{\mathrm{dt}} = k_1 P + k_2 \frac{P(P-1)}{2}$

c. $\frac{dP}{dt} = k_1 P - k_2 \frac{P}{2}$

d. $\frac{dP}{dt} = k_1 P - k_2 \frac{P(P-1)}{2}$ *

e. $\frac{dP}{dt} = k_1 P - k_2 \frac{(P-1)}{2}$

Figure 1 Sample multiple-choice item for mathematizing (choosing a representation)

Results and Interpretation of Rasch Analysis

On Ruby, between 29 to 38 students responded to each item. Ten students were flagged as having response patterns that did not fit model expectations – they had too many missing responses. One item had a large outfit and distractor options with positive item-total correlations. Given the messy response pattern, we excluded the item from further analysis. Ruby was then re-calibrated. Two further items exhibited large outfit values (close to 3) but were kept because the test length would be short for the number of respondents. The Rasch item reliability score was 0.88 (Adj. SD = 0.63) and the person reliability score was 0.63 (Adj. SD = 1.39). We examined the pairwise correlation of item residuals (Yen's Q_3) and a Principal Component Analysis (PCA) of standardized residuals. Both suggested underlying multidimensionality. Multiple item pairs had residual correlations > 0.20 and the first factor had eigenvalue $\lambda = 3.05$.

On Sapphire, between 32 and 41 students responded to each item. We scored two items using a partial credit scale because these items had stems phrased to select an optimal choice. However, most students chose a mathematically correct choice that was not optimal for modeling (Haines et al., 2000). We discuss implications for future test forms below. Most items showed satisfactory fit statistics. One item (Sapphire Item 7, validating) had an outfit value of 1.74 and another (Sapphire Item 5, simplifying) was underfitting (outfit 0.66, infit 0.73). Because the test is short, underfitting items were kept. After recalibration, one common item (Ruby Item 15, simplifying) was removed from just the Sapphire test. Although it performed well on Ruby form, it had high outfit on Sapphire and its residuals were highly correlated with another item's (Sapphire Item 6, simplifying).

Excluding the two problematic items, a recalibration of the Sapphire test produced a Rasch item reliability score 0.88 (Adjusted SD = 1.22) and the person reliability estimate of 0.64 (Adjusted SD = 0.89). Since Sapphire had a larger person reliability estimate, we used it as the anchor form during equating. The Sapphire item-pair correlations and PCA of residuals indicated less concern about multidimensionality than on Ruby form. The two forms were recalibrated from the 10 remaining common items (excluding Ruby Item 15) and anchored to Sapphire's final calibration values. Thus, all Ruby and Sapphire item difficulties could be placed on a common scale. As is customary in mathematics education, we report the Cronbach's alpha as well, for Ruby, $\alpha = 0.91$ and for Sapphire $\alpha = 0.85$.

Table 2 contains the breakdown of each item on the final version of both tests with the competency they target, the context, and the difficulty. The Wright Maps (item-person map) shown in Figure 1 order the ability of the students who took the tests on the left side and the difficulty of the questions on the right side. The left side of the Wright map shows the distribution density of the test takers compared to the item difficulty on the right (high scoring test takers are distributed as positive logits and low scoring as negative). Outside of items 9, 10, and 11, the distribution of the difficulty of the items is good. Items Sapphire 9, Ruby 9, Sapphire 10, and Ruby 10 show high difficulty relative to the ability distribution. Both questions focus on the competency of interpreting in two different contexts (disease and recycling). Item 11 on Ruby and Sapphire which focused on understanding with the context of a wastewater tank, had the lowest difficulty across both tests. Understanding tasks varied in difficulty across the different problems, with Ruby Item 1 being difficulty and Ruby and Sapphire Item 12 having a small negative difficulty (-0.75). Items about mathematizing (excluding Ruby Item 2), simplifying, and validating had difficulty levels clustered around an ability level of 0.

Table 2 Rasch model difficulties (δ) for Ruby (R) and Sapphire (S) forms.

Item #, R	Item #, S	δ, R	δ, S	Competency	Context
1		1.81		understanding	Decay
2		-2.17		mathematizing	Disease
3		-0.31		mathematizing	Population
4		0.32		simplifying	Recycling
5		-0.06		simplifying	Wastewater Tank
6		1.09		simplifying	Wastewater Tank
7		-2.36		validating	Carrying Capacity
8		-0.94		validating	Wastewater Tank
9	9	2.57	2.57	interpreting	Disease
10	10	2.06	0.98	interpreting	Recycling
11	11	-3.35	-3.35	understanding	Wastewater Tank
12	12	-0.75	-0.75	understanding	Disease
13	13	-0.36	-0.36	mathematizing	Wastewater Tank
14	14	0.87	0.87	mathematizing	Recycling
15		0.67		simplifying	Recycling
16	15	-0.98	-0.98	simplifying	Haines & Crouch*
17	16	-0.21	-0.21	validating	Wastewater Tank
18	17	0.53	0.53	validating	Wastewater Tank
19	18	0.67	0.67	validating	Wastewater Tank
	1		0.32	understanding	Recycling
	2		1.08	mathematizing	Wastewater Tank
	3		-1.56	mathematizing	Carrying Capacity
	4		-1.13	simplifying	Recycling
	5		0.24	simplifying	Wastewater Tank
	6		0.32	simplifying	Recycling
	7		-0.2	validating	Carrying Capacity
	8		-0.11	validating	Disease

**Item Ruby 16 is from (Haines et al., 2000) and asks students select variables needed to model the time for passengers to safely exit an aircraft.*

We conducted a Principal Component Analysis (PCA) on the responses for the final forms to investigate any empirically evident dimensionality. The first Ruby component (19.3% of explained variance) contained items 2, 5, 6, 8, 11, 13, 17, 18, 19. These are all but one from the Wastewater Tank context and as a set possess a wide range of difficulties. The items comprise four of the five competencies (4 validating, 2 mathematizing, 2 simplifying, 1 understanding). The second Ruby component (16.8% of explained variance) contained items 9, 10, 12, 13, 15, two of which (9, 10) were the difficult interpreting items. The first Sapphire component (15.8% of the explained variance) includes items 3, 4, 5, 9, 12, 16, from many contexts (2 Disease, 2 Wastewater Tank, 1 Recycling, 1 Carrying Capacity) and competencies (1 each validating, understanding, interpreting, and mathematizing, 2 simplifying). The second Sapphire component (15.6% of the explained variance) included items 2, 14, 17 – 2 mathematizing and 1 validating. Two were Wastewater Tank context and one was from Recycling

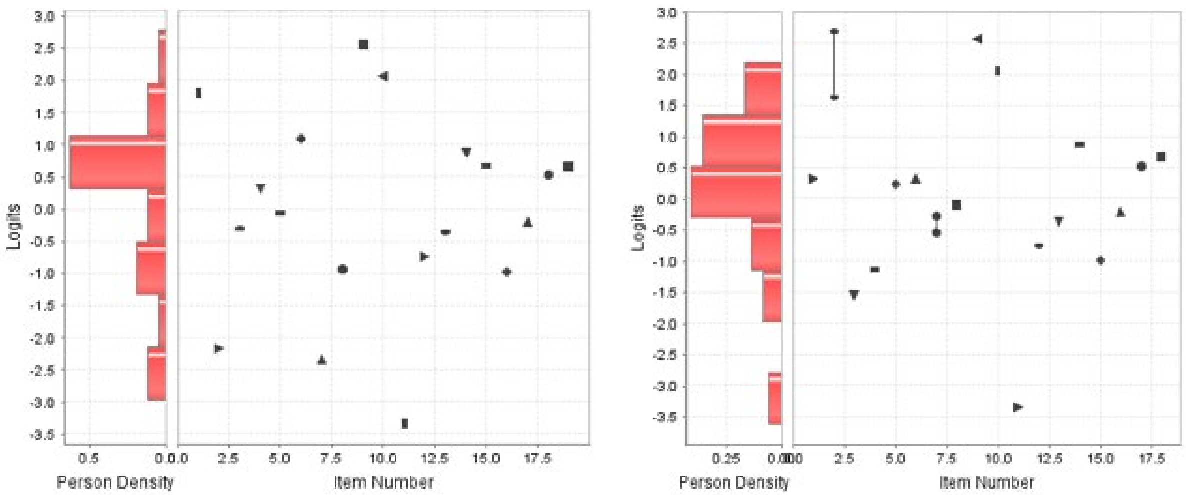

Figure 1 Final anchored Wright (item-person) maps for Ruby (left) and Sapphire (right), ordered by item number.

Discussion and Conclusions

Based on our psychometric analyses, we have created two parallel forms targeting modeling competencies appropriate for tertiary students of advanced mathematics. On the calibrated scale, most items had difficulties $|\delta| < 1$, and the Wright map showed a good difficulty distribution, suggesting that the scales are balanced. The easiest items ($\delta < -1.5$) had a clearly correct answer and could be addressed using test taking strategies to rule out distractors. Items 9 and 10, the most difficult ($\delta > 1.5$), were both interpreting items and had lengthy response options requiring comparison among the options. We hypothesize that a higher cognitive load may contribute to their difficulty, besides the modeling competence.

The low person-ability reliability likely reflects a small sample of test takers, with diverse characteristics, and a relatively short test. It may also show that the test items were not well "targeted" to the ability-levels of students in the sample. We are not pessimistic about this interpretation since we administered the forms as a pre-test to an intervention where students would have the opportunity to practice these skills. Thus, it is sensible that their ability levels would be low, as measured by this instrument. Though administering the forms online permitted us to reach a larger sample from a small population, we note the instrument may be challenging to respond to via mobile platforms and that, because of COVID-19, completing yet another assignment may have been laborious.

Empirically, the forms did not reveal dimensionality according to *a priori* constructs like mathematical content, modeling context, or modeling competency. It is possible that competencies or contexts may form dimensions, but the sample of students was so diverse in terms of their personal characteristics and prior knowledge that the instrument could not detect it. Instead, given the relatively low person reliability (due to large standard error), it is possible that dimensions may include aspects of guessing, English comprehension, test fatigue, or that items may require judgment rather than offering a clear correct answer. One notable exception was that the PCA on responses revealed all the Wastewater Tank problems loading to Ruby Component 1 and it also was strongly present on Sapphire Component 2. We also suspect that other constructs, such as facility with quantitative reasoning, may play a role. In any case, since the breadth of competencies was well-represented on the extracted components, we infer that no one item type is responsible for all the variance. Instead, variance is pleasantly distributed among item types.

Our approach to designing the MCQs is atomistic (Blomhøj & Jensen, 2003), targeting each item toward a competency. This approach facilitated the multiple-choice format but carries limitations in its capacity to assess modeling as a composition of those competencies. More testing is necessary to explore suitability as a measure of individual students' modeling capacity. Future rounds can also examine patterns in item difficulty according to competency or reliance on other latent constructs like quantitative reasoning. We have provided an evidence-based validity evaluation of the internal structure of the parallel forms to evaluate pedagogical innovations. This effort is integral in moving towards a valid and reliable instrument for measuring growth in modeling skills of tertiary students, and more broadly towards establishing a shared empirical basis for interpreting results of studies of student's modelling across education levels.

Advanced Students' Actions for Operationalizing Quantification in Analysis

Paul Christian Dawkins
Texas State University

Michael Oehrtman
Oklahoma State University

Zackery Reed
Embry-Riddle Aeronautical University Worldwide

This study identifies seven categories of student meanings for quantification evoked in the course of reasoning about and proving a theorem in functional analysis. By observing how two graduate students flexibly foregrounded and backgrounded the variation in different quantities within a proving task, we identify ways that quantification operates in proof-oriented reasoning. We call these quantification operationalizations *or* quantops*. While some of these quantops mirror findings from prior studies of reasoning about quantified statements, our framework introduces new aspects of reasoning about quantification. Also, we observe that each quantop has two forms: one that backgrounds quantification and one that foregrounds it. Backgrounding appeared highly important for managing the myriad of quantities constituent to the task.*

Keywords: quantification, analysis, proof

Learning advanced undergraduate mathematics requires fluency in the use of quantifiers, often multiple nested quantifiers, in the same definition or theorem. Like many matters of logic, prior research shows why these ways of reasoning pose challenges to student success in proof-based courses (e.g., Epp, 2003). Unfortunately, we have comparatively fewer insights about successful reasoning and learning. Some recent studies have worked to remedy this limitation regarding research on quantification. Sellers, Roh, and Parr (2021) characterized undergraduates' quantification actions for quantified variables. Vroom (2020) documented how students developed and distinguished different multiply-quantified relationships to express a concept that they sought to define. This investigation builds on productive aspects of those studies by 1) documenting students' quantification actions for multiply quantified relationships as those students 2) sought to express, relate, and justify highly complex relationships.

In particular, we analyze a series of task-based interviews with graduate students taking a functional analysis course to identify their meanings for multiply quantified relationships and their habits for notating and proving about such relationships. These students had years of experience learning proof-based mathematics and working with multiply quantified relationships, so we seek to learn from their expertise. We document the actions they took during problem solving and proving to reason about quantification relationships in the Arzela-Ascoli Theorem and its proof. We call these *quantification operationalizations* or *quantops*. We use the term *operationalization* in part because we observe that the definitions and proofs featured in these interviews involve an impressive number of quantified objects[1] such that reasoners must find ways to manage working memory to imagine the definition of the concepts and the lines of inference for proving implications between them. We extend the insights of prior studies (e.g.,

[1] The Arzela-Ascoli Theorem can be stated "A subset S of $C([a,b],\mathbb{R})(\sup)$ is equicontinuous and bounded if and only if it is totally bounded," but if we substitute the definitions of those terms, which one must coordinate to understand the theorem or write a proof, it would appear as the following: "$\forall S \subseteq C([a,b],\mathbb{R})(\sup), [\forall f \in S, \forall \varepsilon > 0, \exists \delta > 0 \ni |x-t| < \delta \Rightarrow |f(x)-f(t)| < \varepsilon] \wedge [\exists M > 0 \ni \forall f \in S, |f(x)| < M] \Leftrightarrow [\forall A \subseteq S, \forall \varepsilon > 0, \exists \{a_1, a_2 \dots a_n\} \subseteq A \ni \forall f \in A, \exists i \in \{1,2,\dots n\} \ni \forall x \in [a,b], |f(x) - a_i(x)| < \varepsilon]$." We present the second rendering to emphasize that proving this theorem is a rich opportunity to understand how students conceptualize and operationalize quantification.

Durand-Guerrier & Arsac, 2005; Roh & Lee, 2011) especially by documenting how students make meaning of quantification beyond syntactic structure (the order of quantifiers in a claim).

Prior literature on reasoning about quantification

In this section we review mathematics education literature on reasoning about quantified variables and multiply quantified statements.

To which and how many values do variables refer?

The key function of a quantifier in mathematics is to specify for which and how many values of a variable does a statement need to hold to be a true statement. The truth value of a statement like "x is even" or "$x = 2 \cdot k$" depends on the value(s) of the variable(s). If we want to claim such a statement is true for all relevant values of the variables, we use *universal quantfication* (often expressed "for all"). If we only require at least one value to make the statement true, we use *existential quantification* (often expressed "there exists"). These two types of quantification are the most common in mathematics and in prior research. As Sellers et al. (2021) and Vroom (2020) point out, students may also reason about what is conventionally called *unique existence* in which a condition must be true for one value of the variable and false for all others.

Sellers et al. (2021) developed a framework of five meanings undergraduate students exhibited for quantified variables when interpreting statements and deciding their truth values. The first three meanings correspond to the way mathematicians use existential quantification, unique existential quantification, and universal quantification. The fourth meaning describes when students take terms like "any" to mean they can choose one or a few values, which entails variability but not universality. The fifth meaning describes when students showed no evidence of perceiving the variable as varying, typically by picking a single value. This framework provides a rich starting point for understanding quantification as a mental construction that students enact while reasoning about mathematical statements or problems.

Using quantification to interpret multiply quantified statements

Many studies begin by presenting students with quantified statements to interpret and determine their truth value (e.g., Dubinsky & Yiparaki, 2000; Dawkins & Roh, 2020; Roh & Lee, 2011, Sellers et al., 2021). Most such studies use multiply quantified statements, which introduce the complexity of understanding how the two variables take on values in tandem and how they vary together or independently. Such studies tend to focus on the relationship between syntax (the grammatical form of the statement) and semantics (how the statement refers to objects and construes meaning). Durand-Guerrier and Arsac (2005) explored the *dependence rule* that a variable quantified second (in the syntax) generally depends upon the variable quantified before it. Roh and Lee (2011) emphasized the *independence rule* that the variable quantified first must remain independent of the variable(s) quantified thereafter. The order of quantifiers is thus accorded great significance in how mathematicians use such statements.

Using quantification to express and reason about mathematical concepts

Students draw upon quantification to construct and express meaning, in addition to simply reading quantified statements (Vroom, 2020). Apart from mere syntax, students gave meaning to multiple quantification by constructing relationships among various quantities sequentially in order to express a known concept. Dubinsky, Elterman, and Gong (1988) similarly contrasted negating the entire meaning of quantified statements (e.g., failing to be "continuous") from negating layers of quantification.

Methods and Theoretical Framing

The student data presented in this report was taken from a larger study that explored students' understandings of metric space results in function space contexts. The goals of the study were to learn about how students connected function spaces and general metric spaces and how students drew upon prior understandings of analysis concepts in proof construction. We report on data from two students' paired, task-based clinical interviews (Hunting, 1997). The sessions were video recorded, with both students working together on a whiteboard to carry out the interview tasks and responding to prompts from the researchers present.

We recruited these two students, whom we call Adisa and Fenfang, based on initial interviews. The primary purpose of these interviews was to observe students' mathematical activity to make inferences about their in-the-moment understandings and their mental resources for engaging in proof (Clement, 2000; Thompson, 2008). Accordingly, we held no other criteria for selection or paring beyond our anticipation that we could observe and interpret sufficient mathematical activity and utterances from the pairs to make inferences about their thinking from interpretive and conceptual analyses (Clement, 2000; Thompson, 2008).

We report on episodes taken from the third and fourth 90-minute interviews with Adisa and Fenfang. In these interviews, we asked the students to attempt proofs of both directions of the Arzelá-Ascoli theorem: "A subset of $C^0([a, b],\mathbf{R})$ is bounded and equicontinuous if and only if it is totally bounded in the sup metric." The students had attempted the proofs of both directions on a take-home exam prior to the interviews. Fitting for a take-home exam, this is a highly challenging and complex proving task. Unlike many task-based interviews, students had worked on it before the study. Our focus in this analysis was not on Adisa and Fenfang's success or lack thereof in producing complete proofs, but rather to understand their ways of reasoning with and about quantification in the process of proof construction. Their exams show that neither had produced a complete proof, suggesting there was still rich proof production to capture in the interviews, which took place some time later. As we noted before, this theorem relates concepts rich in quantification. Our analysis focused both on their reasoning about quantification and that reasoning's interaction with their problem-solving process more generally. Further, since they had already attempted to prove this version of the Arzelá-Ascoli theorem, we were confident that their familiarity with the equicontinuity, boundedness, and total boundedness definitions would allow them to begin the task of proving without onerous development of each concept.

We approached our study through a Radical Constructivist (von Glasersfeld, 1995) lens, which in this case meant we interpreted students' meanings as schemes to which they assimilate features of goal-oriented activity. We sought to elaborate the specific schemes supporting their reasoning involving quantification. The interviewers frequently asked students to explain and justify arguments they made, describe how they understood the ideas they were utilizing, and how they understood any visual representations they made. In accordance with Thompson (2008), the initial goal of our data analysis was to build second-order models of the students' understandings and their ways and means of operating. Interviewers posed questions to test hypotheses about student thinking, not to foster particular understandings. Once initial models were built of the students' reasoning, we observed commonality across the ways that the students were operationalizing variation and pair-wise relationships. We then returned to the data to engage in interpretive analysis (Clement, 2000) with a particular focus on generating new theoretical models of students' reasoning with multiply-quantified statements.

Our initial models described ways that Adisa and Fenfang reasoned about (or backgrounded) the variation in and interrelationships among the quantities in the proofs. As noted above, we call these actions *quantification operationalizations* because they simultaneously give meaning to the quantification and provide ways of using the quantification for proof construction. We attended to the ways the quantops helped Adisa and Fenfang reason about these highly complex proofs, helped us explain their lines of reasoning, and often entailed actions and counteractions by which quantification could be backgrounded and foregrounded as needed. By iteratively analyzing the students' quantification actions and developing our analytic descriptions of each quantop, we refined a list of quantops 1) that could account for the range of student reasoning across the data and 2) in which each quantop occurred multiple times across the interviews.

Results

We present our results in two sections. First, we present and define the seven quantops. Then, we present illustrative data from the students' work on the Arzelá-Ascoli theorem.

Defining the quantops

We identified seven categories of quantops, each with a foregrounding and backgrounding aspect. These two aspects were important for managing the complexity of the statements and relationships being reasoned about. Table 1 presents all seven of the quantops. There are two forms of each quantop: one that backgrounds the quantification to allow the prover to reason about other matters and another that foregrounds the quantification as the focus of reasoning.

Table 1. The foregrounding and backgrounding forms of the seven quantops.

Quantop	Foregrounding	Backgrounding
Variation quantop	Imagining variation in a quantity	Fixing an otherwise variable quantity
Unitizing quantop	Unpacking variation within some unit	Encapsulating variation in some way
Dependence quantop	Constructing relationships of dependence or invariance	Quantifying two variables with no identified relationship between their variation
Cardinality quantop	Making inferences about a variable by explicitly referencing the cardinality of its possible values	Making inferences about a variable based on implicit imagery or acknowledging possible alternatives in the cardinality of variation
Notational quantop	Explicitly linking notation to some aspect of an object's quantification status	Making inferences about a variable based on implicit assumptions about notation or an image of suppressed notation
Existential quantop	Warranting existence by stipulation or construction	Assuming existence to allow further proof activity
Inference quantop	Tracking a line of inference as quantities vary	Constructing lines of inference within other quantification backgrounding actions

Variation Quantop: Fixing a quantity that varies/ imagining variation in a quantity. Universal quantification is frequently operationalized by reasoning about a fixed, but arbitrary element of the set (often expressed by the word "let"). This means imagining fixing a quantity with the awareness that it could otherwise vary. The complement action to fixing a quantity is intentionally imagining variation in the quantity. It is worth noting that imagining variation can happen in different ways such as imagining continuous variation of a number, imagining iterative variation in some countable set, or imagining variation through elliptical reasoning about a few representatives. The intentional variation may need to be coordinated with any reasoning previously performed on the fixed quantity, which often involves some of the other quantops.

Unitizing Quantop: Unitizing an object that involves variation. This quantification action occurs when the reasoner has some means by which they can encapsulate variation via some representation or property that allows them to reason about a range of values at once. For instance, the graph of a function can be understood to represent the range of values of the input and output. A neighborhood stands for all of the values of the variable bounded within the neighborhood. Graphical representations in particular provide tools for unitizing variation. This allows an association of numerical bounds ($|f(x) - f(t)| < \varepsilon$) with spatial regions (e.g., inside ε-tubes on a graph). The use of neighborhoods to encapsulate a range of values is essential to the interface between topological and metrical interpretations of analysis.

Dependence Quantop: Dependent covariation and independent invariance. In an each-to-some pairwise relationship, one quantity may be understood to depend on the other. Accordingly, varying one quantity results in the dependent quantity varying with it, hence the two co-vary. In a one-to-every pairwise relationship, variation in one quantity does not require variation in the other. The other quantity remains invariant, and hence is considered independent. Constructing relationships of independence/dependence or co-variation/invariance are an essential quantop for reasoning about pairwise relationships, and other quantops are often employed toward this end.

Cardinality Quantop: Attending to the cardinality of a quantity's range of values. This quantop is important for imagining variation and reasoning about dependence/independence. An invariant quantity takes on exactly one value. A covariant quantity takes on the same cardinality of values as the quantity with which it varies (or at least no larger a cardinality). A quantity that varies finitely affords certain actions such as taking a maximum. A quantity that varies countably may be reasoned and proved about iteratively. A quantity that varies uncountably must be reasoned about without taking maximums or assuming a "next" choice.

Notational Quantop: Notating features of quantification. A number of notational tools and conventions are used to maintain a record of the quantops performed to aide reasoning about the range of relevant objects and their quantificational status. When two quantities co-vary, they are often notated with the same subscript or one serves as a subscript for the other (e.g., f_i and ε_i, δ_ε). When a quantity is independent (cardinality of 1), it may be notated using *, lack of a subscript (implying lack of variation or dependence), or some other marker of uniqueness. If a quantity varies countably (including finitely), they are often indexed by the natural numbers to express the cardinality of variation. Mathematical concepts are sometimes named to indicate a particular quantification structure; the adjective "uniform" in analysis often means that a relationship holds independent of the variation in another quantity. However, neither dependence nor variation are always notated. When a proof operates fully by universal generalization, an arbitrary value stands for all possible values without further notation (such as "Let $\varepsilon > 0$").

Existential Quantop: Warranting existential quantification. Proofs of existentially quantified claims require that provers warrant the existence of an object meeting the stated requirements. The two primary ways of warranting existence in a direct proof are by construction or by stipulation. One warrants existence by construction when you show how the quantity could be produced from other quantities (e.g., $\varepsilon = \frac{\delta}{M}$ or $M^* = \max\{M_i\}_{i=1}^{n}$). One warrants existence by stipulation when a definition guarantees that something exists. For instance, if we know a function is bounded we can stipulate that M exists such that $\forall x, |f(x)| \leq M$ (this is sometimes called *existential instantiation*). The complement action to warranting existence is to assume existence. We observed several times when students assumed that some quantity existed to elaborate a line of inference before later returning to warrant that claim. This backgrounds the need to warrant existence to allow progress on the proof.

Inference Quantop: Imagining a line of inference under variation. Proofs entail inferences and constructions performed on quantities within some imagined quantification structure. These lines of inference become nested within other quantops such as fixing or varying certain quantities, which often means the whole line of inference must be analyzed under variation. If a quantity is constructed from another that is temporarily fixed (e.g., $\delta = \min\left\{\frac{\varepsilon}{3}, 1\right\}$), then varying the first quantity may result in varying the newly constructed one. This induces a relationship of dependence. If one wants to justify a relationship of independence, the reasoner must attend to why the construction of one quantity remains invariant while other quantities are allowed to vary (e.g., the maximum or supremum of a set does not vary as the values in the set vary).

Examples from student data: Proving totally bounded implies bounded

We limit our data presentation to Adisa and Fenfang's initial orientation to the concepts since it highlights many of the quantops and is easier to describe succinctly as compared to the extended proof production that followed. They began their work with the statement of the Arzela-Ascoli theorem written on the board as "A subset S of $C([a, b], \mathbb{R})$ (sup) is equicontinuous and bounded iff it is totally bounded." Since we aim to link the imagery of the various quantops to students' goal-oriented activity, we organize this description by the apparent goals the students were pursuing throughout the task-based interviews.

Goal 1: To recall and write the definition of equicontinuous. Fenfang began writing a definition of equicontinuity as "$\forall \varepsilon > 0, \forall n \in \mathbb{N}, \exists \delta > 0,$ s.t. if $|x - t| < \delta$, $|f_n(x) - f_n(t)| < \varepsilon$." Adisa asked if this was "uniform" or "pointwise." Fenfang explained why this was "uniform" in two ways. First, she said that a pointwise meaning would have "$\forall x$" at the beginning. Then, she explained that for pointwise "we fix one x [tracing a vertical line with her hands] and then we have… epsilon and delta." They agreed this expressed "uniform equicontinuous" while Adisa wrote the definition of "point-wise equicontinuous" as "$\forall x, \forall \varepsilon > 0, \exists \delta > 0\ |f_n(x) - f_n(t)| < \varepsilon, |x - t| < \delta. \forall n$." Adisa explained the difference saying, "For every x, there is a δ that you pick such that this will cause [points to the inequality on f values]."

We observe two quantops in this quick interchange. Fenfang fluidly shifted from moving the quantification expression "$\forall x$" to the front of the definition and imagining fixing that quantity before introducing the others (variation quantop). They recognized that this meant the δ that followed depended on the choice of x (dependence quantop). While they expressed this in writing using syntactic order, they did not completely rely on order to express quantification relationships. In the process of writing their definitions, both wrote the final predicate "$|f_n(x) - f_n(t)| < \varepsilon$" before they wrote other quantification expressions. Adisa reversed the common syntax by writing the conditions on x, t, and n after the predicate inequality. Fenfang used conditional "if, then" structure to quantify x and t, which is common for the nested universals in analysis definitions (a backgrounding variation quantop). We thus observe that their ways of constructing and expressing pairwise relations were more robust and varied than mere syntactic order, which remained true throughout the interviews.

Goal 2: To recall and write the definition of bounded. Adisa then questioned whether "bounded" meant "one M for all of them or one M for each one." The interviewer asked the students to explain the difference. Adisa initially said it "boils down to the same" suggesting the two were equivalent. To explain this, Adisa began exploring whether he could prove one from the other. He wrote the definition, "$\exists M > 0$ s.t. $|f(x)| < M\ \forall f \in \mathcal{E}$." He then wondered aloud about the cardinality of $\mathcal{E}$. He explained that if this set were finite and "I could always take the max of all of them and use that as the M for every one of them." He later expressed this writing, "$M = \max\{M_1, M_2, \dots, M_n\}$." Alternatively, he explained that when $\mathcal{E}$ is infinite, this would not be possible since you would have to take the supremum of the bounds (which may not be finite). He thus decided that the definition must mean "one M that bounds all the f's in the subset."

We observe that Adisa used implication between the two possible meanings of bounded to decide what was the correct definition. First, he used dependence and cardinality quantops to interpret how the conditions were different. It seems he implicitly assumed that having one M implied having a bound for each (one M is a stronger condition) and thus focused on proving the converse implication. Within the condition "one M for each," he imagined M varying as f varied so that finitely many functions meant finitely many bounds (variation and dependence quantops). He expressed the maximum of these bounds by constructing the universal bound with no subscript as the maximum of the set of varying bounds with natural number subscripts (notational quantop). He then considered the available inferences on the set of bounds (inference quantop). Since an infinite set of bounds would not always be bounded above, he decided that having many M's did not imply having one M and that the definition was the stronger condition.

Goal 3: To recall and write the definition of totally bounded. Adisa had written on the board "$\forall \varepsilon > 0\ A \subset M\ \exists$ finite covering by ε-ngbhds" as a definition for a totally bounded set M. He elaborated using a diagram of a square, which represented the set A. He said if you fix $\varepsilon = 1$, then there would be a finite set of neighborhoods that cover A. He represented this by drawing circles on the square that covered most of its area. He then elaborated his written definition with the set $\{a_1, \dots, a_k\}$ explaining "every member of A will be in one of these ε-neighborhoods, centered at one of those." As Fenfang explained her interpretation of the diagram by putting a_i at the center of each circle, Adisa also wrote "Let $\varepsilon = \varepsilon_k$. $\{M_\varepsilon(a_i)\}_{i=1}^{k}$." Both students were working to elaborate that the a_i were centers of epsilon neighborhoods with radius ε.

In this discussion, the students constructed a complex each-to-some relationship in which each of the (infinitely many) functions was in some one of the (finitely many) neighborhoods, which involves the cardinality and dependence quantops. However, the specific functions in the neighborhoods were nowhere represented on the board except as locations in the square. This reflects the idea that the cover means that neighborhoods stand for the range of values within them (unitizing quantop). The neighborhoods themselves represented covariation of three entities: center, radius, and set. Adisa began discussing only the radius and centers before he noted that each center represented a whole neighborhood, which he then notated using $M_\varepsilon(a_i)$ (dependence quantop). Both students felt the need to recognize the various moving parts even while they clearly linked them as compound units that covaried. This helps explain why Adisa, after initially fixing ε=1 (variation quantop) later wrote "$\varepsilon = \varepsilon_k$" to show that the radius did not vary with the neighborhood (dependence and notation quantops).

Conclusion

In this paper, we set forth seven categories of quantops that capture the complex ways two graduate students managed the high number of quantities involved in the Arzelá-Ascoli theorem and the relationships between them. These categories contribute to the literature by identifying new aspects of how quantification is enacted in reasoning about analysis proof tasks. Furthermore, we note the interplay between foregrounding and backgrounding quantification to manage the cognitive load of the tasks. Due to space concerns our data presentation was limited to a largely illustrative function. However, we anticipate that future reports and studies can continue this work to characterize how quantification is enacted in reasoning. A natural future step is to explore how learners can develop these highly complex skills for proof production.

A Symbolizing Activity for Constructing Personal Expressions and its Impact on a Student's Understanding of the Sequence of Partial Sums

Derek Eckman
Arizona State University

Kyeong Hah Roh
Arizona State University

This paper reports the results from a set of exploratory teaching interviews designed to engage students in reasoning about partial sums and constructing individualized algebraic expressions (called personal expressions) to describe their meanings for partial sums. Our analysis focused on one particular student, Emily, who constructed two sets of personal expressions to describe her conceptions for partials sums as (a) a process and (b) the result of an additive process, one novel and one based on her image of summation notation. We conjecture that investigating individual students' purposes for creating personal expressions and how these expressions evolve will provide greater insight into how students use mathematical notations and their meanings for particular mathematical topics such as infinite series.

Keywords: Infinite series, symbolization, exploratory teaching interview, calculus, summation symbol

Introduction and Literature Review

Mathematicians and students use semiotic representations such as graphs, algebraic notation, formal statements, and diagrams ubiquitously to convey their images for mathematical concepts. Algebraic notations are often privileged in teaching calculus topics such as infinite series (González-Martín et al., 2011) and constitute a focal point of students' reading of mathematical proof (Shepherd & van de Sande, 2014). Algebraic expressions such as summation notation and limit notation can be difficult for students to interpret because expressions often convey dual meanings, such as a dynamic process (i.e., additive process, limit process) or the result of this process (i.e., sum, limit value), and students must determine which meaning is appropriate in a given context (Gray & Tall, 1994; Güçler, 2013; Kidron, 2002; Martínez-Planell et al., 2012). Gray and Tall (1994) claimed that professional mathematicians' ability to reason about mathematical concepts successfully comes from flexibly using notations to describe either a process or the result of the process. Although cognitive theories related to students' construction of stable concepts from processes abound in the literature (e.g., Dubinsky, 1991; Glasersfeld, 1995; Sfard, 1991), there has been little research on the algebraic expressions that students create in correspondence with this cognitive transition (e.g., Tillema, 2010).

This paper constitutes the results from one portion of a more extensive study designed to investigate undergraduate students' symbolizing activities related to infinite series. In mathematics, the symbolic expression $\sum_{n=1}^{\infty} a_n$ for an infinite series indicates (1) the process of summing consecutive terms of an infinite sequence (a_n) and (2) the metaphorical "result" of this process. The method to establish whether an infinite series converges and the value to which it converges is to determine the limit of the corresponding sequence of partial sums, typically denoted using the expression $\sum_{i=1}^{n} a_i$. To construct the sequence of partial sums, the student must abstract the process of computing individual partial sums into a cognitive entity that can be coordinated with an index to order the partial sums into a sequence.

The conventional algebraic notation for denoting the general term of the sequence of partial sums is summation notation, i.e., $\sum_{i=1}^{n} a_i$. Some researchers have reported the potentially problematic nature of the indices of the notation (i.e., i's in a_i; Katz, 1986) and how students' meanings for the indices can affect their ability to interpret or expand summation notation (Strand et al., 2012; Strand & Larsen, 2013). However, there is scant research on how students impute their various meanings for partial sums to algebraic expressions or the ways in which these expressions change as the student's conceptions of partial sums evolve. Consequently, this paper will describe the evolution of one students' algebraic expressions for individual partial sums as she transitioned from considering the process of computing individual partial sums to envisioning arbitrary partial sums as a concept. The research questions addressed by this study are: (1) *what purposes do students have for constructing and utilizing symbolic expressions for partial sums?* and (2) *how do students' constructed expressions evolve as a student moves from considering partial sums as a process to a result?*

Theoretical Perspective

In this paper, we adopt a radical constructivist ontological perspective on algebraic expressions. Glasersfeld (1995), who initiated radical constructivism, proposed the following definition for symbol: "a word will be considered a symbol, only when it brings forth in the user an abstracted re-presentation" (p.99). In this context, a *re-presentation* is an abstracted component of an individual's previous experience that she posits in her mind's eye to metaphorically re-experience the situation. From this standpoint, an algebraic expression itself becomes a symbol (to a student) only when she imputes a component of her previous experience (e.g., relationship, process, concept) to the expression.

We will use the term *personal expression* to denote an algebraic expression that a student has created and to which, in the researcher's mind, the student has imputed a re-presentation. We will call the basic unit of an *expression* an *inscription*, which we define as a written mark utilized by an author to succinctly describe a property, action, or relationship that the author has envisioned. A student may adopt a conventional notation to construct a personal expression or create a unique and novel expression. However, we will only call an expression a personal expression if it appears, to the researcher, that the student has "something to say through [it]" (Thompson & Sfard, 1994, p. 6).

There are several "things" that students say through their personal expressions. For example, Gray and Tall (1994) identified three meanings that a student can impute to an expression: (a) a process or mathematical operation such as adding consecutive integers, (b) a concept such as the sum of the first ten positive integers, or (c) a dualistic meaning encompassing both the process and the concept such that either may be called upon at will. Gray and Tall (1994) used the term *procept* to identify the third meaning, a personal expression that a student employs fluidly to re-present either a process or a concept (according to her needs). In the results section of this paper, we report a student's construction of a set of personal expressions that she initially utilizes to re-present a process (meaning "a") and her subsequent construction of a new personal expression to re-present a proceptual meaning for partial sums (meaning "c").

Methodology

The data for this study consisted of four 90-minute individual exploratory teaching interviews (Castillo-Garsow, 2010; Moore, 2010; Sellers, 2020) conducted during the Summer 2021 session at a large public university in the Southwestern United States. This paper focuses on the first two interviews, which entailed tasks related to the sequence of partial sums. The student participants were enrolled in a second-semester calculus course and completed the unit on sequences and series between the two interviews. Due to the pandemic, the interview was conducted remotely, and student work was recorded on a collaborative whiteboard application. The first author served as the teacher-researcher, and the second author served as the witness.

The task sequence was based loosely on a three-phase approach described by Radford (2000). In the first phase, the students described how they might determine individual partial sums from a set of five infinite series presented in expanded form (e.g., $1 + \frac{1}{2} + \frac{1}{4} + \cdots$). In the second phase, the teacher-researcher prompted the students to reflect on their actions during Phase I and construct a written rule for determining an arbitrary partial sum. In the final phase, the teacher-researcher introduced the concept of a personal expression, asked the students to construct personal expressions to denote an arbitrary partial sum, and describe their meaning of partial sums, the sequence of partial sums, and infinite series through their expressions.

Results

This section focuses on one student, Emily, and her journey to construct a personal expression that she could use to re-present her image for partial sums. Emily was a chemical engineering student who had just finished her freshman year and took second-semester calculus during the Summer 2021 session. We focused our analysis of Emily's interviews on (a) describing the purposes that Emily had for constructing her written rule and personal expressions to describe partial sums and (b) examining the evolution of her personal expressions throughout the interviews. In the following subsections, we discuss Emily's actions and personal expressions during each of the three phases of tasks, focusing mainly on her construction of expressions to describe a process for computing a partial sum and adopting a holistic view on partial sums.

Phase I and Phase II: Reasoning about Partial Sums and Developing a Written Rule

During the Phase I task, Emily developed a four-step process to determine the value of an arbitrary partial sum. These steps included (a) examining the initial terms in the series to develop a recursive or explicit pattern to generate additional summands, (b) test the potential pattern on all known values in the series, (c) use the pattern to generate all terms in the series until the desired term (e.g., 37^{th} summand), and (d) add the terms together to compute the partial sum. In the Phase II task, Emily constructed a written note to reflect these four steps (see Figure 1). Her purpose for constructing this note was to describe the process of computing a partial sum in clear, distinct steps, as evidenced in the transcript below:

Interviewer: Go ahead and explain to me your rule, your written note.

Emily: Ok, so first, um. Well, first, before, when I was thinking about how, like, what steps I would do [*to determine a partial sum*], I could not describe a way that I would tell someone it, because. I'm a visual learner, and I would have to show, I would have to have a sequence (*Emily used sequence and series interchangeably*) in front of me to show them like, "Ok, this is what you do." So, I was like, Ok, so I'm going to change it and I'm going to put it like an instruction manual. Um, so, in that tense, the first step is to…

In this episode, Emily was unsure how to describe her thinking in written form until she decided to create an ordered set of instructions delineating her method to determine an arbitrary partial sum. After Emily decided that the purpose of her written rule was (to her) to depict a process, she quickly and efficiently wrote the four-step written note shown in Figure 1. In this regard, we conjectured that Emily could leverage her *describe-a-process purpose* for developing her written rule to construct a personal expression through which she could re-present to herself this process.

Phase III, Purpose 1: Developing a Personal Expression to Describe a Process

During the Phase III task in the first interview, we presented Emily with a video clip describing the meaning of personal expressions and providing examples of constructing personal expressions (the video clip may be viewed at https://youtu.be/PdKkhZVPulA). After the video clip, we asked her to create a personal expression for an arbitrary partial sum and record any inscriptions that she created in a glossary. Emily's written rule, personal expressions, and glossary are contained in Figure 1.

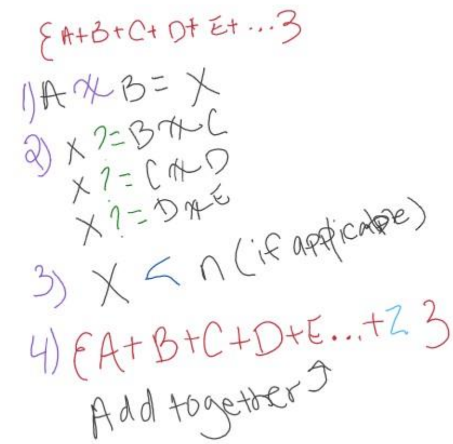
Emily's written note:

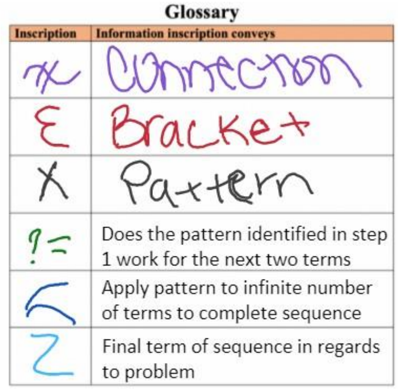
In order to find the sum of any number of terms in a series, follow these steps:

1) Compare the first and second terms in the series. Meaning look at these first two terms and think about how they connect to each other. Ex: 1 > 2 (Explain how you can get from 1 to 2 and usually you will find the pattern to the whole sequence quickly.
2) Once you think that you have figured out the pattern. Use it on the rest of the sequence. If it works out with all of your terms then you have found the pattern correctly. If not return to step 1 and repeat until correct.
3) After you have found the correct pattern for the sequence. All you have to do is apply it until you reach the term you wish to calculate.
4) Now you have calculated the correct number of terms needed. Lastly, you will take all of your solutions and add them up to find the sum of your number of terms.

Then CONGRATs you have found the sum of the number of terms.

Emily's Personal Expressions





Glossary

Inscription	Information inscription conveys
ϰ	Connection
{	Bracket
X	Pattern
?=	Does the pattern identified in step 1 work for the next two terms
≺	Apply pattern to infinite number of terms to complete sequence
Z	Final term of sequence in regards to problem

Figure 1. A comparison of Emily's written rule, personal expressions, and glossary

In Emily's personal expression, the order of the summands of the series is designated by capital English letters. Emily used her "connection" inscription to indicate a relationship between consecutive summands in the series and her quantification of this "pattern" with the letter x. Emily's use of these two inscriptions closely corresponded with Step 1 of her written rule, such that Emily could re-present the first step in her written note through line (1) of her personal expressions. Emily's introduction of her fourth inscription in the glossary, $?=$, functioned as a testing operator through which Emily could re-present the second step of her written note—testing subsequent pairs of summands to determine whether pattern x holds for all summands. Emily utilized her fifth inscription, similar in appearance to $\prec$, to re-present the process of generating the first n summands of the series by repeatedly applying the pattern x to consecutive terms. Finally, Emily introduced a sixth inscription, Z, through which she could designate the value of the nth summand to re-present the partial sum generated by computing the sum of the terms. Although Emily's personal expressions more closely resemble a form of shorthand than a conventional mathematical expression, her personal expressions fulfilled the purpose that Emily proposed when she initially constructed her written note: to serve as a symbolic medium through which she could re-present her process for computing individual partial sums. After Emily successfully created the personal expressions to re-present her instruction manual for determining individual partial sums in the first interview, we decided to challenge Emily's thinking in the second interview by asking her to describe individual partial sums and the infinite series itself with her expressions in the second interview.

Phase III, Purpose 2: Developing a Personal Expression to Describe a Procept

In the second interview, Emily utilized her personal expressions from the first interview to describe the sum for any number of terms in a series. When the teacher-researcher asked Emily to use her personal expression to describe the "entire series," she immediately stated that she would need to create a new inscription. After creating and rejecting a novel inscription, Emily proposed using a variation of conventional summation notation, Σx, to convey a "holistic view" of a partial sum, as evidenced in the following transcript:

Interviewer: Why did you pick this inscription [Σx] for representing the entire series?

Emily: I used it because, so, I know it is used in, like, you know, like, official math symbols, and it's used quite a lot, at least in calculus it's used a lot. And, I do not think I 100% really understand the importance, or maybe the, um, symbolism that this little thing (*indicates sigma*, Σ) does. But I do know that it's used to represent a holistic view of something. And so, that's the closest symbol I can think of. All my symbols were going to look something like that, the ones I was thinking of before I made it. So, I do like the holistic view of what it means no matter, whenever it is used, it always means, like, all of something. So that's why I choose it.

At this moment, we claim that Emily's purpose for constructing a personal expression changed from a *describe-a-process purpose* to an *adopt-a-holistic-view purpose* that resulted in constructing a personal expression to re-present both the additive process of computing a partial sum and the result of the process. We further claim that Emily's "holistic" personal expression functioned as a *procept* through which she could fluidly consider either the process of generating summands and adding them together or the resultant sum. The transcript below indicates this fluidity in re-presentations that Emily imputed to her "holistic" expression, which she employed to describe specific partial sums for individual series (see Figure 2).

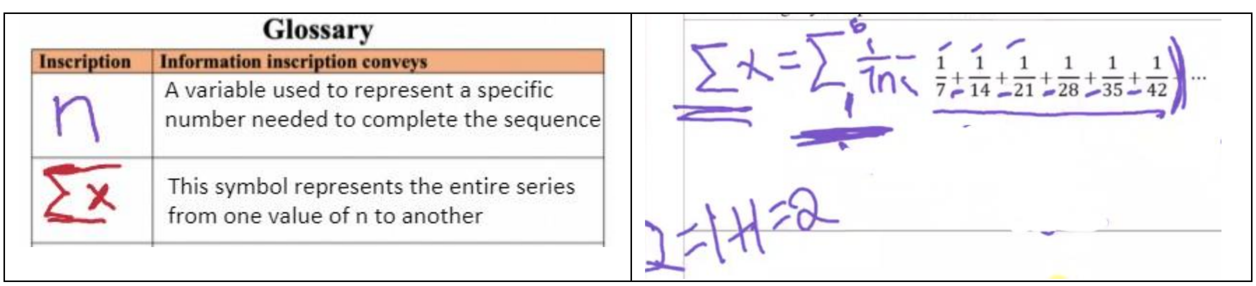


Figure 2: Emily's personal expression for a "holistic" view of a partial sum

Emily: So $1+1=2$, right? So, if you have this $(1+1)$ equals to Q (*writes* $Q=1+1=2$), then Q equals not only $1+1$, but it always equals 2. Does that make sense? So, yes, in the inscription ($\sum_1^6 \frac{1}{7n}$) when you say what it equals, it would equal all of these written out (*indicates* $\frac{1}{7}+\frac{1}{14}+\frac{1}{21}+\frac{1}{28}+\frac{1}{35}+\frac{1}{42}$). But when you add them together, it also equals that (*indicates* $\sum_1^6 \frac{1}{7n}$) .

Emily's new personal expression through which she re-presented partial sums became a powerful tool for her to describe partial sums, infinite series, and components of infinite series throughout the remainder of the second interview. However, Emily also continued to use her original shorthand personal expressions (see Figure 1) to describe computing individual partial sums in the series task following the introduction of her "holistic" personal expression. For example, after Emily constructed instantiations of both types of personal expressions to describe (a) the process of computing any partial sum (using expressions in Figure 1) and (b) the partial sum itself (using expressions in Figure 2), the interviewer asked Emily whether her personal expression for an arbitrary partial sum, $\sum_1^n x$ (part "b"), could be used to compute any partial sum (part "a"). The transcript below details Emily's response, which indicates that she was beginning to consider that her "holistic" personal expression might subsume her original personal expressions that functioned as shorthand for her written rule:

Emily: Yeah, you could because, like I said before, as long as this top n does not equal infinity, x, or you know whatever, this (*indicates* $\sum_1^n x$) equals this (*indicates* $\frac{1}{3}+\frac{1}{8}+\frac{1}{13}+\frac{1}{7}+\frac{1}{35}+\cdots$)… But, um, so this, the "holistic" inscription that I made equals the $\frac{1}{3}+\frac{1}{8}+\frac{1}{13}+\frac{1}{7}$. So, yes, as long as n is not infinity in the way that I've written it, um, this whole thing (*indicates* $\sum_1^n x$) can answer number 1 [part "a"] and number 2 [part "b"].

For the remainder of the interview, Emily utilized only her "holistic" personal expression, $\Sigma_1^n x$, to describe partial sums and series. However, the remainder of the tasks were related to describing infinite series or partial sums as results, so we do not have clear evidence that Emily would not have utilized her original shorthand personal expressions to describe computing individual partial sums. This experience indicates that even though Emily created an expression through which she could re-present a proceptual view of partial sums, the "holistic" expression might not have entirely subsumed her original shorthand expressions. Instead, Emily's two types of personal expressions likely evolved to fulfill two separate (to her) purposes: re-presenting the process of computing a partial sum and re-presenting the result of this process.

We acknowledge that because Emily participated in an accelerated sequences and series unit in the week between the first and second interview, it is likely that summation notation was more readily available to her in the second interview than the first. However, we make two points about Emily's use of summation notation to clarify that her exposure to summation notation in her course did not unduly affect her construction of personal expressions. First, Emily persisted in using her original personal expressions in both interviews to re-present the process of computing a partial sum, including after the portion of the interview where she created her "holistic" personal expression, $\Sigma_1^n x$. It appeared that only when Emily's purpose for constructing a personal expression changed from a *describe-a-process purpose* to *adopt-a-holistic-view purpose* did the need for summation notation arise. Second, Emily initially stated that she did not want to use summation notation but settled on this convention after realizing that her image of what summation notation conveyed (i.e., a holistic entity) aligned with her purpose for constructing a personal expression.

Conclusion and Discussion

The research questions for this paper addressed (a) the purposes for which students construct personal expressions and (b) how these personal expressions evolve as students' thinking changes about partial sums. We have shown the example of one student, Emily, who created two distinct sets of personal expressions—one entirely novel, the second borrowed from convention—to re-present to herself the process of computing partial sums and the resulting partial sums. We have further indicated that neither of Emily's personal expressions seemed to wholly subsume, even as her purpose for creating the expressions changed from re-presenting a process to re-presenting a result. At one point near the end of the Phase III tasks, Emily claimed that (to her) her personal expression resembling summation notation could be used to answer the questions that she had previously utilized her process-oriented personal expressions to answer. However, there is insufficient data to conclude whether she believed her "holistic" personal expression could wholly replace her initial instruction-based shorthand personal inscriptions.

It is worthwhile to note that conventional mathematical symbols all began as personal expressions for individual mathematicians. For example, suppose that a theoretical mathematician spends several months considering a hitherto unreported topic within a particular branch of abstract mathematics. During this research, the mathematician identifies a novel process or concept that she would like to report to the mathematical community formally. In order to both name this mathematical idea and distinguish it from others, the mathematician proposes a new mathematical symbol—or a variation of an existing symbol—to indicate this idea. In other words, the mathematician constructs a personal expression to re-present to herself the mathematical idea that she has constructed. After the publication of the mathematician's work, other scholars might adopt and utilize the newly-constructed symbol in their own work. Over time, the symbol might evolve into a convention with a "normative meaning" assigned by the mathematics community. Mathematicians and instructors might then utilize the conventional expression for decades, or even centuries, to convey this "normative meaning" in their practice. However, the conventional expression would not exist without the work of the original mathematician, who considered an idea that was (to them) unique and constructed a personal expression to which they could re-present their meaning for their novel idea.

We acknowledge that research on communication and symbolization between individuals is essential and helpful to further understanding social dynamics and education at the group level. In this paper, we step even further and move the discussion on symbolization to the realm of individual student cognition. Exploring students' creation of personal expressions is a novel approach that does not focus on the power of semiotic representations to foster communication between individuals and groups. Instead, the focus is on an individual's designation of a semiotic device as an instrument through which she can re-present her meanings to herself (a prerequisite to effective communication with others). In this regard, personal expressions almost always make sense to students, both from a semantic and syntactic perspective, because students create or adapt them to re-present their specific meanings. Research investigating students' personal expressions, students' purposes in creating personal expressions, and how students' personal expressions evolve and interrelate can better identify the various meanings that students impute to their expressions. Individuals construct their own meaning, and by studying students' construction and utilization of personal expressions, we can potentially gain deeper insight into how students use symbolic notations and their meanings for mathematical topics such as infinite series.

Confronting Abstraction: An Analysis of Mathematicians' Concept Images and Definitions

Kyle Flanagan
Virginia Tech

Mathematicians frequently engage in mathematics involving highly formal and abstract concepts. These concepts are often challenging or impossible to accurately visualize. However, mathematicians are still successful at answering new, difficult mathematical problems, despite confronting this obstacle of mathematical abstraction. This study attempts to understand how mathematicians think about and understand abstract mathematical concepts. Tall and Vinner's (1981) notion of concept image and definition are used to model and analyze the understanding of these mathematical concepts. One research mathematician participated in an individual Zoom interview, where both interview questions were answered, and a mathematical task was completed. Analysis provided evidence that for abstract mathematical concepts, a large portion of a mathematician's evoked concept image consists of informal and visual examples. These examples are supplemented with important formal definitions and properties from one's concept image. Implications for the teaching of undergraduate and graduate mathematics are discussed.

Keywords: Abstract algebra, Concept image, Mathematical abstraction, Research mathematician

Introduction

In academic settings, mathematicians frequently engage in solving difficult mathematical problems. For these mathematicians, and in particular those who study pure mathematics, these problems often involve highly formal and abstract concepts. With the introduction of more recent mathematical theories, such as category theory, much of the newest, most cutting-edge mathematical research is teeming with exceedingly abstract terminology, definitions, theorems, and proofs. One research area in which the extent of the abstraction can be clearly acknowledged is in the broad field of abstract algebra, which includes some subfields such as algebraic geometry and commutative algebra. A major challenge in understanding abstract, formal mathematics is that as the abstraction grows, the ability to accurately visualize the mathematics frequently becomes more challenging. In contrast, much of primary and secondary school mathematics consists of concepts that can be, at least somewhat, visualized. Simple algebraic concepts like functions can be visualized in the Cartesian plane, geometric objects are easily sketched on paper, and core calculus concepts, such as differentiation and integration, can be visualized through rate of change and area under a curve. This is not to question the difficulty of learning these mathematical concepts, but it illuminates a new obstacle that mathematicians encounter when studying mathematics. However, despite the abstraction of formal mathematics, mathematicians continue to be successful at solving problems and publishing new results. Thus, it is worth investigating how mathematicians think about abstract mathematical concepts.

In mathematics education, the research of mathematicians' mathematical practices is largely uncharted territory. Moreover, there is even further scarcity in the literature on how mathematicians think about and understand mathematics. One mathematical practice that has been closely studied is how mathematicians interact with proofs, such as their reading, writing, and evaluation of them (e.g., Mejía-Ramos & Weber, 2014; Weber, 2008; Weber & Mejía-Ramos, 2011, 2013). Leone Burton (1999) conducted an interview-based study of seventy research mathematicians about how they "come to know" mathematics. Though this study is insightful, her emphasis was on their mathematical practices and how they engaged in mathematical communities of practice, not on modeling the mathematicians' thinking.

Furthermore, mathematicians are valuable members of the broad mathematical community. They instruct and mentor undergraduate students, and they are responsible for the presentation of much of the advanced mathematics that these students will encounter. In addition, some of these students will go on to teach mathematics in primary and secondary schools. Thus, understanding how mathematicians think about and understand mathematics could provide valuable insight into mathematicians' teaching practices and why they are successful or not. Moreover, this could then also have far-reaching benefits for the undergraduate and graduate students who are taught by these mathematicians. Lastly, mathematicians are excellent at understanding highly abstract concepts. Working to understand and model their mathematical thinking may be advantageous in learning how to help and instruct students to develop this same level of understanding.

Literature Review

The term "abstract" in mathematics is often used to describe formal mathematics because formal, or pure, mathematics is centered on the use of generalized definitions, concepts, and symbolism. I will define *abstraction* to be the process of generalizing a concept, phenomenon, or observation by extracting the underlying properties or structures, without reference to the particular instances that they came from. In formal mathematics, abstraction serves a pivotal role because it allows mathematicians to solve the general case of a problem, rather than just a specific scenario. As an individual continues to learn new mathematics in a specific field, it is likely that the mathematical concepts may become more abstract. Dienes (1961) describes this notion as follows: "When we say 'more abstract', we mean that more, seemingly rather different, situations may be described at the same time… Getting more abstract then means extending the field of applicability" (p. 293). Moreover, Hiebert and Lefevre (1986) use the term "abstract" to refer to the degree to which a unit of knowledge is tied to specific contexts (pp. 4-5).

To be successful, mathematicians need to be proficient at understanding and utilizing abstract concepts, and potentially also, constructing new abstract concepts. This raises the question of how are mathematicians able to successfully work with abstraction in mathematics? More specifically, how do mathematicians understand and think about mathematics that they cannot accurately visualize? One thread of research that begins to address this question is on how mathematicians leverage the use of examples to explore and prove conjectures (Lockwood, Ellis, & Lynch 2016; Lynch & Lockwood 2019). Constructing examples for an abstract concept allows for a way to connect the unfamiliar mathematical concept to a familiar concept that is already known or understood. Lynch & Lockwood (2019), when comparing the use of example between mathematicians and students, observed that "mathematicians were much more explicitly attuned to the logical structure of conjectures and how examples fit into those structures" (p. 337). Though this observation is in the specific context of mathematical proof, it demonstrates that for mathematicians, examples and the formal concepts they exemplify are deeply intertwined. Vinner and Dreyfus (1989) also state that, "The student's image [of a mathematical concept] is a result of his or her experience with examples and nonexamples of the concept" (p. 356). It could then be assumed that mathematicians' understanding of a concept is, at least partially, structured by, and reliant on, insightful examples that illustrate the properties of that concept.

Theoretical Framework

The theoretical constructs of *concept image* and *concept definition* (Tall & Vinner, 1981) have been used in a variety of contexts. Tall and Vinner define the concept definition to be "a form of words used to specify that concept" (p. 152). This concept definition can vary over time, and different definitions can be used in varying contexts. Furthermore, this definition can differ from the formal concept definition that is generally accepted by the mathematical community at large. The more complex construct is that of the concept image, which Tall and Vinner define as "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p. 152). In particular, the concept image not only consists of visual imagery. Vinner (1991) states that an individual's concept image "can be a visual representation of the concept in the case the concept has visual representations; it also can be a collection of impressions or experiences" (p. 68). A person's concept image will likely change over time, and at any given moment, a portion of a person's concept image may be used and become activated, which Tall and Vinner (1981) define as the *evoked concept image*. Moreover, two different components of one's concept image or definition may be in conflict with one another, which can lead to any number of negative responses. Tall and Vinner refer to this notion as a *potential conflict factor* (p. 153). Research related to concept image and definition frequently focuses on content from high-school or undergraduate mathematics courses, such as calculus, linear algebra, or abstract algebra (e.g., Melhuish et al, 2020; Rösken & Rolka, 2007; Wawro, Sweeney, & Rabin, 2011). I am unaware of there being any research utilizing concept image and definition to study mathematical content beyond the undergraduate level.

Methods

Research questions

On the basis of the aforementioned background and framework, I examined mathematicians' concept images and definitions for various graduate-level abstract algebra concepts. These concept images and definitions are then used to analyze how mathematicians think about and understand abstract mathematics. The following two research questions are central to this study:

1. How much of a mathematician's concept image for an abstract mathematical concept is composed of visual components and images?
2. What other components of mathematicians' concept images of abstract mathematical concepts are evoked when engaging in mathematical thought and activity?

Design of the study

The participant in this study was one male mathematics professor at a large public university in the southeastern United States. The participant (Luke) is an assistant professor with research interests in various topics in abstract algebra. He was contacted and asked to participate based off of his personal background and experience in mathematical research relating to abstract algebra. The data for the study was collected through an individual interview, where interview questions were answered, and Luke engaged in a mathematical task.

The participant first participated in one 15-minute Zoom meeting where he was asked about his mathematical background and understanding of certain algebraic concepts. The answers provided during this meeting informed which mathematical task was given during the interview. No data was collected during this preliminary meeting. Luke later participated in one 45-minute individual, semi-structured Zoom interview, which was recorded for more-detailed analysis. The interview started with questions pertaining to how he thinks about modules, tensor products, and direct limits, which are abstract concepts commonly used in algebra. These interview questions were designed to help begin delineating his concept images and definitions for these three mathematical concepts. Motivation for the phrasing of the questions was taken from how

Melhuish et al. (2020) articulated their questions about concept definitions of homomorphism and function. For example, two of the interview questions were:

1. How would you define what a module is?
2. What other mathematical concepts, objects, or ideas do modules make you think about?

Interview questions mentioning the word "example" were purposely excluded from the interview, in order to ensure that he was not influenced into sharing examples, but any examples he shared would be an unbiased part of his evoked concept image. Afterward, he was given the following mathematical task, asking him to compute the direct limit of a particular direct system of modules. The task was chosen because it was a problem that he had likely never encountered.

Consider the directed set on $\mathbb{N}$ given by the partial ordering $m \leq n$ if and only if m divides n. Define the directed system of $\mathbb{Z}$-modules $\{M_i\}_{i\in\mathbb{N}}$ where $M_i = \mathbb{Z}$ for all $i \in \mathbb{N}$ and $f_{mn} : M_m \to M_n$ is multiplication by $\frac{n}{m}$. Compute $\varinjlim M_i$.

Figure 1. Mathematical task from the interview, asking Luke to compute a specific direct limit of modules.

The participant utilized tablet screen-sharing to display his work while completing the task. The participant was encouraged to also communicate verbally what he was doing and thinking. The task took about 20 minutes, and all written work was collected after the interview to assist in the data analysis. After the task was completed, interview questions pertaining to how the participant thinks about and approaches mathematical abstraction were asked. This provided an opportunity to collect data tailored more directly to the broad research questions, while also allowing him the opportunity to reflect on the task he had just completed. Following the interview, the interview data was transcribed and analyzed. The analysis process focused on identifying key components of the participant's concept images and definitions, as well as identifying how he approached and understood mathematically abstract concepts. Recurring components were noted and used for more guided analysis.

Results

From the analysis, I found that Luke's evoked concept images for modules, tensor products, and direct limits primarily consisted of examples and visual images, as well as some relevant formal mathematical properties. Pertinent results from the interview are discussed below. Furthermore, results are also presented on how he spoke about mathematical abstraction and how he confronted it. Lastly, Luke was unable to complete the mathematical task during the allotted time of the interview, and some possible reasons for this are discussed below. It should be noted that not every part of the interview, relevant to the research study, is mentioned and discussed.

Examples and visual images

When asked about modules, Luke commonly spoke using simple, visual examples. For example, he often referenced vector spaces when discussing modules. In particular, consider the following interaction:

Interviewer: How would you define what a module is?

Luke: It would probably depend on who I'm talking to, but to a student who has already done linear algebra, I would say that a module is just like a vector space, except the scalars come from a ring rather than a field.

Even though a vector space is a well-behaved, special case of a module, the core properties of this structure can be visualized through images evoked by the concept of vector spaces. Vector spaces also resurfaced in the interview when asked to define what a tensor product is. After Luke discussed the process of finding a basis for a tensor product of free modules, he states:

> If you're just doing vector spaces, every module is free, and you can work with it this way. But it's not always good to pick a basis. We like to work independent of basis, so there is a very abstract way to think about tensor products.

Interestingly, despite the fact that the tensor product of vector spaces provides a way for Luke to better comprehend tensor products, he acknowledges that there are limitations to this restricted understanding. This acknowledgement of an imprecise, but helpful, correspondence between simplified, visual descriptions and formal mathematical properties reoccurred throughout the interview. For instance, he described tensor products as "in a sense like multiplying the two modules."

Later in the interview, when asked to define what a direct limit is, Luke immediately stated, "The simplest possible case of a direct limit is when you have an increasing union." Luke never addressed the formal definition in his discussion of direct limits but chose to primarily provide examples to describe the structure. As we will see later in the discussion, it is likely that this was because he was not certain about his formal concept definition of the direct limit.

Formal mathematical properties

There were multiple instances where the participant called on formal mathematical properties or definitions when answering questions about these mathematical concepts. Some of the examples he provided in the discussion were highly abstract and connected with his specific area of research. However, this was significantly less prevalent than his providing of simple, visual examples and informal descriptions. The first instance of referencing formal mathematical properties is when Luke referred to how he would define what a module is to a class. He mentioned, "If I was teaching a class, I would say that a module is an abelian group together with a map from $R \times M \rightarrow M$ where you have the distributive property and the associative property. So, I would just write all those nuts and bolts out."

Predominantly, Luke mentioned formal mathematical concepts and properties when asked to reference other related mathematical concepts and ideas. One example of this came during the discussion of direct limits:

> *Interviewer*: What other mathematical concepts, objects, or ideas do direct limits make you think about?
>
> *Luke*: Definitely one of the biggest ones is what's called the stalk of a sheaf. And another instance of this is when you talk about, it's the same concept actually, germs of holomorphic functions…Let's just talk complex analysis.

Immediately following this, Luke proceeded to elaborate on many of the details related to the concept of "stalk of a sheaf", using a variety of formal terminology from complex analysis and category theory, such as "contravariance." Another observation is that as the major concepts (module, tensor product, direct limit) became more abstract or complex, Luke tended to answer questions with more informal language and examples. This is interesting because as mathematics becomes more abstract, the formal definitions and properties become that much more important. However, it is possible that he relied on simpler, more visual components of his concept images to effectively understand and communicate his thoughts about abstract mathematics.

Confronting mathematical abstraction

After completing the task, Luke answered more general questions pertaining to abstraction in mathematics. When asked what he does when encountering new mathematical concepts or problems he does not know how to solve, without hesitation he said that one has to do examples. Additionally, he made comments about using strategies such as relating it to something known, understanding the object's properties, and trying to simplify the object. This is evidence that one method of confronting abstraction is to relate the new concept to simpler components of other related concept images. When asked about concepts he cannot accurately visualize he stated:

Interviewer: How do you understand and work with mathematics that you cannot accurately visualize?

Luke: You have to have a way to write it down and work with the objects, and if I can't visualize it, I have to focus symbolically on how can I represent this object, and what manipulations can I do to it.

Luke stated that when he cannot visualize the concept, he has to resort to symbolic manipulation. Even though a visual understanding may not exist for the concept, a formal, symbolic understanding can exist and still be successful in working with the concept. Finally, Luke ended his interview with sharing an informative comment about mathematical abstraction. He asserted, "I think abstraction is useful, extremely useful for, as a lens to view things through and to see general properties. But it always has to be balanced with examples… I don't see much value in abstraction just for abstraction's sake. There has to be a rich class of examples that it applies to." These "rich classes of examples" provide a way to support the formal and abstract components of one's concept image.

Potential conflict factors and mathematical problem solving

While working on the mathematical task, Luke did not complete the problem in the allotted time. The primary reason for this appeared to be that he conflated properties of direct limits and inverse (or projective) limits. Prior to the task, Luke remarked, "For the dual notion, the projective limit, I actually know more." Even though he demonstrated that his concept image for the direct limit was full of coherent examples and informal properties, it is likely that he is more familiar with using inverse limits in his own mathematical work. He later repeated this comment while working on the task. When starting the task, Luke began writing down some of the transition maps between modules in the directed system. Luke stated that he wanted to "use the universal mapping property", but he applied the universal mapping property of the inverse limit instead of the direct limit. He expressed concern that he may have the property backwards.

Here we can see that two different components of his concept image for direct limits were at conflict, which led to a conflict factor. Since his formal concept definition is at odds with another part of his concept image, this led to cognitive conflict when working through the problem. Luke eventually made a guess for the answer, despite using an incorrect definition. However, after working to verify his prediction, he concludes that his prediction cannot be correct. In particular, Luke constructs a homomorphism to help check his prediction, but he realizes that the map is not compatible with the original transition maps he wrote. Nonetheless, after the interview, Luke sent me an email later that day with the correct answer to the problem, providing further evidence that the formal definition was a conflict factor in this situation.

Discussion

The notion of concept image and definition have been utilized to a great extent to try to model mathematical thinking and understanding for secondary school students and undergraduates (e.g., Melhuish et al, 2020; Rösken & Rolka, 2007; Wawro, Sweeney, & Rabin, 2011). However, I was unable to find any instances where this framework was used to study graduate students or mathematicians. I utilized concept image and definition to try to model their thinking in the context of understanding how they confront abstraction. The primary goal of this study was to determine, for a specific abstract mathematical concept, how much of the concept image consists of visual components, and what other aspects are prevalent in that concept image. The analysis shows that mathematicians' concept images may be heavily comprised of visual components, examples, and informal descriptions. However, these visual and informal components are supplemented by relevant formal mathematical properties and definitions. This agrees with Lynch and Lockwood (2019), who state that mathematicians are well-accustomed to how examples fit into logical structures. I note that this study consisted of only one male mathematician with research focusing on abstract algebra, and the mathematical concepts that were analyzed were all algebraic structures. In order to further support these conclusions, it would be valuable to conduct similar studies interviewing more mathematicians, also with a more mathematically diverse group of individuals.

The analysis also demonstrates that Luke's main response to confronting mathematical abstraction and new mathematical problems is to work through examples. For example, when discussing direct limits, Luke mentions:

> Some people are just really good at seeing an abstract definition and getting it. I really think the examples have to be right there to sort of get a feeling for it… I would lean on examples to understand what the concept is about.

Thus, in order for Luke to develop a coherent concept image for an abstract mathematical concept, the concept image needs to also consist of relevant, supportive examples. This supports the claim by Vinner and Dreyfus (1989) that, "The student's image is a result of his or her experience with examples and nonexamples of the concept" (p. 356). A major implication of this analysis is that it highlights the value of integrating supportive examples and visual mathematics into one's concept image for an abstract mathematical concept. More specifically, it could be beneficial to guide students into this process of integrating examples and visual images when learning new mathematical concepts. Moreover, teachers should provide opportunities for students to not only see relevant examples, but also successfully integrate them into their concept images by understanding their value and relationship to the concept. Lynch and Lockwood (2019) came to a similar conclusion about example-related activity in proof, "An implication of this is that it may be beneficial to provide students with experiences of seeing and constructing powerful examples that give insight into a conjecture or a proof" (p. 337).

The task in this study was specifically chosen to represent a concept that was familiar to the participant, but he was uncomfortable working with it. This would provide opportunities to analyze how mathematicians think and work in contexts where they must actively struggle with the mathematical problem. Though he did not complete the task during the interview, the analysis illuminates the value of the formal concept definition in the overall concept image for an abstract mathematical concept. The non-task interview analysis demonstrated the importance of having well-chosen, supportive examples and visual images in one's concept image, but the task showed that the formal properties can be equally valuable in doing mathematics. Luke was able to provide well-chosen examples of direct limits in the interview, but this was not enough for him to overcome the conflict factor with the formal concept definition. In future studies, it could be valuable to see what mathematicians' evoked concept images are in the case where the task was completely solved. Furthermore, analyzing mathematicians' thinking through different mathematical tasks could provide further support for these conclusions.

We survey and synthesize the literature from 2000 to the present about the teaching of proof-based undergraduate mathematics courses and find that the field has learned a great deal about what instruction looks like and why mathematicians teach the way that they do. We identified 112 papers that explored teaching via surveys, interviews, or observations. We report the findings in three broad categories; (1) what occurs in class, (2) the beliefs, knowledge, and rationales that shape instruction, and (3) the relationship between teaching and learning.

Keywords: Teaching, Lecture, Non-Lecture, Literature Review

In undergraduate mathematics education, there are a number of compelling reasons that researchers should explore mathematicians' beliefs, goals, and practices around teaching and learning. First, if we, as a research community, want to better explain the ways that student' mathematical behaviors, understandings, and beliefs, then it is useful to examine how they were taught. An understanding of mathematical instruction can provide us with a lens to analyze students' mathematical knowledge and behavior and provide explanatory accounts for how those behaviors arose. Second, mathematicians are successful learners of mathematics and have a large body of practical teaching experience and expertise, especially in terms of advanced undergraduate proof-based mathematics. Hence, studying their insights and practices can provide a rich source of insight into both students' reasoning and behavior in proof-based mathematics (Alcock, 2010). Third, as Alcock (2010) and Larsen (2017) noted, mathematicians have amassed a large body of expertise on many aspects of pedagogy, including how students reason mathematically and how students can be movtivated.

Based on their literature review published in 2010, Speer, Smith, and Horvarth observed that there was a noticeable gap in the undergraduate mathematics education literature. Although there was a large and growing body of literature on undergraduate students' understanding of mathematical concepts, there was little research on how they were taught. Without knowing how undergraduate mathematics were taught, we do not know why students develop the (often problematic) understandings that they do. Further, without knowing how mathematicians typically teach, mathematics educators may find it challenging to identify aspects of their instruction that are problematic or to suggest areas for improvement. In the last decade, the situation certainly has changed in the context of advanced mathematics courses. We have undertaken a literature review as a sequel to Speer, Smith, and Horvarth's (2010) influential review of research on university mathematicians' teaching practices. In their review, Speer et al. (2010) accurately documented the dearth of empirical research into mathematicians' teaching practices. Since the publication of this review, mathematics educators have answered Speer et al.'s call, so much so, that the field needs a clear picture of what we know and what questions continue to need additional research. Since the Speer et al. (2010) review, there has been substantial work exploring mathematicians' beliefs, goals, and practices in a variety of areas, especially in advanced undergraduate mathematics courses. This growth in research necessitates a sharper focus to the literature review. In the following study, we set the goal of synthesizing the different papers in the area of proof-based mathematics and summarizing what we, the field, know and outline future directions for research. That is, the purpose of this article is to synthesize the growing research literature on mathematicians' pedagogy when teaching advanced mathematics courses.

Methods

Corpus Search and Selection

We did an initial search of Ebsco Education, Ebsco ERIC, and Scopus for papers published since 2000 in 16 journals that focus on mathematics (and science) education. We also added papers (including conference proceedings) found in citations and books if we knew of them. We acknowledge that there might have been papers published in more general journals that we might have missed as a result. We searched on language in both the abstract and title using Boolean 'or' and 'and' to attempt to find all possible relevant papers. This initial search resulted in 774 potential papers. At that point, a member of the research team read the title, abstract, and, as needed, the methods section of the paper to determine whether papers are 'relevant' to our goals of describing the teaching of proof-based undergraduate mathematics courses. Meaning, from the pool of papers, we excluded those that were about undergraduate mathematics teaching, but not proof-based courses, were not about mathematics, or not related to what happens inside the classroom.. If a paper included exploration of both proof-based and other undergraduate courses we kept it in the corpus. This parsing left 112 studies that explore issues of teaching of proof-based undergraduate mathematics in the corpus.

Analysis Scheme

For each of the 112 papers in the remaining corpus, two members of the research team read each. We first parsed them as either empirical or not. For the empirical papers, we then noted where the study was carried out, the course content. We also coded a study an intervention if the authors of the paper attempted to directly influence the way that the class was taught, either by having a member of the research team teach the course or by working with the instructor to change his or her instruction. A study was coded as observational if the research team merely observed some aspect of the instruction or the beliefs of the instructor, without trying to change his or her teaching. We also drew on the study's characterization of the classrooms as either lecture or 'not-lecture.' For interview studies where this was not made explicit, we assumed lecture based on the relative frequency of lecture as found in large-scale surveys (Johnson, et al, 2019). We described the means by which the data was collected (e.g., interview, observation, survey) and number of participants. Where both professors and students were participants, we noted each and further distinguished between professors and Graduate Teaching Assistants. Finally, we described the main claims of each article and how those claims were warranted. Because we wanted to focus on instruction, we developed three broad categories of reporting for each of lecture and non-lecture pedagogies and synthesized results within those categories. Those categories are (1) what occurs in class, (2) the beliefs, knowledge, and rationales that shape instruction, and (3) the relationship between instructor actions and student learning.

Results

Lecture

Most advanced mathematics courses continue to be taught by lecture and practices share many commonalities. The evidence for this claim comes from two sources. First, Johnson, Keller, and Fukawa-Connelly (2018) and Johnson, Keller, Peterson, and Fukawa-Connelly (2019) administered surveys to 219 algebraists from the United States who had recently taught an abstract algebra course, where the participants were solicited from a range of universities, including Ph.D granting institutions to institutions only offering a bachelors degree. Among those at research universities, Johnson et al (2018) found that 85 percent of their respondents claimed that they taught via lecture. When considering all universities, they found that 83% of the respondents reported using lecture at least one quarter of the time. These findings are largely consistent with mathematics educators who have observed mathematics teaching. Artemeva and Fox (2011) observed 50 mathematicians teaching both calculus courses and advanced mathematics courses in seven different countries. Fukawa-Connelly, Weber, and Mejía-Ramos (2017) summarized the teaching practices of 11 mathematicians teaching a variety of advanced mathematics courses in the United States.

Commonalities in lecture practice. There are significant commonalities across countries and universities within the United States. Artemeva and Fox (2011) observed 50 mathematics teachers teaching university mathematics courses in seven countries, at the calculus and advanced mathematics level. What struck these scholars were the commonalities across all the lessons they observed. Artameva and Fox found that these teachers collectively engaged in a genre of teaching that they called “chalk talk”. Chalk talk consists of lecturing where (a) the lecturer writes mathematical results as inscriptions on the blackboard; (b) the lecturer would concurrently provides a running commentary in which she verbalizes what was being written and her thought processes as she was doing this mathematics (i.e., modeling the “doing” of the mathematics that was written); and (c) the lecturer occasionally stops to offer meta-commentary, reflecting more globally on what was written. They also claimed that questioning is a very common practice among lecturers.

By analyzing 11 individual lecturers in different mathematical classes, Fukawa-Connelly et al. (2017) corroborated Artameva and Fox’s claim that mathematics courses were taught in the genre of “chalk talk” lectures. Fukawa-Connelly et al. further documented that mathematicians made seven mathematical contributions. Fukawa-Connelly et al found the following contributions: definitions, theorems, and proofs (which the authors labeled as “formal mathematics”) and methods/heuristics, informal representations, modeling mathematical behavior, and examples (which the authors called “informal mathematics”). Their main findings were the following: There were many informal mathematical contributions in the mathematics lectures. The formal mathematical contributions were nearly always written on the blackboard. With the exception of examples, the informal mathematics was only said orally and rarely written down.

Why do mathematicians continue to lecture? It is natural then to wonder why mathematicians continue to lecture, especially considering mathematics educators’ frequent contention that lecturing in advanced mathematics leads to poor learning outcomes (e.g. Leron & Dubinsky, 1995). The answer to this question is surely multifaceted (Fukawa-Connelly et al., 2016), but the simplest answer is that mathematicians teach via lecture because they believe lecture is the best way to teach. This finding is warranted by the writings of professional mathematicians (Krantz, 2015; Pritchard, 2010, 2016; Wu, 1999), surveys with mathematicians (Fukawa-Connelly et al., 2016), and interviews with mathematicians (Woods & Weber, 2020).

The practice of lecture varies and the variation can generally be explained by differences in professors' beliefs, goals, and rationales. Pinto (2019) described two mathematicians, Yoav and Amit, implementing the same lesson plan in a real analysis course. The formal content of the lessons was the same: both mathematicians introduced the formal definition of the derivative, stated a theorem about derivatives (differentiability implies continuity), and showed several examples and applications. However, Pinto argued that their lectures were markedly different. For instance, in elaborating on the formal definition of derivative, Yoav looked at each term in the definition of the derivative and then offered a precise definition of each term. In contrast, Amit used visual and metaphorical imagery to give an informal account of what the derivative meant, describing the derivative in terms of "cones", "swings", and "traps". Yoav and Amit further presented different narratives of how students should make sense of definitions when they encounter them.

Weber (2004) described similar variance in real analysis lectures. Weber presented a case study of a single mathematician, Dr. T, and illustrated how Dr. T's lecturing style changed over the course of the semester. A theme across both studies is that mathematicians may emphasize different types of "informal content" (in the sense of Fukawa-Connelly et al., 2017) in their lectures, which lead to different lecturing styles, even when the formal content remains the same (Pinto, 2019). The key point that we wish to draw from Pinto's and Weber's studies is that mathematicians' different beliefs about how mathematics is done and what students need to do, and their related pedagogical goals, can exert a strong influence on their pedagogical actions. In short, Mathematicians' beliefs and goals can explain variance in their pedagogy. This depth of thought about teaching is also illustrated and warranted by numerous interview studies.

Researchers have also observed substantial variation in how mathematicians engaged students in mathematical activity during their lectures. In their survey, Johnson et al. (2019) found that many mathematicians who lectured frequently professed to use some non-lecture-based student-centered activities in their classes some of the time, such as having students work collaboratively to solve a problem. Dawkins (2012, 2014) and Fukawa-Connelly (2012a) presented case studies of highly interactive classrooms along with analyses of the classroom norms that encouraged student participation. Alcock (2018) described techniques that she used in her own lectures to engage students, such as asking them to explain the meanings of concepts to a peer. The key point here is that while most lectures in advanced mathematics are largely teacher-centered where the students are passive, there are some lectures that seem to be at least somewhat interactive. The existence of lectures in which students are somewhat active is important. Alcock (2018), Braun et al. (2017), and Dawkins and Weber (in press) argued that mathematicians need not radically overhaul their teaching to improve it. Finding ways to *improve* lectures rather than *replace* them is an avenue for future research in undergraduate mathematics education.

There is little research on how lecturers' actions influences students' learning. The extant research illustrates one mechanism by which students may fail to learn from lectures. Students may fail to recognize the purpose of a lecture, which can lead them to ignore aspects of a lecture that are considered most important (e.g., Lew et al., 2016) or to misinterpret what the professor is asserting (Krupnik et al. 2018). However, while the preceding research illustrates how this may occur, the fact that there were only two studies with a limited number of participants naturally leads us to question the generalizability and robustness of these findings.

Non-Lecture

In some ways, the literature on the teaching of more student-centered or inquiry classes has quite a different focus with the research questions, methods, and claims about instruction in lecture classes. Notably, this literature base is dominated by intervention studies and also includes a few small scale case studies of exceptional teaching. This focus makes sense as lecture is the primary mode of instruction and thus more active classrooms can be seen as counter to the norm and often occurring via intentional change. Out of 39 papers that reported on interventions to teaching, 23 described any of the work of teaching rather than focusing on task sequences or student outcomes. Those 23 papers studied 125 total classrooms (some lecture for comparison) or professors with 46 classrooms actually observed. Eleven of those papers studied a single classroom and only four studies included more than 10 classes or professors. We also note there were studies (e.g., Laursen, et al., 2014) covered a broad array of undergraduate mathematics classes (including, but not limited, to proof-based mathematics), but did not distinguish between the courses and thus are not included in these counts. In this section, we broadly attend to the complement of the prior section: non-lecture courses broadly defined those that include students being actively involved in generating disciplinary ideas.

The Literature on Active Learning is Dominated by the "Inquiry" Paradigms. As recently discussed in Laursen and Rasmussen (2019), much of the reform in advanced undergraduate courses stem from either Inquiry Based Learning or Inquiry Oriented Instruction. In Laursen and Rasmussen's theoretical paper they sought to operationalize such instruction as hinging on common underlying principles related to "student engagement in meaningful mathematics, student collaboration for sensemaking, instructor inquiry into student thinking, and equitable instructional practice to include all in rigorous mathematical learning and mathematical identity-building" (p. 129). Further, Kuster et al. (2019) and Hayward et al. (2016) have developed and use observational measures that incorporate specific rubrics that operationalize and serve to measure inquiry-oriented and inquiry-based teaching practice, respectively.

In contrast to the lecture literature base, we do not know much about how non-lecture unfolds in classrooms that are not associated with a researcher intervention. In the literature, there are only a handful of case studies about such instruction (e.g., Dawkins, et al., 2019; Fukawa-Connelly, 2012b; Ticknor, 2012). While the Johnson, et al. (2018) survey discussed above points to 85% of abstract algebra instructors self-report lecturing, that leaves 15% of instructors teaching in more active manner. We argue that there is still a substantial amount to learn about non-lecture instruction observationally. The Johnson, et al. survey found that self-identified non-lecturers were not using the researcher-designed materials that have been the primary focus of research in this area point to a mismatch between actual practice most research.

Non-lecture instructional practice is varied, even by different teachers using the same curriculum. This variation can generally be explained by differences in beliefs, goals, and knowledge. Much like the case of lecture above, student-centered instruction is similarly not a monolith, and instructors' beliefs and knowledge shape their instruction. Two large-scale studies point to this Kuster et al.'s (2019) study of instructors implementing inquiry-oriented curricula and Laursen et al.'s (2014) study on inquiry-based instruction. In one sense, we can see commonalities across classes including more time that is student-centered, less instructor authority, and more formative feedback than in lecture courses. On the other end, the reported standard-deviations and range of rubric scores point to differences. For example, in Kuster et al.'s (2019) analysis of 13 instructors implementing the same inquiry-oriented abstract algebra lesson, the degree to which teachers engage students in each other's reasoning which ranged from a score of 1.5 to a score of 4.5 (on a 5-point) scale. Thus, even within a relatively constrained setting, teaching practice can have substantial range.

Differences in practice has been tied to several sources including: tensions in managing coverage concerns; beliefs and values about mathematical practice; and challenges involved in incorporating students' thinking in genuine and productive ways. In some ways, teaching practice becomes more complex in classrooms where students are generating ideas -- ideas that may be unexpected. For example, Johnson and Larsen. (2013) illustrated ways that a mathematician implementing inquiry-oriented abstract algebra can be supported by common content knowledge, but may be constrained by a lack of pedagogical content when listening to interpret students and progress the lesson based on their ideas. Andrews-Larson et al. (2019) found that inquiry oriented linear algebra instructors increased their pedagogical knowledge and are better able use student ideas with support and repeated use of the curriculum.

Mesa et al. (2019) and Johnson et al. (2013) provided insight into instructors' views and beliefs when implementing mandated inquiry-based learning linear algebra and a voluntary inquiry-oriented abstract algebra, respectively. In both cases, there was discussion of the tension between coverage and active learning. This is an idea echoed in surveys of why instructors do not lecture (Johnson, et al., 2017) and amongst those who design interventions such as Nwabueze (2004) who suggested an interactive approach to abstract algebra would not allow for covering the full material. Johnson et al.'s study of three mathematicians implementing inquiry-oriented curriculum similarly pointed to general pacing tensions, but like in Mesa's study the instructors' individual beliefs shaped their concern and management of such a tension. One mathematician valued content goals as the primary outcome of the course and therefore was most concerned with coverage; one mathematician saw disciplinary activity as the primary goal of the course and was not concerned about coverage; while the third occupied a middle ground emphasizing the importance of "student opportunity to interact with math on their own terms" (p. 751) in order for students to learn. The hierarchy of goals and values is consistent with other studies of instructors who select an inquiry approach, such as in Dawkins et al. (2019) where the instructor stated their goals for an inquiry-based real analysis course was focused on student creation of mathematics and overcoming challenges. In general, beliefs and goals mediate instruction; however, these studies are few and are situated in particular intervention settings.

There are cautiously positive results related to student learning and non-lecture interventions. Unlike the general results about lecture, non-lecture interventions have generally pointed towards positive (or in some cases mixed) results linking teacher practice and student learning. There are two large-scale studies that warrant this result: Laursen et al. (2014) and Johnson, et al. (2021). Laursen et al. found that students in inquiry-based learning classes (some proof-based) reported greater learning gains than those in lecture. They also found that IBL courses seemed to have a positive impact on womens' confidence and interest. Johnson, et al. provided a more mixed result finding that students in inquiry-oriented abstract algebra courses scored just as well on a content assessment, but it was only the men in these classes that saw estimated test scores higher than lecture sections. Smaller intervention studies have found positive links such as between modeling reform teaching and pre-service teachers' view on the nature of discourse in mathematics classes (Blanton, 2002), and questioning and discussion practices supporting students in more authentic activity norms and taking responsibility for knowledge (Fukawa-Connelly, 2005). Further, a great deal of literature illustrates productive ways that students engage in proof activity within intervention contexts; although the details of instructor practice is often left underspecified (e.g., Larsen & Zandieh, 2008; Yee, et al., 2018).

Discussion

Based on the 24 published papers, we have a strong understanding of what goes on in lectures in advanced mathematics. With regard to lecturing, we have good evidence that most mathematicians teach by lecture and they do so because they believe that it is the best way to teach. We also know that most lectures consist of the mathematician writing the official mathematics on the blackboard, while offering a running commentary about the informal meaning of the mathematics and metacommentary about the nature of doing mathematics orally. While mathematics lectures show some uniformity, there is also variance in what informal mathematics that the mathematicians choose to emphasize and how they use student-centered activities (if they use them at all). Finally, we know that mathematicians can offer sophisticated rationales for their instructional choices. However, much of the research examining other phenomena tends to involve conducting case studies or exploratory analysis, with the output being "frameworks." Unfortunately, these frameworks have not been applied in future research. One consequence of research into how mathematicians lecture is that the most basic suggestions for how to improve instruction—such as not being overly formal, offering explanatory proofs, and explaining the reasoning and motivation behind definitions, theorems, and proofs—is not likely to be helpful. Mathematicians already do these things. What we know little about is how the instructional actions the professors' take influence student learning and why the apparently sophisticated and nuanced thought that goes into lecturing has not produced more promising learning outcomes. Indeed, we do not yet have good evidence that changes to lecturing influences learning at all. More research in this area is needed.

The literature on non-lecture includes 39 papers, 23 of which included any study of classroom activities while 16 focused on task-sequences and/or student outcomes. Most of the papers about non-lecture report on mathematics-educator developed curricula in the RME or IO traditions. This is, even though the data suggests that the majority of non-lecture classes rely on instructor-developed curricula. With interventionalist studies, we have obained a rich understanding of how task sequences and classroom environments affects and improves students' practices and understandings. We are still developing our understanding of productive teaching practices in these environments, as well as the challenges that instructors face when using student-centered curricula. More research in this area is needed.

An understudied area is what mathematicians who do not lecture choose to do in their classrooms. There are many studies of how mathematicians or mathematics education researchers behave when teaching with inquiry-oriented curricula developed by mathematics educators. However, the mathematicians who use such material is scant (cite your survey showing that this is so). There are far more mathematicians who do not use lecture, but also are not influenced by mathematics education research (cite your survey showing this). This is a sizeable population that has received little attention, but could produce interesting findings about how mathematicians change their practice and what they are willing to do.

Characterizing Undergraduate students' Problem Posing Products and Processes in an Introductory Business Mathematics Course

Joash M. Geteregechi
Ithaca College

This study investigated the nature of students' problem posing products and processes and the potential for using these products and processes to assess students' level of learning. First, the kinds of modifications made to existing problems are examined followed by the impact of these modifications on the students' solution strategies. I argue that by examining the students' solution strategies alongside the strategies that they encounter in class, we can gain insights into the students' understanding of the concepts learned. Furthermore, posed problems that are unsolvable but consistent and coherent can be used as a launchpad into new topics and ideas in mathematics.

Keywords: Problem Posing, near transfer, far transfer, Coherence, Consistence

Although many researchers have consistently documented the benefits of engaging students in mathematical problem posing (PP), many students, especially at college level, experience PP less often than they do problem solving (Lavy, 2015, Silver et al., 1996). This is despite some researchers (e.g., Mestre, 2002) asserting that PP could be cognitively more engaging than problem solving (PS). Much research into why PP has not been adopted as widely as PS agree that the main reason behind this is the limited knowledge about students' cognitive processes when they are engaged in PP (Cai et al., 2015). Specifically, there is need for the field to understand how undergraduate students pose mathematical problems and if PP is a skill that can be taught and learned (Crespo & Sinclair, 2008). Furthermore, the question of how PP can be used to assess students' learning in mathematics is still less explored. In calling for more research into PP, Cai and Huang (2013) noted that:

> Little is known about the cognitive processes involved when students generate their own problems and therefore about the ways problem posing can be used as an assessment tool. Furthermore, little research has been done to identify instructional strategies that can effectively promote productive problem posing or even to determine whether engaging students in problem-posing activities is an effective pedagogical strategy. (p. 58).

To understand the cognitive processes involved when students engage in PP, it is necessary to first understand the nature of the student-posed problems (SPPs) in relation to the problems that they meet as part of their learning (class problems). This consideration is important since much of PP literature (e.g., Cai & Cifarelli, 2005; English, 1998) suggests that problem modification is one of the ways through which students pose problems. Thus, an examination of the aspects of class problems (CPs) that students modify and how they do so is important in understanding the students' cognitive processes in PP. Furthermore, to be able to use PP in assessment of learning, an important consideration would be whether or not students recognize the consequences of their modifications on the solution processes. To address these issues, this study sought to answer the following questions:

1. What kinds of modifications do undergraduate students make on class problems in order to generate their own problems?

2. How can these modifications and their consequences on solutions be used to gain insights into the students' level of learning?

Background and Theoretical Framework

Role of Problem Posing in students' mathematics education

There is consensus among most studies that PP is an important skill that should be included in the mathematics curriculum at all levels of schooling (Bonotto, 2013). Some of the benefits of PP that these studies have documented include better problem solving skills (Cai & Hwang, 2003), higher creativity in mathematics (Voica & Singer, 2013), and increased motivation towards learning mathematics (Akay & Boz, 2010). Despite these benefits, however, PP has not been made a prominent part in mathematics curricular (Lu & Wang, 2006).

Defining Problem Posing

Problem posing has been conceptualized in various ways in the mathematics education literature. For example, Silver (1997) pointed out that PP and PS are naturally intertwined, and that PP occurs at various phases when someone is engaged in PS. For example, *before-solution* PP happens when one rephrases or breaks down a problem in order to understand what is required while *during-solution* PP serves the purpose of checking one's progress in PS as a way to monitor their PS process. On the other hand, *post-solution* PP happens after the PS process is complete and serves the purpose of reflecting on one's solution process to check if the final answer(s) makes sense. Silver's (1997) view of PP implies that PP happens spontaneously as long one is involved in PS.

Stoyanova and Ellerton (1996) on the other hand view PP in terms of the conditions under which it occurs. They offer three categories of PP including *free*, *structured*, or *semi structured*. In *free* PP someone is asked to create a problem without being given any specific conditions or a starting problem. One can write any problem drawn from any content in mathematics. In *structured* PP, one is given a starting problem and is asked to make modifications to come up with a new problem. *Semi-structured* PP, on the other hand, provides a limited set of conditions such as a topic or context that must be adhered to.

Brown and Walter (1990b) suggested a PP strategy known as the "What-If-Not?" strategy. In this strategy, one comes with a new problem by altering the givens of an existing problem. This strategy is similar to Stoyanova and Ellerton's (1996) structured PP but focuses mainly on the constraints in a problem. I argue that there are other modifications besides changing the constraints of a given problem that students may use. For example, a student may add new parameters to a problem that could create a need for a change of other aspects of the problem. Thus, the current study is based on Ellerton and Stoyanova's (1996) notion of semi structured PP and an expanded form of Brown and Walter's "what if not" strategy.

Analytic Framework

Voica and Silver (2013) developed a framework for analyzing mathematical problems in terms of their textual elements and the relationships between the elements. According to the framework, a mathematical problem includes some or all of the following elements: a *background theme, parameters,* data, *operating schemes,* and *constraints*. As an illustration of these elements, consider the following problem posed by one of the participants called Zive (all names are pseudonyms).

Marco can get a $ 50, 000 loan from one of two banks. The first charges 7%(12) and the second charges 7.05%(2). If he thinks he will pay off the loan in five years, which bank offers a better deal?

The *background theme* of a problem is what the problem is about or the context in which the problem is based. Zive's problem above is about an individual (Marco) making financial decisions. To provide more detail to the background theme, a mathematical problem needs parameters. In the case of Zive's problem, the *parameters* are bank interest rates, loan periods, and the loan limit. For the problem to make sense, these parameters need to be associated with *data*. The data in the problem include 7.05% (2), 7%(12), and $ 50, 000. *Operating schemes* are the actions suggested in the problem such as a comparison of the rates for the two banks. Finally, *constraints* are ways to preserve certain relationships in the problem structure by imposing restrictions on the other elements. An example of a constraint in the above problem is that Marco can get the loan form only one of two banks. The interest rates and the associates compounding periods can also be interpreted as constraints on the data. Furthermore, the loan amount cannot exceed $50,000. If someone modifies the data by changing the $50 000 value to $55 000, the resulting problem is considered a new problem even though the overall structure of the solution could remain unaltered. Various modifications to existing problems have various impacts. For the purposes of this study, modification is not limited to changing the data, rather it can include extending the problem by adding data or even adding more elements not in the starting problem. If one adds a third bank, for example, that charges simple interest, that is an extension of the problem. A problem that provides its elements in a correlated manner with no ambiguities is said to be *coherent* whether it is solvable or not. On the other hand, a problem for which a certain mathematical model can be assumed, has at least one solution (or a proof that there is none) and for which the data are not contradictory is said to be *consistent*. Zive's problem above is an example of a *coherent* and *consistent* problem. It is possible for a problem to be coherent but inconsistent and vice versa.

In this study, I used Voica and Silver's framework to characterize the SPPs and compared them with CPs to determine the kinds of modifications that students made. If the modifications made to a problem significantly impacted the structure of the starting CPs, then, I called such problems *far transfer* problems. Similarly, modifications that resulted in little impact on the overall structure of the problem (e.g., changing the data values only) were labelled *near transfer* problems (Pelca & Voica, 2011). To gain deeper insights into students' understanding of the learned material, I compared the solutions that the students had encountered in class with the solutions that they presented in their SPPs. If a student was able to adapt a class solution in such a way that they were able to use it on a far transfer problem, then, that served as an indicator of deeper learning. I made a similar determination whenever a student used a novel strategy (not used in class) on any *near transfer* problems.

Method

Participants and Setting

I gathered data from 16 undergraduate students enrolled in a mathematics course on financial mathematics during the fall semester of 2020. There were three chapters covered in the course namely, simple interest, compound interest, and annuities. The students completed a comprehensive problem posing assignment (PPA) towards the end of the semester that required them to pose at least one problem from each of the chapters covered. In this PPA, students were asked to state the starting CP that they used to pose their own problems, explain their posing processes and then solve the problems. Students' written artifacts were the main data sources for this study. There were also one on one meetings with some of the students via zoom during which they clarified their work and explained their solutions.

The main data sources for the study included written artifacts in form of students' posed problems alongside explanations and solutions. The PPA was graded based on three-point criteria involving creativity, solvability, and complexity. This rubric was made clear to the students. They were free to use any CPs as starting points as long as they indicated so as part of their PP process explanation. Problems that greatly resembled class problems scored low on creativity than those that did not. Similarly, problems that were linguistically well articulated and provided clear context scored high on complexity. Problems that required use of more operations or concepts from multiple sections also scored high on complexity. One received maximum credit on solvability if their problem had at least one solution and an attempt at finding such solutions was made.

Analytic Procedures

The data analysis was conducted in three phases. In the first phase, my colleagues and I independently coded the SPPs using codes derived from Voica and Singer's (2013) framework and determined the relationships between the elements. Following this, we classified each SPP into one of four categories namely category A (coherent and consistent), category B (coherent but inconsistent), category C (consistent but incoherent), and category D (incoherent and inconsistent). We later met to compare our coding/classification and the inter-rater agreement for this part turned out to be 96%.

In the second phase of analysis, we compared the SPPs with the corresponding CPs to determine if they were *far* or *near transfer* problems. To do this, we examined the modifications made to various elements of the CPs and the impact of such modifications on the solutions to the CPs. Modifications to a CP were regarded significant if they called for a different a solution strategy or a modification of the solutions presented in the CP. Significant modifications resulted in far transfer problems while insignificant ones resulted in near transfer problems. In some cases, students used completely different strategies from the ones presented in CPs. In such cases, the problems were considered far transfer even if they only reflected minor modifications on CPs. This is because the students viewed them in different perspectives.

Results

First, I present the findings related to the first research question, addressing the kinds of modifications that students made on CPs during their PP processes. To provide context on how the findings were generated, we provide an illustration of elements in one CP (Figure 1) and how a student made modifications on the CP to generate their own SPP (Figure 2).

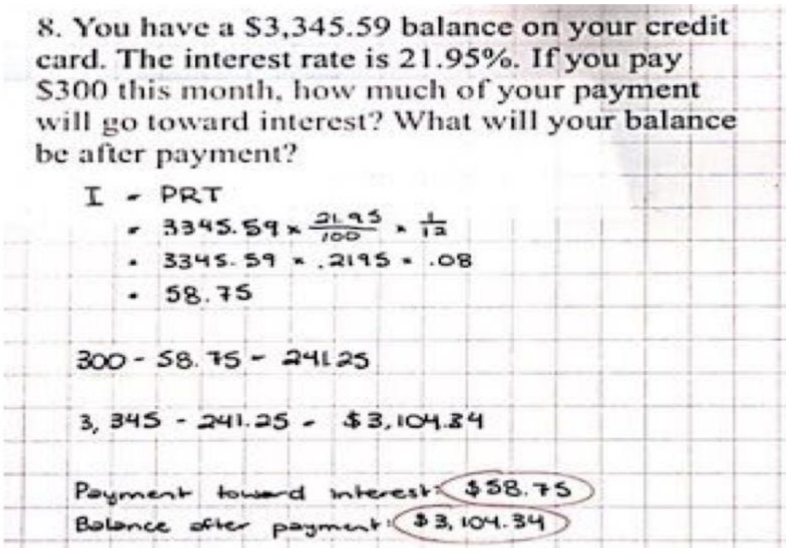

Figure 1. Sample CP from chapter 1

This CP is situated in the context of credit cards (background theme) with two main parameters namely credit card balance and interest rate. The corresponding data for these parameters are $3,345.59 and 21.95% respectively. The $300 repayment amount is a constraint that sets up the problem question (the new balance). Based on this CP, Cegra posed and solved the problem in Figure 2.

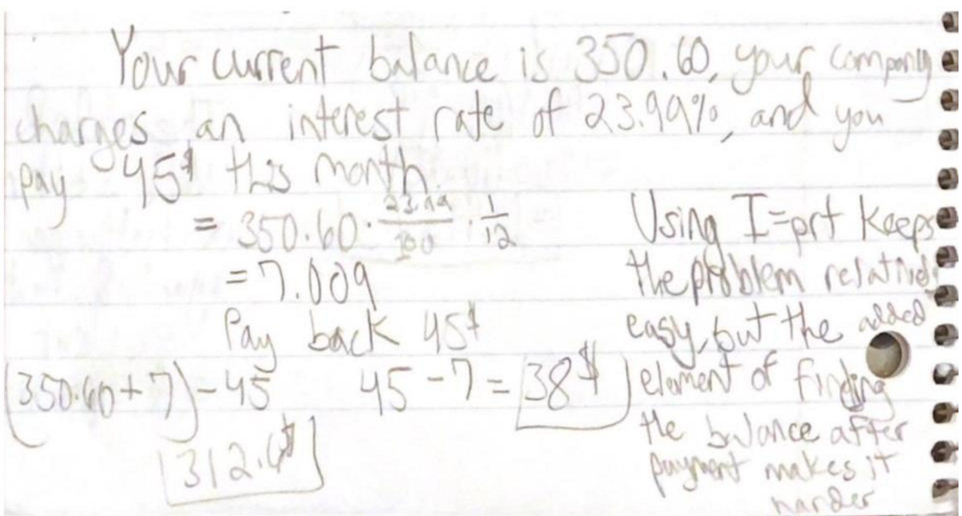

Figure 2. Cegra's problem from chapter 1

An examination of Cegra's problem shows that it keeps most elements and the overall structure of the CP (Figure 1) on which it was based. The background theme, the parameters, and the operating schemes (finding the new balance) are all unchanged. Her modifications only targeted the data (i.e., she changed $3,345.59 to $ 350.6 and 21.95% to 23.99%). Although Cegra's problem is a lot similar to the CP, we still found it to be both consistent and coherent (category A) since all elements are well correlated and the problem has a solution. All SPPs were classified in an analogous manner. The results are presented in Table 1.

Table 1. Classification of SPPs by Modified Elements and whether or not they were Category A

Modified element in a CP	# of problems (n=46)	# of Category A problems (n=30)
Background theme only	2	3
Data only	15	13
Constraints only	8	6
Operating schemes only	3	1
Multiple elements	18	7

Table 1 shows that most students (39.1%) made modifications to multiple elements in the CPs. Of the 18 SPPs that had multi-element modifications, however, only 7 (38.9%) were category A problems. The next most represented group were problems that had modifications on the data only (32.6%). These problems involved changing certain numbers but keeping everything else about the problem. Interestingly, most of these problems (86.7%) turned out to be category A problems.

Regarding the second research question, we found that a majority of category A SPPs (80%) were near transfer problems. The accompanying solutions to these near transfer problems were also strikingly similar to the CP solutions that the students had encountered. Of the 7 category A *far transfer* problems, 5 (71.4%) came from problems that had multi-element modifications. Table 2 provides a summary of the problem transfer alongside the modifications that the students made on CPs.

Table 2. Problem Transfer vs Modified Element

	Modified Element				
Problem Transfer	Background theme only	Data Only	Constraints only	Operating Schemes only	Multiple elements
Far	0	1	1	0	5
Near	3	12	6	1	2

Although we expected far transfer problems to have solutions that were different from ones in CPs, we found a couple of cases where students attempted to use the strategies used in CPs without any modifications. We concluded that such students did not have a deeper understanding of the concepts learned. Nevertheless, there were a few students who posed far transfer problems and modified the CP strategies in a manner that reflected a deeper understanding of the concepts learned. Rano's problem (see Figure 3), for example, is based on the earlier CP (see Figure 1). Her modifications involved expanding the background theme to include two loan scenarios and adding more parameters/data. These modifications also made it necessary that she change the operating schemes in the problems. An examination of her solution strategy to this problem shows awareness of the impact of such modifications. This awareness resulted in relevant modification on the solution strategy presented in the CP. For example, she used algebraic manipulations involving an unknown value (A) representing the amount owed on the car and used it to solve the problem. It should be noted that there was no CP of this kind or that required the solution strategy implemented by Rano. Therefore, Rano's problem can be considered a *far transfer* problem and her solution as evidence of deeper learning.

You owe a total credit of 13,900 on your car and on your boat from different companies charging you 14% pa and 11% respectively. If the total amount of interest charged this month is \$146.16, how much do you owe on your boat?

Let A = amount owed on car

$\Rightarrow$ 13900 − A = amount owed on boat.

$$\text{Int on car} = A \times \frac{14}{100} \times \frac{1}{12} = 0.01166\,A$$

$$\text{Int. on boat} = (13900 - A) \times \frac{11}{100} \times \frac{1}{12} = 127.42 - 0.0092A$$

$$\text{Total interest} = 0.01166A + 127.42 - 0.092A = 146.16$$

$$0.00246A = 146.16 - 127.42$$

$$\frac{0.00246A}{0.00246} = \frac{18.74}{0.00246}$$

$$\boxed{A = \$7{,}712}$$

$$\text{Amount owed on boat} = 13900 - 7{,}712 = \boxed{\$6188}$$

Figure 3. Rano's Problem from Chapter 1

Discussion

The findings of this study show that when students are asked to pose their own problems by modifying existing ones, they tend to focus more on multiple elements as opposed to single elements. When doing this, however, they tend to end up with inconsistent and/or incoherent problems. Nevertheless, these problems provide students with opportunities to use existing strategies in new ways and hence a possibility for new knowledge. If the goal is simply to pose more consistent and coherent problems, the findings of this study suggest that modifying single elements (especially data) is the most successful strategy. It should be noted that doing this also results in solutions that are highly related to the already encountered solutions and hence less room for creativity. The findings of this study also suggest that if we are to understand the depth of student learning in a certain topic, far transfer problems are more superior. This is because they challenge the students to modify already learned strategies so as to use them in novel settings.

Finally, I note that even when students are unable to solve their far transfer problems, they still gain from attempting such solutions. Instructors can leverage the difficulties arising from such situations to help students delve into new topics if the posed problems require so.

Connecting STEM Retention to Student Affect in Pathways Mathematics Courses

Jason Guglielmo
Arizona State University

Zac Bettersworth
Arizona State University

Ishtesa Khan
Arizona State University

We investigate how particular dimensions of student affect (e.g., sense of community, mathematical identity) relate to student retention in STEM in the context of active learning college algebra and precalculus classrooms. We developed and implemented a survey with Likert-style questions informed by four known dimensions of student affect and used exploratory factor analysis to identify five distinct factors actually being measured in the survey. These include student perceptions of their instructor's actions, mathematical identity, confidence, and feelings of belonging. We report on statistically and practically significant relationships between student affect and two indicators of continuation in STEM: (a) their expected grade in the course; and (b) their status as a STEM major. These results contribute to our growing understanding of how student affect may impact STEM retention.

Keywords: active learning, student affect, STEM retention

Student retention has long been a focus of STEM education research, particularly within the context of introductory mathematics courses at universities in the United States. Much attention has been focused on single-variable calculus, but courses which prepare students to take calculus (e.g., college algebra, precalculus) are also high enrollment gateway courses which many students must pass through on their way to a STEM major. However, students starting in precalculus at the university level are less likely to complete a STEM major than students who start in calculus (Bowen et al., 2019; Krause et al., 2015; Wilkins et al., 2021; Van Dyken & Benson, 2019). Some proposed reasons for precalculus courses reducing student retention in STEM include poor quality of instruction (Olson & Riordan, 2012; Seymour & Hewitt, 1997) and departments not allowing students to take introductory engineering courses without precalculus (Van Dyken et al., 2015). We posit that another reason is student affect in their introductory mathematics courses.

In this paper, we define student affect in the general psychological sense, as any expression of the student's feelings or emotions. We use exploratory factor analysis to examine dimensions of student affect relative to students' ability to complete a STEM degree (i.e., they have to pass STEM classes and be a STEM major) to answer the following question: How does student affect (e.g., sense of community, mathematical identity) relate to students' major and expected grade in online college algebra and precalculus courses taught using active learning principles?

Literature Review and Framing

Our framework is comprised of the four dimensions of student affect we intended to measure when we initially designed our survey. We define each of the four dimensions to convey what we had in mind when we decided which items aligned with a particular dimension.

Four Affective Dimensions

The research team chose four affective dimensions - mathematical caring, sense of community, sense of inclusion, and mathematical identity - to investigate student affect in relation to students' major and expected grade in active learning Pathways college algebra and precalculus courses. Note that these items are not wholly independent of one another. For instance, students' sense of inclusion in the classroom may impact their perception of the mathematical caring relationship between themselves and their instructor, or the development of their mathematical identity.

Mathematical caring. Hackenberg (2010) defined mathematical caring relations (MCR) as "a quality of interaction between a student and a teacher that conjoins affective and cognitive realms in the process of aiming for mathematical learning" (p. 237). Hackenberg argued that if students are continually asked questions they are not prepared to answer, they may leave the classroom with negative perceptions of their experiences which may ultimately impede the learning process. As such, MCR provide an important connection between cognitive and affective impacts on students' perception of their instructor's actions within the classroom.

Sense of community. We operationalize students' sense of community using Strike's (2004) four C's of community: coherence, cohesion, care, and contact. Strike argued that schools must have a shared vision, care about initiating students into this vision, and have structural features that facilitate this care in order to establish a sense of community. A key aspect of community to LeChausseur (2014) is social space, which includes "people and their relationships; assets and liabilities; rules, regulatory bodies, and punishments; opportunity structures; the diffusion of power; and connections to other communities" (p. 307). Not only must school administrators and teachers construct a shared vision and give students the opportunity to align with that vision, but the students must *choose* to align with these structures while forming relationships with one another. Taken together, Strike and LeChasseur's definitions of community account for both the structures and the interpersonal relations needed to develop a sense of community.

Sense of inclusion. Roos (2019) conducted an extensive literature review to investigate how the notion of inclusion was leveraged in mathematics education studies on both a societal level and a classroom level. Within the classroom level, some studies use inclusion to refer to participation in the classroom and some refer to inclusion in relation to exclusion. We use inclusion to refer to students' sense of being included in the classroom as it is related to their participation: participating in the classroom discourse and contributing to group work.

Mathematical identity. Cribbs et al. (2015) defined mathematical identity as "how students see themselves in relation to mathematics based on their perceptions and navigations of everyday experiences with mathematics" (p. 1049). In this paper, Cribbs et al. found that students' perceptions of themselves (in terms of interest in mathematics, recognition of mathematical ability, and competence/performance with mathematics) had both direct and indirect impacts on students' mathematical identity. The link between students' mathematical identity and their self-perceived performance in their math class informs our investigation into mathematical identity.

Methodology

Curricular Context

The students in our study were enrolled in courses taught using the *Pathways* precalculus curriculum. This research-based and conceptually-driven curriculum has been implemented and refined over the past few decades at multiple colleges and universities. The pedagogical goals of Pathways have been to support students' meaning making (Clark et al., 2008) and construction of conceptual understandings for constant rate of change, exponential growth, and trigonometric functions (Carlson et al., 2015; Kuper & Carlson, 2020; Moore, 2014). The conceptual emphasis of the course is highlighted by structured task sequences designed for group work. At the university where these data were collected, instructors are encouraged to attend a weekly teaching seminar focused on the mathematical and pedagogical goals of Pathways. Since student thinking is the emphasis of the pedagogical approach of Pathways, most Pathways courses tend to de-emphasize lectures. Many of the modules and investigations are accompanied with dynamic applets and instructional videos to support students' repeated reasoning about the relevant course topics. In such a class, student-student interaction and discussions of their own mathematical thinking may impact student affect differently than in a didactic lecture setting.

Participants and Data Collection

The survey was conducted at a large research university in the U.S. toward the end of the Fall 2020 semester. The participants of the surveys were enrolled in College Algebra (CA) and Precalculus (PC) classes. Both courses were taught using the research-based Pathways Precalculus curriculum, though CA introduces fewer topics. The survey was distributed and completed electronically using the online survey platform Qualtrics (2021). Instructors distributed the survey to their students, and many instructors offered extra credit to their students for taking the survey, in accordance with approved procedures from the university's institutional review board. A total of 193 students agreed to participate in the study and responded to the survey questions. Data was collected from two sections of CA taught by the same instructor (n=106), and seven sections of PC taught by seven different instructors (n=87). These data were collected during the COVID-19 pandemic, and all the classes used either online or hybrid (online and in-person) instruction. The courses were taught in a synchronous virtual format using an online video conferencing software.

Survey Instrument

The survey was designed to understand student experiences inside and outside of the mathematics classroom relative to four primary constructs: mathematical caring, sense of community, sense of inclusion, and mathematical identity. The survey questions and design were informed by both literature on each construct and former published surveys (Apkarian et al., 2019; Carlson et al. , 1999; Code et al., 2016; Walter et al., 2016). The survey consists of 55 Likert items asking students to indicate the extent to which they agree with given statements on a four-point scale: 1 (Disagree), 2 (Slightly Disagree), 3 (Slightly Agree), or 4 (Agree). The survey also consisted of demographic and contextual questions, including asking for student major (STEM, not STEM, or unsure), type of course (PC or CA), and expected grade in course (A(±), B(±), C(±), D, E, or other).

New Likert items were written for our survey when previously validated instruments did not adequately or directly attend to these constructs. All items were reviewed by the project team to ensure face validity, and items were organized into groups based on the focal aspect of the question (i.e., instructor, classmates, self) as opposed to being grouped by theoretical constructs. This was intended to reduce cognitive fatigue on the part of participants. A web-based version was then created in Qualtrics (2021) for distribution.

Analysis

Analysis was conducted on de-identified survey data (aliases were used for instructors), and free response answers (which sometimes named students, GTAs, or instructors) were kept separately from these multiple-choice data. The underlying constructs driving students' responses to the Likert items were first identified using exploratory factor analysis (EFA), and the resulting factors were used to create composite scales; these scale scores were then tested against other student responses using analysis of variance (ANOVA) testing, and main effects were investigated using Tukey's HSD post hoc test. EFA is a multivariate statistical method for identifying relationships between measured variables (here, responses to each individual Likert item). Instead of depending on the four a priori constructs we intended to measure, we used EFA on student responses to detect underlying constructs which were salient to students (these factors are described in the results section). Composite scale scores were calculated as the average of students' responses to each item in the detected factor. As response options ranged from 1 (disagree) to 4 (agree), a composite score of 2.5 can be interpreted as "neutral" with respect to the factor; scores below 2.5 indicate disagreement while those above indicate agreement. We tested for relationships between composite factor scores and (a) major (three levels); and (b) expected grade (six levels). This was done using ANOVA, while Tukey's HSD post hoc test was used to interpret the results of the ANOVA. Analyses were performed in R (R Core Team, 2021). These tests were performed in the aggregate and disaggregated by enrolled course.

Results

Factor Analysis Results

Comparison of multiple models using EFA established that a seven-factor model was satisfactory (RMSEA = 0.043; Tucker Lewis = 0.871). Two of the resulting factors consisted of fewer than four items and did not have face validity; these were not included in the subsequent analysis. Descriptions of the five retained factors and sample items from the clusters are presented in Table 1. While not entirely aligned with the initially targeted dimensions, these five factors do capture aspects of student affect.

Table 1. Descriptions of and examples for the five factors determined through EFA.

Factor	Description	Item Examples
Factor 1	Items about the instructor (their role, actions, orientation); related to mathematical caring.	"My instructor tries hard to help students understand." "My instructor cares about my learning."
Factor 2	Items about students' perception of their mathematical identity and abilities.	"I am confident in my ability to verify the correctness of my answer." "Thinking about mathematics makes me anxious."
Factor 3	Items related to participation and belonging in the classroom community.	"I am a valued member in this mathematics class." "My classmates motivate me to try my best in class."
Factor 4	Items related to students' orientation towards a sensemaking approach when doing math, and their instructor's encouragement, expectation, or facilitation of such approach.	"When making sense of a mathematics word problem, I represent the situation with a drawing." "My instructor expects us to explain the thinking we used to determine our answer."
Factor 5	Items about students' insecurity or discomfort with their own mathematical ability.	"The course moves so fast that I don't have time to understand ideas well." "I do not like to share my thinking during class."

We used composite scores for each participant in each factor and investigated distributions of data based on these composite scores. Specifically, we used ANOVA and Tukey's HSD post hoc test to look for relationships between factor scores and the variables (a) students' expected grade in the class (GradeExpected, possible responses: A(±), B(±), C(±), D, E, Other), and (b) students' enrollment in a STEM major (MajorSTEM, possible responses: Yes, No, Unsure). Based on the results of a chi-square test for independence ($\chi = 11.98$, $p > 0.10$), the variables GradeExpected and MajorSTEM were determined to be independent.

The average factor scores for each response of GradeExpected and MajorSTEM in the full data set is provided in Table 2. No students reported expecting an E or "other" grade in the course, so those items have been omitted from the table.

Table 2. Average factor scores based on GradeExpected or MajorSTEM items in full data set.

Variable	Item	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
GradeExpected	A(±)	3.72	3.12	2.67	3.47	1.65
	B(±)	3.61	2.91	2.55	3.28	1.88
	C(±)	3.55	2.32	2.41	3.16	2.16
	D	3.03	1.60	1.92	2.63	2.44
MajorSTEM	Yes	3.61	3.01	2.64	3.40	1.87
	No	3.63	2.77	2.56	3.25	1.79
	Unsure	3.67	2.72	2.36	3.33	1.99

ANOVA and Tukey's HSD Post Hoc Test Results

A collection of ANOVA models was used to determine the effects of ExpectedGrade and MajorSTEM on each factor. The full data was examined, as well as data for the CA and PC courses individually. GradeExpected was determined to be a main effect ($p<0.05$) on (a) the full data for Factors 1, 2, 4, and 5; (b) the CA data for Factors 2 and 4; and (c) the PC data for Factors 1, 2, 4, and 5. MajorSTEM was determined to be a main effect on (a) the full data for Factor 2; (b) the CA data for Factor 3; and (c) the PC data for Factor 2.

We then used Tukey's HSD post hoc test to look at the differences between particular MajorSTEM and ExpectedGrade responses for the relationships that appeared significant in the initial ANOVA. We omit discussion of expected grade comparisons involving those expecting to receive a D, as there were only 5 such students. A difference of 0.5 corresponds to a difference of half a scale-point on the agree/disagree response scale; we further omit discussion of these results as their practical significance cannot be established. Thus, we restrict further discussion to two main findings: (a) differences in Factor 2 scores between students expecting an A-grade and those expecting a C-grade; (b) differences in Factor 3 scores between students intending to major in STEM and those who reported being unsure if they would major in STEM or not (Table 3).

Table 3. Noteworthy differences in factor responses based on ExpectedGrade or MajorSTEM.

Factor	ExpectedGrade Difference	MajorSTEM Difference
Factor 2	Full Data, C(±) - A(±), diff = -0.80 ***	N/A
Factor 3	N/A	CA, Yes - Unsure, diff = 0.58 *

Note. Three pieces of information are given for each difference: where the data comes from (Full Data, CA = College Algebra Data, PC = Precalculus Data), which items are being compared, and the statistical significance of the difference (* = p<0.05, ** = p<0.01, *** = p<0.001).

Discussion

We briefly discuss the results of the exploratory factor analysis in comparison to the affective dimensions initially targeted. We then discuss the two findings above, difference in average Factor 2 scores based on ExpectedGrade and difference in average Factor 3 scores based on MajorSTEM. These two findings support the notion that student affect is related to a students' ability to remain in STEM.

Factor Analysis

The survey was constructed with four dimensions of student affect in mind: mathematical caring, sense of community, sense of inclusion, and mathematical identity; exploratory factor analysis instead identified five robust factors. While not identical to the original design, these factors are not unrelated to the original affective dimensions. In particular, Factors 1, 2, and 3 primarily aligned with the constructs of mathematics caring, mathematical identity, and sense of community, respectively.

Firstly, Factor 1 closely aligned with the construct of mathematical caring. Many of the items in Factor 1 were similar to the example items provide in Table 1, in that they asked about students' perceptions of their instructor's actions and motivations. These affective student perceptions form the basis for Hackenberger's (2010) mathematical caring relationships. Secondly, Factor 2 closely aligned with the construct of students' mathematical identity. The examples in Table 1 show items related to students' recognition of their mathematical ability and their interest in math, two factors associated with mathematical identity (Cribbs et al., 2015). Other items in Factor 2 were related to Cribbs et al.'s constructs of recognition, interest, and competence/performance. Lastly, Factor 3 closely aligned with the construct of sense of community. As shown in Table 1, the items in Factor 3 primarily focused on students' relationships to other in their class, an important aspect of LeChasseur's (2015) social space. The remaining factors incorporated some items from these three constructs, as well as the construct of sense of inclusion.

Factor 2 Discussion

We interpret Factor 2 as a measure of students' mathematical identity. The Tukey's HSD post hoc test showed a difference of -0.80 in average Factor 2 scores between students expecting a C(±) in the course (M = 2.32) and students expecting an A(±) in the course (M = 3.12), for all students (CA and PC combined). This practical significance, along with the statistical significance of this result ($p < 0.001$), implies that the students that responded to this survey who expect a C(±) in their Pathways College Algebra or Precalculus course on average report a weaker mathematical identity than students who expect an A(±). In particular, C-expecting students have an average score below 2.5, implying they generally disagree with statements that align with positive mathematical identity, while A-expecting students have an average score above 2.5.

We acknowledge that expected grade is not a comprehensive measure of a students' self-perception in their classroom, but it does provide some insight into how students either (a) view their ability to do math in their classroom, or (b) view their teachers' perception of their mathematical ability. In either case, this finding weakly supports the finding by Cribbs et al. (2015) that there is a connection between mathematical identity and self-perception. We conjecture that having a more robust understanding of how a student connects their expected grade in the course to their self-perceived mathematical ability may provide more insight into how a student develops their mathematical identity.

Factor 3 Discussion

We interpret Factor 3 as a measure of students' sense of community. The Tukey's HSD post hoc test showed a difference of 0.58 in average Factor 3 scores between students who were definitively STEM majors ($M = 2.79$) and students who were unsure if they were or were going to be STEM majors ($M = 2.21$), for students enrolled in the College Algebra course. This is a small, but still meaningful, practical difference which is also statistically significant ($p<0.05$). That is, student respondents who are sure of their status as STEM majors on average report a greater sense of community in their classroom than students who are unsure about their status as STEM majors.

We note that there was not a statistically significant difference in Factor 3 scores between students who identified as STEM majors and those who identified as non-STEM majors. This suggests that the uncertainty of students who responded "Unsure" is an important factor in this difference. This result complicates the finding by Rainey et al. (2018) that students who report a greater sense of belonging are more likely to persist in STEM. Perhaps the students who are unsure of their status as STEM majors might consider sense of belonging as a bigger factor than others in deciding to stay in STEM.

Conclusion

We have shown that in the context of a research-based undergraduate active learning mathematics curriculum, there is a connection between (a) students' mathematical identity and their expected grade in the course, and (b) students' sense of community and their major. More generally, our data support the notion that students' affective needs are related to their potential to complete a STEM degree. Our study shows a correlation though, not a causation. Future work needs to be done in examining the complexities of these relationships and leads to further questions: How are these factors related to one another? Do students who report higher affect according to our survey graduate with STEM degrees at higher rates? We believe that by answering these questions, we will be better equipped to attract, support, and retain STEM majors.

Further directions for this work include a redesign of the survey items to better align with the factors that were discovered. In particular, the survey items designed to elucidate students' sense of inclusion in the classroom should be reexamined and rewritten. Further, to better understand the transferability and validity of our EFA model, more data from other institutions implementing the Pathways innovation should be gathered. This is especially important given that these data were recorded during the COVID-19 pandemic, where instructional practices were constantly changing and adapting.

The Relationship Between an Instructor's Mathematical Meanings for Teaching Sine Function and Her Conception of and Intended Use of an Applet: The Story of Kendra

Aysia Guy	Abby Rocha	Julia Judson-Garcia
Arizona State University	Arizona State University	Arizona State University

Digital technologies including graphing software and applets are frequently included in mathematics curricula as resources for supporting students' learning and performance (Swidan, 2019; Thompson, Byerley, & Hatfield, 2013). Research has shown that teachers' conception of didactic objects is largely influenced by their mathematical meanings (Thompson, 2002; 2008; Guy, 2021). As such it seems reasonable that there is a relationship between teachers' mathematical meanings for teaching (MMT) and their conception of and intended use of an applet. This report presents results that demonstrate how a graduate student instructor's (GSIs) MMT influence her conception of and intended use of an applet. Moreover, we illustrate how a teacher's use of an applet can lead to advances in her MMT.

Keywords: Applets, Didactic Objects, Quantitative Reasoning, Mathematical Meanings

As technology advances, new and emerging technology is being regularly adopted to support both teachers and students in the teaching and learning of mathematics (Pope, 2013). Current research has documented that teachers play a critical role in the integration process of technology in curricula (e.g., Artigue, Drijvers, Lagrange, Mariotti & Ruthven, 2009; Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010; Daher, 2009). As one example, teachers are using applets – interactive computer-based objects – to support students in visualizing attributes of specific mathematical ideas (Gadanidis, Gadanidis, & Schindler, 2003). The dynamic abilities of an applet can promote discussions that focus on quantities and their relationships within a problem context as they vary in tandem (Moore, 2009). Cobb, Boufi, McClain, and Whitenack (1997) referred to these discussions as reflective discourse. A teacher strives to engage in reflective mathematical discourse when implementing an applet as a *didactic object*.

Thompson defines didactic object as "a thing to talk about' that is designed with the intention of supporting reflective mathematical discourse" (Thompson, 2002, p. 198). An object is not considered didactic until the teacher conceptualizes an image of a conversation designed to support students in constructing coherent mathematical meanings. A teacher's conceptualization of a didactic object largely depends on the instructor's *didactic model*. A didactic model is "a scheme of meanings, actions, and interpretations that constitute the instructor's or instructional designer's image of all that needs to be understood for someone to make sense of the didactic object in the way he or she intends" (ibid, p. 212). A teacher's didactic model is thus largely dependent on her MMT, and therefore may be different from the instructional designers of the applet.

Thompson (2016) described a teacher's mathematical meanings for teaching (MMT) as her images of the mathematics she teaches and intends students to have. As such a teacher's MMT encompass her meanings for the idea together with the teacher's (1) image of epistemic students, (2) image of how to support students in developing similar meanings, and (3) an image of activities to support students' construction of these meanings (Silverman & Thompson, 2008). Although researchers have used applets as didactic objects to support students' learning of mathematics (Moore, 2009; Guy, 2020), few have investigated the relationship between teachers'

MMT and their use of applets. This report addresses the following question: *In what ways does teachers' MMT influence their conception of and intended use of an applet while teaching?*

Theoretical Perspective

Prior research has identified *quantitative reasoning* (Thompson, 1990, 2011) as a foundational way of thinking for supporting students' understandings and teachers' instruction of angle measure and trigonometric functions (Moore, 2010, 2014; Hertel & Cullen, 2011; Tallman, 2015; Tallman & Frank, 2018; Rocha & Carlson, 2020; Rocha, 2021). An individual engages in *quantitative reasoning* when she conceptualizes a situation in terms of *quantities* and *quantitative relationships* (Thompson, 1990). A *quantity* is an attribute of an object that one imagines measuring. When someone has conceived of three quantities, two of which determines the third, they have conceived of a *quantitative relationship.*

A productive meaning for sine function involves quantitative (Thompson, 2011) and covariational reasoning (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). Covariational reasoning entails the coordination of changes in two quantities' values while attending to those changes as the quantities vary simultaneously. Specifically, sine function relates the measure of an angle swept out from the 3 o'clock position to the vertical length of the point on the terminal ray of the angle (*terminal point)* measured from the center of the circle. Moore (2012, 2014) found that is productive to measure an angle's "openness" (i.e., the length of arc from the initial ray to the terminal ray) by determining the fraction of the circle's circumference that is subtended by the angle. Meaning "for the measure of the angle to be independent of the size of this circle, the subtended arc must be measured in a unit whose magnitude is proportional to the magnitude of the subtended arc and the circumference of the circle that contains it" (Tallman & Frank, 2018, p. 5).

The value of sine can be determined by leveraging relative size reasoning in comparing the length of the terminal point's vertical distance from the center of the circle to length of the circle's radius. One of the benefits of conceptualizing sine function in terms of the radius's length is that "the values convey numerical measures for every circle all at once because regardless of the circle, one obtains equivalent numerical values when the quantities are measured relative to that circle's radius" (Moore, 2014, p. 13). Similarly, other trigonometric functions require one to formalize a relationship between the covariation of angle measure and a ratio of lengths (see Figure 1).

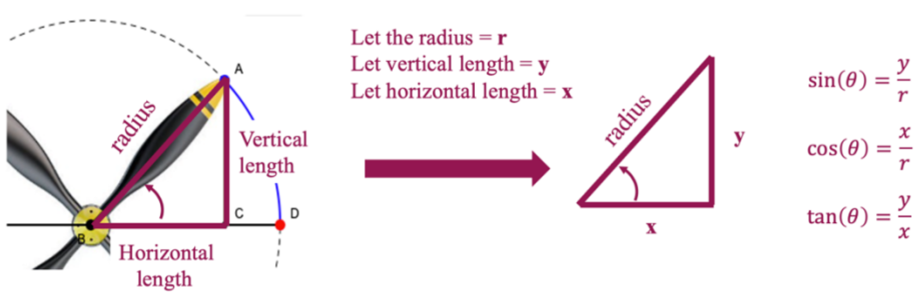

Figure 1*: A connection between unit circle trigonometry and right triangle trigonometry.*

The Fan Blade (FB)-Applet (Figure 2) was designed to promote quantitative meaning for sine if engaged in an instructional conversation that focuses on the directed vertical distance for a given angle measure for various radius lengths. For instance, for an angle measure of 0.79 radians (or 45 degrees), one may increase and decrease the radius (point D) of the circle which produces various arc-lengths and vertical distance measured in feet. But, in radius lengths (radii), the measure of the directed vertical distance measured in radii is the same numerical value as the vertical distance of the terminal point from the center of any circle rotated at 0.79 radians is constantly proportional to the length of the radius. This meaning for sine function is especially productive for students who view the unit circle as a basis for any circle context, in which they rotate 0.79 radians, view the vertical length of the terminal point to be $\sin(0.79) \approx 0.71$ radius lengths, then multiply the radius of the circle in the given context (e.g. a propeller blade with a length of 3 feet) to the value of $\sin(0.79)$ to produce the accurate y-coordinate of the fan blade's vertical position from the center of the circle (i.e. $3 \cdot \sin(0.79) \approx 3 \cdot 0.71 \approx 2.12$ feet).

Methodology

The purpose of this study is twofold (1) to investigate teachers' meanings for sine function and (2) to investigate how teachers' meanings for sine function influence their conception of and intended use of an applet. To accomplish this goal, we interviewed an instructor who was in her second-year teaching precalculus with a research-based Pathways curriculum (Carlson, Oehrtman, & Moore, 2018) at a large public university in the southwest United States. During the interview, the instructor was asked to respond to two tasks (shown in Table 1) designed to reveal her meanings for sine function. The GSI was also presented with an applet designed to support instructors' teaching of sine function. The instructor was then asked to think aloud as she interacted with the applet and its features. The first author then posed questions to the instructor to gain insight into her perception of the applet including the mathematical ideas and understandings the applet could support and if/how the instructor intended to use the applet while teaching. The first author analyzed the clinical interview using Simon's (2019) three phases of analysis to form a second-order model (Steffe & Thompson, 2000) of the GSI's thinking and meanings for sine function.

Table 1. Tasks posed to instructors during the clinical interview.

Task 1	Jamie is a pilot for Beta Airlines. He noticed that there was a piece of gum stuck at the tip of one of the propeller's fan blade. The length of each fan blade from the center of the propeller is 3 feet. Jamie rotates the fan blade with the gum attached in a counterclockwise (CCW) direction from the 6'oclock position. Two of your fellow teachers constructed the following graphs that represents the gum's vertical length (position) from the center of the propeller with respect to how far the gum at the tip of the fan blade travelled from the 6'oclock position. Which graph is most appropriate and why? Task 2	Let's say you were lesson planning and prepping to present this problem (below) in class to your students. *Jamie is a pilot for Beta Airlines. He noticed that there was a piece of gum stuck at the tip of one of the propeller's fan blade. The length of each fan blade from the center of the propeller is 3 feet. Jamie rotates the fan blade with the gum attached in a counterclockwise (CCW) direction from the 6 o'clock position.* Create a graph that shows how the gum's vertical length from the horizontal diameter varies with the angle swept out by the gum's fan blade as it rotates CCW from the 6 o'clock position.

Results

We share the following results from a GSI's interview that entail her responses and interactions with Task 1, Task 2, and the FB-Applet included in a research-based Precalculus curriculum (Carlson, Oehrtman, & Moore, 2018). We first highlight the GSI's meanings for sine function. We follow this with a description of the GSI's goal(s) for supporting students in developing coherent meanings for sine function. This includes a description of the GSI's image of a productive meaning for sine function and the questions she intends to pose to students while using an applet in class. We conclude with a description of the GSI's interaction with applet and the meanings for sine function she expressed while interacting with the applet.

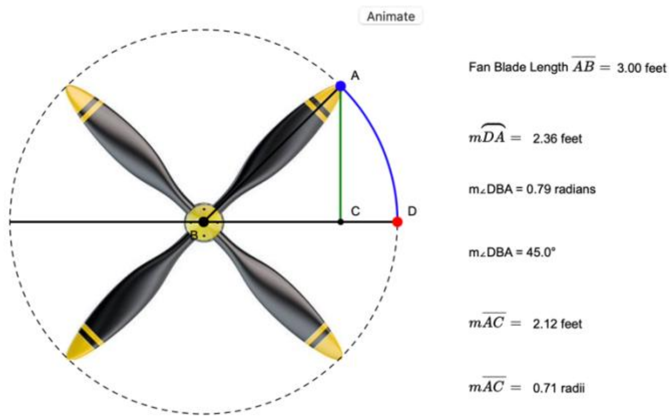

Figure 2: *Fan Blade (FB)-Applet*

Kendra's Meaning for Sine Function

When responding to task 1, Kendra immediately identified the red graph (see Table 1) as the correct graph of sine function. She then expressed that the phrase "how far the gum traveled" (included in task prompt) is a description of a rotation from the 6 o'clock position. Following this she labeled the red graph's horizontal axis as angle measure and the vertical axis as the vertical distance from the center of the fan blade (see Figure 3). When Kendra was asked how she intended to support students in identifying the correct graph in the first task, she expressed that she wanted students to compare changes in the vertical distance of the terminal point over equal-sized intervals of the domain. Specifically, Kendra expressed that in the fourth quadrant (see Figure 3), she wanted her students to focus on the amount of change in the vertical distance of the gum for "equal changes of radians" in the counterclockwise direction (CCW). Although Kendra expressed that she wanted her students to coordinate changes in the vertical distances of the gum with changes of radians, she did not make explicit how one could measure the vertical distance of the gum from the horizontal diameter.

Figure 3: *Applet 1 - Angle Measure*

When Kendra was asked to describe the meanings for sine that she wanted students to have she expressed that she wanted students to think of the sine as a function machine that relates the terminal point's vertical length from the horizontal diameter (the output) to an angle of rotation from the 3 o'clock position (the input). Kendra further expressed that she could determine the vertical distance of the terminal point above the horizontal diameter by comparing the relative size of the vertical length of the gum's position to the length of the radius (Excerpt 1). As one example, Kendra explained that if the gum's terminal point was along a circle's circumference (indicated by blue point in Figure 2), then one can estimate the vertical length (solid vertical blue line) to be 0.9 or 90% of the radius's length (the dashed vertical blue line on vertical diameter).

Excerpt 1

Kendra: So if my terminal point is here [draws the blue point], I'm going to be measuring this length [draws the blue vertical line from the blue terminal point to the horizontal diameter] in comparison to my entire radius [draws dashed line to represent the radius] so that [the solid blue line] will never be bigger than my one radius length so we'll be taking basically a proportion of that radius length. So, how many times as large that vertical length is compared to the length of my radius. Maybe, this one [references the solid vertical line] is point nine. So, your output for the sine function without adjusting it will be between negative one and one every time because it can't go beyond one because you'd be outside the circle."

Kendra explained that by measuring the vertical length in units of the radius, she hoped students would recognize that the output of sine function must range between -1 and 1 units of the radius. She further explained that no matter the size of the circle, the vertical length of a terminal point along a circle's circumference whose rays are centered at the center of the circle will be proportional to the size of the circle's radius.

Excerpt 2

Kendra: To find the vertical distance of that terminal point above the horizontal diameter, in terms of radius's length [i.e. from units of radius lengths to feet]. Then we can multiply by the radius's length [i.e. 3 feet] to get it in terms of the units that the radius length is measured in. Because if I have an output of one and I multiply by 3 …I'm going to get 3, so my radius length of 3 feet that value three is 3 times as large as the radius length itself being one. And if I know that my vertical distance is 0.9 times as large as the radius length, then, if I multiply that by 3, that's going to tell me how many feet it would measure.

Excerpts 1 and 2 show Kendra's conceptualization of both radius lengths and feet as an appropriate unit of measurement for the gum's vertical distance from the ray's terminal point to the center of the circle. Moreover, it appears as though Kendra's meaning for sine function is grounded in quantitative reasoning as she identified an attribute to measure (vertical distance of the terminal point above the center of the circle), a unit of measure (radius length or units of the radius (i.e. feet)), and a process to measure the vertical distance (determining the relative size of the vertical distance to the radius length) (Tallman & Frank, 2018).

Kendra's Expressed Meaning for Sine through Fan Blade Applet

The start of Kendra's interaction with the FB Applet entailed animating the applet, searching for what points on the circle she could move, and the meaning of the information displayed on the right side of the panel (Figure 2). The first thing Kendra discussed was her interest in varying the length of the radius (i.e. dragging point D horizontally to the right which varied the size of the circle). As she did this, she began to describe the affordances of being able to vary the length of the radius (see Excerpt 3).

Excerpt 3

Kendra: The affordance of this is that I can change the size which can adjust my output when it's in terms of feet, but I like that [*moves her mouse to circle in the bottom right corner of the FB applet*]…I like this *m* times AC is always going to stay 0.93 matter what size right because it doesn't matter what size the circle is if we're talking about in terms of radius length.

Following this, Kendra expressed her appreciation for the designer in choosing to not include the term "sine function" on the applet as she imagined having an initial conversation with her students about the quantitative relationships between the arc-length, the radius, and the vertical position of the gum as they vary in tandem prior to defining sine function explicitly in her lesson. Kendra then described the affordance of the applet's dynamic capabilities – the ability to physically rotate the gum's position along the circumference of the circle could support a conversation with students about the quantities involved in the problem and how they vary together. This was important as this aligned with her initial goal of supporting students' imagery of two quantities covarying. While interacting with the applet, Kendra also expressed that she felt it was important to have a fruitful discussion with her students about the applet's capabilities and to observe their reactions. Moreover, Kendra anticipated that students would have difficulties constructing the meaning she intends to convey from the applet in the absence of her (the teacher's) support based on prior experiences from teaching this idea.

Once Kendra seemed comfortable using the applet and all its features, we asked her to describe if and how she would use the applet in class to support students in constructing the meaning for sine that she had described previously. Kendra explained that she would first animate the applet and ask students "what all is changing or staying the same". Kendra expressed that she wanted to animate the applet to allow students to "silently internalize [the] animation and develop their own understanding for what's there or maybe start thinking about what they don't understand." Kendra then expressed that her students might notice that "there are multiple things changing at the same time", which would then provide an opportunity for a conversation on the "need for breaking down" each mathematical notation (see Figure 2) and how it relates to the image shown in the applet. She stated the following:

> "When I vary the size of this propeller, which values are changing, and which values are staying the same. That's definitely something I want to point out, because you can clearly see the arc length is changing the length of the radius is changing, vertical length is changing in feet, but it's staying the same with radii when in terms of the radius, that kind of re-emphasizes that if we measure something in radius length it doesn't matter, the size of the circle, so when we start multiplying it [vertical length in radii] by a number to get an output in feet, that is really dependent upon on a circle's size and a specific context. Whereas the regular sine function is just talking about in general, any circle. And we can relate that vertical length to the radius's size and that's always going to remain proportional, no matter how big or small that circle is. That's definitely something I'd want to emphasize with this one."

It is important to note that while expressing her image for how she intends to use the applet to support an instructional conversation, Kendra continuously dragged point D and varied the length of the radius. She later stated that without the applet, she did not think she would be able to support students in recognizing the proportional relationship between the vertical distance of the terminal point above the horizontal diameter and the radius of the circle as one could demonstrate with the applet. To further explain, Kendra described that the feature at the bottom of the applet that states $m\overline{AC}$, which is the length of the vertical distance measured in units of the radius, continuously staying the same as she varies the radius length, and the size of the circle is a form imagery that she believes displays a productive way of seeing the proportionality of the vertical length to the radius length. Lastly, Kendra also expressed that the applet could be used to support conversations about (1) other applied trigonometric problems and (2) the construction of the sine graph.

Discussion and Conclusion

The results of this study illustrate a teacher's MMT sine function and how her MMT sine function influenced her conception of and intended use of an applet while teaching. During the clinical interview, Kendra expressed a meaning for sine function grounded in quantitative reasoning. Namely, Kendra, described sine as a function "machine" that relates the vertical distance of a terminal point above the center of a circle and the measure of an angle swept out as they vary in tandem. Kendra also expressed that the value of sine represents how many times as large the vertical distance of the terminal point is to the radius of the circle, no matter the size of the circle. Her meaning for sine function supported her conception of the applet's features including the varying radius, angle measure, and vertical distance within a problem context of a fan blade. It is important to note that Kendra's image for supporting her students in conceptualizing how various quantities within the problem context vary in tandem through an instructional conversation (see Thompson 2002 for a more detailed description) was prevalent as she conceived of ways in which the applet could be implemented during those discussions. Specifically, Kendra expressed that she wanted to support students in developing an understanding of sine that encompassed a proportional relationship between the terminal ray's vertical position from the center of the circle to the length radius. She stated that the use of the applet's ability to vary the circle's radius as the vertical length of the terminal point from the center measured in radius lengths stayed constant aligned with her goal for in supporting students in conceptualizing this proportional relationship.

From our findings we hope to interview more instructors to further investigate in what ways teachers' MMT influence their conception of and intended use of an applet while teaching. Future research should investigate teachers' use of applets and how it may support their development of images of teaching practices to advance students' learning. More concretely, we hypothesize that a teacher's MMT influences their conception of an applet and its features, and conversely, a teacher's use of an applet enriches their MMT to include new images of effective teaching practices (e.g., ways to use an applet's features to support students' covariational reasoning). It is important for researchers and professional development leaders to be aware of the relationship between teachers' MMT, their conception of and intended use of an applet, and how they implement the applet within the classroom to advance students' mathematical understandings. In additional studies, we hope to investigate the interactions of four graduate student instructors' MMT for sine function and their conception of and intended use of an applet(s) over multiple sessions while exploring teachers' experiences of using the applet(s) in a classroom.

Making Mathematics Meaningful for All Students: An Exploration of Self-Efficacy in Teaching Mathematics

Ahsan Chowdhury
George Mason University

Andrew Richman
Lesley University

Eric Henry
Tufts University

Making math meaningful for all students is a consistent expectation held by students and a fundamental requirement of teaching for equity. Yet little is known about what makes instructors self-efficacious in helping students find meaning in the mathematics they study. This paper presents results from interviews with four college math instructors during the 2019 spring academic year. The instructors taught several different courses and described having significantly different senses of self efficacy for making math meaningful. A characteristic of those instructors who had strong senses of self-efficacy was notable background experiences with marginalization. Through analysis of these interviews we present evidence showing how these background experiences supported self efficacy in addressing meaningfulness questions in classroom instruction.

Keywords: Meaningfulness of Mathematics, Teacher Self-efficacy, Teaching Self-efficacy, Marginalization

Students in mathematics courses have often voiced complaints to the effect of "when is this ever going to be useful?" (Gough, 1998). We interpret this question and others like it, such as 'why are we learning this?', 'why should we care?' as students asking for the purpose, usefulness, relevance, and/or meaningfulness of what they are learning. Under the assumption that these terms are closely related, if not synonymous in an instructor's and students' eyes, we group these questions under an umbrella term we call the 'meaningfulness question(s).' Such questions put an onus on instructors to make mathematics meaningful to their students, especially marginalized students who are documented as receiving mixed messages about the importance of mathematics in their lives (Martin, 2000).

Some instructors, however, may not feel confident in their ability to meet this challenge. Although little is known about mathematics teaching self-efficacy in higher education, K-12 mathematics teachers differ in their feelings of self-efficacy for teaching mathematics. Furthermore, these differences impact their practice in domains such as their use of high-quality instructional practices (Depaepe & König, 2018) and their willingness to experiment with new approaches (Evers, Brouwers, & Tomic, 2002; Ghaith & Yaghi, 1997). It is, thus, worth exploring what differences might exist in instructor self-efficacy for the more specific domain of making mathematics meaningful.

This kind of work has not been a priority in the field thus far. Research on K-12 teacher self-efficacy, such as the studies cited in the previous paragraph, focus on the broader construct of mathematics teacher self-efficacy (Xenofontos and Andrews, 2020). There has been little explorational work of other, more fine-grained aspects of teacher self-efficacy (Xenofontos and Andrews 2020). Thus, there is a need for qualitative work that investigates more specific components of teacher self-efficacy in mathematics such as self-efficacy in making mathematics meaningful for students. Given the lack of research on mathematics teacher self-efficacy in higher education, work in higher education is especially important. In this study we explore this issue by investigating the research question, *What makes undergraduate instructors' self-efficacious with respect to making mathematics meaningful for all students?*

Theoretical Framework

How then can instructors think of the terms 'meaning' and 'meaningful'? Drawing on Brownell (1947) and social theory, Chowdhury (2021) describes four types of responses to students' meaningfulness questions which derive from different ways to construe the term 'meaning' in mathematics. Brownell (1947) initially talks about the *meaning of mathematics* as referring to the understandings required to grasp a concept mathematically, e.g., the *meaning of* arithmetic requires understanding whole numbers, fractions, operations. By contrast, the *meaning for mathematics* entails understanding mathematics' significance for non-mathematical purposes, e.g., applications to life beyond the classroom or even skills for test performance.

These two conceptions focus on how an individual understands meaning. An individual makes sense of concepts mathematically by understanding requisite concepts (*of*) or values mathematics for its everyday applicability (*for*). However, some may focus on neither, instead focusing on preparing to be a functioning member of the mathematics community or society more broadly (e.g., critical citizenship). For these reasons, Chowdhury (2021) expands the prior by drawing on social theory, specifically aspects of Wenger's (1998) framework. Wenger holds "Practice is about *meaning as an experience of everyday life*" (p. 52, emphasis added). Synthesizing these and Wenger (1998) more generally, Chowdhury interprets Wenger as saying that meaning is how one engages in the everyday experiences of a specific community. Thus, individuals can become competent members of the mathematics community by learning how to engage in the everyday practices of mathematicians or individuals can learn how to engage in practices that enable them to function in non-mathematics communities. Chowdhury proposes that instructors' goals could be oriented towards having students learn practices of either kind, but also mathematical understanding or personal relevance as Brownell originally outlined, as shown in Figure 1 below.

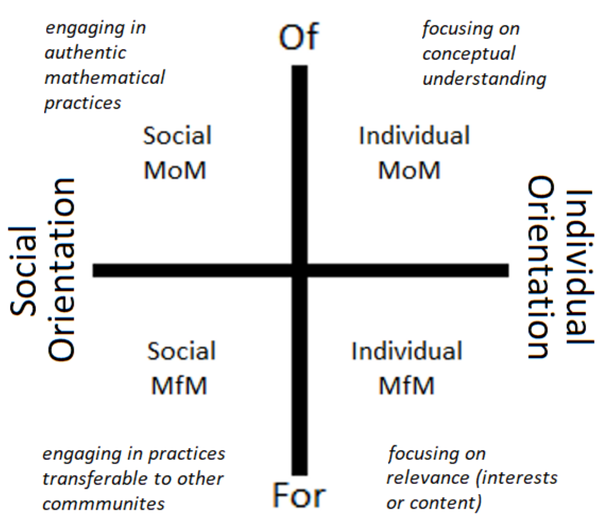

Figure 1. Four Orientations of Mathematical Meaning as a Model of Instructors' Goals.

Thus, Chowdhury (2021) outlines four categories, or *orientations*, for responses instructors could have to students' meaningfulness questions. The *individual meaning of mathematics* (iMoM) refers to meaning as conceptual understanding of mathematical ideas while the *social meaning of mathematics* (sMoM) refers to engaging in the practices of the mathematics community. The *individual meaning for mathematics* (iMfM) refers to the relevance of mathematics to non-mathematical things in an individual's life while the *social meaning for mathematics* (sMoM) refers to engaging in practices transferable to non-mathematics communities. Chowdhury uses the four resulting orientations on meaning to categorize instructors' goals, where some of those goals could be instructors' responses to students' meaningfulness questions.

Methods

The data in this study is from a larger multiple case study of four instructors teaching during the 2019 spring term at a Western U.S. university (Chowdhury, 2021). Each of the instructors taught a different course. Archy (he/him) taught quantitative literacy for non-STEM majors. Jordan (she/her) taught introductory statistics for health science and business majors. Benjamin (he/him) taught calculus III for STEM majors. Natalie (she/her) taught mathematics for teachers to preservice teachers. Jordan, Benjamin and Natalie all had substantial prior experience teaching their courses. Archy was teaching his course for the first time.

The data used in this study were interviews, class observations, collected homework, notes, and email correspondence. Chowdhury interviewed each instructor three times throughout the term. The first interview focused on an instructor's background and course goals. The second and third interviews followed Speer's (2005) video clip interviews: Chowdhury brought clips he suspected may have implications for an instructor's goals and asked the instructor what they did, their goals in the moment and how those goals related to the goals the instructor voiced in the first interview. Interviews were transcribed and analyzed following Braun and Clarke's (2006) approach to thematic analysis. For the analysis, Chowdhury assigned initial codes regarding goals, beliefs, instructor background, and concerns. He then looked over the codes to find broader themes and create thematic maps to see how coded experiences, beliefs, and meaning orientations were organized.

Findings

In the following sections, we will first pose representative examples of instructional goals as evidence of the different meaning orientations as answers to students' potential meaningfulness questions. We will then highlight one way that this distinction in meaning orientations for goals can matter: instructors can have differing senses of teaching self-efficacy to meet goals with different orientations. We will then posit a possible explanation for why this difference in teaching self-efficacy exists (experiences of marginalization).

Instructor's Goals

Instructors had goals spanning all four meaning orientations that they posed in response to students' meaningfulness questions. In terms of goals we classified as iMoM- and sMoM-oriented, instructors had goals around building conceptual understanding and doing mathematics that they posed in response to the meaningfulness question. Natalie had students engage in reconstructing mathematical knowledge to convey that "there aren't all these different individual concepts to learn. that there's bigger ideas." Natalie was having preservice teachers reconstruct mathematical knowledge to see that there are bigger connected ideas (this reasoning being the justification for the iMoM-orientation). Archy stated, “you can just enjoy it [math] the way you enjoy playing basketball. It's just like, basketball's meaningless too, but it's fun.” In trying to convey this fun then, Archy devoted a section of his class to covering sequences and series. There, he wanted students to go through and see how there was a “sweet connection” between sequences of partial sums to the sum of the first n integers. The aspect of showing “sweet connections” focused on drawing connections (iMoM-oriented) while the focus on having students *do* mathematics the way one plays basketball focused on engaging in the practices of mathematicians (sMoM-oriented), and Archy connected these to being meaningful in their own right. Benjamin’s main goals consisted of conveying two overarching “storylines” (sequences and series and preparing for calculus in 3D), and he talked about how he fell back on these goals in response to meaningfulness questions. He stated, “what I end up focusing on more, is simply that this subject [mathematics] is fascinating, … it doesn't have to have anything to do with the people around you, that it can just be its own safe haven.” In all the prior examples, a focus on having students understand mathematical concepts and how they connect to other mathematical concepts (iMoM-oriented) or on doing mathematics (sMoM-oriented) were posed in response to students’ meaningfulness questions.

In terms of goals we classified as iMfM- and sMfM-oriented, instructors had goals around building community engagement and personal relevance that they posed in response to the meaningfulness question. For example, Benjamin had personal relevance goals of building students’ algebra skills by picking algebraically complicated problems because “maybe they'll have spent this much extra time being forced to do hard algebra that that will be a skill that they can carry on and actually utilize in their lives.” Similarly, Archy devoted a section of his class to personal finance. Generally, these personal relevance goals instructors connected to students’ meaningfulness questions focused on promoting competencies for students’ individual use outside any commitment to the discipline of mathematics (i.e., iMfM-oriented goals). On community engagement, Jordan talked about bringing in articles on how statistics were used because “they may not use this specific statistic in their life going forward, but… we hope that they become more educated consumers and not get fooled by statistics… understand that that statistic was manipulated by a politician.” Similarly, Archy had a section on data collection so that his students could critically evaluate claims propagated throughout society. Here, Jordan and Archy are focused on getting students to learn how to function as critically informed citizens in a democratic society. Natalie talked about how “the whole point is to teach them [preservice teachers] useful math…‘Why are we doing it this way? Why aren't you just telling us [how] to do it?’ One of my answers would be, you know, this is how people learn.” The point here was that having the preservice teachers understand math in this way will enable the future teachers to teach their students math effectively (which is sMfM-oriented). In all of these, instructors focused on preparing students to function in (non-mathematics) professional communities or society more broadly and positioned this work as meaningful. The focus on community engagement signals an sMfM-orientation.

Why Might Orientations Matter?

So why do the orientations matter? We found while no instructors described self efficacy concerns relating to i/sMoM-oriented goals, there was a stark contrast in self efficacy in meeting goals with i/sMfM-orientations that broke down along background (childhood experiences, gendered experiences in mathematics, etc.). We note that the absence of voiced concerns about i/sMoM-oriented goals does not establish that all the instructors had high levels of self-efficacy when attending to those goals, but we find it significant that no concerns were stated relating to i/sMoM-oriented goals while some concerns were stated relating to i/sMfM-oriented goals.

Benjamin and Archy expressed discomfort attending to some i/sMfM-oriented goals. For instance, Benjamin commented, "how can we get more people of African American heritage to take math classes and be successful in math classes, and how can we make math relevant to them? I don't have an answer for that question." Benjamin noted the importance of i/sMfM-oriented goals because of racial inequalities. We took Benjamin's view of math as "relevant" as either iMfM- or sMfM-compatible since he went on to talk about cultural relevance, and it was not clear if this meant relevant to an individual (iMfM-oriented) or relevant to functioning in the African American community (sMfM-oriented). As a result of his discomfort in the last quote he noted, "but what I end up focusing on more, is simply that this subject [mathematics] is fascinating, … it doesn't have to have anything to do with the people around you, that it can just be its own safe haven." Since Benjamin did not feel he had the resources to attend to i/sMfM-oriented goals that could be important for students from marginalized populations, he focused on i/sMoM goals. Archy described similar difficulties when he stated, "my concern is that like I don't have any material for this course and that like I'm just making it all up." He later went on to say "I've never done anything useful...if I had examples on point, then I would be able to definitely hit the, the more personal side of how is this gonna effect you, like either via society or directly." Like Benjamin, Archy noted preparation struggles to meet i/sMfM-oriented goals.

By contrast, the Natalie and Jordan felt comfortable implementing i/sMfM-oriented goals. Natalie highlighted how mathematics connects to other topics so that the preservice teachers can more effectively do their job. She stated, "I care about them [preservice teachers] engaging our students and that's [connecting to other topics] a way to engage." Here she demonstrated personal relevance and community engagement goals, which we previously discussed as generally being i/sMfM-oriented. Jordan highlighted how statistics play into other fields and broader culture. She stated, "I always, on the last day, emphasize to them that they may not use this specific statistic in their life going forward but … we hope that they become more educated consumers and not get fooled by statistics." Here she demonstrated the community engagement goal, which we previously discussed as generally being sMfM-oriented.

Possible Explanation of Difference in Self-Efficacy

One possible explanation of this contrast in self efficacy is a difference in the instructors' historical mathematical identities, specifically experiences of marginalization amongst the women and lack thereof amongst the men. Benjamin always had a curiosity around mathematics and had his interests supported. He noted that in the fifth grade, "my teacher saw that I just had a knack for mathematics and … allowed me to do both the 5th and 6th grade math together. … and after that I was always a year ahead." Archy stated, "some component of my identity is… you know how people are. They're like, 'that's a math person.' And I'm like, well I guess I am." Those around both men recognized and supported their mathematical interest. By contrast, Jordan grew up struggling to learn mathematics in her childhood and later in a patriarchal college environment devaluing women. For example, she noted, "I took an engineering course, ... and then I sit down and he [the professor] announced to the whole class, 'yeah we actually have a girl in here. Don't worry, she won't be here by the end.'" She further stated, "it [patriarchal college environment] pissed me off in a lot of ways and I wanted to change those views … I still am up against sexism constantly in my committees and in the work I do." While Natalie was supported in her success in mathematics, she struggled to integrate that success into her identity. She recalled, “my mom remembers me being horrified to have to go up and get this math award….I was definitely not excited to be recognized.” Natalie had further experience with mathematical marginalization when she taught historically marginalized students as part of a teacher certification program centered around issues of access and equity.

Thus, all of the instructors described a need to focus on i/sMfM-oriented goals of personal relevance and/or civic community engagement, sometimes because of how societal inequalities have kept underserved minorities and women from achieving in STEM. However, there was a noteworthy demarcation in translating these realizations into practice. The men with historical identities rooted in mathematics expressed discomfort attending to these i/sMfM-oriented goals, while the women, who had more contentious historical identities associated with mathematics, felt confident attending to these goals.

How might we explain this contrast in self-efficacy? While we don’t have evidence of a mechanism for iMfM-oriented goals, we suspect that, with respect to sMfM-oriented goals, the experiences of marginalization amongst the women may have been a motivational resource. The women went out of their way to find how mathematics is meaningful for life in various professions or society more broadly. Jordan was observed pulling up and discussing various research articles using different statistics. When asked why she did this, she stated,

> I think the point of this is, just this course in general is just to give them a taste of what they may see in a research article or in the media or maybe they're setting up their own surveys … I have about six different articles I'm going to show them that kind of use the things that we've been using throughout the quarter, like where they might see a p-value in a research article. There's one on a replication of a study. So it was a study that was never able to be replicated. And then there's another story I cite where the data was faked.

In this example, it’s notable that Jordan goes out of her way to find ways in which statistics is applied to various fields, but more specifically how to be critical of studies (which related to her community engagement, sMfM-oriented goals). As was mentioned before, Natalie similarly showed how mathematics plays into other fields (e.g., geology) because it would help preservice teachers draw in their students, thus enabling the preservice teachers to function in their profession (sMfM-oriented). In contrast, Benjamin demonstrated less motivation to improve his ability to address sMfM-oriented goals,

> We don't have to have applications for students to appreciate what it [math] is ... really, the breadth of where this could be used is well beyond my understanding and my knowledge. People come up and show me things that-, where math is used, all the time, that I've never seen before and I'm always fascinated [by]. I'm like, 'that's so cool. I wish I had the time and energy to go and like study that specific thing more.'

Benjamin laments the personal knowledge gaps that inhibit his self efficacy, but does not make filling these gaps a priority.

There is a clear contrast between Benjamin who admits to not having the expansive knowledge to attend to some sMfM-oriented goals, and the women who go out of their way to attend to such goals. By having experiences of marginalization, the woman perhaps saw a greater need to push themselves to become knowledgeable of how to draw these connections to other professions. This need could have been motivated by their own learning needs, which was in fact the case with Jordan, or the learning needs of others, as Natalie may have realized as a result of teaching in underserved communities. The example above only applies to sMfM-oriented goals of community engagement; we do not know if a similar dynamic holds for iMfM-oriented goals.

Conclusions and Implications

We found that, for this group of instructors, attending to different meaning orientations (Chowdhury, 2021) provided a useful lens and possible explanation for understanding differences in self-efficacy in making mathematics meaningful for students. None of the instructors expressed self-efficacy concerns with respect to i/sMoM-oriented goals, while two of the four instructors expressed concerns with respect to i/sMfM-oriented goals. The instructors who were more comfortable addressing students' potential i/sMfM-oriented questions were those with contentious historical mathematical identities and experience with marginalization, while those with self-efficacy concerns in this area had positive identity-shaping experiences in mathematics during their childhood. For the case of sMfM-oriented goals, our analysis suggests that these experiences with marginalization acted as a motivational resource.

Thus, a characteristic that would traditionally be thought of as a deficit, marginalization in the instructors' experience, could be a resource for instructors to meet the needs of marginalized students. This finding builds on previous work demonstrating the effectiveness of K-12 teachers of color in working with students of color (McKinney de Royston et. al., 2021; Milner, 2006). In addition to shared racialized experiences, shared experiences of marginalization could support instructor success in making mathematics meaningful to students. This finding also builds on previous work suggesting that normative identities and mathematical abilities may alienate marginalized students from teachers who emphasize i/sMoM-oriented goals (Mayes-Tang, 2019, Martin, 2003). Students with meaningfulness questions may make stronger emotional and intellectual connections with instructors who have and demonstrate a deeper understanding of the marginalization that informs their queries.

One question in our work is the role of gender. We posited that background experiences with marginalization in mathematics could explain the difference in self efficacy to meet i/sMfM-oriented goals, but it is worth noting that this difference in experience also fell along gender lines. It may be that gendered experiences, instead of solely experiences with marginalization in mathematics, could explain the difference in self-efficacy. Or even that both gendered experiences and marginalization intersect to impact instructors' sense of self efficacy to answer the meaningfulness question in various ways. Another limitation to our work is Archy's lack of experience teaching math for liberal arts; he might develop more examples as he teaches his class, and build his sense of teaching self-efficacy in attending to various meanings, regardless of his lack of experience with marginalization.

The surprising finding, that a historically consistent and strong mathematical identity could be a liability in instructor self-efficacy with addressing students' meaningfulness questions, is worth further exploration. If it is indeed a broader phenomenon, it has important implications for instructors and teacher educators. For instructors with mathematical backgrounds similar to Archy and Benjamin, this finding suggests value in consulting with their peers who may have a stronger understanding of how to bring meaning to the mathematics they teach. For teacher educators, this finding suggests that understanding pre-service teachers' historical mathematical identities is a valuable undertaking that could have important implications for individual pre-service teacher needs in teacher preparation. If the field of math education can address these issues and, thus, better attend to instructor's feelings of self-efficacy in making mathematics meaningful for all students, a future where all students see meaning of and for mathematics in their classes could be within reach.

Differential Impacts on NSTEM Graduation: Exploring a Multi-Institutional Database

Williams College

Calculus is a quintessential "gatekeeper" course to degrees in the natural sciences, technology, engineering, and mathematics (NSTEM). However, first-year courses in chemistry or physics, for example, can also impact an institution's ability to retain high-quality students in the NSTEM pipeline. For women and underrepresented students, these courses may be particularly impactful. Using the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD), we investigated the role of sex and race/ethnicity on graduating with a NSTEM degree while controlling for prior academic experience and students' first experiences with NSTEM courses. This project highlights the utility of and need for databases such as MIDFIELD. We estimate the probabilities of students from various sexes and races/ethnicities of obtaining a NSTEM degree as they intended when starting college.

Keywords: Differential Outcomes, Race/Ethnicity, Gender/Sex, STEM, Graduation

The American job market is poised for an 8% increase in science, technology, engineering, and mathematics (STEM) careers during the 2019-2029 decade, over twice the growth expected for all careers (Zilberman & Ice, 2021). While this is a fantastic opportunity, there are serious hurdles to filling those positions. For instance, we struggle to retain students in the STEM pipeline (Pell, 1996). Indeed, only about half of students who begin college seeking a degree in STEM will attain such a degree within six years (Ehrenberg, 2010). Ellis, et al. (2016) reported that after taking calculus the odds of a woman switching out of a STEM major are 1.5 times those of a comparable man. This hemorrhaging is not exclusive to women as race matters, too. Asai (2020) reported that students classified as science PEERS—persons excluded because of their ethnicity or race—are over-represented at the start of pursing STEM degrees but leave at a much higher rate than non-PEERs.

While numerous studies have explored factors contributing to differential outcomes for women and other under-represented students, they tend to coalesce around topics such as academic preparedness and course grades (Ehrenberg, 2010), and student persistence/confidence (Ellis et al., 2016; Harris et al., 2020; Riegle-Crumb et al., 2019). Academic performance in gateway courses, such as calculus, plays a central role in such studies.

Within this landscape, we sought to address two research questions. First, we explore differential outcomes by sex and race on graduating with a degree in the Natural Sciences, Technology, Engineering, or Mathematics/Statistics (NSTEM), accounting for their academic preparedness as well as their performance *in initial NSTEM courses*. Second, we look at the probability of a student attaining such a degree.

An important aspect of our work is a narrowing of the National Science Foundation's definition of STEM (National Science Foundation & National Center for Science and Engineering Statistics, 2013). Specifically, we restrict to the natural sciences (e.g., physics, chemistry, biology, etc.), instead of all sciences. Thus, the primary difference between NSTEM and STEM is that we have excluded the social sciences (e.g., psychology and sociology) as well as the health sciences (e.g., kinesiology, nursing).

Methods

To explore our research questions, we drew upon the Multiple-Institutions Database for Investigating Engineering Longitudinal Development (MIDFIELD; Ohland & Long, 2016). Currently consisting of 20 partner institutions with engineering programs from across the United States, the database consists of all student records (not just engineering students) who attended each institution as reported by their respective registrars. The oldest records stretch from 1988 all the way to 2018. While there are more than 1.7 million student records in MIDFIELD, we have restricted our attention to students who began college between 2005 and 2012, inclusive, following them to 2018 ($N = 225{,}944$). This time window allowed us to look through the six years after each student started to see if they graduated and with what degrees as well as having consistent ACT and SAT scores (avoiding significant changes in how these scores get calculated). Additionally, this time frame situates the data after Chen (2013) while overlapping with MAA's national calculus student (see Ellis et al., 2016) and many of the studies reported in *Talking about Leaving Revisited* (Seymour & Hunter, 2019).

Given the size of our restricted sample, we used a 70%-30% train/test split for our logistic regression model fitting, stratifying along sex and race/ethnicity. We wish to emphasize that there are important distinctions between sex and gender. While the database uses "sex", there is ambiguity as to whether this attribute refers to sex or gender. In our models we will use the term sex for reproducibility purposes. We controlled for past academic preparation through students' high school GPA (Galla et al., 2019) as well as standardized tests (ACT and SAT). We used ACT composite scores and a concordance table (ACT & College Board, 2009) to convert SAT scores to ACT composite when ACT was missing. In addition to variables for sex and race, we also included variables for students' intent to get a NSTEM degree as well as the number of Ds, Fs, and withdrawals ("W"s) students received in NSTEM courses in their first term (semester or quarter).

To account for the multiple/simultaneous inference problem, we have two inference families. The first are the regression coefficients for the multiple logistic model, which we have controlled using a False Coverage-Statement Rate method for selective interval construction (Benjamini & Yekutieli, 2005) at 5%. This method strikes a balance between frequentist and Bayesian approaches while directly dealing with the selection of important terms in fitting a regression model. Our second family consists of the probability estimates for student profiles using Šidák's method to control the familywise Type I error rate at 5%.

Population

There are 12 participating institutions who provided student records for our selected time frame. However, we dropped one institution when that institution's reported student demographics substantially departed from their publicly available demographics. This left 11 institutions varying from a small, private liberal arts college to public R1 and R2 universities.

Of the 225,944 students (with complete information) in our sample, approximately 13.4% ($n = 30{,}368$) graduated within six years of beginning at their institution with at least one degree in a NSTEM field. Table 1 provides the breakdown of the sample by race and sex. Given the racial demographics in U.S. higher education as a whole, it is unsurprising that the sample is majority white.

Table 1. Student Demographics—Race and Sex.

Race	White	Asian	Black	Hispanic/Latinx	Native American	Total
Male	101,076 (44.73%)	6028 (2.67%)	5,427 (2.4%)	8,160 (3.61%)	1,259 (0.56%)	121,950 (53.97%)
Female	85,871 (38.01%)	4,180 (1.85%)	5,291 (2.34%)	7,328 (3.24%)	1,324 (0.59%)	103,994 (46.03%)
Total	186,947 (82.74%)	10,208 (4.52%)	10,718 (4.74%)	15,488 (6.85%)	2,583 (1.14%)	225,944 (100%)

Students' ACT composite scores varied from a 3 to 36, with a *sample arithmetic mean* (*SAM*) value of 24.46 (*standard deviation* [*SD*] value of 4.02) and a *sample median* value of 24 (*median absolute deviation* [*MAD*] value of 4.45). Their high school GPAs varied from 1.0 to 5.0, values for the *SAM* and *sample median* of 3.36 and 3.4, respectively. The values for the *SD* and *MAD* are 0.57 and 0.58, respectively. We calculated the number of Ds, Fs, and Ws each student received in their first term for core NSTEM courses (mathematics/statistics, chemistry, technology, biology, and physics). The number of DFWs went from a low of 0 to a high of 7 courses. Approximately 83% of the students had no DFW's in NSTEM courses in their first term, another ~13% had only one DFW, while the remaining 4% had two or more DFWs.

Of the students in our sample, approximately 60% (n = 135,387) did not intend to get a NSTEM degree at the onset of their college experience while 40% (n = 90,557) did. Nearly 6% of the total students (n = 13,384) switched into NSTEM programs and 14% of students (n = 31,708) switched out of NSTEM programs.

Results

We present our results in two parts. First, we present information about the multiple logistic regression model and then share results of student profiles. The first part allows us to examine the general impacts of various factors on students attaining a NSTEM degree while the second provides a more interpretable look at the model through profiles of students. In both cases, the response attribute of our model is a student's attainment of a NSTEM degree within six years of starting at their MIDFIELD participating institution.

Model

Our multiple logistic regression model consists of two covariates (ACT composite score, high school GPA), three factors (sex, race, and no NSTEM intent), as well as a potential mediator, the number of NSTEM DFWs in the student's first term. We included several interaction terms (sex and race, NSTEM DFW count by race, NSTEM DFW count by sex) in the model as well. The estimates provided below come from the 70% split of the data. To check the model's fit, we used a receiver operating characteristic (ROC) plot and the area under the curve (AUC; Bowers & Zhou, 2019) shown in Figure 1. The ROC curve and the AUC of 0.841 taken together indicate that our model explains the data well.

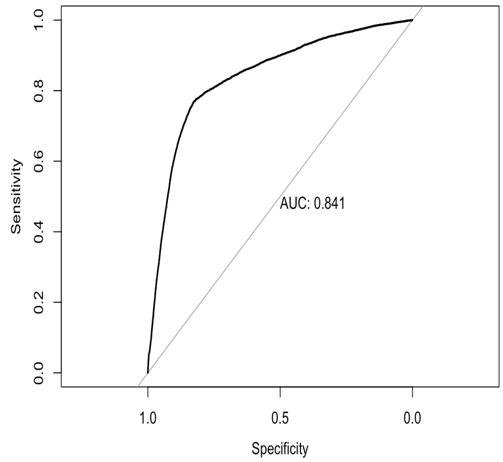

Figure 1. ROC Curve of Fitted Model on Testing Data Set

Table 2. Odds Ratios from Logistic Regression Model

Term	Estimate (Std. Error)	95% Adjusted Conf. Interval
Odds of White, Male, NSTEM Intending, Student with 0 ACT, 0 GPA, and 0 DFWs (Intercept)	0.046 (0.078)	(0.040, 0.53)
High School GPA	2.173 (0.017)	(2.105, 2.44)
No NSTEM Intent	0.070 (0.019)	(0.068, 0.73)
NSTEM DFW Count	0.589 (0.024)	(0.563, 0.616)
Female	0.751 (0.020)	(0.724, 0.780)
Hispanic/Latinx	0.720 (0.051)	(0.655, 0.792)
Black	0.652 (0.074)	(0.568, 0.749)
ACT Composite Score	1.008 (0.002)	(1.003, 1.012)
Black and NSTEM DFW Count	0.769 (0.102)	(0.636, 0.930)
Native American	0.741 (0.131)	(0.581, 0.945)
Female and Hispanic/Latinx	1.180 (0.075)	(1.027, 1.356)
Female and Asian	1.184 (0.077)	(1.027, 1.366)
Female and Black	1.160 (0.102)	Non-significant
Asian	0.933 (0.048)	Non-significant
Asian and NSTEM DFW Count	1.109 (0.074)	Non-significant
Native American and NSTEM DFW Count	0.905 (0.186)	Non-significant
Female and Native American	0.902 (0.193)	Non-significant
Female and NSTEM DFW Count	1.013 (0.039)	Non-significant
Hispanic/Latinx and NSTEM DFW Count	1.004 (0.076)	Non-significant

Note: Based on n = 158,156 observations (~70% split).

Table 2 presents the point estimates from our resulting logistic regression model. We've transformed the regression coefficients from log odds to odds ratios except for the intercept. This term's estimate represents the odds of the reference class attaining a NSTEM degree vs not; that is, a white, male student who intends to get a NSTEM degree with a high school GPA of 0, an ACT Composite score of 0, and no NSTEM DFWs in their first term. All remaining estimates are odds ratios. We've reported adjusted confidence intervals for those terms which are selected as significant following the Benjamini-Hochberg procedure in conjunction with the Benjamini-Yekutieli procedure for a false coverage statement of 5% (i.e., the probability of constructing an interval which does not cover the true value is no more than 5%; Benjamini & Yekutieli, 2005).

From Table 2, we notice several things. First, consistent with Galla, et al. (2019) a student's high school GPA is a much stronger predictor of attaining a NSTEM degree than their ACT composite score. Second, holding all other factors constant, a woman student's odds of attaining a NSTEM degree are only 0.751 times as large as a similar man student's. This is consistent with Ellis, et al.'s (2016) finding that women students were 1.5 times as likely to switch as comparable men students. Our estimate is equivalent to an estimate of 1.33 in Ellis et al.'s framing. Third, while the number of DFWs in NSTEM courses matter in attaining a NSTEM degree, race and sex are still conditionally associated with NSTEM degree attainment above and beyond DFW counts.

Student Profiles

While the logistic model can offer some insights, odds ratios are not very intuitive, especially when you wish to vary multiple factors and covariates simultaneously. However, we can use the model to estimate the probability of various students attaining a NSTEM degree within six years. For our profiles of NSTEM degree intending students, we used a fixed high school GPA of 3.5 and ACT composite score of 26 as these are consistent with the values of the *SAM* and *sample median* of NSTEM intending students in our sample. The resulting profiles (varying race, sex, and number of NSTEM DFWs in the first term) appear in Table 3.

Table 3. Predicted Probabilities of Attaining NSTEM Degree

		Number of NSTEM DFWs		
Race	Sex	0	1	2
White	Female	0.388 (0.375, 0.401)	0.274 (0.254, 0.295)	0.184 (0.154, 0.214)
Asian	Female	0.412 (0.366, 0.458)	0.317 (0.259, 0.374)	0.234 (0.151, 0.318)
Black	Female	0.324 (0.273, 0.376)	0.180 (0.131, 0.230)	0.092 (0.041, 0.142)
Hispanic/Latinx	Female	0.350 (0.310, 0.390)	0.244 (0.196, 0.292)	0.162 (0.099, 0.225)
Native American	Female	0.298 (0.199, 0.396)	0.186 (0.088, 0.284)	0.110 (0, 0.221)
White	Male	0.458 (0.447, 0.469)	0.332 (0.315, 0.349)	0.226 (0.201, 0.252)
Asian	Male	0.441 (0.404, 0.477)	0.340 (0.286, 0.393)	0.251 (0.169, 0.334)
Black	Male	0.355 (0.302, 0.408)	0.200 (0.144, 0.255)	0.101 (0.044, 0.159)
Hispanic/Latinx	Male	0.378 (0.341, 0.415)	0.264 (0.216, 0.312)	0.175 (0.110, 0.241)
Native American	Male	0.385 (0.288, 0.482)	0.250 (0.134, 0.366)	0.151 (0.006, 0.296)

Table values are the predicted probabilities with 95% Šidák corrected confidence intervals.

The predicted probabilities in Table 3 paint a stark picture: not even the advantaged white males who intended to get a NSTEM degree when they started college reach the status of a fair coin flip for attaining a NSTEM degree. Across the board, women students are less likely than men students of the same race to attain an NSTEM degree (odds ratios: White students—0.75, Asian—0.89, Black—0.87, Hispanic/Latinx—0.89, Native American—0.68).

The number of DFWs in NSTEM courses do not affect students equally. White and Asian men students who have at least one DFW in NSTEM courses in the first term have a higher probability of attaining a NSTEM degree than Black and Native American women students who don't have any DFWs. Black and Native American women and Black men with 2 DFWs in their first term will obtain a NSTEM degree no more than 11% of the time. However, for White and Asian men as well as Asian women with the same number of DFWs will get NSTEM degree more than 20% of the time.

Discussion

This study leveraged a large, multi-institutional database (i.e., big data) to explore factors contributing to differential outcomes in NSTEM degree attainment. However, there are several important limitations to this work.

Limitations

An important limitation is that our models are not causal in nature. Our work might best be viewed through the lens of exploratory data analysis (Behrens, 1997) and is observational in nature. Further, our sample does not constitute a random sample of students or institutions. Institutions self-select to participate in the MIDFIELD program and students self-select universities. The sheer size of our sample brings benefits that small, random samples do not. As comparisons, Chen (2013) used a sample of 13,400 students, Ellis, et al. (2016) used 2,266 students, and Riegle-Crumb, et al. (2019) used a high of 4,828 students for some of their models. The size of our 70% training set (n = 158,156) is nearly 12, 70, and 33 times as large as the aforementioned sample sizes, respectively. While large sample sizes are not a replacement for random sampling (e.g., there is still the existence of bias in big data), they do come with the risk of making Type I errors based off the sample size and not any actual effect from the factors/predictors. We have guarded against this by using a training/test split and adjustments for multiple comparisons. While the previous work is important and contributes to our collective understandings of (N)STEM disparities, the prior three studies did not account for multiple comparisons (or, if they did, made no mention of it); a weakness we sought to overcome.

This large sample size would not have been possible without the MIDFIELD data. However, such a database comes with its own limitations. Participating institutions use their own idiosyncratic methods for coding student data. While the data stewards do what they can, using such a large-scale database does require considerable time in cleaning/processing the data. For example, within the race attribute of students we encountered two categories which we omitted from our analysis: Other/Unknown and International. These two categories are too vague for interpretable use of even though there might be important effects related to underrepresented minorities within them. (A similar Other/Unknown category appeared for sex.) Second, high school GPAs exist on at least two scales: 4.0 and 5.0. It is unclear whether institutions converted all GPAs to the same scale before sending their data to MIDFIED. After much internal discussion, we opted to work with GPAs as reported.

A final limitation we wish to mention relates to both the database and our response attribute (attaining a NSTEM degree within six years from the institution they started at). While using six years is a ubiquitous practice, perhaps future work could re-examine such a limit. More importantly though is that the MIDFIELD database is constrained by what *registrars* can report in anonymized ways. Other longitudinal studies make use of *student self-report* data collection methods which allow for knowing whether the student did graduate (up to study attrition). For our data, once a student leaves a MIDFIELD participating institution, they effectively vanish as registrars are not going/able to track such a student outside of that institution. A NSTEM intending student could start at a participating institution but then transfer to a non-participating one and still graduate with a NSTEM degree. In terms of a generalizable model, such a student would be ultimately misclassified as not attaining a NSTEM degree. However, from the institutional level perspective, they are not misclassified. This is an important limitation of the current work. We see such an issue as an opportunity for the development of databases such as MIDFIELD as well as push for better data collection/standardization and sharing.

Key Points

Our present work highlights the utility of large, multi-institutional databases for modeling issues in education, especially as related to issues of diversity, equity, and inclusion. When working at a single institutional level, the number of students in a demographic category might be 0 at worst and small number at best. This often leads researchers to collapse many categories together and/or forgo intersectional analyses of overlapping traits (e.g., race and sex). For example, at one of the institutions included in this study, there were only two black female students who began college between 2005 and 2012. Using the MIDFIELD database allowed us to overcome these issues.

Our resulting model, while observational, is in alignment with the results of several other studies (e.g., Chen, 2013; Ellis et al., 2016; Riegle-Crumb et al., 2019; Seymour & Hunter, 2019). Our work also expands the prior work not only by using MIDFIELD data, but also moving away from the typical notion of gateway/gatekeeper courses (e.g., calculus). Rather than exclusively looking at students' grades in just Calculus I, we looked at students' grades in all the NSTEM courses they took in their first term. Not only does this bring in the potential of gatekeepers directly in computer science, engineering, physics, chemistry, and biology, this expands the mathematics/statistics side to include courses such as college algebra and pre-calculus. This expansion allows us to better capture the impact of students' first experiences in college/university NSTEM courses, especially given that higher proportions of under-represented minority students often begin in developmental/remedial math courses (Chen, 2016). Our results suggest that we can't just focus single mindedly on addressing issues in Calculus I; we need to take a broader view of the experiences of our NSTEM intending students.

Our model also highlights the effects of sex and race which are not attributable to course grades. We take this to signal that those efforts focusing on academic support for women and under-represented minority students might only see marginal gains. We believe that for successful transformations, institutions must consider students holistically as well as critically examining and addressing their own systemic biases. The probabilities of attaining a NSTEM degree for various student profiles provides a useful tool for institutions. Using their own data, institutions can calculate the proportions of various student profiles that attain a NSTEM degree and then compare those proportions to the values in Table 3. While a blunt instrument, such comparisons can be eye-opening to institutional leaders/administrators, bringing the issue of differential impacts of NSTEM degree attainment home.

A final note we wish to make is that our results appear to be in line with Galla, et al. (2019) for the usefulness of standardized test scores in predicting the attainment of a NSTEM degree. While not a focus of this work, our results raise new questions for exploration and continued calls to question whether the benefits of using standardized tests such as ACT/SAT outweigh their (historical) systemic, racial problems (Rosales & Walker, 2021).

Researchers have documented differential outcomes within the (N)STEM pipeline for many years. Our work affirms and expands the previous research in this important arena by using a large, multi-institutional database. However, this work is but a first step. We need to take the knowledge from studies such as this and begin working towards meaningful changes at multiple levels (class, department, institutional, societal) to fully tap into the creativity and talent which leave the (N)STEM pipeline.

Acknowledgments

The Practice of Naming and its Role in the Collective Productive Struggle of an Undergraduate Summer Research Community

Casey Hawthorne
Furman University

Grace Stadnyk
Furman University

Grace Morrell
Furman University

Elizabeth Harris
Furman University

We explore productive struggle as a disciplinary practice in the context of undergraduate summer research. In contrast to the classroom, students and professors collectively engage in productive struggle, providing a rich context to study how professors model and support students in appropriating the nuances of this practice. Results elevate a particular sub-practice of productive struggle, that of naming, which the summer research group used to jointly clarify and negotiate their differing understandings. We identify the different components of naming and discuss how they support collective productive struggle (CPS). While naming is a mathematical practice familiar to most mathematicians, taking the lens of CPS to analyze this process elevated the important role that discourse and other social mechanisms have in perseverance. Comparing different instances of naming, we document how such a process supported the group in grappling with both conceptual and symbolic ideas and ultimately establishing a unified understanding.

Productive struggle has been identified as a key component of learning mathematics with understanding (Hiebert & Grouws, 2007). To make sense of the mathematical structure of problems presented as well as the underlying mathematical concepts, students must be given opportunities to explore and navigate situations where the path forward is not immediately apparent (NCTM, 2014). Such authentic experiences promote deeper, more flexible reasoning and problem solving skills. Students develop the ability to draw on their own resources to resolve problematic situations rather than resorting to the authority of others. Moreover, engaging in productive struggle fosters in students a positive attitude about learning and a confidence in their own self-efficacy as learners (Jackson & Lambert, 2010; Hassi & Laursen, 2015). This results in an increase in student empowerment, as students are able to see their own role in generating mathematical insight instead of viewing mathematics as a discipline that only involves the application of procedures and the ideas of others.

To date, most studies have focused on the instructional methods and environments that teachers use to foster and support productive struggle. Researchers have explored and documented how teachers navigate the natural tension that exists between maintaining cognitive demand and simultaneously encouraging students to engage in productive struggle. For example, several studies have highlighted the type of questioning that supports productive struggle (e.g. Freeburn & Arbaugh, 2017). Warshauer (2014), offering a more comprehensive framework, characterized different types of struggle and offered up a continuum of possible teacher responses that vary in the level of cognitive demand they support. This detailed study illustrated the situatedness of productive struggle and how it differs depending on the students, the task, and the norms of the classroom. Notably, when these situational factors overwhelmed students, teachers responded with direct guidance, often telling students what to do and lowering the complexity of the mathematical task.

Productive Struggle in the Context of Undergraduate Research

In contrast to previous work, we chose to explore productive struggle in the context of undergraduate research. Such engaged learning programs have become increasingly popular in undergraduate institutions. However, these programs create an experience of productive struggle for students that differs from the typical instructional setting. In a classroom, the teacher is already familiar with the solution method and must judiciously decide when and how to offer support to students (NCTM, 2014). In a mathematics research setting, the path forward and even the ultimate destination are often unclear to both the students and the professors. As such, instead of being tasked to create an environment that supports productive struggle for the class, the professors themselves experience struggle along with the students. Consequently, in an undergraduate research setting, productive struggle arises naturally and manifests itself as a quintessential disciplinary practice which professors engage in firsthand, modeling how they react and overcome the challenges presented. This type of authentic participation in productive struggle highlights how summer research takes place in a community of practice (Wenger, 1998). In contrast to a classroom, understanding of productive struggle in a research setting occurs as the group works together towards a common goal. Students appropriate the norms and strategies associated with productive struggle as they interact with the professors, grappling together with how to productively move forward.

Research Question

Leveraging this context, we endeavored to understand how such a community collectively engages in the disciplinary practice of productive struggle. Specifically, we explored the research question: How does the practice of collective productive struggle manifest itself in an undergraduate mathematics research setting?

Theoretical Framework

An individual's willingness to engage in productive struggle is usually viewed as a personal disposition, denoted by a tendency to embrace struggle or an appreciation that struggle is a key component of learning (e.g. NCTM, 2014). For example, DiNapoli (2018) offered a detailed characterization of productive struggle, distinguishing it from other character traits such as grit and persistence. He maintained that productive struggle, like perseverance, is characterized by the flexibility to switch tactics and improvise to accommodate in-the-moment challenges. Moreover, he analyzed productive struggle through the lens of the individual, choosing not to incorporate the contextual features that shape how individuals respond to adversity.

No doubt the community and its norms provide resources from which we draw on to persevere. As Warshauer (2014) noted, the nature of student struggles seemed related to the sociomathematical norms that were in place in the different classrooms she studied. This finding suggests that the sociocultural practices established in the classroom, which impact and mediate students' learning behaviors (Yackel & Cobb, 1996), should be expanded to include productive struggle.

Collective Productive Struggle

In contrast to the individual perspective, Sengupta-Irving and Agarwal (2017) conceptualized productive struggle as a collective enterprise in a middle school classroom setting. They documented the interplay between group members, illustrating how the collective group supported each other in engaging in productive struggle. Students problem-solved independently, but repeatedly reconvened, to share ideas and draw upon their collective thinking to move forward together. Taking such a collective lens, they documented the teacher's impact on groups' collective engagement in struggle. Expanding on Vygotsky's notion of Zone of Proximal Development (ZPD), they leveraged the "collaborative ZPD" (Goos, Galbraith, & Renshaw, 2002) to emphasize that benefits of interaction are bi-directional between all members of a community. A collaborative community does not simply expand the problem-solving ability of the novices, but that of the entire group.

As student research takes place in a community of practice, we adopt a collective view of productive struggle. By taking a broader view of productive struggle, we aimed to explore the environmental and social resources that summer research groups draw upon and use to support each other in productive struggle.

Naming

Our exploration within a collective research context elevated one particular sub-practice, which we refer to as naming. Naming involves group members initiating a conversation to negotiate and define a mathematical idea that has collectively emerged as significant, but that has not been explicitly discussed. As Hewitt (2007) wrote in describing his theory of symbolic interactionism, names are linguistic symbols that are social in nature. They draw their meaning from a community adopting them and using them in a consistent way. Symbols transform abstract ideas into concrete entities, giving rise to a new form of social interaction and enabling the transference of ideas (Hewitt, 2007). As such, in the context of mathematical research, the act of naming not only supports the group in communicating their divergent ideas with each other, it serves to establish a new mathematical idea, embedding the dense often divergent thinking into a single symbol or name. Moreover, names serve as a repository of those ideas that have proven important for a particular community (Hewitt, 2007). The process of naming signals to a research community a productive idea, focusing their attention and creating a newly created tool to use moving forward.

Methods

This study takes place during a summer research program in a mathematics department at a small liberal arts university. This program supports a wide range of projects in pure and applied math and the groups involved vary in size, experience, and community norms. After observing multiple small research groups, we focused our analysis on one group that was attempting to determine the minimal number of time steps required to move a fixed number of objects along the edges of a directed graph. This group consisted of two students, a female rising junior, Allison, and a male rising senior, Bobby, as well as a female and male professor, Dr. Alister and Dr. Brown, respectively. We focused our analysis on this group because the students and professors were highly collaborative in their approach. Not only did they discuss their work aloud, they used a large white board to record their collective ideas and support their interactions. Such public communication, both verbal and written, allowed us to observe their collective thinking. Moreover, from the very first observations, it was clear the group had established strong norms, where they listened and built off each other's ideas, providing a rich context to explore their mutual engagement in productive struggle.

Data was collected over the last three weeks of an eight-week, daily summer research project. To understand how the group collectively engaged in productive struggle, we observed and filmed the research group working together each day, two hours with all four group members and two hours with the students only. To understand how the group collectively engaged in productive struggle, we identified specific moments when the group worked together to overcome a challenge that emerged.

Analysis

One significant moment emerged through this process in which the two students and two faculty members collectively grappled with naming and defining a particular concept that had emerged. Three members of our research team reviewed this instance and met to discuss observations and to identify salient moments within the instance that seemed to support the group in productively moving forward. We then returned to the data to look for other cases of naming. Taking this lens, two other instances were identified. To understand the different components of naming and their apparent purposes for the group, we compared these three instances looking for commonalities and differences. Contrasting these moments enabled us to identify several significant markers in the collective naming process (see Table 1), as well as two distinct classes of naming instances (conceptual naming and symbolic naming). This analysis resulted in a framework for classifying critical stages in the naming process that highlights the manner in which naming--a common practice in mathematical research--supports collective productive struggle. We describe this framework in detail in the results section that follows.

Table 1. Stages in the naming process and their presence in naming exemplars

Stages	LMC	W	C-1-2
1. Elevation of the concept	✓	✓	✓
2. Negotiation			
• Establishment of collective definition	✓	✓	
• Discussion of importance	✓		✓
• Discussion and choice of name	✓	✓	✓
3. Adoption of name	✓		

Results

The first interaction consisted of the research group naming what they called a “leftmost minimal cut” (LMC). This was an example of conceptual naming and was the most robust exchange of the three instances. Notably, it was the only interaction in which group members engaged in all stages of the framework (see Table 1) and the only one in which all group members participated. The second interaction focused on the concept which the researchers referred to as “waits” (W). This interaction involved only the two students and illustrated their appropriation of the practice. While similar to LMC, the W interaction exhibits evidence of only parts of the naming framework. The final interaction, which we call C-1-2, is the only example of what we identified as symbolic naming. While this example differs from the other two instances in both representation and substance, it is similar in that it involves the group attaching a single name to a fundamental notion or in this case a reoccurring algebraic expression.

In all of these instances, the group possessed what we call a preliminary collective understanding. One researcher’s understanding of a notion that is central to the mathematical exploration of the group may not always completely coincide with the understanding of another researcher within the same group. We thus view the preliminary collective understanding as the intersection of the individual conceptualizations of the idea being named.

The first stage of the naming process is marked by an assertion and shared understanding that the idea being named is central to the mathematical exploration; evidence of this stage often includes repeated references to the concept during conversation or problem solving. In the LMC interaction, we can see the idea first introduced when Dr. Alister interjected, “You know, I wonder if there’s something to that.” Shortly afterwards, Dr. Brown elevated the same idea, stating, “The beauty of the minimal cut, though, is…” and “[the] important thing [is], whether or not [a minimal cut] occurs, you know?” In all of these examples, various group members interjected in an attempt to focus the attention of the group on a concept they saw as central to the mathematical investigation with which they were engaged. At this point in the process, group members possessed different conceptualizations and ways of reasoning about the idea at hand. While the repeated inclusion of the idea elevated the concept, the individual group members’ understanding of the concept remained mainly implicit. In fact, Stage 1 results in the (often diverging) individual conceptualizations being made public. Notably, all three instances of naming we analyzed contain evidence of this stage. As such, this initial stage appears essential to the naming process; without it, there is no motivation for the group to engage further in naming the concept, as the concept is not sufficiently elevated to warrant a name.

Stage 2 is characterized by a collective negotiation of the concept. We identified several components that support this process: establishment of collective definition, discussion of importance, and discussion and choice of name. This negotiation process can be quite disjointed as the meandering discussion in the LMC interaction exemplifies. At the beginning of this stage the different members of the group attempted to come up with an initial collective definition. Dr. Brown revoiced his understanding of Dr. Alister’s interpretation, saying “Just so I understand what you’re saying [...],” and Dr. Alister’s reply with the question, “What’s the definition of minimal?” These different interjections illustrate the group’s attempt to arrive at consensus. The negotiation ultimately arrived at the following exchange, where it is clear that the group had come to an initial agreement about the concept being defined:

Dr. Alister: I am changing the definition[...]
Dr. Brown: No don’t change the definition, come up with a new definition
Dr. Alister: This is a new definition that I don’t have the terminology for yet
Bobby: Can we call it a minimal ideal cut, maybe?
Dr. Alister: Why is it ideal?
Bobby: Because it is as far back as we can do it and that’s how you really define it.
Dr. Alister: Ok [...] be careful because ideal means something else in algebra
Bobby: Ah ok nevermind
Dr. Brown: So let’s just be clear, so minimal [...]
Dr. Alister: What about a quasi-min? Or pseudo-min?
Dr. Brown: Let me ask you this question though, if you have a minimal cut, why could that ever be bad?

This interaction also included a second part of the negotiation stage, discussion of importance. During this component of the negotiation phase, participants discussed what makes the concept central to the mathematical exploration and in doing so, identified the key aspects of the concept that they believed should be reflected in the name. Dr. Brown’s questioning of the importance of this concept at the end of this exchange illustrates this reflection.

The exchange above also illustrates a third part of the negotiation stage: discussion and choice of name in which members of the group propose various names and collectively consider the affordances, drawbacks, and implications of each name. As the exchange above illustrates, a critical part of this stage is the group intentionally selecting a name which they believe conveys important information about the mathematical idea they are discussing and avoids a name that could potentially be misleading. After the negotiation above, the group finally arrived at the name of "leftmost minimal cut" as we see in the following, which occurred shortly after the previous exchange.

Allison: So are we just saying `find one and …'

Dr. Alister: Well [Bobby] is suggesting that because of the special properties of these graphs, that maybe if you find one, you can adapt it [...] so in some sense you achieve a ...

Dr. Brown: ...Leftmost cut...

Dr. Alister: ...A leftmost minimal cut

We highlight that the negotiation stage is inherently fragmented as the discussion can meander among various tangential ideas with different components occurring simultaneously or out of order. For example, at the end of the exchange above involving the choice of name, Dr. Brown brought the group back to a discussion about the importance of the concept by asking them to think about whether this particular type of cut is really important to the exploration. This comment encouraged the other researchers in the group to question the significance of the particular type of minimal cut they were attempting to define, even after they had begun proposing names.

Finally, Stage 3 is an ongoing stage marked by the adoption of the chosen name by all group members. Following the LMC interaction, the name "leftmost minimal cut" was employed by all group members whenever the notion was being discussed. However, as the following exchange later the same morning illustrates, the group was still working to internalize the name and concept.

Dr. Brown: If you had minimal cuts and you had a notion of a…

Dr. Alister: ...Leftmost minimal?

Dr. Brown: ...Leftmost or topmost, does that solve the problem?

Notice that Dr. Alister used the name established earlier, leftmost minimal cut, despite the fact that the group was examining a graph that was oriented differently than their previously examined graphs, and thus the notion of "leftmost" was in fact "topmost." However, all group members tacitly accepted the name "leftmost," even though it did not reflect the more general case they were discussing. It seemed that since all group members were fully involved in the earlier LMC interaction, the name "leftmost minimal cut" did not lead to any discrepancies or confusion despite the name failing to accurately represent the notion being considered. Such acceptance suggests that the earlier discussion around the meaning and importance had established a strong, collective understanding of the concept.

It is also noteworthy that a group can engage in the naming process without engaging in all of the stages. For example, in the W interaction, Allison and Bobby did not discuss the importance of the name (Stage 3) nor collectively adopt the name (Stage 5). In the exchange below we see in Allison's first comment that the group was engaging in Stage 1 and began the negotiation. Bobby also participated in the negotiation process, by suggesting names.

Allison: Should we say, like, stretch or, like, add... how can we explain adding those loops?

Bobby: I've been thinking of them as w-a-i-t, waits but you could also think of them...

Allison: I think it's so funny because we have so many different meanings for so many different words

Bobby: yeah add stalling, I guess, or wait

However, the establishment of a collective definition was strikingly less intentional in this interaction than in the LMC interaction. The two students discussed the name, but while the potential for misunderstanding was acknowledged ("I think it's so funny because we have so many different meanings for so many different words"), it was never resolved. This interaction also did not reach the "adoption of name" stage: Bobby continued to use the name he proposed (waits), despite Allison's apparent confusion about the name he was using. Ultimately, both referred to the same concept using different names (Bobby using the word waits while Allison used the word pauses), even within the same presentation to researchers outside of the group. Though the negotiation stage was not as robust in this instance (missing the discussion of importance) and the group failed to engage in the adoption of a name, the interaction still supported productive struggle by indicating Bobby's understanding of the concept given his name suggestions, and displaying a potential misunderstanding.

Similarly, the C-1-2 interaction is missing some stages, but still supports productive struggle. Specifically, the C-1-2 interaction did not include an explicit discussion of the importance of the concept being named, nor did it include an adoption of the name by group members; the conclusion by the participants in the interaction was that the concept was not fundamental to the mathematical exploration and this symbolic naming was only motivated by a need to save space on the board (Bobby says, "we can name it, sure, but we're gonna get rid of it in just a second," to which Allison replies, "well we're just running out of space.") The discussion and choice of name in the C-1-2 interaction is also less substantial than in the LMC interaction, possibly precisely because it is an example of symbolic naming, which seems to require less discussion of implications associated with possible names.

Discussion

Naming is a mathematical practice familiar to most mathematicians. As demonstrated by the various exchanges of the research group, the act of naming signals the perceived importance of a concept, brings to light possible divergent understandings among group member, and results in an expansion of their collective understanding. This work sheds light on the process of naming by decomposing the practice and identifying constituent parts. Such analysis highlights the critical role that discourse and other social mechanisms play in collective problem solving and in supporting perseverance.

While it is notable that the students found value in this naming practice and adopted it to support their problem solving in the one case we analyzed in which they worked independently, our investigation revealed they omitted stages that were present in the interactions involving the professors. We suggest that the disciplinary practice of naming and the understanding of its importance and effectiveness was not fully established in the mathematical problem-solving toolkits of the students. Notably, the student researchers each continued to refer to the notion using their own preferred nomenclature, even using their own preferred terms within the same presentation to other researchers in the program outside of their research group. We propose that the missing stages help to establish a common understanding of the concept. This supports our claim that these stages are critical in supporting group progress and we encourage other research groups to use this framework to guide their work in engaging in collective productive struggle. We suggest that professors endeavor to demonstrate and instill the practice of naming in their students, conscious of the need for a robust discussion for the naming to be an effective tool.

How Students Learn Math Best: Tutors' Beliefs about Themselves Versus Their Tutees

Sloan Hill-Lindsay

Anne M. Ho
University of Tennessee

Mary E. Pilgrim
San Diego State University

Erica R. Miller
Virginia Commonwealth University

Undergraduate and graduate tutors play an important role for students who utilize math tutoring centers. Here we draw on our previous work on our modified version of the Teacher Beliefs Interview (TBI) protocol by Luft and Roehrig (2007) to assess mathematics tutor beliefs (Pilgrim et al., 2020). While validating item wording through cognitive interviews, we noted tutors had different beliefs for how their students learn math best compared to how the tutors themselves learn math best. This paper investigates this difference and describes the process, coding, and results of this qualitative data as well as implications for tutor professional development programs.

Keywords: Tutors, Belief, Practice, Professional Development

Of 105 higher education institutions surveyed in 2015, 102 indicated that they had a tutoring center—of these, 87% had undergraduate tutors and 33% had graduate tutors (Johnson & Hanson, 2015). In another study specifically on higher education mathematics centers, 96% of the 75 centers utilized undergraduate tutors and 65% used graduate tutors, some of whom also had instructional responsibilities as graduate teaching assistants (Mills et al., 2020). Both studies show that undergraduate and graduate tutors are commonly involved in providing academic support to undergraduate students. Their work in tutoring centers can impact academic outcomes such as tutees' final course grades, persistence, retention, understanding, and academic confidence (Colver & Fry, 2016; Kostecki & Bers, 2008; Rasmussen et al., 2014). However, tutors' personal views and biases influence how they perceive their tutees, which can then affect their approaches to tutoring including session goals and instructional decisions.

In one study by Derry and Potts (1998), tutors were shown to use adaptive modifications to tutoring sessions in terms of content, pedagogy, and complexity based on their categorizations of tutees. This study's tutoring context was different from the current study in that three of the five tutors were assisting tutees with a computer-based instructional system, and only four out of the five tutors were tutoring math. Derry and Potts also utilized Kelly's (1955) personal construct theory to identify constructs that the individual tutors used to think about tutoring sessions. In this context, *constructs* can be thought of as "major components or elements" that tutors use to distinguish tutees (p. 70). Overall, the two main constructs or types of classification had to do with motivation and intellectual ability.

Having an adaptive tutoring style can be desirable, but it could be also problematic if a tutor is incorrectly categorizing a tutee or making poor tutoring decisions. Because of this, understanding tutor beliefs and designing tutor professional development are important for the success of a tutoring center. In particular, tutors' reflection on and awareness of their own beliefs and biases can initiate reform to their pedagogical practices (Nardi et al., 2005).

To improve tutor professional development, we first need a way to measure beliefs. Our tutor beliefs research group has modified the Teacher Beliefs Interview (TBI) protocol (Luft & Roehrig, 2007), a semi-structured interview protocol designed to "explore the beliefs of beginning secondary science teachers" (p. 38), in order to create an open ended survey instrument that assesses the beliefs of undergraduate and graduate tutors. Our goal with the modified TBI is to assess changes in tutor beliefs over time as a result of experience and professional development. In our pilot study, we utilized seven TBI open-response items, and we coded the data in a way similar to Luft and Roehrig but adapted for the tutoring context (Pilgrim et al., 2020). Responses were coded on a spectrum (Figure 1) that ranged from *instructive* (i.e., more traditional approaches to instruction) to *adaptive* (i.e., more closely aligned with reform methods of instruction). During this process, we found that some tutor responses contained excerpts that spanned across the codes including ones that are not adjacent on the spectrum. This highlights the complexity of responses for general tutor beliefs. We will provide detailed examples in the next two sections.

Figure 1. Codes for the qualitative responses.

Before deploying our modified TBI questions to tutors at higher education institutions across the United States, we wanted to assess the validity of our items through cognitive interviews (Desimone & Carlson Le Floch, 2004). For this article, we focus on the question of how students (including tutors) learn math best, which is a component of our larger project's research question: what are the mathematical beliefs and practices of graduate and undergraduate tutors? In the next sections, we describe the cognitive interview process, details of coding, findings, and implications about tutor professional development.

Methods

We conducted two rounds of three cognitive interviews (i.e. six interviews total) to test the validity of the TBI item wording. This allowed us to ensure that participants were interpreting questions with consistency and were considering similar contexts while responding to the items (Desimone & Carlson Le Floch, 2004). The first three participants who voluntarily responded to a recruitment email were part of the first round of interviews and the next three individuals who responded were part of the second round of interviews. All interviews were conducted over Zoom. They started with participants reading the TBI items and then verbalizing their streams of consciousness while interpreting the questions, recalling relevant experiences, and determining their answers. Before the interviews, we predicted where item wordings may be problematic, and we preemptively created follow up questions addressing these concerns. However, spontaneous follow up questions were additionally asked when the interviewer wanted clarification or elaboration on a previous response (Betty, 2004). These interviews were recorded and transcribed for later analysis.

After the first round of interviews, we made a modification when the transcripts indicated participants were not interpreting and answering the questions as intended or with similar contexts in mind. The modified item wordings were then used in the second round of cognitive interviews. All participants attended the same urban, public research institution. Tutors 2, 3 and 4 were undergraduate tutors who regularly worked in the campus math tutoring center and who led precalculus review sessions. Tutors 1, 5 and 6 were graduate students who worked in the campus math tutoring center in addition to holding office hours for college algebra or precalculus. For simplicity, we refer to both graduate and undergraduate tutors when we say tutors.

One of the items on our modified TBI was, "How do students learn math best?" (Our modification of the original TBI merely replaced "science" with "math"). We were initially concerned that some respondents may interpret the group "students" to include themselves since they were current undergraduate or graduate students. We thought that some might also restrict "students" to the group of students they tutor, thereby excluding themselves. Because these two interpretations could influence the way respondents were answering the question, it could influence the validity of claims based on responses to this TBI item. Therefore, in the first round of cognitive interviews, we asked the follow up question, "Did you include yourself in the group 'students' when originally answering this question?" In this case, all three participants answered, "no," so we further asked if their answer would change if they did include themselves. When all three of these participants did change their response, we decided to modify the protocol. In the second round of cognitive interviews, we first asked, "How do students learn math best?" and immediately followed with, "How do you learn math best?" In both rounds of interviews, there was a qualitative difference between the tutors' responses to the two questions, so we investigated this further using the coding scheme previously developed in Pilgrim et al. (2020).

In addition to the aforementioned spectrum, we further describe the details of the codes here. The *instructive* (red solid pattern) code was applied to responses that primarily focused on doing practice problems and mimicking instruction. In contrast, the *adaptive* (blue polka dot pattern) code was applied to responses that involved transferring knowledge to new problems and making conceptual connections. *Transitional* (yellow zig zag pattern) was in between, with such responses being characterized by engaging in mathematics in various ways (e.g., in groups) and going beyond pattern matching or following a recipe to solve problems. Example responses for each of instructive, transitional, and adaptive can be found in Pilgrim et al. (2020). Some responses could not be strictly coded as instructive, transitional, or adaptive. At times, responses constituted a blend (orange horizontal stripe pattern or green vertical stripe pattern) of these categories. Here is one example: "Student[s] learn math best by doing. Some examples of this include group work and homework." This was coded as a blend of instructive and transitional (orange horizontal line pattern) because while there is an aspect of working problems in the response, there is also an awareness that students learn through collaborative group work.

However, there were challenges in applying single codes to some responses, especially lengthy ones. At times, parts of responses encompassed both *instructive* and *adaptive* codes, so averaging to *transitional* did not seem appropriate for the entire excerpt. Thus, for this analysis, we applied multiple codes to responses by pinpointing specific portions of the answers. This was more appropriate for the cognitive interview data given the longer descriptions and because respondents changed their answers when asked about different contexts.

Findings

In both rounds of the cognitive interviews, we noted a difference in tutor descriptions of their tutees' learning in comparison to their own.

Differences in Belief Spectrums

In some cases, the baseline methods for learning mathematics were the same, but the tutors described additional methods for learning when talking about themselves (see Table 1). For instance, Tutor 6 believed that tutees learn math best "by seeing examples and then repeating it themselves," an idea that Tutor 5 also expressed. When describing their own learning, Tutor 5 agreed that "do[ing] a bunch of problems" was still helpful, but they also added that "working collaboratively with others" or asking questions "to fill in the gaps" was helpful too. Tutors 1 and 4 had a more instructive response for the tutees but a wide range of instructional, transitional, and adaptive descriptions for themselves. Tutor 4, for example, gave a broad range of ways to learn for themselves by suggesting that the best ways to learn are to work on practice problems, to check answers, to "understand why it's happening," and to utilize multiple problem-solving methods. In another case, the descriptions of the tutee and tutor learning methods were on completely different ends of the spectrum. For instance, Tutor 2 had an instructive description for the tutees and an adaptive description for the tutors. When asked to describe the learning of tutees, Tutor 2 brought up how "students who don't like math or aren't confident [in] their mathematical abilities do best when they do a lot of practice." Yet, when describing their own learning, Tutor 2 preferred to reflect about the problem, "break the problem into pieces," and "try a different way" as needed. Tutor 3 also had very different responses for tutees versus tutors, but in their case, they primarily described how they were "anti-homework" for their tutees since "bad practice" only leads to students "not understanding it." Since Tutor 3 answered in the negative, we coded their response as not-red/solid pattern and not-orange/horizontal-stripes, but this did not necessarily mean that they had transitional or responsive answers.

Tutors Categorize Mathematics Learners into Various Groups

We noted tutors making various, explicit comparisons of two different groups during the six cognitive interviews.

Mathematics Course Level. Sometimes the tutors categorized students into lower level versus upper level courses or undergraduate versus graduate courses. Tutor 1 even described the changes in their own learning when comparing their personal experiences in high school, undergraduate work, and graduate studies. In their case, they found that study groups were useful in graduate school "because everyone has a different perspective." Tutor 1 did not explicitly generalize to all high school and undergraduate students, but they implied that their own experience with groups was not truly collaborative prior to graduate school, so they did not think it was a particularly helpful resource for their tutees. On the other hand, "working independently" on problems is a reliable method of learning math for Tutor 1 across all categorizations. Interestingly, Tutor 1 also referred to how they think "the whole entire curriculum is based on tests" for the tutees. Because they perceived their tutees' classes to be problem- and test-oriented, then it made sense to Tutor 1 that doing problems was the best way to learn in those courses. Tutor 4 did not refer to the curriculum but also echoed Tutor 1's thoughts by saying that doing practice problems "doesn't necessarily give you the same ability to differentiate and use a different method, but, at the very least you can still get the result that you're looking for." This implies that Tutor 4 also thinks the answer is more important than the process for the tutees' coursework.

Types of Learners. Some of the tutors also categorized students into types of learners. For example, both Tutors 1 and 3 mentioned "visual" or "auditory" learners without any prompting from the interviewer. Tutor 3 used these types of learners to talk about their tutoring decisions. They sought to be "super flexible" tutors—if a tutee did not appear to be one type of learner (e.g. "visual learner"), then they would "switch to something else." Tutor 1 also mentioned these categorizations of learners in the context of types of courses. Tutor 1 believed that many people were visual learners, but that the subject of abstract algebra was "pretty auditory," so "being able to articulate math in a high level" is another level of understanding as it is "more like telling a story and how all the pieces come together." In addition, Tutors 2 and 3 also discussed "creative" versus "logical" thinkers. Tutor 2 described themselves as always having been "a logical thinker versus a creative thinker." They associated their logical thinking with their mathematical thinking, and for them, it was their logical thinking that differentiated them from their tutees. In fact, Tutor 2 even said that math learning is "a lot more different for [the tutor] and [their] precalc students." Tutor 3 also mentioned creativity but in a very different way than that of Tutor 2. Tutor 3 said that many of their tutees "feel bad about themselves" when facing math courses and that they "can't be creative" when they are "terrified of failing." Rather than contrasting creativity with logic, Tutor 3 seemed to value creativity in math problem-solving but believed that affective factors held their tutees back from learning math in the best way possible.

Discussion

Although their responses varied on the coding spectrum, the cognitive interview process indicated that our questions about tutor beliefs were consistently interpreted across tutors. In the case of the questions about how students learn math best, tutors had a range of responses from adaptive to instructive, and their answers were different for themselves versus tutees. For multiple tutors, categorizing tutees by math course or by perception on type of learner was important for how the tutors adapted their tutoring sessions.

Our findings are similar to those of Derry and Potts (1998), whose study indicated that experienced tutors largely classified students by motivation level and intellectual ability for the purpose of adapting their tutoring sessions. These categories are different from the ones we observed with our tutors, but there are overlaps in the tutors' decision-making. For instance, Tutor JS in Derry and Potts' study would give more "direct verbal instructions" with "weaker students," which would be coded as instructive for us. On the other hand, Tutor JS would have "discussions of theory" with "stronger students" and would allow "higher ability students" to lead the tutor sessions tasks, which is a more transitional (or possibly a blend of transitional and adaptive) response in our coding scheme. This seems to parallel our Tutor 1's remarks about higher levels of understanding for students in upper level math classes. Additionally, Derry and Potts' Tutor PM "emphasized the goals of independence, understanding, self-evaluation, and enjoyment for all students [...] little direct instruction was given by Tutor PM. Rather, content was conveyed by discussions that employed the conceptual language of mathematics" (p. 83). We would code this excerpt as a more transitional or even adaptive response. Lastly, for three out of the five tutors in the Derry and Potts study, "motivational/affective considerations were reported as more important than judgments of cognitive ability" (p. 95). Although the reasons behind this were not further explored, this is related to our cognitive interview comments from Tutors 1 and 4 about problem- and test-oriented courses. In our case, these two tutors implicitly suggested that tutees' motivations were affected by an instructive course structure. Because of this, the tutors also chose instructive methods in their tutoring sessions to match the course's instructive style.

For some of our tutors, authentic mathematical practices (such as understanding connections between concepts, being able to utilize a variety of methods to solve problems, and working collaboratively in a group) only became necessary for students in upper division or graduate courses. Tutor 1 explicitly indicated that they formed this distinction by examining how undergraduate courses are structured and because of the types of mathematical activities necessary to succeed on assessments. Tutor 1 expressed awareness that many lower division courses merely require students to memorize equations and procedures for solving problems, and that this type of "curriculum is kind of controlling how you teach it." This distinction between lower and upper division undergraduate mathematics courses is not unfounded, as seen in studies on assessments. Multiple studies have found that lower level assessments largely focus on applying procedures and utilizing algorithmic reasoning, while upper level assessments had more emphasis on higher order skills such as evaluating or creative reasoning (Mac an Bhaird et al., 2017; Maciejewski & Merchant, 2016).

It also seems likely that tutees themselves are aware of the requirements for success in lower division undergraduate mathematics courses. This may explain why Tutor 6 said, "I feel like very few students actually care about the why." Maciejewski and Merchant (2016) found that non-expert conceptions of mathematics correlated with superficial, procedural approaches to studying. Furthermore, they found that those conceptions and procedures could result in obtaining a desired course grade in lower level courses but not in higher level courses. On the other hand, expert conceptions of mathematics correlated with deep approaches to studying, which they found to increase the chances to succeed in upper level courses. Additionally, Code and colleagues (2016) found that students moved away from expert-like orientations about mathematics after taking a semester or year of an introductory undergraduate mathematics course, but they reported more expert-like orientations after taking a specialized mathematics course. The implication here is that students who are successful using superficial approaches in lower level courses will likely underperform in upper level courses if they are not supported in changing their studying approaches or their beliefs about mathematics.

There is a tension that exists between what tutors experience as students, what they perceive to be important, and what they may be taught during training and professional development activities. While student-centered approaches to tutoring are recommended by mathematics education research and emphasized in tutor training and professional development, institutional practices can often still reflect teacher-centered instructional practices (Carlson & Rasmussen, 2008; Stains et al., 2018). It may be that these practices are pressuring tutors to engage with students in ways counter to the recommendations from mathematics education literature. Alternatively, it could be that instructors' reformed practices have not been clearly communicated to the tutors, or that tutors' roles haven't been updated to match these practices.

In any case, tutors will likely have varied beliefs and practices reflected in their tutoring, and we advocate for training activities to meet tutors where they are, allowing for differentiation in their professional development process. If a tutor's initial beliefs are aligned with more *instructive* approaches, then activities to support their growth to a more *transitional* approach may be more appropriate than *adaptive* activities, as such tutors may not be ready for this shift. Additionally, tutors may think that some adaptive approaches are only fit for certain tutees, so unpacking these complex beliefs and potential biases can better train tutors to foster more adaptive approaches for all students. Furthermore, we recommend that those running tutor professional development explicitly examine their own tutors' beliefs. It may be that tutors have a limited view of the curriculum, so their beliefs are misaligned with those of the instructors. In this case, professional development activities to align tutor and instructor beliefs may be appropriate. It may also be that tutor beliefs and practices are appropriately reflecting departmental differences between lower division and upper division courses. In this case, it may be appropriate for a department to reevaluate the course structures and assessments to ensure that best practices are available to all students.

Oral Assessment in University Mathematics: The Role and Variations of Follow-up Questions

Nicole Engelke Infante
University of Nebraska at Omaha

Nurul Schraeder
West Virginia University

Ben Davies
University College London, UK

We investigate how four assessors conducted a virtual oral assessment for an Introduction to Proof course when minimal direction was given. Our qualitative analysis of assessors' behavior showed that most, but not all students were asked follow-up questions during their oral assessment. When the assessor engaged students in follow-up questions, we identified four purposes of these questions: to seek details of the thought process, to fill gaps in a student's presentation, to provide the student access to the problem, and to foster deeper learning. Although the assessors had been given minimal guidance on how to follow-up with students during the assessment, there were several instances of assessors asking similar questions. Our findings culminate in suggestions for others wanting to use oral assessments with multiple assessors.

Keywords: Oral assessment, online education, reasoning and proof, technology in assessment

Creating assessments of student knowledge is a critical part of course design. Romagnano (2001) argued that designing an objective mathematical assessment is an impossible task. However, instructors can include a variety of assessments to provide multiple perspectives of their students' knowledge and capabilities (Iannone & Simpson, 2012). By having multiple sources of evidence, instructors are more likely to produce a more accurate picture of students' knowledge and understanding (Romagnano, 2001). While written modes of mathematics assessment are dominant in the English-speaking world, it is well-documented that varied assessment practices add valuable and arguably necessary insights into students' understanding (Iannone & Simpson, 2012). Implementing less-familiar assessments in your classroom comes with advantages and disadvantages to both students and the teacher. In this paper, we will evaluate our implementation of a less-familiar assessment in U.S. higher education mathematics classrooms: oral assessment.

Background

Oral assessment allows an instructor to have a constructive dialog with students. In this alternative to written exams, students can express their knowledge in a variety of ways, and the assessor can ask clarifying questions when needed. Studies have shown several positive aspects of oral assessment, such as helping students develop communication skills (Iannone & Simpson, 2015), being more authentic (Iannone & Simpson, 2015), and being more inclusive (Huxham et al., 2012). For instructors, oral assessment allows them to rephrase a question so that a student can demonstrate more knowledge than may have been evident from a written response (Huxham et al., 2012). For students, providing a verbal explanation may generate deeper understandings of material (Iannone & Simpson, 2015). Additionally, cheating on an oral assessment is much harder than on a written assessment (Huxham et al., 2012; Joughin, 1998). This last benefit is particularly pertinent given the widespread use of virtual instruction and assessment due to the global pandemic. As is demonstrated by the data we present, oral assessments are highly adaptable to the virtual environment with minimal disruption in the implementation and integrity of the assessment.

There are potential drawbacks to oral assessment with overwhelming workload, fairness, and anxiety among them. Oral assessment requires more time to proceed, especially when the class is large. The workload issue could be minimized by conducting a group oral assessment or using multiple assessors. The issue of fairness can arise from the absence of anonymization, variations in students' experiences, and difficulties with post hoc moderation by assessors not present in real time. These issues around fairness were addressed by Iannone and Simpson (2015). Students in their study were concerned about fairness because different assessors would ask different follow-up questions when working on the same problem. Lastly, students' stress and anxiety were more likely to be high because of unfamiliarity with oral assessment (Akimov & Malin, 2020). The data presented here were from a practice quiz that was one of several low-stakes opportunities for students to experience oral assessment throughout the semester.

This exploratory investigation considers the practicalities of this implementation in terms of grading and variation in students' experiences when a virtual setting was used, and limited direction was provided to each assessor. This led us to the following research questions:

1. How consistent are assessment ratings when using a minimally directed oral assessment protocol in an introduction to proof course?
2. How consistent is a post hoc assessment of the same student population?
3. What are the purposes of follow-up questions that students are asked in an oral assessment? What are the differences and similarities in these follow-up questions?

Methods

Participants

Twenty-five of 29 students enrolled in an introduction to proof class at a large, research focused university in the United States agreed to participate. One student was excluded from data analysis because she misunderstood the instructions and prepared for the wrong assessment. The four assessors were all experts in mathematics education with graduate-level backgrounds in pure mathematics: an associate professor who was also the course instructor, a post-doctoral scholar, and two doctoral students. Depending on their mathematics course history, students' may have been familiar with any subset of the assessors as all were instructors of mathematics courses (including the calculus sequence prerequisites) at the institution. All data were anonymized using pseudonyms prior to data analysis.

Procedure

This oral assessment under consideration here is a 'practice quiz' conducted in week 4, one week before their first low-stakes oral assessment that counted toward their course grade. One week ahead of this quiz, students were provided with a set of problems that they would be asked to talk about and to which they could prepare solutions in advance. Each problem on the quiz had multiple parts, and assessors had the freedom to ask students to present any or all parts. This study focuses on the second question of the quiz, presented in Figure 1. This item was chosen as it had the smallest number of parts and was the only item that all assessors used all parts for their assessment with every student.

Before assessing students individually, all assessors met to discuss some general rules such as ethical considerations and options for which problems to ask during the assessment. For example, the first problem on the assessment had four parts covering the set definitions for subset, powerset, union, and intersection. It was discussed that in the interest of time, students need not be required to answer all four parts. Rather, the assessor could ask them to explain their reasoning for part one that focused on unions, and then ask them how the answer changes if the union were changed to an intersection. It was discussed that if a student was stumped, then it was ok to restate the problem or give hints to help the student make progress. If substantial hints were needed, then the student should receive a score of growing or not yet (rather than success) with encouragement and suggestions for future studying. This discussion included how to start the assessment (brief introductions) and how to handle incorrect responses.

2. Concept Check 2. I can state the definition of a Cartesian product and use this definition to describe the elements of the Cartesian product of two given sets.

   (a) List all the elements of the set: $\{x \in \mathbb{R} : x^2 = 2\} \times \{x \in \mathbb{R} : |x| = 2\}$

   (b) Sketch the set $X = \{(x, y) \in \mathbb{R}^2 : 1 \leq x^2 + y^2 \leq 9\}$ on the plane $\mathbb{R}^2$. On the second set of axes, shade in the set $\overline{X}$.

Figure 1: Quiz problem 2

The practice quiz was conducted through one-on-one video meetings that lasted approximately 30 minutes. Students shared their prepared responses using the website scratchwork.io; a whiteboard application that allows collaboration with others in real-time. This platform let students display pictures or pdf files, which was important for this study because the students were allowed to prepare their answers and could display and present their responses from those files if they wished.

The course instructor provided all assessors a three-point rubric: *success*, *growing*, and *not yet* that was used to give students immediate feedback on their responses. This was the rubric that would be used to assess their responses on all quizzes throughout the semester. Raw, anonymized grading data and rubrics are available at [redacted].

Analysis

Each member of the research team conducted about one-fourth of the oral assessments. After all data was collected, each member of the research team watched the recordings of the other assessments and scored them independently. An inter-rater reliability analysis revealed that reliability between assessors was very high; there was disagreement between assessors on only two items. This high level of agreement suggests that students' course grades would not be substantially different regardless of who conducted their oral assessment. Numeric or categorical ratings are a small part of the oral assessment picture. To better understand how students' experiences may differ in this setting, we conducted a qualitative analysis of the recordings.

We used an inductive thematic analysis approach in which the codes and themes were driven by the data itself without any pre-existing codes (Braun & Clarke, 2012). The qualitative data came from the 24 video recordings of each one-on-one oral assessment meeting. After watching all videos and choosing to focus on question 2, the relevant parts of the videos were transcribed using online resources (e.g., zoom transcript) and edited as needed. Transcript excerpts presented here have been lightly edited for readability. Each member of the team wrote notes on what they observed during the initial video viewing, such as who assessed which questions and characteristics of follow-up questions. We observed that different assessors asked different follow-up questions and sometimes no follow-up questions. We then proceeded with a more detailed analysis of the transcripts, focusing on how each assessor used followed up questions. This analysis led to the identification of two broad categories and three sub-categories of follow-up questions, and the roles they play in oral assessment.

Results

Purposes of Follow-up Questions

It is natural that assessors would ask different follow-up questions during an oral assessment, especially given the minimal guidance provided. In Table 1, we summarize the types of follow-up questions asked by each assessor. We noticed that some question types were asked by multiple assessors despite no guidance on this. For example, both Paige and Sandy asked questions about how the definition of Cartesian product was applied in the given context, but Nancy and Barb did not. There were follow-up questions that were only asked by one assessor, such as Barb asking about the size of a Cartesian product in general terms.

We first distinguished two broad categories for follow-up questions: directly related to the problem and not directly related to the problem. We found that questions that were directly related to the problem had three main purposes: probing details, filling gaps, and bridging access for students in need. Meanwhile, only Barb asked questions that were not directly related to the problem, such as 'what is the size of $A \times B$ in a general sense?' or 'is $A \times B = B \times A$?' We observed that these types of follow-up questions played a role in fostering learning.

Table 1. Follow-up questions identified among assessors

	Part (a)	Part (b)
Paige	- No follow-up - How Cartesian product works	- Did not assess
Nancy	- How to get elements of each set - Elicitation of missing element(s)	- The length of radii of the circles - Inclusion/exclusion boundary
Sandy	- How elements of sets were attained - How Cartesian product works	- Inclusion/exclusion boundary - How they got the circular shape
Barb	- Clarification of terminology - Elicitation of missing element(s) - Size of $A \times B$ in general sense - Whether $A \times B = B \times A$	- Inclusion/exclusion boundary - How they got the circular shape. - Identify length of radii of the circles - Slight modification of the problem to a new problem

Probing details

Oral assessment provides an opportunity for an interaction between assessor and student in which the assessor may ask questions to probe the student's knowledge and reasoning. We found that some assessors sought details in students' reasoning even after students presented a complete answer to the problem.

When following up on part (a), some assessors asked for details on students' thought processes for obtaining the Cartesian product, such as "how did you get this set as your Cartesian product?" (Sandy to D2) or "So, how did you end up getting those, those ordered pairs? What was your thinking there?" (Paige to A6). In another instance, Nancy asked C6 how she obtained the elements for one of the sets in the Cartesian product, "how did you figure that out?"

For part (b), some students explained the why the boundary would be solid or dashed without being prompted. When the student did not address why they had drawn the boundary as they did, we noticed that all assessors asked further questions about the boundary. The questions were often, "why was the boundary included/excluded/solid/dashed?"

Follow-up questions that seek additional details are likely asked to ensure that students can speak and reason knowledgeably about what they are presenting. This was especially important because the students could use any resources to prepare their answer ahead of time. Furthermore, we found that the questioning provided opportunities for students to recognize errors and misconceptions. In the following excerpt, we observe how the probing question from Sandy let D1 recognize her misconception.

D1: All right, so since it's between one and nine, I just kind of saw that it was, if you took one and one, that would be one. So, I know it’s at least here, here. And then the largest part is nine, so three squared plus three squared is nine.

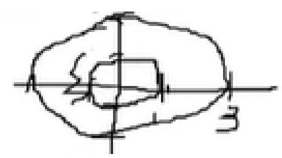

Figure 2: Diagram drawn by D1

Sandy: Hold on, you said three squared plus three squared equals nine?

D1: I did not mean to say [mumbling]. I think I screwed up somewhere in my thoughts. [long pause]. All right. Hold on.

Sandy: Take your time.

D1: I feel like it still is a washer with a radius with the inner circle being a radius of one. And I think that at the end that it's a radius of three still. I just didn't understand exactly how…

Based on her drawing (Figure 2), we can infer that D1 knew what the shape of the graph looks like, but her explanation for how she obtained that did not follow. Although the correct result was presented, it may have been obtained through memorization, help from someone else, or the use of graphing software. If this were a written assessment, this issue might go undetected by both student and teacher while the teacher thought the student had mastery of the problem.

Filling gaps

We identified filling gaps in a student’s presentation as another role of follow-up questions. For instance, two students missed the element $-\sqrt{2}$ when listing the elements of the factor set for problem 2(a). Barb and Nancy asked questions in hopes of eliciting the missing element. The initial questions were broad and moved towards being more explicit when the student continued to struggle. In the transcript excerpt below between Barb and B2, the student quickly realized that something in their solution needed to be addressed when Barb expressed a qualm about the presentation.

Barb: So, I agree with everything you said. Except we have one small qualm. It is about the first set. So, you’ve told me that we’re looking for all real numbers x such that x squared equals two.

B2: Oh, wait…

Barb: Can you think of any other numbers that might be in that set?

B2: So, this … [writes negative root two on the scratchwork board]

From this excerpt, we observed that a brief prompt from Barb caused B2 to realize that she was missing something. However, filling the gap was not always easy. Another case shows that the student needed more explicit direction.

Nancy: So, the square root of 2 definitely makes that true. Is there any other real number that also makes that true?

C2: Something square root…I don't think so…
Nancy: What about negative square root of two?
C2: Yeah… (smiling)

In both situations, we observed that through follow-up questions, the assessors led the students to think and help them realize that something had been missed.

Bridging Access to Knowledge

Students who cannot access problems, such as those who do not know a certain definition or those who do not understand what is being asked, might become discouraged and would most likely receive a low score on a written assessment. However, we found that oral assessment could help those students by providing some "help" without losing the integrity of an assessment. Let us look at the following excerpt in which Nancy was providing a bridge for C6 to access problem 2a.

C6: I wasn't like entirely sure when we have um... like for example when it says x squared equals to 2 and then the Cartesian product of absolute value of x equals 2. I don't understand how you would do that.
Nancy: So that's telling you the two sets of your Cartesian product. So, that first one, that means x is a real number such that x squared is equal to 2. So, what value of x makes x squared equal to 2? that are real numbers?
C6: Um… negative square root of 2 and square root of 2.

This reiteration of the problem seemed to be a big help to C6. She was able to proceed with the rest of this problem on her own. Note that Nancy did not provide a hint to the problem, but she just restated the set notation in language that was more accessible to the student.

Fostering Learning

Across our data set, Barb was the only assessor to ask follow-up questions that were not directly related to the problem. These questions were mostly in the form of a modification of the actual problem or a generalization of some aspect of the problem. It appears these questions were asked to encourage deeper student reflection and learning. For instance, after students presented their answers for part 2(a) correctly, Barb asked about the order of $A \times B$ in general. In the transcript excerpt below, Barb asks about the size of a generic Cartesian product of sets.

Barb: So, if I told you that the size of a set, some random set A was four, and the size of a different set B was five, and I asked you how big was A cross B? or the Cartesian product of A and B, without knowing what the elements were, would you be able to know how big that set is?

When assessing part b, follow-up questions included modifications of the problem, such as changing the inequality into a strict inequality. For instance, Barb followed B1's explanation for 2(b) with, "say we took away the less than or equal to, and we made that just less than. What does the picture look like now?" On another occasion when following-up on part b, Barb modified the universal set to $\mathbb{R}^3$.

Discussion

Using multiple assessors resulted in different experiences among students. During our quizzes, some students experienced no follow-up questions while other students received follow-up questions that were beyond the problem they were presenting. Although the students had different experiences, scoring was highly consistent among assessors. Hence, we conclude that students' grades would not be negatively affected regardless of who their assessor was. The differences in student experience were related to the nature of the follow-up questions they received. Each of these contribute to answering our research questions.

In answer to our first two research questions, we found that the assessors in our study were surprisingly consistent in their ratings of student performance, even when assessing student knowledge after the fact. Although our sample was small, we have evidence supporting Iannone and Simpson's (2015) claim regarding the feasibility and consistency of post hoc moderation of oral assessments in undergraduate mathematics.

In answer to our third research question, we identified four purposes for asking follow-up questions: seeking details, filling gaps, building a bridge for students to access problems, and fostering learning. There were often similarities to the questions asked by assessors. As noted, all four assessors asked follow-up questions about how the boundaries of the circles were decided to be solid or dashed. Three of the assessors asked questions related to the equation of the circle and how the radius of the circle was determined. The questions that were similar across assessors were the ones that sought details and filled gaps.

Questions that sought details or asked for additional information to fill gaps allowed the student to demonstrate the depth of their knowledge. When students found themselves unable to proceed, questions that created bridges to knowledge allowed the students to extend their learning by making connections between their ideas and their representations. Follow-up questions that fostered deeper learning asked a student to make a generalization or modification of some aspect of the problem. Each type of follow-up question provided a path for students to reflect and learn more, which is the ultimate goal of education.

We conclude that in preparing to administer an oral assessment, many follow-up questions could be prepared in advance. This aligns with Joughin's (2012) advice to have prepared probing questions to help provide uniformity and consistency in both grading and students' experiences. To prepare these questions for a mathematics setting, we recommend writing questions for each problem that: 1) probe for detail and fill gaps by asking for explanations on key ideas/concepts, 2) bridge access to knowledge by anticipating trouble spots and scaffolding hints, and 3) foster reflection and deeper learning by extending ideas beyond what was initially asked. We acknowledge that it is impossible to prepare for all possible scenarios in team preparation, but an extensive list of possibilities should improve the experience and consistency. It is encouraging that even with the minimal guidance our assessors had, the scoring of students was highly consistent. This consistency was likely due, in part, to using an assessment scheme that was quite coarse.

We believe that our implementation of a virtual oral assessment was a successful endeavor considering its novelty in undergraduate mathematics classrooms in the United States, and we have learned much from this experience. Student evaluations of the course were very positive, with one student writing, "I was pleasantly surprised by how much I preferred the oral quizzes to normal quizzes. It allowed me to really think about difficult questions beforehand, and I often had breakthroughs in the middle of the quizzes." The most promising benefits to students when incorporating oral assessments into assessment practices are the opportunities to demonstrate their knowledge using modalities beyond writing and to deepen their learning by engaging in authentic mathematical conversations. When used as part of varied assessment practices, the focus of classroom activities will shift away from merely trying to accumulate enough points for a given grade to one in which students are working toward richer mathematical knowledge.

Conceptions of active learning held by undergraduate mathematics instructors participating in a statewide faculty development project

We explore the perceptions about "active learning" among college and university mathematics faculty involved in early stages of the Mathematical Inquiry Project (MIP), which supports long-term collaboration across mathematics departments at the 27 public institutions of higher education in the state of Oklahoma. Our analysis indicates that faculty beliefs about active learning varied widely across individuals and significantly differed from the MIP characterization, even though participants believed their conceptions to be aligned. We document changes in participants' beliefs as a result of participation in the MIP that faculty attributed to engagement in rich mathematical tasks, conversations with other participants, small group discussions of research literature, and conversations with project team members. Participants also reported enacting their conceptions of active learning in their classrooms more often as a result of their involvement in the professional development.

Keywords: Community of Practice, Inquiry-Based Learning, Entry-Level Math, Active Learning, Professional Development

Introduction and Background

The Mathematical Inquiry Project (MIP) is a statewide collaboration among mathematics departments at the 27 public institutions of higher education in Oklahoma to foster sustainable, large-scale reforms to improve instruction in entry-level mathematics courses. To promote awareness of and attention to the mathematical, epistemological, and affective considerations in instructional design, the MIP is guided by definition of *mathematical learning through inquiry* that entails three interdependent components: (a) engaging students in *active* learning, (2) incorporating *meaningful applications*, and (3) supporting students' development of broader *academic success skills*. These components are defined as follows:

Students engage in active learning when they work to solve a problem whose resolution requires them to select, perform, and evaluate actions whose structures are equivalent to the structures of the concepts to be learned.

Applications are meaningfully incorporated in a mathematics class to the extent that they support students in identifying mathematical relationships, making and justifying claims, and generalizing across contexts to extract common mathematical structure.

Academic success skills foster students' construction of their identity as learners in ways that enable productive engagement in their education and the associated academic community.

The MIP aims to foster instructors' professional growth by fostering a *community of practice* (Wenger, 1998) in which participants engage in a joint enterprise to design, disseminate, and implement instructional resources, as well as develop as leaders within the community's emerging view of expertise. In this report, we focus on faculty perceptions of *active learning*.

In the summers of 2019-2021, the MIP led five multi-day initiation workshops during which Oklahoma mathematics faculty identified key priorities for courses in the four state pathways—

functions and modeling, college algebra/precalculus, quantitative reasoning, and Calculus I—as well as on academic success skills across all courses. Participants engaged in readings, presentations, and small- and whole-group discussions about the three components of inquiry, their dependence on conceptual analyses (Thompson, 2008), and their implications for constructing hypothetical learning trajectories (Simon & Tzur, 2004). The purpose of the initiation workshops was threefold: (a) to initiate a statewide community of practice, (b) to build the capacity for faculty to design and implement instructional materials that support learning through inquiry, and (c) to identify the key conceptual threads in these entry-level courses for future instructional design collaborations. Following the workshops, the MIP participants were encouraged to join Collaborative Research and Development Teams (CoRDs) comprised of groups of 2-5 faculty tasked with developing, testing, and refining an instructional module related to one of the conceptual threads identified in an initiation workshop. Later stages of the MIP will involve broadening the community of practice through disseminating resources via the MIP website, regional workshops, and peer mentoring.

Research on faculty professional development highlights that change strategies should seek to alter individual's beliefs as opposed to enacting top-down policy to impact teaching or disseminating "effective" curricular resources (Henderson et al., 2011). This demonstrates the importance of characterizing faculty's conceptions of mathematical learning through inquiry and describing how particular professional development experiences contributed to their evolution. Furthermore, by adopting communities of practice as a model of faculty change, the project forgoes attempting to directly impact participants' conceptions of inquiry-oriented mathematics instruction, leaving that to emerge as part of the community's shared priorities. As such, we sought to evaluate participants' conceptions of active learning after having participated in one or more of the MIP initiation workshops. Specifically, we were interested in the extent to which participants' conceptions of active learning aligned with the MIP's definition and what project activities facilitated any changes in these conceptions. We consider the following research questions:

1. What are participants' conceptions of active learning, and to what extent do they align with the MIP's definition of active learning?
2. What aspects of the MIP influenced participants' conceptions of active learning?

We expect our exploration of these research questions to inform how we might operationalize the general mechanisms of individual learning through social engagement articulated by Wenger (1998) to influence the conceptions of active learning held by mathematics faculty at different stages of participation in a statewide professional development project.

Theoretical Framing

The MIP seeks to effect changes in the cultural practices of mathematics instructors by cultivating a community of practice that enables professional growth through individual participation. A community of practice is a social entity in which individuals negotiate meaning through their mutual engagement in a joint enterprise around a shared repertoire of reified artifacts (Wenger, 1998). Each stage of the MIP seeks to engage mathematics faculty in experiences that require their negotiation of meaning around the MIP's three components of inquiry.

The purpose of this research study is to explore how individuals experience their involvement in the MIP community of practice as they negotiate meaning through their engagement with other members and through their interaction with the community's established set of reified artifacts. Through an individual's interactions with other members of the community and its reified artifacts, they become increasingly cognizant of the knowledge base and skillset required to participate competently within the community. A central goal of the MIP is to cultivate a community of mathematics faculty that, through their participation in the community's activities, negotiate a notion of competence reflecting the three components of the MIP's definition of mathematical learning through inquiry. Characterizing participants' initial and developing conceptions of the three components of inquiry is essential to this effort as these characterizations can inform the MIP Team's participation in the community and allow for the strategic introduction of reified artifacts into the community's activities.

Methods

We conducted semi-structured interviews over Zoom with 15 MIP participants in spring 2021. The interviews were audio recorded and transcribed for use in analysis. The interview questions included the following:

1. Please describe your image of active learning in entry-level college math courses.
   a. Why is this important for entry-level math courses?
   b. Can you describe a specific example of active learning in an entry-level math course, yours or someone else's?
   c. What made this example effective? What could have been better?
   d. Has your participation in the MIP activities changed your thinking about active learning? How?
2. Here is the MIP's definition of active learning. [Participants were presented with the definition].
   a. Are there parts of this that you think are important but haven't discussed yet?
   b. Do you particularly agree or disagree with emphasizing any aspect of the MIP definition for improving instruction in entry-level college mathematics?

We employed the constant comparative method (Strauss & Corbin, 1994) to identify themes in the data. One author read all the transcripts, highlighting words and phrases that characterized participants' images of active learning. When a new word or phrase was added to the list, the author reread all previous transcripts seeking instances of that word or phrase. This generated a list of 30 items. The author then grouped similar items into themes and described them using the words/phrases from the list (Table 1), resulting in a list of open codes. The author then re-coded the transcripts using the working descriptions of the codes, and then refined these descriptions until they captured all highlighted words from the first reading. We note that that these codes are not mutually exclusive; for instance, if a participant discussed motivating students with real-world examples, that was coded as both 'real world examples' and 'affective.' Similarly, a participant suggesting enacting active learning with a class discussion was coded both a 'format in which learning would take place' because it described the plan for the lesson, and as 'nature of student engagement' because students would be interacting with other people.

Results

Our analysis suggests that participants' conceptions of active learning focused on three major themes: the class setup, the mathematical content of a lesson, and the affective facets and benefits of active learning.

Table 1. Emergent themes

Theme	Sub-theme(s)	Description
Class setup	Nature of student engagement	Participant describes a way students might be involved, such as answering questions, interacting with other students, a class discussion, exploring, group work, students giving presentations
	Format in which the learning will take place	The participant describes something that could be thought of as lesson planning, like group work, class discussion, guided work, scaffolding information, using manipulatives, using Desmos or a graphing calculator, doing projects
Content	Problem solving	Participant mentions “problems” or “problem solving” without explicitly identifying that it is a novel task
	Problematic situations	Participant mentions engaging students in a productive struggle and/or in situations that are problems (not exercises), or describes students selecting, applying, and evaluating tools or actions
	Understanding	Participant describes that active learning should help students understand or know rather than memorize
	Real-world examples	Participant mentions that active learning should entail real world examples
Affective	n/a	Participant describes active learning in terms of its implications for, or dependence on, students’ interests, motivation, perseverance, mindset, anxiety, etc.

Regarding class setup, all participants mentioned that they associated active learning with particular instructional formats, such as collaborative group work or a class discussion. This demonstrated participants’ attention to ways students might interact with each other or with mathematical tools (e.g., graphing calculator or dynamic visualization software) and the class structure (e.g., scaffolding information instead of lecturing, making a class like a lab or workshop). Jack, who attended one workshop and was on one CoRD, described his class:

> I incorporate a lot of collaborative project learning.... I like to use a lot of manipulatives. I have a limit of how much I want to actually speak to them in a formal setting and having

> them actually do things while I'm there as a mentor is a lot more helpful ... the more I can make my class like a lab, the better I am at really letting active learning [happen].

Most participants provided both examples of active learning that foregrounded the structure of students' mathematical activity and its relation to their conceptual development and an example that foregrounded students' participation without attention to how the activity might support students' construction of particular mathematical meanings. For example, Reagan, who had attended two workshops and was on a CoRD, said in response to interview Question 1b,

> In the college algebra class when we talk about the function rate of change and like a main concept at the beginning.... I designed the pre class activity for students to work on [review] problems.... I also let a student to come up with examples. So I give problems, I give applications and let them come up with what kind of additional related example in the real life they can come up with.... so like in the rate of change when we talk about constant rate, normally we start with talking about the distance and the time.... some of students will come up with... go to the grocery store and you buy the grocery and it to sell by the pound, what is the unit price? That is also a constant rate.

Reagan did not connect her example of students working on review to a specific conception of rate of change that she intends students to construct. We consider this portion of Reagan's statement to be more aligned with a colloquial meaning of active learning because, although she referenced a mathematical topic (rate of change), she did not specifically attend to how the problems in question might elicit actions that reflect the multiplicative structure of a function's constant (if linear) or average rate of change. Instead, Reagan considered the example she proposed to be an instance of active learning because students were working on problems (instead of observing her work on these problems in lecture). On the other hand, she related students production of an example of average rate of change to the underlying structure of corresponding changes in quantities' measures such as changes in "distance and time" and the proportional relationship between a grocery item and its weight and cost. Her attention to aspects of the specific conceptual structure of rate of change in this activity indicates the potential for the students to select actions whose structures are equivalent to the concept to be learned.

All participants acknowledged the affective requirements and affordances of engaging in active learning. Actively engaging in meaningful applications of mathematics both requires and fosters academic success skills (e.g. mathematics self-efficacy, growth mindsets, persistence in problem solving). Adam and Eden's comments are representative of those coded under this theme. Adam had worked on a CoRD, and Eden had attended three workshops and was participating on a CoRD at the time of the interview.

> *Adam*: I think [active learning] is important [because] students who engage with math tend to have better perception of it. ... I think it allows the students to gain a sense of autonomy and, um, confidence in math that they may not be accustomed to.
>
> *Eden*: it's self-efficacy, the whole thing and that goes into the academic success skills, but I mean it's building, especially for students that are going to need to take math past that entry level, it's, you're, you're, you're creating if you like your own machine, you're, you're starting at the entry level and getting them used to this idea. So, as they progress through their math courses, they will be more successful.

Both Adam and Eden discuss the affective benefits of active learning: Adam's response focused on students' developing a sense of autonomy, potentially increasing their mathematical confidence, and Eden's remarks highlight the importance of mathematical persistence.

Affective affordances and requirements of active learning were not part of the MIP's definition of active learning, but do appear in the MIP definition of academic success skills. The MIP three components of inquiry are interdependent, and we agree that active learning can both require particular affective states (e.g., a willingness to engage in productive struggle) and afford particular affective states (e.g., foster increased willingness to engage in productive struggle). The MIP had explicitly stated affective affordances and requirements only in the definition of academic success skills. That participant talked about affective affordances and requirements in active learning indicates negotiating meaning in the community of practice. Specifically, participants seemed to favor a definition of active learning that incorporates the affective affordances and requirements of active learning explicitly.

The participants also reported that various aspects of their engagement in the MIP influenced their conceptions of active learning. Generally, participants cited specific examples of rich tasks, conversations with other participants, small group discussions of research literature, and conversations with project team members. For example, Ellison, who attended one workshop and was on a CoRD, felt the problem-solving literature she read for her CoRD had influenced her thinking that an important part of active learning was not to give the answer too soon. Gemma, who attended one workshop, said

> I really liked those types of problems that we did as samples... something that gets you to think outside of the box on math and not have to be like... sitting there doing x's and y's and whatever. Thinking about real life and how can I connect this and then you know problem solving

The sample problem Gemma referred to were generated by the MIP team. The goal of the problems was to model a conceptual analysis, hypothetical learning trajectory, and how those informed the design of tasks that operationalize the three MIP components of mathematical inquiry. We take Gemma's statement about the problems making students to "think outside of the box" and "problem solving" as possibly indicative that she attended to the tasks as problematic situations.

Discussion

We developed the MIP definition of active learning to foreground the implications of the nature of students' activity for their construction of particular mathematical meanings and to serve as a guide for the project design of engaging faculty in a community of practice. While we expect to see some change of participant's goals, values, and beliefs that might make aspects of the MIP definition more meaningful to them, we equally expect the community to develop its own priorities and standards. We present our characterization of participants' goals, values, and beliefs about active learning to inform subsequent project activities in ways that will better support participants to (a) understand the nature of their conceptual learning goals; (b) act in ways that foster those goals in their instruction; and (c) reinforce the development of the community of practice toward similar sensitivities.

While participants universally described general formats in which students might be participate in class (e.g., group work, class discussions, and projects), they often did not attend to the nature of students' engagement with carefully designed mathematical tasks that deliberately support abstraction of underlying mathematical structure. We note that many of these perceptions were internally consistent, based on individualized implicit learning theories and prior experience, and thus highly stable. However, it is important to the PD project to know that participants' definitions of active learning did not explicitly attend to students' selecting, performing, and evaluating specific mental actions, because we view the ‘active’ in ‘active learning’ as *mental activity*, and hence propose that focusing on the nature of the mathematical tasks (as opposed to whether they will be done in groups, or in back-and-forth question-and-answers between the class and instructor) is critical in effective instruction. In short, there is some misalignment with participants’ definitions and the MIPs in regard to how each views what ‘active’ means in active learning.

The organic evolution of a normative conception of competence within a community of practice—which reflects the current and developing conceptions of those participating in it—restricts the range of possible interventions that seek to influence how participants conceptualize both the practice in which they engage and the nature of competence this engagement requires. Participation in the community is the mechanism of individual identity transformation (i.e., learning), and is directed towards the normative conception of competence implicitly negotiated by the community through its pursuit of a joint enterprise. A principal affordance of becoming aware of one’s own conceptions of learning is that it positions an instructor to *purposefully* develop and implement instructional sequences that are consistent with it (Tallman, 2021). We view a central priority for the project to be fostering the community of practice to (a) make these goals, values, and beliefs explicit; (b) create the intellectual need for critical reflection on them; and (c) provide opportunities to develop, implement, evaluate, and refine new strategies based on the MIP characterization of inquiry. Based on our analysis, we recommend the following forms of interventions that might support the refinement of participants’ conceptions of active learning through their engagement in the MIP community of practice:

- *opportunities to engage in instructional design with community-recognized experts to foster the MIP components of inquiry*
- *opportunities to critically evaluate curricular artifacts that reflect explicit operationalization of the MIP components of inquiry*
- *feedback from peers that suggest concrete ways to modify their proposed instructional materials to support more effective implementation of the MIP components of inquiry*
- *guided reflection on results of pilot lessons and refinement to improve implementation of the MIP components of inquiry*

Future research

One direction for our future research is to include additional data sources. For example, recordings of participants teaching or artifacts from their class materials could lend additional insight into participants’ conceptions of active learning and the extent to which they align with the MIP’s definition. An analysis of such data would provide more robust findings by allowing us to describe how participants enact their conceptions of active learning.

This research report focuses on documenting the conceptions of and relationships between three interrelated components of mathematical learning through inquiry (active learning, meaningful applications, and academic success skills) demonstrated by an experienced mathematician throughout a series of semi-structured clinical interviews concurrent with the participant's engagement in a large-scale professional development initiative. Our analysis revealed that the participant demonstrated stable and coherent conceptions of the three components of mathematical learning through inquiry that were generally resistant to intervention. We reflect on the implications of our analysis for influencing the conceptions of inquiry-oriented instruction held by undergraduate mathematics faculty.

Keywords: Active Learning, Mathematical Inquiry, Professional Development, Teacher Knowledge, Case Study

Introduction

Researchers, professional organizations, and policymakers have emphasized a need for instructors to attend to meaningful student engagement in mathematics classes (CBMS, 2016; Freeman et al., 2014; Kober, 2015; NRC, 2012; NSTC, CSE, 2013; PCAST, 2012; Saxe & Braddy, 2015). Instruction with higher levels of student interaction enhances problem-solving skills (Prince 2004), demonstrates greater conceptual gains (Freeman et al., 2014; Hake, 1998; Svinicki, 2011), and improves retention of information (Dirks, 2011; Prince, 2004; Sokoloff & Thornton, 1997). Although a preponderance of evidence indicates the benefits of active learning, many mathematics instructors struggle to effectively engage students in active learning experiences. Active learning strategies realize their potential when an instructor operates with an explicit understanding of *how* the actions in which students engage might engender the cognitive mechanisms necessary to construct productive meanings for targeted mathematical ideas (Tallman, 2021). Unfortunately, undergraduate mathematics instructors are rarely afforded the opportunity to construct this essential component of pedagogical content knowledge.

Perceptions that mathematics lacks relevance to one's interests and goals is a common deterrent to engaging in active learning. Students with this perspective tend not to appreciate the broader skills they can acquire by studying mathematics. Modeling real-world problems with mathematical tools can provide students with greater opportunities to understand course content and its relevance (Frykholm & Glasson, 2005; Jacobs, 1989; Koirala & Bowman, 2003; Pyke & Lynch, 2005). However, due to a need to cover a broad range of topics, the techniques in entry-level undergraduate mathematics courses are rarely taught in the context of real-world situations. Additionally, even when applied contexts are incorporated into instruction, students often struggle to notice similarities in mathematical structure that would allow them to apply content learned in other contexts (Gick & Holyoak, 1983; Lobato & Siebert, 2002). These observations establish a need for instructors to incorporate relevant applications into mathematics courses for the purpose of both promoting students' positive affect and engaging them in active learning.

Students' conceptions about the origin of mathematical intelligence and the skillset they attribute to being proficient at mathematics have additional implications for their capacity to engage in active learning. Fortunately, students' mindsets are not immutable psychological traits, and specific supports can enable them to reconceptualize what it means to become proficient at mathematics (Middleton, Tallman, Hatfield, & Davis, 2015). Tallman and Uscanga (2020) specified the types of support instructors might provide to foster the positive affect necessary for students to meaningfully engage in active learning. These scholars also cautioned against the ineffectiveness of common efforts to foster students' productive affective engagement in mathematics by reducing these efforts to a list of pedagogical prescriptions without consideration for the mathematical conceptions they are supposed to support.

Taken together, the literature summarized above demonstrates that designing instruction to effectively engage students in active learning is a complicated task for which undergraduate mathematics instructors often receive insufficient preparation, and are thus generally underprepared. To address this need, we designed the Mathematical Inquiry Project (MIP) to support mathematics faculty at all 27 public institutions of higher education in Oklahoma to engage students in learning through inquiry in entry-level mathematics courses. More broadly, the MIP complements principles of organizational change with social learning theory to foster effective, scalable, and sustainable cultural shifts in mathematical learning through inquiry defined in terms of *active learning*, *meaningful applications*, and *academic success skills*.

This research report focuses on documenting one MIP participant's conception of these three interrelated components of mathematical learning through inquiry. In particular, we explored the following research questions: (1) *What conceptions of the three elements of mathematical inquiry and their mutual influence are held by an MIP participant?* (2) *To what extent do these conceptions align with the definitions proposed by the MIP?*

Theoretical Background

Active Learning

At the level of student engagement, the MIP synthesizes constructivist, neo-constructivist, and social-constructivist perspectives, in which conceptual structure is consistently characterized as abstracted from reflection on the structure of one's *actions* to resolve a problem (diSessa, 1982; Gravemeijer, Cobb, Bowers, & Whitenack, 2000; Hickman, 1990; von Glasersfeld, 1995; Piaget, 1970, 1980). The MIP operationalizes this perspective through emphasizing processes that focus students' attention to the nature of a problem, selection of appropriate mathematical tools, application of those tools, and attention to the reciprocal influences of the tool both applied to, and evaluated against, the problem. The MIP definition of active learning is:

> *Students engage in active learning when they work to resolve a problematic situation whose resolution requires them to select, perform, and evaluate actions whose structures are equivalent to the structures of the concepts to be learned.*

Designing this level of student engagement first requires an instructor to become cognizant of the targeted concept's conceptual structure (Tallman & Frank, 2020), and then to purposefully inquire into students' mathematical thinking by listening, interpreting, and respond to the interplay between intuitive and informal ways of reasoning students express.

Meaningful Applications

The MIP leverages educational theory and empirical research that offers insight into how relevant applications might effectively support active learning. One of the most immediate features of our emphasis on applications is that mathematical representations refer to real-world objects and quantities that can be described and imagined to support intuitive reasoning, which is often not elicited when students only encounter abstract representations. This concrete reasoning enables students to engage in mental constructions that can subsequently be represented abstractly by variables, expressions, diagrams, and graphs. The MIP definition of meaningful incorporation of applications is:

> *Applications are meaningfully incorporated in a mathematics class to the extent that they support students in identifying mathematical relationships, making and justifying claims, and generalizing across contexts to extract common mathematical structure.*

Ultimately, for applications to be used effectively, they must foster students' engagement in the mental activity on which they will later reflect to construct targeted understandings of particular mathematical concepts. Additionally, the phrase "generalizing across contexts" should be interpreted within the domain of mathematics and not across other academic disciplines.

Academic Success Skills

Students' active learning is initiated and sustained by components of their affect. The MIP leverages research about growth versus fixed mindsets, the nature of memory and expertise, the integration of academic and social communities, academic identity, stereotype threat, and study skills to equip instructors with the tools to support students active learning of mathematics. We express this amalgam of affective qualities, dispositions, and states as *academic success skills*, which the MIP defines as follows:

> *Academic success skills foster students' construction of their identities as learners in ways that enable productive engagement in their education and the associated academic community.*

Methods

The lead author conducted 11 semi-structured clinical interviews (Clement, 2000; Hunting, 1997) with an experienced professor of mathematics (Robert) from a small, liberal arts university in the Southern United States. The focus of these clinical interviews was to elicit products of Robert's conception of the three components of mathematical inquiry defined by the MIP and to explore their relation to Robert's values, beliefs, and commitments, and instructional goals.

Our data analysis was guided by grounded theory procedures (Corbin & Strauss, 1990; Strauss & Corbin, 2007). The lead author first identified segments of interviews during which Roberts' remarks captured the essence of his conception of one of the three components of mathematical inquiry, or the relationships between them. This initial analysis enabled us to become sensitive to not only *what* Robert said but also *how* he expressed it. From these segments of data, the lead author abstracted Robert's expressed ideas into larger codes and categories (an application of axial coding) and later combined and related these codes and categories into more general clusters, often through several iterations, resulting in a stable set of final themes.

Results

Active Learning

Robert participated in four interviews during which he responded to a series of questions specifically related to active learning (Interviews 1, 2, 6, and 10). During the first interview, Robert described active learning as synonymous with genuine mathematical engagement, which occurs when students solve non-routine problems for which they cannot uncritically apply a rehearsed procedure. At the beginning of the second interview, Robert proposed the following definition of active learning:

> *Students are engaging in active learning when they are asked to engage with a problem themselves (as opposed to passively observing an instructor solve the problem).*

As this definition suggests, Robert's conception of active learning foregrounds the idea of student *engagement*. This definition does not explicitly address the relationship between the mental actions in which students engage and the cognitive structures they might be expected to construct for the targeted concept of a lesson. Towards the end of Interview 2, Robert requested to revise his original definition. His only modification was to replace the word "engage" with "struggle and wrestle." This modification, as well as Robert's comments throughout Interview 2, revealed his perspective that an essential feature of active learning is that it entails students making strategic decisions in the service of overcoming some sort of struggle. Robert considered such strategic and impasse-driven decision-making to be an essential feature of genuine mathematical activity, and thus active learning.

Robert's emphasis on decision-making as a feature of active learning was apparent during a discussion of what might distinguish a student who is engaged in active learning from one who is not. Addressing this question, Robert explained that students "have to be asked to think critically about the problem. They have to make some decisions. They have to make some determinations. So, decision making would be- for me would be the, the, the line." These decisions, Robert clarified, need to be "strong" decisions, and he provided an example from calculus of students struggling to determine whether to apply the method of *u*-substitution instead of integration-by-parts. A few minutes later, Robert concluded: "As long as they're actively, they're, they're trying hard, they're struggling with it, if there's maybe, maybe the defining line should be there has to be a, a level of struggle with a problem." This comment reinforces the claim that Robert considered students' experiencing struggle to be the essential criterion of active learning. There was no evidence in Robert's responses to suggest that he conceived students' struggle as a precondition for engaging in the cognitive activity necessary to construct specific *meanings* for targeted concepts. Generally, Robert gave no indication throughout the series of interviews that his conception of active learning related to an instructor's goals for students' mathematical learning. Instead, Robert's characterizations of the features and requirements of active learning were dominated by his expectation that students' activity should reflect a mathematician's experiences while engaged with a challenging problem. Indeed, Robert's introspection on his own mathematical activity consistently appeared to be the source of the various features of active learning he proposed.

Meaningful Applications

The lead author conducted four interviews with Robert during which he responded to questions specifically related to meaningful applications (Interviews 1, 3, 7, and 9). Robert proposed the following definition of meaningful applications at the beginning of Interview 3:

Applications are meaningfully incorporated in a mathematics class when problems are presented that piques student interest and highlights a key concept (or some key concepts) of the lesson.

There are two fundamental components of Robert's definition: stimulating student interest and highlighting a key concept of the lesson.

When Robert was asked to interpret the MIP definition for meaningful applications in Interview 1, he recognized that this definition was useful for instructors, but "from a student view, meaningful application would be something that, just a problem that they're, that engages them, intrigues them, has to be some kind, spark some kind of interest." One way that a problem might intrigue students is if it relates to them personally or is an applied, real-world problem that enables students to appreciate the applicability of the mathematics they are learning. When asked about his interpretation of the word "meaningful" in the third interview, Robert stated that meaningful is something that "interests me" and has a "hook" to promote interest.

Robert's interpretation of the word meaningful arose from a student perspective (e.g., piques students' interest) as well as an instructor's perspective (highlights a key concept). Robert stated that another interpretation for the word "highlights" is demonstrates: "Demonstrates is (*pause*), it brings to (*pause*), it shows the, shows the usefulness of these concepts. It demonstrates why, why we're doing what we're doing." Robert offered an illustration for how an instructor might highlight or demonstrate the usefulness of a concept:

> If I can come with an application, a problem that forces you, really encourages you to use one over the other, that's a meaningful application, right. If I, if I try to teach you a shell method, right, usually a shell after the washer method, right, but if I give you a problem where I, where students can just as, just as easily solve it using the washer method, then what's the point, right?

Robert echoed a similar sentiment later in the interview, stating that if he were teaching the shell method he would "steer away" from problems that can be solved equally easy using either the shell method or the washer method (unless he wanted to highlight that sometimes either approach is appropriate).

Academic Success Skills

The lead author conducted three interviews with Robert during which he responded to questions specifically related to academic success skills (Interviews 1, 4, and 8). At the beginning of Interview 4, Robert constructed his definition:

Academic Success Skills are behaviors/actions that help people/students succeed academically (i.e., in their studies/research). Examples include: detailed note taking, a sense of curiosity, the grit/determination to tackle/solve a problem—from several approaches if necessary, and to think critically.

Robert's conception of academic success skills centered around thinking critically and exercising grit and tenacity to persist in satisfying curiosity. According to Robert, *thinking critically* entails making "deliberate decisions" and operating *intentionally* when solving problems as opposed to using a particular technique because peers used it, the book encouraged it, or it proved useful in another context. Critical thinking is a key facet of the academic success skills Robert values most:

> For me, the most important academic success skill is being engaged, and being, uh, curious, and being, and just really getting, getting down and really exploring the concept,

> right, having the grit, uh, and tenacity to, to, work on the problem. I, that to me, that, for me, hands down, that's the most important.

Robert's latter statement offers insight into how he might develop tasks to support students' academic success skills. He expects that the affective qualities he values in students can be reinforced by engaging them in tasks that elicit productive struggle, and encouraging them to reflect on their attempts to solve the problem.

While students may be able to enhance their determination from engaging in tasks that facilitate productive struggle, the interviewer asked Robert if the ways in which an instructor teaches a *specific mathematical topic* can promote students' curiosity, tenacity, or grit. Robert's response emphasized how instructors' actions can be *problematic* for promoting these affective characteristics, stating that making math "mechanical" makes it become artificial and tedious.

Throughout the series of interviews, Robert frequently described active learning as dependent upon students' curiosity and tenacity. The interview data consistently indicated that Robert's conception of active learning was closely connected to his image of mathematical problem solving and the curiosity and tenacity that initiates and sustains it. Robert reasoned that curiosity and tenacity are essential to active learning since the former is both the origin of genuine mathematical problems and the affective state that compels a student to want to solve a problem. Additionally, Robert expressed that tenacity is required to persevere through the struggle inevitably encountered when reasoning about a novel problem. He explained that curiosity and tenacity is "what made me successful in my schooling," again revealing Robert's reflection on his mathematical activity to infer essential features of active learning and their relation to students' affect.

Robert clarified his image of the relationship between active learning and students' academic success skills during Interview 2:

> My style of teaching is for students to struggle with a problem, understand why that problem is hard and why that problem is interesting, then I will come back around and show them a way that is easier. Then they can learn to appreciate the new knowledge that I am trying to teach them.

This excerpt suggests that Robert considered active learning in terms of students' engagement in the precise activity that results in their experiencing an intellectual need for the mathematical content that he will eventually present to them. Robert's comments indicate that he valued this type of activity because it can ultimately position students to more intently and purposefully absorb the mathematical meanings, skills, and strategies he communicates. That is, active learning makes students more receptive to *perceiving* the mathematics that Robert conveys and/or demonstrates. This conception of the relationship between active learning and students' affect stands in contrast to the MIP definition of active learning, which views students' activity as the experiential basis of their knowledge construction through abstraction. The excerpt above reveals Robert's expectation that the insight, method, or strategy required to solve a problem should ultimately be provided by the instructor, rather than constructed by the students through their mathematical activity.

Summarizing Robert's conception of the relationship between meaningful applications and active learning, he described meaningful applications as providing contexts that can stimulate students' curiosity and then require them to be tenacious and perseverant to solve a contextual problem. There was no evidence in Robert's remarks to suggest that he interpreted "meaningful" as a reference to the meanings an instructor expects their students to construct.

Discussion and Implications

Robert' conception of active learning centered around student engagement in thinking critically, making decisions, and wrestling with problems. According to Robert, active learning can occur in many forms, and the distinction between students who are engaged in active learning and those who are not depends on students making decisions and struggling to solve non-routine problems. A primary feature of Robert's conception of meaningful applications includes a context that *cultivates students' interest*. Robert also explained that a meaningful application should also *highlight the key concept* of the lesson, which could involve demonstrating the usefulness of a particular technique (e.g., disc vs. shell method in calculus). Robert's conception of academic success skills focused on students acting on their curiosity with grit, determination, tenacity, and critical thinking skills to solve a novel problem.

While Robert claimed that his conceptions of the three components of inquiry had been influenced through his involvement in MIP activities, his comments throughout the series of clinical interviews demonstrated that he underemphasized and perhaps undervalued the importance of designing tasks that promote students' construction of particular mathematical meanings. Additionally, Robert's remarks revealed his inattention to the nature and development of students' conceptions.

A fundamental distinction between Robert's conception of active learning compared to the MIP definition is that Robert considered struggle, effort, and strategic decision-making as sufficient criteria for engaging in active learning, independent of the *meanings* he expected students to construct. Similarly, Robert conceptualized the incorporation of meaningful applications as having primary implications for students' affective engagement, specifically motivation and interest. In his own practice, Robert explained that he motivates students by providing *interesting* contexts or by demonstrating the *usefulness* of a particular problem-solving approach.

Notably, Robert's comments throughout the series of interviews highlight a fundamental epistemological distinction: that he underemphasized, devalued, or was inattentive to the instructor's role in designing tasks informed by conducting a *conceptual analysis* (Thompson, 2008) for the purpose of enabling students to progress through a *hypothetical learning trajectory* (Simon & Tzur, 2004). While promoting students' affective qualities is important, particularly related to academic success skills, the MIP definition is centered around supporting students' construction of operative mathematical schemes by identifying and clarifying the nature of the mental actions and conceptual operations required to construct an understanding of a mathematical idea in a particular way.

Importantly, this discussion is neither intended to diminish nor devalue features of Robert's instructional design or pedagogical practices, nor to criticize his interpretation of three elements of inquiry proposed by the MIP. Rather, we offer these distinctions to highlight the potential for Robert's conceptions to be extended and refined to include attention to epistemological considerations of students' mathematical learning. Our results suggest that intensive measures are required to disrupt and modify Robert's established, stable, and coherent conceptions of the three components of mathematical inquiry.

Undergraduate Math and Science Instructor's Attitudes, Beliefs, and Views on Diversity, Inclusion, and Equity

Estrella Johnson

Charles Henderson
Western Michigan University

Melissa Dancy
Western Michigan University

Alexandra Lau
American Physical Society

In Fall 2020 we collected 1,064 responses to a survey asking instructors of first-year math and science courses questions about their attitudes, beliefs, and views of diversity, inclusion, and equity. Here we provide descriptive analyses on three aspects of the survey: items aimed at instructors' views of certain factors that might contribute to disproportionate representation of different race-gender groups in STEM; items that asked participants about their views on strategies for addressing race-gender disparities in STEM; and items about respondent's personal experiences with discriminatory behavior. About two-thirds of respondents recognize that systematic advantages are afforded to white men in STEM and an overwhelming majority agree that they have a personal responsibility to address inequities. However, we also found stronger support among participants for passive actions than more active ones and a sizable proportion of these instructors also believe that different race-gender groups have different interest levels in science and mathematics.

Keywords: postsecondary STEM, instructor beliefs, DEI attitudes

It is well known that the demographic landscape of science, technology, engineering, and mathematics (STEM) professionals in the USA does not reflect that of the population. This inequity is the product of individual actions as well as systemic barriers. The road to a STEM degree starts in first-year mathematics, chemistry, and physics courses. These courses frequently serve to "weed out" potential STEM majors and disproportionately affects students from marginalized populations (Seymour & Hewitt, 1997; Seymour & Hunter, 2019). Black and Latinx students who begin in STEM are most likely to switch majors or leave college altogether, a phenomenon not seen in other majors (Riegle-Crumb et al., 2019); Black women, among all women entering STEM majors, are the most likely to choose physics, engineering, math, and computer science fields, yet attrition rates are also the highest among Black women (Ma & Liu, 2017). These disparate attrition rates are not due to innate characteristics of the students, but rather to features of the societal, institutional, and classroom environments they must navigate.

The lack of diversity, equity, and inclusion (DEI) in STEM is a function of systemic issues, which require systemic change to address. Individual actions by members of the system are required to make these changes. Postsecondary STEM instructors have access to several levels of higher education and disciplinary systems, including: hiring and promotion, research, mentoring, campus and society DEI initiatives, and, of course, teaching. Their beliefs and attitudes in relation to DEI issues and initiatives shape their ability and willingness to agitate for change. It is difficult to create effective change towards DEI without understanding these beliefs and attitudes. To that end, we administered a survey in Fall 2020 and received 1,064 responses describing respondents' professional identity and context, assumptions about the experiences of eight race-gender groups in STEM, their beliefs about (and engagement with) efforts to increase diversity in their fields, and their departmental and personal experiences with discrimination.

Guiding Theories & Relevant Literature

In line with our personal beliefs and the tenets of critical theories, we hold that STEM is not a neutral field with respect to personal identities or circumstance; higher education trades on a myth of meritocracy in which access and success are controlled by greater social structural inequalities that are reflected in postsecondary institutions (Liu, 2011). Thus, our goals of improving postsecondary STEM education to better engage, support, and serve students must include efforts to remove barriers to access *and* to shift the wider culture toward equity and inclusion. Institutional culture determines the implementation and enactment of policies, and so we must consider various stakeholders in these institutions and their potential role in upholding or dismantling the status quo (Reinholz & Apkarian, 2018; Schein, 2010). Instructors are key members of the STEM higher education ecosystem, as they exist at the intersection of their institution, department, discipline, and classrooms; they are broadly the most important actors in the creation, evolution, and enforcement of “the culture” (Kezar, 2014; Reinholz & Apkarian, 2018). Shifting culture (practices, policies, and attitudes) toward a more desirable state requires documenting the current state and identifying appropriate levers and fulcra for various types of change (Henderson & White, 2019). It is in this avenue which our work is relevant – we have documented instructor beliefs about DEI issues and initiatives in STEM (and postsecondary STEM education), and are engaged in an ongoing analysis of how opinions may have shifted during the year 2020, which saw interruptions from the COVID-19 pandemic as well as highly publicized demonstrations for racial justice.

An intersectional lens is critical when considering issues related to DEI. For example, Asian people are overrepresented and women are underrepresented in STEM compared to the US population, which obscures the situation of Asian women (Castro & Collins, 2021). While Asian men are well-represented in academic STEM environments, they face discrimination and stigma (Shah, 2019). Studies of women students’ interactions in STEM courses reveal stark differences in white and non-white women’s perceptions of belonging and instructor care, as well as decisions to continue in STEM (Rainey et al., 2018, 2019). Elementary and high school students of Mexican descent are often tracked toward vocations, as opposed to college, and are pushed out of the educational pipeline at high rates which vary by gender, citizenship status, and family income (Covarrubias, 2011). It is clear that many people experience barriers in STEM education and careers based on their gender and race. These barriers must be addressed as a matter of moral justice, and to fill the “missing millions” who are needed in the science and engineering workforce (National Science Board, 2020).

Data and Methods

The data collected for this paper consists of survey responses from a national sample of postsecondary STEM instructors who had already participated in a larger survey related to STEM instructional practices. The larger survey targeted postsecondary instructors teaching introductory STEM courses at two-year colleges, four-year colleges, and universities in the United States. Data collection for that project was conducted in Spring 2019, and the final sample consisted of 3,769 respondents who were primary instructors of a general chemistry, single-variable calculus, or introductory quantitative physics course in the 2017-18 or 2018-19 academic year. At the end of the initial survey, participants were asked if we could contact them for a follow-up survey focused on diversity, equity, and inclusion in STEM. Of the 3,769 who completed the primary survey, 2,229 indicated a willingness to be contacted for this follow-up. In Fall 2020, all 2,229 were sent invitations for this follow-up, and we received 1,064 usable responses. Of these 1,064 participants, 387 taught first-year (General) Chemistry, 305 taught first-year Mathematics (Calculus), and 372 taught first-year Physics.

Here we focus on three aspects of the DEI survey: items aimed at instructors' views of certain factors that might contribute to disproportionate representation of different race-gender groups in STEM, which provide insights into how faculty might explain the relative over- and under-representation of different identity groups; items that asked participants about their views on strategies for addressing race-gender disparities in STEM, such as affirmative action style hiring policies and diversity statements; and items about respondent's personal experiences with discriminatory behavior. Here we provide descriptive analysis of the survey responses.

This sample is not random and is not representative. However, we have enough information to conjecture about the direction in which this bias might skew our results. First, self-selection bias was introduced through the voluntary nature of participation. Our sample includes people willing to participate in education research, and who were willing to receive a survey about diversity, equity, and inclusion issues in STEM, and who then completed that survey. This suggests that our participants are more likely to be aware of, and possibly supportive of, ongoing DEI work in STEM than a truly random sample of STEM faculty. This group may, through their increased awareness, be even more susceptible to social desirability bias. This second form of bias refers to a tendency for survey-takers to provide answers which they think will be viewed positively by others. Broadly speaking, this means that our results likely portray STEM instructors as more aware of DEI issues and engaged with DEI initiatives than the true population.

Results

Perceptions of Reasons for Disparities

Four survey questions captured instructors' views of certain factors that might contribute to disproportionate representation of different race-gender groups in STEM, suggesting how faculty might explain the relative over- and under-representation of different identity groups. The first, and broadest, of these asked whether STEM culture affords an overall advantage or disadvantage to members of eight race-gender groups. Responses to this item are displayed in Figure 1.

White men were the only group that a majority of respondents identified as having a systematic advantage in STEM; Black women, Hispanic/Latinx women, Black men, and Hispanic/Latinx men were perceived by the majority of respondents as having an overall disadvantage in STEM; the majority of respondents perceive that Asian men, White women, and Asian women have neither an advantage or disadvantage. These perceptions have some relation to the actual representation of these race-gender groups in STEM: white men receive the largest share of chemistry and physical science BA/BS degrees, PhD's, and faculty positions; Asian men are the most over-represented compared to their share of the US population at all levels of STEM; Black and Hispanic/Latinx men and women *combined* make up less than 10% of STEM faculty while accounting for 30% of the US population. We note that these responses suggest that participants view Black and Hispanic/Latinx men and women's disadvantagement similarly, but distinguish between men and women among white and Asian groups; this reflects the broader understanding of how racism and sexism intersect in STEM (Castro & Collins, 2021).

The next questions were prefaced with the statement that "more than half of the PhDs awarded in 2017 in mathematics and the physical sciences were received by white men." Again, we asked participants to consider three possible factors contributing to disparities in representation (aptitude, interest, and opportunities) for different race-gender groups; this time the question specifically asked about phenomena *relative* to the dominant group. Participants' responses are summarized in Figure 2.

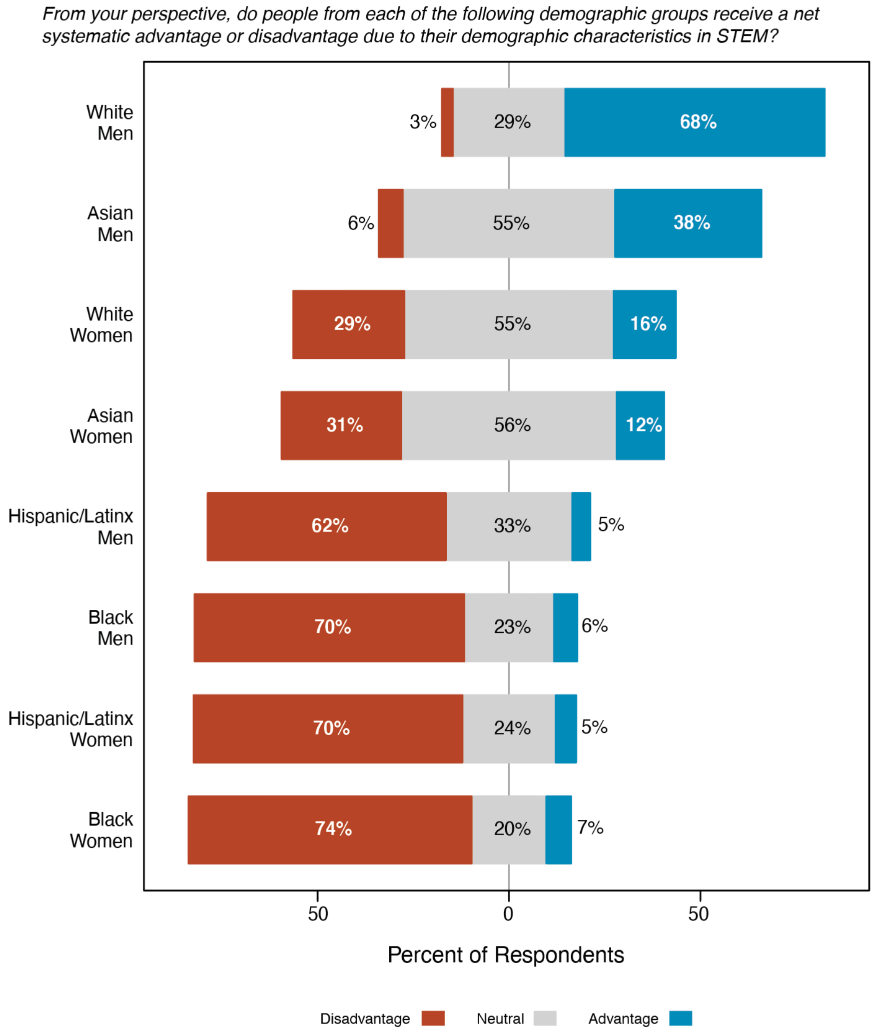

Fig 1. Percentage of respondents reporting that each race-gender group receives a net disadvantage (red, left), neutral (gray, center), or net advantage (blue, right). N=1015

Historically, claims of differential aptitude for mathematics, science, and learning have been used to defend discriminatory policies including segregation and eugenics (Tucker, 2007). These claims have, of course, been refuted, and over 90% of our respondents indicated that members of each race-gender group have equal aptitude for science and mathematics as compared to white men. The other 6-8%, however, are not distributed evenly across groups. The higher ratings of Asian men and women's aptitude for STEM conforms to damaging stereotypes (Shah, 2019; Trytten et al., 2012); the lower ratings for Black and Hispanic/Latinx men and women conform to unfounded racist and sexist tropes. The presence of these beliefs, even among a few, may hamper efforts to diversify our fields; self-selection and social desirability bias likely mean that there are more in the general instructor population who think aptitude is inherently related to race and/or gender than our respondents reported on this survey.

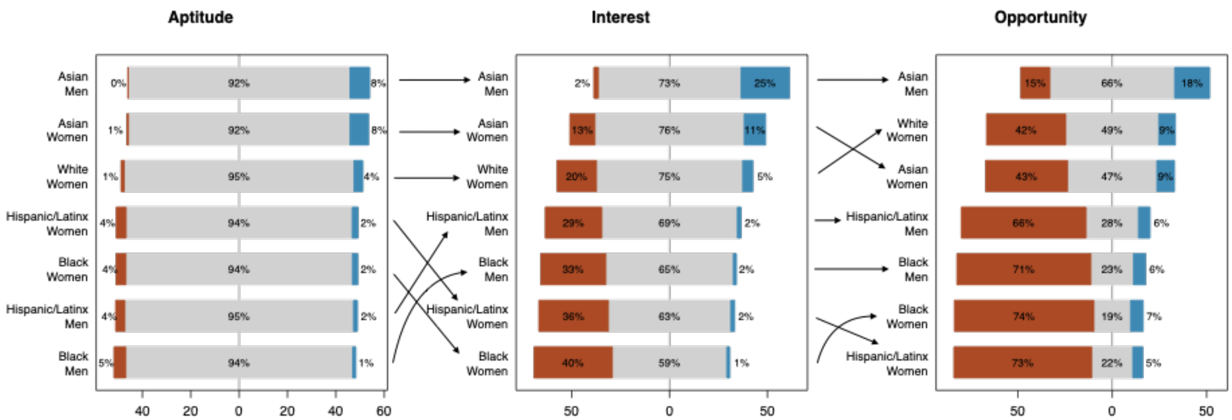

Figure 2. Percent of respondents reporting that, as compared to white men, each race-gender group have less (red/left), equal (gray/center), or more (blue/right) (A) aptitude for; (B) interest in; (C) opportunities to do [your field]. Groups are ordered based on survey responses; arrows indicate changes in group order from one graph to the next. N=1015.

Interest in the field is another justification for unequal representation in STEM (Estrada et al., 2016). We see evidence that many STEM faculty believe that interest in science and mathematics varies across race-gender groups. Many instructors (40%) of introductory courses believe that Black women have less interest in their STEM field than white men. Regardless of where this belief comes from, it is indicative of a significant bias that may play out in a variety of ways that impact students. For example, who is more likely to be seen as a "good fit" for a lab opportunity; who receives what kind of mentoring. Believing that certain types of students are "simply not interested" in STEM shifts the locus of responsibility onto the students, and away from inequitable practices and policies.

Conversations about diversity and equity often also include the topics of access, or opportunities to experience and participate. A large majority (66-74%) of first-year instructors report a perception that Black and Latinx women and Black and Latinx men have less opportunity than White men; just over 40% report the same for Asian and White women. A substantial majority (66%) report that Asian men have equal opportunity as compared to White men. This apparent recognition of systemic disparities in opportunity is heartening as it relates to unpacking the myths of meritocracy which pervade higher education (Liu, 2011). However, additional investigation is needed to understand how this impacts instructors' interactions with their students and their willingness to support or engage with initiatives aimed at redressing disparities. It may contribute to perceptions that individuals from underrepresented groups are less prepared to succeed; or that outreach to certain populations is a priority; or that fault lies with pre-college experiences; or that affirmative action-style policies should be implemented.

Mechanisms for Addressing Disparities

With a general consensus that some race-gender groups are systemically (dis)advantaged, and that opportunities and interest - but not aptitude - are unevenly distributed, we asked participants about strategies for addressing race-gender disparities in STEM. A heartening 86% report efforts to diversify STEM are beneficial for their field (12% had no opinion; 2% said such efforts are detrimental); this is likely inflated by self-selection and social desirability biases. When asked about specific types of initiatives (Figure 3), we find a similarly high proportion of instructors support "diversity, equity, and inclusion statements" by their professional societies, institutions, and departments; a smaller majority support affirmative action-style policies for faculty hiring and student admissions. These results are a positive indicator of support for efforts to diversify the field, but the lower levels of support for more direct actions need further investigation. DEI statements are passive acts, which may not have a direct impact on instructors or DEI; policies related to student admissions and hiring are more active and have direct impacts on the communities. The latter has also been shown to have a concrete and lasting impact on diversity (Bowen & Bok, 1998; Murrell & Jones, 1996), though equity and inclusion do not automatically follow from presence. Understanding what impacts instructors' support, or hesitancy, will contribute to building STEM faculty buy-in for evidence-based strategies for change.

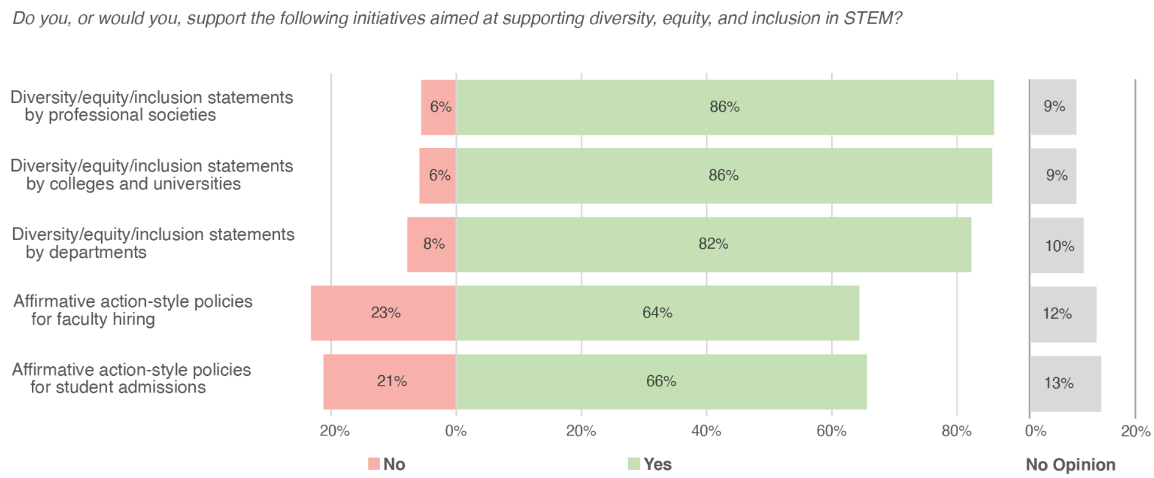

Figure 3. Percentage of respondents indicating that they do not support (red, left), do (or would) support (green, center), or have no opinion (gray, far right) five existing models of DEI initiatives. N=1055, 1054, 1058, 1058, 1057

Personal Experiences with Discriminatory Behaviors

Lastly, our survey asked respondents about their personal experiences with discriminatory behavior. In general, the majority of our respondents reported that they believe their own departments are pretty welcoming, with nearly 70% reporting that they believe their department is either "very welcoming" or "welcoming" to people of different identities, and only about 6% reporting that they believe their department is "hostile" or "very hostile" (with the remaining respondents reporting "neither hostile nor welcoming").

However, a significant proportion of respondents also reported witnessing discriminatory behaviors in a professional setting in their field in the last 3 years: 53% of chemists, 39% of mathematicians, and 45% of physicists. Of those who reported witnessing such behaviors, 66% of chemists, 68% of mathematicians, and 72% of physicists reported intervening and/or speaking up, in the moment or after the fact. Taken together, nearly half of the respondents recently witnessed discriminatory behaviors in a professional setting and, of those, about a third abstained from intervening. We anticipate that responses to this question are particularly likely to be impacted by social desirability bias, suggesting that the true number of people in this sample who have intervened or spoken up about discrimination they have witnessed is lower than reported; self-selection bias suggests that recognizing and responding to discrimination is likely less frequent among the general population. We also note that intervening or speaking up about discrimination carries different risks for different people, so that refraining from speaking out may in some cases be an act of self-preservation.

The question about discriminatory behavior “in a professional setting” could refer to contexts outside a participant’s own departmental context (e.g., research conference), but raises questions about what threshold these instructors might use to consider their department “hostile.” Nearly half of our participants report witnessing discriminatory behavior, and yet 94% report that their department is not hostile toward people of different identities. Perhaps the presence of individuals who commit discriminatory acts is not considered sufficient to categorize the department as a whole as hostile; alternatively, these behaviors are only occurring (or being perceived as occurring) outside their home department.

Conclusion

Undoing systems of marginalization (e.g., racism, sexism, ableism, elitism) requires systemic change through cultural transformation. In the distributed systems of STEM higher education, change can come about best when a critical mass of constituents recognizes existing inequities, believe change is necessary, and act in concert to change systemic structures. Our results provide room for cautious optimism about the potential for future progress. There are at least 688 instructors in American postsecondary institutions who recognize that systematic advantages are afforded to white men in STEM. Furthermore, an overwhelming majority of our respondents (92% of chemists; 89.7% of mathematicians; 90.8% of physicists) agree that they have a personal responsibility to address inequities. While these 1064 survey respondents represent a small fraction of the profession, and may be unrepresentative of the professoriate as a whole, this is still a significant number of first-year math and science instructors who indicate a personal responsibility to address inequity. While we see this number as cause to be hopeful, many questions remain that need to be investigated as new DEI initiatives are designed and implemented.

In our survey, we found that support is stronger among our participants for passive actions (statements) than more active ones (admissions/hiring practices) but whether this support is based on practical convenience and/or beliefs about the impacts of these practices is unknown. Instructors believe that different race-gender groups have different interest levels in science and mathematics - but we don’t yet know if this is viewed as a cause or a result of disproportionate representation. It is also unknown how this perception impacts instructional practice, mentoring relationships, or hiring decisions. Based on our findings here, and questions raised but not answers, thus we argue that future research is needed to document these DEI beliefs more widely and more specifically, including (a) ways in which they impact teaching, hiring, and mentoring; (b) variation across ranks and status; (c) variation by identity group; (d) where they come from; (e) how to change these views in individuals. Answering these questions, among many others, can inform research-based interventions aimed at engaging STEM faculty in more equitable practices and structures.

Acknowledgments

Data was collected through an NSF funded project (DUE No. 1726328, 1726281, 1726042, 1726126, and 1726379). We would like to acknowledge the work of Jeffrey Raker and Marilyne Stains on the design and analysis of the original survey as part of the larger project.

The Impact of the COVID Pandemic on Departmental Efforts to Implement Active Learning in Precalculus through Calculus 2 Courses

John H. Johnson, Jr.
The Ohio State University

Deborah Moore-Russo
University of Oklahoma

Nathan Wakefield
University of Nebraska-Lincoln

David C. Webb
University of Colorado Boulder

For mathematics departments across the United States, everything changed in March 2020 as institutions rapidly moved their instructional delivery model to a model based on remote instruction. This study investigates how four institutions leveraged organizational structures and initiatives to cope with these changes. The findings suggest that the four institutions studied had solid foundations for implementing active learning in their various entry level mathematics classes. Their plans involved different pedagogical, coordination, and communication practices. In light of the strain that the pandemic placed on these efforts, some were found to be more robust and able to leverage digital resources to continue to make progress to their goals for active learning implementation than others. Departments would do well to consider their range of preparedness and the robustness of their efforts to directly impact instruction in Precalculus through Calculus 2 (P2C2) courses and the related coordination and communication.

Keywords: Precalculus through calculus 2 (P2C2); Organizational structures; Active learning; challenges; COVID-19 pandemic

Amongst the challenges present in STEM education, one of the most significant may be the percentage of students receiving grades of D, F, or Withdraw (W) in mathematics courses. Nationally, between 20% and 30% of students receive a D, F, or W in courses ranging from Precalculus through Calculus 2 (P2C2; Apkarian & Kirin, 2017; Bressoud, 2015). Several large-scale efforts have aimed to better understand this problem and work toward reducing DFW rates (Bressoud, 2015; Rasmussen, Apkarian, Hagman, Johnson, Larsen, Bressoud & Progress through Calculus team, 2019; Ström, Webb, Voigt, & Funk, 2021). These studies have found and studied institutions that have had great success reforming courses and reducing DFW rates using a variety of tools (Bressoud & Rasmussen, 2015; Smith, Voigt, Ström, Webb, & Martin, 2021). Most studies have focused on changes that were made at a course, department, or institutional level where individuals or groups of individuals were working to reform instructional methods, student placement, leadership, or department culture. However, in these studies the external environment remained relatively static.

Everything changed in March of 2020 when institutions across the United States shifted their instructional model in response to a rapidly changing environment as the world responded to a pandemic (Sahu, 2020). The recent pandemic provided a unique opportunity to consider the impact of significant alterations in external conditions on P2C2 instruction. This study aims to better understand how departments responded to a radical environmental change and the perceived effectiveness of those responses. Specifically, this study aims to answer the following research questions: *How did the COVID pandemic impact mathematics departments working to include active learning in their P2C2 classes? What organizational structures and initiatives were leveraged in order to make progress toward more active P2C2 practices and to cope with the challenges of the global pandemic?*

Theoretical Framework

The theory that was used as a lens for the study came from Weisbord's Six-Box Model (1976), which has been used in previous case study research for qualitative analysis of P2C2 courses offered by math departments (Moore-Russo, Kornelson, Savic & Andrews, 2021). To better understand how math departments responded to a rapidly shifting environment, we found it useful to analyze how they operated as organizations. Each of the six boxes describes a dimension that should be considered when studying how organizations function. In the first box, *purpose,* are the goals, objectives, missions, and perspectives of the organization. The second box, *structure*, refers to how work is facilitated or divided in an organization. The third is *relationships*, which deals with how organizational members are connecting and their interpersonal interactions. It includes how members behave, communicate with, and regard one another. The fourth box is *rewards*, which includes both formal and informal incentives that motivate (or demotivate) individuals. The fifth box is *mechanisms*, which are the "procedures, policies, meetings, systems, committees, …that facilitate concerted efforts" (Weisbord, 1976, p. 443). It is important to note that in this box the systems, resources, and policies that are available or used to help people plan, budget, and carry out their work as well as coordinate with others may "actually help or hinder people in accomplishing their work" (Yousefi, & Sajadie, 2017). The sixth, and final box is *leadership*, which includes those who have power or influence over other organizational members or over the allocation of resources. The *environment* involves all external demands and pressures that impact (and are impacted) by the organization.

Methods

The four mathematics departments examined in this paper are drawn from a research project involving two dozen mathematics departments engaged in the implementing and sustaining active learning practices in the undergraduate calculus sequence. We loosely define active learning practices to be methods of instruction that acknowledge students should be engaged in the learning process through meaningful mathematical tasks, with peer-to-peer and student-to-instructor collaborative processing of mathematical ideas, and instructor use of student thinking while fostering equity and inclusion (Laursen & Rasmussen, 2019; Strom, Webb, Voight & Funk, 2021). Each mathematics department completed a proposal that described their rationale for increasing the use of active learning, the strategies they were going to use to support changes in practice, and how improvement would be documented. Each mathematics department utilized a localized strategy that considered the degree of instructor buy-in, mathematics instruction, indicators of student success, and ways they might contribute to a Networked Improvement Community (NIC; Bryk et al., 2015) of mathematics faculty and benefit from participating in the NIC.

Mathematics departments participated in the NIC in two groups: a first group received funding in fall 2018 to support the work outlined in their proposal; a second group was invited in spring 2020 to participate in the NIC but without funding to enact their proposed work. Any funding received by the second group was provided by state or campus sources, and not the research project. Both groups participated in and contributed to the NIC, but participation was staggered by about 18 months. Pertinent to this paper: the second group, from which the four cases in this study are drawn, joined in spring 2020 right as the COVID pandemic caused nearly all university instruction to move to remote and online instruction. For this paper, we selected four mathematics departments from the second NIC group after a preliminary analysis using the six-box model. The four departments were selected because they varied in size and geographic locations, and represented a broad range of experiences in the shift to remote instruction: from pre-pandemic changes to a flipped instructions with robust administrative support and departmental buy-in facilitating the transition to remote instruction to significant disruption and retrenchment of previous change efforts. In a P2C2 context, these departments' experiences reflect larger trends surveyed in undergraduate mathematics programs (Kirkman, Blair & Barr, 2022).

For the four mathematics departments analyzed and discussed in this paper, we interviewed mathematics tenure-track faculty, teaching faculty, graduate student instructors, and campus and department administrators between summer and fall 2020. This group of interviewees also included those who co-authored the local proposal for active learning. Each of these interviews was conducted using a common protocol and included questions pertinent to the role of the interviewee in the proposed work. Since the data collection for these four cases occurred after the onset of the pandemic, we also asked questions about how the pandemic influenced classroom practices and department policies. These specific questions from the interview protocol included:

- *In what ways have active learning efforts been impacted by the COVID disruptions?*
- *How successfully has the mathematics department handled the shift to remote instruction for precalculus and calculus classes?*
- *What factors have been important in helping make this transition?*
- *What has the department learned from online instruction that may be used for precalculus and calculus instruction in the future?*

Interviews were conducted virtually using video conference software. These virtual meetings were recorded and transcribed. After the transcriptions were cleaned for accuracy, teams of researchers collaborated in the analysis of interviews for themes that emerged from the interviews. The original proposal from each institution was also used as a data source that documented both the rationale for the proposed work and expectations for progress over the short term. The qualitative analysis of these interviews contributed to summary reports that were sent to the project lead for each mathematics department to confirm and correct how the research team described goals, progress and recommendations from the data sources which included interviews with mathematics instructors, graduate students, and department and campus administrators. In this paper, using the six-box model we used these data sources and summary reports as the basis for our analysis of how each of four mathematics departments responded to rapid changes in the environment.

Weisbord's (1976) model was used to construct cases for four mathematics departments using each of the six constructs. Similarities and differences in these organizational constructs were identified and related to descriptions of departmental responses to the pandemic. Thick descriptions for each case were also developed that included narrative descriptions of topics such as: use of course coordinators, professional development, conceptions of active learning, levers that were utilized, and challenges encountered. Themes and relationships between organizational constructs and responses to the pandemic were then summarized and reanalyzed for lessons that could be learned from departmental approaches and responses to the COVID pandemic.

Findings

The data set came from four different mathematics departments. All four departments are situated in public institutions with a Carnegie classification of a Doctoral University: High

Research Activity. Enrollments and institutional locations varied between institutions, as are described below.

Mid-Size City Campus (MCC)

MCC is a public university located in an urban location with a student population of approximately 15,000. At the outset of the study, the mathematics department at MCC undertook the goal of reforming instruction in P2C2 by including training for P2C2 instructors, focusing particularly on part-time instructors, the development of more shared materials for P2C2 courses, and the hiring and training of both graduate and undergraduate learning assistants for P2C2 courses. Historically, tenure line faculty at MCC do not teach courses below calculus; instruction in these courses is relegated to adjunct faculty. The proposed mechanism for change was a bottom-up approach in which individual instructors make changes with the goal of reaching a critical mass that can eventually influence the faculty at large. In 2019, a new senior vice chancellor noted that math courses were a bottleneck for graduation and committed resources to the math department, particularly, the hiring of a Director of Quantitative Reasoning. The institution has established relationships with another institution that has an established active learning in mathematics (ALM) program; MCC leveraged that relationship to borrow and adapt materials that could be used in many of the P2C2 courses. Active learning is not an expectation for promotion/tenure. However, using innovative teaching methods is grounds for receiving a distinguished rating on teaching.

The pandemic forced MCC to rethink a lot of things ranging from what ALM involved to departmental priorities. One instructor stated, "*We just can't do things, you know, engagement and active learning look very, very different. It's almost non-existent to be honest, you know. You can't let them be talking to each other close to each other.*" However, another instructor argued that the move to remote classes forced instructors to reconsider lecture and the inability to "*[cram] stuff down there in a lecture.*" At MCC, it appears that some instructors felt like they were able to transition into ALM remotely while others felt unable to adapt ALM to remote instruction. The chair at MCC noted that the pandemic interrupted the department's work, "*We missed the last two full department meetings because there was just too much COVID stuff to deal with*." The chair continued to discuss how prior to COVID there were departmental level discussions of how Calculus could be changed, but "*they got blown up because of COVID*." Nevertheless, the chair remarked that they had learned a lot through COVID and the experience would certainly change the teaching in the department.

Large City Campus (LCC)

LCC is a public, urban university of ~25,000 students. Prior to participation in the NIC, LCC engaged in an effort to improve STEM education and increase the flow of students to engineering majors. LCC's upper administration made a key hire to oversee the courses leading to calculus; this director was given authority over hiring, firing, and the budget of all courses before Calculus. The director oversaw a cohort of five instructors who met regularly and were given release time to work on curriculum. Courses were redesigned to include evidence-based practices including active learning. The director created relationships with feedback loops with other "client" disciplines (e.g., Schools of Engineering and Business) as well as the Math Department Chair. He used data to study DFW rates in P2C2 courses as well as in other STEM courses that had math prerequisites. As a result of these efforts, DFW rates in courses leading to calculus dropped significantly and the number of students moving on to calculus grew substantially.

COVID forced classes to change to an online platform. The curricular innovations that had been adopted were mostly abandoned as instructors moved online, both in synchronous and asynchronous environments. Even when classes were allowed to return to in-person instruction, all students faced forward with six feet of separation. The tendency was to return to lecturing, and instructors who tried to engage students struggled. As one instructor said, "*Remote [instruction] is very different from when we are in class.... Previously, the instructor circulated, students might go to board, but instructors weren't really the person who drove things. The groups were. Remotely, I have not found a way to not be the leader of the activity. You can do the pregnant pause all you want, but there isn't the communication between them [the students] that was so integral to the activities we were doing. There has to be a better way, but I haven't found it, and I don't think others in my area have either*."

The feedback loops also faltered due to COVID. Rather than in-person meetings with rich discussion, most communication during this period was via email. Almost all communication flowed through the director in an overwhelming fashion. Communication between the director and the Math Department Chair and heads of the client disciplines fell away. The Chair reported that, "*There is a lot of frustration. Everyone is tired.*" The fatigue and frustration came out in the director's interview. The director questioned the sustainability of what they had accomplished pre-COVID stating, "*COVID has stalled us. COVID has set us backward….I've gotta figure out how to create an active learning environment online, and I don't know where to begin on that.*"

Large Research Campus (LRC)

LRC serves over 30,000 students. Their proposal to expand active learning focused specifically on the move from "*large, coordinated lectures in Calculus I to a system of flipped classroom delivery of this vital course*." Faculty involved in the proposal argued that student success in the large lecture version of the course was mixed and that quality of instruction in the course needed attention. The vision was to move the course into the 21st century using active learning practices.

The leadership for this effort was significant. A well-respected member of the mathematics faculty with an interest in student learning organized the move to flipped classrooms to create more opportunities for student discussions in classrooms (instead of lecturing). Campus leadership noticed these curricular and instructional developments in the mathematics department and described how infrastructure funds were made available to support the shift from large lecture stadium seating to classroom seating that supported group activities and peer interaction. Funding for the hiring of additional tenure line and teaching faculty was also allocated to the mathematics department, in response to these curricular and structural changes in the design and teaching of calculus. As new faculty were brought in, they took over as course coordinators which gave them authority to make structural changes in how communication between instructors was organized. Improved coordination allowed for better uniformity of topics, instructional materials, and assessment. More regular meetings to support this coordination improved communication between calculus instructors.

The move to flipped classrooms motivated an investment in technology-enhanced instruction with video recordings that students could watch before attending in-person sessions. Coincidentally, this all occurred prior to the pandemic. In March 2020, when the transition to remote learning occurred, the move was relatively smooth according to most interviewees as materials were already online and instructors were more comfortable with using technology to support teaching and learning. The motivation of a key leader in the math department to craft a proposal for instructional innovation, the work of calculus instructors to convert course activities to support a flipped classroom model, and the campus support for classrooms that support active learning all converged to support progress toward the goal to expand and sustain active learning. These factors allowed for synergistic processes to emerge amidst the pandemic.

College Town Campus (CTC)

CTC is a STEM-focused university with a student enrollment of ~6,000. Similar to the other institutions, CTC has both tenure-stream ladder-rank faculty and VITAL (i.e., visiting, instructional, TAs, adjunct, and lecturing) faculty. Prior to CTC's participation in the NIC, its stated goal was to improve coordination within and between courses in their calculus sequence for a more uniform experience for both students and instructors. Every lower-division large enrollment course (with one exception) is coordinated with coordinators mainly drawn from the teaching faculty. Two of the common concerns among the teaching faculty were the lack of cohesion among P2C2 faculty and the lack of a unified vision on the role of coordination.

Prior to COVID, the teaching faculty self-organized a departmental-based professional learning community (PLC) open to all faculty and offered during the fall and spring semesters. Participation was voluntary but incentivized with lunches funded by the department. The PLC served as a meeting ground to discuss teaching, active learning techniques, and readings from math education and scholarship in teaching and learning literature (e.g., MAA Instructional Practices Guide). However, the COVID pandemic and the switch to remote instruction put an abrupt halt to these meetings (at least during the fall semester) and funded lunches. One interviewee noted, "*We haven't tried it [having the PLC without lunches] yet. I don't think we've had the bandwidth to do it [the PLC] this fall."* The lack of the PLC meeting was especially missed in creating a community amongst the VITAL faculty. One interviewee reported, "*Some people might be missing, just the community piece and talking to someone."* The interviewees were split between waiting to bring back the PLC during the 2021-2022 academic year or during the 2020-2021 spring semester. In contrast, the department's GTA Teaching Seminar, their PLC aimed at graduate student instructors offered as a regularly scheduled class, continued throughout fall 2020. In response to COVID, a teaching session on using Zoom features of breakout rooms and polling was added to the GTA Teaching Seminar.

With the shift to remote and hybrid instruction, Calculus 1 at CTC was delivered in a flipped model with pre-recorded lectures students viewed before class and in-class activities. There was ambivalence expressed by one of the coordinators on continuing with the flipped model: "*Oh, I mean it [the flipped model] certainly could [continue]. I think it could work but I don't know that I want to do it that way.*" However the coordinator liked the activities created for the flipped model and expressed interest in using these activities in a class model with more in-class lecture-based delivery interspersed with activity-based days.

Discussion

In our case analysis several themes emerged with respect to how mathematics departments responded to a common change in *environment* imposed by COVID. Prior to the pandemic, each mathematics department proposed a plan to make progress toward a common *purpose*, namely increasing the use of active learning in P2C2 courses. As such, *leadership* articulated potential *mechanisms* for enacting change for the support, use, and expansion of active learning. Differences in the emerging development of *structures* and *relationships*, however, created a range of preparedness for managing a crisis that directly impacted instruction in P2C2 courses and the related coordination and communication of norms and practices.

Prior to the shift toward online and remote instruction, LRC had developed their coordination *mechanisms* using resources to change large lecture courses to flipped classroom models through a combination of lecture videos and revised instructional materials to support student discussions in small groups. We acknowledge that the timing of LRC's campus initiatives (*rewards*) to hire coordinators and support curriculum development for flipped classrooms was serendipitous; nevertheless, regular meetings focused on course redesign helped LRC develop communication *structures* and *relationships* while providing resources for an unforeseen crisis. The pandemic motivated faculty at CTC to redesign courses using a flipped model, but urgency to develop and use that model under challenging conditions may have stigmatized use of flipped instruction when CTC returns to in person instruction.

In the cases of MCC, LCC and CTC, communication was disrupted during the pandemic; professional development meetings were discontinued; and instructional resources that could be used in technology-intensive environments were underdeveloped. Many of the existing instructional and communication *mechanisms* faltered in online settings. *Structures* for promoting student engagement and creating a supportive instructional community that had worked while in-person often did not transfer to online platforms. Certainly, there was no way to predict the advantage of developing videos or tech-friendly tasks to support active learning prior to March 2020; however, *the importance of developing robust communication norms and practices as mechanisms to maintain and advance structures and relationships when a department encounters challenges is noteworthy*. When mathematics faculty are working toward a common purpose, there is a need for communication. When workload intensifies, the *relationships* that are supported by communication can create opportunities to share the load through the coordination and delegation of instructional resources, assessments, and ways to implement active learning in virtual environments.

Boosting Student Preparation in Flipped Multivariable Calculus with Low-Stakes, Daily Quizzes

Matthew T. Johnson
United States Air Force Academy (USAFA)

Shelby R. Stanhope
USAFA

Leann J. Ferguson
USAFA

Brandon M. Kim
USAFA

Rita E. Jerome
USAFA

Motivating students to watch pre-lesson videos to prepare for class is among the most significant challenges cited with flipped learning. We demonstrate boosting student preparation by up to 29% by implementing start-of-lesson quizzes. This is shown through comparison of a flipped control group without the quizzes to flipped experimental groups including the quizzes. Results indicate daily, low-stakes quizzes can also reduce failure/withdrawal rates and help maintain student motivation to prepare for class. A marginal increase in performance was also noted for students in the experimental group in spite of their lower pre-test scores. Lastly, statistically significant correlations were found between student perceptions of the class and their video-viewing habits, homework completion and graded event scores.

Keywords: Flipped Learning, Low Stakes Quizzes, Daily Quizzes, Student Preparation, Multivariable Calculus

Flipped learning has been implemented in numerous undergraduate mathematics courses with varying instructional activities leading to varying degrees of success. The instructional activity showing the strongest positive effect on student learning appears to be conducting formative assessments during each lesson (Chung, Khe, & C., 2017). This study follows with research questions asking:

- How do low-stakes, daily quizzes affect students':
  - Preparation?
  - Retention of motivation to prepare throughout the semester?
  - Failure/withdrawal rates?
  - Exam performance?
- Does it matter whether the daily quizzes are at the start or end of the lesson?
- How do student perceptions correlate with study habits and performance?

Background

The United States Air Force Academy (USAFA) has a goal of graduating over 50% STEM majors to better satisfy degree requirements of various career fields (NRC, 2010). Multivariate calculus, or Math 243, is a required math class for most USAFA STEM majors, but has a historically high withdrawal/failure rate approaching 20%. Failure rates for multivariate calculus at other universities are high as well, often in the 20-40% range (Caerols-Palmaa & Vogt-Geisse, 2019; Groen, Coupland, Langtry, & Memar, 2015). We therefore seek to reduce failure and withdrawal rates in Math 243 while continuing to uphold high academic standards.

Benefits and Challenges of Flipped Learning

USAFA recently changed Math 243 to a flipped modality, which we define for the purposes of this study as "a technology-enhanced pedagogy that delivers parts of the course materials through video resources before class, followed by the integrated use of assessments, mini-lectures, individual problem solving, and small-group learning activities inside the classroom" (Chung, Khe, & C., 2017). This modality has been shown in other studies to decrease failure rates by 8-30% due to increased active learning and opportunities for targeted feedback and instruction (Clintondale High School, 2014; Cronhjort, Filipsson, & Weurlander, 2018; Petrillo, 2016; Schroeder, McGivney-Burelle, & Xue, 2015).

Aside from decreasing failure rates, flipped undergraduate mathematics courses have also been shown to increase student performance. Seven recent studies of undergraduate integral and multivariate calculus classes examined the performance of students in flipped vs. traditional groups (Adams, 2016; Braun, Ritter, & Vasko, 2014; Kennedy, Beaudrie, Ernst, & St. Laurent, 2015; Maciejewski, 2016; Petrillo, 2016; Schroeder, McGivney-Burelle, & Xue, 2015; Scott, Green, & Etheridge, 2016). On average, the studies showed a performance improvement of 0.14 standard deviations.

Primary challenges were captured in a meta-analysis of 61 studies on flipped mathematics courses. The challenge of student unpreparadness was found to be second only to the challenge of student unfamiliarity with flipped learning (Chung, Khe, & C., 2017). The challenge of unpreparedness is where the benefits of start-of-lesson quizzes comes in.

Benefits of Start-of-Lesson Quizzes

Despite an average increase in performance shown for classes incorporating a flipped pedagogy, study results differ based on differing instructional activities implemented. For example, Figure 1 shows effect sizes for seven studies of flipped learning in undergraduate calculus, three of which incorporated start-of-lesson quizzes (shown in red), and four that did not (shown in blue). Notice that those without start-of-lesson quizzes do not see the same level of benefit as those that did. In fact, a meta-analysis including 22 flipped mathematics courses showed that including quizzes at the start of class sessions led to an average performance improvement of 0.57 standard deviations as compared to only 0.20 for those not including them (Chung, Khe, & C., 2017). Incorporating start-of-lesson quizzes thus appears to be a distinguishing component towards increasing the effectiveness of flipped instruction.

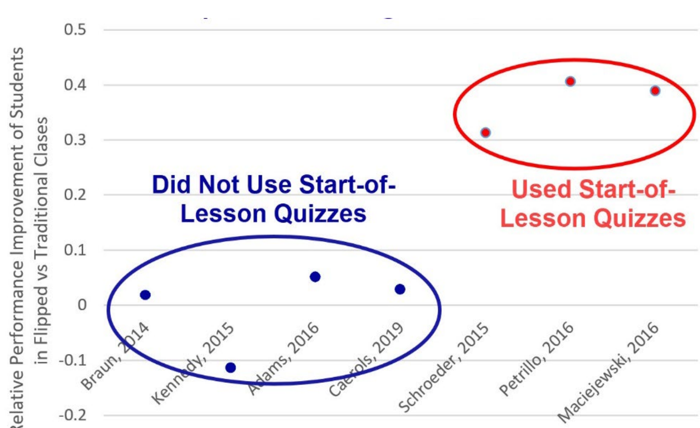

Figure 1. Effect sizes of flipped calculus studies yielding an average mean improvement of 0.14 standard deviations. Red/blue markers indicate studies that did/did-not incorporate start-of-lesson quizzes, respectively.

Theoretical Perspective

The theoretical benefits of low-stakes, daily quizzes include the five primary components listed below:

a) Motivation to prepare: Assigning course points provides extrinsic motivation to come to class prepared, and is considered a best practice (Kennedy, Beaudrie, Ernst, & St. Laurent, 2015).
b) Retrieval Practice: Even no-stakes quizzes have been shown to increase learning from videos (Schacter & Szpunar, 2015) as the required recall process strengthens neural pathways to the required information.
c) Targeted Feedback: The quizzes provide the instructor with helpful feedback on where their students require additional instruction, allowing instructors to address misconceptions before they become entrenched. This type of feedback has been identified as among the most powerful influences on learning and achievement (Hattie, 2007), and is a critical component of frequent low-stakes quizzing (Agarwal P. K., 2021) (Butler & Roediger, 2008).
d) Activation of Prior Knowledge: Quizzes at the start of class activate student knowledge, laying a solid foundation on which students can build their learning during class (Merill, 2002).
e) Attendance: Quizzes at the start of class have also been shown to improve attendance (McBride, 2015). However, this can be separated out of this study since attendance is mandatory at USAFA.

Student perceptions

A complete picture of any intervention requires consideration of student perceptions as well as performance. Studies on flipped instruction often assess both. A recent literature review of flipped mathematics courses showed that of fifteen undergraduate calculus studies, ten reported generally positive and two reported generally negative student perceptions of the flipped vs. traditional methods (Kooistra, 2018). The generally positive perceptions indicate students are typically amenable to the method.

Novelty of Study

Most of studies reviewed above compare the performance of an experimental, flipped group, to a control, traditional group. This study is different in that both experimental and control groups are flipped. This tighter control setting allows investigation into the effects of daily quizzes, including any differences between start-of-lesson and end-of-lesson quizzes. Another important contribution of this study are the correlations examined between students' perceptions, study habits and performance, which is largely absent in the literature on flipped learning.

Methodology

The difference in class structure between the groups is shown in Figure 2. Before class, all groups have the opportunity to earn extra credit by answering a question based on the first video for each lesson. This is recommended to motivate video watching and allow for student practice and self-checking (Chung, Khe, & C., 2017).

Unlike the control group, experimental groups 1 and 2 would take a low-stakes quiz during class. Experimental group 1 would take the quiz towards the end of class, while experimental group 2 would take the quiz at the start of class. Both control and experimental groups would incorporate active learning exercises during class. Experimental group 2 was unique in offering some class time for students to work on homework with peer and instructor assistance during class time. The quizzes consisted of 3-5 short response and/or multiple choice questions based on the associated pre-lesson videos. The quizzes were proctored within 5 minutes through

Microsoft Forms within Microsoft Teams. This facilitated ease of viewing results to provide feedback, ease of grading, and allowed students the ability to review their performance and score on each problem. Open-notes were allowed to encourage use of the notetaking documents provided to align with the pre-lesson videos.

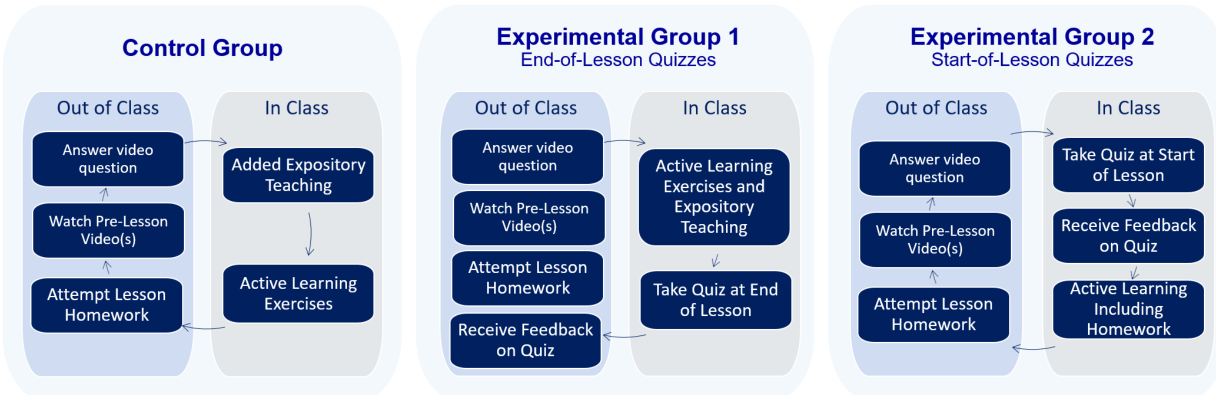

Figure 2. Typical in and out-of-class processes for control and experimental sections.

The control and experimental groups were tightly standardized with the same syllabus, course calendar, learning objectives, homework, midterm exams and final exam. The only significant differences were with 75 out of 1000 course points and the in-class structure. These 75 points were allocated to two medium-stakes quizzes in the control group and to 30 start-of-lesson quizzes in the experimental groups. The two lowest quiz grades were automatically dropped for each student in the experimental group, as recommended to relieve student pressure (Agarwal & Bain, 2019).

The pre-lesson videos were mostly created in prior semesters by various Math 243 instructors to align with course objectives and better establish the student-instructor connection. Videos were typically broken up into 5-10 minute segments as recommended to enhance student engagement (Guo, Kim, & Rubin, 2014). The videos were hosted on Echo360, which enabled tracking of video-watching habits for each student.

Instructor equivalence was controlled for with two instructors teaching the experimental groups and five instructors teaching the control sections. There were a total of 49 students in the experimental groups and 162 in the control group who finished the class. Our primary findings are limited to 1st-year students who took integral calculus the previous semester, which eliminated 7/29 students from the experimental/control groups, respectively. This reduced the sample size but allowed the students' integral calculus final exam scores, taken just 3 weeks before the start of the semester, to be used as a 'pre-test' to control for student equivalence.

Student perceptions were investigated through feedback collected using mid and end-of-semester questionnaires. Student names were associated with their responses in order to draw correlations between perceptions, habits and performance. The questionnaires and analysis were handled in such a way as to guarantee the confidentiality of student responses in order to ensure transparency and reliability of feedback.

Results

Video Viewing

The percentage of students in the control and experimental groups who viewed each of 121 videos in the course can be seen in Figure 3. Each column represents a video with the green, red and grey bars representing the percentage of students who watched the video before the associated lesson, after the lesson, or did not watch it at all, respectively.

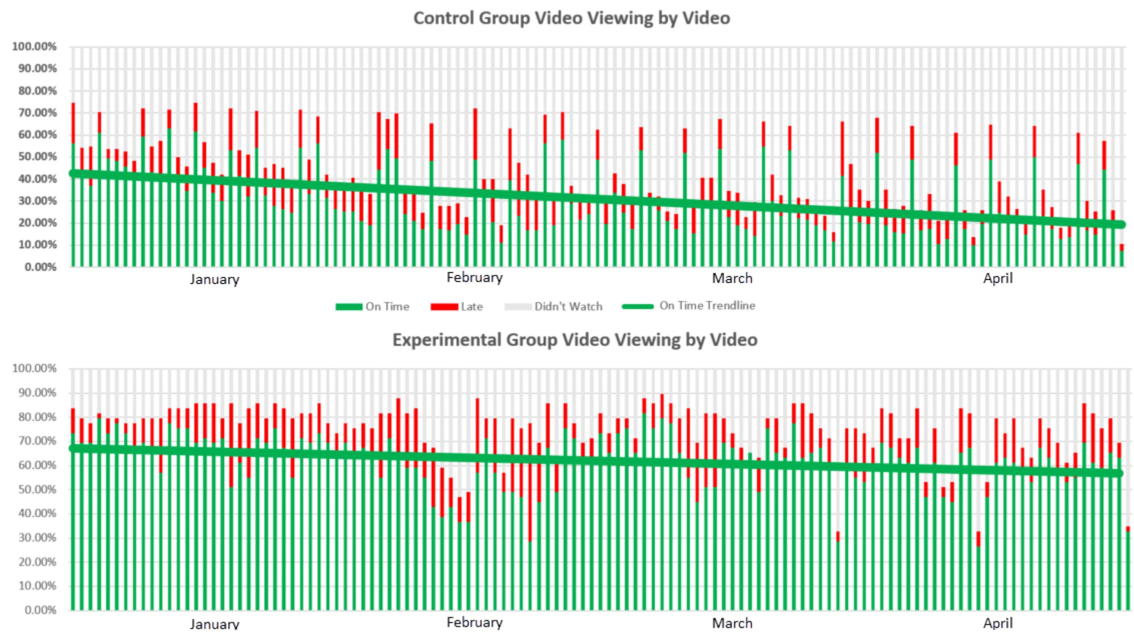

Figure 3. Video viewing percentages of students in the control and experimental groups. Each column represents one of 121 videos in chronological order through the semester.

The green trend lines in Figure 3 show the general decline of video viewing throughout the semester. This is consistent with another multivariate calculus study on flipped learning showing a 30% decline in video viewing throughout the semester (Caerols-Palmaa & Vogt-Geisse, 2019). It is noteworthy, however, that viewership in the experimental group only declined by 10% as compared to a decline of greater than 20% in the control group. It thus appears the start-of-lesson quizzes motivate both increased and sustained pre-lesson preparation.

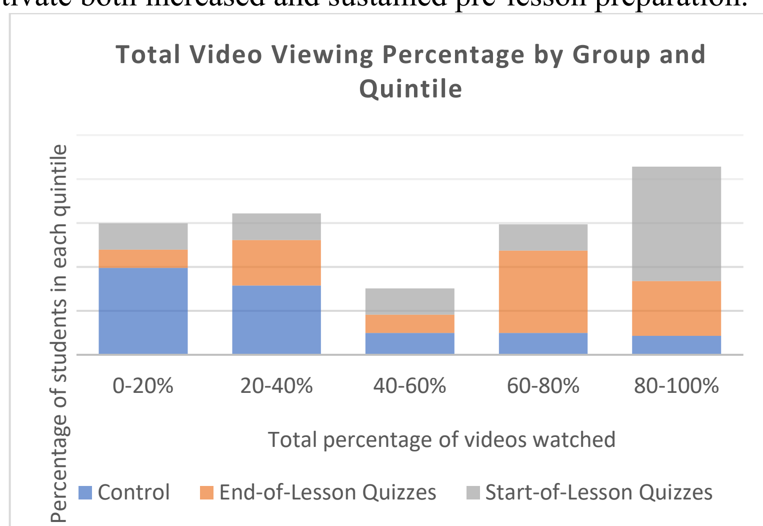

Figure 4. Total video viewing percentage (before or after associated lesson) by group and quintile, showing the lowest/highest percentage of video viewing amongst students in control/start-of-lesson-quiz groups, respectively.

There are noteworthy, periodic spikes in the control group data corresponding to the first video of each lesson. These viewership spikes are due to both the control group instructors emphasizing the importance of watching the first video, and the motivation from extra credit for students who responded to the pre-lesson questions, which were based exclusively on content in the first video of each lesson.

Students in the control, end-of-lesson quiz and start-of-lesson quiz groups watched a total of 49.0%, 61.5% and 78.2% of the 121 videos, respectively, revealing a 29% boost from start-of-lesson quizzes. This can be seen from a different perspective in Figure 4. It shows students with the start-of-lesson quizzes were most diligent in watching the videos before class, while the control group students were the least diligent. Having the quiz at the start vs. the end of class likely led to greater motivation to prepare since having the quiz at the end of class might have led students to trust they could learn the pertinent quiz material during, instead of before, class.

On the mid and end-of-semester feedback, only 9% and 0% disagreed with the statement "The daily quizzes increased my motivation to watch the pre-lesson videos". This confirms, along with the data above, the impact quizzes can have towards motivating student preparation.

Student Performance

Students in the experimental group slightly underperformed by 0.9% on the pre-test and overperformed by 0.3 and 0.5%, respectively, on the midterm exams and final exam. Further detail can be seen in the whisker plot shown in Figure 5.

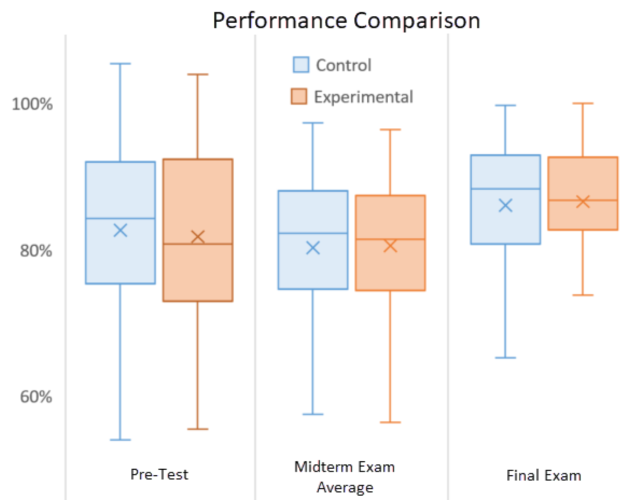

Figure 5. Performance comparison between control and experimental groups on their pre-test, midterm exams and final exam. The mean is shown by the X, the median by the horizontal line, the lower and upper quartiles by the boxes, and the minimum and maximum by the whiskers.

This slight performance improvement from including daily quizzes is perhaps not as pronounced as might be expected from Figure 1. It should be noted, however, the control group in this study also had a flipped modality and implemented many excellent learning activities, such as hands-on and computer-aided 3D visualization techniques, computer-aided calculation tools, active learning exercises, field trips, and pre-lesson video questions. The control group scores also got a slight boost from the late withdrawal of the seven students mentioned earlier.

A performance comparison between the two experimental groups shows students with end-of-lesson quizzes came in underperforming by 2.9% on the pre-test and slightly under and over performed by 0.5% and 0.5%, respectively, on their midterm exams and finals. The end-of-lesson quizzes may have better motivated student attention during class, and the in-class homework done with the start-of-lesson quiz group may have been counterproductive to the benefit they might have gained from completing their homework on their own outside of class.

Withdrawal/Failure Rates

Out of 235 students who started the class, 24 did not pass. Two of these 24 students were in the experimental group and withdrew on the first day of class. Four students in the control group failed the class, seven of them withdrew at some point after the first three weeks of class, and eleven withdrew within the first three weeks of class. Given the expected withdrawal/failure rate of 13% in the control group, the single variable chi squared p value for a correlation between the experimental group having only two students who did not pass the class is 0.08, indicating a good likelihood the daily quizzes increased the odds of students successfully passing the class.

In the mid and end-of-semester feedback, 88% and 93% of students, respectively, agreed with the statement "The daily quizzes helped keep me on pace in the course." Keeping students on pace may very well have contributed to their likelihood of successfully passing the course.

Correlations between student perceptions, effort and performance

Statistically significant correlations were found between student perceptions of the class and their video-viewing habits, homework completion and graded event scores, as shown in Table 1. Students' opinion of the course was determined by their choice of six Likert scale responses to the question "Overall, this course is:"

Table 1. Correlation between first and second items found using the Spearman rank correlation method.

First Correlation Item	Second Correlation Item	ρ value	p value
overall course opinion	video viewing percentage	0.183	0.038
overall course opinion	online homework completion	0.144	0.104
overall course opinion	average performance on midterm exams	0.392	$4.29 \cdot 10^{-6}$

These correlations suggest students who buy into the flipped modality are more likely to adequately prepare for class, complete their assigned work, and perform better on exams.

Conclusion

The vast majority of prior studies on flipped learning compare the performance of an experimental, flipped group, to a control, traditional group. This study is different in that both experimental and control groups are flipped, allowing us to zoom in on the effects of daily quizzes. We find that proctoring low-stakes quizzes at the start of each lesson leads to a significant, 29% increase in students' pre-class video viewing. This confirms the theoretical benefit of daily quizzes that they increase student motivation to prepare. The proposition that daily quizzes also reduce withdrawal/failure rates is supported with a p value of 0.08. This can likely be attributed to the theoretical benefit of targeted feedback from daily quizzes, helping students keep pace in the class. Lastly, while correlation analysis is largely absent in studies of flipped math courses, this study showed that positive perceptions of the course correlate with increased pre-class preparation and better exam performance.

Acknowledgments

The authors would like to acknowledge Lt Col Jessica Tompkins and Dr. Lauren Scharff for assistance in developing and fine-tuning the study from start to finish.

Transitioning Active Learning STEM Recitations Online

John Kerrigan
Rutgers University

Sheila Tabanli
Rutgers University

Geraldine Cochran
Rutgers University

Matt Charnley
Rutgers University

Sally Mulvey
Rutgers University

As part of a more extensive study on transitioning active learning STEM recitations to the online setting, twenty mathematics instructors and course coordinators took part in a survey on transitioning their traditional in-person recitations to an online setting. Participants were asked to reflect on what elements from in-person recitations were retained and lost in the online setting, along with challenges and considerations for both students and instructors. The instructors taught coordinated recitation courses in the Pre-Calculus to Calculus II track for engineering and non-engineering students. Key themes that emerged from the surveys included sustaining collaboration, maintaining student engagement, and administering activities to keep students accountable. This article summarizes our findings and provides recommendations for future online recitation implementations.

Keywords: Active learning, gateway courses, online recitations, course transformation

In the broadest sense, active learning refers to classroom strategies that move away from instructor-centered lectures toward a learner-centered teaching model that focuses on learners' problem-solving and knowledge creation skills (Theobald et al., 2020). As instructors continue to explore active learning strategies in their fully online and hybrid courses, knowing which techniques and tools best enable active learning is necessary for determining the feasibility of implementing such tools in an online setting. This paper examines the rapid transition to online mathematics instruction due to the global impact of COVID-19. Specifically, we look at the transition from active learning face-to-face mathematics recitations to active learning online recitations from a faculty perspective. Our online implementations were done in response to "emergency remote teaching" (Hodges et al., 2020) with the anticipation that many sections would return to in-person sections over time. For the sections that will remain online in the future, we tried to extract the key findings that will support an online implementation of an active learning classroom environment.

Review of the Literature

Research in mathematics education demonstrates the effectiveness of active learning in student success (Hsu et al., 2008). In the "active learning" setting, the instructor takes on more of a facilitator role in helping students master targeted learning outcomes (Mayer, 2004). The benefits of active learning have been widely studied in many contexts and have a demonstrated history of students' improved critical thinking and writing skills (Baepler et al., 2014; Bonwell & Eison, 1991; Freeman et al., 2014), stronger learning outcomes on posttests (Freeman et al., 2014), lower overall course failure rates (Baepler et al., 2014; Reinholz, 2015), and stronger conceptual understanding of targeted concepts (Hake, 1998). Active learning instructional strategies in STEM also have been advocated to promote better exam performance (Freeman et al., 2014), to focus on recruiting and retaining racially minoritized students (Dirks, 2006), to reduce the achievement gap (Haak et al., 2011; Seymour et al., 2019), to elevate racially minoritized student persistence (Estrada et al., 2017), to increase the success of female students (Laursen et al., 2014), and to enhance performance across multiple outcomes such as grades and persistence (Kuh, 2008). Some of the most convincing support for active learning came from the Freeman et al. (2014) meta-analysis of 225 studies on active learning in the STEM fields. They concluded that in comparing active learning to traditional learning, students achieved an increase of 6% on examinations in active learning settings. In the following subsections, we relate active learning and recitation research to teaching active learning-based online recitations.

Online Active Learning

With the rapid shift to emergency online instruction due to the COVID-19 pandemic, instructors accustomed to implementing active learning activities in the face-to-face setting were forced to implement active learning in the online environment. Examples of active learning methods for the online setting used include activity-based frameworks, role-playing, problem-based learning, and the jigsaw method (Amador & Mederer, 2013; Anderson & Tredway, 2009; Baker & Watson, 2014; Lebaron & Miller, 2005). More recent studies in online active learning involve students creating their own content under the instructor's guidance. Student-created videos in undergraduate STEM courses (Campbell et al., 2020) and "viral videos" in marketing classes (Purinton & Burke, 2020) are two such more recent attempts at building online active learning opportunities that have led to students' increased understanding of the course content.

Collaborative learning through video tutorials and flipping the classroom also fall under the active learning umbrella. Flipping the classroom has been done for many years and has primarily been used in blended settings where students watch videos or read before coming to class to apply their knowledge to more complex problems once they arrive at the face-to-face class (Bergman & Sams, 2012). Many studies have touted increased learning gains, improved transfer of information, and positive student perceptions in flipped classrooms, particularly in undergraduate mathematics (Adams & Dove, 2018; Albalawi, 2019; Sun et al., 2018; Wasserman et al., 2017). Outside of specific instructional approaches, another study found that successful implementations of online active learning require strong interpersonal interactions and frequent and effective student-instructor interactions to foster a climate of active learning and academic achievement (Jaggars & Xu, 2016).

STEM Recitations

Recitation courses have a long-standing history of supplementing the lectures' content by using smaller class sizes where active learning can be more easily implemented (Laursen et al., 2019). Recitations sometimes include hands-on components to encourage engagement and conceptual understanding (Etkina & Van Heuvelen, 2007). Some rely on computer simulations to provide near-life experiences with illustrated phenomena. Incorporating active learning and collaborative activities in recitation is rooted in the theory that collaboration involves the metacognitive activities of discussing goals and ideas that improve learning and retention (Bruffee, 1984; Hillocks, 1986). Indeed, studies have shown that setting up collaborative groups in recitations has led to students' increased success in mathematics (Bonsangue, 1994; Herzig & Kung, 2003; Springer et al., 1999), physics (McDermott et al., 1994), and chemistry (Gosser & Roth, 1998).

In one such large-scale recitation study in Calculus 1 for STEM majors, Watt et al. (2014) implemented three different types of recitation sessions over six years, each of which had some variation of an active learning component. The most significant improvement in students' learning outcomes was when students had to actively co-construct knowledge on Verbal, Graphical or Geometric, Numeric, and Algebraic (VGNA) concept activities in recitation. The VGNA activities allowed students to explore calculus problems together from various vantage points to develop a shared understanding of key calculus concepts. This form of active learning used in an introductory undergraduate mathematics course improved students' post-test results and increased retention and decreased DFW rates across the course. This study suggests that active learning opportunities in recitations lead to stronger learning outcomes for students.

The aforementioned literature suggests that for active learning to occur in a recitation, the instructor must design purposeful activities and opportunities for students to engage more deeply with the content, with the instructor, and with one another. Achieving this in the online setting is a bigger challenge since novel ways to engage with the content, instructor, and peers must be developed and promoted. Our research project aims to bridge the literature on STEM recitations and active learning by analyzing the recitation course transformation process for Mathematics, the efforts to include active learning in the transformed courses, and the takeaways from the experience.

Theoretical Framework

Constructivist learning theory emphasizes that individuals learn through connecting new ideas and experiences to existing knowledge and experiences to form new or enhanced understanding (Bransford et al., 1999). Instructional strategies that include active learning foster the cognitive work recognized as vital for learning by constructivist learning theory. Active learning methods also habitually involve cooperative learning groups and peer interactions, similar to the recitation instructors' breakout rooms in their online classrooms. As we aim to investigate the components of active learning preserved and modified in the process of transitioning recitations, we utilized the Teacher-Centered Systemic Reform (TCSR) Model (Woodbury & Gess-Newsome, 2002). The TCSR is an instructional model used in secondary and post-secondary contexts that views instructional reform at a systems level. It looks closely at how personal factors, teacher's thinking, and contextual factors influence an individual's instructional practices. Since many instructors came into the Fall 2020 semester having previously used active learning techniques in the in-person setting, it was important to us to see how their practices stayed the same or changed based on the new online context.

The TCSR Model explains "personal factors" as the collection of past teaching experiences, past and present pedagogical training, and demographic profile. Of particular importance in this study is the extent of the instructors' preparation to teach recitations in the online setting and their efforts to continue learning how to incorporate active learning into online instruction. The TCSR Model explains "teacher's thinking" as the collection of the instructor's knowledge and beliefs about learning, teaching, students, and content, sense of individual dissatisfaction with the teaching process, and teacher self-efficacy for implementing instructional strategies. Our study examines some of these aspects of teacher thinking, specifically in the context of active learning in the online setting. Last, the TCSR Model explains "contextual factors" as the broader picture of how the instructor is embedded within the classroom, department, school, and professional organization. The TCSR hypothesizes that the teacher's thinking and contextual and personal factors impact instructional reform efforts. In our study, transitioning in-person active learning recitations to online active learning recitations can be viewed as a reform effort across gateway STEM courses, with instructional decisions impacted by teachers' thinking and personal factors.

Method

This paper addresses the following research questions (RQ):

RQ1: What elements of the recitations were retained in the transition to online teaching?
RQ2: What elements of the recitations were lost as a result of the transition to online teaching?
RQ3: What were the challenges faced and lessons learned during the abrupt transition to

online teaching?

Study Participants and Data Collection

In order to include all variants of the faculty observations that are relevant for our study (Yanow, 2000) and to ensure information-richness (Fossey et al., 2002), the mathematics faculty included four lecturers teaching the large lectures, 15 recitation instructors, and nine course coordinators of gateway courses as survey participants. Some faculty served in more than one capacity during the Fall 2020 semester. These faculty all taught or oversaw recitations in either Pre-Calculus, Calculus 1 (for the Engineering and for Life & Social Sciences tracks), and/or Calculus 2 (for the Engineering track). The small-class recitations were offered for 80 minutes once a week, which met in addition to two full 80-minute large-class lectures twice a week. All but three respondents used Zoom as their recitation platform, whereas the remaining respondents used a comparable platform, Canvas's BigBlueButton Conferences tool. An 18-question Qualtrics survey including the research questions was sent to faculty members during the last three weeks of the Fall 2020 semester. The open-ended and multiple-choice survey questions allowed participants to describe the setup of their online recitations' setup and elaborate on class preparation, group work, learning activities, and assessments. Participants were asked to describe how they collaborated with their colleagues to execute the recitations. The survey concluded with a series of questions on elements of the recitations that were retained, lost, and modified due to the transition to online recitations.

Analysis and Results

All responses were cleaned and coded using a semi-open coding scheme (Corbin & Strauss, 2015) to look for themes across question responses. After several passes of semi-open coding, a frequency count was determined for all open codes. Codes were collapsed into larger categories, such as "accommodations," "in-class activities," "collaboration," and "interpersonal interactions," and "participation." The following sections elaborate on the themes that emerged during our analysis process.

Elements Retained Online

Respondents enthusiastically agreed that they retained many traditional elements of an in-person recitation once it was transitioned online: quizzes, group problems, homework review by the instructor, example problems. One respondent commented that the online format seemed to allow more students "at the board" to work out problems, whereas three respondents indicated that it was challenging to ensure students completed the assigned tasks. Respondents were asked if they continued to grade work completed during online recitations. 80% of respondents showed that they retained grading work as part of the recitation. Of the remaining 20% who did not require submitted work, one respondent shifted from assigning graded work to not assigning it online by citing the challenge of not being able to observe breakout rooms concurrently.

Elements Lost Online

Respondents interestingly shifted their responses from tangible items (worksheets, quizzes, etc.) to behaviors when describing components lost in the online transition. Sixty percent of the respondents described losing interpersonal interaction, coaching opportunities, student interactions, and before/after class opportunities to ask the instructor a casual question. Twenty percent of respondents commented on losing group work once recitations moved online. The remaining respondents took their face-to-face recitations and fully transitioned all elements to the online setting.

Collaboration

When asked about offering collaborative group work opportunities in the online setting, six respondents reported administering no collaborative group work, four of whom previously promoted collaborative group work in person as a form of active learning. Their reasons for the switch included lack of student participation in breakout rooms and the resulting independent work with unresponsive classmates. Some of the fourteen respondents who had online collaborative group work echoed the same difficulty of continuing collaborative learning in the online classroom. One instructor noted that the average student seemed to participate at the same level, whether in person or online, but the less involved students' lack of participation was exacerbated in collaborative groups. Two instructors cited effective methods of ensuring collaboration, including self/peer evaluations and allowing students an opportunity to first enter their responses in the chatbox before working out the problem in a breakout room.

Recitation Setup

Almost all respondents described online recitations as being divided into three phases: a teacher-led "review" phase, followed by a student active learning phase, then a closure phase. The recitation instructor devotes about 10-30 minutes to summarize the week's content, review sample problems, and answer questions in the review phase. In the active learning phase for about 30-50 minutes, instructors create learning opportunities such as online poll questions and breakout groups where students work on new problems. Finally, most respondents reported spending the last 20 minutes on an online recitation quiz to assess what students learned from the previous week's content. Two respondents stated that to have a focused recitation introduction, they had students submit the homework review problems ahead of time.

Challenges Faced

Respondents indicated a wide variety of both controllable and uncontrollable challenges. The stability of internet connection, availability of power, and availability of pens and tablets were cited as challenges students faced when accessing and engaging in online recitations. Three respondents cited the authenticity of students' work on assessments as proctoring methods and availability of answers on the Internet can influence students' academic integrity. Another five respondents cited getting students motivated to participate as a significant challenge. One respondent noted learning various online technologies as a challenge faced by faculty.

Lessons Learned

The final question asked participants what they learned from the experience of transitioning their recitations online and what they think other recitation instructors should learn from their experiences. Two respondents discussed being accommodating. One respondent felt that being graceful with students and submission due dates helped foster stronger relationships, whereas the other respondent had a different perspective stating that, "lenient or inconsistent policies about tech issues and late assignments lead to students trying to abuse the system in the end of the semester." Another instructor suggested holding office hours on the same day as recitation, as office hour attendance typically seemed high when it was on the same day as recitation. One instructor discussed accessibility and building a structured learning management site containing recorded lectures. The remaining respondents shared ways to engage and involve students, such as mandating the microphone over the chatbox, allowing an anonymous live discussion stream during class, having interactive slides that every student gets a copy of and that the instructor can monitor, virtual whiteboards, and using breakout rooms at least one time during every recitation.

Discussion

Although instructors were forced to move their recitations online due to the impact of the COVID-19 pandemic, our survey responses reflected many of the same elements and challenges instructors typically associate with in-person recitations. Some aspects of administering recitations online, including assessment, accessibility, and developing engagement and interpersonal connections, seemed to be amplified in the responses as areas needing more attention as online recitations continue to be developed. Our participants described a typical online recitation structure similar to that of a face-to-face one but expressed concerns about ensuring engagement during the active learning phase. Many of these feelings can be tied back to teachers' thinking and personal factors associated with many years of running in-person recitations in a tried and true, highly structured format (Woodbury & Gess-Newsome, 2002). In the following paragraphs, we discuss recommended changes to instructional practices based on our findings. We consider both online and in-person implementations of active learning recitations, as both formats will be available in the future.

Assessments

Transitioning the mode of in-person assessments from weekly paper/pencil quizzes to online quizzes made the coordinators and the instructors aware of the availability of a new form of assessment. One of the main recitation components instructors hope to retain is to change in-person, paper-based quizzes to online quizzes regardless of the recitation medium. The advantages of this change are three-fold: (1) allowing more dedicated class time for student-student and student-instructor interaction, (2) providing accommodations to students by extending the time frame (about 12 hours to 24 hours) to take the online quizzes instead of the old practice of taking the quizzes in the last 15-20 minutes of class time, and (3) assessing students in the same format as their homework and midterm/final exams are administered. From a personnel management perspective, this also better repurposed full-time and part-time faculty members' time to avoid traveling, printing, and copying assessments for large classes. During the pandemic, it also eased safety concerns of bringing students' papers home and, as a result, saved faculty members time with the removal of some manual grading.

Collaboration

The challenge of managing online group work was mentioned by many of our respondents across multiple questions and was a significant obstacle for many instructors who wanted to replicate the in-person active learning environment online. Setting up group norms and expectations at the start of the semester is one critical step needed to facilitate effective group work regardless of the recitation medium. Instructors also found it essential to develop student-student and student-instructor communications within the group setting. Since students also tend to be more isolated in online classes, the student-student interactions can be very limited in this environment. Keeping group sizes small, coupled with a low stakes graded assignment due shortly after recitation, could be a way to foster more engagement in online groups. Asking questions that cannot be solved by an online program or Google search can improve engagement and authenticity. This can be applied to both online and in-person recitations.

Engagement

Moving into future iterations of online recitations that do not fall under the umbrella of emergency remote teaching, we realize one of the biggest concerns from faculty was student participation and engagement. One possible solution to promote more active participation is to give all students an individual virtual whiteboard or one shared virtual whiteboard that the instructor can monitor. As many respondents noted, assigning a small grade for the classwork can also motivate students to be more active during recitation, provided there is a small window of time to submit the assignment after recitation. Small pre-class assignments and preparation of worksheet problems and solutions before recitation also seemed to help improve engagement in online recitations.

Accessibility

Across all questions, a theme of accessibility also emerged. Contextual factors play the most significant role here, as instructors have many resources available within and outside the department and organization to help students (Woodbury & Gess-Newsome, 2002). We propose having students participate in future online recitations through various means, including microphones, written text in the chatbox, and Google Form submissions. Some students may be more inclined to participate through written text, whereas others may prefer something oral or on video. Being accommodating and demonstrating clarity are also essential components of an accessible course. Students know what is expected of them, find what they need, and connect with their instructors. We recommend consistently providing explicit directions, organized Learning Management Systems (LMSs), and multiple ways of contacting the instructor (Piazza, e-mail, Discord) to accommodate students' learning preferences.

Acknowledgments

This research study was made possible by a generous grant from the Provost's Office. We are also thankful for our colleagues who took part in the survey.

Secondary-tertiary Transition and Undergraduate Tutoring:
Novice Tutors Make Sense of their Teaching of First-Year Students

Igor' Kontorovich
The University of Auckland

Tikva Ovadiya
Oranim Academic College of Education

Drawing on the commognitive framework, we construe the secondary-tertiary transition (STT) as a distinctive thread of communication that pervades pedagogical discourses of various communities. Our interest rests with university tutors (or "teaching assistants") in light of the emergent recognition of their impact on undergraduates' mathematics learning. We aim to understand the role of STT-communication in tutors' reflections on incidents that took place in their tutorials. Our participants were undergraduate students at the advanced stages of their mathematics degrees in a large New Zealand university and who enrolled in a mathematics education course. Throughout a semester, the participants led tutorial sessions for groups of first-year students and wrote reflections on noticeable mathematical incidents. In this paper, we focus on how STT-communication woven into tutors' descriptions of classroom incidents and their sense-making of unexpected actions of their students.

Keywords: commognition, pedagogical discourse, secondary-tertiary transition, teaching assistants, undergraduate tutoring

Annie is a soon-to-be mathematics major and a novice tutor (or a "teaching assistant") in a first-semester mathematics service course in a large New Zealand university. In one of the tutorials, her students were given $f(x) = x^2 - 2$ and asked to find $f(2 - x)$. This is how Annie reflected on an incident that she noticed in her classroom:

> During the tutorial, I had more than three students asking me how to solve this question. I tried to explain it by telling them that function is like a factory. $2 - x$ is the input and $x^2 - 2$ is like a machine. This is what my maths teacher used as an example when he taught us the definition of functions in school. But they told me they didn't understand it at all. […] After the tutorial I remembered the first time my maths teacher used the factory example and at that time I also didn't understand it. But things are way more paced in school, I can't imagine how hard it must be for a first-year student to meet this idea for the first time.

Putting the accuracy of Annie's description of the incident aside, notice all the places where she referred to the secondary-tertiary transition (*STT* hereafter). On the face of it, it seems only reasonable for her to bring up STT. Indeed, Annie was aware that this was the first tertiary mathematics course that her students have taken, so why wouldn't she comment on "a first-year student"? And it was not that long ago that Annie was in the same shoes as her students, which explains why she recalled her first encounter with "the factory example". On the other hand, Annie worked with the same group of students throughout a whole semester, and yet, she did not acknowledge STT in all of her reflections on the incidents that occurred in her tutorials. This allows us to propose that weaving STT into her reflection was not an unavoidable necessity derived from how Annie communicates about pedagogy, but rather a deliberate move made as part of her sense-making of her teaching.

In this investigation, we explore how the concept of STT finds its way into the reflection of university tutors who teach undergraduates in transition, the discursive characteristics of their communication on STT, and its roles in tutors' sense-making of their teaching. The literature on the transition from school to university mathematics has been prolific (e.g., Gueudet, 2008; Holton, 2001; Thomas et al., 2015). Yet, to our knowledge, this is the first research attempt to consider students' STT from the tutors' perspective. Our participants are undergraduates themselves. By working with a cohort that was experienced in mathematics learning and was making its first steps in teaching, we were hoping to gain access to vivid stories on STT and observe the impact of these stories on tutors' emerging pedagogical thinking.

Related research

This investigation resides in the intersection of research on undergraduate tutoring and on teachers' perspectives on STT.

Undergraduate tutoring

Over the last two decades, international research has become interested in undergraduate tutors – mostly students of mathematics who are employed by their respective departments to contribute to the instruction of specific undergraduate courses (e.g., Speer et al., 2005). Research indicates that the scope of tutors' responsibilities can vary from one country to another (e.g., Oates et al., 2005; Yee et al., 2020), ranging from marking students' assignments, through leading regular tutorial sessions, to solely teaching a whole course. This diversity can explain the lack of universal terminology for referring to this cohort (e.g., see Speer et al., 2005 for "teaching assistants", Yee et al., 2020 for "graduate student instructors", and Nardi et al., 2005 for "tutors"). Previous research in New Zealand context has used the term "tutors" (e.g., Oates et al., 2005) and we continue this tradition.

In many educational contexts, tutor-student interactions constitute a significant course component, which positions the former as potentially having a considerable impact on the learning of the latter (e.g., Speer et al., 2005). In New Zealand, tutors are often in charge of planning and instruction of weekly sessions that the course students are expected to attend regularly throughout the semester. These tutorials bring together sub-sets of the course students (usually less than 50) and engage them with questions related to mathematics discussed earlier in a whole-course forum (often called "lectures").

Research into undergraduate tutors has explored a range of aspects. Given our interest in tutors' sense-making of their teaching, we mention the Undergraduate Mathematics Teaching Project (e.g., Nardi et al., 2005). Through reflective interviews, the project aimed to unpack the complexities of tutors' epistemologies, pedagogies, and craft knowledge. To avoid discussions on some general and dis-embedded levels, the project engaged its participants in reflections on specific incidents that took place in their tutorials.

University teachers' perspectives on STT

Only a few studies tapped into university teachers' perspectives on STT. Klymchuk et al. (2011) developed a short survey, which was answered by 63 university teachers from 24 countries. One of the survey questions asked teachers to propose reasons for the gap between school and university mathematics. The researchers grouped the responses in categories, the most popular of which was "higher level of thinking at university mathematics". Klymchuk et al. illustrate this category with quotes, in which the respondents criticize school mathematics instruction (e.g., "very mechanical and situational") and emphasize its inadequacies in the context of university mathematics ("we expect more out of the students").

The views surveyed in Klymchuk et al. (2011) seem to go beyond individuals and recent times. Back at the third ICME in 1976, a study group brought together delegates from 15 countries to discuss STT. In their report, STT is described as a problem, the three major aspects of which are: unavailability of "topics supposedly covered in the secondary curriculum […] when needed in later study" (Fey, 1977, p. 406), "[m]any students who […] are unable to see the relations between specific ideas" (ibid), and "students leaving secondary school [with] a narrow and formal approach to mathematics" (ibid, p. 407). Put in less deficient terms, echoing perspectives can be found in the report of the London Mathematics Society (1995).

We notice the connections between perspectives on STT and the actions taken by those in tertiary education. For instance, remedial courses are often presented as a "solution" to the "problem" of school graduates' under-preparedness (e.g., Clark & Lovric, 2008; Fey, 1977; Klymchuk, et al., 2011). On the other hand, endorsing Sfard's (2014) perspective on school and university mathematics as almost distinct disciplines, Pinto (2019) discusses pedagogies that university teachers can implement in their courses to "smoothen" the transition.

Theoretical Framework

We turn to the commognitive framework (Sfard, 2008) for theoretical foundations and analytical tools for our study. Being interested in rather nuanced aspects of tutors' reflections, thinking, and self-making, we were hoping to capitalize on the framework that has been renowned for offering operationalizations for elusive constructs of this sort (e.g., Morgan, 2020). In university mathematics education, commognition has been acknowledged for its capability to account for the complexity of this context (Nardi et al., 2014) and has been used to explore teaching (e.g., Kontorovich, 2021; Pinto, 2019). Furthermore, commognition "has been developed within the field of mathematics education and is designed to address the problems arising in this field" (Morgan, 2020, p. 226). As such, it provided us with a set of theoretically coherent tools to attend to issues of mathematics and its pedagogy.

Commognition assumes that *discourses* underlie all aspects of human activity (both communicational and practical), dividing the society into partially overlapping discourse communities (Sfard, 2008). In the context of teaching, Heyd-Metzuyanim and Shabtay (2019) introduce the notion of *pedagogical discourse* as something that shapes and orients teachers "towards *what* to teach students, *how* to teach them, *why* certain teaching actions are more effective than others and, often not talked about but still very important, *who* can learn (or not learn)" (p. 543, italics in the original). The researchers discuss pedagogical discourses in relation to school teaching, but there seems to be no reason to confine the construct to a particular educational setting. Indeed, Viirman (2014) uses the same term and with a similar meaning to investigate communicational practices of university mathematics lecturers. Given that "the membership in the wider community of discourse is won through participation in communicational activities" (Sfard, 2008, p. 91), we consider university tutors as a community that participates in pedagogical discourse.

When engaging with new discourse, a person is likely to find themselves in unfamiliar situations, in which they consider themselves bound to act. Lavie et al. (2019) explain one's capability to perform in new circumstances with *precedents* – "past situations which she interprets as sufficiently similar to the present one to justify repeating what was done then, whether it was done by herself or by another person" (p. 160). For instance, novice teachers can draw on their learning experiences as precedents and replicate narratives and actions of their former teachers.

In this investigation, we are focused on tutors' sense-making rather than on their actual teaching. Then we build on Sfard's (2020) approach to discourses as a special type of communication that "has been construed along history as a toolbox for constructing potentially useful accounts of different segments of reality" (p. 90). Discourses offer conventional building blocks (specifically, keywords, visual mediators, narratives, and routines) to construct such accounts, but they rarely predestinate individual choices. In other words, the selection of what to bring into a discursive existence and how to do so rests with the individual. This is especially the case when people come to capture in words "segments of reality" that unfold in a classroom. Such *pedagogical accounts* belong to the communicational sphere, which makes their objects *discursive*, i.e. arising through humans' keywords and narratives. For instance, when generating a pedagogical account, a teacher needs to decide how to refer to humans: by name (e.g., “Alex”), their assumed role (e.g., “a student”), gender (e.g., “the girl”), et cetera (cf. Dubbs, 2021).

Deficit approaches have been recognized as a common characteristic of pedagogical accounts. Informed by the Critical Race Theory and sociopolitical perspectives, Adiredja and Zandieh (2020) describe *deficit narratives* as those that “focus on students’ academic and intellectual shortcomings and attribute them to deficiencies located in the students, their values, families, and/or cultures” (p. 240). We direct the readers to the previous section for examples of such narratives and to the work of Adiredja and colleagues for a comprehensive discussion and alternatives ways to construct pedagogical accounts.

The Study

In tune with the commognitive framework, we conceptualize STT as a thread of communication that can feature in pedagogical discourses through distinctive keywords and narratives pointing at the transition from the secondary to tertiary educational context. We use “thread” as a metaphor to highlight that this is only one fiber that occasionally weaves into the fabric of pedagogical discourses. To foreground the discursive nature of this conceptualization, we use the term *STT-communication*. Accordingly, the central question underpinning this investigation is “how does STT-communication manifest in tutors’ reflections on incidents that took place in their tutorials for first-year students?”

Context and participants

Our data comes from an undergraduate course in mathematics education (*MathEd* hereafter) offered in the mathematics department at a large New Zealand university. The course mostly attracts students in the second half of their mathematics majors who are interested in educational issues. In a collaborative and student-centered environment, the students engage with various aspects of university mathematics education (for additional course details see Oates et al., 2005). Mathematics tutoring of first-year students is the central activity of the course.

All students in the MathEd course tutor in *Preparation* or *Service* mathematics courses. The former course can be construed as remedial mathematics and it is intended for students who qualified for university studies but do not have the standards that are necessary to succeed in first-year courses. The service course is a general entry course for non-mathematics majors, usually students of commerce, life sciences, and social sciences.

The novice tutors[1] are adjacent to specific groups for the whole twelve-week semester and expected to co-lead, in pairs, ten 50-min long tutorial sessions. Nearly a week before each tutorial, the lecturers of the Preparation and Service courses publish sets of questions on which the course students are expected to work during the tutorial. In the preparation for each session, the tutors are expected to engage with the question sets, raise issues that could emerge, and develop strategies to address them. Overall, the expected role of a tutor role can be described in the words of Moore (1968, p. 18):

> The tutor is not a teacher in the usual sense: it is not his job to convey information. The student should find for himself the information. The teacher [sic] acts as a constructive critic, helping him to sort it out, to *try* it out sometimes, in the sense of exploring a possible avenue, rejecting one approach in favour of another.

[1] From here onwards, we use “tutors” to refer to students in the MathEd course in relation to their teaching in Preparation and Service courses. Those who attended the tutorial sessions as part of their enrolment in these courses are called “students”.

Data collection, corpus, and analysis

As part of the individual MathEd coursework, the tutors were assigned to submit weekly 500-word reflections on an incident that drew their attention in their tutorial session that week (cf. Nardi et al., 2005). The guidelines directed tutors to distinguish between their incident of choice and its interpretations. To enhance the potential usefulness of the reflection process, tutors were asked to formulate "take-outs" for their further teaching.

Overall, we collected 363 reflections from 42 tutors over four semesters. To construct the data corpus, we scrutinized the reflections in search of STT-words, phrases, comments, and narratives. Eventually, our corpus consisted of 58 reflections generated by 38 tutors. We conceptualized each reflection as a snapshot of the tutor's pedagogical discourse; a snapshot where the tutor was the one to initiative STT-communication.

Our data analysis was informed by the commognitive distinction between "mathematizing" – narrating about mathematical objects and "subjectifying" – narrating about participants of mathematical discourse (Sfard, 2008). Focusing on the objects of STT-instances, we distinguished between narratives about mathematics and its entities, courses the participants tutored, and people. The last category was especially diverse, and then we drew on Heyd-Metzuyanim and Sfard's (2012) three levels of generality of subjectifying narratives. The levels distinguish between somebody's performance of a particular action, a routine performance associated frequently or most of the time with a person, and inherent properties that identify a person in a particular manner. With this classification in mind, we arrived at the corresponding distinction between tutors' descriptions of someone's *actions* (e.g., "I tried to explain it by telling them"), descriptions of *routines* (e.g., "This is how our lecturer taught us"), and *general narratives* identifying people or "things in the world" (e.g., "When coming to uni many students struggle"). The level of detail that the participants provided in their reflections varied, and then we use "routine" in a rather general sense as actions that repeat themselves (see Lavie et al., 2019 for an alternative approach). To interpret the roles of STT-communication in tutors' reflections, we approached each instance with such questions as "what does it do to the reflection?", "what is its added value to the story the tutor tells?", "how will this story change if the instance is deleted?".

Findings

The analysis revealed a range of ways in which STT-communication manifested in tutors' reflections. The manifestations were neither strictly distinct nor exclusive to each reflection. Indeed, a rare reflection contained STT-instances that were ascribed to a single category. Due to space limitations, we focus on two manifestations: describing tutorial incidents and making sense of students' unexpected actions.

Describing tutorial incidents

The reflection guidelines explicitly asked the tutors to separate between their descriptions of an incident and its interpretations. Yet, theorizing, evaluations, and judgement found their ways into many incident descriptions. STT-communication often pervaded tutors' descriptions, turning into a building block in tutors' pedagogical accounts.

Let us consider an excerpt from the reflection of Betty. She wrote:

> After visiting a few groups, it surprised me when I found out that there actually were a lot of [Preparation] students who were struggling with fractions. Most of them had some idea of what fractions are, but they had many misconceptions that they brought from school, they did not know how to multiply or add fractions, or find common

factors. […] Some students with richer background math knowledge did finish all tutorial questions"

In this excerpt, Betty writes about her "Preparation students", whom she identifies as "having some ideas" and "many misconceptions". She points at "school" as a source of both. In turn, those students who completed the tutorial questions are identified through "richer background math knowledge". Betty's association of her students' "math knowledge" with their previous school studies in not obvious. To recall, students come to the tutorial sessions less than a week after relevant mathematics has been discussed in lectures. Then, Preparation course appears as an alternative point of reference for addressing tutorial students' successes and challenges. In other reflections, tutors referred to their students and their learning in relation to the university (e.g., "First-year students" and "students who are new to uni").

In the descriptions of the incidents, students were not the only ones that were identified in relation to STT. Some reflections depicted "mathematics", "a topic", or specific questions around which the incidents revolved with comments affiliating them with school or university. For instance, "to remind them of *this concept from the school math* I said […]", "this tutorial was on *vectors which is the first university math in this course*", "the students used a *notation from high school and not proper math*".

Making sense of students' unexpected actions

Many reflections contained descriptions of incidents, where actions (or lack thereof) of some tutorial students appeared as deviations from what the tutors expected, planned, or hoped for. This made room for tutors to account for this gap, which opened the door for STT-communication. Specifically, two approaches emerged from the data analysis through which the tutors seem to make their peace with what students did: *commonizing students' actions* through general STT-narratives and *associating with the students* through drawing on personal STT-narratives. Due to space limitations we illustrate both approaches with the presented excerpt from Annie's reflection.

Annie's writing suggests that after explaining that "function is like a factory", she was not content with the students telling her that they "didn't understand it all". Probably no teacher would evaluate this development as felicitous, including Annie who was invested in her tutoring. However, students "not understanding" appears differently if considered under the assumption that "a fist-year student […] meet[s] this idea for the first time". Through the lens of this general STT-narrative, what looked special and unexpected becomes a logical derivation of a broader pedagogical "truth". Indeed, if "the factory example" is "hard", especially if encountered in a quickly paced first-year course, there seem to be little surprise in the fact that "more than three students" raise questions and repeatedly declare their "not understanding". We use the term "commonization" to underscore that a tutor accounted for students' actions through drawing on some general STT-narratives, through the lens of which these actions presented as less special and more expected.

Another approach that we associate with Annie making sense of her students' actions is providing a personal STT-narrative. Specifically, she writes that the first time she encountered "the factory example" she "also didn't understand it". Drawing parallels between what Annie presents as a recollection of her experience as a student and the actions of her tutorial students, illuminates the latter in a different light. Now that Annie has access to more than one precedent of what appears as a similar re-action of different people to what she describes as a similar situation, it makes sense to re-evaluate her students' "not understanding". Furthermore, Annie is one of these people, which provides her the opportunity to relate to students on a more personal level. Indeed, we read her sentence "I can't imagine how hard it must be" as an exaggerated version of "I *can* understand how hard it must be because I was in a similar situation".

Summary and Discussion

In this study, we construed STT as a communicational thread that weaves into the pedagogical discourses of various communities and is endowed, by commognition, with the power to shape people's thinking and actions. We focus on tutors' community, whose impact on undergraduate students' learning has been recognized (e.g., Ellis, 2014; Speer et al., 2005). To our knowledge, this is the first study to consider tutors as actors in students' STT.

We explored STT-communication of novice undergraduate tutors in New Zealand as it emerged from their written reflections on incidents that took place in their tutorials. Given the diversity of educational systems worldwide and the specificity of our setting, we abstain from generalizing the obtained findings. Nevertheless, it is hard to ignore the similarity between some general STT-narratives that our tutors generated and existing research. For instance, similarly to the lecturers in Klymchuk et al. (2011), a portion of tutors' narratives was de-evaluative of students' mathematics studies at school. On the other hand, there also were narratives acknowledging the difficulty of tertiary mathematics and transitioning into it.

The two manifestations of STT-communication that we presented in this paper appear to play a role in tutors' sense-making of their teaching. Mason (2002) acknowledges that it takes time and effort to learn to write teaching accounts that are free from theorizing, evaluation, and judgement. The first manifestation demonstrates that maintaining this separation between an incident and its interpretation can be not easy for beginning tutors. Metaphorically speaking, it can be said that STT was "in the air" in some incidents and constituted a segment of the tutor's pedagogical reality; a segment that they could not leave behind when constructing their accounts (cf. Sfard, 2020). Further research is needed to establish whether this manifestation of STT-communication has been specific to our context and tutors or whether this kind of talk is typical to university teachers, working with students in transition.

The second manifestation pertains to tutors accounting for students' actions that deviated from tutors' plans, expectations, and hopes. This is where general STT-narratives became handy as they commonized students' actions by turning them from attention-drawing oddities into instantiations of broader patterns. Unfortunately, this commonization often drew on deficit narratives about students, their knowledge, and abilities. Furthermore, let us recall that these narratives emerged from reflections that the tutors submitted as part of coursework. This may suggest that they did not consider deficiency-based interpretations of students' actions as an issue. In this case, these interpretations may be illustrative of the gap between novices to pedagogical discourse and the growing anti-deficit movement in the research community (e.g., Adiredja & Zandieh, 2020). In the school context, professional development appears as a conventional counter-measure to teachers' deficit approaches (e.g., Anthony et al., 2018). We are not familiar with systematical efforts of this sort in the tertiary context in Australasia. This situation draws attention to colleges and universities in the US, where the development, evaluation, and scrutiny of professional development programs for tutors have been institutionalized (e.g., Speer et al., 2005; Yee et al., 2020).

In their reflections, many tutors harked back to their time as students and shared their experiences through personal STT-narratives. They recalled situations that are similar to the focal incidents of their reflections and, having referred to their own personal struggles and difficulties, wrote that they "relate", "understand", and "empathize" with their students. We note that a sizeable portion of reflections in our data contained tutors' personal STT-narratives. This may result from the accessibility of these narratives to our tutors, who were in their students' shoes not so long ago. Such accessibility may be out of reach to other tutoring cohorts, such as graduate students and research mathematicians, for whom STT is often a fading memory (cf. Speer et al., 2005). We then direct attention to what may be a characteristic attribute of tutors who are undergraduates themselves and invite future research to explore how personal STT-narratives can be leveraged in mentoring undergraduate tutors.

A Collective Case Study of Three GTAs Participating in the M-DISC Professional Development

Valentin A. B. Küchle
Michigan State University

Three graduate teaching assistants (GTAs) took part in a one-semester teaching professional development (T-PD) based on the "Mathematics Discourse in Secondary Classrooms" (M-DISC) (Herbel-Eisenmann et al., 2017) T-PD. This report presents a collective case study highlighting one finding per GTA to understand how their classroom discourse changed (i.e., whether it became more productive) and how the GTAs made sense of these changes.

Keywords: Case Study, Graduate Teaching Assistants, M-DISC, Professional Development

From the *Progress through Calculus* survey (Apkarian & Kirin, 2017) we know that U.S. institutions offering graduate degrees in mathematics do not necessarily offer their graduate teaching assistants (GTAs) any teaching professional development (T-PD). Where a GTA T-PD is offered, it is typically confined to GTAs' first year of teaching as indicated by over 80% of responding institutions. The short duration of such T-PDs seems problematic given how much there is to learn about teaching and given that many GTAs find themselves in a stage of *survival* during their first year of teaching (Beisiegel et al., 2019). GTAs may be more receptive to topics beyond classroom management in later years of their teaching, when they find themselves in the stages of *consolidation*, *renewal*, or *maturity* (Beisiegel et al., 2019; Katz, 1972).

To address the lack of support that mathematics GTAs receive beyond their first year of teaching, I adapted and offered the "Mathematics Discourse in Secondary Classrooms" (M-DISC) (Herbel-Eisenmann et al., 2017) T-PD in spring 2021 to three GTAs who were: (a) teaching undergraduate mathematics, (b) no longer in their first year of teaching, and (c) at an institution offering only a first-year T-PD. The M-DISC T-PD covers a range of topics in service of two overarching foci: cultivating *productive* and *powerful* discourse in the classroom. As the M-DISC developers (Herbel-Eisenmann et al., 2017, p. xxxi) explain:

> We use "productive discourse" to mean "discourse that provides students with opportunities to make meaningful mathematical contributions toward particular mathematical learning goals" (Cirillo et al., 2014, p. 142) and "powerful discourse" to mean "discourse that positions students as people who are capable of making sense of mathematics and supports students' developing identities in terms of status, smartness, and competence in mathematics class" (Cirillo et al., 2014, p. 142).

Beyond the practical goal of offering such a T-PD, I was interested in learning whether taking this T-PD was helpful for the participants and their students. For this report, I focus on how productive discourse was fostered by the participants over the course of the semester that they partook in the T-PD. In particular, the research questions I sought to answer were:

1. How does the participants' classroom discourse (as described by the usage of teacher discourse moves and dimensions of the EQUIP [Reinholz & Shah, 2018]) change over the course of the T-PD?
2. How do participants make sense of these changes in their classroom discourse?

To answer these questions, and given the small-scale implementation of this T-PD, I employ what Stake (1995) termed a *collective case study* approach. In this instance, this approach boils down to three *instrumental case studies* of graduate students participating in the M-DISC T-PD.

Brief Overview of the M-DISC T-PD

The M-DISC seeks to help its participants cultivate productive and powerful discourse in their classrooms. To achieve these ends, the M-DISC materials draw on notions like *discourse* and *register* from systemic functional linguistics (Halliday, 1978; Pimm, 1987) and notions inspired by it (e.g., *communication context*), Chapin et al.'s productive talk moves (2003), and positioning theory (Harré & van Langehove, 1999). Structurally, the M-DISC T-PD consists of an introduction, five core "constellations," and an action research capstone experience. The five core constellations are: (a) engaging students in mathematics classroom discourse, (b) teacher discourse moves and positioning, (c) planning for rich discourse, (d) setting up and gathering evidence of student work, and (e) concluding and contemplating evidence.

Through correspondence with the first author of the M-DISC materials B. Herbel-Eisenmann (personal communication, November 22, 2020), I learned that: (a) the first three constellations are "the most substantial parts," (b) constellations 4 and 5 provide opportunities to explore the ideas from constellations 1–3 in more depth rather than introduce new content, and (c) she has omitted constellations 4 and 5 in some past M-DISC implementations. Thus, when I offered the M-DISC in spring 2021, I implemented an abridged version of the M-DISC T-PD that omitted constellations 4 and 5. Further, as its name suggests, the M-DISC was originally designed with secondary classrooms in mind. Thus, where possible, I modified T-PD tasks to be more relevant to undergraduate mathematics without changing the purpose of a task (e.g., replacing a transcript, working on an abstract algebra problem, working with undergraduate mathematics texts). In the end, my implementation of the M-DISC T-PD consisted of thirteen weekly 2-hour meetings during one semester that were held via Zoom due to the coronavirus pandemic.

Relevant Literature

Since classroom discourse—when not a one-way street—is an exchange between teacher and students or students and students, I chose a two-pronged approach to studying the participants' classroom discourse: one prong focusing more on students, the other more on the instructor.

Discourse (Student Focus)

To learn about the mathematical contributions that students were making in the participants' classes, I drew on the dimensions of the "Equity QUantified In Participation" (EQUIP) tool: *discourse type*, *student talk length*, *student talk type*, *teacher solicitation method*, *wait time*, *teacher solicitation type*, and *explicit evaluation* (Reinholz & Shah, 2018). Although each of these dimensions has been linked to being relevant to issues of equity, each of these is also relevant to understanding how productive classroom discourse is.

One dimension I wish to highlight, given its appearance in the Results section, is *student talk type*, which provides a window into understanding whether students are engaging in reasoning or only limited to supplying memorized facts and doing calculations. Reinholz and Shah (2018) drew on Braaten and Windschitl (2011)'s explanation tool to distinguish between *what, how*, *why*, and *other* student talk type. Braaten and Windschitl (2011)'s distinction, however, stems from differences in explanation in science education. The meaning ascribed to these terms in the context of mathematics discourse by Reinholz and Shah (2018) is not fully clear. Thus, for the purposes of this report, *what* statements are claims made by student without a rationale (e.g., "the answer is 12"), *how* statements focus on the process (e.g., "after adding x on both sides, you then need to divide by y"), and *why* statements are claims made by students with a rationale or providing the rationale to an already made statement.

Discourse (Instructor Focus)

To learn more about the instructor's discourse, and with the T-PD materials in mind, I draw on the teacher discourse moves (TDMs) discussed in the M-DISC materials (Herbel-Eisenmann et al., 2017) and various publications (e.g., Cirillo et al., 2014; Herbel-Eisenmann et al., 2013), which are based on Chapin's productive talk moves (Chapin et al., 2003). The six TDMs are *waiting, inviting student participation*, *revoicing, asking students to revoice*, *probing a student's thinking*, and *creating opportunities to engage with another's reasoning*.

Given their appearance in the Results section, I want to foreground *waiting* and *probing a student's thinking*. As Rowe (1986) demonstrated, increasing the time a teacher waits after speaking (wait time 1) and after a student's turn (wait time 2) can have remarkable effects on student participation, reasoning, confidence, and achievement. By *probing a student's thinking*, the M-DISC developers mean "following up with an individual student's solution, strategy, or question. The goal here is to have the student elaborate on or clarify his/her ideas" (Herbel-Eisenmann et al., 2017, p. lvi).

Method

Participants

Three doctoral students from a large public university in the Midwest participated in my implementation of the M-DISC T-PD: Alice, Finnegan, and Valeria (all pseudonyms). Alice and Finnegan were both mathematics doctoral students, whereas Valeria was a mathematics education doctoral student. I had never interacted with Alice and Finnegan before I contacted them to see if they would be interested in participating; Valeria was a friend. All three had multiple years of teaching experience, be it as teaching assistants at universities (Finnegan and Valeria) or schoolteachers (Alice [*sic*]). None received any compensation.

Data Sources

This study is part of a larger study, and the complete set of data sources consist of audio-recordings of all participants' classes, anonymized chat histories from the classes, three semi-structured 60-minute interviews with each of the participants, video-recordings of all thirteen T-PD meetings, and reflections written by me after every T-PD meeting. For the purposes of this report, I will be drawing on a subset of the classroom audio-recordings and anonymized chat histories, as well as the semi-structured interviews.

Classroom audio-recordings & chat histories. All participants shared audio-recordings of their Zoom classes with me as well as anonymized chat histories that excluded the contents of private messages. Using the chat time stamps, I merged the chats with the classroom transcripts. For Alice and Finnegan, who each taught twice a week for 50–80 minutes, I decided to analyze nine classroom recordings: three from the start of the semester (after the syllabi had been discussed), three from the middle of the semester (after the TDMs had been introduced), and three from the end of the semester (before exam reviews). For Valeria, whose audio-recordings were typically around 60 minutes long and who taught only once a week, I decided to code all twelve classroom recordings. (Valeria taught two sections of the same course, but rather then code parts of both, I decided to code all of one section's classroom recordings.)

Semi-structured interviews. Each participant was interviewed before the start of the T-PD and semester, after 7–8 T-PD sessions in the latter half of the semester (after TDMs had been introduced), and 2–4 weeks after the end of the T-PD (i.e., 1–3 weeks after the end of the semester). The first interview served as an opportunity to get to know each other, whereas the last two served to learn about the participants' reflections on the T-PD and their teaching.

Data Analysis

To answer my first research question, that is, how does the participants' classroom discourse change over the course of the semester, I picked nine classroom recordings from the beginning, middle, and end of semester for Alice and Finnegan and all twelve classroom recordings for one of Valeria's sections. These were then coded along two sets of dimensions.

EQUIP. Each classroom recording was coded along six of the seven EQUIP dimensions (i.e., *discourse type*, *student talk length*, *student talk type*, *teacher solicitation type*, *teacher solicitation method*, *explicit evaluation*). *Wait time* was not coded for but considered in a separate analysis. To align with the TDM of *revoicing*, I also coded whether a turn was revoiced.

For the purposes of the EQUIP, a student's turn is any number of student utterances that are not interrupted by another student (but possibly interrupted by a teacher). Since the EQUIP's focus is on positioning, it makes sense to combine a student's utterances, even when they are neither thematically nor temporally linked for it captures the lack of different speakers. Yet, since productive discourse was foregrounded for this part of my analysis, I modified the unit size to define a student turn as any number of student utterances that are linked topically either by responding to the same question or by elaborating on a previous utterance (even when interrupted by the teacher).

TDMs. Each classroom observation was also coded with respect to five of the six TDMs. Again, waiting was omitted and analyzed for separately. In addition to TDMs, I also coded each instance of an instructor making a mathematical solicitation. Although the EQUIP includes a code for *teacher solicitation type*, it does so only in reference to a student turn. Thus, the EQUIP's *teacher solicitation type* code does not cover no-response teacher solicitations, prompting me to code for teacher solicitations separately.

The combination of coding for the EQUIP dimensions and the TDMs then provided data to answer my first research question regarding how the classroom discourse had changed. Combing carefully through the interviews after the EQUIP/TDM-analysis provided context for how the participants made sense of the discourse in their classrooms and served as triangulation for any impressions gained from looking at the EQUIP/TDM data.

Results

The richness of a case study is at odds with the severe length limitations of a conference proposal, and I am forced to paint with very broad strokes in this report. With each case serving as an instrumental case study, each participant's case serves as an example of what it can mean to be a doctoral student partaking in the M-DISC T-PD and each case brought to light different issues. My goal, given the spatial limitations, is to focus on only one classroom discourse issue per participant and elaborate how the participants made sense of it. Before delving into the cases, I want to note that the participants' teaching needs to be viewed in the context of the coronavirus pandemic; the challenges it brought about cannot be understated.

Finnegan: Probing

Finnegan was nearing the end of his mathematics Ph.D., and he loved teaching. The class he was teaching that semester was an algebra class with over 60 students. He frequently solicited mathematical input from his students, averaging almost 1 solicitation per minute (0.941) during the three observations at the start of the semester. Yet, as we can see from Table 1 under

"Student focus," although students communicated mathematics frequently (note: non-mathematical discourse is excluded from the counts), few student turns were *why*-type discourse at the start of the semester (CR1–CR3).

Looking across the nine recordings, one can see that Finnegan embraced the TDM of *probing a student's thinking* after it was introduced in the T-PD. As can be seen in Table 1 under "Instructor focus," the number of probing interactions in classroom recordings 4–9 appears to have increased in comparison to CR 1–3. (Recall: CR4–CR6 are from the middle of the semester after the introduction of the TDMs and CR7–CR9 are from the end of the semester.) As he described in the mid-semester interview, he used to respond to a student's contribution by "assuming that they got the right answer and then trying to put it in more mathematical terms" but was now trying to "dig deeper." He also felt that students had responded well to probing.

In the post-T-PD interview he provided more detail on how he liked to probe:

> I did actually find a lot of use in probing, when it's like, "Well, why do you think this is true?" or, uh, like my, my prime example is, I was like we're, we're dealing with this, we're dealing with this square root function and, "What does this plus c on the outside does [*sic*]?", and somebody answers and like, "Okay, why do you think it does that?" and they draw the connections. So, I did find a lot of use in probing.

As suggested by his remarks and as suggested in the T-PD, there are different ways of probing. The type that especially resonated with Finnegan is what I call *deepening-probing* in Table 1 and involves following up with a student's answer to go deeper with the content of the original turn (e.g., "Why do you think that?", "How did you get that?"). As suggested by the table, this was the main way in which Finnegan used probing. (The second most common way was asking students to clarify their turn—*clarifying-probing*. For example, "What do you mean by […]?")

Switching to the student perspective, one can see that most of the student turns that were why-talk were in response to probing interactions. (Included in this count are why-responses by students who were not addressed by the probing but chose to answer anyway.)

In summary, the TDM of *probing a student's thinking* was taken up by Finnegan after it was introduced in the T-PD and it helped him create a classroom in which students had and seized more opportunities to reason—perhaps the most central discursive practice in mathematics.

Table 1. Table showing parts of the instructor-focused and the student-focused coding of Finnegan's recordings.

Classroom Recording [# of min. spent together as a class]	CR1 [67]	CR2 [55]	CR3 [82]	CR4 [60]	CR5 [64]	CR6 [49]	CR7 [58]	CR8 [81]	CR9 [82]
<u>Instructor focus</u>									
Probing (total)	1	3	2	6	13	13	11	17	9
Deepening-Probing	0	1	2	3	9	12	8	9	6
Solicitations (total)	59	60	76	60	76	59	59	94	74
Solicitations (why)	0	1	1	3	7	7	6	9	2
<u>Student focus</u>									
Student talk type (total)	126	89	101	58	73	54	52	101	85
Student talk type (why)	0	3	3	6	7	8	6	13	4
Student talk type (why) (post-probing)	0	1	0	3	6	5	5	11	3

Valeria: Waiting 1

Valeria was in the middle of her doctoral career and teaching a mathematics content course for preservice elementary teachers with around 30 students. She wanted teaching to be joyful and expressed at the beginning that she wanted her students to feel supported and comfortable asking questions. A main reason she shared for joining the T-PD was learning about positioning.

Her concerns for positioning appear to have expressed themselves when she reflected on the TDMs in the mid-semester interview:

> I noticed that the things that I grab onto the most are things that I can do, or like, that rely more on what I'm doing than on what my students are doing. So, for example, wait times, I can do that. I can wait a little bit longer, and I can wait after my students, uhm, respond. And then for example, I can also revoice my students' answers, so that I have been trying. I think it's when it involves me asking someone else to do something when I'm like a little bit insecure of trying that out, because of the fear of how it, how they might respond. […] I think I have a very hard time, finding ways, to make people do things, without it sounding like I'm forcing them.

This reflection paired with her observation (made during the T-PD and after listening to her own classroom recording) that she felt she did not wait long enough after asking a question led me to wonder about her implementation of wait time, particularly wait time 1. For the wait time 1 analysis, I rounded the wait time after every teacher solicitation to the nearest second in two classroom recordings from the start and end of semester. As the left of Figure 1 (below) suggests, by the end of the semester, Valeria waited longer for student responses when soliciting questions or asking whether something made sense. (Note that the left-hand graph only includes solicitations that were *not* responded to by students.)

Something the right side of Figure 1 suggests is that Valeria had success in getting students to respond to her questions, even if it meant waiting a very long time (particularly towards the end of the semester). (Note that the right-hand graph excludes wait times if students did *not* respond to the question. After also mapping the wait times after teacher questions that students did *not* respond to, I saw no striking patterns.)

In summary, wait time 1 was a TDM Valeria already used at the start of the semester, but through the T-PD, she waited even longer for responses, particularly after asking for student questions. As aforementioned, analyzing her own classroom recording may have played a large part in that. With an eye towards productive discourse, it is unclear from looking at the coded EQUIP dimensions whether students engaged in more reasoning.

Alice: Identifying Obstacles to Using TDMs

Alice was also in the middle of her doctoral career and taught an algebra class with over 50 students. She wanted her students to know that mathematics was about discovery and creativity. Although she tried out several TDMs and was a proponent of some of them (e.g., revoicing and wait time), I want to focus instead on why she found some TDMs more difficult to incorporate into her teaching as she was very articulate about this matter.

As Beisiegel et al. (2019) had noted, GTAs can return to *survival* mode when teaching a new class. This appears to have been the case for Alice, who had multiple years of experience teaching high school mathematics but found herself both teaching this class for the first time and teaching synchronously online for the first time. She expressed being frustrated with herself because she had not implemented as much of the T-PD as she would have liked because she was feeling such pressure from covering the class' content. She added that, "I feel like I'm focusing so much on just like trying to move the class forward that I'm not spending as much time as I would like to on, uuh, creating like meaningful, group work and like meaningful experiences for students to interact with the material."

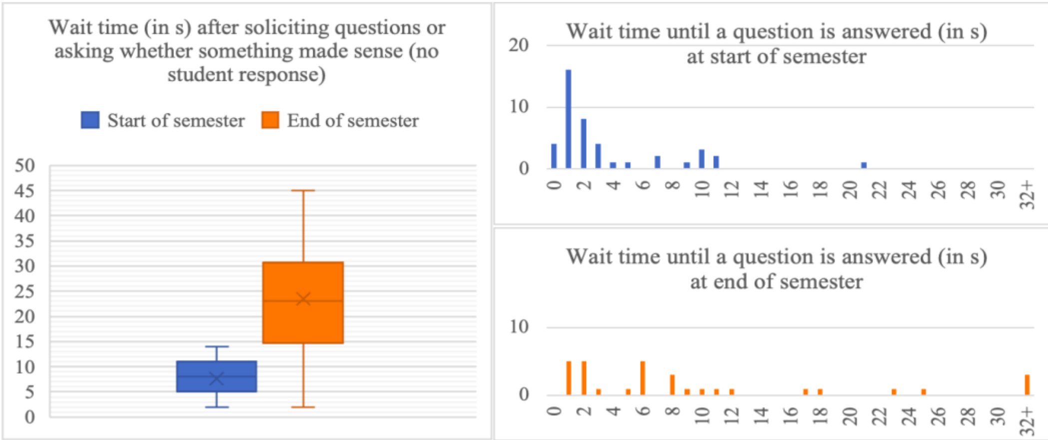

Figure 1. A two-part wait time 1 analysis. The left diagram focuses on wait time after asking students for questions whereas the right two diagrams are focused on wait time after posing questions to students.

In addition to struggling to try out TDMs while teaching a new course in a new mode and suffering from time pressure, Alice noted in the mid-semester interview that some TDMs were just more natural to her: "Like the revoicing and probing and wait time I feel like, uhm, you know, kind of are, they, they kind of naturally happen." Others, like asking students to revoice, was something she noted she did not naturally do. In short, the unnaturalness of some TDMs seemed to present a barrier to Alice to fully committing to them. Some TDMs were more natural but still posed problems: Alice struggled with implementing wait time 2 as she found it difficult to wait after a student's response because she felt the need to reassure them.

Finally, Zoom itself posed some challenges. Although she stated that all TDMs could have been used on Zoom, she felt that Zoom made using them more difficult—a sentiment also echoed by Finnegan who noted the struggles of interacting when many bodily cues are absent.

In summary, Alice encountered and articulated several obstacles to implementing TDMs: feeling too much under time pressure to use novel TDMs, finding some TDMs unnatural, having her teaching style clash with a TDM (i.e., wait time 2), and teaching via Zoom.

Discussion

As seen through the cases of Alice, Finnegan, and Valeria, the M-DISC T-PD encouraged the participants to use at least a subset of the TDMs: (a) Finnegan grew fond of several TDMs, chief among them *probing a student's thinking*, which helped him engage his students in more why-type discourse, (b) Valeria liked wait time (and revoicing) and noted that some of the TDMs were more difficult to use for her because they required asking students to do things, and (c) Alice spoke about using revoicing, probing, and waiting. At the same time, all of them noted struggling to implement certain TDMs, and Alice's case shone light on some of these challenges.

With respect to making discourse more productive in the T-PD participants' classrooms, the M-DISC demonstrated some modest success—although it remains to be seen whether the participants will continue using the TDMs. Yet, the modest success should also be interpreted taking into account that the participants were implementing the T-PD while teaching an ongoing class in which certain discursive norms may have already been established. Further, with the T-PD focusing on productive *and* powerful discourse, the above tells at best half the story.

A Case Study of Abstract Algebra Learners' Fluency for Quotient Groups towards Efficacy Research

Jessica Lajos
Colorado State University

Abstract: Abstract algebra education researchers continue to document that the quotient concept is difficult for undergraduates (Dubinsky et al., 1994; Melhuish et al., 2020). This proposal explores an undergraduate, a first-year graduate, and second year graduate student's fluency as they work on a "collapsing structure" quotient task in Group Explorer across several registers: Cayley tables, formal-symbolic mappings, and Cayley to Schreier coset digraphs. In addition, it illustrates an avenue for extending a qualitative case study to a mixed efficacy study.

Keywords: representational fluency, semiotics, quotient group, homomorphism

Introduction and Literature Background

A substantial amount of work and funds have been put forth over the past two decades to develop an inquiry-oriented (IO) curriculum for introductory group theory (Fukawa-Connelly, Johnson, Keller, 2016; Larsen, Johnson, & Bartlo, 2013). This curriculum is based on Guided Reinvention and Realistic Mathematics Education principles. Lockwood, Johnson, and Larsen (2013) described the IO curriculum, "Each unit begins with a reinvention phase in which students develop concepts based on their intuitions, informal strategies, and prior knowledge. The end product of the reinvention phase is a formal definition constructed by students and a collection of conjecture" (p. 777). These units are developed through Local Instructional Design Research which entails the creation of in-class activities, anticipation of how learners may interact with the instructor and activities, testing activities by conducting small-scale teaching experiments, data analysis, and refinement. According to a recent large-scale survey study that pooled from 200 institutions across the United States, the IO curriculum materials are not in wide use, in fact there is "almost no uptake" (Fukawa-Connelly, Johnson, and Keller, 2016, p. 280). A possible reason for apprehension or non-incorporation of IO curriculum materials could stem from a lack of sufficient evidence to either support or reject the efficacy of the IO group theory curriculum compared to other approaches.

Recent advances are opening new doors for efficacy studies such as quantitative measures that characterize the instruction environment (IOIM; Kuster, Johnson, Rupnow, and Wilhelm, 2019). However, aside from Johnson et al. (2020), as study that compared IO and non-IO groups with respect to the Group Theory Concept Assessment (GTCA; Melhuish, 2019) and gender, no other large-scale efficacy studies that compared IO to other instruction with quantitative analysis were found.

The purpose of this paper is to propose an avenue towards efficacy research that is restricted to a particular local instructional unit beginning with quotient group concept (Larsen & Lockwood, 2013). Rather than an overall assessment such as the GTCA, this research aims to develop additional local in-depth cognitive assessments for the quotient group concept. This paper illustrates a case study of three learners as they work on a quotient group task and a prototype methodology to assess their conceptual understanding, representational fluency, and flexibility for the quotient group concept. The conceptual understanding dimension includes "conceptual metaphors", language interpretation, and connections between concepts such as equivalence relations, normality, homomorphisms, quotient groups, and FTH (Melhuish et al., 2020; Rupnow, 2021; Lakoff & Nunez, 2000, p. 5). The theoretical framework section covers the representational fluency dimension. Flexibility refers to awareness of multiple solutions or the switching from an invalid to valid solution approach. These dimensions are not completely separable (Heinze, Star, & Verschaffel, 2009).

Theoretical Framework: Representational Fluency

Conversions and Pseudo-Semiotic Representations

A conversion is a maneuver in which a learner generates a representation for a mathematical object in one register and translates it to another (Duval, 2017). The theoretical construct of a pseudo-semiotic representation is proposed in this paper out of a need to describe counter-phenomenon of representational fluency observed in this study. A pseudo-semiotic representation is a sign, interpretation, and signified object triangle in which the signified object assigned to a sign-interpretation pair generated by the learner does not exists mathematically or is not accurately portrayed. The literature was revisited to find existing constructs that resembled the observed pseudo-semiotic phenomenon established by other researchers. A pseudo-semiotic representation could be thought of as a specialized instance that fell under the more general umbrella of pseudo-conceptual behavior proposed by Vinner (1997), hence the added qualifier "pseudo" to the semiotic representation construct proposed by Duval (2006). Vinner (1997) termed "pseudo-conceptual behavior to describe a behavior which might look like conceptual behavior, but which in fact is produced by mental processes which do not characterize conceptual behavior" (p. 100). Vinner admitted that this definition was not satisfactory and provided additional examples of what he meant by pseudo-conceptual processes. He explained that a more novice learner may gravitate towards these processes because they are "simpler, easier, and shorter" (p. 101). Moreover, novices "start looking for ways that will enable them to perform the task. These ways are not necessarily the way thought by the designers of the task when they decided to present it to the students. The task designers probably intended conceptual thought processes; the students came up with pseudo-conceptual processes…formed in a spontaneous way…and not necessarily taught to them by teachers or other agents. Sometimes they are natural cognitive reactions to certain cognitive stimuli. The students use them without going through any reflective procedure, control procedure or analysis of any kind" (Vinner, 1997, p. 101).

The concept image and concept definition distinction proposed by Tall and Vinner (1981) falls under the broad umbrella of pseudo-conceptual behavior in cases where there is conflict between the concept image and definition, however it does not detail differences between various modes of language production (Duval, 2017) or object-specific registers (Lajos, 2021; Ely, 2017). Pseudo-conceptual behaviors that have been described through a semiotic lens includes "gesture and speech mismatch" (Goldin-Meadow, Alibali, & Church, 1993, p. 279). Gesture and speech are two modes of semiotic, language, production (Duval, 2017). This mismatch generalizes to the notion of conflicts between registers (i.e., modes of language production) for a specified concept.

Participants and Settings

Participants were recruited via purposive sampling using the condition that they had exposure to a first-semester undergraduate or graduate-level abstract algebra course. Three students, Max, Jenni, and Alex agreed to participate. They represented cases for three consecutive levels in the same mathematics program at a central R1 level research university in the United States. Max was a fourth-year undergraduate mathematics major in a first-semester introductory abstract algebra course. Jenni was a first-year master's in science (MS) student, she had completed the undergraduate introductory course the previous year. She did not have exposure to the graduate course yet. Alex was a second-year graduate student in the doctoral track program and had completed the graduate course. This sampling is characterized as "maximum variation" which "documents diverse variations of individuals" and "increases the likelihood that the findings will reflect differences or different perspectives" (Creswell & Poth, 2018, p. 159).

Instrumentation and Data Collection

Audio-video data and whiteboard work was collected through semi-structured task-based interviews. The interview task was designed to investigate the registers that students naturally used to support their reasoning about quotient groups, fluency in converting an initial natural response in one register to an alternate register, and flexibility switching strategies. A methodological tactic when Duvalian semiotic theory is used is to design conversion tasks in which the researcher fixes the order of the initial and target registers prior to data collection. For example, McGee and Moore-Russo (2015) phrased a calculus task in a way that directed the participant to go from a numerical to geometric register. Rather than creating tasks with apriori initial and target registers, the present study displayed stimuli for various registers, Cayley digraphs, tables, group presentations, and cycle graphs, and allowed the participant space to choose their initial register(s) and complete their responses before introducing switch prompts that directed them to various targets.

The collapsing structure task prompt asked, "Is the quaternion group of order eight and the dihedral group of order eight isomorphic?" followed by "Is there some way that you can modify both the dihedral group and quaternion group by losing information or collapsing some structure so that the resultant modifications are isomorphic?" The collapsing structure task consisted of four major sub-tasks: determining if the dihedral group and quaternion group of order 8 were isomorphic or not, constructing a homomorphism or quotient from the dihedral group to an image group, repeating the previous sub-task for the quaternion group, and showing an isomorphism between the image groups. The "collapsing metaphor" refers to the identification of elements in a group to form cosets of equal size in which the cosets form a partition of the initial group (Melhuish et al., 2020; Rupnow, 2021). The metaphor of losing information was intended to invoke the fact that a homomorphism loses specificity regarding the orders of elements. The researcher set up the collapsing structure task by arranging *Group Explorer* cards into piles as shown below in Figure 1.

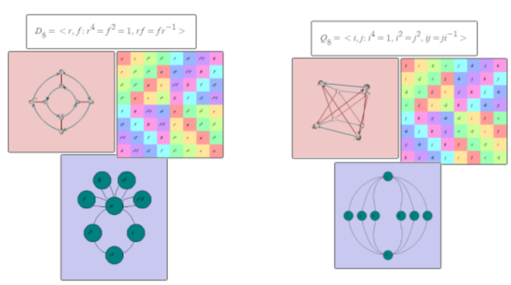

Figure 1. Collapsing Structure Task Display

Participants also interacted directly with groups dynamically through the *Group Explorer* software. They had access to other digraph representations depending on a choice of generators. After these cards were presented, the researcher left it open to the participant to choose an initial register and noted the participant's first natural response. If the participant's natural first response consisted of predominantly visual intuitive responses, such as constructing a quotient map in the digraph register, the researcher followed up with a switch prompt that asked the participant to translate their response using formal-symbolic language. If the participant provided a predominantly formal response that involved writing down cosets or maps using formal notation the researcher applied a switch prompt that asked them to translate what they did using the digraphs.

Data Analysis: Four-Level Coding Framework for Fluency

Notes contained the cues that students noticed or did not notice in certain registers, in what order were registers visited, ways in which representations were used either as a source to stimulate ideas or as a check, and conversions from initial registers entered to prompted registers. These notes were used to develop a chronological summary for how each participant's approach to the task evolved. A comparison highlighted that the three participants invoked many interpretations of what losing information and collapsing structure meant to them within the context of the task. Several strategies that the participants explored were identified in the interview transcripts such as: work towards the Klein-four group, the cyclic group of order two, and the impossible strategy to obtain the cyclic group of order four. Participants also exhibited multiple sign-interpretation pairs for the same sign.

This preparatory round of analysis led to the analytic coding framework in Figure 2. Level 1 of this framework consists of collapsing interpretation themes. Level 2 displays strategies that a learner may enter. Level 3 denotes the registers that learner may use in unimodal sequential order or multiple registers used in parallel. Level 4 focuses on the finest units of analysis, learners' sign-interpretation pairs within each of the registers and conversions between registers.

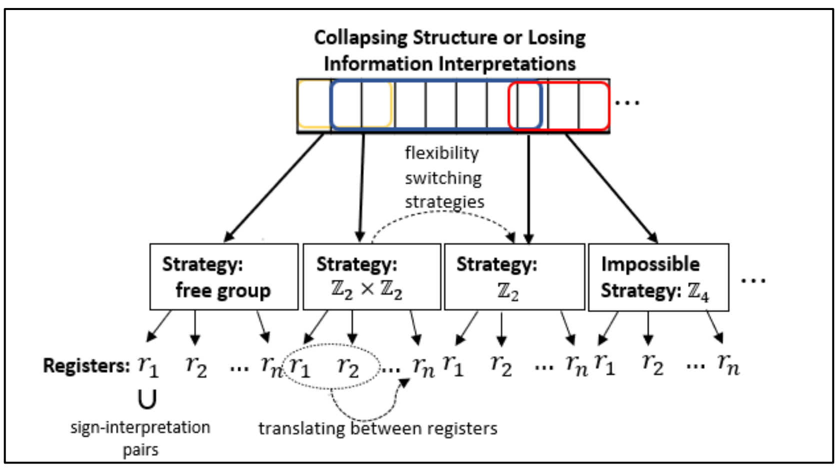

Figure2. Four-level analytic coding framework for quotient fluency

Next, Audio-video files were imported into the Qualitative Data Analysis Software NVivo 12. A hierarchical code book that mirrored the four-level analytic frame was also set up in NVivo as shown in Figure 3. The parent nodes: interpretations, strategies, registers, and sign-interpretation pairs and conversions. Additional selected register codes, Cayley tables, digraphs, group presentations, etc., and open codes were created as sub-nodes under parent nodes. Open coding is the process of abstracting and labeling regularities or perhaps unique instances that are found after immersion in the data (Creswell & Poth, 2018). After coding in NVivo, a summary list of codes across all participants was transferred into a table as depicted in Figure 3.

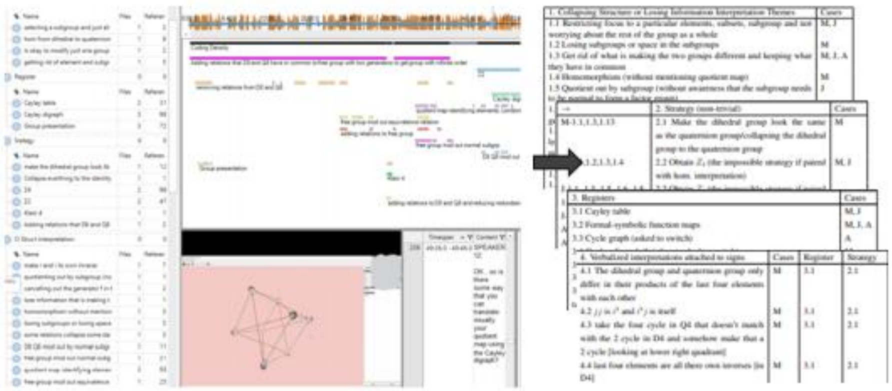

Figure3. Coding in NVivo 12

This table captured aspects of learners' paths in Figure 2. Data was combed through a final time to systematically collect any pseudo-semiotic representations invoked by participants related to their homomorphism or quotient constructions. A pseudo-semiotic representation as a unit of analysis is given by Figure 4.

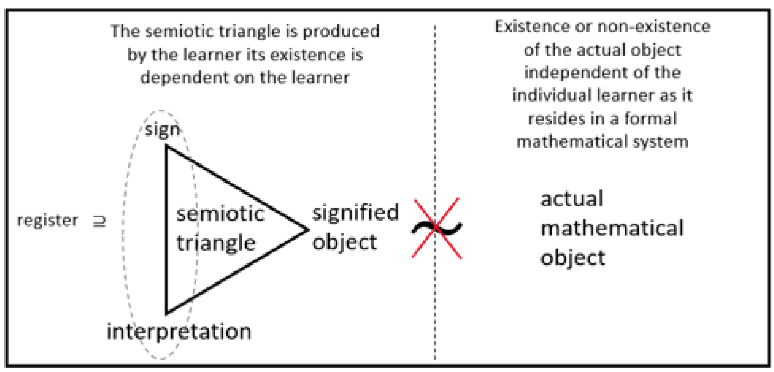

Figure 4. Pseudo-semiotic representation

Results and Discussion

There was a great deal of variability among Max, Jenni, and Alex with respect to their approach to the same task, what collapsing and ignoring information meant to them, their register use, and the sign-interpretation pairs that they produced.

Collapsing, Losing, and Ignoring Structure Interpretation Themes and Strategies

Several of Alex's and Jenni's interpretations of collapsing aligned with the mathematical process of constructing quotients. This included: combining or identifying elements into sets of elements, modding out by an equivalence relation, and partitioning. Max associated the collapsing metaphor with a homomorphism and "losing subgroups or space in the subgroups" but had not assimilated the quotient concept to his conceptions of a homorphism. The initial task prompt was rephrased for Max using the term homomorphism.

In contrast to Alex, Max and Jenni combined interpretation themes in ways that conflicted with the actual mathematical object of a homomorphism. They both mixed the interpretations of getting rid of what was making the two groups different and keeping a subgroup that two groups have in common with a homomorphism. These interpretations manifested into attempts to carry out the impossible strategy, to obtain the cyclic group of order four. The mixing of general every day problem-solving processes, such as looking for perceptual commonalities and differences in the group presentations, with the homomorphism concept led to an implicit assumption that a subgroup of a group would be an image of a homomorphism. However, the image of a homomorphism need not be a subgroup of the domain group. This thinking may have blocked Max and Jenni from entering the Klein-four strategy. During a follow-up interview, Jenni expressed an evolving awareness of this conflict and self-corrected stating that "if I quotient by a subgroup that is not just leaving me with a subgroup" of the starting group.

Quotient Map Conversions for Valid Strategies

Max did not enter a valid strategy to obtain a homomorphisms from the initial dihedral and quaternion groups to the cyclic group of order two or the Klein-four group. Jenni showed flexibility in moving away from the impossible strategy and to the valid strategy of constructing quotient maps from the initial groups to the cyclic group of order two. Alex produced solutions for both valid strategies and never mentioned the impossible strategy. Prior to the researchers switch prompts, Jenni and Alex gave valid solutions in a formal-symbolic register leveraging group presentations. Table 1 summarizes the quotient map conversion that Jenni and Alex made from their initial registers they went to on their own and the prompted digraph register in Table 2. None of the participants performed quotient map constructions in a Cayley table register for valid strategies. Due to time constraints a Cayley table switch prompt was not applied.

Table 1. Quotient map constructions prior to switch prompts

Register/Strategy	M	J	A
Formal-symbolic leveraging group presentation from initial groups to cyclic group of order two	None	$D_4/\sim$ $Q_8/\sim$	D_4/N Q_8/N
Formal-symbolic leveraging group presentation from initial groups to Klein-four group	None	None	D_4/N Q_8/N
Cayley tables/cyclic group of order two	None	None	None
Cayley tables/Klein-four	None	None	None
Digraphs/cyclic group of order two	None	None	None
Digraphs/Klein-four	None	None	None

Table 2. Quotient map constructions following digraph switch prompt

Register/Strategy	J	A
Digraphs/cyclic group order two	$D_4/\sim$ $Q_8/\sim$	D_4/N Q_8/N
Digraphs/Klein-four	None	D_4/N Q_8/N

Pseudo-Semiotic Representations

Max could comfortably recall the formal definition of a homomorphism but produced several pseudo-semiotic representations of a homomorphism across multiple registers. The digraph register offered additional insights into Max's difficulty with the homomorphism concept, as illustrated in Table 3. Rather than combining elements into sets of equal size and viewing these sets as elements, Max wanted to erase vertices and edges in the digraph to reduce visual complexity. Max did not mention cosets, partitions, or equivalence relations during the task. Connections between these more fundamental underlying concepts and the homomorphism concept were missing.

Max: Then I guess if I was going to describe what I did, I guess like take this inner piece [circles inner green cycle] and just pull it out and make it hang out by itself and this is a new group. And you don't need to worry about the relationships between these guys or those guys, because those guys don't exist anymore (Table 3, Interpretation 1).

Max: …it's just the cycles in between the inner and outer cube, or squares, are just more complicated. And so, I guess again, I just selected one of the, either top or bottom and took it off on its own. So, if you straighten it out to where the green box is facing down. So, on the top, the top square, there's one four cycle between those elements. And then I just selected those, took them off by themselves. Then I don't have to worry about what they do with the other things on the bottom, because I'm just looking at the top (Table 3, Interpretation 2).

Table 3. Max's pseudo-semiotic representations in a digraph register.

Register	Sign	Interpretation	Signified Object
Digraph		1	Homomorphism from dihedral group of order eight to cyclic group of order four
Digraph		2	Homomorphism from quaternion group to cyclic group of order four

The incorporation of the digraph register made it apparent that Jenni's difficulties and strengths related to a homomorphism were not the same as Max's. Jenni related the term collapsing structure with the quotienting process of modding out by an equivalence relation and viewed sets of elements as elements in the image. She showed a strong understanding of underlying fundamental set-theoretic concepts related to the quotient concept. She consistently partitioned groups into equal size cosets in more formal-symbolic and digraph registers. She got hung up with how to make a partition of a group into a group and did not recall the necessary well definedness/normality condition.

Jenni: My initial instinct when looking at it was that all of these connections [red arrows] were like s's [flips] and so if you just get rid of the s's you collapse these two points into a point and these two points into a point and so you end up with a square and that was along with my process to get to Z four.

Concluding Remarks and Future Directions Towards Efficacy Research

To work towards an efficacy study restricted to the quotient concept, qualitative themes led to a rubric for how qualitative data for the collapsing structure task could be transformed into quantitative data. The quantitative compression revealed that Max had low, Jenni moderate, and Alex had high fluency levels for the quotient concept. This will be discussed further during the talk along with two questions towards future mixed efficacy research. What are educators doing in practice to support undergraduate learners' fluency for the quotient group concept? How can researchers determine if their interventions to provide support are working?

The World in a State of Panic: Disaster Vulnerability and Digital Technology in Emergency Remote Undergraduate Mathematics Courses

Melinda Lanius	Tiffany Frugé Jones	Nicole Sullivant
Auburn University	Sam Houston State University	University of Arizona

For undergraduate students across the United States, 2020 was the year of learning alone, together. Each experienced the COVID-19 pandemic and emergency measures in their own way, with interruptions impacting all facets of life: social, political, economic, and educational. Our study catalogues how the pandemic affected students' experience(s) of learning math. We utilized typed free responses - from 461 undergraduate students - to a set of five question prompts. "The world in a state of panic" is the phrase one undergraduate used to describe the backdrop of remote learning. Employing disaster vulnerability theory, a systems theoretic framework borrowed from social work research, we coded for themes of vulnerability and capability within our undergraduate mathematics ecosystem. Our findings indicate that the necessity of learning through digital technology was the greatest source of disruption, with vulnerabilities occurring in internet access, faculty digital literacy, digital content resources, and communication.

Keywords: COVID-19, Social Justice, Mathematics Education Systems, Digital Technology

Introduction

Although Spring 2020 teaching and learning donned the digital trappings of online education, it is vital to not conflate the two. Education practices in Spring 2020 are most accurately characterized as emergency remote learning: a temporary measure deployed during a time of stress to protect students and teachers (Ray, 2020). For some students, the measures taken proved to be beneficial; for other students, the abrupt but necessary changes were detrimental. Thus, the global COVID-19 pandemic provided a unique stressor that allows us to newly assess the strengths and weaknesses of our education systems, with a view towards correcting pre-existing inequity and improving access for all as we build to a new normal. Because of mathematics' unique role in university education as a gatekeeper to degree and career options for individual students (National Mathematics Advisory Panel, 2008), we focus our study on undergraduate mathematics education.

Theoretical Framework

Disaster Vulnerability & Disaster Resiliency Theory (Zakour & Gillespie, 2013) is a subset of system theory; it is primarily used in social work research to understand how and why communities become disrupted and to document the extent of disruptions during a disaster. While this framework is typically deployed in the context of natural disasters such as hurricanes or tsunamis, the theory has been utilized in the context of higher education structure, particularly around inclusive education and supporting students with disabilities (Cedeño, Meza, & Majía, 2018; Moriña, 2017).

Detecting disaster. To justify our use of a disaster vulnerability framework, we need to contextualize the COVID-19 pandemic as a "disaster". Most present-day academic definitions of disaster focus on community-disruption fallout rather than the hazards causing the interruption (Perry, 2018). A *disaster* is a form of collective stress with serious community-wide disruption of social, economic, and environmental conditions (Zakour & Gillespie, 2013). Accordingly, the massive disruption and change in our work and education systems in 2020 constitutes a disaster. A system is *vulnerable* if it has a reduced capacity to adapt in a disaster. Our research lens will identify vulnerabilities in emergency remote undergraduate mathematics education, where some students are resilient and others are injured by our systems.

Liability and capability. Zakour and Gillespie (2013) define a *liability* as a negative characteristic causing reduced capacity. A positive characteristic that allows adaptation is called a *capability*. A model of a disaster can include characteristics of individuals, small sub-communities, or nation-wide policies. Structural factors create vulnerability, which allows hazards to trigger a disaster. The vulnerability existed before and may persist after the hazard and, in fact, disasters exacerbate pre-existing social injustices (Le Masson & Lovell, 2016). We can utilize the process of identifying liabilities and capabilities to characterize our collective disaster experience and to foster community capabilities. From here it is possible to build a more inclusive and resilient normal.

Research Questions

Our study focuses on undergraduate student impressions of emergency remote math instruction at the University of Arizona during the Spring 2020 semester. We considered the following research questions: How did the experience of learning math in the context of a post-secondary mathematics course change as a direct consequence of the pandemic? What aspects of the experience did students view as harmful or beneficial to their learning? In the presence of the novel COVID-19 hazard, what underlying sources of inequity were revealed in our educational systems?

Methods

We conducted a survey in Summer 2020, hosted digitally on Qualtrics. Following IRB approval through the University of Arizona's Human Subject Protection Program, we used a Department of Mathematics email list to invite the 6,761 students who took an undergraduate (100 - 400 level) mathematics course at the University of Arizona main campus in the previous semester, with 461 students responding to five free response questions (see Figure 1).

Q1	After the transition to remote learning, how did aspects of life outside of school affect your experiences in your math class?
Q2	After the transition to remote learning, what aspects of your math class hindered your learning?
Q3	After the transition to remote learning, what aspects of your math class supported your learning?
Q4	Congratulations, you successfully completed the Spring 2020 semester and overcame the emergency transition to remote learning! Imagine that a friend asks for advice in an upcoming remote learning math class. What advice would you give?
Q5	What advice would you give to the instructor of an upcoming remote learning math class?

Figure 1. Free response questions, summer 2020 survey

The qualitative data we analyze in this report is a subset of the data gathered in the surveys, which also included a variety of quantitative measures. Because our free response questions were novel, we presented a draft of the survey to four undergraduate students to assess survey language and structure. Each student participated in a 30 - 45 min individual interview conducted by one-two researchers who asked the students to describe their interpretation of the questions after reading the survey. In compensation for their time, each received a $20 gift card to an online retailer (e.g. Amazon).

We utilized concept coding (Saldaña, 2016) to reveal themes of vulnerability and capability in our data. In our initial coding, we discovered a distinct division between the topics students discussed in relation to their emergency remote learning experience: aspects internal to their math courses and aspects external to their math courses. Aspects inside their math courses included interactions with the instructor or peers, the content, and technology used to create the remote classroom. Outside their math courses, students were affected by the blurring of boundaries between the microsystem, mesosystem, and exosystem (in the vein of (Bronfenbrenner, 1979)). In this paper, we will focus on the themes that emerged internal to the math courses. In future work, we will discuss our findings concerning external aspects that affected their mathematics learning experience.

Results

One of the primary goals of disaster vulnerability theory is to document the structure of a disaster, or how a hazard interacted with the system to cause community-wide disruption. Although we developed our model after careful consideration of the particulars emerging from our data, we present the model first because it informs how we present the underlying vulnerabilities that emerged during coding.

Our Disaster Model

Because technology has become more ubiquitous in our society, especially in educational settings, Kenneth Ruthven (2012) explains an updated version of the classic didactic triangle, see Figure 2. It is important that the didactic triangle be updated to a tetrahedron rather than a quadrilateral, because in an in-person teaching and learning environment, technology is a choice; learning can still occur without passing through the technology node. In other words, there is teaching and learning of mathematics that is not mediated by some form of technology. This updated model allows us to analyze multifaceted complexities, where the vertices, edges, and faces each carry importance and meaning. For example, the leftmost face (digital technology - learner - teacher) addresses "content-independent pedagogical aspects" while the back face (digital technology - learner - mathematical content) concerns "content-specific learning pathways" (Prediger, Roesken-Winter, & Leuders, 2019, p. 411).

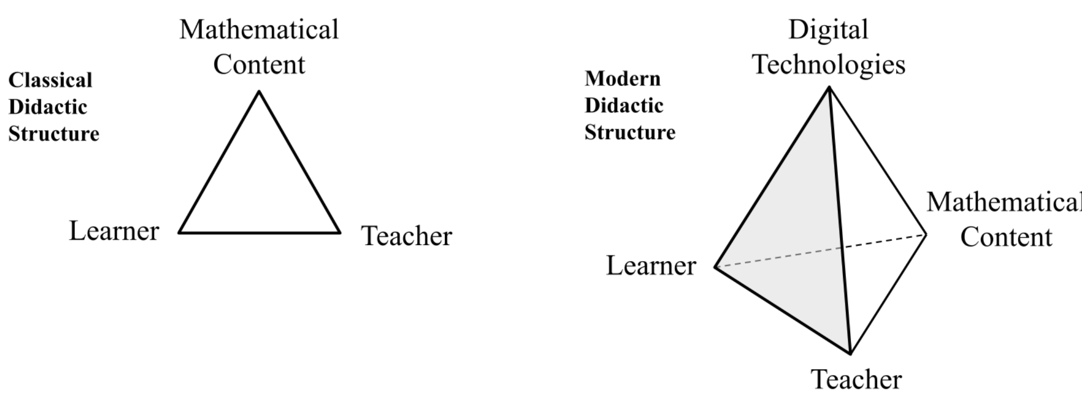

Figure 2. The classic didactic triangle and a modern didactical tetrahedron

When the global pandemic hazard interacted with this educational structure, the classic didactic face was excised from the modern didactic tetrahedron, triggering a disaster, shown in Figure 3. For example, video conferences took the place of office hour conversations between learner and teacher, digital whiteboards replaced chalk-boards, and 2-dimensional digital representations approximated 3-dimensional demonstrations. While technology can be of great value in the classroom, the tragedy was that unexpectedly*, all learning was mediated by technology*. Our emergent themes are inseparable from the digital backdrop in which they occurred.

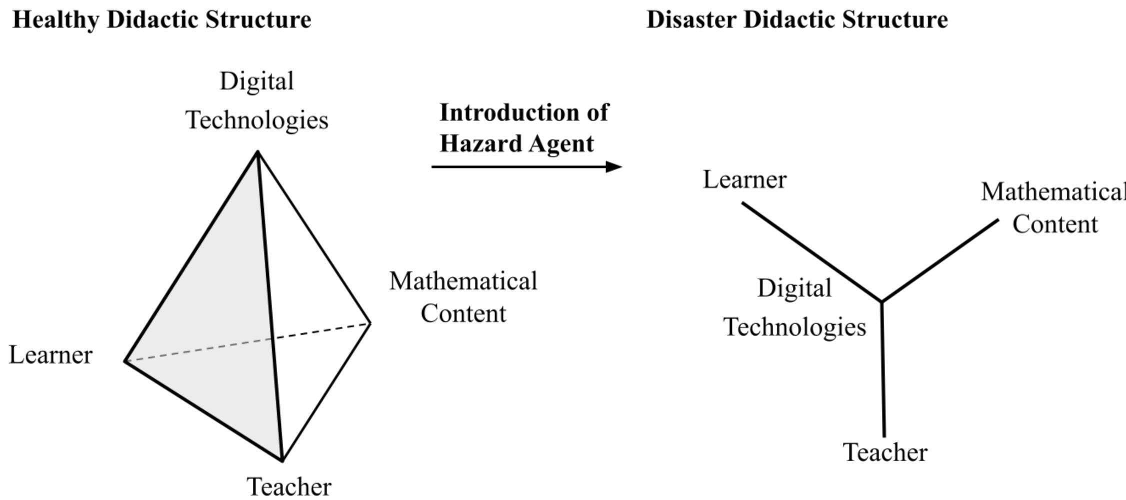

Figure 3. The excised didactic tetrahedron after the introduction of the COVID-19 hazard

A Summary of Vulnerability: The Gap Between Capability and Liability

We will discuss the most common points of capability and liability internal to the emergency remote classroom: internet access & quality, faculty digital literacy, content resources, and communication. Because the gap between capability and liability indicates vulnerabilities in our system, our goal is to understand the broad range of experiences wherein some students did not adapt to emergency remote instruction (see Figure 4). In Table 5, we provide a table with the number of students who experienced each item as a capability and the number of students who experienced it as a liability.

Internet quality & access. Students described inadequate internet as an obstacle to participating in their courses. One student wrote, *"My internet connection is terrible at home, leading to rushes or unfinished assignments."* Some students simply did not have the internet available at their home because of their isolated location (such as on a reservation) or, while the internet was available, it was too costly and they had to wait for COVID relief funds in order to afford it. Students with quality internet celebrated how it improved their access to content and digital resources that assisted in the learning process. One writer described, *"Having the internet and other resources DURING class helped guide learning."*

Faculty digital literacy. Sometimes faculty were not effectively using the available technology to convey course material, i.e. writing on a real-life chalkboard out of view of the webcam. More frequently, students shared how their instructor did not know how to use a program or the video conferencing software. One student wrote, *"My teacher did not know how to use technology and had endless problems that resulted in no lectures some days… "* When an instructor was comfortable with their technology, students appreciated how their remote course felt just like an in-person course. One writes, *"Both of my professors were extremely flexible. I especially appreciated their multiple formats of lecture notes and use of tablet technology to annotate the screen live as they went through content."* In fact, some faculty utilization of digital technology allowed their students to learn better than they would have without these tools.

Digital course documentation. Overwhelmingly, students want video recordings of their lectures to access later. One student expressed, *"being able to record the lectures so i can go back whenever i wanted if i needed help or forgot something was like a miracle happened."* That being said, other students warned that video recordings can hinder their learning process. For example, a student wrote, "*Do live lectures instead of recorded lectures because student will just skip through recorded lectures and there's less incentive to watch them*," while another confided, "*I also lost motivation to attend the Zoom lectures, telling myself that I would watch the recordings, but more times did not*." Other students were frustrated with a lack of documentation of their courses, or they found the quality to be poor. Sometimes a big delay in the posting of lecture recordings left students without the necessary support to participate in their courses.

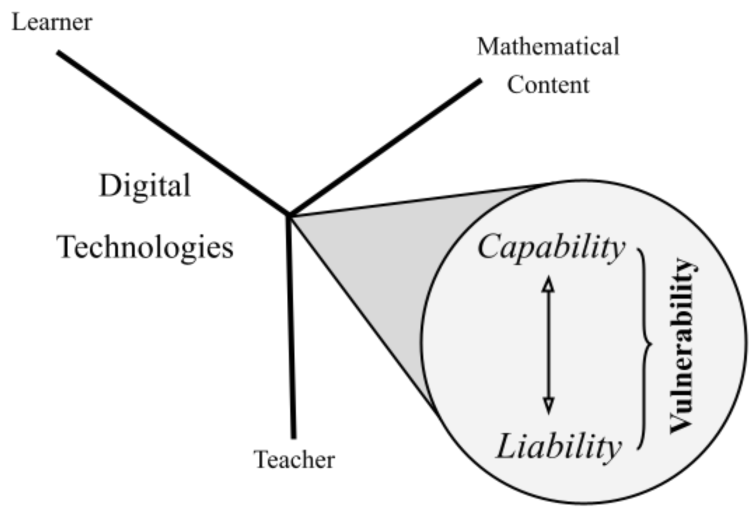

Figure 4. A gap indicates vulnerability in the system

Table 5. Capability and liability frequencies among the 461 participants.

Number of students for which it was a…	**Capability**	**Liability**
Internet Access & Quality	14 (**3%**)	74 (**16%**)
Faculty Digital Literacy	43 (**9%**)	96 (**21%**)
Internal Content Resources	192 (**42%**)	37 (**8%**)
External Content Resources	36 (**8%**)	-
Communication with instructor	160 (**35%**)	120 (**26%**)
Communication with peers	48 (**10%**)	96 (**21%**)

Online communication. Communication with the instructor was extremely important to students. Many expressed frustration that they could not interact in the way they had before the pandemic, for example, *"I think it was harder to ask questions online and explain where you are going wrong because I couldn't actually show my teacher my work."* Other students felt like they could not reach their instructor, with one sharing, *"It became difficult to reach my teachers. They didn't respond to emails and would quite often cancel their office hours."* For some students, online communication is much more comfortable than in person interactions. One participant confided, *" the general anxiety of in-class lectures and having to stop a lecture to ask a question in a giant room of 200+ people was eliminated with zoom questions. It was very easy to communicate mid/post-lecture with my professor and ask questions."*

Roughly two thirds of students who mentioned communication with their peers in the remote classroom discussed how much they missed the in-person experience and the limitations of online engagement. One wrote, "*Breakout rooms for group work don't really work half the time, no one likes to talk over zoom."* For some students, group work online created anxiety: *"It is already stressful enough to work with strangers in person, but that is expected. Trying to work with strangers online is even worse and ends up with no work getting done."* On the other hand, one third of students were satisfied with the online connections that they formed, with one participant explaining, *"I was able to better connect with the people online, as that I don't particularly like in-person speaking, and could more effectively be a better classmate when someone is stuck, and even make better friendships."*

Symptoms of Disaster

We also monitored responses for signs of negative outcomes after a disaster, such as fatalism (Zakour & Gillespie, 2013). Table 6 shows the number of students exhibiting fatalism or erosion of social trust. One student wrote, *"quit school. don't even bother with online learning,"* while another gave the advice, *"Mute your mic if you need to cry."* Some felt abandoned by their instructor: *"My teacher gave up on my class when we went online,"* while others felt abandoned by their country: *"why care about a math test when my country is letting thousands die?"* There were several outpourings of anger at the university, the math department, or the instructor.

Table 6. Fatalism & erosion of social trust frequencies among the 461 participants.

Number of students exhibiting signs of...	
Fatalism	47 (**10%**)
Erosion of Social Trust	28 (**6%**)

On the other hand, we also saw plentiful signs of students adapting to the emergency. A student shared, "*I just want teachers to know they are appreciated for their hard work during this weird time in our lives*," and another wrote "*Stay positive and keep doing what you are doing. We appreciate everything you've done for us!*"

Discussion and Conclusion

Internet infrastructure is a nation-wide level concern. This summer the National Telecommunications and Information Administration (NTIA) released an interactive map that shows the areas of the United States where citizens are not utilizing high-speed broadband internet (McGill, 2021). When triggered by the COVID-19 hazard, this infrastructure liability led to greater harm for certain students. As departments and individual teachers, we are not able to correct this vulnerability, but we can take measures to lessen the harm done to students by adopting a position of grace and understanding.

Prior to 2020, there was a well-documented gap between the digital technologies available and faculty utilization of these resources (Bourrie, Jones-Fermer, & Sankar, 2016). One primary cause is lack of training and support at the university level. TopHat surveyed 808 higher education faculty and support staff in the United States and Canada and found that “40% and 38% of respondents who indicated that learning to use tools to teach synchronously and asynchronously, respectively, has either been a small or non-existent part of the training they received” (TopHat: Higher Ed, 2020). With the increased expectations on faculty to use digital resources in the classroom, we hope to see universities invest more in support and training in these technologies.

Increased documentation of what occurs during class has both the potential to increase access to learning as well as to harm the learning process. From the lens of inclusive education (Moriña, 2017) or becoming a “student-ready-college” (McNair, Albertine, Cooper, McDonald, & Major, 2016), recording class allows students with disabilities or students experiencing a challenge in their personal life to still engage in education. However, increased documentation may lead to students engaging in rote learning, rather than deeper comprehension of the subjects. In fact, Lithner explains that this problem with memorizing over understanding predated the pandemic: “the gravity of the problem, as a main cause behind learning difficulties, is not fully apprehended by students, teachers, textbook writers, syllabus constructers, administrators, politicians, and perhaps also among many researchers” (2008, p. 273). Further, prior to the pandemic, Muir found that online and in-person students utilized online resources differently (2013). With the blending of the online and face-to-face modes, further research is warranted into course documentation that both supports inclusive education while also fostering relational understanding over memorization.

The importance of communication in an effective emergency remote course is becoming well-documented, see (Lanius, Frugé Jones, Kao, Lazarus, & Farrell, 2022), (Pagoto et al, 2021), or (TopHat: COVID-19, 2020). This area is one where individual instructors can make an impact, lessening the gap between capability and liability, removing a vulnerability in our educational systems. It is unreasonable to expect a single instructor to reply to a massive volume of student emails. However, by adopting more novel modes of communication, such as a digital platform which allows students to ask questions in a class forum, instructors can find ways to effectively and efficiently meet this student need.

Research limitations. The primary limitation of our data collection is that we administered it through the internet, which poses a serious obstacle to documenting the experience of students without internet access. We also may have a negative response bias, where students with a negative experience with emergency remote learning might be more likely to respond.

Future directions. We conducted a follow-up survey in Summer 2021. We will complete an analysis to see how our educational systems fared in a prolonged disaster state. In our 2020 data, we see a potential for online education to decrease anxiety for some students. We will further explore what aspects of the online environment can alleviate anxiety and how that might be incorporated into the in-person classroom. Finally, with heightened documentation in classes, we plan to explore how students are utilizing resources and the impact on their understanding.

Isis Quinlan
Virginia Tech

We present the results of a classroom teaching experiment for a recently designed unit for the Inquiry-Oriented Linear Algebra (IOLA) curriculum. The new unit addresses orthogonality and least squares using Realistic Mathematics Education design principles with the intent to implement the new unit in an IOI (Inquiry-Oriented Instruction)-style classroom. We present an analysis of students' written responses to characterize how they thought about the notion of shortest distance, travel vectors, orthogonality, and dot product in the "Meeting Gauss" context.

Keywords: Linear Algebra, Inquiry-Oriented Instruction, Least Squares Method

Least squares in linear algebra is often introduced as a method for finding the "best possible solution" when solving a system of linear equations, a vector equation, or a matrix equation that has no exact solution. As part of a larger research project involving designing new linear algebra task sequences for classrooms implementing inquiry-oriented instruction (IOI), we designed a task sequence, the "Meeting Gauss" unit, that would facilitate student exploration in $\mathbb{R}^3$ of the notion of "best possible solution" and lead to the reinvention of the approximation equation $A^T A\hat{\boldsymbol{x}} = A^T\boldsymbol{b}$, least squares solution $\hat{\boldsymbol{x}}$, projection, and least squares error. In the Meeting Gauss task, students were asked if they could reach Gauss' location using three transportation vectors. Students determined they could not reach Gauss and were tasked with finding a location that is closest to Gauss' initial location. Gauss' location is represented by a vector, $\boldsymbol{g}$, in $\mathbb{R}^3$ located off the plane that is the span of the transportation vectors. The shortest distance Gauss could travel corresponds to the magnitude of the orthogonal vector pointing from Gauss' location to the plane. We notate the shortest distance between Gauss and the meeting location as the length of $\boldsymbol{e}$ (error) to be minimized and the vector from the origin as $\boldsymbol{p}$ (Figure 1).

In this paper, we analyze two "snapshots" of student reasoning from the first and second day of a classroom teaching experiment (CTE) (Cobb, 2000) using students' reflection writings as data. Our research question is: *How do students interpret and use notions of shortest distance and travel vectors when learning least squares through an inquiry-oriented task in a linear algebra class?* We investigate various ways students interpreted finding the "shortest distance" (i.e., how students determined which direction Gauss should travel so that his trip is the shortest possible distance). Further, we characterize students' interpretations of the relationships (e.g., orthogonality, projection) that we perceive as important aspects for learning least squares.

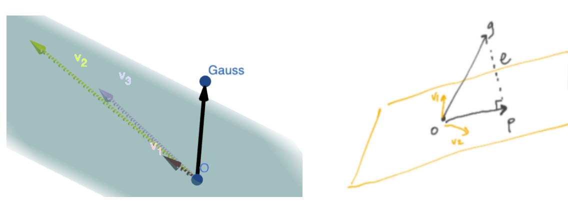

Figure 1. Meeting Gauss task setting in GeoGebra (Left) and Class instruction (Right)

Background Literature and Theoretical Framing

There is little literature on the teaching or learning of least squares or closely related topics within the context of linear algebra. Turgut (2013) created a lesson in which students used Mathematica to solve least squares problems involving finding lines or curves of best fit. He reflected on how students' use of these tasks incorporates Harel's (2000) concreteness, necessity, and generalizability principles. Donevska-Todorova (2015) used Hillel's (2000) three modes of description (arithmetic, geometric, and axiomatic) to explicate three definitions of dot product. Arithmetic referred to multiplying vector components and adding. Geometric referred to the cosine definition and the axiomatic definition was in terms of general properties. She also designed an applet to support students' understanding of dot product of vectors in a dynamic geometry environment (DGE). Cooley et al. (2014) created a module for teaching dot product using the cosine of the angle between two vectors. Their task sequence focused on comparing frequency vectors to determine whether or not the same author wrote two different texts.

Our instructional materials were designed to support students' ideas and support instructors in facilitating conversations around students' ideas. Students make mathematical progress as they participate in class and group discussion, ask questions, and explain their ideas. Instructors guide classroom activity by encouraging students to share their thoughts, asking their thinking about how and why they make decisions, and leveraging their ideas to move forward. Specifically, for developing our instructional sequence, we adopted the instructional design heuristics of Realistic Mathematics Education (RME) informed by Freudenthal (1991). When designing instructional task sequences, we leveraged the notion of *guided reinvention* to support students' transition towards more formal mathematics (Gravemeijer, 1999). From the students' perspective they are not re-inventing anything, our intent with the least squares task sequence is to support students in advancing their mathematical activity through symbolizing, algorithmatizing, and defining (Rasmussen et al, 2005). We designed the "Meeting Gauss" task in the least squares instructional sequence to be an experientially real starting point. This is similar to the Magic Carpet task in the first unit of the IOLA curriculum (Wawro et al., 2012; Wawro, Zandieh, et al., 2013). Students could engage in mathematical activity immediately, and their initial activity should constitute a basis for more formal mathematization.

Rasmussen and Keene (2019) used a river journey metaphor to capture what many in the mathematics education research field know as hypothetical learning trajectories (Simon, 1995). We use the river journey metaphor intentionally to move away from the image of a learning trajectory as a singular path that a researcher hypothesizes as the only way to learn a particular idea. We agree with Rasmussen and Keene that the image of a learning trajectory as the only path to learn a mathematical idea is not representative of the learning process. Further, Rasmussen and Keene utilized the notion of waypoints (Corcoran, Mosher, & Rogat, 2009) from the learning progression literature as "islets" within their river journey metaphor, acknowledging that students may, or may not, visit each of the islets (waypoints) outlined in the river journey (learning progression). To be clear, Rasmussen and Keene's waypoint journey for student reasoning about ODEs is a hypothetical research tool stemming from seven semester-long classroom teaching experiments and years of design-based research. The waypoint journey presented here is more of a "first journey down the river" in the context of a new task being used in an Inquiry-Oriented Linear Algebra (IOLA) classroom for the first time.

Methodology and Research Setting

This study is a part of a larger linear algebra curricular development project funded by the NSF. We conducted a classroom teaching experiment (CTE) to study the first implementation of our instructional sequence and to study how students' reasoning evolves throughout the task sequence (Cobb, 2000). The tasks implemented in the CTE used an *experientially real* situation designed to help students *reinvent* the least squares method. The CTE was conducted with STEM students in two Linear Algebra classes at a large public university of the Southeastern United States. Due to COVID-19, the course was taught synchronously online via Zoom. The course prerequisite a B or better in Calculus I or passing Calculus II. There were 33 students enrolled in one class and 38 students in the other. The CTE lasted four consecutive class days over the course of two weeks towards the end of semester. The fourth author was the course instructor and last author acted as a TA throughout the semester. The breakout group composition was kept as consistent as possible unless student absences necessitated the rearrangement of groups. In total, 22 students consented for their work to be used in research.

Description of the Task

The Meeting Gauss task begins with a callback to a previous IOLA task from earlier in the semester[1]. The vectors $\boldsymbol{v_1}, \boldsymbol{v_2}$ and $\boldsymbol{v_3}$ are presented as three modes of transportation, Gauss lives at a location $\boldsymbol{g}$ in 3D, and students are trying to determine where they can meet Gauss. The Meeting Gauss task is comprised of two parts (Figure 2): (1) investigate if it is possible to reach Gauss at his specific location using the three modes of transportation, (2) explore the trips that you and Gauss should make given the fact that Gauss needs to meet you somewhere you can reach because his house ($\boldsymbol{g}$) is not reachable using the given modes of transportation (i.e., the travel vectors).

Part 1. Remember those modes of transportation you used for 3D travel?

They were $\boldsymbol{v_1} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \boldsymbol{v_2} = \begin{bmatrix} 6 \\ 3 \\ 8 \end{bmatrix}, \boldsymbol{v_3} = \begin{bmatrix} 4 \\ 1 \\ 6 \end{bmatrix}$

Let's say they are a hoverboard, magic carpet, and jetpack, respectively.

Using those modes of transportation, can you get to Gauss if he lives at $\boldsymbol{g} = \begin{bmatrix} -1 \\ 1 \\ 4 \end{bmatrix}$

Part 2. Gauss agrees to meet you somewhere you can actually reach. He wants his trip to be the shortest distance possible. So, our big guiding questions are:

a) Where should Gauss meet you?
b) Along what vector would Gauss travel to get to your meeting point?
c) What distance would Gauss's trip be?
d) How would you get to your meeting point using your modes of transportation?

Figure 2. Statement of the Meeting Gauss task

On Day 1 of the CTE, students discussed their ideas related to Part 1 in breakout rooms. At the end of class, students were asked to write a reflection giving their initial thoughts, intuitions, or ideas for questions a)-d) of Part 2. On Day 2, the instructor began class by incorporating many of the students' reflection writings into her mini-lecture. The instructor highlighted students' reflections that incorporated Gauss' shortest trip distance and the span of the travel vectors. In the first breakout session of Day 2, students used two previously created GeoGebra applets to further explore the second part of the Meeting Gauss task. Many of the breakout groups used the applets to obtain estimates for Part 2, questions a)-d). Afterwards, students were called back to the whole class session to share their ideas with other groups and to listen to a set of mini-lectures about lengths of vectors and dot products. In addition to the given transportation vectors $\boldsymbol{v_1}, \boldsymbol{v_2}, \boldsymbol{v_3}$, and the Gauss vector $\boldsymbol{g}$ from Part 1, the instructor defined the vector Gauss travels

[1] In particular, Task 3 from the "Magic Carpet Ride" unit, which introduced linear independence (Wawro et al., 2012).

along as $\boldsymbol{e}$ and the vector from the origin to the meeting point as $\boldsymbol{p}$ (as pictured in Figure 1). In the second breakout session, students were tasked with using the given information and mathematical relationships developed during class (see Figure 3) to provide exact solutions to a)-d). After Day 2, students wrote a reflection summarizing the progress either they or their group made in finding the exact answers for questions a)-d) along with something that was clear and something that they wondered about.

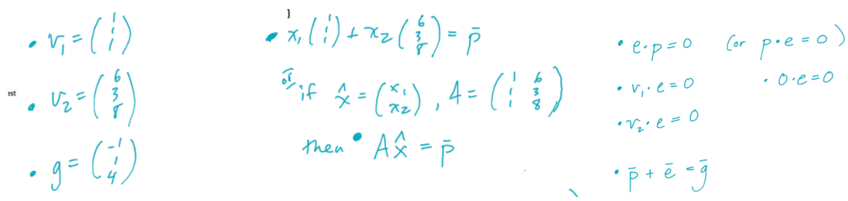

Figure 3. The known information and mathematical relationships developed during class.

Data Sources and Analytic Method

Our data sources include classroom videos, breakout group videos, Jamboard pages, and students' reflections. The whole class discussions and the breakout sessions were recorded via Zoom by the last two authors. The students used Jamboard to communicate and record their work in breakout rooms. Students' reflection writings submitted after Day 1 and Day 2 of the CTE were our main data source. The first two authors watched the whole class discussions and breakout group videos to gain a sense of how class was organized. The first two authors reviewed the Jamboard pages to see how students expressed their mathematical ideas during the breakout discussion. Consenting students were given pseudonyms, and their reflection writings were deidentified and transcribed by the last author. The first two authors engaged in open coding (Strauss & Corbin, 1990) of all four days of student reflections. A code book was created from attending to both (1) student thinking and (2) their descriptions of their methods/symbolization. We used our set of 26 initial codes to analyze students' Day 1 and Day 2 reflections line by line in a spreadsheet. After our initial pass at coding students' Day 1 and Day 2 reflections we identified several categories that emerged within and across our codes. Figure 4 displays our final categories and codes, which were agreed upon by the first three authors. Our process of creating an initial set of codes that identify trends within and across our data is consistent with an emergent coding method (Glaser & Strauss, 2017).

Results

Our findings can be thought of as two snapshots on the river journey. The first snapshot captured students' reflections at the end of Day 1. From their reflections, students were beginning to recognize a number of features of the Meeting Gauss scenario and how those are related. Day 1 reflections are grouped into two themes: (1) shortest distance and (2) the location of the transportation vectors. Students wrote about shortest distance as (1) a point-to-point trip, (2) an orthogonal/perpendicular direction, and as (3) ways to find the distance including the distance formula, the Pythagorean theorem, and trial and error. The second snapshot captures students' reflections at the end of Day 2. From their second reflection, students had moved down the river in various ways. We grouped their writing into (1) a more developed notion of the error vector, $\boldsymbol{e}$, as perpendicular to the plane and transportation vectors, (2) the dot product as providing information about orthogonality and ways to calculate relationships between vectors, and (3) the use of matrix multiplication and systems of linear equations (SLEs) to symbolize the relationships between the perpendicular vectors in ways that allow for finding the error vector.

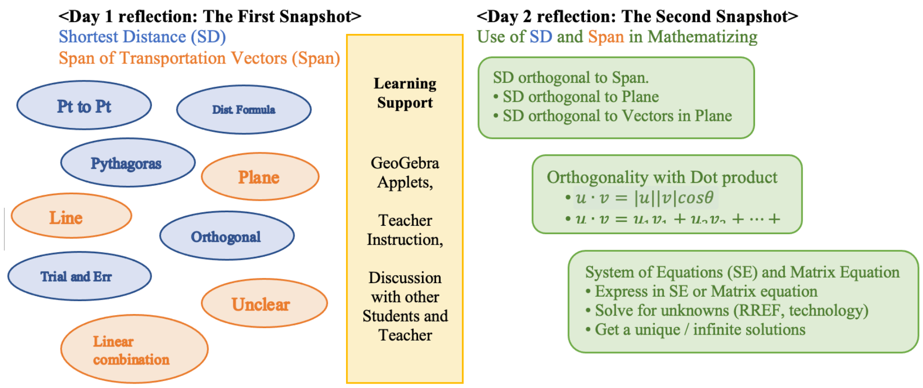

Figure 4. Overview of codes from students' Day 1 and Day 2 of the CTE reflection writing.

First Day of the CTE Snapshot Analysis

On Day 1, most students used row reduction to conclude that Gauss is not reachable using the transportation vectors (see Figure 5). Some students included geometric explanations in their reflections including descriptions of how the span of the transportation vectors was a plane.

Figure 5. A snippet of a group's Jamboard from working on Part 1 of the Meeting Gauss task.

Most students recognized that Gauss can travel around freely to meet the traveler, but the traveler's movement is restricted to use of the given transportation vectors. We will now present examples from students' reflections demonstrating our codes pictured in Figure 4.

Interpretation of shortest distance. Our analysis revealed that students' intuitive notions of Gauss' shortest travel distance included ideas such as *point-to-point distance* and *orthogonality*. Ten students answered that they needed to determine the shortest distance between two points: Gauss' location and the point on the plane closest to Gauss. For example, "We can *minimize the distance* from the *point to a point,*" (Cecil), and "Gauss should take *the shortest distance from his point* (-1, 1, 4) *to the closest point on the plane* our transportation modes cover," (Iliana). Some of the students' thinking of the *point-to-point distance* indicated that they would apply the distance formula or a calculus-based methods to minimize the distance. Five students noted that Gauss's path is perpendicular to the plane. Some of those students also noted that the span of the travel vectors is the plane. For example, "If I had to imagine, Gauss would *travel in a straight line orthogonal to the plane* formed by the three vectors," (Liam) and "…*the vector he travels along should be perpendicular to the final mode of transportation's vector*" (Luka).

Some students mentioned how they would calculate the shortest distance. We view each of the following methods used for measuring the shortest distance as related to *point-to-point distance* thinking: *distance formula*, *Pythagorean theorem*, and *trial and error*. Three students explicitly mentioned that they would apply or did apply the distance formula. For example, "Not sure how to calculate distance, *maybe plot the vectors and then use distance formula,*"(Damien). Tuan did apply the distance formula "Distance: sqrt((-1-(-1))^2+(-1-(-2))^2+(-1-(-5))^2) =

sqrt(0+1+16) = sqrt(17)," There were two students who mentioned they would use the Pythagorean theorem to find the shortest distance. For instance, "We could use *pythagroas theorem to find the distance* of the projection," (Anton).

Interpretation of transportation vectors. Our analysis further revealed that students thought about the transportation vectors in various ways. Some students tended explicitly to the notion of span such as *vectors generate the plane* or *vectors generate a line*. While 13 students mentioned the transportation vectors generate the plane, not every student explicitly mentioned where the plane came from. Other students explicitly used the terms span or linear combination in their descriptions. For example, "The way I am thinking about this is to locate *a spot that is within the area that the 3 vectors span,*" (Ani), "Since Gauss is getting to *the plane that is the span of the three modes of transportation*, a *linear combination* of the three vectors will get us there as well," (Lureyna). Lureyna's response tends specifically to both the idea that the span of the transportation vectors creates the plane, and the traveler must use those modes of transportation to reach the meeting point with Gauss.

Second Day of the CTE Snapshot Analysis

In the following three subsections, we briefly outline the various sections of the river that students went down in the second snapshot from Day 2 of the CTE. Each subsection corresponds to one of three groupings of students' responses outlined in Figure 4.

The 'e' (error) vector is orthogonal to the plane. Our analysis revealed that students' description of orthogonality between the vector $\boldsymbol{e}$ and the plane is multifaceted. We categorized their descriptions into two ways: (1) The $\boldsymbol{e}$ vector is orthogonal to the plane, (2) The $\boldsymbol{e}$ vector is orthogonal to the vectors that constitute the plane. For example, "...We knew that *the line of travel from Gauss to the plane must be orthogonal to the plane*..." (Bianca). From Bianca's response, we see that she made a connection between the plane and the orthogonal path to said plane. On the other hand, some students stated the **e** vector is orthogonal all vectors parallel to the plane. For instance, "I know that *e has to be orthogonal to p and v1, v2,*" (Annalisa).

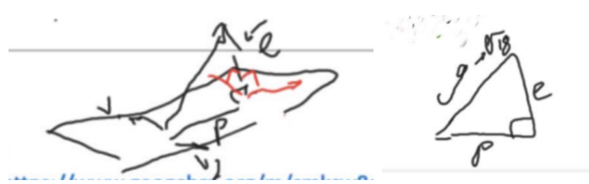

Figure 6. Lucia's pictures from her CTE Day 2 reflection

Dot product and orthogonality. After students returned from the first breakout group session, the instructor gave a set of mini-lectures deriving the lengths of vectors and defining dot product. Students' written descriptions about how they thought about dot product was subtle and sometimes difficult to characterize. For example, Lucia stated (Figure 6, right), "The vectors p and e create vector g, from origin to Gauss, *and the dot product of p and e is zero because they are perpendicular,*". Lucia seemed aware that orthogonality is related to dot product. She also mentioned " We had *tried to combine the statements p·e=0, e·v1=0, and e·v2=0 into one big equation*, and *I think you can eliminate the ||e|| from all sides*, but the issue is that *I do not know how to get the angles between the different vectors* and such," (Lucia). From Lucia's complete response, it was possible to determine she was leveraging the cosine definition of the dot product in her thinking. Further, some students expressed the orthogonal relationship between the error vector ($\boldsymbol{e}$) into a system of dot product equations (Figure 7, left). Other students mentioned that they knew they could use the dot product equations in some manner, but it was unclear if they were thinking about orthogonality. There were some students who seemed to try connecting dot product with the transportation vectors and the $\boldsymbol{e}$ vector but were not comfortable with the transition towards a more formal mathematical expression. For example, "...looked at *plugging in the v1 and v2 vectors into their dot product equations with e* ...using the coefficients we found as a matrix, *whose dot product with e was 0*. This didn't make much sense to me..." (Iliana).

Systems of equations and the matrix equation. Some students appeared to be moving towards formalizing the notion that the $\boldsymbol{e}$ (error) vector was orthogonal to each travel vector to create a matrix equation $\boldsymbol{A^T e} = \boldsymbol{0}$ using their system of dot product equations. For example, "From the dot product of e and v1 and the dot product of e and $v2$, we were able to create a matrix, $[[111], [638]]$, which when multiplied by e would equal 0... if two vectors are orthogonal, their dot product must be zero, which is very helpful..." (Lureyna) and "...we had the matrix A that was $v1$, $v2$ times $e\ (x\ y\ z)\ = 0$…but didn't know where to go from there...I know that e has to be orthogonal to p and $v1, v2$," (Annalisa). Other students, like Cecil (Figure 7, middle), expanded his dot product equations into a system of linear equations (SLE). Cecil used a SLE to write a matrix equation that we recognize as $\boldsymbol{A^T e} = \boldsymbol{0}$. We are unsure how Cecil thought about the result of his row reduction since he stopped after row reducing.

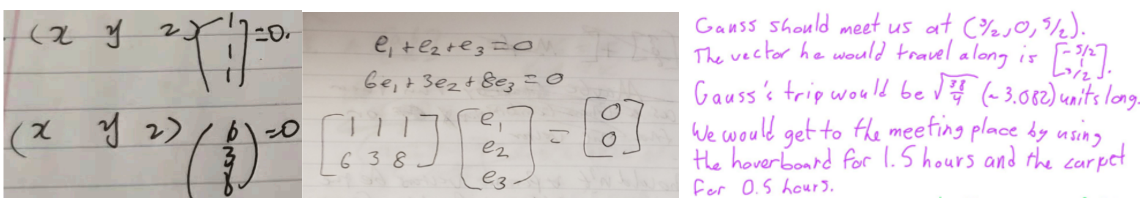

Figure 7. Min's(Left), Cecil's (Middle), Vaki's (Right) written solution.

Discussion

In the first journey down the river of developing the least squares solution method, we see that some of the students leveraged their intuitive notions of shortest distance and the span of the transportation vectors towards a more formal symbolization using the dot product. Students traveled down the river in their own way, spending different amounts of time on each piece of the river journey as seen in the variety of answers within both snapshots. One takeaway is that the least squares river journey may require more time in more areas than others. Vaki was one of the only students to interpret $\hat{\boldsymbol{x}}$ as the amounts to travel on each mode of transportation to meet Gauss. This meaning of $\hat{\boldsymbol{x}}$ is what we as experts recognize as the least squares solution to the Meeting Gauss context. This paper is limited to an analysis of the first two days of the CTE. Future work may investigate students' progress on the final two days in formalizing their thinking towards reinventing the least squares solution $\hat{\boldsymbol{x}} = (A^T A)^{-1} A^T \boldsymbol{b}$. On our next journey down the least squares river, we intend to reflect on where students ended at the end of each day of the CTE to inform future revisions of the Meeting Gauss context within the IOLA curriculum.

Learning to Teach Reasoning and Proof in an Online Setting: The Case of Nancy

Jinqing Liu
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Preparing prospective secondary teachers (PSTs) to teach mathematics with a focus on reasoning and proving is an important goal for teacher education programs. A capstone course, Mathematical Reasoning and Proving for Secondary Teachers, *was designed to address this goal. One component of the course was a school-based experience in which the PSTs designed and taught four proof-oriented lessons in local schools, video recorded these lessons, and reflected on them. In this paper, we focus on one PST – Nancy, who took the course in Fall 2020 during the pandemic, when the school-based experience moved online. We analyzed how Nancy's Mathematical Knowledge for Teaching Proof (MKT-P) evolved through her attempts to teach proof online and through repeated cycles of reflection.*

Keywords: Reasoning and Proof, Prospective Secondary Teachers, Online Teaching, Reflection.

Supporting prospective teachers developing skills needed to teach mathematical reasoning and proof is an important goal of mathematics teacher preparation (Association of Mathematics Teacher Educators, 2017). However, there is limited theoretical or practical knowledge on how to provide prospective teachers with such support (Stylianides, Stylianides, & Weber, 2017). To address this knowledge gap, Buchbinder and McCrone (2018, 2020) developed a capstone course *Mathematical Reasoning and Proof for Secondary Teachers* and studied the development of PSTs' dispositions towards proof and Mathematical Knowledge for Teaching Proof (MKT-P), with a particular focus on the manifestations of MKT-P in classroom practices. Among other things, this involves an ability to plan and enact proof-oriented lessons.

The breakout of the global pandemic and the schools' pivoting to online teaching in 2020 put additional demands on PSTs who had to learn how to teach proof online "on the spot." We report on a case study of one such PST, Nancy (a pseudonym), who successfully surmounted these challenges. Rather than choosing a "representative" case, by focusing on a successful and articulate PST like Nancy and studying her learning processes and strategies, we hoped to gain insights that could inform the mathematics education community (Seawright & Gerring, 2008).

Theoretical Framing

Mathematical Knowledge for Teaching Proof

It has been suggested that in order to support students' learning of reasoning and proof, teachers need a special type of knowledge: Mathematical Knowledge for Teaching Proof (MKT-P). Several researchers (e.g., Lesseig, 2016; Stylianides, 2011; Steele & Rogers, 2012) proposed frameworks delineating the components of MKT-P and the relationships among them. Akin to Steele and Rogers's (2012) approach, Buchbinder and McCrone (2020) conceptualized MKT-P beyond declarative knowledge captured by written tests to include related classroom practices. Their resulting framework comprised three facets: Knowledge of the Logical Aspects of Proof (KLAP), Knowledge of Content and Students (KCS-P), and Knowledge of Content and Teaching (KCT-P). Each knowledge facet has its corresponding classroom practices. In the context of mathematics classrooms, KLAP corresponds to the use of precise mathematical language and notation adjusted to students' grade level, and the remediation of students' reasoning errors.

KCS-P corresponds to facilitating discussions that address students' common proof-related misconceptions and make proof concepts explicit. KCT-P corresponds to designing and enacting proof-oriented tasks. The three knowledge facets are interrelated, e.g., designing proof-related tasks (KCT-P) requires knowledge of students' proof-related conceptions (KCS-P) and proof-specific subject matter knowledge (KLAP). Distinctions between the MKT-P facets aided the design of learning experiences enhancing PSTs' MKT-P and the design of MKT-P assessments both in written form and through lesson planning and enacting (Buchbinder & McCrone, 2021).

Reflective Noticing

Teachers advance their professional expertise by reflecting on teaching (Seidel et al., 2011), which, in turn, entails teachers noticing elements of classroom environments that are most likely to support student learning (Sherin, Jacobs & Philipp, 2011). Although many definitions of noticing exist, we follow Stockero's (2021) definition of noticing as comprised of attending and interpreting. While noticing is often tacit, reflecting requires conscious engagement and processing. In this paper, we use the term *reflective noticing* to capture both of these processes.

There are several types of reflection according to timing: reflection-*in*-action, which occurs during teaching; reflection-*on*-action, which occurs after teaching (McDuffie, 2004; Schön, 1987), and reflection-*for*-action, which connects particular events to future actions (Jay & Johnson, 2002). Since merely descriptive, anecdotal, or non-critical accounts of teaching have little benefits for learning, researchers suggested that *productive* reflection entails attending to multiple aspects of classroom environments; interpreting, analyzing, and integrating them, and connecting them to theoretical principles, future actions, and past experiences (Moore-Russo & Wilsey, 2014). We take the last part of this definition - connecting to the past experiences –as yet another type of reflection: reflection-*back*.

Although PSTs often do not have access to classrooms, whenever possible, PSTs should be encouraged to reflect on their teaching (Jacobs et al., 2010; van Es, 2011). Learning to notice and analyze classroom instruction has been shown to benefit PSTs' professional development (Stockero, 2021). Similarly, Buchbinder et al. (2021) identified a variety of learning opportunities afforded by PSTs reflecting on their own teaching using 360° video technology.

In this study, we examine an overarching question: "How did Nancy's MKT-P evolve as a result of her planning, enacting, and reflecting on four proof-oriented lessons? We operationalize this question by examining:

1. How did Nancy integrate reasoning and proof in her planned and enacted lessons?
2. What did Nancy notice in the video recording of her lessons; how did she reflect on her lessons, and what learning was afforded by this?

Methods

This study is a part of the larger project that designed and studied the capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020). The course includes four modules, each focusing on one proof theme: (1) direct proof and argument evaluation (DP); (2) conditional statements (CS), (3) quantification and the role of examples in proving (RE), and (4) indirect reasoning (IR). Each module includes activities to help PSTs *crystalize* their subject matter knowledge of a particular proof theme, *connect* that knowledge to students' proof-related (mis)conceptions and to secondary curriculum, and *apply* that knowledge through a structured, school-based teaching experience. In this experience, the PSTs *plan* a 50-minute lesson on a particular proof theme, *enact* the lesson with a group of students from local schools, record the lesson using 360° cameras that capture both students and the PST, and *reflect* on the lesson. This process repeats four times during a semester, once for each proof theme. In Fall 2020, due to the pandemic, the PSTs taught their lessons online, via *Zoom*. Otherwise, the structure of the course remained the same.

The Case of Nancy

Nancy was a senior mathematics education major in a high school certification track. Prior to taking the capstone course, Nancy completed a prerequisite course on Mathematical Proof, a proof-writing-intensive Geometry course, and one Mathematics Education course. Nancy was a straight-A student in both mathematical and educational coursework. She regularly tutored undergraduate students taking entry-level calculus courses at the university tutoring center but had no classroom teaching experience. Like other PSTs in the course, Nancy completed the pre- and post- MKT-P questionnaire and Dispositions towards Proof survey (Buchbinder & McCrone, 2021). Her high scores on the pre- instruments indicated strong mathematical knowledge and positive dispositions towards proof. In addition, Nancy was very articulate and active during the class discussions, making her a strong case to study (Seawright & Gerring, 2008).

Nancy was placed in Ms. Meyer's high school geometry classroom. Due to the pandemic, a yearly geometry course was condensed to one semester, and Ms. Mayer relied on Nancy to plan lessons closely aligned with her curriculum. Ms. Meyer taught the whole class via *Zoom* for about 30 minutes and then divided students into two groups: one group remained with her, while another group (6 – 7 students) learned with Nancy. Ms. Meyer determined the geometric topic of the lesson, while the capstone course schedule dictated the proof theme.

Data Sources and Analytic Techniques

Data sources include four of Nancy's lesson plans, four Zoom video recordings of the lessons, and four reflection reports. To analyze planned and enacted lessons, we used analytic techniques developed in our prior research (Buchbinder & McCrone, 2020), outlined here briefly.

We analyzed the *lesson plans* by first noting the percent of time planned for reasoning and proof integration. We also ranked each lesson plan on a three-point scale (high, medium, or low) on three dimensions: (1) the extent to which the plan focused on the intended proof theme, (2) the alignment between the objectives and the tasks, (3) how appropriate was the choice of technology for proof integration.

The videos of the *enacted lessons* were analyzed using the *Lesson Enactment Rubric* (Buchbinder & McCrone, 2020), aligned with the MKT-P framework. The rubric has three dimensions: quality of proof-specific language (KLAP), making the proof theme explicit to students (KCS-P), and actions for promoting student engagement with proof (KCT-P). Each lesson was ranked on a three-point scale (high, medium, low) on each of these three dimensions.

When completing the *reflection reports,* the PSTs watched the video on *Canvas* Learning Management System and used the commenting feature to write reflective comments for every 5-minutes, about 8-9 total comments per lesson. Using open coding (Strauss & Corbin, 1994) in conjunction with the noticing literature (e.g., Stockero, 2021; van Es, 2011), we identified four main categories of noticing in Nancy's comments. These are (1) *instructional decisions*, e.g., 'One teaching move that I liked during this lesson was creating a theme for the lesson."; (2) *student engagement*, e.g., "I was impressed that one of the students was able to see that"; (3) *technology*, e.g., "I think the transition from the *Prezi* presentation to *GeoGebr*a was pretty smooth," and (4) *time*, e.g., "I felt pretty crunched for time." We also coded whether Nancy reflected on-, for-, or back- on her teaching (see examples in the Results section).

Results

Abbreviated Summaries of Nancy's Proof-Oriented Lesson Plans

Lesson 1. *Direct proof and argument evaluation: Supplementary and Vertical angles.* Initial group discussion: "what makes a good two-column proof"? Expected responses: generality, mathematical correctness, but can follow different paths. Teacher-led exploration of Vertical angles theorem using *GeoGebra*; first with specific angle values, followed by a generalization. Students contribute ideas as the teacher writes the proof.

Lesson 2: *Conditional statements: Isosceles and Equilateral Triangles***.** Introduction of a conditional statement and its converse and using mathematical examples (*Prezi*). Student-led exploration in *GeoGebra* of three conditional statements about triangles. For each statement, students first determine if it is true or false (if false, construct a counterexample), then write a converse and determine whether the converse is true or false.

Lesson 3: *Quantification and the role of examples: Triangle Similarity Theorems.* Introduction of universal and existential statements; the role of examples in proving/disproving universal statements. A reminder of the three similarity theorems. Students work on one SSS similarity proof by typing their work on an individual slide in a shared *Google Slides* document. Next, students find counterexamples to three universal statements (e.g., All isosceles triangles are similar) and find confirming examples proving two existential statements (e.g., There exist two right triangles that are similar).

Lesson 4: *Indirect reasoning: Coordinate proofs.* The lesson is structured as a game, "The Quadrilateral Detective," where students use distance and slope formulas to determine what type of quadrilateral is given by a set of four coordinates. Next, students create two statements of the form "This quadrilateral cannot be ___, because otherwise ___," e.g., "The quadrilateral cannot be <u>a kite</u> because otherwise <u>it would have no pairs of parallel sides.</u>" After one teacher-led example, students work individually; write their proofs on paper, take a picture and paste it into a shared *Google Slides* document. Indirect reasoning is defined during the lesson summary as "a type of reasoning that shows that something is impossible since it leads to a contradiction."

As the description above shows, Nancy succeeded in integrating each of the four proof themes with the mathematical topics requested by Ms. Meyer in creative and engaging ways. Each lesson had 3-4 objectives, all focused on reasoning and proof, e.g., "Students will come up with counterexamples to disprove mathematical statements," and additional objectives related to student engagement in mathematical discussions. The tasks were closely aligned with the proof theme and with the mathematical content of the lesson. The lesson plans were written in a high level of detail. The percent of time planned for reasoning and proof in each lesson was above 67%, while the rest of the time was devoted to icebreakers in the beginning of the lesson and exit tickets at the end. Nancy's plans used a variety of technological tools: *GeoGebra, Prezi, Google Slides* to facilitate active student engagement.

Nancy's Enactment of the Four Proof-Oriented Lessons

Nancy's *enacted lessons* closely matched the planned ones in terms of content, but not the time. Nancy's lessons were planned for 30 minutes, but since the students had no other class afterward, they stayed between 34 to 56 minutes, allowing Nancy to finish all the planned activities. Table 1 summarizes the analysis of the enacted lessons. Throughout the lessons, Nancy used precise mathematical language and proof-specific vocabulary to discuss proof themes with the students. She used appropriate visual, symbolic, and verbal methods to make the main concepts and key ideas of the proof themes explicit to students. The percent of lesson time devoted to reasoning and proof was very high (above 80%), although the time devoted to the proof themes differed between the four lessons. The two proof themes: Role of Examples and Indirect Reasoning received much less class time and were less of the focal point of the lesson, which is consistent with the lesson plans. Nevertheless, Nancy still explicitly addressed these proof themes in her lessons. The first two enacted lessons - Direct Proof and Conditional Statements - were highly successful on almost all dimensions of the *Lesson Enactment Rubric*.

Table 1. Analysis of Nancy's Four Proof-oriented Enacted Lessons

Dimension on the *Lesson Enactment Rubric*	Lesson			
	1DP	2CS	3RE	4IR
Quality of proof-specific language (KLAP)	High	High	High	Medium
Explicating specific proof-theme (KCS-P)	High	High	Medium	Medium
Actions to promote student engagement (KCT-P)	Medium	High	High	High
Percent of time devoted to proof (KCT-P / KCS-P)	83%	84%	91%	82%
Percent of time devoted to the proof theme	83%	84%	30%	25%

Nancy's Reflective Noticing on the Enacted Lessons

Figure 1 shows the distribution of Nancy's categories on noticing in percent of the total number of comments, which varied by lesson. In the first lesson, Nancy mainly reflected on how her instructional decisions affected student engagement. In lessons two and three, the focus of reflection shifted away from instructional decisions towards technology and time management. This was when Nancy started having students themselves interact with technology (*GeoGebra*, *Google Slides*) providing space for productive struggle and free exploration. By doing so, Nancy had less control over the time spent on each planned activity and thus encountered challenges in coordinating technology, content, and time. The Indirect Reasoning lesson was most challenging for Nancy to enact, as evident in the percent of reflective comments focused on her instruction.

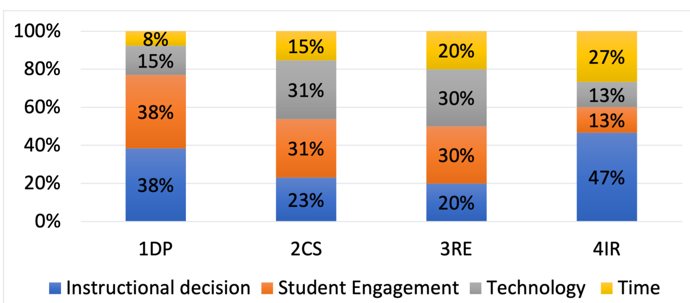

Figure 1. Distribution of Nancy's categories of noticing across four lessons

Table 2 shows the distribution of Nancy's reflective comments along with the four categories of noticing and the three types of reflection: *on, for* and *back*.

Table 2. Distribution of Nancy's categories of noticing and types of reflection

Categories of Noticing	Reflection on	Reflection for	Reflection back	Total
Instructional decisions	11	5	1	17
Student Engagement	6	6	2	14
Technology	6	4	1	11
Time	5	2	2	9
Total	28	17	6	51

Table 2 shows that the total number of Nancy's reflections-*on* (only) was much larger than the number of reflections-*for*, which, in turn, was larger than the total number of reflections-*back*. Most of Nancy's reflections-*on* focused on her instructional decisions. When reflecting-*for,* Nancy focused almost exclusively on instruction, students, and technology; when reflecting-*back* Nancy attended to all four categories.

The following excerpt illustrates the three types of reflection in Nancy's comments. In lesson #1, Nancy attempted to develop a set of criteria for a "good" proof with the students.

Nancy: What do you need [in order] to make our proof a good proof?

S1: Uhm, you need a proof.

Nancy: Yeah, so, we need a proof, right? So we need to be able to show that we can start with our given and then come up with our solution, right? So what are the parts are there in the proof? So we have two parts, right? So what are they to make up the two parts or the two columns?

When reflecting-*on* this exchange while watching the video, Nancy wrote: "one student said that you need a proof, when asked what makes up a "good" proof. This wasn't exactly what I was looking for. It was too general, but I tried to guide her response and make it more specific". Nancy followed by a comment reflecting-*for* the future: "What I should have done was ask the student directly and say something like "I like that idea, S1, what do you mean by that?" Then it would give her a chance to elaborate." In lesson #2, Nancy had a chance to act on her intentions and reflect-*back* on her improvement. She wrote: "I asked them what bisecting means. This is important because I wanted to make sure that they understood what the conditional statement was saying. […] I liked this part is because I asked this question as a follow up to a student's answer and that was something that I had mentioned wanting to work on after last time".

This progression shows how the three types of Nancy's reflections played out to support her gradual improvement of responding to student inputs and leading discussions about proof. Figure 2 shows the distribution of different types of Nancy's reflections in each lesson.

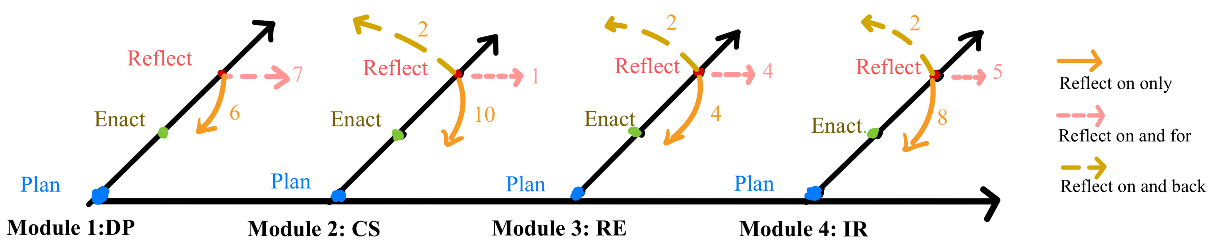

Figure 2. *Distribution of Nancy's types of reflection across four lessons*

Not surprisingly, the majority of Nancy's reflective comments were on the particular lesson she taught. Nancy learned from the teaching experience by making decisions on how to improve her teaching (reflecting-*for*) and kept herself accountable for these changes by reflecting-*back*. These processes supported Nancy's learning through reflecting on her own teaching practices.

Discussion

This paper examined the case of Nancy – a PSTs with a strong mathematical background and positive dispositions towards proof – as she progressed through a capstone course *Mathematical Reasoning and Proof for Secondary Teachers*. We attempted to trace how Nancy's MKT-P classroom practices evolved throughout the teaching experience component of the course. In particular, we focused on Nancy's ability to plan and enact proof-oriented lessons. Our analysis revealed that Nancy integrated the four proof themes with the topics from a regular geometry curriculum using creative and engaging activities, as evidenced in the description of her lesson plans. This is a non-trivial accomplishment, especially since the choices of the mathematical topics and the proof themes were outside of Nancy's control, and due to the shift online.

The analysis above shows that the Role of Examples and Indirect Reasoning proof-themes were most challenging for Nancy to integrate into the lesson plans and to enact (Table 1). This outcome concurs with the results of the previous study (Buchbinder & McCrone, 2020). The fact that the Indirect Reasoning lesson occurs towards the end of the course is probably a contributing factor, especially when the natural end-of-semester fatigue is exacerbated by the pandemic.

Not surprisingly, Nancy's enacted lessons differed from the planned ones (Stein, Remillard & Smith, 2007). When judging the enacted lessons, it is important to note that Nancy's educational coursework did not prepare her to teach online – she had to come up with teaching strategies and technological tools that were new to her and to the students. This willingness to take pedagogical risks makes Nancy's teaching performance even more impressive.

While reflecting on the video of her lessons, Nancy noticed four main aspects: instructional moves, student engagement, timing, and technology. The first three categories of noticing are consistent with those of Sherin and van Es (2005) and Stockero (2021). Nancy's focus on technology is understandable due to the unusual and unfamiliar circumstances of online teaching. As Nancy became more comfortable with the students and her own teaching, she tried new teaching approaches, e.g., having students explore conjectures in *GeoGebra* and naturally encountered new challenges, causing her noticing to shift towards technology and time.

Further examination revealed that Nancy used three types of reflections: *on* a particular lesson, *for* future practice, and *back* to past lessons. Collectively, these three types of reflection are characteristic of productive reflection (Jay & Johnson, 2002; Moore-Russo & Wilsey, 2014). Indeed, Nancy went through repeated cycles of identifying areas for improvement (reflect-*on*), devising a course of action (reflect-*for*), and checking her progress with respect to previous lessons (reflecting-*back*) (Figure 2). Developing purposeful and explicit reflective practices allowed Nancy to leverage her challenges into learning opportunities (Tekkumru-Kisa et al., 2020) and helped her to learn how to learn from teaching (Hiebert, Morris, & Glass, 2003).

Interpreting Nancy's teaching performance in terms of the MKT-P framework suggests that her areas of strength were the quality of proof-oriented language (KLAP) and actions for promoting student engagement (KCT) (Table 1). The areas of improvement, which Nancy reflected *–on*, *for,* and *back* were facilitating discussions (KCS) and using productive teaching moves (KCT), as evidenced in the data excerpt.

Nancy's case serves as a "proof of existence" that it is possible to support PSTs learning teach reasoning and proof through a structured educational experience of the kind provided by the capstone course described above. Nancy's challenges are not unique and sometimes are even more pronounced with less advanced PSTs (Buchbinder and McCrone, 2020). What we found unique and enlightening is how Nancy addressed those challenges and how her reflective practices seem to support her professional growth. Teacher educators can model and promote the use of such reflective practices to support PSTs' professional growth in other teacher preparation programs.

Slope and the Differential Calculus of Two-Variable Functions

Rafael Martínez-Planell	Vahid Borji	María Trigueros
University of Puerto Rico at Mayagüez	Charles University, Dept. of Mathematics Education	Instituto Tecnológico Autónomo de México

We discuss results of a second research cycle on student understanding of the differential calculus of functions of two variables, focusing on the role that slope plays in a meaningful understanding of plane, tangent plane, total differential, and directional derivative. Results compare the performance of students in a section that used research-based activities and a corresponding pedagogical strategy, to that of students in a regular section. We show how students using the research-based activities were able to construct slope as an object they could build upon in order to understand other important notions of the differential calculus, while students in the regular section showed the same understandings of slope in the differential calculus as reported in previous studies.

Keywords: functions of two-variables, APOS, slope, differential calculus, multivariable calculus

Multivariable calculus is important to model different phenomena in science, mathematics, engineering, and other fields. However, its teaching and learning has not been as fully explored as that of one-variable functions (Martínez-Planell & Trigueros, 2021). In particular, there are relatively few publications dealing with the didactics of its differential calculus (e.g., Weber, 2015; Bajracharya et al., 2019; Moreno-Arotzena et al., 2020). Martínez-Planell, Trigueros, and McGee (2015, 2017) and Trigueros, Martínez-Planell, and McGee (2018) presented the results of a first cycle of research on student understanding of the differential calculus of two-variable functions. In these studies, they used an idea of Tall (1992) to emphasize the local linearity of differentiable two-variable functions. Martínez-Planell et al. (2015) started with a model of mental constructions (genetic decomposition) that builds upon the notion of slope in 3D, to describe how students may construct the idea of vertical change on a plane (see Figure 1). Then, this idea was used in the model to describe how students might construct the point-slopes equation of a plane, tangent plane, total differential, and directional derivatives. The model was tested with student interviews and results of the study led to refining the genetic decomposition and designing pedagogical activities to help student do the revised proposed constructions. A second research cycle was then undertaken to test the refined genetic decomposition. Here we report some of its results. Our research question is: what is the effect of a research-based activity set on student understanding of slope and the differential calculus of two-variable functions?

Theoretical Framework

We use Action-Process-Object-Schema (APOS) theory (Arnon et al., 2014). In APOS an Action is a transformation of a mathematical object that the individual perceives as external. This perception results from its relative isolation from other mathematical knowledge of the individual, who, as a consequence, will not be able to justify the Action. An Action could be the rigid application of a procedure, which may have been memorized. When an Action is repeated and the individual reflects on the Action, it might be interiorized into a Process. A Process is perceived as internal and this allows the individual to omit steps, anticipate results, and thus generate dynamical imagery of the Process, without having to explicitly perform it. The individual will also be able to justify the Process. When the individual is able to think of the

Process as a whole in itself, the Process is encapsulated into an Object and the individual is able to do Actions on it. A Schema is a coherent collection of Actions, Processes, Objects, and other previously constructed Schemas dealing with a specific mathematical notion.

The progression from Action, to Process, and then to Object conceptions, may appear as a dialectical progression where students may appear to go back and forth between stages, as they assimilate new problem situations to their existing Schemas, or accommodate the Schemas to deal with new problem situations. Hence, in order to classify an individual's conception of a mathematical notion, one needs to consider the individual's overall tendency on different problem situations involving the concept. A model proposed in terms of the structures and mechanisms of APOS of how a student may construct a particular mathematical notion is called a genetic decomposition (GD). A didactic strategy frequently used in APOS studies and the implementation of APOS-based activities is the ACE cycle (work in small groups of students, class discussion, and exercises for home). This strategy foments reflection, necessary for the construction of Processes and Objects.

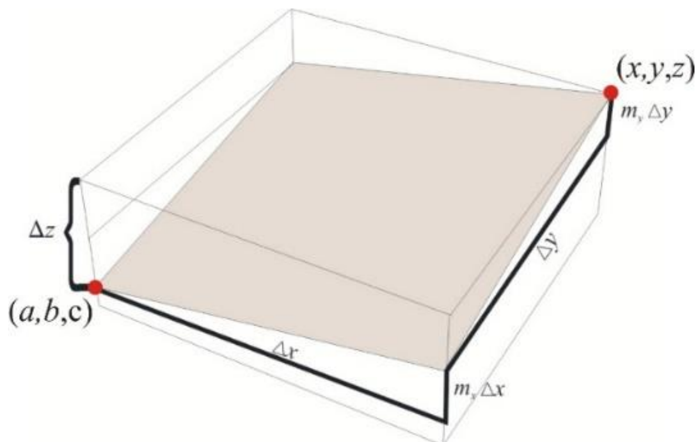

Figure 1. Vertical change on a plane $\Delta z = m_x \Delta x + m_y \Delta y$.

Methodology

In this study we used research-based activities resulting from a previous research cycle (Martínez-Planell et al., 2015) together with the ACE didactical strategy in a section (APOS section) taught by one of the researchers, while another section (regular section) taught by an experienced professor, not one of the researchers, used mainly lectures with the usual textbook exercises. Eleven students from each section volunteered to participate in post-semester semi-structured interviews, designed to test the GD. All students used the same textbook and had the same instructor (the professor of the regular section) in their previous calculus course. Participating students from both sections were chosen so that their grades in the previous calculus course were comparable. Each student interview had two parts, approximately of one hour each, conducted in different days. Interviews were transcribed, translated to English, individually analyzed by the researchers, discussed as a group, and differences were negotiated. The interviews were analyzed in terms of the constructions proposed in the GD. They were also graded as an aid in the search for patterns.

Results on Slopes in 3D

Students in the APOS section showed they had constructed a more robust understanding of slope in three-dimensional space than students in the regular section. Indeed, eight of the 11 students in the APOS section gave evidence of having constructed an Object conception of slope while only one of the 11 students in the regular section gave such evidence. Student A7 showed to have an Object conception of slope and exemplifies the typical response pattern of students in the APOS section as it regards slope. He was an average student in the sense that he had the 6th highest score in the interview (of 11 students) in the APOS section and the seventh highest grade in the previous calculus course among the 11 students in the same section. A7 could generalize a geometric conceptualization of slope (Moore-Russo, Conner, & Rugg, 2011) to 3D to find the slope of the line in bold in Figure 2:

> The slope of this line is m_x. On the line in bold the vertical change is 3, from 2 to 5, and the horizontal change is 1, from 1 to 2, so its slope is $m_x = \Delta z/\Delta x$ … which is 3.

Similarly, A7 was able to compute the slope in the *y* direction of the plane given in Figure2.

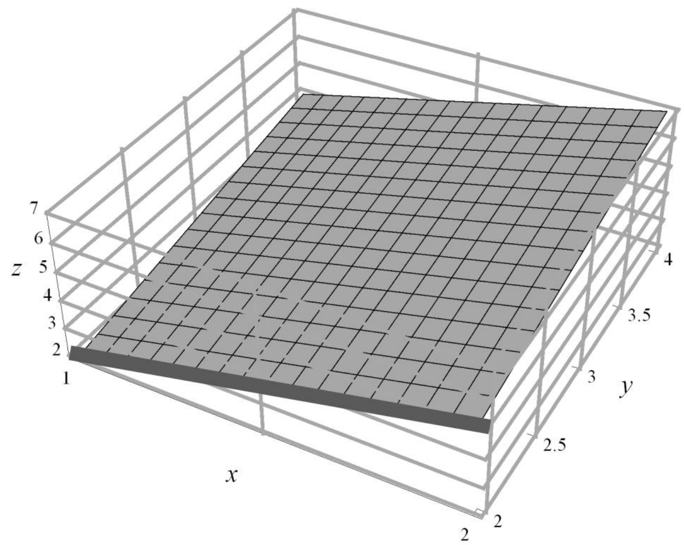

Figure 2. Plane for finding slopes in the x and y directions and vertical change for $\Delta x = 4$ and $\Delta y = 5$.

A7 also used the notion of slope to deal with problems related to vertical change on a plane, the equation of a plane, partial derivatives, directional derivatives, tangent plane, and total differential. This shows he had established significant connections between his notion of slope and other studied mathematical objects. When A7 was asked to find how much the *z* coordinate changes if, starting at any point on the plane, $\Delta x = 4$ and $\Delta y = 5$ [see Figure 2] he replied:

> We know m_x is 3, and $3 = \Delta z/\Delta x$, since Δ*x* is 4 so we have Δ*z* as 3×4 which is 12. We know also m_y is 1, and $1 = \Delta z/\Delta$y so this vertical change which is in the *y* direction is umm $\Delta z = 1 \times 5$ which is 5. So, the *z* coordinates increase as 12 plus 5 which is 17.

So, his construction of vertical change on a plane was based on his doing Actions on slope. In the case of partial derivative, A7 used slope to interpret geometrically partial derivatives and find their sign from the graph of the function. He also used it to approximate a partial derivative given a tabular representation or a contour diagram of the function. By being able to consider slope as independent of representation, this student gave evidence of his construction of a Process conception of slope. For example, when asked to find the sign of $\partial f/\partial y(3.5{,}0)$ given the graph of the function in Figure 3, he said:

In $\partial f/\partial y(3.5,0)$ we know that the *x* coordinate is fixed at 3.5, so I have the point here, now I draw the tangent line to the surface in the *y* direction, we can see this line is an increasing line so its slope is positive and it means the sign of $\partial f/\partial y(3.5,0)$ is positive.

When dealing with directional derivatives, A7 could decide the sign of $D_{\langle -2,1\rangle}f(4,0)$ with the function given by the graph in Figure 3, as he did for partial derivatives.

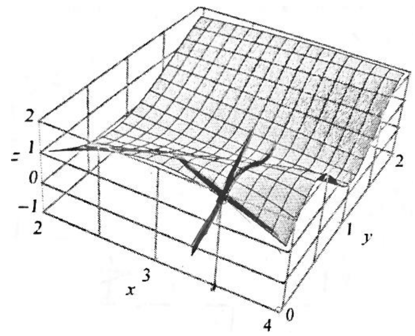

Figure 3. Surface for sign of partial derivative and A7's work

In another problem, he was given the graph in Figure 4, and told to suppose that point *P* moves towards point *Q* at a constant speed along the curve that joints them, then he was asked how may the graph of $D_{\langle 1,-1\rangle}f(P)$ look as a function of time. His response shows that he could generate the dynamical imagery necessary to answer the question. His responses demonstrated the construction of a Process conception of directional derivative and his possibility to consider the slope Process as a whole, which is consistent with an Object conception of slope.

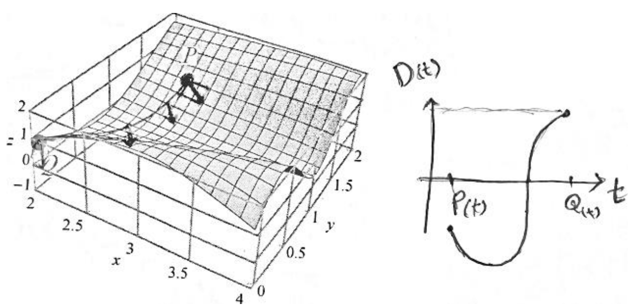

Figure 4. Directional derivative as P moves towards Q

Student A7: I have to draw the graph of the directional derivative respect to time. I first check the points umm they move from P to Q. So, I have my points umm now I check the direction vector for the directional derivative umm it's the vector $< 1, -1 >$ so I check the tangent slopes at different point in this fixed direction.

Interviewer: Okay, draw D.

Student A7: First the slopes are negative umm so the graph of D is negative at this interval then slopes are negative and more negative so the graph of D is decreasing until may be here. Then the slopes are going and going to 0 and somewhere between P and Q the tangent line in the given direction has slope 0 so the graph of D goes to be increasing and cuts the time axis.

Interviewer: Okay, continue to the point Q and draw your graph completely.

Student A7: After 0 umm the slopes are positive because the tangent lines in the given direction are increasing so the graph of D at this interval is increasing.

So, we may say that A7 demonstrated the encapsulation of slope when he acted on it in order to construct directional derivative. He also used slopes as a tool to relate vertical change on a plane, tangent plane, and total differential:

Student A7: [Given the graph of the tangent plane in Figure 5, he was asked about what he could say of the change in the value of the function, if *x* increases 0.02 units and *y* decreases 0.02 units] I first have to find m_x and m_y umm m_x is $\Delta z/\Delta x$ using this line in the x direction it's $\frac{1-0}{2-1}$ which is 1. To find m_y I use this line umm on this line *z* is from 0 to 3 and *y* is from 2 to 4 so m_y is $\frac{3-0}{3-2}$ which is 3

Interviewer: Ok, continue

Student A7: Here we have $d_x = 0.02$ and $d_y = -0.02$. We know also the formula $d_z = m_x d_x + m_y d_y$ which gives us the change in the z coordinates or the change in $f(x,y)$. [Note that he talks about "change in *z*", that is, vertical change on a plane, relating it to notation he next uses for the total differential] By plugging the changes in this formula, we have $d_z = 1(0.02) + 3(-0.02)$ so d_z is 0.02-0.06 which is -0.04

Student A7: [In the next problem, when asked for the total differential] I know the formula for the total differential is $d_f = m_x d_x + m_y d_y$ so it's $d_f = 1(d_x) + 3(d_y)$ and this is equal to $d_f = d_x + 3d_y$.

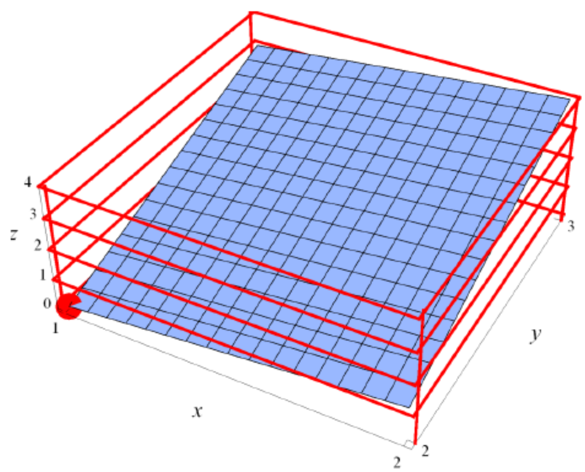

Figure 5. Tangent plane to the graph of a differentiable function $z = f(x,y)$ at a point $(1,2,0)$.

When examining A7's overall tendency when working in different problem situations involving the notion of slope, we noted that he referred to slope when using or discussing partial derivative, directional derivative, the equation of a plane, tangent plane, and total differential. He also seemed to think of slope in different representations. Further, he was able to use slope in his sense making and problem solving. As we found evidence showing that he was performing Actions on slope as an Object, we concluded that he had constructed an Object conception of slope which he used to construct his understanding of other concepts involved in the differential calculus of functions of two variables.

It is interesting to compare, in general, the behavior of students in the APOS and regular sections as it concerns slope. Five of the 11 students in the regular section showed not to have constructed the notion of slope in 3D, while all 11 students in the APOS section showed they had. The average score on four interview problems directly dealing with slope, was 95% for students in the APOS section, while for students in the regular section it was 53%. Given that the students in both sections had obtained comparable grades in their previous calculus course, where both groups had the same professor, one may consider that the emphasis on geometric interpretation given to the development of the two-variable function differential calculus in the APOS section helped those students to develop a more robust understanding of slope. In order to have a wider perspective, it was considered as worthwhile to compare the number of times that students acted on slope (i.e., used slope and explicitly referred to it either verbally or symbolically) when solving the interview problems. Results are shown in Table 1.

Table 1: Number of actions on slope per student and section

Section/student	1	2	3	4	5	6	7	8	9	10	11	Total
APOS	14	16	15	12	12	10	15	14	5	7	5	125
Regular	9	0	4	7	2	4	4	0	0	0	0	30

It is clear from the table's data that students in the APOS section acted in a fundamentally different way with regards to slope when constructing their understanding of the differential calculus of two-variable functions when compared to students in the regular section. The students in the regular section who did not construct slope in 3D responded similarly as students R5 and R9:

Student R5: [Figure 2] I don't know how to find the slope of a line in 3D. For a line in 3D umm its points are like (x, y, z) and have three components. I have never learned how to find the slope of a line in 3D.

Student R9: [Figure 2] The formula for the slope is $\frac{\Delta y}{\Delta x}$ and it's equal to $\frac{y_2-y_1}{x_2-x_1}$. I need two points to find the slope, a point here like $A(1,2)$ and umm the other one here $B(2,2)$. So, the slope will be $m = \frac{2-2}{2-1}$ which is 0.

Note that R5 had not reconstructed slope in the new three-dimensional context of two-variable functions. As shown by Moore-Russo et al. (2011) and McGee et al. (2015), this needs to be explicitly considered in class. Also, note that R9 unsuccessfully tried to directly generalize the formula for slope without doing a needed reconstruction. More interesting is to consider the case of R2, a regular section student who did construct slope in 3D, but seemed not to recur to it while solving problems. She was the second highest scoring student in the regular section in terms of her course score in the previous calculus course, and the third in terms of the interview instrument.

When asked to compute the slope of the line in bold in Figure 2, she initially showed some doubts but was eventually able to generalize slope to 3D:

It's a line in $3D$ umm I don't know how to compute the slope of a line in $3D$ because we have three variables x, y, and z in $3D$. Let me to find two points on the line in bold. We have the points $(1,2,2)$ and $(2,2,5)$ on the line, I have to check how their coordinates change. The y coordinate is fixed at 2 in both points, the x coordinate change from 1 to 2, and the z coordinate change from 0 to 3. So, I ignore y in my computation, and I use the formula $\frac{z_2-z_1}{x_2-x_1}$, by plugging in the formula I have $\frac{5-2}{2-1}$ which is 3 as the slope.

It has been observed that in a 3D context, students may be aware of rates of change in the x and y directions but not know how to combine them to obtain a rate of change in another direction (Yerushalmy, 1997; Weber, 2015). The following excerpts exemplify this observation and also show that R2 has yet to relate slope in 3D to directional derivative:

I am thinking how we can find the slope of a line in $3D$ if all the three coordinates x, y, and z change from first point to the second point. I have no idea for finding the slope of such points because in these cases the formulas $\frac{z_2-z_1}{x_2-x_1}$ and $\frac{z_2-z_1}{y_2-y_1}$ don't work…

[Later, when asked to determine the sign of a directional derivative given the graph of the function in Figure 3] The problem is we don't have the expression of $z = f(x, y)$ and I don't know what directional derivative means on the surface.

When asked for vertical change on a plane given the graph of the plane in Figure2 and $\Delta x = 4$ and $\Delta y = 5$, she did not use a simple argument based on slope like student A7, but rather used the more cumbersome procedure of computing the point-normal equation of the plane and then plugging in values. She did the same thing when given the graph of the tangent plane at a point (Figure 5), she had to approximate the change in the value of the function in a neighborhood of the point. When asked to approximate a partial derivative given a tabular representation of a function, she said "I need to find an algebraic expression of x and y such that these 9 points satisfy it". In problems dealing with the graphical interpretation of second order partial derivatives she said: "The problem here umm is that we are in 3D and actually we have three variables x, y, and z umm and we don't have any equation. The graph of f is very complex and it's impossible to guess an algebraic equation for it". These problems could be done by reflecting on the graphical meaning of slope at given point in a given direction in 3D, as the points move. That is, the problems required to consider the Process of slope as an Object to do Actions on it.

So, R2 showed she was able to solve some problems doing more complex computations than those involved in finding vertical change on a plane, while also showing her relying in algebraic rather than geometric reasoning for important ideas of the differential calculus. According to Duval (2006), it is important to distinguish a mathematical object from its specific representations. R2's dependence on algebraic representations all along the interview showed she still needed to construct geometrical representations to avoid such confusion. It seemed she needed more opportunities to think of slope and to apply it in a way that would enable her to fully understand ideas of the differential calculus of functions of two variables.

Conclusion

The results of this study indicate that students who used APOS-based activity sets with the ACE didactic strategy, developed a meaningful understanding of slope, that contributed to construct different differential calculus concepts for two-variable functions. For the most part, these students related slope to different important notions like, partial and directional derivatives, equation of a plane, tangent plane, and total differential. Students in the regular section showed the same kind of behavior that has been documented in the literature (McGee & Moore-Russo, 2015; Martínez-Planell et al., 2015, 2017; Trigueros et al., 2018; Weber, 2015). That is, for the most part, they showed dependence on algebraic representations in order to do computations, instead of comparing different representations. They also seemed to have constructed isolated notions of the differential calculus, resulting in the use of memorized algebraic calculations.

The study also shows the potential of APOS theory to foster students' deeper understanding of the differential calculus of two-variable functions and their possibility to relate the concepts involved in it. It also shows that through the use of research cycles as practiced in this theory it is possible to progressively improve the design of tasks to be used by students and, in this way, contribute to improving student understanding. Our future research activities include examining the data for students' construction of Processes of partial and directional derivatives, and the differential calculus Schema for functions of two variables.

In this contributed report, we document results from the third and final round of interviews with 14 mathematics instructors. In the interviews, we presented two teaching scenarios about a racial microaggression and white-supremacy messaging, and asked what the instructors would do if they encountered such a scenario in their own classroom. Results from our study indicate that some of the participants would do nothing to address the scenario publicly in class. This neutrality resembled similar responses as those from our second round of interviews, but there was a nuance that differentiated the third interview results. That is, of the participants that opted not to address the scenario publicly, they also condemned the scenarios privately as something that was inappropriate, as opposed to avoiding and minimizing the situation. We find that doing nothing in response to a potentially problematic social justice scenario can be interpreted in two distinct ways.

Keywords: race, microaggression, teaching scenarios

With the push for increased diversity and inclusion efforts in higher education (U.S. Department of Education, 2016), university educators should be prepared to engage with and encourage the incorporation of diverse thoughts and experiences that our students bring to the classroom. Diversity not only leads to new ideas coming from different lived experiences, but as technology continues to improve in the hands of the newest generation, a diverse workforce in STEM may curtail the impact of biased systems such as facial recognition software (Garvie & Frankle, 2016; Nkonde, 2019), and machine learning (Garcia, 2016). Advocating for justice in the STEM classroom is the first step to allow students and instructors to recognize their own prejudices and biases. This is particularly important as women, people of color, and other marginalized groups of students are at a higher risk of failing introductory mathematics, being pushed out of STEM altogether (Koch & Drake, 2018; Weston et al., 2019). The idea of failure and marginalization is reinforced for these groups with every offensive comment made, which is why university instructors should be prepared to handle difficult conversations in the classroom and support the students that need it most.

As research has demonstrated, active learning classrooms have the potential to provide superior learning environments compared to non-active ones (Freeman et al., 2014; Theobald, 2020). However, with the use of active learning comes the potential for conflict in the classroom, as students are encouraged to engage with one another's ideas and interact much more compared to lecture classrooms. That is, within any setting of peer-to-peer interaction, problematic discussions around race, politics, gender, and other topics may arise. University instructors are not necessarily trained to handle these situations, which may lead to unproductive conversations and the marginalization of certain groups of students. Such problematic scenarios may present themselves as explicit acts of racism, sexism, homophobia, etc. Although, they may also occur as more subtle acts of hostility and enmity known as microaggressions.

As a research team composed of faculty, graduate and undergraduate students, our stance is that the university classroom should be a space where students learn how to engage with one another around controversial ideas. If university is not a place to challenge students' ways of reasoning and encourage civil discourse, then where is the right place? Research suggests that having these discussions in class can be difficult, but has the potential to foster the development of productive community engagement and tolerance (Camp, 2020; Hess & Gatti, 2010; Moran, 2009). With that in mind, we challenged a group of university instructors by presenting to them a set of potentially problematic teaching scenarios in which they were asked to respond as if they were the instructor. The goal of presenting these scenarios was to answer the following research question: *In what ways can a neutral stance by university mathematics instructors be interpreted when addressing racial microaggressions and supremacist attitudes in the classroom?*

Literature Review

Mathematics instructors at the college-level typically have undergraduate and graduate degrees in mathematics or closely related fields. This extensive background in mathematical content makes them experts in the discipline. However, there is often limited training on a major component of their roles at universities – teaching – where most doctoral students only take one course on undergraduate teaching (Baum & McPherson, 2019). Effective teaching requires knowledge of the content, strategies to teach the content, practices to assist with classroom management, and knowledge of learners and learning (Eggen & Kauchak, 2006). Student learning not only includes specific content but also the development of interpersonal and cross-cultural competencies, expected outcomes of a college degree.

Engagement strategies shown to promote student learning in mathematics classrooms, like the utilization of group work or active learning (Smith et al, 2021), increases the need for college faculty to have competent classroom management skills. Duek (2000) and D.W. Johnson and Johnson's (1989, 1991, 1992, 1994) research on productive cooperative learning environments supports the argument for additional training on classroom management practices. Two of the six elements of productive cooperative learning environments, value of heterogeneity and interpersonal communication, require skills to manage classroom discussion. As students engage in conversation with one another through group work, conversation may move to current events, like racial tensions or political conflict. When these emotionally charged conversations occur between students, faculty should be prepared to respond appropriately to ensure the classroom environment is operating as an inclusive space. Student belonging is an important element of inclusion, and ample research has linked belonging to persistence in higher education (Solorzano et al., 2000; Clark et al., 1999; Mercer et al., 2011; Torres, et al., 2010; Bair & Steele, 2010; Salvatore & Shelton, 2007).

In the context of this study, we are operating under the assumption that race and racism is inherent to society's systems, including the education system, and is difficult to address if not directly acknowledged (Delgado & Stefancic 2017; Bourdieu, 2018). Research suggests that there is a lack of noticing or acknowledgement of bias in the classroom for STEM educators (Boysen et al., 2012). For educators who do recognize the inequity and issues of racism in the classroom, they often struggle to devise a response in practice (Duncan-Andrade, 2009; Solórzano & Delgado-Bernal, 2001). They may not feel qualified to craft a response or confront larger issues in practice, even though they hold a critical stance on the issue at hand.

The prior research within the field of education suggest that faculty must respond to microaggression incidents in order to avoid “siding with the offender” and creating a hostile environment for the affected students, typically students of color, women, and people in the LGBT community (Boysen et al., 2012; Sue et al., 2007; Hernandez et al., 2010). Faculty can ameliorate the situation through a variety of actions, the first being a recognition of their own biases. This idea is often conveyed in critiques of modern liberalism in which neutrality and colorblindness are upheld as critical practices to eradicate issues of race and racism (Delgado & Stefancic, 2017). This neutral perspective generally does not address more covert acts of racism in society and can only address the most egregious and outward forms of racism. This also extends to arguments of the right to free speech, in which hate speech toward minoritized groups may be protected (Delgado & Stefancic, 2017), highlighting how societal structures allow racism and microaggressions to occur. The argument to ensure rights to free speech may even prevent the formation of close communities, which develop through mutual negotiation and dialogue (Wenger, 1999).

Researcher Positionality

As a data collection and analysis team, our personal identities represent diversity in gender, sexuality, race/ethnicity, and academic ranks. We recognize that the data collection team’s positionality likely impacted the rapport, comfort, and safety of participants to share their lived experiences and beliefs. Our personal experiences and positionality were also leveraged to interpret and understand the shared experiences of our participants. While inherently reductionist, we share some of the identities of the authorship team to help contextualize our positionality. Author 1 identifies as a cisgender straight Chicano, Author 2 as a cisgender queer white woman, Author 3 as a cisgender Asian and African American woman, Author 4 as a cisgender white queer man, Author 5 as non-binary queer Chicanx person, and Author 6 as a cisgender white queer man.

Methods

The data from this study draws on a set of interviews with 14 mathematics instructors (see table 1) from nine institutions who agreed to participate in a Professional Learning Community (PLC). The PLC activities started in September 2020, with virtual meetings occurring every two weeks, focusing on diversity and inclusion in undergraduate mathematics. The nine different institutions were all partners in the NSF-funded SEMINAL project which was examining departmental change efforts to infuse active learning in introductory mathematics courses. Participants were interviewed three times at the start, middle, and end of the year-long PLC. The interviews included questions about instructional practices, departmental support, and responses to a set of 4-5 teaching scenarios. The 1-hour long semi-structured interviews were conducted by members of the research team in pairs via Zoom and were audio and video recorded. The interview transcripts were automatically generated by Zoom, reviewed by the research team for clarity, and loaded into the qualitative coding software MAXQDA for analysis. The transcripts and audio recordings were linked within MAXQDA to ensure interpretability, tone, and pauses.

The analysis in this manuscript focuses on three different teaching scenarios. The first scenario, *Zoom Microaggression*, describes a situation in which a student posts a racial microaggression about another student in the chat during class and instructors were asked how they would respond. The Zoom microaggression scenario was presented in the first and third interview. The second scenario, *Classroom Microaggression (BLM)*, describes a situation where a student is wearing a Black Lives Matter hat, and another student reacts saying "All Lives Matter." The third scenario, *Classroom Microaggression (Alt-Right)* is a variation on the Classroom Microaggression (BLM), but in this scenario a student is wearing clothing in their mathematics classroom with the insignia of an Alt-right movement (Proud Boys, Neo-nazis).

Table 1. Participant Gender and Racial Identity as Perceived by the Researchers

Gender and Racial Identity	Pseudonym
white woman	Emma, Shea, Lacy, Kathleen, Crystal, Cassandra
white man	Thomas, Bill, Mark
Woman of Color	Shivya, Camila, Aadaya
Man of Color	Robert, Collin

As a research team, we conducted a thematic analysis of the interviews, which is "a method for identifying, analyzing, and reporting patterns (themes) within data" (Braun & Clarke, 2006, p. 79). We used a cyclical approach to our analysis, analyzing and reporting results from the first interviews (Machen et al., 2021), followed by the second interviews (Ralston et al., 2021), and we present new findings from the third interview in this manuscript. Prior analysis by Machen and colleagues (2021) identified five archetypes emerging from the first round of interviews and included the: Action Taker, Cautionary, Connector, Confidant, and Thinker. Some participants had overlapping archetypes based on their reactions to the microaggression scenario. During the second set of interviews a sixth archetype was identified (Ralston et al., 2021), the Neutral, as many of the faculty's responses indicated hesitation or an interest in keeping their actions neutral due to the concern of impinging on free speech. Analysis of the third set of interviews which included issues of free speech, politics, and covert racism, suggested that the actions (or lack thereof) by faculty were more nuanced than the Neutral category suggested from prior analysis.

Results

We found that the participants' responses were nuanced enough to merit the splitting of the Neutral archetype into two strands, *Apolitical* and *Conflicted*. As we were coding the responses to the third interview, we noticed that the existing Neutral archetype that was generated from the second round of interviews was not entirely capturing some of the participants' responses to the Far-Right scenario. For this reason, we went back to the Neutral codes from the BLM scenario and compared those with the responses that were being coded as Neutral for the third interview. Below we highlight some excerpts from the BLM scenario that are representative of the Apolitical archetype. We then provide excerpts of participants' responses that characterize the new framing of the Conflicted archetype.

The Apolitical archetype that emerged from the responses to the BLM scenario in the second interview generally reflected a sense of not wanting to take a side in the situation. A common motif was the idea that, as one participant put it, "everybody is entitled to their own view or their own opinion." Other participants would have liked more context and clarification on the scenario in order to determine how they would respond, as Collin suggested, "I've had the joke with my friends that we'll mockingly say 'all lives matter' to each other, just to mock the people who have that sort of opinion." Even without the additional context, Collin went on to say that he thinks intervening into the situation and saying something to the students is "more dangerous for me, as an instructor, to make a bigger deal of it than is being made by the students." This theme of causing more harm than good was echoed by other participants characterized with the Apolitical archetype as multiple instructors were apprehensive about taking attention away from the mathematics. Cassandra described the actions they would take to try and redirect the focus back to mathematics:

> *My initial reaction would be like 'hey that's not math content, take it outside' you know, or … 'we can work on math today, and you guys can talk about that later' or … 'this is not the time or the place for this conversation.' You know, and I would try to say something like, 'we all have different opinions about different things, but right now we're working on co-functions, so can we work on co-functions, please.' You know, just try to defuse the situation.*

Generally, the Apolitical archetype characterizes an approach that would prefer to move past the situation, either because the instructor does not see the offending students' actions arising to a level that warrants an intervention or having a discussion in class is not appropriate for a mathematics class. Four of the 14 participants responded to the BLM scenario with some action that was characterized as Apolitical; however, it is important to note that these are not fixed traits that we are assigning to the participants. In some cases, a participant might suggest one approach reflecting an Apolitical preference, but also later take an approach as a Confidant in that they would pull the offending student to the side to have a one-on-one conversation or with the aggressed student about what had occurred in class.

What we noticed with the Far-Right scenario represented a different stance altogether. That is, for the Apolitical archetype, the participants' actions could be categorized as not taking a side or not wanting to intervene because they did not see it as appropriate. In contrast, participant responses to the Far-Right scenario characterized a situation in which the participant would take a stance (in theory), but would not intervene, even though they knew that something should be done. The important distinction that we are making here is the idea that the responses reflecting the Conflicted archetype generally take an approach of *condemnation*, rather than one of *minimization*. Lacy's reaction to the scenario describes the Conflicted archetype well in that they know that this Far-Right scenario is problematic, but is unsure about how to respond given the context of the situation:

> *To do nothing is not acceptable. I think, in years past, to just ignore it and go on was acceptable. I don't think it's acceptable, [the instructor] needs to do something. What [they] need to do, I don't know because I don't know the makeup of the class … The only thing I can say is yes, it needs to be addressed, yes, something should be done. Even if it's after the fact, I think [addressing the scenario] should be done.*

Although Lacy takes a firm stance that something should be done and this scenario is unacceptable, she does not describe what she would do herself because she is unsure about the context. From our perspective, we interpret this as not taking action but still having a condemning stance on the issue, stating that this scenario is unacceptable. Another instructor had a different reason as to why they would not address the scenario in class,

> *The student who is wearing [the far-right clothing] is wearing it because they want to stir the pot, they want to offend people, they want attention right? So, if this was me, am I going to call this person out? No, because that's what the student wants, right? They want to make this space about them, and these ideas. So I don't think I would do something publicly … I don't think people that wear neo-Nazi t-shirts are unaware that that is offensive right? They do it because they want to offend people, they want attention.*

Bill's response was something that we initially interpreted as apolitical given that they did not explicitly condemn the scenario as being problematic. However, we interpret Bill's response as a condemnation in that Bill does not want to give the offending student a voice in the classroom to spread hate and neo-Nazi ideals. We also saw a Conflicted response from Kathleen, as she wanted to do something about this scenario, and offered one potential avenue to stop the student from wearing far-right clothing, but was grappling with her ideals of freedom of speech.

> *This is really tough because I believe in freedom of expression … I do think that these shirts are inappropriate. Because the shirt is specifically promoting hate … The university must have some kind of dress code and if the dress code mentioned something about hate speech or this kind of propaganda or promotion, then, absolutely … If it doesn't, I don't think that [the instructor] really has a right to tell the student what they can and cannot wear. However, if we're doing some kind of group work and somebody doesn't want to work with the student because they find what they're wearing is offensive, or it makes them feel uncomfortable, then I'm not going to force them to stay in a group.*

Three participants reflected a Conflicted response to the Far-Right scenario, with the Conflicted archetype also arising twice with the Zoom Microaggression scenario in the third interview. One participant, Bill, had a Conflicting response to both the Far-Right scenario and the Zoom microaggression scenario. Overall, four participants from the third interview provided responses that we coded as the Conflicted archetype. Interestingly, we did not characterize any of the responses from the third interview as Apolitical. In Table 2 we document the definitions of the two archetypes for posterity.

Table 2. Definitions of the Apolitical and Conflicted archetypes.

Apolitical	The "Apolitical" archetype reflects actions that avoid and dismiss the situation. Respondents that fall into this category often did not want to take a stance on the issue and leave it to the students to handle any potential conflict. Some characterized as Apolitical worried it might trigger an emotional reaction from students, and/or they did not feel capable of facilitating a meaningful discussion about social justice issues. As a result, actions represented by this archetype tend to minimize the situation to avoid bringing discussions about politics or racism into the classroom.
Conflicted	The "Conflicted" archetype reflects actions that avoid, but condemn the situation. Respondents that fall into this category often know that the situation is wrong and something should be done to resolve any potential conflict, but may not know the best approach to do so. We see the actions of those characterized by the Conflicted archetype as a minimum requirement of allyship with the marginalized and oppressed; knowing that an injustice has occurred is the first step to intervening and facilitating a productive conversation about social justice issues.

In the next section we provide a summary of the two new archetypes that emerged from the third interview and our thoughts as to why we saw the emergence of the Conflicted archetype, and absence of the Apolitical, in the third interview.

Discussion

Our research study involved presenting 14 university mathematics instructors with difficult teaching scenarios and asking how they would respond to those scenarios if they were teaching in the classroom. After the third and final interview with the research participants, we noticed a nuance in the instructors' responses to neutrality that we considered to be valuable to unpack. This nuance was particularly interesting in that the action that the instructors would take was, in fact, no action at all. That is, in the second interview, the participants that mentioned that they would not address the scenario in class often wanted to move past the scenario by downplaying the seriousness of the comments made, opting to rely on the idea that everyone is entitled to their own opinions or commenting that the mathematics classroom was not the space to have those types of conversations. This approach was referred to as the Apolitical archetype. In this manuscript, we highlight the emergence of a new archetype, the Conflicted, as a similar, but different approach. With those that fell into the Conflicted category, they also opted not to address the scenario in class, but wanted to make it clear that the scenario was unacceptable or something should be done as a way to condemn the action taken by the offending student. Our purpose with highlighting the difference between the Apolitical and Conflicted archetypes is to consider what it means not to address these difficult conversations in class from a critical perspective.

A particular point of interest based on our results is the absence of the Apolitical archetype in the third interview. We hypothesize that verbal microaggressions are easier to minimize and ignore compared to a physical manifestation or racial aggression such as the far-right messaging on the clothing. Furthermore, it may be easier for mathematics faculty, and particularly white faculty, to notice and condemn white supremacy compared to facilitating more nuanced discussion of race, racial microaggressions, and political movements. Moreover, what are the implications of approaching difficult scenarios as Conflicted compared to Apolitical? We consider this as an open question for future research, but for now we offer a few of our thoughts.

From our perspective, we see the BLM scenario as an easier scenario to downplay and ignore, due to the fact that it was a verbal microaggression and the potentially ambiguous nature of the context in which the microaggression occurred. However, we would like to address the microaggression for what it is, covert racism in the classroom. We see the responses that were categorized as Conflicted to be a productive step in that the instructors that opted for a "neutral" stance still condemned the overt act of white-supremacy, as teaching is inherently a political act (Kozleski & Waitoller, 2010). They knew that *something* should be done, even though they did not know exactly what that *something* was. We see the identification of how one might approach these difficult situations as an important professional development practice that all instructors should consider. Future work will address how all of the archetypes that emerged from the three rounds of interviews might impact our teaching practices, and we will explore what it means to bring conversations of racism, politics, and equity into the mathematics classroom.

Responding to Students' Suggestions: Attribute Substitution and Heuristic Approaches

Anna Marie Bergman

Rina Zazkis
Simon Fraser University

Knowing how best to respond to students' mathematical inquiries is an important skill for all teachers to develop. A class of pre-service teachers (PSTs) was presented with a scripting task in which a student conjectured that 1/6.5 was "exactly in between" fractions 1/6 and 1/7. However, instead of addressing the student's inquiry directly, many of the PST's responses contained a variety of explanations for more general information about fractions and their various representations. We offer a classification of the responses using the ideas of attribute substitution along with the availability and representativeness heuristic.

Keywords: Fractions, Fraction Representation, Attribute Substitution, Representativeness Heuristic, Availability Heuristic

Introduction

An important aspect of classroom discourse is how teachers respond to students' mathematical inquiries. Alternative interpretations of content may naturally arise in the course of any lesson, and it is the responsibility of the teacher to respond to student ideas in a meaningful way. However, it is often the case that, rather than responding directly to a particular question, individuals respond to a different, but related question without realizing that they have done so.

Building on prior work by Marmur, Yan, and Zazkis (2019, 2020a), we presented pre-service teachers (PSTs) with a scripting task in which a student conjectured that 1/6.5 was "exactly in between" fractions 1/6 and 1/7. While many of the PSTs in our sample directly addressed this suggestion, several focused on mathematical information that was tangentially related to the task, such as fundamental ideas about fractions and fraction representations. In this report, we present a classification of PSTs' responses in terms of questions that were answered, rather than what was asked. We frame the responses using the notions of attribute substitution (Kahneman & Frederick, 2002) and the representativeness and availability heuristics described by Kahneman and Tversky (1972) and Tversky and Kahneman (1973).

On Fraction Representations

Students' struggles with fractions at the K-12 level are well-documented (e.g., Behr, Wachsmuth, Post, & Lesh, 1984; Clarke & Roche, 2009; Mack, 1990; Vamvakoussi, Christou, Mertens, & Van Dooren, 2011; Zhou, Peverly, & Xin, 2006). Both in-service and pre-service teachers have been shown to struggle with fractions in many of the same ways that students do, leading to an increase in research on prospective teachers' knowledge of fractions (Ball, 1988; Post, Cramer, Lesh, Harel, & Behr, 1993; Post, Harel, Behr, & Lesh, 1988; Sowder, Bedzuk, & Sowder, 1993; Zhou, et al., 2006). Despite the identification of at least five distinct conceptualizations of fractions, such as fraction as measure and fraction as ratio (Brousseau, Brousseau, & Warfield, 2004; Kieren, 1976, 1993; Lamon, 2007; Sowder, Philipp, Armstrong, & Schappelle, 1998), the part-whole conceptualization remains dominant in both students' and teachers' reasoning about fractions (Ball, 1988; Newton, 2008; Post, et al., 1993; Post, et al., 1988; Sowder, et al., 1993; Weller, Arnon, & Dubinsky, 2009; Zhou, et al., 2006).

Many of the difficulties learners experience with fractions stem from the variety of representations and ways of conceptualizing them (Čadež & Kolar, 2018; Charalambous & Pitta-

Pantazi, 2007; Pantziara & Philippou, 2012). Vamvakoussi and Vosniadou (2004) showed that middle school students may reason about equivalent fractions (such as 1/2 and 2/4) as if they were different numbers instead of different representations of the same number. Marmur, et al. (2019, 2020a) observed a similar result in pre-service teachers who rejected the value 1/6.5 as a candidate for a number between 1/6 and 1/7 but allowed the equivalent fraction 2/13, suggesting that it is not the number itself, but its non-standard representation, that presented a challenge for PSTs. Overall, it was demonstrated that the prospective elementary school teachers in their study experienced difficulty in assigning meaning to 6.5 when it appeared as the numerator or denominator of a fraction.

We extend this work on PSTs' perceptions of non-standard representations of fractions, and in particular, the ways they conceive of and interact with the representation 1/6.5. Our research aimed at addressing the following question:

How do prospective teachers respond to a student's idea that 1/6.5 is exactly in the middle of 1/6 and 1/7? In particular, how does the non-traditional representation shape their responses?

We presented a group of pre-service middle and high school teachers with a hypothetical classroom dialogue in which one student, Cory, asked what number will be "exactly in between" 1/6 and 1/7, and another student, Alex, conjectured that 1/6.5 was the desired value. As the PSTs extended the dialogue to address Alex's suggestion, many of them focused on other aspects of the scenario, responding by re-teaching foundational knowledge about fractions, trying to give meaning to the number 1/6.5, or addressing this representation's status as a fraction or as a number of any kind.

Theoretical Perspective

Attribute Substitution

We adopt the perspective of Kahneman and Frederick's (2002) *attribute substitution* model. Responding to related questions that were never asked is an example of attribute substitution: "We will say that judgment is mediated by a heuristic when an individual assesses a specified *target attribute* of a judgment object by substituting another property of that object -- the *heuristic attribute* -- which comes more readily to mind" (Kahneman & Frederick, 2002, p. 53).

In daily life, people often respond to questions with the answer to a different, but related, question. Consider, for example, the following exchange between a mother and her son:

Mother: Do you need help with your math homework tonight?
Son: It's not due until Friday.

The mother's question asked about the son's need for assistance on his assignment, but the son has instead responded to the related question "When is your homework due?" Despite the fact that this question was never asked, one can clearly infer the implied answer to the question that was asked. In the dialogue we presented above, the target attribute referred to by Kahneman and Frederick (2002) is that which the original question asked about: the son's need for assistance. The heuristic attribute is the property to which the response pertained: when the assignment is due. In this case, it is up to the mother to infer from her son's response that he does not need help, but this may not necessarily be the case. He may require help, but only on

Thursday night. The clarity of attribute substitutions in the response to the original question may depend on the particular situation and the particular relationship between the interlocutors.

This response pattern is consistent with Kahneman and Frederick's attribute substitution model. Attribute substitution refers to the cognitive process in which an individual unwittingly thinks about related attributes of an object or concept instead of the one which is under direct scrutiny.

Attribute Substitution and the Representativeness and Availability Heuristics

Research on attribute substitution has so far focused mainly on the representativeness heuristic (Grether, 1980; Gualtieri & Denison, 2018; Kahneman & Tversky, 1972; Tversky & Kahneman, 1974) and availability heuristic (Agans & Shaffer, 1994; MacLeod & Campbell, 1992; Pachur, Hertwig, & Steinmann, 2012; Tversky & Kahneman, 1973).

Chernoff (2012) described attribute substitution when examining prospective mathematics teachers' responses to tasks related to relative likelihoods (i.e., which outcomes are more likely than other outcomes in a given set). Although respondents were asked to identify which of two given answer keys to a multiple-choice test was probabilistically more likely to occur, several respondents were found to have responded to the related question, "Which of these two answer keys is more *representative* of the collection of possible answer keys?" Thus, while many respondents provided objectively incorrect responses to the question that was asked, it was determined that these individuals were still thinking mathematically – but were in fact responding to a question that was not asked using the representativeness heuristic.

Furthermore, when responding to questions about relative likelihoods, such as "Which string of outcomes of successive coin flips is more likely: HTTH or HHHH?" individuals may appeal to the representativeness heuristic rather than use their knowledge of probability (Chernoff, 2012). A generic outcome of the process of tossing a coin four times is one in which some number of the tosses result in H and the others result in T, thus a sequence of tosses that includes no T may be perceived as less representative of the event space than one resulting in some combination of H and T. Individuals reasoning according to the representativeness heuristic may respond that the sequence HTTH is more likely to occur than HHHH, as it looks more like a generic outcome. Rather than responding to the question about the relative likelihoods of these two events, these individuals provided a response to the related question, "Which of these two sequences is more representative of a typical element of the event space?"

The Study

Participants and Setting

Prospective secondary and middle school teachers (n=34) participated in this study. They were in the last term of their teaching certification program, enrolled in the methods course for teaching secondary and middle school mathematics. The participants held Bachelor's degrees in Mathematics or Science; the latter included a sufficient component of mathematics courses required for teaching certification.

The course provided participants with an opportunity to explore and extend their own mathematical thinking, while focusing on the learning and teaching of mathematics. During the course, as part of exploring instructional materials and didactical approaches, participants prepared for instruction by completing several scripting tasks (see section 4.2.1); their responses to one such task, Fraction in the Middle, are analysed in this report. Prior to completing the Task, the class discussion attended to various representations of fractions and operations with fractions

-- topics that initially appear in elementary school, but are revisited in middle school, as they are known to present difficulties for many learners. The Task was presented to participants as an individual assignment, which they were asked to complete within two weeks.

The Task

The Task presented below belongs to the genre of "Scripting tasks" developed in mathematics education to explore and strengthen teacher knowledge, while considering instructional situations. Scripting tasks used in prior research usually included a *prompt*, which is a beginning of a dialogue between a Teacher-character and Student-characters. In most cases the prompt introduced a student error (e.g., Zazkis, et al., 2013a), a student question (e.g., Marmur & Zazkis, 2018; Zazkis & Kontorovich, 2016), or a disagreement among students (e.g., Marmur, Moutinho, & Zazkis, 2020; Zazkis & Zazkis, 2014), to which the scriptwriters had to respond by continuing the dialog. The scripted dialogue demonstrated teachers' "awareness-in-action" (Mason, 1998, p. 255) by showing the envisioned response in practice, rather than in theory, to student errors, queries, or unusual ideas.

The "Fraction in the middle" Task

The "Fraction in the middle" Task included the prompt in Figure 1.

Teacher:	So we have discussed different ways to find a fraction between two fractions. Let us look at 1/6 and 1/7 . Can someone please summarise what ways were mentioned?
Alex:	[…]
Teacher:	Thanks. Let someone else continue.
Brook:	[…]
Cory:	But what number will be exactly in between?
Teacher:	What do you mean?
Cory:	Like, in the middle of these.
Alex:	It will be 1/6.5
Teacher:	This is a very interesting suggestion. Why do you think so?
Alex:	Clearly, 6.5 is exactly in the middle between 6 and 7, so 1/6.5 should be exactly in the middle between 1/6 and 1/7 .
Teacher:	[…]

Figure 1. The "Fraction in the Middle" Task Prompt

Continuing the dialogue – in particular, addressing a query of Cory (what number will be exactly in between) and an unexpected suggestion of Alex (it will be 1/6.5) as well as justification for it by drawing analogy to whole numbers – was the main part of the Task.

The prompt was developed building on the study by Marmur, et al. (2019), in which prospective elementary school teachers responded to a student conversation about the possibility of finding a number between any two numbers. While a student-character in the prompt developed by Marmur, et al. (2019) suggested that there were no numbers between 1/6 and 1/7, the reference to 1/6.5 appeared in several scripted conversations. The study examined several cases in which student characters grappled with the unconventional representation, either rejecting it as a viable number or seeking a way to make sense of it.

We were interested to learn how 1/6.5 would be interpreted and treated by prospective secondary teachers when it is referenced in the context of seeking the number in the middle of the two "pseudo-successive" fractions. We focused on a pair of pseudo-successive fractions, as such fractions are frequently perceived as consecutive numbers with no numbers in between (e.g., Vamvakoussi & Vosniadou, 2004). As in Marmur, et al (2019), we kept the numbers small enough to simplify the calculations, but chose numbers that would inhibit immediate conversion to decimals, as the use of decimal representation is known to simplify the identification of numbers in between (Van Hoof, Degrande, Ceulemans, Verschaffel, & Van Dooren, 2018).

Data Analysis

Participants' responses to the Task "Fraction in the Middle" comprise the data analyzed in this study. The analysis of the data began with a thorough reading of all the scripts to get a general sense of how the PSTs responded to the task. We then narrowed our focus to the PSTs' responses to Cory and Alex's discussion on what number would be "exactly in between" 1/6 and 1/7 and the ways PSTs addressed the suggestion of 1/6.5.

We initially noticed the wide variety of mathematical approaches and representations that were present in the PSTs' responses. The PSTs' mathematics included but were not limited to averaging algorithms, number lines, decimal representations, descriptions of graphs, and part-whole fraction models. On a second read through of the scripts, we focused on how the PSTs were responding to Cory's inquiry in particular. We noted that the responses provided by the PSTs were typically not mathematically incorrect, but they seemed either irrelevant to or only tangentially related to Cory's question and Alex's suggestion. Although some responses of the participants seemed to us inappropriate for the given task, they did seem appropriate for *a different* task related to fractions. Revisiting the data, we identified 10 questions which were implicitly addressed by the participants in their scripted instructional interactions and explanations. We then classified each of the explanations provided within the scripts as a response to one of these 10 questions. We further grouped these 10 questions under three themes, as some questions addressed related content.

Our unit of analysis was an explanation provided by a PST within a script. An explanation could have been provided by a teacher-character or by a student-character and accepted by a teacher. All of the PSTs provided multiple explanations within their scripts: for example, they might have begun with an explanation of the relative size difference between 1/6 and 1/7, thus addressing the pseudo-ordering of the fractions, then transitioned into a discussion of different algorithms for identifying fractions between a given pair of fractions. Instances like this were categorized as two distinct responses and were analysed separately. Thus, although our sample consists of 34 scripts, the total number of responses we considered in our analysis is 127.

Results

Overview

Again, each script contained multiple explanations, yielding a total of 127 explanations to 10 questions across the three themes as organized in Table 1. The three themes we identified were explanations related to prerequisite knowledge of fractions, explanations focused on ideas around the number 1/6.5, and explanations related to the middle of 1/6 and 1/7.

For this proposal, we briefly address the results of the first theme and then discuss these findings using through the lens of attribute substitution in the discussion.

Table 1. Themes and questions identified in responses.

Themes and related questions	Number of explanations
<u>1. Focus on pre-requisite knowledge related to fractions</u>	
How do you properly order fractions by relative size (i.e. 1/7<1/6)?	9
Why can't you compare fractions with different denominators?	9
How do you find a common denominator?	9
<u>2. Focus on number representations, specifically for 1/6.5</u>	
What is a fraction? Is it a single number of two numbers?	3
Why isn't 1/6.5 a rational number (issue with decimals in fraction)?	8
How do you manipulate a fraction containing a decimal?	8
<u>3. Focus on the middle</u>	
How do you find the middle of two fractions?	24
What is the middle of 1/6 and 1/7?	29
Is 1/6.5 the middle of 1/6 and 1/7?	20
Why isn't 1/6.5 the middle of 1/6 and 1/7?	6

Focus on pre-requisite knowledge related to fractions

Many of the explanations highlighted prerequisite knowledge related to fractions, where the PSTs used their response as an opportunity to re-teach elementary concepts. Focusing primarily on the fractions 1/6 and 1/7 given in the prompt, 27 of the 33 scripts contained explanations to three different questions related to fractions, specifically: "*How do you properly order 1/6 and 1/7?*", "*Why are fractions with different denominators not comparable?*", and "*How do you find the common denominator given two fractions?*"

Of the 27 explanations focused on pre-requisite knowledge, 9 attended to the pseudo-successive ordering of the fractions 1/6 and 1/7, highlighting the fact that 1/7 is smaller than 1/6. Another 9 explanations were provided for why fractions with different denominators cannot be compared. Most of these explanations contained visual representations including pizzas and number lines, often highlighting the inevitable size difference between the fractions and concluding in statements such as, *"1/6 and 1/7 aren't on the same number line, sort of like they are speaking different languages" (Student 19)*. Lastly, 9 explanations provided details for how to find the common denominator between two fractions, a skill we would consider pre-requisite for secondary mathematics.

Focus on Prerequisite Knowledge and the Availability Heuristic

We view the scripts in which the main attention was directed towards providing prerequisite fraction information as a consequence of the availability heuristic. The availability heuristic involves an attribute substitution by which an individual makes decisions about an event by recalling familiar instances of similar events (Tversky & Kahneman, 1973).

The number 1/6.5 presented our prospective teachers with an unfamiliar representation (fractions containing decimals) of familiar mathematical objects (fractions more generally). Rather than responding to Cory and Alex or addressing the value of the number or its unfamiliar representation, some PSTs chose to respond with information about fractions that was more easily retrievable, including familiar facts, representations, and commonly taught models. Several of these responses focused on the fact that 1/7 < 1/6 (despite the fact that 6 < 7) or on constructing a visual representation for fractions in standard form, like cutting a pizza into 6 pieces of equal area to represent 1/6 (part-whole model), taking one pencil away from three to represent 1/3 (set model), or placing fractions on a number line (measure model). These responses explained fundamental concepts and procedures, such as why the magnitudes of fractions with different denominators cannot be compared and the necessity for finding equivalent fractions with a common denominator as well as procedures for doing so.

Indeed, from a pedagogical perspective, these explanations resemble standard lessons on fractions and ways of thinking about them. The prospective teachers in our sample have likely experienced several lessons like these and discussed central ideas related to teaching and learning fractions in their coursework. As such, a familiar topic and strategy for a fraction-related lesson served for some scriptwriters as an available heuristic attribute.

Discussion and Conclusion

The results of our investigation highlight the difficulty of PSTs' experience when asked to respond to students' ideas that describe a particular strategy for finding a midpoint, and to unconventional representation of fractions.

With respect to the former, we argue that pre-service teachers should be given more practice responding to students' suggestions and focusing on their approaches and reasoning rather than on the correctness of the solution. Scriptwriting is a good opportunity to engage in such practice in a hypothetical situation, before teachers engage in "thinking on their feet" in actual instructional interactions.

With respect to the latter, we note the PSTs' uneasiness in dealing with 1/6.5 as a number. While treating this number as "illegal" or "not allowed" by prospective elementary school teachers was noted in prior research (Marmur, et al, 2020a), we were surprised to find a similar uneasiness and similar expressions used by prospective secondary school teachers, who in their mathematics courses had significant exposure to fractional forms involving all kinds of real numbers, such as $\frac{\pi}{2}$, or algebraic expressions in numerators or denominators.

In addition to extending research on unconventional representations, our contribution is in describing the pedagogical choices of PSTs in terms of attribute substitution. The concern that some teachers chose to devote major attention in their scripts to issues that are not central to the mathematics at hand was depicted in prior research as a "pedagogical shield". This included detailed discussions related to prerequisite concepts (Koichu & Zazkis, 2013b), considering examples that that are peripheral to the mathematical core of the task (Marmur & Zazkis, 2018) or limiting the scope of the issues under consideration (Zazkis & Kontorovich, 2016). That is, the "shield" metaphor was used as means designed by teachers to protect themselves from uncertainty in how to deal with the presented mathematical situation. We analysed such pedagogical choices in terms of availability and representativeness heuristics.

Prior research used attribute substitution in describing judgment in cases of uncertainty in probabilistic decisions. We extend the applicability of this construct to cases of uncertainty in making pedagogical decisions. Future research will examine additional heuristic attributes in instructional situations that explicitly or implicitly divert attention from responding to students' mathematical ideas.

Students' Mathematical Reasoning With and About Representations

Wesley K. Martsching
University of Northern Colorado

In mathematics, problems are solved and communicated to others using various forms of representation. For this reason, many mathematics courses are designed to develop and foster student fluency with mathematical representations. However, it is equally important to understand how students naturally produce and use representations when solving problems. Using intentional questioning in task-based, semi-structured interviews, I sought to identify emergent themes relating to what representations students construct in solving mathematical tasks, how they use these representations, and the relationship between their conceptions of the tasks and their constructed representations. Two Calculus I students participated, individually, in an interview comprised of two novel tasks. Inductive coding of interview transcriptions and participant representations identified three purposes of representation construction: as direct interpretations, as auxiliary objects, and as constraints. Results suggest that tasks provide students with the opportunity to construct and reflect on their own representations and compare them to other available representations.

Keywords: Calculus, Mathematical Reasoning, Representations

The importance of students' ability to utilize and understand various representations when engaged in mathematical contexts has been heavily emphasized in policy and curriculum-standard documents (e.g., CCSSI, 2010; CUPM, 2015; NCTM, 2000). In all levels of mathematics preparation of students (e.g., PreK-12 to post-secondary), the guidance of these standard documents includes fostering students' ability to reason about, model, prove, and communicate mathematical ideas and concepts. Student construction of verbal or written utterances, models using manipulatives or figures, and formal or informal proof that communicate or convey mathematical ideas or concepts all exemplify some form of representation in mathematics (Goldin, 2014; Goldin & Kaput, 1996; Goldin & Shteingold, 2001).

In this study, I situate students' utilization and interpretation of representations within the context of mathematical reasoning; that is, "purposeful inference about mathematical entities or relationships" (Conner et al., 2014, p. 183; see also Moshman, 2004). Through a constructivist lens, I seek to describe two students', Seris and Samantha, reasoning with and about representations in a mathematical setting.

Background Literature

There exists a plethora of research investigating students' use of representations in mathematical settings. However, previous research has focused on students' use of representation in relation to specific mathematical content including algebra (Clement, 1982; Moon et al., 2013; Stylianou, 2011), arithmetic (Carraher, Carraher, & Schliemann, 1985), calculus (Mamolo & Zazkis, 2012; Stylianou, 2011), conic curves (Moon et al., 2013), and prime numbers (Zazkis & Liljedahl; 2004). Related literature also tends to investigate students' construction and held meanings of *specific* representations including algebraic functions or equations (Carraher, Carraher, & Schliemann, 1985; Clement, 1982; Mamolo & Zazkis, 2012; Stylianou, 2011), contextual situations and word problems (Carraher, Carraher, & Schliemann, 1985; Clement, 1982; Mamolo & Zazkis, 2012; Stylianou, 2011), graphs (Moon et al., 2013; Stylianou, 2011), tables (Stylianou, 2011), "transparent" representations (Zazkis & Liljedahl, 2004), and verbal definitions (Mamolo & Zazkis, 2012; Moon et al., 2013). Thus, modern research has yet to investigate the utilization and held meanings of students' naturally constructed representations in contexts not designed to directly elicit construction of traditional representations.

DiSessa et al. (1991) investigated students' reinvention of graphing that was centered around activity meant to promote students' invention (or reinvention) of the concept of cartesian graphing. In this activity, the goal for the students was to use technology to create a simulation of the motion of an object depicted in a given scenario, and then, using pencil and paper, construct a static motion picture that could be used to express, in as much detail as possible, their simulations of the original scenario. The use of a contextual problem, its origin void of any direct relation to those representations which our students have been conditioned culturally to use, may be the catalyst for opportunities to invent representations by the students in the study.

In relating expert mathematicians' and students' use of representations in problem solving situations, Stylianou (2011) identified emergent themes relating to use of representations in individual and sociocultural settings. Stylianou determined that, in individual problem-solving, participants used representations as means to understand information, as recording tools, as tools facilitating exploration, and as monitoring or evaluating devices. In social settings, participants further used representations as presentation tools, tools to negotiate, and as tools to co-construct meaning. Taken together, Stylianou's (2011) and DiSessa et al.'s (1991) studies provided motivation for the following research questions: (a) what representations do students construct when engaged in novel mathematical tasks, (b) how do students use their constructed representations when engaged in these tasks, and (c) how do the meanings students imbue in their constructed representations relate to their conceptions of the tasks at hand.

Methods

Participation was solicited from College Algebra and Calculus I courses at a mid-sized university in the Rocky Mountain region. These courses were chosen for solicitation based on the perceived diversity of student backgrounds and interests and because instruction in these courses often emphasizes the use of traditional representations in mathematical reasoning. Two students, Seris and Samantha (participant selected pseudonyms), participated in this study. Due to unanticipated restrictions on social interactions with the Covid-19 pandemic, no further participants were added to the study. Both Seris and Samantha were enrolled in a Calculus I course at the time of the interviews. Seris and Samantha each participated in a single one-on-one task-based clinical interview with the researcher. Each interview lasted approximately 75 minutes. Two tasks were utilized in these interviews.

Interview Task Design

Individual interviews were centered around two purposefully constructed tasks; each task was comprised of multiple parts and were unique in the prerequisite knowledge required and the types of representations they were predicted to elicit.

Task 1-Loveland Task. This task was developed from Saldanha and Thompson's (1998) research investigating students' covariational reasoning. The original task was created in GeoGebra and allowed a student to move the point associated with a car along a slider representing a road on which the car traveled. As the student varied the car's position on the slider, a secondary representation would display the relationship between the car's distance relative to reach of two cities positioned on either side of the road.

Modifications to the task by Stevens et al. (2017) added a third city and named each of the cities, situating the car's path of travel within a context relative to the region in which their study was conducted. Further, in their goal of constructing tasks specifically designed to elicit students' covariational reasoning, Stevens et al. removed the function allowing students to manipulate the cars position themselves and the secondary representation depicting the relationship between the car's distances between each of two cities. Students were then asked to construct the graph relating the cars distances relative to each of two cities themselves. The graphs that this non-trivial task yielded were utilized by Martsching (2019) to provide students with multiple representations to discuss relative to the same prompt. These on-screen representations were utilized to investigate students' eye-movements as they reasoned covariationally about each representation.

The Loveland Task was thus created void of any mention of traditional representations to encourage students to construct their own non-traditional representations to convey meaning, and further incorporated a speed element to make utilization of traditional representations more non-trivial. The context for the Loveland Task is provided below:

> Loveland Task: Sam is driving from Ft. Collins to Greeley. Before leaving, she notes that her map shows Loveland is about 13 miles due south of Ft. Collins, and Greeley is about 19.5 miles due east of Loveland. Sam's trip from Ft. Collins to Greeley can be described as follows: Sam begins driving due south from Ft. Collins at a constant speed of 40 miles per hour. After 12 minutes, Sam turns and begins driving due east at a constant speed of 45 miles per hour. After six minutes, she again turns south, driving for four minutes at 75 miles per hour. She then turns east and, after 20 minutes at 45 miles per hour, finally arrives at Greeley.

This task had multiple subtasks which were intended to build in complexity in a sequential manner. The themes of these subtasks were: a) construct a representation of the trip, b) construct a representation of the car's distance from a given city with respect to time, and c) construct a representation relating the car's distance between each of two cities.

Task 2-Compound Interest Task. The second task was inspired by my observations as a teacher and as a researcher of student difficulties in relating contextual, verbal, and figural representations involving percentages. This task was included in this study because of its prevalence in algebra courses at both the K-12 level and the undergraduate level and the perceived association between it and traditional symbolic and figural representations (e.g., $A = P\left(1 + \frac{r}{n}\right)^{nt}$, exponential models, etc.). This association with traditional representations in conjunction with explicit verbal reasoning was anticipated to cause perturbation with students' reasoning and reveal the prominence of their deeper contextual understanding.

> Compound Interest Task: Brian invests $1,000 into a savings account with an APR of 5%, compounded annually (i.e., at the end of each year, 5% of the account's current value is added to the account).

This task had two subtasks: a) discuss aloud how the value of the account changes over time and b) sketch a graph of the value of the account with respect to time. The explicit verbal representation was predicted to elicit focus on meaning of the contextual representation provided and prompt reasoning about discrete changes in the account's value, whereas figural representations where anticipated as allowing students to strip the task of its context and reason about the value of the account in traditional, pre-conditioned ways.

Data Collection

The video and audio data relating to participant verbal utterances and physical gestures were collected via a camera positioned over-the-shoulder and behind the participant. Primary video data relating to participant in-the-moment constructions of representations were collected via screen recording of a touchscreen tablet. Secondary audio data was collected via a portable audio recording device.

Both Seris and Samantha engaged in the Loveland Task first. However, the first subtask (construct a representation that could be used to convey the trip to someone else) yielded rich discussion and took longer than anticipated. Because of time restraints, some subtasks of the Loveland Task had to be omitted from the interviews. Further, based on Seris's reasoning during the Compound Interest Task, the order of the two subtasks was changed for Samantha so that she was asked to construct a graphical representation prior to constructing an explicit verbal representation of the context.

Analysis

Following the interviews with Seris and Samantha, the primary datasets for each participant (i.e., over-the-shoulder video and audio; screen-recording videos) were superimposed to display verbal, gestural, and written representations simultaneously. Audio data were transcribed in their entirety. The superimposed videos were reviewed by the researcher in conjunction with the transcriptions to familiarize the researcher with the data prior to coding.

While deductive coding utilizing the themes described by Stylianou (2010) may have been fruitful, in this study I was interested in students' construction of representations in solving mathematical problems. In particular, in this study a representation or a collection of representations were often the product or solution to a problem, rather than tools by which a problem was solved. Inductive coding was thus deemed a more appropriate tool for analyzing the data in this grounded theory study. The data sets were hence coded based on (a) instances in which each participant constructed or interacted with a representation, (b) the participant's held meaning of the representation of focus, and (c) the participant's use of the representation of focus.

Results

Through analysis of Seris' and Samantha's mathematical reasoning with and about representations in the context of the Loveland Task and the Compound interest Task, I determined that these students used representations in three distinct ways. Both Seris and Samantha constructed *Representations as Direct Interpretations* of the context provided. For the Loveland Task, Seris and Samantha constructed "maps" depicting the orientation of and distance between the three towns in addition to representations of the trips constructed with vector representation to depict directionality, speed, and time spent traveling. Seris and Samantha also demonstrated their construction and use of *Representations as Constraints*. This theme was recurring throughout the Loveland Task in Seris' and Samantha's "maps", Samantha's conclusion that subtasks c and d were impossible to complete, and in Samantha's modification of her interpretation of the context in the Compound Interest Task to match her constructed graph. Finally, both Seris and Samantha constructed *Representations as Auxiliary Objects*; that is, they constructed representations that were to be used in conjunction with one another, but that did not necessarily fulfill their intended purpose alone. This use of representation was evident in Seris's triangular map, his "time series", and in Samantha's use of equations and table in the Compound Interest Task.

Representations as Direct Interpretations

The purpose of each task was to construct a representation that could be used to communicate or depict the information of a given context, hence the representations constructed by participants were the end products of a solution rather than tools used to find a solution. To achieve the goal of communicating such a context, the most appropriate and readily available representation for participants was the context itself. Rather than quantifying the information given and reproducing it using traditional (or normative) mathematical representations (e.g., tables, graphs), participants constructed still images depicting the context itself as they perceived it. These representations served as direct interpretations of a context and sought to capture emergent components through non-traditional means.

Task 1, subtask a) asked students to create a representation that they could use to convey Sam's trip from Ft. Collins to Greeley to someone else. Seris began by constructing a representation depicting the relationship between towns themselves (see the top-left representation of Figure 1a), stating "so I guess with any problem like this, the first thing I would do is draw out kind of the basic elements that I know". Similarly, Samantha also depicted the orientation of the towns and the distances between each within a rectangular "map" (Figure 1c).

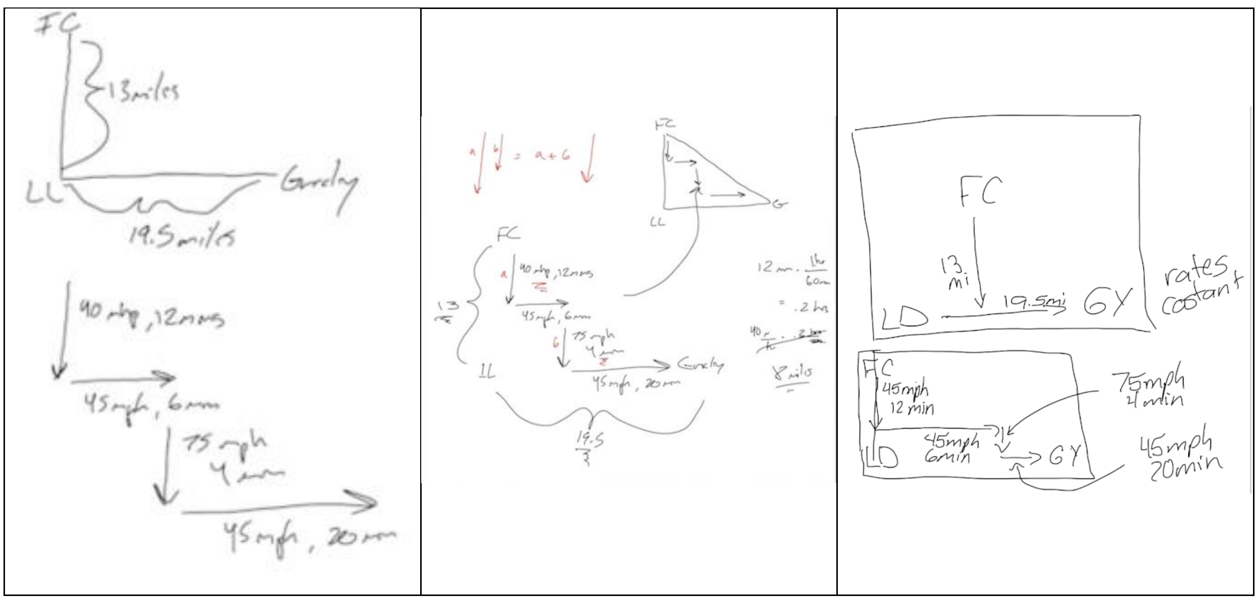

Figure 1. Seris's initially constructed representations (a; left), Seris's final constructed representations (b; center), and Samantha's final constructed representations (c; right) for the first subtask of the Loveland Task.

When depicting the trip itself, both Seris and Samantha utilized vectors to convey the speed and linear directionality of the car's travel. In addition to assigning directionality and units for speed, both Seris and Samantha included with each vector the time, in minutes, that the car spent traveling in a given direction at a given speed (see the bottom representations of Figure 1a and Figure 1c). Further, Seris stated that his original representation (see top left of Figure 1a) was "grounding to what these vectors actually mean".

When engaged in the Compound Interest Task, Seris was asked to first reason verbally about the prompt before constructing any written representations. He quickly determined that the money in the account only changed at the end of each compound period, at which time the account grew by 5% of its current value. Thus, when asked to construct a graphical representation, Seris paid little attention to symbolic manipulations, and immediately constructed a step function depicting the constant value of the account within each compound period. This instance was determined to be exemplary of Seris constructing his graph as a direct interpretation of the context of the task, as he constructed the trace of the function whilst simultaneously describing the emergent change in the accounts value over time.

Representations as Constraints

Whether implicit or explicit, contexts in which a problem is situated typically contain parameters that constrain or limit a solution strategy. Similarly, representations used to convey information can be validated or made more accurate by imposing characteristics that serve to represent these constraints.

Upon remembering that his goal for the Loveland Task was to convey the trip to someone else, Seris himself opted to construct the "map" seen at the top of Figure 1b. By situating the trip inside the depicted triangle that "constrain[s] the problem geometrically", Seris asserted that this depiction including both the vectors and the orientation of the towns depicted the trip in simplest terms to get from one town to another. When calculating how far the car had traveled during each leg of the journey to Greeley, Seris further stated that "you could use that as a way of understanding like, if you are leaving this triangle then I guess either it shows that her pathing is weird […] or it kind of constrains you and tells you like, okay, I did something wrong in this initial kind of calculation". To Seris, if any of his calculations meant that the car would travel outside of the triangle, then either the original context did not correctly describe the car's path, or his calculations were wrong.

In the third and fourth subtasks, asking participants to create a representation showing how the car's distance from Loveland changes over time and to create a representation showing how the car's distance from Ft. Collins and its distance from Loveland relate, respectively, Samantha claimed that the task could not be answered. To Samantha, the phrase *from Loveland* implied that the car had to have been *in* Loveland at some point, and that the distance being described was in fact the car's distance travelled as it travelled *from* Loveland. Like Seris's triangular map, Samantha's interpretation of the task at hand was a representation in and of itself that constrained her ability to solve the problem. To Samantha, the constraints that she'd created, although she constructed no tangible representation of them, implied that the task was an impossible one.

Representations as Auxiliary Objects

When constructing representations used to convey information from a given context, it may be challenging to create a single representation that adequately captures all of the information of interest, particular when the context is a dynamic one. In this case, secondary representations may serve as auxiliary objects to the primary representation of focus; that is, additional representations may be constructed to enhance or organize the information of another.

When Samantha related her two representations in Figure 1c, she stated that her second representation represented that Ft. Collins was directly opposed to being above some point in between Loveland and Greeley, and that her initial representation was "more like a compass". To Samantha, this compass oriented her construction and interpretation of her primary "map".

Seris, in stating that "maps are 2D so you can put them on a coordinate plane" situated the vectors of his trip on the coordinate plane shown in Figure 2a. In realizing that this representation alone did not convey how the car's distance from Ft. Collins changed with respect to time, Seris constructed what he referred to as a "time series" (top-right of Figure 2a). He justified this construction by recognizing that the velocities along each vector were held constant, enabling him to break the overall trip into "discrete coordinates" that, when related to the corresponding point in the time series, could be used to depict time spent travelling, horizontal distance travelled, and vertical distance travelled relative to Ft. Collins. In this way, Seris constructed the compass shown to illustrate that a $-y$ value corresponds to southward travel, whereas a $+x$ value corresponds to eastward travel. In representing how the car's distance from Ft. Collins and its distance from Loveland related during the trip, Seris drew the red and blue vectors shown in Figure 2b. Seris "zoomed in" on two corresponding vectors to illustrate how the distances from each of the two cities related at that point on the trip. Like the "time series", these vectors added a layer of information to Seris's original representation of the trip.

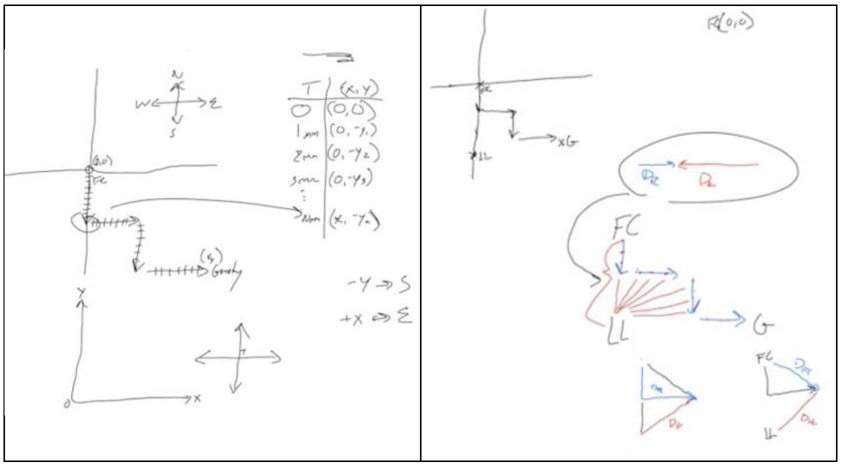

Figure 2. Seris's constructed representations (a; left) for subtask b of the Loveland Task, and Seris's constructed representations (b; right) for subtask d of the Loveland Task.

Discussion

Because each interview capped at 75 minutes, there was difficulty in fully completing both tasks with both participants. The restriction on time meant that only two tasks were able to be used in the study; due to COVID-19, restriction on contact also meant the study was limited to two participants. Future studies should investigate students' construction of non-traditional representations when solving contextual problems to determine if any additional purposes in representation construction arises.

The results of this study echo the discussion brought forth by Gravemeijer et al. (2017), who questioned what mathematical proficiency was needed by members of society. In their review of mathematical workplace tools, the authors described how workers utilized noncanonical graphs and problem-solving practices that differed significantly from what is taught and used in the classroom. Workers are motivated to use nontraditional representations as practical tools to arrive at efficient solutions and, like Seris and Samantha, tailored them to the affordances and constraints of the context from which they were derived. As was evident in the results of DiSessa et al.'s (1991) study, students provided with more time on the tasks in this study would likely have been able to move beyond the use of representations as auxiliary objects and may have the opportunity to reconstruct more meaningful representations. I believe that these results warrant investigation of the design of tasks and practices that both encourage students' construction of practical representations and promote reflection on the accuracy and efficiency with which their representations communicate mathematical ideas.

STEM disciplines and especially mathematics are turning to alternative forms of instruction and assessment in order to improve learner outcomes. Here, we report on assessment outcomes in a mastery-based Precalculus course (N = 464) at a large, public research university. In particular, the impact of behavioral nudges on students' assessment scores is evaluated using regression with academic performance covariates. We find a positive effect of two types of nudges on student assessment scores that span the semester. These results provide evidence that behavioral nudges can help students make choices that ultimately lead to higher scores, and presumably improved learning, in Precalculus.

Keywords: Behavioral nudges, Mastery-based grading, Nudge theory, Precalculus, Regression

Unique among STEM disciplines, introductory math courses in the U.S. have come to hold a hegemonic place in the university curriculum (Reinholz et al., 2019). For most universities and STEM degree programs, students must minimally either pass one or two math courses or demonstrate "proficiency" through a mechanism like a placement exam or earned transfer credit. With math being a foundational discipline across degree programs and at the K-12 level, it is concerning that, historically, learners have had a fraught relationship with the subject (Solomon, 2008). As a discipline, math faces the serious challenges of inducing student anxiety and effecting negative student perceptions (Eden et al., 2013; Sonnert et al., 2020). Some student groups are affected by these challenges more than others; poor learning outcomes and negative changes in affect are felt disproportionately by women, low-income students, and students of color especially in courses prior to calculus (Larnell, 2016; Larnell et al., 2014; Martin, 2019; McGee & Bentley, 2017), and these groups of students are also more often pushed out of STEM degree programs (Seymour & Hunter, 2019). The Common Vision report succinctly stated that "the status quo is unacceptable" (Saxe & Braddy, 2015, p. 1) and called for removing barriers that keep students from progressing, especially for courses taken during the first two years.

In this milieu, mastery-based pedagogy has shown promise at addressing these challenges by centering student progress in relation to their demonstrated understanding of learning objectives (Marzano, 2011; Sadler, 2005; Zimmerman, 2017) and emphasizing the importance of learning through struggle and revision, collaboration over competition, and that all students can succeed when properly supported. Mastery-based pedagogy has been correlated with gains in student achievement in several disciplines (Beatty, 2013; Boesdorfer et al., 2018; Buckmiller et al., 2017; Diegelman-Parente, 2011), including math (Riordan & Noyce, 2001; Schoen et al., 2003; Tarr et al., 2008). Mastery-based pedagogy may provide a productive pathway for course transformations, but much remains to be understood about the process of course redesign for mastery and its impacts on students and instructors, especially in high-enrollment courses with large instructional teams.

Here, we report on the impact of an intervention designed to improve student behavior with respect to an important aspect of mastery-based pedagogy: the opportunity to make multiple attempts on course assessments and improve over time. The intervention is a short series of personalized reminder emails and was conceived of as a behavioral nudge, an economics concept describing subtle and low-cost changes in an environment that help to promote a desirable action. Our research question is: To what extent can behavioral nudges improve student outcomes on mastery-based assessments in Precalculus? We found that engagement with the reminder emails increased students' scores on 40% of assessment opportunities, even while controlling for relevant covariates.

Theoretical Framework

The definition of behavioral nudges is often drawn from the work of Richard Thaler and Cass Sunstein (2008) who summarized them as "choice architecture that alters people's behavior in a predictable way without forbidding any options or significantly changing their economic incentives" (p. 6). In the face of cognitive limitations, nudges can make some choices more salient; for example, stocking produce near the cashier at a grocery store improves the rate at which it is purchased (Kroese et al., 2016). Importantly, nudges are conceived of as low-cost, non-coercive, and easy to ignore, leaving autonomy with the person exposed to the nudge. Though ideas about nudges and nudge theory have been criticized for being vague and having wide applicability across too many domains (Kosters & Van der Heijden, 2015), small changes to learning environments have been shown to effect positive outcomes and student achievement in myriad educational settings with students, instructors, and even parents (Damgaard & Nielsen, 2018). In contrast with interventions that change default and passive behaviors (e.g., opting in versus opting out), the nudges employed in this study are informational, providing an addition to the decision environment that students can actively use (Damgaard & Nielsen, 2018).

Methods

Context

This research took place at the University of Michigan (U-M), a large, public university where the Precalculus course of interest (herein called Math 101) enrolls approximately 600 students annually across small sections of about 20 students each. Recently, the Math 101 teaching team began work to shift the course assessments from a traditional model of three high-stakes exams to a mastery-based model including approximately 10 repeatable assessments and standards for each letter grade (Bennett et al., 2022). The new assessment structure now has 55% of students' course grades determined by the repeatable mastery assessments and a further 15% from work done during class meetings and on assignments. These scores plus two short, low-stakes exams comprise students' course grades, and there is a guaranteed scale for the course: students know in advance what grade they will get for a given course average and work. This assessment structure replaces a model in which 95% of students' course grade was generated by three timed (and necessarily high stakes) exams and a scaled grade distribution.

In the study period, students could complete the mastery assessments for a grade up to twice per day. Most assessments included five problems and were scored out of 5 points; students earned partial or full credit for scores of 4 or 5, respectively, but zero credit for scores of 3 and lower. The final assessment had 10 possible points and a similar credit/no credit assignment. During the first term with mastery assessments, instructors observed that students tended to make their first attempt close to the due date and that they overall used few of the available attempts. Thus, an email-based nudge intervention was designed with the goals of 1) encouraging students to make their first attempts earlier (each assessment was open for 10 to 14 days), 2) giving students feedback about their current score and number of remaining attempts, and 3) adjusting norms so that, in contrast to typical perceptions of quizzes and exams, initially low scores were seen as okay. The intervention was implemented with ECoach, a software platform already in use in Math 101. ECoach is an award-winning web-based student "coach" that supports success in large courses through tailored feedback (IMS Global, 2021; Matz et al., 2021). ECoach uses student survey responses, prior performance metrics, and information about how students are doing (e.g., homework scores) to provide tailored messages and resources like advice about exam preparation.

The nudge intervention consisted of two short reminder emails tailored to each student's behavior and sent with ECoach for each of the 10 mastery-based assessments. The first reminder (Reminder 1) was generally sent five days before the due date to all students and included information about students' current score, their remaining number of attempts, and tailored feedback. For example, students who hadn't yet started were encouraged to make their first attempt at least three days ahead of the due date, and students who had already made several attempts but still had low scores were encouraged to consider getting help during office hours. The second reminder (Reminder 2) was generally sent two days before the due date but only to students who had not yet earned any credit for the assessment (i.e., a score of 3 or lower). Students again received information about their current score and number of remaining attempts, and the feedback was tailored based on whether the student was not passing because they hadn't started the assessment or because they hadn't yet earned a passing score. Together, these reminders reflect a combination of two techniques identified by Münscher and colleagues (2016) in their framework for choice architecture: the nudges assist with "decision information" by showing students their scores and how many attempts they have remaining, and the nudges serve as a reminder about due dates, which is a form of "decision assistance."

Data Collection and Analysis

In the semester of interest, 464 students enrolled in Math 101. A demographic profile is provided in Table 1 showing that, compared to the rest of U-M, Math 101 tends to have higher proportions of students who are female, first-generation, low income, and members of racial and ethnic groups historically excluded from STEM (Asai, 2020). We also collected several variables from the ECoach database including 1) students' maximum mastery assessment score for each assessment, 2) whether students read the reminder emails for each assessment, and 3) whether students read their other Math 101-related ECoach emails throughout the semester as a gauge of their general proclivity to read similar emails.

Further, we collected students' grade point average in other courses (GPAO), a relevant metric of college-level academic performance. GPAO is calculated as the cumulative college GPA through the given semester excluding the course of interest and thus acts as a measure of student performance in all their other courses (Huberth et al., 2015; Koester et al., 2016). Most Math 101 students (≥80% in this study period) are in their first year, so GPAO is essentially a measure of their first-year college GPA (excluding Math 101). We note that at U-M, GPAO has been found to outpace the predictive value of all other typical covariates (e.g., high school GPA and standardized exam scores) with respect to student academic performance, namely course grades. The data were imported into and analyzed using IBM SPSS Statistics (version 27). Following basic descriptive statistics, we used linear regression to evaluate the impact of reading the reminder emails on assessment scores using GPAO and the extent to which students read their other Math 101-related emails as covariates. This study was determined by U-M's Institutional Review Board to be exempt research.

Table 1. Summary of demographic information for students in Math 101 during the study period compared to all full-time U-M undergraduates in the same term. [a]Only binary sex information was available. [b]Students were considered continuing-generation if any parent had any college experience. [c]Students self-report estimated gross annual family income. We use a $50,000 cut off because it is approximately 200% of the federal poverty guidelines for families with four persons (Office of the Assistant Secretary for Planning and Evaluation, 2021).

Characteristic	Math 101		U-M

≥$50K	257	55	62
<$50K	128	28	13
Missing	79	17	25

Limitations

One key limitation in using these data is that we know whether a student has *viewed* the reminder email but not actually whether they *read* the reminder email. That is, the ECoach database records the timestamp at which the reminder was viewed and there is no way based on the current data infrastructure to know the length of time that a student interacted with the reminder, though we were able to assess if students opened the same reminder multiple times. Throughout this study, then, we assume readership based on viewership and acknowledge that other methods of data collection would be needed to better understand the quality of student engagement with the reminders.

Results

Results from this pilot semester of email nudges are encouraging. Overall, the reminders were read by most eligible students (Figure 1). This pattern holds across both reminders which is somewhat surprising because it might be reasonable to suspect the group of students that is sent Reminder 2 (students who hadn't yet achieved a passing score two days before the due date) to be different in some academically relevant ways compared to the aggregate group that is sent Reminder 1. Readership drops over the course of the semester but levels out at approximately 60% by the fourth assessment, due about half-way through the term. Overall, students read these reminders at a slightly lower rate (M = 67%, SD = 27%) than that at which they read all their other Math 101 emails from the ECoach system (M = 72%, SD = 28%; $t(463) = 5.2$, $p < .001$).

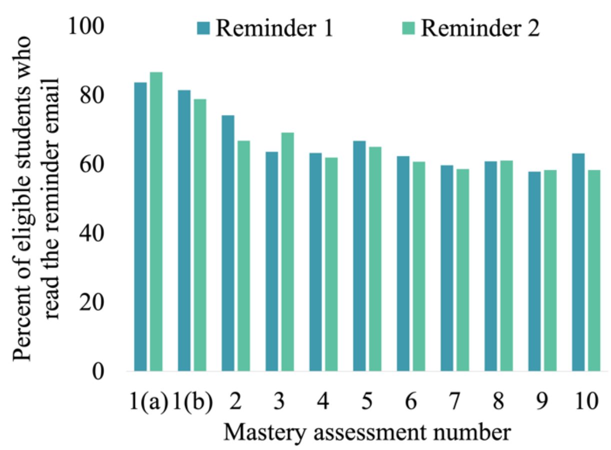

Figure 1. Percent of eligible students who read each reminder email. Because of a scheduling disruption at the beginning of the semester, there was a double set of reminders—1(a) and 1(b)—for the first assessment.

Students who read the reminder emails earned higher average scores on every assessment compared to students who did not for both Reminder 1 (Figure 2a) and Reminder 2 (Figure 2b). These score differences are statistically significant for 12 of the 20 total reminders (we used only the data from the first set (1a) of reminders for assessment #1; see Figure 1 for details).

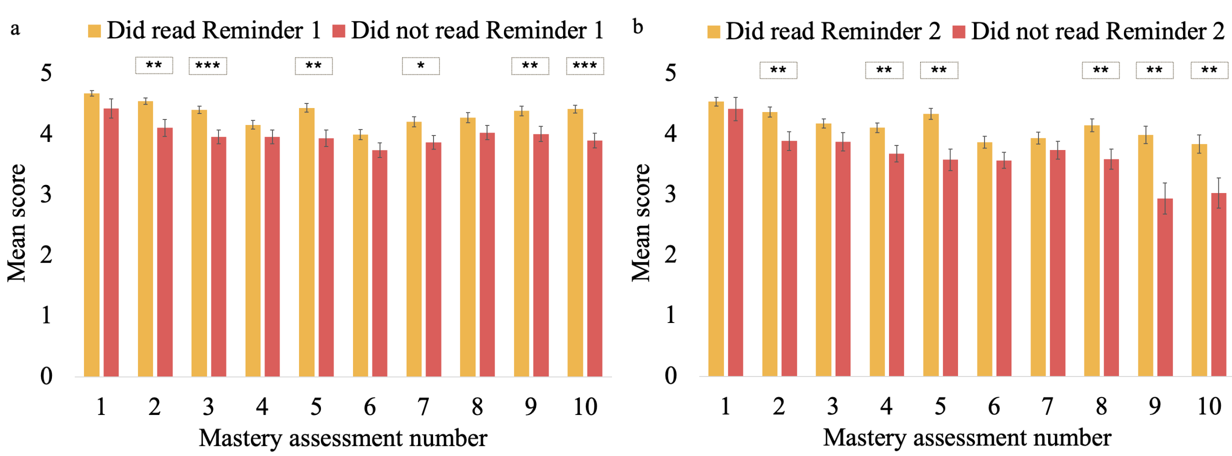

*Figure 2. Mean scores +/- standard error of the mean on each mastery assessment parsed by students who did and did not read Reminder 1 (a) and Reminder 2 (b). Comparisons for statistically significant differences were made by independent samples t-tests; *p < .05, **p < .01, ***p < .001.*

While it might be expected that students who read their email exhibit other behaviors that support earning higher scores, this result was stable for six of the reminder emails across four of the ten mastery assessments (#2, #5, #9, and #10) even after using linear regression to account for prior performance (with GPAO) and how much students read their Math 101 ECoach email in general (Table 2). In these cases, reading the reminder emails was associated with higher assessment scores by somewhere between 0.27 and 0.84 points on the 5-point assessment scale. Average variance inflation factors (VIF) close to 1 indicate that multicollinearity between covariates does not substantially bias the models, even considering the expected and observed relationship between reading the reminders and reading other course-related emails (correlations not shown). Inspection of the standardized residual plots for each model indicated that the assumptions of linear regression were met.

*Table 2. Linear regressions relating whether students read Reminder 1 or Reminder 2 emails and assessment scores. "Other email" refers to the percent of other eligible Math 101 emails sent through ECoach that students read. CI = confidence interval; LL = lower limit; UL = upper limit. Each model was significant with p < .001; *p < .05, **p < .01, ***p < .001.*

Discussion

Here, we find a positive effect of behavioral nudges on student performance on mastery-based assessments in Precalculus. These improvements are observed in assessments that span the semester, indicating some robustness to variation in student workload and the mathematical concepts and exercises at hand, and they are observed for both Reminder 1 and Reminder 2 though these nudges are targeted differently. Mastery-based pedagogy and similar assessment frameworks (e.g., standards-based grading and ungrading) are gaining attention in introductory STEM courses and specifically mathematics as a route for supporting positive student outcomes, both cognitive and affective. The results described here provide evidence that within a mastery-based framework, non-coercive behavioral nudges can be effective in helping students make choices that ultimately lead to higher scores and presumably improved learning.

Importantly, this study provides an example of successful personalized nudging. Improving the precision and effectiveness of behavioral nudges through more personalized default rules is an active area of research (Mills, 2020; Sunstein, 2013). With evidence that broadly applied homogeneous rules can have unintended effects and even harm specific subpopulations (Thunström et al., 2018), understanding the nature and extent of efficacious personalization in learning environments is important. There is also a relationship between this work and efforts to cultivate growth mindsets with students, especially for those in developmental courses (Mills & Mills, 2018). By design, mastery-based pedagogy asks learners to focus on evaluating their progress toward achieving learning goals, a key characteristic of students who exhibit intrinsic motivation to learn (Middleton & Spanias, 1999). Supporting students' growth orientation and intrinsic motivation to learn may be particularly crucial in math, and evidence that mastery-based pedagogy supports growth orientation is building (Collins et al., 2019; Prasad, 2020).

Future research will report on the quality of interactions that Precalculus students have with the reminders and insights into the mechanisms by which they affect outcomes. Certainly, student mindset about learning in math, and especially in mastery-based courses, is an important area for future work that can provide momentum toward the improvements in undergraduate education sought by the larger mathematical sciences community (Saxe & Braddy, 2015).

Easy, Medium, and Hard: Structuring Space in 2D and 3D by Way of Linear Combinations

Matthew Mauntel
Florida State University

Understanding linear combinations is at the core of linear algebra and impacts their understanding of basis and linear transformations. This research will focus on how students understand linear combinations after playing a video game created to help students link the algebraic and geometric representations of linear combinations. I found that having students reflect upon the game and create their own 3D version of the game illustrated which elements of 2D understanding could be translated into 3D. Also, students creation of easy, medium, and hard levels provided insight into how students progressively structure space.

Keywords: Linear Algebra, Linear Combinations, Game-based Learning

Understanding linear combinations in a variety of dimensions is core understanding linear algebra. In addition, it is important that students can reason through a variety of representations of multiple concepts including linear combinations (Hillel, 2000; Sierpinska, 2000; Larson & Zandieh, 2013). Well-designed games created with learning theories in mind can help students associate multiple representations and problem-solve (Ke & Clark, 2019). Vector Unknown (Zandieh et al., 2018; Mauntel et al, 2019; Mauntel et al., in press) is a game designed using the tenants of Realistic Mathematics Education (RME). The focus of the game is to help students connect geometric and algebraic representations of linear combinations with vector equations. This paper is part of a larger project where the goal is to analyze how students structure two-dimensional space space after playing the game *Vector Unknown,* and how this two-dimensional space structuring informs their structuring of three-dimensional space.

Literature Review

Vector Unknown is based on the Magic Carpet Ride task (Wawro et al., 2013) which is the first task in a sequence that cover linear combinations, span, linear independence. The task uses travel as a metaphor for taking linear combinations of vectors. Stewart and Thomas (2010) found that linear combinations were central to students' understanding of basis, span, and linear independence. Dogan-Dunlap (2010) utilized Sierpinska's modes of reasoning (2000) and found that students who were able utilize both geometric modes of thinking were also able to utilize analytic modes of reasoning. This research indicates that bridging the gap between geometric and algebraic representations of vectors and linear combinations can be beneficial for students learning linear algebra. Coordinating the ideas of linear independence and span is a key area of difficulty related to organizing linear combinations and transitioning from two-dimensional to three-dimensional space. These areas could be addressed using game-based learning as they can be represented in multiple ways including a visual mode that may difficult to represent on paper.

Well-designed games follow good learning principles (Gee, 2003). Gee (2003) postulates that one of the reasons video games are so popular is because they keep students pleasantly frustrated with well-ordered problems that engage them in complex reasoning. Furthermore, intermittent periods of reflection and gameplay have been shown to be successful in helping students learn from video game environments (Foster & Shah, 2015). For this reason, this research will involve having students play the game *Vector Unknown*, reflect upon the game, and then use this reflection to design their own three-dimensional space version of the game.

Study Context

The Game Vector Unknown

In this section I describe the game *Vector Unknown* (https://tinyurl.com/linearbunny) its creation, and describe some gameplay. The game *Vector Unknown* was developed as a coordination between math educators, experts in game-based learning, and programmed by a team of capstone students at Arizona State University to help students understand the connection between a vector equation and its geometric representation. Zandieh et al. (2018) designed the game *Vector Unknown* based upon a theoretical framework that intersects GBL with RME (Zandieh et al., 2018). The goal of the game is to have the player select two vectors, adjust the scalars, and press GO to guide the rabbit to the basket. In the first level (Figure 2), the game presents with a collection of four different vectors. Once players have chosen at least

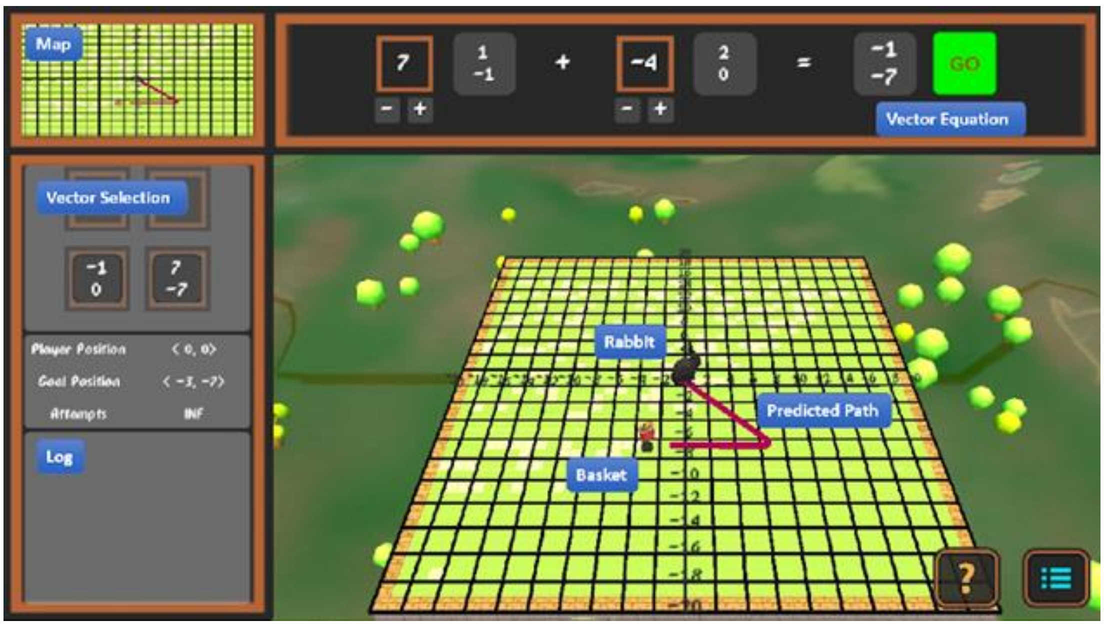

Figure 2. First level of the game *Vector Unknown* from Mauntel et al. (2019)

one vector, they can adjust the scalars in front of the vectors. Feedback received by the players includes a red predicted path generated from the rabbit illustrating each component of the vector equation. The result of the vector equation adjusts as the player adjusts the scalars in the vector equation. Above the log, players can view their position and the position of the basket location. The map in the upper left–hand coordinates provides an alternate view of the map. After the player presses GO, the rabbit moves along the path towards the basket and the log provides all vector equations used.

Prior Research on Vector Unknown

Mauntel et al. (in press) previously categorized game-play strategies from two main lenses: geometric or numeric. The geometric lens is when students focus on utilizing the graphical components of the game relating to the graph in particular the Predicted Path. Numeric thinking relates to when the player focuses more on the Vector Equation. One of the main goals of the game is to encourage the player to transition fluidly between the two different lenses. Mauntel et al. noticed several strategies that students employed while playing the game.

One of the strategies, quadrant-based reasoning, is when players utilize direction to anticipate to make their vector choices. The term quadrant is used because players start at the origin and often they would choose vectors that corresponded to the quadrant of the basket location. In the numeric lens this presented itself as a player choosing vectors that shared the same sign as the basket. In the geometric lens, students would often drag a vector and try it to see its direction to determine if it were in the same direction as the basket. Often players would transition between lenses for instance there are times when players would find the slope between two points by counting the change in *y* and change *x* on the Cartesian plane and then using this information to find the vector switching to a more numerical lens.

For the strategy focus on one vector, players would choose a single vector and then scale that vector as close to the basket as possible and then choose another vector to complete the trip to the basket. This theme presented itself in the numeric lens as scaling a vector until it was as close to the basket location in the vector equation as possible. In the geometric lens, players would scale the vector until the predicted path was close to the basket location, and then choose another vector to complete the trip. The fourth theme, focus on one coordinate, involved the players trying to use a vector or combination of vectors to reach a value or destination that matched the *x*- or *y*-coordinate of the basket location. This theme presented itself frequently when standard basis vectors were involved.

Theoretical Framing

My research will focus on analyzing student's mathematical activity in the sense of Freudenthal (1971, as cited by Gravemeijer & Terwell, 2000) as it relates to the taking linear combinations of vectors in two dimensions and the emerging activity that it generates. From this mathematical activity, I want to characterize a new type of emergent activity which I call structuring space use the term emerging activity as opposed to emerging models to indicate that tasks are not designed to guide the students to a fixed emergent model or formalize a particular concept, rather this research is focused on what models are possible to inform future development of an RME sequence. I call the students' emerging activity their structuring of space. After the students structure two-dimensional space, they will be asked to structure three-dimensional space. This transition is meant to induce a model of/model for transition as their structuring of two-dimensional space is utilized for structuring three-dimensional space. This research will utilize a realistic starting point of the video game Vector Unknown. Also, I will be looking at a how the student's structuring of two-dimensional space impacts their gameplay to gain more insight into how their ideas of structuring space relate to the game context. My research questions are:

1. How did students structure two-dimensional space with respect to linear combinations in relation to the game Vector Unknown?
2. How did students adapt their structure of two-dimensional space to a three-dimensional setting when designing a three-dimensional game based upon Vector Unknown?

This paper is part of a larger dissertation project and in this paper I will present a portion of my findings for research questions 1 and 2 for one group of students.

Interview Protocol

The interview took place over the course of four sessions. During the first session students played the game Vector Unknown individually. In the second section students were paired with another student based upon their gaming experience and were given a set of four vectors taken from the Vector Selection in the game and asked to list all possible locations to place the basket. Then, they were asked to create an easy, medium, and hard difficult set of vectors that could reach the basket location at (-3, 5). Finally, during the third session, participants were asked to design a three-dimensional space game based upon the two-dimensional space game by either creating an Easy, Medium, and Hard difficulty game with vectors and potential basket locations or design three sets of vectors (Easy, Medium, and Hard) that could be used to reach a basket placed at (3, -4, 5).

Participants, Data Sources, and Methods of Analysis

For this paper I will be looking at two students from a large Southern University. Neither student had taken linear algebra at the time of the interview. Students were asked to self-identify their race and gender. Both students identified as women, with one identifying her race as white (given the pseudonym Gabby) and the other identifying her race as other (given the pseudonym Delores). Also, both students played video games for less than 5 hours per week and thus were classified as non-gamers.

Interviews were conducted over Zoom, recorded to a secure server, and auto-transcribed using Zoom's automatic transcription service. The videos and associated transcripts for the second and third sessions were then reviewed for instances of structuring space in two and three dimensions respectively. These instances were then detailed using captured images and quotations from the transcripts edited for accuracy when necessary. The two-dimensional and three-dimensional structuring spaces were then reviewed for connections and cross-cutting themes consistent with grounded theory (Strauss & Corbin, 1990).

Findings

In this section I present several examples of structuring space induced by the game *Vector Unknown* and the post-play reflections. Delores and Gabby had several ways of thinking about linear combinations of vectors in two- and three-dimensional space. In two-dimensional space, Delores and Gabby focused on creating increasing more complex linear combinations of the vectors that would reach the basket of (-3,5). When designing the three-dimensional space game, they created easy, medium, and hard version of the game and chose to illustrate all the possible locations that could be reached by the vectors. With the basket location not fixed their method of creating different difficulties of the game was based upon creating basket locations that were more difficult to reach rather than creating different sets of vectors.

Easy, Medium, and Hard in two-dimensional space: Numerical Structuring leads to Vector Equations

Gabby and Delores's work in creating Easy, Medium, and Hard vectors led them think about vector equations and how they could be solved. Gabby and Delores designed their Easy vectors by thinking about the numerical relationships of the vectors in relation to the basket at <-3,5> (Figure 2). They wanted the vectors to sum to the basket location without having to scale. This activity resulted in breaking apart the vector <-3,5> in terms of x and y coordinates (for <0,5> and <-3,0>) or finding numbers that sum to -3 and 5, for example <-1,3> and <-2,2>. Gabby described their strategy for finding Medium vectors by comparing it to their strategy for finding easy vectors:

So that one would be more medium, I guess, because, instead of just having the numbers right there you actually have to multiply the numbers to get the ones you want. For medium, we can do like negative one zero and then zero negative one, so that way it's less addition and more multiplication.

Medium difficulty is the first instance that Gabby and Delores transition to using linear combinations of vectors that included addition and multiplication. Gabby's idea for the first two vectors led to Delores's idea for finding the remaining vectors by writing down a vector equation.

Easy	Medium	Hard
<-1,3>, <-2,2>, <0,5>, <-3,0>	<-1, 0>, <0,-1>, <-1,2>, <-1, 1>	<6,7>,<-9, -2> <4,7>, <9, 26>

Figure 2. Easy, Medium, and Hard Vectors Selections

Here Delores first started with trying to find two vectors that would add up to <-3,5> knowing that she wanted to use -2 as a weight (Figure 3). She eventually dropped the negative and through a process of guess and check was able to find vectors that worked. For the Hard set of vectors both Gabby and Delores agreed that larger numbers were appropriate. Delores created the pair of vectors <6,7> and <-9,-2> to sum to the basket location of <-3,5>. Gabby used a similar technique to Delores to design the Vectors <4,7> and <9,26> by choosing a scalar of -3, selecting the vector <4,7> and multiplying it by -3, and finally finding solving for each coordinate to find the vector <9,26>. Gabby's work did not indicate clearly if she had guessed and checked both vectors or if she chose -3 and <-4,7> and found then solved for <9,26>.

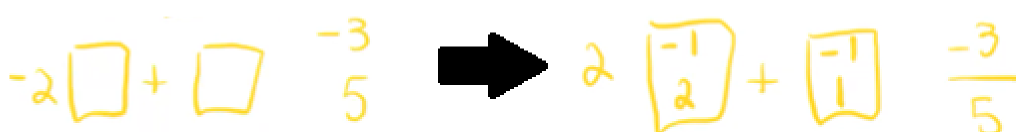

Figure 3. Vector Equations as drawn by Delores for Medium Difficulty

After designing Easy, Medium, and Hard vectors, the interviewer asked the participants how they would explain to a programmer a technique for creating vectors. They focused on describing their process for Medium and Hard difficulty vectors. Delores explained that you could create the vectors by "just take four random numbers and subtract them until I get my, until I get either the -3 or 5" (Figure 3). Here Delores is describing her process of trying random numbers in the vectors until you find a combination that works for the x and y coordinate. This indicates that Delores is thinking about using subtraction to identify individual coordinates instead of whole vectors. This corresponds strongly with the focus on one coordinate strategy in the Vector Unknown game.

Figure 3. Random Vector Equation

Gabby built on this idea and stated that "you would already have the point specified that you want like (-3,5) and then picking random numbers for Vector 1 … then the number you multiply it by and then solving for Vector 2." This suggests that Gabby has started thinking about Vector Equations as equations in themselves, subtracting whole vectors as opposed to just thinking in terms of individual coordinates.

Easy, Medium, and Hard in three-dimensional space: Working with Vector Equations

When asked to design a three-dimensional space game, Gabby and Delores chose to create Easy, Medium, and Hard games and illustrate all the possible locations where the basket could be located. This contrasts to the exercise in the previous session where they were designing easy, medium, and hard vectors to reach a specific basket location. The interviewer introduced them to GeoGebra three-dimensional space since neither student had worked in three-dimensional space previously. They began by designing by choosing random numbers for easy vectors and taking all combinations of the easy vectors for possible locations of the basket indicated by points A-F which were sums of the vectors <0,2,0>, <-1,2,3>, <2,0,1>, and <-4,3,-1> (Figure 4).

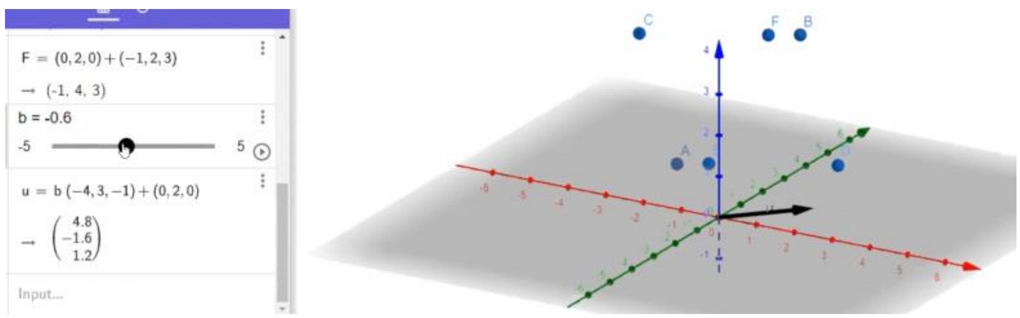

Figure 4. Creating the basket locations for the Easy and beginning goals for Medium

When they transitioned to Medium rather than change the vectors, they decided to change the possible basket locations by placing scalars in front of one vector in each sum that represented a basket in the Easy mode of the game. Figure 5 illustrates one basket location from easy and how it was adapted to medium and hard.

Basket Locations for Easy	Basket Locations for Medium	Basket Locations for Hard
(2,0,1) + (-1,2,3)	b (2,0,1) + (-1,2,3) (2,0,1) + b (-1,2,3)	b (2,0,1) + c (-1, 2, 3)

Figure 5. Easy, Medium, and Hard basket location comparison

Both students focused on how they could adapt expression that they had developed to find the basket location. Here Gabby and Delores used reasoning about the Easy, Medium, and Hard vectors where an increase in difficulty resulted in more scalar multiplication in the context of their linear combinations.

After creating Easy, Medium, and Hard difficulty, Gabby and Delores were asked to describe geometrically some of their basket locations:

Interviewer: What does G = (-4, 3, -1) + b (0,2,0) look like geometrically?
Delores: It would go all around the board because it has negatives and positives…[Delores adjusts her slider] It stays on one side of the board.

Gabby: I can't tell if the vector stays on one side because the graph is three-dimensional space. We cannot use the quadrants anymore.

Here Delores and Gabby are trying to build on different knowledge they used previously in the interview. Delores is trying to first use a mainly numerical argument using signs until she adjusts the sliders and discovers that the basket location seems to be on one side of the board. Gabby could not decide if she was convinced Delores's statement is correct. This indicates that Gabby is trying to adapt the notion of quadrants to three-dimensional space and what it means to be on "one side." This is important because one of the keyways that student's reason about the game in two-dimensional space was quadrant-based reasoning. If students were using quadrant-based reasoning to reason about three-dimensional space, they need a new way to reconceptualize quadrants. One possible way of dealing with this involves thinking about the controls of the video game and their relations to the scalars as suggested in the following conversation:

Interviewer: If you want to look at all the places you put a goal [basket] with the equation b <2, 0, 1> + c <-1, 2, 3>, can you describe it?
Gabby: b makes it move the vector move up and down and c makes it move side to side
Interviewer: So if I were to plot all the goals [baskets], what would it look like?
Delores: It would look like an L-shape and on the left side.

This indicates that thinking about the way the basket moves with the slides similar to the controls of the game might be a way to think about the location movement of the basket. Delores's comments highlight the point that while she has conceptualized some points in the linear combination b <2, 0, 1> + c <-1, 2, 3>, the basket locations that require moving both b and c eluded her description. This could be a result of the limited time of the session or because she thought there might be constraints on what scalars were used at what points. Either way it illustrates that points that involve changing the scalars on each vector simultaneously

Discussion

While students were reflecting upon the two-dimensional game and designing their own three-dimensional game, they provided valuable insight into how they organized linear combinations, solved vector equations, and conceptualized span (all possible basket locations). While this work only analyzed one group of students and thus lacks generalizability, it illustrates that certain aspects of two-dimensional space like quadrants, lines dividing space, and balancing multiple coordinates do necessarily translate easily for students to three-dimensions. In addition, the linear combination $av_1 + bv_2$ for vectors v_1 , v_2 and scalars a,b can prove difficult to understand and may need additional geometric representational support in order to be fully understood. Additionally, game-based scaffolds such as easy, medium, and hard type levels can provide insight into how students scaffold their conception of structuring space and taking linear combinations. This could be valuable as well-designed video games contain several scaffolds to create pleasantly frustrating experiences for the player (Gee, 2003). I can see having students analyze these scaffolds and design games with these scaffolds could be a rich area of research that allows students to structure their ideas and provide valuable insights into their thinking.

Future research includes interviewing more students and seeing how they structure space and transition from two-dimensional structuring to three-dimensional structuring. Also, additional analysis will compare the student's gameplay strategies from the their playthrough of the game with their structuring of space in two and three dimensions.

Student Experiences with Stereotype Threat in Undergraduate Mathematics

Colin McGrane
San Diego State University

Mathematics education is a racialized and gendered space in the US, with white males historically holding dominion. One form of oppression manifests in the establishment and perpetuation of stereotypes involving innate mathematical ability. Students who identify as a stereotyped population often perform under extra pressure to not align their performance with stereotypes, and this extra pressure is known as stereotype threat. In this report, I amplify student voices from undergraduate introductory mathematics courses at multiple universities across the US and value their lived experience. We analyze a subset of free response survey data where three broad populations of experiencing stereotype threat emerged: Asian, Pacific Islander, or Desi American (or APIDA) students, Black or African American students, and women or female students. As students relate their identities to their own mathematical ability, our results show that their experiences with stereotype threat are distinct.

Keywords: Stereotype Threat, Student Experience, Identity, Precalculus, Calculus

Introduction and Background

While a multitude of students buckle under the stress of overlapping midterms, increasingly complex schedules, living away from home for the first time, and trying to make new friends, many are also laboring silently, negotiating their own identities as they learn and grow (Swann, 1987; Ting-Toomey, 2015). There are some identity groups that have stereotypes involving their ability to do mathematics imposed upon them, irrationally based on race or ethnicity, which effectively work to place some students of color in a hierarchical positionality (Shah, 2017). Members of stereotyped groups often feel extra pressure to not perpetuate these narratives by performing in a way that aligns with the stereotype (Spencer et al, 2016), and this pressure that hinders students' academic ability is referred to as stereotype threat (Steele & Aronson, 1995).

One way that mathematical stereotypes have shaped student experience is through this mechanism of stereotype threat, which is driven by implicit and explicit references to racial or gendered mathematical narratives. Stereotype threat has been shown to significantly affect test performance in women and minority groups (Nguen & Ryan, 2008; Spencer et al, 1999), create barriers for the success of Black students (Johnson-Ahorly, 2013), and negatively affect the ability of women and minority students to identify with school culture (Steele, 1997). This evidence leads to the striking realization that without effort to learn about and combat racial and gendered stereotypes, students of many identities will continue to experience inequities in opportunities to perform and succeed in mathematics classrooms.

Although mathematics is often referred to as a perfect, objective, race-free, universal language, the disparities found in women and historically oppressed students' achievement in mathematics compared to their white, male counterparts suggest otherwise (Voyer & Voyer, 2014, Jeynes, 2015). The perpetual enforcement of meritocratic ideals that exist within US society permeates the education system, enforcing the belief that anyone can do well at math if they just try hard enough. In a country founded on capitalism, meritocracy, and white supremacy, these ideologies have certainly bled into our educational institutions. They linger today in the assumptions we make about students, the narratives we have heard about their ability to do mathematics, the implicit biases we all have, and the inequities that emerge throughout undergraduate student experiences.

This exposition values undergraduate mathematics students' voices, as they report their experiences in introductory mathematics courses. Students tell stories of how they relate their identity with their ability to engage and succeed in mathematics and the implicit role that stereotype threat plays in their success in Precalculus through Calculus II courses (P2C2). Through the analysis in this study, I make a connection between undergraduate mathematics students' identity and their experience with stereotype threat by asking the research question: How are students experiencing stereotype threat in undergraduate P2C2 mathematics courses?

Methodology

In this study, I analyze data collected through a modified version of the Postsecondary Instructional Practice Survey for undergraduate students (S-PIPS), developed by Apkarian et al. (2019). The NSF-funded initiative called Student Engagement in Mathematics through an Institutional Network for Active Learning (SEMINAL) administered the S-PIPS survey to nine different institutions over the course of three semesters: Spring 2018, Fall 2018, and Spring 2019. The dataset for this study is comprised of 12,188 responses from students in Precalculus, Calculus I and Calculus II courses across the US.

One free-response item on the S-PIPS survey asks, "is there anything about who you are (or your identity) that affects your ability to do or learn mathematics?" Out of the 16,523 total responses to the survey, there were 5,787 responses to this item that specifically targets student's relation of their identity to ability in mathematics. These responses were analyzed using MAXQDA, a qualitative data analysis program that affords the ability to code responses using an open, axial coding method described by Miles, Huberman, and Saldana (2014). Through this thematic organization of emergent categories and super categories, a system of codes was developed to illuminate the patterns hidden within the thousands of responses. A subset of these categorized themes are presented in **Figure 1**, to illustrate the extent of my coding process for the focus of this study.

Parent Code	Code	Sub-Code
Race (40)	Asian (22)	Good at Math / Threat
		Seek Help
		Family/Society Pressure
	Black / African American (18)	Prejudice
		Pressure / Prove a Point
		Representation
Woman/Female (25)	Inferiority (9)	
	Male Dominated Space (9)	
	Extra Work (6)	
	Representation/Inclusion (5)	

Figure 1. Parent code, code, and sub-codes for Race and Woman/Female themes. A number after a code indicates the number of unique responses with that code.

Since the dataset is combined responses of undergraduate students from several universities all with very different individual stories, it is important to note the demographic analysis of our dataset as a whole. Respondents are college students from 9 universities identifying their own gender as: 51% men, 41% women, <1% gender fluid, <1% transgender, and about 7% other. Racial demographics break down to 48% white, 13% Black or African American, 18% APIDA, 18% Hispanic or Latino, <4% other, with many students choosing two or more ethnicities. Attaining enough data to analyze responses qualitatively is inherently difficult in a space where white males hold dominion, but the diversity and cardinality of this dataset helps populate the next section with quotes from many unique students from all over the US.

Results

Gender identity and race play a significant role in the results of the qualitative analysis of the free response question, "Is there something about who you are that has impacted the way you experience mathematics here at [institution]?" Within those broad categories, there are emergent themes that reference common stereotypes and harmful narratives regarding racial and gender identities.

Being "Good at Math" is a Burden

One of these harmful narratives is regarding "Asians" (Central/East Asian, Pacific Islander, Desi American (APIDA) students that are presumed to be "Asian" in the US) and their supposed innate proficiency at mathematics. While "being good at math" can be viewed objectively as a positive trait, this analysis shows that there are multiple ways expressed by APIDA students of how this stereotype is actually harmful. While APIDA is a pan-ethnic term that collects several large umbrella racial descriptors, it is important to note that there exist hundreds of identities, cultures, and languages that fall into this complex group of students.

This analysis shows that not all APIDA students are experiencing stereotype threat in the same way, especially with subtle differences in the language that they use to describe their experience. For example, some students appear to lend some accuracy to the narrative that Asians are good at math by saying, "I am an Asian so I should be good at math. But I'm not." Another student reflected on how they were, "wishing the Asian stereotype was true." Another student recalled a previous semester of their math course when they, "heard a student say that all Asians are good at math." This last quote exposes the relevance to stereotype threat in current undergraduate mathematics culture when students experience racism in their classroom, rather than solely being aware of a popular narrative. While these minor differences in perception of how the narrative is accepted, rejected, or experienced for these individuals, there are multiple themes that emerged that show how qualitatively different APIDA student experience can be when it comes to stereotype threat.

Awareness of the stereotype and bringing it up in response to a question that asks to relate their identity to their ability in mathematics suggests that the expectation and pressure to perform a certain way are on these students' minds. Cognitively, these students could be at a disadvantage from paying some amount of attention to the potential judgement of their performance. On top of this constant awareness, several students' responses paralleled the following sentiment: "as an Asian, I feel as if I am expected to be good at math, but honestly I suck." Another student mentions how they have, "beaten the stereotype by being an Asian who is terrible at math." The prevalence of low self-efficacy and self-doubt caused by individuals comparing themselves to the stereotype of being good at math appears in more students' stories, as they describe how they are an, "Asian who is not good at math so I feel perpetually judged."

This theme of prejudice, fear of judgement, and pressure to succeed also goes beyond the individual, the classroom, and the math department. Intersectionality of identities and their relationship to mathematical ability also begins to take shape in the analysis, as this student explains,

> There is always this stress that East Asians have to [perform in math] well. It is an unsaid law from your parents, family, and society though they say they do not. Furthermore, coming from a junior college with academic excellence in mathematics, I have more stress to do it well.

APIDA student experiences with family, culture, and intersecting identities are shaped in and out of the classroom, and even appears to influence interpersonal relationships when a student claims,

> Yes, so I am a Asian, and I feel like all my other Asian friends are good at math that they do not study much but they understand everything. Thus, it gives me somewhat pressure in [passing] mathematics at [institution].

The final example for APIDA students is a result that was unique to this group, due to the nature of prejudice they faced from students and faculty alike. Through multiple students' stories, the analysis revealed that when students are assumed to be adept at math, or have greater math skills in comparison to their peers, they feel unable to ask for help in mathematics. One student spoke to their experience regarding this phenomenon: "I guess the stereotype of Asians being smart at math is something I think a lot about. With this, I feel less encouraged to actually seek for help if I don't understand something." While they explained how stereotype threat hindered their ability to seek help, another student's experience aligns with this sentiment and additionally speaks out against the well-known narrative:

> As an Asian student, people will infer that I am good at Math. So a lot of them are shocked when they [find out] I need help. Actually, I do need help and not every Asian is good at Math.

In a society that has accepted broad, over-generalized narratives about how groups of people learn and experience mathematics by the way they look, act, talk, or behave, these stories demonstrate the personal, affective impact on so many P2C2 students across the US.

Underestimating Black and African American Students

Black and African American students share the burden of prejudice and implicit bias, but in a qualitatively different way than the APIDA students that responded to this survey. This analysis uncovers multiple themes across the students who identified as Black and African American, who were treated as a single group in this analysis in order to amplify their unique voices and develop their story as respectfully and thoroughly as possible.

The first theme that was a glaring difference for Black and African American students was a severe lack of representation in higher education, specifically in their calculus classes. NameB1 says, "not having enough African Americans students in my upper division classes with me is very saddening and discouraging!" While other students shared similar frustration, NameB2 added to the detail of how this isolation can affect them in a social dimension and, in turn, affect their ability to succeed in mathematics:

> As a black person at [mostly white institution], there is often a feeling of isolation. This leads to less opportunities to work in a group setting on math problems outside of the classrooms.

Along with under-representation, students also expressed that they felt significant prejudice in mathematical contexts. One student explains that, “being black, people automatically underestimate me”, and another student follows with, “sometimes I feel as if being black and go to use the resources such as the [Math and Sciences Resource Center] have limitation with how people look at me when I ask and need extra help.” So in these cases, the actions and reactions of how others treat these students make them feel as though they are believed to have some lack of ability to do or understand mathematics. These feelings can build over time and translate into pressure to succeed, such as when this student explains, “being African-American I can feel pressure to do good to prove a point.” Another student explains that, “being an African-American student in the classroom often times I feel pressure being one of the only student or few students in the classroom, leading me to take a more regressive role in the course dialog and overall participation.” Feeling pressure to prove a point could add a cognitive load onto these students that is not present for some of their peers, and is compounded by their intersecting identities such as this young African American female:

> As an African American female, it can be uncomfortable entering spaces as the double minority: being one of few African American students in the [calculus] class as well as being an African American woman. Attempting to receive help often ends with a continued confusion of the material and an added question of if the wasted time was due to my lack of ability to grasp the material, the helper’s (whether it be the instructor or recitation instructor) lack of teaching skills to properly help, or if their inability to help my understanding is linked with a sexist or racist issue.

This response indicates an effect that is unique to her experience in this dataset: any interaction with a teacher or recitation instructor that transpires in an unsatisfactory way always has the possibility of racism or sexism as some part of the cause, even if that was not the case. After so many inappropriate or negative interactions over a lifetime of schooling, black students may be faced with the need to question the intent and the reality of their experiences with people in positions of power and positions to help gain access and opportunity for succeeding in mathematics. This student’s story also exposes the dynamic landscape students must traverse while negotiating multiple intersecting marginalized identities, such as women of color.

Mathematical Inferiority of the “Lesser Sex”

Women who responded to this survey also shared deep and sensitive experiences as undergraduate mathematics students in a male-dominated space. Some of them feel intimidated from the lack of representation and mentioned in several ways that the dominance of male presence in their class affected the way they learn or do mathematics. This analysis revealed that not only was the presence of significantly more men in their math class problematic in terms of lack of representation, but also how some men act towards women in math classes. One student explains that, “being a woman in mathematics courses people often underestimate your abilities and belittle your accomplishments”. This quote opens the door to an unfortunate truth of the disparity between how women and men experience mathematics courses so differently: women are assumed to be inferior to men in mathematics. Another quote adds to the frustration these women feel from their experience in math courses: “I am a woman in STEM, so often my fellow male students will treat me like I’m stupid (even when I help them time and time again with homework).” So even when these women demonstrate their capability their peers, they still must fight against prejudice of their mathematical ability. Women respondents also shared experiences of rude behavior that was unique to their plight in this analysis, such as several women corroborating the sentiments that “sometimes guys just talk over me when I’m trying to explain a problem because I’m a woman”, and that, “… the men in my recitation class tend to overlook me because of my gender.”

Women respondents also find themselves experiencing the compounding effects of identities that intersect multiple marginalized groups, such as a Black woman who felt that the double minority status of their identity has them notice that, “people tend to be shocked when I frequently answer questions during lecture.” The underestimation and prejudice that Black students experienced in this analysis stacked on top of the historic marginalization of women in the sciences creates a critically problematic experience in their mathematics courses. Unfortunately, these issues do not begin or end in the mathematics classroom. Rather, students come from backgrounds and educational experiences that shape the way they perceive the world and their success relative to others: “Being a girl and a minority who attended public school has been a detriment and given me a disadvantage compared to a lot of other people.” While this could be perceived as a dig at public education in general, it could also reflect injustices and inequities that plague the US through the defunding of public education, gerrymandered school districts, and a general disregard for schools that need the most support.

The extra pressure stereotyped groups feel to perform in a certain way does not escape women in mathematics. In fact, the results of this analysis show that women were affected by stereotype threat in a different way than other groups. While other students mentioned proving themselves, women were the only group that stated in multiple occasions the idea that the general belief of the inferiority of women in STEM motivated them in some way to become advocates for other women. This sentiment is echoed in this student’s experience, where she not only wants to meet expectations, but break them and show the next generation that they should not fit the mold:

> I believe that being female in a male dominant field has made me want to succeed more than anything in mathematics. Not only that, though, I want to be at the top of my class just to prove that women are capable. I want to inspire other girls to realize that math is fun and easy. Math should not be something to be intimidated by.

Advocacy for equitable experiences in mathematics and motivation to succeed is important, but the stereotype threat that women experience still inhibits them from performing the way they should, having their contributions taken seriously, and being perceived as equals in mathematical spaces. So, while a positive motivation to break the cycle of problematic narratives can be beneficial, women are still greatly affected by stereotype threat in the mathematics classroom.

Discussion

The results indicate that dozens of minoritized, stereotyped students experienced struggles related to stereotype threat, but that different groups experienced stereotype threat in qualitatively different ways. All three large demographic groups that emerged through analysis (APIDA students, Black students, and Women) expressed their frustration with extra pressure to perform a certain way, encountered prejudice of their mathematical abilities based on race or sex, and experienced negative interactions with others in the mathematical community. However, the way that identities were tied to specific ways of experiencing these hardships suggests that stereotype threat is not the same for every stereotyped group. The thread of continuity through all these intersecting, dynamic, and unique experiences is the unseen psychological, physiological, and cognitive battles some students are constantly fighting behind the typical outward-facing roles and identities they assume when in school. While there is no realistic way of separating identity from the dynamically intersectional social sphere that juggles power, rightful presence, and proving self-worth, beginning to form an understanding of the nuances of each groups' unique experiences empowers and emboldens the identities of students who need the most support.

Unpack Student Identity-Related Experiences

It is important to note the fluidity and dynamic nature of identity, especially when studying experiences in mathematics education directly to identity. For example, students have the agency to reject false narratives about their own abilities in mathematics. However, their identity is also shaped by the way people think and talk about them, informed in some degree by their implicit biases or perhaps belief in a narrative about innate mathematical ability. As the results of this study show, these reflexive influences appear to have a particular significance in the mathematics classroom due to the relevance of mathematics to the "Asians are good at math" narrative.

Black and African American students related their identities directly to how their abilities in mathematics are perceived by others. They also affiliated who they are by birth in relation to mathematics, which is certainly related to how narratives around mathematical ability are constructed and perpetuated. Through visible physical features such as dark skin or high cheek bones, people will utilize these features to inform themselves about the identity of a student. The identity of the students in this study appears to be what is directly tied to the shaping of narratives and beliefs that have such an incredible impact on experience in mathematics courses. Black students are recognized as Black, and their abilities in mathematics are scrutinized, connecting their identity to their ability in mathematics. How other people talk about their students and how other students act and talk about each other feed into an existing narrative that Black students are aware of and actively fighting against throughout their mathematical career.

Throughout this analysis, women respondents often referred to the position of power that their male counterparts unrightfully place themselves in. This identity is shaped through an othering of women in science and mathematics, historically bestowing the majority perspective and representation to the men in the class. The responses from women in this study indicate that men are known to disregard contributions from women, believe their mathematical abilities to be inferior to their women counterparts, and even talk over them in an acute demonstration of superiority. Women have long been marginalized in this hierarchical manner regarding ability, and this extends into the mathematics classroom as well.

Conclusion

As long as the imperfect, racist, classist, sexist, ableist society that shapes the people and policies that run US institutions remain, they will continue to be a detriment to the historically oppressed identities within US higher education. Furthermore, as long as there are narratives that tie broad-sweeping identities to specific abilities in science and mathematics, some students will be fighting an internal battle of not living up to certain ways of being or performing while in a mathematics classroom. This constant, yet often silent, battle is part of what shapes the experiences of so many students in US undergraduate mathematics courses today. As I have shown in this paper, the subtle ways in which different groups experience stereotype threat differently can inform instructors and fellow students how to address these stereotyped students' specific needs.

Honorable Mention

This study would not be possible without efforts of the NSF-funded SEMINAL Team.

On the Composition of Even and Odd functions

Niusha Modabbernia
Simon Fraser University

Xiaoheng Yan
University of Toronto

Rina Zazkis
Simon Fraser University

We attend to the composition of even and odd functions, as featured in imagined dialogues between a teacher and students, composed by sixteen teachers in a professional development program. Data were analyzed as aimed at addressing students' intellectual needs, with particular attention to the need for causality and the need for certainty. The results indicate that participants bring into account a myriad of explanations that either complement or replace algebraic definitions of even and odd functions. We provide possible explanations for such a phenomenon in the discussion of the findings.

Keywords: even and odd functions, intellectual needs, visualization, teacher education

The concept of a function is central in mathematics and is central in mathematics education research. Given the breadth of the function concept, researchers focused on particular families of functions, such as linear (e.g., Glen & Zazkis, 2020; Knuth, 2000; Moschkovich, Schoenfeld, & Arcavi, 1993), quadratic (e.g., Zaslavsky, 1997), trigonometric (e.g., Weber, 2005) or exponential (e.g., Confrey, & Smith, 1995). Our research also attends to a particular "cross-cutting family", that of even and odd functions, which are found within polynomial, rational or trigonometric functions, among others.

Brief Background

Our study focuses on the composition of even and odd functions. We are not aware of any research that attends to this explicit focus. As such, in this section we turn to prior research on the related topics: (a) function composition and (b) even and odd functions.

On Composition of Functions

Function composition is one of the standard topics in the undergraduate mathematics curriculum that causes great difficulty for students (Ayers, Davis, Dubinsky, & Lewin, 1988). A possible source of this difficulty is that composing functions necessitates the switch between the process and object views of a function. In order to form a composition $f \circ g$, one needs to start with two mental objects for f and g and to call one process at a time. Then "to form a new mental process that consists of first performing the process of g, generating a result, and then performing the process of f on that result. The new process is interiorized, and the resulting mental representation is encapsulated as the new function $f \circ g$" (p. 247). Ayers et al. (1988) suggested that programming experiences help students construct the concept of function composition as they necessitated operating on functions as cognitive objects. This suggestion is echoed by Vidakovic (1996), who argued that a computer environment might enhance students' ability to understand the concepts of function composition and inverse function.

Meel's (2003) study found that prospective teachers had difficulty establishing the composition of two functions – more than half of the participants treated the composition as a product. In the study of Lucus (2006), teachers were asked to describe the main ideas involved when they teach composition of functions. The participants focused on "how to do this, how to substitute" (p. 101), omitted the definition of function composition, and did not attend to the domains of functions to be composed. Consequently, the participants did not complete the task of composing functions correctly when the range of one function did not correspond to the domain of another.

Steketee and Scher (2012) advocated for the use of multiple representations in the teaching of composition of functions. They suggested that such an approach “can help students generalize the concept of composition, overcome the tendency to tie function concepts to a single representation, and develop a more robust and mathematically rigorous understanding of the topic” (p. 267).

On Even and Odd Functions

A function $f(x)$ is defined to be even when $f(-x) = f(x)$ for all x in the domain; and $f(x)$ is odd when $f(-x) = -f(x)$ for all x in the domain. These definitions imply that the domain of even and odd functions is symmetrical around the origin. Graphically, even functions have a reflectional symmetry with respect to the y-axis and odd functions have a 180-degree rotational symmetry with respect to the origin. Given the analytic and graphical formulations, the topic of even and odd functions may serve as a “conceptual intersection between symmetry, which is encountered most often in visual contexts such as geometry, and functions, which are often explored through analytic means” (Zazkis, 2014, p. 32).

Even and odd functions are important in many areas of mathematical analysis, particularly in studies of power series and Fourier series. The literature on the teaching and learning of even and odd functions, however, is limited. Rasslan and Vinner (1997) found that when the concept of even and odd functions was introduced by the power function $f(x) = x^n$ where n is a natural number, students related the concept of even and odd function with the even and odd exponent of a polynomial function. In fact, if a polynomial or rational function has only odd exponents, then it is odd (for example, $f(x) = x^5 + x^3$); and if it has only even exponents, then it is even (for example, $f(x) = x^6 + x^2 - x^{-2}$). However, an exclusive reliance on exponents is unhelpful when a combination of even and odd exponents is present.

Sinitsky, Leikin, and Zazkis (2011) noted that the terminology of even and odd for functions could be related to the Maclaurin series expansion, where for even functions it consists of only even powers of the variable, and similarly for odd functions is consists only of odd powers of the variable. The authors also suggested that students’ difficulties with even and odd functions may come from their former conceptualization of even and odd numbers, as students tended to borrow and transfer the properties of even or odd numbers to even or odd function.

In addressing arithmetic operations with even and odd functions, Sinitsky et al. (2011) suggested that “Exploring the composition of even and odd functions is an appropriate task for students” (p. 34). The Task developed in our study explicitly focuses on the composition of even and odd functions, starting with particular examples of student interpretations. In particular, we are interested in how teachers determine the evenness and oddness of a function which is a composition of even and odd functions, and how they guide students in this endeavor.

Theoretical Underpinnings: Intellectual Needs

Every instance of mathematical knowledge, explicitly or implicitly, serves a purpose. However, as Harel (2010, 2008) argued, the purpose of introducing a new fragment of mathematical knowledge is gravely overlooked in mathematics curricula at all grade levels. Important questions, such as how to intellectually necessitate the transition from trial and error to analytic and abstract thinking, and how to intellectually necessitate the transition from empirical proof scheme to deductive proof, are rarely addressed in the classroom.

Intellectual need refers to the perturbational stage in the process of justifying how and why a particular piece of knowledge came into being (Harel, 2013). The notion of *intellectual need* consists of the following five categories – certainty, causality, computation, communication and structure – of which we focus here on the first two.

- *The need for certainty* refers to the need to prove, to remove doubts. It is the need to determine whether an assertion is a fact or a conjecture.
- *The need for causality* refers to one's desire to explain the causes of a phenomenon, to understand what makes a phenomenon the way it is.

"Humans' instinctual desire to explain phenomena in their environments serves as a cognitive primitive to mathematical justification" (Harel, 2013, p. 126). In the history of mathematics, however, a long debate during the sixteenth and seventeenth centuries focused on the distinction between achieving *certainty* and finding *causality* in mathematics. Some mathematical solutions and proofs are non-causal – they provide certainty but do not identify a cause for the observed phenomenon. Therefore, they offer little insight into why a result is true. Proofs by contradiction, for example, show that a given assumption leads to an absurdity, yet do not explain the causal relationship between the premise and conclusion (Harel, 2013).

Moreover, the empirical approach to proof, that is, the use of multiple examples to achieve certainty, often leaves the causes unexplained. In fact, Harel (2013) argues that the transition from undesirable proof schemes, especially the empirical proof schemes, to deductive proof schemes is dependent upon students' attention shift from certainty to cause.

In our study, we address the following research questions:

1) In what ways do teachers explain the behavior of composition of even and odd functions?

2) How can teachers' explanations related to composite functions be interpreted through the lens of *intellectual needs*?

The Study

Participants and Setting

Sixteen practicing secondary mathematics teachers participated in this study. At the time of data collection, they were enrolled in a professional development program in mathematics education. Their mathematics background and experience varied significantly, but all held degrees in Mathematics or Science and had at least three years of teaching experience. The particular course aimed at strengthening the participants' mathematical knowledge and investigation skills while focusing on topics that are not usually attended to in school, but which do not require mathematical knowledge beyond school curriculum.

The topic of even and odd functions was one such topic chosen for exploration. At a class meeting the participants were either reminded of or recalled the definitions of even and odd functions from their undergraduate studies and connected these to the graphical representation of functions. The participants revisited various examples, and discussed properties in discord with expectations carried forward from experience with even and odd numbers. For example, the sum of two odd functions is an odd function, and the sum of an odd function and an even function is neither odd nor even. Following in-class discussion, the participants were presented with the task related to function composition, described in the next section.

The Task, the Data and Data Analysis

The Task presented below belongs to the genre of "scripting tasks" developed in mathematics education to explore and strengthen teacher knowledge while considering instructional situations. Initially, scriptwriting was introduced in mathematics teacher education as a lesson play, a task in which participants script interaction between an imaginary teacher-character and student-character(s) (Zazkis, Liljedahl, & Sinclair, 2009; Zazkis, Sinclair, Liljedahl, 2013). Juxtaposed to a classical lesson plan describing merely content and activities, the lesson play reveals how a teaching-learning interaction unfolds. In later research, the idea of a lesson play was extended to an activity of writing an imaginary dialog that is not necessarily restricted to a lesson, referred to as scriptwriting. When used in teacher education, scriptwriting is a tool related to "approximations of practice" (Grossman, Hammerness, & McDonald, 2009), which "include opportunities to rehearse and enact discrete components of complex practice in settings of reduced complexity" (p. 283).

Prior research that analyzed scripting tasks described multiple affordances of scripting tasks for teachers, teacher educators, and researchers. In particular, as teachers script-writers imagine themselves in a role of a teacher, it highlights how they imagine the unfolding of a lesson or of any interaction with students (e.g., Marmur & Zazkis, 2018).

The following prompt was developed as the beginning of an instructional dialogue. The participants were asked to continue the dialogue addressing the student-characters' suggestions.

Teacher:	Is $f(x) = \sin(\frac{1}{x^2})$ even or odd?
Alex:	I know $f(x) = \sin(x)$ is an odd function. Therefore, for any function $g(x)$, $\sin(g(x))$ is an odd function.
Brian:	I totally agree with Alex. With the same logic, $\lvert sin(x) \rvert$ is an even function because $\lvert x \rvert$ is an even function.
Teacher:	Let's talk about these ideas....

Figure 1. Prompt for the Task

In addition to continuing the dialogue, the participants were asked to include commentary on their chosen approaches, addressing mathematics and pedagogy involved in their composed scripts, and reflect on their experience of completing the task.

The responses of the teacher-character in a scripted dialogue shed light on a teacher-scriptwriter's mathematical and pedagogical knowledge. In particular, the prompt includes one correct claim ($\lvert\sin(x)\rvert$ is an even function) and one incorrect claim (for any function $g(x)$, $\sin\big(g(x)\big)$ is an odd function). Both claims are based on the same reasoning, extrapolating from the oddness of $f(x) = \sin(x)$ and evenness of $f(x) = \lvert x \rvert$. However, this faulty reasoning results in one correct and one incorrect conclusion. We were interested in how the scriptwriters would explain this unexpected result in the voices of their characters.

The scripts for the dialogue between the teacher- and student-characters, along with accompanying commentary comprise the data for our study. The claims provided by a teacher-character or by one of the student-characters for evenness or oddness of a composition of even and odd functions, served as a unit of analysis. As the writers attributed the claims to either student-characters or the teacher-character, we considered the teacher's claims as well as claims provided by students accepted by a teacher in the script as reflecting the scriptwriter's choices for what is an acceptable explanation.

Having repeatedly read the data, we compiled all the data excerpts in which claims of interlocutors recognized functions as being either even or odd and attempted to justify the observation. We then considered what students' intellectual needs were aimed to be addressed by the provided examples and explanations.

Results and Analysis

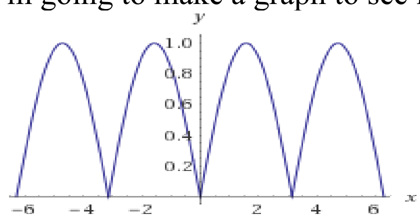
As mentioned, we focused on claims that attend to evenness or oddness of a function composition. We identified several clusters of explanations by the main focus: (1) algebraic manipulation vs. graphical representation, (2) consideration of dominance, and (3) consideration of examples. While causality was our main focus initially, we also considered whether the provided approach attended to other intellectual needs, in particular the need for certainty. We briefly exemplify below clusters (1) and (2).

Algebraic Manipulation vs. Graphical Representation

Evenness or oddness of a function can be determined by considering whether it satisfies the algebraic definition. However, the teachers in scripts did not guide student-characters towards the algebraic determination. Even when the algebraic justification was provided, alternatives were sought. Excerpt A exemplifies this occurrence.

A.1 *Jess:* The inside function is $\sin(x)$ and the outside function is $|x|$. If we test the input $-x$ into the inside function, we get $-\sin(x)$. But taking the absolute value of that gives us $\sin(x)$. Therefore $|\sin(x)|$ is even, just like you said, Brian.

A.2 *Sam*: That makes sense. I'm going to make a graph to see if you're right.



A.3 *Alex*: That is definitely even.

A.4 *Teacher*: Excellent. What do we conclude?

In Excerpt A, Jess proved that $|\sin(x)|$ is an even function algebraically [A.1]. In fact, she not only connected the definition of an even function to the given function, but she also explained how the input $(-x)$ affects the consideration of evenness. We note that Jess' claim was an attempt to address the need for causality. Nevertheless, Sam suggested to make a graph [A.2] and check if the graph is symmetrical about the y-axis. That is, the algebraic proof has not addressed the need for certainty about what has been proven, but the graph, which is "definitely even" [A.3] by observation, satisfied the certainty. Alex's conclusion was implicitly reinforced by the teacher [A.4]. While checking answers was consistently encouraged by teachers, our interpretation of the provided conclusion is that algebraic justification was insufficient in drawing the desired conclusion.

Considerations of "Dominance"

Determining the evenness or oddness of $f(x) = \sin\left(\frac{1}{x^2}\right)$ – a function that is a composition of even and odd functions – pointed to an interesting general question, which function is "dominant" in determining the evenness or oddness of the composite function

The metaphorical reference to "dominance" appeared in discussions in several scripts. However, mathematically, using the language of dominance, evenness is the dominant factor in specifying the evenness or oddness of function composed of even and odd functions. Furthermore, the outcome does not depend on the order in which the functions are composed. This explains why Brian's claim was correct – the function that has been specified as the dominant factor is even, regardless of its order in the composition. However, the similarity of these two claims (focusing on the outsider function) could be very confusing. The situation described in the task invited the scriptwriters to address students' reasoning, regardless of the correctness of their conclusion.

The exchange in Excerpt B follows the teacher's invitation to consider composite functions of even and odd functions.

B.1 *Student 1*: How about $g(x) = (\cos(x))^3 - \cos(x)$?
B.2 *Teacher:* Okay. If you test $g(-x)$ what do you get?
B.3 *Student 1*: $g(-x) = (\cos(-x))^3 - \cos(-x) = (\cos(x))^3 - \cos(x) = g(x)$
B.4 *Student 2*: So, $g(x)$ is even!
B.5 *Alex*: Yes, because an even function inside any other function still is even.
B.6 *Teacher*: Very good. Now we still must discuss Brian's claim that $|\sin(x)|$ is even.
B.7 *Brian*: No, I don't think that anymore! It's odd because $\sin(x)$ is odd. It's the inside function that matters.

Following the teachers' invitation to consider $g(-x)$ [B.2] led to the conclusion that the suggested composite function was even [B.4]. However, Brian was "stuck" in his thinking that the *order* of composition is the factor that determines parity, so he replaced his initial idea, at least temporarily, with "it's the inside function that matters" [B.7]. As such, concluding from the example, the dominance in distinguishing parity of the composite functions was assigned to the "inside function". The implied dominance assured causality of the conclusion. Eventually, Brian's conjecture was refuted by considering the graph, which assured certainty and further causality was not sought.

Some script-writers used the language of dominance with examples from genetics to focus on even functions as dominant factor. This is exemplified in Excerpt C.

C.1 *Alex:* Look at Teacher's example, $f(x) = \sin(\frac{1}{x^2})$. It's a composite function made of an even function x^2, inside an odd function $\sin(x)$. Yet, when I graph the entire composite function it is even.
C.2 *Brian:* Well maybe, even functions are dominant functions within composite functions?
C.3 *Teacher:* What do you mean?
C.4 *Brian:* Well in biology we learned about dominant and recessive genes, where the dominant gene always overrides the recessive gene. Maybe even functions within a composite function are more powerful over odd functions. So as long as there is an even function involved, the resulting composite function would be even. My example from earlier, $|\sin(x)|$, would follow this.

Brian drew the analogy between the role of even functions in composite functions and the role of dominant genes [C.4]. In a way, it is the dominance of even function that "overrides" an odd function in the composite function. The analogy appeared to address the need for causality. As the script continued, a variety of examples was considered and the dominant role of even functions in a composition with odd functions was confirmed.

Discussion

In this study we explored how secondary mathematics teachers explain the behavior of a composition of even and odd functions. The teachers responded to a task in which they were invited to craft a script for an imaginary dialogue between a teacher and students, discussing student ideas about the parity of a composite function. We focused on how the scriptwriters' explanations can be interpreted through the lens of *intellectual need* (Harel, 2013).

The results indicate the prevailing attention of the scriptwriters to the graphs of composite functions, which appeared to address *the need for certainty*. *The need for causality* was addressed by demonstrating how switching signs of the input affects the result of the composition in considering the algebraic definitions of even and odd functions. However, algebraic considerations were consistently supplemented by attention to graphs. In addition, causality was sought by considering what function is "dominant" in the composition.

Several decades ago, Artigue's (1992) and Hitt's studies (1998) showed that both mathematics students and future mathematics teachers tended to avoid the graphical representation of the concept of function while preferring the algebraic expression. In particular, researchers noted not only the preference towards algebraic methods, but also students' "reluctance to visualize" (e.g., Eisenberg & Dreyfus, 1991, Lowrie, 2000). However, in a more recent study, Zazkis (2014) noted that "the script-writers showed evidence of being comfortable with both analytic and graphical modes of representing odd and even functions, drawing appropriate connections between the two" (p. 42).

The results of our analysis appear to be in discord with prior research. The participants, in the voices of their characters, who used the algebraic approach initially, attended to the definitions of even and odd functions but avoided claiming definite conclusions. They sought confirmation by considering graphs. It appeared that algebraic manipulation was perceived as unreliable; a confident conclusion, appealing to the *need for certainty,* was derived only by attending to graphical representation. The increasing availability of digital graphing provides easily accessible demonstrations that substitute the reliance on formalism. The ease of access and immediate availability of a graph are the reason for the participants' preference and dependence on the visual.

Conclusion

Our study contributes to research on learning and teaching functions, focusing on the unexplored niche of even and odd functions and their composition. The behaviour of a composite function appeared unexpected to many of the participants, yet they sought and employed various approaches to verify and explain the surprising result.

When considering a real-valued function, we attend to the correspondence that connects x and y as well as the domain for which the function is defined, though the name of a function is often used as a shortcut. For example, students often claimed that "the sine function is odd" or "sin (anything) is odd". In such claims, which we consider incomplete rather than incorrect, the implied interpretation attends to the function $f(x) = \sin(x)$ where the domain is the real numbers, $\mathbb{R}$. However, the name "sine" does not apply to one particular function, but to a family of functions, given that the domain can be any subset of $\mathbb{R}$. While some features of $f(x) = \sin(x)$, such as periodicity or range, are applicable to a wide range of functions in the sine family, other features are not preserved. For example, while $f(x) = \sin(x)$ is an odd function and $f(x) = \sin(x^2)$ is an even function, $f(x) = \sin(x)$ where $0 < x < \pi/3$ is a function that is neither even nor odd. Considering the function name without attention to the argument or the domain points to a reduced abstraction level which could be a source of errors.

Our results point to the need to re-examine the role of visualization, in particular graphs of functions, in considering function properties. Additionally, we call instructors' attention to the potential dangers in referring to functions exclusively by their name. The sine function, for example, is odd or even? Most learners will likely answer that the function is odd, while such a question cannot be answered without specifying the argument and the domain.

Moving Beyond Solving Equations: Characterizing Elementary Pre-service Teachers' Development of Algebraic Reasoning

University of Delaware

Although elementary pre-service teachers (EPSTs) often have experience with high school algebra topics, early algebra (or algebra designed for elementary learners, commonly involving story problems and diagrams) may be novel to them. In this study, we seek to examine EPSTs' initial algebraic reasoning and shifts in that reasoning after completing a college course in early algebra. Specifically, we examine their algebraic reasoning related to linear equations, story problems, and diagrams by analyzing three aligned problems from a pre- and post-test. We found that, although EPSTs' initial strategies with linear equations were deductive, their work with story problems and diagrams was not. After the course, however, deductive strategies were more commonly identified across all representations. We discuss the implications for the design of mathematical experiences to support EPSTs' algebraic reasoning across representations.

Keywords: Algebraic reasoning, Elementary pre-service teachers, Early algebra, Diagrams, Deductive reasoning

Algebra knowledge and algebraic thinking are critical for success in calculus and beyond. However, for many students, high school algebra is where their mathematics development falters or even ends (Kaput, 1998; Loveless, 2013). Moreover, difficulties with algebra have historically been more pronounced among students of color and other marginalized populations (Gamoran & Hannigan, 2000; Matthews & Fuchs, 2020; Moses & Cobb, 2001). Introducing algebra in elementary grades has been theorized as an approach that will better prepare students for high school algebra (e.g., Carpenter & Levi, 2000). However, those advocating for this approach emphasize that algebraic reasoning in the elementary grades should be fundamentally different from algebra in high school (Carraher et al., 2008). To distinguish algebraic reasoning in elementary grades from algebra in high school, we use the label *early algebra* (e.g., Blanton et al., 2018).

Despite early algebra's potential to improve student outcomes, there currently is a lack of systematic development of algebra ideas in the elementary grades (Blanton et al., 2019). Preparing teachers to teach early algebra could help address this issue. Given the recency of the early algebra movement, elementary teachers and elementary pre-service teachers (EPSTs) often have not had experiences with early algebra in their own schooling (Hohensee, 2017), which may complicate their teaching of these topics to elementary students. We conjecture that EPSTs' required undergraduate teacher education mathematics content courses can provide opportunities to support them in developing their algebraic reasoning and early algebra meanings, thereby potentially increasing the traction of early algebra in schools more widely. In this report, we advance toward this goal by characterizing EPSTs' algebraic reasoning with linear equations, story problems, and diagrams prior to and after experiencing such an undergraduate mathematics content course focused on topics of early algebra.

Theoretical Framework: Algebraic Reasoning and Early Algebra

Researchers (e.g., Blanton et al., 2018; Kaput, 2008; Stephens et al., 2017) have identified the following three broad concepts as being fundamental parts of algebraic reasoning: (1) generalized arithmetic; (2) equivalence, expressions, equations, and inequalities; and (3) functional thinking, which involves representing relationships between two quantities. These are concepts that are seen as cutting across high school and early algebra.

Importantly, early algebra researchers view algebraic reasoning as not dependent upon a representational modality; rather, generalized arithmetic, equivalence, and functional relationships can occur in a variety of representational forms. For this reason, while high school algebra often emphasizes symbolic representations (like *equations*), early algebra can focus on representing the same ideas through *story problems* (Empson et al., 2011) and *diagrams* (Carraher et al., 2006). Although early algebra includes many of the same concepts covered in high school algebra, such as solving for unknowns (e.g., Smith & Thompson, 2008), and exploring variables and functions (Carraher et al., 2008), the algebraic representations used are one of the key distinctions between high school and early algebra.

An additional aspect of mathematical reasoning that played an important role in our study was the extent to which students employed deductive reasoning, part of what Jeannotte and Kieran (2017) conceptualized as the structural aspect of mathematical reasoning. We characterize deductive reasoning as systematic and logical, featuring activity that maintains algebraic equivalence as students solve a problem. For example, and as exemplified in our results, we consider a student removing equivalent quantities in a story problem to determine an unknown amount as a deductive strategy. We characterize non-deductive strategies as those that do not apply a systematic and logical approach to algebraic equivalence. For example, we consider guessing-and-checking strategies to both story problems and algebraic equations as a non-deductive strategy. We differentiated between students' deductive and non-deductive strategies as we addressed our research questions: *What are ways EPSTs reason about linear equations, story problems, and diagrams prior to taking an undergraduate content course on early algebra? What shifts in EPSTs' strategies occur after taking an undergraduate content course focused on their developing algebraic thinking and early algebra meanings?*

Methods

In this section we first describe our participants and the setting of the course. We then describe the three problems we analyze and our data analysis efforts.

Participants and Setting

Participants were EPSTs enrolled in a required undergraduate mathematics content course in a four-year teacher education program at a university in the Mid-Atlantic region of the United States. The participants were sophomores and juniors. We invited all 51 students to participate in a pre- and post-assessment. 45 EPSTs engaged in the pre-test and 28 engaged in the post-test. In the pre-test, we asked participants to provide information about the previous math courses they had taken, with 44 responding to this prompt. All 44 EPSTs indicated they had taken Geometry or Algebra 2. Further, 39 (89%) indicated they had taken Precalculus, 15 (34%) indicated they had taken Calculus, and 21 (48%) indicated they had taken a course in statistics. Hence, the students had varied but numerous experiences with high school algebra content.

The early algebra content course associated with this study was the third of three required semester-long mathematics content courses in the elementary teacher preparation program. The first two courses covered whole numbers, decimals, number operations, rational numbers, ratios, and proportions. The pre-test was conducted at the beginning of the early algebra course (i.e., after participants had passed the first two courses and before instruction began in the third course). The course covered topics including representing unknowns, variables, equations, and functional relationships using discrete, linear, and strip diagrams to represent quantities and relationships between quantities. Students were asked to consider novel ways to represent and reason about situations they had previously represented and reasoned about with algebra symbols. For example, in the early algebra course, we encouraged EPSTs to determine the solutions to story problems by constructing and operating on strip diagrams, rather than writing equations and solving them algebraically. We conducted the post-test at the end of the course.

Data Source

We used the same assessment for the pre- and post-test. The four-problem assessment was administered online through a Desmos activity. For this report, we analyzed three of the problems in alignment with our research questions. To assess students' reasoning about *linear equations*, Problem 1 (P1) asked participants to solve $(3x + 2) + (x + 4) = 5x + 3$. Problem 2 (P2) asked participants to consider the following *story problem*: "Charles buys 6 bags of apples and \$10 worth of oranges. Julien buys 3 boxes of strawberries and \$10 worth of oranges. Charles and Julien spend the same amount of money. What can you say about the cost of a bag of apples and the cost of a box of strawberries?" For this problem, we provided space for students to type a response and/or draw using Desmos's tools, stating, "Feel free to draw a picture and/or type your thinking." Problem 3 (P3) entailed a strip *diagram* representation of a story about two friends who together spent as much money for fruit as a third friend (Figure 1). Although the equation from P1 could apply to this story, we asked participants to write on the provided diagram to solve this problem.

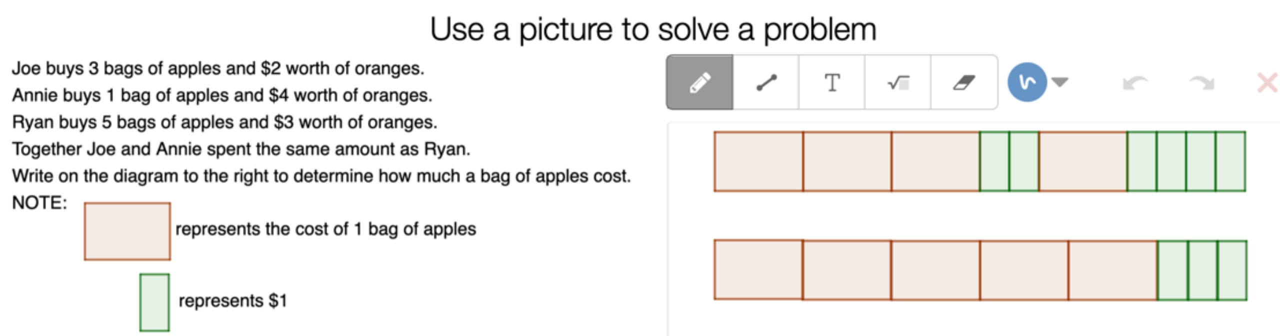

Figure 1. Problem statement and diagram in P3.

Data Analysis

To answer our research questions, we engaged in conventional and directed content analysis (Mayring, 2015). We began by individually reading through EPSTs' responses and making notes about ways they reasoned about equations, story problems, and diagrams within each problem. We then met to compare observations and develop codes that could apply across problems. We used both a priori codes (e.g., deductive reasoning; Jeannotte & Kieran, 2017) and emergent codes (e.g., binomial multiplication), as per Miles et al. (2014). Once we agreed on features for coding, each author independently coded nine pre-test and six post-test responses for each problem. Interrater reliability for codes ranged from 80-100%. After reliability was established and consensus reached for all responses in the samples, one author coded the remaining responses for each problem. Difficult decisions were brought to the team for discussion. For brevity's sake, we do not provide complete descriptions of the codes, instead presenting them as needed to help the reader understand the results.

Results

In the sections that follow, we present results that respond to our research questions, 1) characterizing the ways EPSTs reason about linear equations, story problems, and diagrams prior to taking an undergraduate content course on early algebra and 2) characterizing the shifts in EPST reasoning with these representations after taking this course. To do this, we present our analysis of the features of algebraic reasoning in EPST responses to the three questions (P1, P2, and P3) on the pre-test and post-test.

Reasoning with Linear Equations (P1)

Our first finding is that EPSTs largely engaged in deductive strategies with linear equations in their work on P1 both before and after the early algebra course. Specifically, 35 of 45 pre-test responses (78%) and 23 of 28 post-test responses (82%) involved a strategy that maintained algebraic equivalence in the solution process, suggesting that most EPSTs could recognize and symbolically operate on linear equations both prior to and after instruction (see Figure 2, left, for one example). Among the responses that did not apply a deductive strategy with the equation, 7 responses on the pre-test (16%) and 3 responses on the post-test (11%) approached the problem via binomial multiplication instead of a binomial addition (see Figure 2, right, for an example). We interpret the popularity of these two strategies as indicative of the salience of EPSTs' high school algebra experiences coming into the study (e.g., experiences FOIL-ing in high school). It also suggests the stability of these experiences during interventions that targeted early algebra.

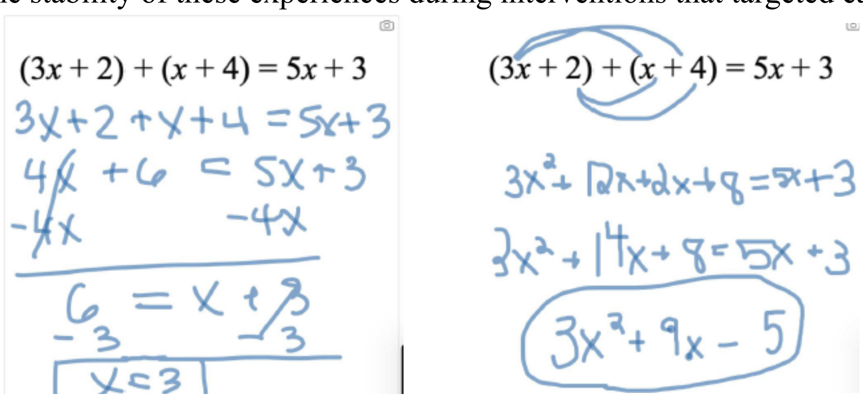

Figure 2. (left) An example of deductive reasoning with a linear equation and (right) an example of interpreting binomial addition as multiplication in a linear equation.

Reasoning with Story Problems (P2)

Whereas EPSTs' strategies with linear equations were consistent and deductive in the pre- and post-tests, EPSTs demonstrated a notable shift in their algebraic reasoning with story problems. Prior to completion of the early algebra course, EPSTs' responses to P2 included 1) infrequent justification of conclusions and 2) frequent exclusively typed or symbolically represented responses. With respect to the first feature, only 8 of the 42 total EPST pre-test responses (19%) included what we coded as justification (a clear, generalized connection between the given information and their conclusion) to support an accurate comparison between the quantities. We interpret justification as central to a logical solution, so this feature also indicates a lack of evidence for EPSTs' deductive strategies with the story problem. With respect to the second feature, Table 1 shows an overview of coded representations. We note 21 of the 42 total pre-test responses (50%) provided no representational support beyond words. Furthermore, consistent with EPSTs' high school algebra experiences, responses on the pre-test that did include a representation most frequently included algebra symbols (13 of 42 responses, 31%).

Table 1. Number of responses coded for each representation to support their solutions to the story problem in P2. (Note: if a student included more than one representation, each was counted independently.)

Representation	Pre-test (n = 42)	Post-test (n = 26)
Equal sized components	2 (5%)	10 (39%)
Non-equal sized components	8 (19%)	8 (31%)
Algebra symbols	13 (31%)	3 (12%)
No representation	21 (50%)	7 (27%)

After EPSTs' completion of the course, responses to the story problem in P2 included 1) frequent justification and 2) frequent diagrams, particularly those with equal sized components. Whereas only 19% of EPSTs responses were coded as providing a justification in the pre-test as described above, we coded 15 of 26 responses (58%) on the post-test as providing a justification. Additionally, 8 of the 26 responses presented diagrams with non-equal sized components (31%, Figure 3, right) reflecting the problem's quantities and an additional 10 featured diagrams with equal sized components (39%, Figure 3, left) reflecting not only the problem's quantities but also their magnitudes and relationships. Taken together, the combined increases in both justification and diagram use after completing the course suggests the impact of deliberate instruction of early algebra topics on algebraic reasoning with deductive features for EPSTs.

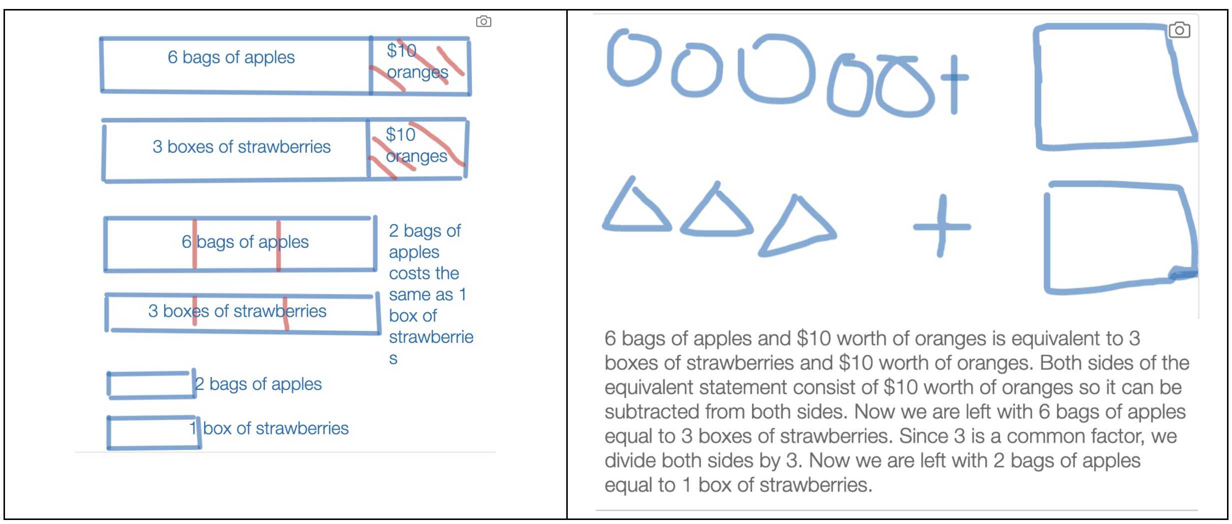

Figure 3. Correct and justified responses involving (left) equal sized components and (right) non-equal sized components.

Reasoning with Strip Diagrams (P3)

We also observed shifts in EPSTs' strategies toward deductive reasoning when working with strip diagrams in responses to P3. Table 2 presents a full summary of these findings. Prior to instruction, we note that EPSTs tended to implement verification strategies (15 out of 40 total responses, 38%) and partitioning strategies (13 out of 40 responses, 33%). Verification strategies involved checking a solution, which could stand alone or be combined with other strategies (see Figure 4, left); partitioning strategies involved breaking apart at least one of the red components without any deductive strategy elements, suggesting measurement or estimation (see Figure 4, center). Furthermore, while five EPSTs (13%) used an equation representing the situation to deductively determine a solution, only one EPST (3%) provided a strategy indicative of deductive reasoning with the diagram itself; such findings are consistent with Hohensee's (2017) finding that EPSTs lack experiences with early algebra in their own school experiences.

Table 2. Students' strategies for P3 when using a diagram to solve a problem. (Note: if a student used more than one strategy, each was counted independently.)

Strategy	Pre-test (n = 40)	Post-test (n = 25)
Verification	15 (38%)	6 (24%)
Partitioning	13 (33%)	3 (4%)
Inaccurate equation	2 (5%)	0 (0%)
Deduce with equation	5 (13%)	4 (16%)
Deduce with diagram	1 (3%)	14 (52%)
No or unclear strategy shown	9 (23%)	3 (12%)

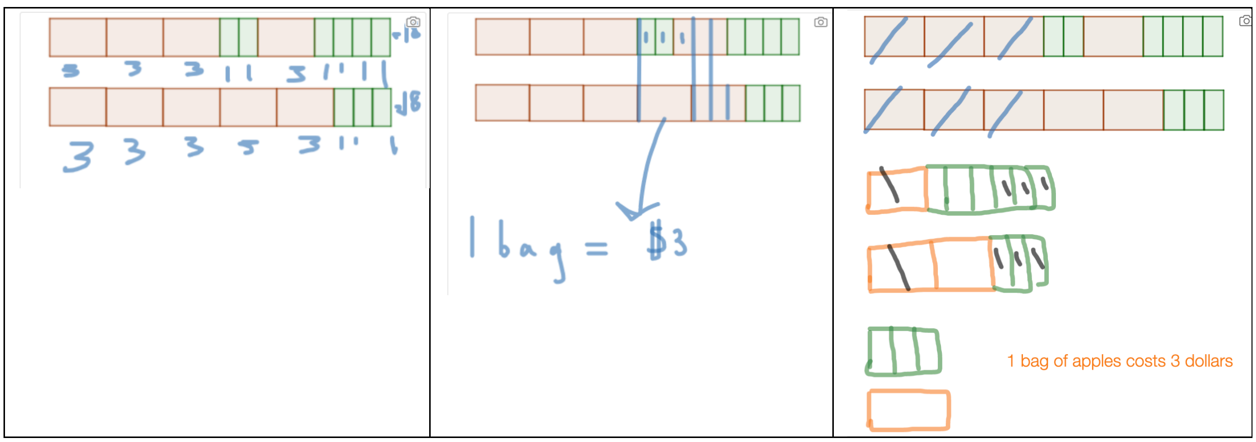

Figure 4. (left) An example of a verification strategy, (center) an example of a partitioning strategy, and (right) an example of a deductive strategy with the diagram.

After instruction, EPSTs' responses indicate a strong shift toward strategies that involved deductive reasoning with the diagram. Deductive reasoning with the diagram showed a logical process to group or eliminate quantities to determine a solution. For example, the student's work in Figure 4 (right) shows first removing 3 bags of apples from each diagram by crossing out three orange rectangles, before re-drawing two new strip diagrams. The student then removed 1 bag of apples by crossing out one orange rectangle and $3 by crossing out three green rectangles. They then re-draw two new strip diagrams representing the cost of 1 bag of apples. Whereas only one student leveraged such a strategy in the pre-test, 14 out of 25 post-test responses (52%) featured this strategy in the post-test.

A Note on Solution Accuracy in P1, P2, P3

While our analysis has demonstrated features of EPSTs' initial algebraic reasoning and shifts in that reasoning after an undergraduate course on early algebra, we also wish to provide additional context about the accuracy of students' solutions across the pre- and post-test. These findings are detailed in Table 3. We highlight two key observations from this table. First, prior to early algebra instruction, the accuracy of EPSTs' conclusions was relatively high (e.g., 80% of pre-test responses in P3 reached the solution of $3). Second, the proportion of EPSTs providing accurate responses on the post-test was slightly higher than on the pre-test (e.g., 88% of post-test responses in P3 reached the solution of $3). This finding suggests that the accuracy of responses remained high and moderately improved alongside the noticeable changes in features of EPSTs' algebraic reasoning with respect to diagrams and story problems early algebra instruction.

Table 3. Number of accurate responses / number of EPST responses (as a percent) to P1, P2, and P3 on pre- and post-test.

Subheading	P1	P2	P3
Pre-Test, Accurate	35 / 45 (78%)	27 / 42 (64%)	32 / 40 (80%)
Post-Test, Accurate	25 / 28 (89%)	21 / 26 (81%)	22 / 25 (88%)

Discussion

Addressing our first research question, we note that prior to taking an undergraduate content course focused on early algebra, EPSTs' reasoning was largely focused on algebraic symbols and manipulations with limited evidence of deductive strategies in story problem contexts and with diagrams. Addressing our second research question, we noticed that justification in responding to story problem contexts (P2) and deductive strategies with the diagram (P3) increased substantially after completing the course. Further, as observed in P2, more students used non-symbolic representations to support their thinking. We hypothesize diagrams may support EPSTs' justifications (and thus, deductive reasoning) in story problems. This is supported by the prevalence of diagrammatic deductive strategies in P3 in the post-test as well, suggesting that the course supported ESPTs' ability to translate their algebraic reasoning to diagram representations. We interpret these findings to suggest positive impacts of the early algebra course on the students' algebraic reasoning across a wider variety of representational modalities.

We note that the students' prior school experiences likely created a ceiling effect in terms of the number of correct responses; as all students had multiple experiences solving equations and story problems, they were able to determine correct solutions prior to instruction. However, we contend the course fostered the EPSTs' early algebra meanings as they developed ways of representing and reasoning that will support their future teaching of elementary students.

Our findings support the claim that, prior to a course on early algebra, many EPSTs may possess understandings of algebra focused on symbols and manipulations that may be challenging to transfer to their future teaching of story problems and diagrams. We also provide evidence to support the claim that undergraduate courses focused on EPSTs developing early algebra meanings can support their content knowledge needed to teach such a course. The findings from the pre- and post-test establish the need for an undergraduate mathematics content course for EPSTs focusing on early algebra. Such interventions are critical if we intend for EPSTs to become teachers who support their future students' success in algebra as part of their pathway to advanced STEM courses and future STEM careers.

Student Engagement with Interactive Instructional Media in Calculus

April Paige Richardson

Michael Tallman
Oklahoma State University

Zackery Reed
Embry-Riddle Aeronautical University Worldwide

Many topics in calculus require students to reason about situations quantitatively and covariationally. Furthermore, such quantitative constructions are often the foundation of mathematical abstractions that enable students to construct robust and productive understandings of concepts throughout the course. With targeted design, dynamic media and virtual manipulatives can support students exploring the interrelationships of varying quantities and to leverage this reasoning to solve problems that support concept formation. In this paper, we report on student interactions with a variety of curricular resources involving such dynamic and interactive design to promote productive understandings of the central concepts in calculus. Our findings suggest that although strategic use of virtual manipulatives can support students' quantitative reasoning and conceptual development, even highly constrained activities allowed students to focus on irrelevant features and seek memorized procedures. Interviewer guidance was generally critical to the productivity of the students' problem-solving activity and concept development.

Keywords: calculus, virtual manipulatives, formative assessment, quantitative reasoning

Studies have shown that covariational and quantitative reasoning supports students in developing productive understandings of calculus concepts (Thompson & Carlson, 2017; Carlson et al., 2002). However, when confronted with calculus tasks, students may revert to executing routine procedures rather than attending to the quantitative and covariational aspects of the task. Moreover, it can be difficult, if not impossible, for students and instructors to explore the effects of varying quantities in a calculus context using pencil-and-paper constructions or static imagery. We developed a variety of instructional materials—including iClicker activities and accompanying online quizzes—which rely on dynamic imagery, animations, and interactive virtual manipulatives to demonstrate calculus concepts. We describe students' interactions with these resources and the extent to which these resources supported students in developing productive ways of reasoning about the central concepts in calculus.

Background/Literature Review

Quantitative and Covariational Reasoning

Several scholars have demonstrated the affordances of *quantitative reasoning* (Smith & Thompson, 2007; Thompson, 1990, 2011) and *covariational reasoning* (Carlson et al., 2002; Saldanha & Thompson, 1998; Thompson, 1994b) for constructing a robust understanding of a variety of ideas in algebra, precalculus, and calculus. Quantitative reasoning is comprised of the mental actions involved in conceptualizing situations in terms of *quantities* and *quantitative relationships*. A *quantity* is an attribute, or quality, of an object that admits a measurement process (Thompson, 1990). Conceiving a process by which one might measure a quantity often involves an operation on two or more previously defined quantities. Such a *quantitative* *operatios* may result in a new quantity, which itself represents the measure of an attribute, may be unitized and partitioned, and related to other quantities. (Thompson, 1990, p. 12).

Covariational reasoning refers to the mental actions involved in coordinating the values of two or more varying quantities while attending to how these values change in relation to each other (Carlson et al., 2002). Productive covariational reasoning entails coupling quantities to form a *multiplicative object* of their measures in variation (Thompson & Carlson, 2017) in which one recognizes that for every possible value that a given quantity can assume, the other quantity also has a value (Saldanha & Thompson, 1998).

Physical and Virtual Manipulatives

Physical and virtual manipulatives have been used in mathematics education to support students' construction of abstract mathematical concepts (Moyer et al., 2002) and to advance their ability to reason quantitatively and covariationally (Thompson, 2002). Moyer et al. (2002) describe a virtual manipulative as a "web-based visual representation of a dynamic object that presents opportunities for constructing mathematical knowledge" (p. 373). Much of the research literature on the use of virtual manipulatives in particular, and multimedia learning resources generally, is informed by information processing models of cognition and seeks to identify universal principles of their design that contribute to students' encoding and retention of information (Pampel, 2017). We additionally focus on features of the students' engagement with the manipulatives that contributed to their mathematical reasoning (e.g. quantitative and covariational reasoning) or their construction of targeted mathematical meanings (e.g. approximation metaphors for limits, rate as a proportional correspondence between changes in two quantities, etc.).

Methods

The purpose of this study was to examine calculus students' interactions with instructional media including a variety of illustrations, animations, and virtual manipulatives. We conducted semi-structured task-based clinical interviews (Hunting, 1997) with each participant individually via video conferencing software. All students enrolled in Calculus I classes at a large public university in Spring 2021 were recruited for this study, and five students agreed to participate. Of these, two students participated in one interview, one student participated in two interviews, and two students participated in six interviews. Each interview focused on one of five different calculus concepts and was conducted shortly after that concept had been covered in their class.

The first portion of each interview consisted of the student answering multiple choice and numerical response questions designed for use during instruction (i.e., iClicker activities). Some questions were part of a sequence intended to help develop students' understandings of a particular concept, while others were summative in nature. If a student had already seen the activity in their calculus class, they were encouraged to recreate their problem-solving rather than remember which answers were correct from class. Students were asked to explain their answers and show their work.

During the second portion of each interview, the students completed online quizzes based on interactions with a virtual manipulative designed to focus attention on the relevant quantities and quantitative relationships. Students were instructed to complete each question of the quiz as if they would without the interviewer present, pausing after each question for the interviewer to ask them to explain their thinking or decisions. Interviewers focused specifically on students' interactions with the virtual manipulatives, particularly on how students decided to move the manipulatives, how they interpreted the results of their actions, and how they used this to answer the quiz questions. At the end of each activity in the interview, students were asked what they thought the main ideas of the activity were, what they thought they were supposed to learn from the activity, and if they found any aspects of the activity particularly helpful or unhelpful in learning about the topic.

Each author reviewed the video of all interviews and noted instances or absences of the following for each student: quantitative interpretations, strategic decision making, abstraction, and the ability to parse questions. Moreover, each author focused on perceived primary sources from the interview materials which yielded these instances or absences, namely: virtual manipulatives, animations, or representations; previous questions or scaffolding; context and applications; prior knowledge; and textual descriptions and aids for students' parsing questions. In particular, we documented which of these instances yielded a notable change in students' patterns of actions and reasoning throughout the interviews.

Results

Routine engagement

Many of the students initially engaged in most of the iClicker and quiz sequences with the expectation that they should know and implement specific procedures to successfully answer the questions. If students did not immediately know how to answer a question, they often applied whatever strategy or procedure they thought most appropriate so that they might receive partial credit. When the interviewer presented and discussed the solution to an interview problem, students often interpreted the feedback as a minor correction to their initial attempt, which they should remember for future use on similar problems. In these cases, students attributed incorrect responses either to insignificant mistakes or to a momentary inability to recall a correct procedure. In most of these cases, however, the research team's assessment was that the student's difficulty with the problem was due to more significant limitations in their current understanding of the targeted concept. We interpret students' tendencies to associate rehearsed procedures to particular types of tasks and attribution of incorrect responses to lapses in memory or minor procedural errors as evidence that the students were largely not approaching the tasks from a problem-solving perspective necessary to reason quantitatively and thus to develop productive meanings from the activity.

Throughout most of her interviews, Kellen claimed that she was generally able to complete individual steps of calculus problems but "Sometimes in calculus, I have trouble piecing all of the information together." She did not, however, refer to specific concepts or methods she might connect or how that association might inform her interpretation of the problem. In her interview about related rates, Kellen started, "I think I'm supposed to take some type of derivative, and I'm confused as to what part.… I know what it's asking for, but I get a little confused as to how to get there." She often attended to surface-level features of the problem statement to determine the appropriate procedures to execute. For example, when presented with a related rates problem involving a triangle, Kellen said, "I'm assuming I can just do trig, using like the Pythagorean Theorem and trig," without attending to the quantities involved and the nature of variation in this particular situation. For Kellen, the triangle itself served as a cue to apply either trigonometric ratios or the Pythagorean Theorem. Perceiving the context in terms of quantities and quantitative relationships might have enabled Kellen to purposefully construct an equation to express the relationship between the relevant quantities and to recognize the need to implicitly differentiate this equation with respect to elapsed time and manipulate the resulting equation to solve for and evaluate the requested rate of change.

Kellen tended to quickly answer the multiple-choice questions presented during the interviews, doing little or no calculations. When asked to explain her answers, Kellen would often recount her process of eliminating choices she thought were incorrect and selecting what she perceived as the most plausible answer from those that remained. She was also quick to accept explanations for why her answers were incorrect and why the correct answers were indeed correct. For example, in response to an explanation about an iClicker question that she had answered incorrectly, "Estimate $f(2.1)$, assuming that $f(2) = 1$ and $f'(2) = 3$, using the Linear Approximation," she said "I know we have to have a derivative times a difference because we're looking for the area between 2.1 and 2, which is really accurate…. We're not looking for a larger number. We're looking for a smaller approximation." When the interviewer revealed the correct answer, Kellen quickly stated that she accepted the interviewer's claim this answer was correct without being provided an explanation by the interviewer. When asked to then explain the meaning of the correct answer in her own words, she responded by describing the appearance of addition to increase an approximation value, "You would add $f(2)$ to the $f'(2)(2.1 - 2)$ because... so you're looking for, if $f(2)$ is one, you're probably going to need a little bit more than one, $f(2.1)$. So that's why I can see you would add."

Quantitative reasoning

The iClicker and Quiz questions were designed to require students to interact with the associated illustrations, animations, and interactions in ways that focus attention on the relevant quantities and quantitative relationships. In some cases, this design was sufficiently robust that students interacted in the intended ways even when only routinely engaged. In other cases, the interviewer was able to ask guiding questions that prompted such interaction.

The virtual manipulatives did seem to support Kellen in enacting more quantitative reasoning as opposed to a focus on procedures. The quiz over related rates involved two virtual manipulatives. The first context involved a common problem involving a person walking away from a lamp post and the related rates of change in the their distance from the post and length of their shadow. Students could select "Walk" and play an animation of the person waling at a fixed speed or click and drag the figure to manually move it to different locations. In either case, the manipulative illustrated the two relevant similar triangles and a single distance scale from the lamp post, but it did not display a numerical measurement for the individual's position, x, or length of their shadow, s. Before reading the first question, Kellen played the animation, then paused it and manually moved the individual. Kellen then read the first question requesting the relationship between Δx and Δs. Kellen manually moved the figure to 0 meters, and successively moved the figure to the right 2 meters at a time, concluding, "Every time there is a change in x, the change in s is increasing, but Δx and Δs are not equal." She then selected the correct answer choice. Kellen explained that she observed how the shadow changed as she moved the figure, "as he kept going [i.e., as she successively moved the figure to the right by increments of 2], the shadow isn't necessarily the same change every time. There's always an increase in the change every single time." Although her description was not entirely correct, Kellen attended to all of the quantities, changes in quantities, and covariational relationships needed to successfully answer the question and interpret the task situation as intended quantitatively.

Pseudo-empirical abstraction

The iClicker and Quiz questions were designed to require students to reason in ways that promote the desired mathematical abstractions for the lesson. While routine engagement was never sufficient to support such abstraction, when students did engage in problem-solving activity, they did demonstrate aspects of the desired generalized mathematical reasoning.

In a quiz based on a virtual manipulative illustrating quantities involved in a Riemann sum approximation of the energy required to lift a 1 kg mass to geosynchronous orbit, Jarrod was supported in making critical initial pseudo-empirical abstractions of the results of his interactions with the manipulative. This manipulative displayed the quantities in a contextual diagram alongside a graph of force of Earth's gravity on the mass as a function of the distance r from the center of the earth. The manipulative included three sliders in which students could choose the following: the locations of evaluation points on a continuum from a left sum to a right sum, the “number of segments” (subintervals), and the “subinterval to evaluate.” The diagram and graph then illustrated energy and area associated with the corresponding term of the appropriate Riemann sum. Although Jarrod’s class had recently covered Riemann sums, he did not initially recognize the notation used in the quiz and was confused about what the various slider variables represented in the context and the graph. He answered the first two questions based on unit analysis, computing values that would merely have the same units as the quantities requested. When asked to find the force used in the second term of L_{10}, Jarrod did turn to a more meaningful interpretation of the relevant quantities, but pointed to the first two intervals in both the picture and graph and multiplied his change Δr by 2 indicating the combined length of the first two intervals. He divided the value of the energy for only the second interval by this distance to obtain the incorrect force, despite the illustration highlighting the correct distance in both the picture and graph.

When asked to compute M_7, however, Jarrod scrolled the sliders for “number of segments” and “segment to evaluate,” observing their effects in the diagrams. He asked if the question was asking for “all of the [energy components] added up.” Upon confirmation, he scrolled to the first segment and said “I could write this one down,” scrolled to the second, “write this one down and like add it,” then scrolled through the remaining segments writing down the displayed energy values and added them together. He explained this represented “the whole area of all of like the rectangles… It’s the total energy needed to, uh, the total energy needed to get that object into space in that many intervals.” When asked what the individual terms represented, he explained it was just the energy needed for that interval, not cumulative from one to the next, a departure from his initial incorrect interpretation. When asked what proportion of the trip used half of the energy required, he noted that the first term in M_7 was nearly half of the total, and correctly estimated $1/7^{\text{th}}$ of the trip, justifying “as you get further the gravity of earth is gonna affect you less and if you’re close it’s gonna affect you more so it’s going to take more energy to push past it.” Jarrod summarized the purpose of using an integral as,

> I think specifically like with energy and force it's because… if you want to calculate energy using force, the force has to be constant. And so, it makes it where you can make the force constant by dividing it into different intervals. And so you can kind of work like that for like anything if you need to.

When asked how he could make his estimate as accurate as possible, Jarrod indicated a left sum would generate an overestimate and a right sum would generate an underestimate.

> I think midpoint maybe the best just because like there are parts that go over but there's also parts that go under because it's in the middle… the ones that are over and under kind of makeup for themselves. I would bring it to the largest number of segments and I'd set it to a midpoint. For like the like the total energy, I would like add up each segment energy.

Role of the instructor

As noted in the previous sections, the primary challenge to the instructional effectiveness of the iClicker and Quiz sequences was students' disinclination to problem-solving engagement. In many cases the interviewer was able to ask questions that disrupted this routine engagement, resulting in the desired quantitative reasoning and pseudo-empirical abstraction.

When interacting with the quiz and manipulative covering Riemann sums described above, Kellen correctly calculated the distance from the surface of the Earth to the satellite. Proceeding to the next question, "How far is each distance Δr (in m) used in the computation for L_{10}?" Kellen first observed that each segment would have the same length, then attempted to visually estimate the width-measures of the rectangles corresponding to L_{10}. "I'm looking at how the graph is broken up… I just wanted to see if the radius [the variable *r* for the distance from the center of the Earth] was an even number [i.e. an easily determined whole-number] but it appears not to be." The interviewer prompted her to reference her previous answers and attempt another solution method. Kellen sought a formula to answer the question, "So, we know that our energy is equal to the force times the change in distance, which is going to be that Δr in this case." Kellen then focused on the current selected segment and attempted to read the height of the rectangle from the graph to represent the approximate force with which she could divide the energy approximation for that segment to solve for the distance Δr. Again, unable to read the numerical value accurately from the graph, Kellen conceded to being stuck.

After the interviewer reminded her of her previous observation that L_{10} separates the total distance interval into 10 equal parts, she responded "Oh so I could easily use a different part if I wanted to." Kellen then moved the slider to select the second segment, which highlighted a rectangle with a height of 4. "So here, you have an even 4 … so 4 - with an energy of 14.38 mega Joules over 4 is going to give a Δr." Kellen then answered the question after performing a unit conversion.

We note that, in this interaction, the interviewer's two responses merely prompted Kellen to further reflect on what she knew, and to persist in her problem solving. Kellen's responses to the prompts included incorporating a quantitative operation into her activity (deriving the radius change from the equation $E = F \cdot d$ as well as the height-width product constructing each rectangle), and then manipulating the slider to find a rectangle that provided her with a suitable height for her computation. This slider manipulation followed from her observation that each interval had the same size, and so she only needed to find one width (segment length) in order to calculate all of them. We consider this interaction to be akin to a teaching interaction possible in a classroom implementation of this activity, and note that the actions of the interviewer supported Kellen's completion of a solution by building from the reasoning that she had already brought to the task. As such, the actions of the interviewer supported Kellen's engagement in further quantitative reasoning, whereas the task merely provided an opportunity to engage in quantitative reasoning, possibly constraining her activity at best.

Discussion

At the heart of our study is an investigation of the ways that students might bring forth and possibly alter their mental organizations of mathematical activity during their engagement with our tasks, hopefully working to support students' reasoning quantitatively and covariationally. By exploring Kellen's task interpretation, her goal setting process, and the reasoning that she brought forth when solving these tasks, we gain initial insights into the different ways that students might interact with our designed materials. We also use her interactions with the interviewer as an opportunity to discuss the importance of accounting for both student and teacher interactions when designing interventions.

As seen through Kellen's routine engagement, her primary problem-solving approach aligned with test taking strategies (e.g. eliminating wrong answer choices) and attempts to recall particular steps taken in accordance with cues from the problem statement (e.g. presence of a triangle in a problem suggests use of the Pythagorean theorem, related rates problems involve taking derivatives). Accordingly, her engagement with quantities was subservient (at times nonexistent) to her primary routine. This constrained her activity when questions required nontrivial considerations of quantities at play, which Kellen described as an inability to "[piece] all of the information together".

One fundamental goal in the development of these tasks was supporting students' engagement in quantitative reasoning. We note that some tasks, particularly for the virtual manipulatives, corresponded to her engagement with quantities. Despite this, an important result from analyzing Kellen's work is that her activity was indeed constrained in the absence of engagement with quantities, but this constraining itself was insufficient to support her learning of our desired mathematical concepts, or her adoption of particular ways of reasoning. We highlight that the didactic expectations and ways of interacting in class that students bring to bear when solving tasks can fundamentally influence their goal-oriented activity. One manifestation of this for Kellen was her quick verbal acceptance of a stated right answer and its justification from the interviewer with minimal or no evidence of reflection on what contributed to her selecting an incorrect response, including a lack of reflection on ways that the correct answer reflected the coordination of the quantities at play in the task. We point out that this kind of interaction might occur in classroom assessment contexts, where students might reflect little on *why* they got incorrect answers instead focusing on *what* the correct answers were. This is in line with Kellen's routine engagement, as if she thought the activities themselves to operate much like an in-class quiz.

As such, we consider that while tasks can serve to constrain and orient students' activity, teaching interactions can support students' mental activity within the confines of attempting the tasks. Though not an aspect of her routine engagement, Kellen did demonstrate the potential to productively consider quantities, particularly in moments of interaction where the interviewer supported such attention. Though the original goal of the tasks (individually and wholistically) was to support students' engagement with quantities and their learning through abstraction, we found that Kellen's engagements in these mental processes were supported by the interviewer in moments where her activity was constrained by the task. This is perhaps unsurprising, as instructors' teaching actions provide an integral aspect of the interactions within a classroom environment. We find that, for our purposes, identifying this distinction between interactions that constrained Kellen's activity versus interactions that supported her adoption of particular cognitive processes to be important.

With our eyes particularly towards relevant features of design work, we consider it important that future iterations of these materials attend not just student interactions with the task, but also the teacher's role in implementation. More generally, we consider accounting for instructors' views of the tasks, goals for instruction, and means of implementation to be vital components of meaningful design research made evident by our renewed awareness of the idiosyncratic nature of student interactions with tasks through analysis of Kellen's work. Our future iterations will specifically incorporate a greater awareness of the instructors' roles in implementation of these materials.

Active Learning in the Language Diverse Undergraduate Math Classroom

Jocelyn Rios
University of Arizona

Active learning is generally considered to be an equitable teaching approach in math education. More post-secondary math classrooms have adopted active learning pedagogies to improve student learning and promote equity. However, given active learning's emphasis on verbal communication and peer interaction, it is important to consider how bilingual students experience active learning. This study espouses a sociopolitical perspective to examine the experiences of bilingual students in active learning undergraduate math classrooms. Data was collected from interviews with twenty-eight bilingual students for whom English is an additional language. Findings suggest that most students participated less than their peers during group discussions, were often positioned as peripheral members of their groups, and were not able to use their home language as a resource in their learning. Findings suggest the need for more research on implementing active learning so that it is equitable in language diverse classrooms.

Keywords: active learning, group work, language diverse classrooms, equity

Introduction

At the post-secondary level, math classrooms are becoming more reflective of the multicultural landscape that we live in (Durand-Guerrier et al., 2016). Undergraduate math classrooms in the United States are often no longer monolingual spaces that serve predominately native English speakers. It is becoming more common that these classrooms are rich, multilingual spaces where students use different cultural, linguistic, and experiential knowledge to make sense of mathematics. This calls into question whether teaching approaches developed within the context of monolingual classrooms are still meeting the needs of bi/multilingual college math students today.

Active learning is a teaching approach that is also becoming more common in post-secondary math classrooms. Ample amounts of research suggests that active approaches to teaching improve student learning (Freeman et al., 2014). Furthermore, Ballen (2020) discusses the general consensus in the literature that active learning promotes equity in undergraduate STEM classrooms. To illustrate this, Theobald et al. (2020) performed a meta-analysis of the post-secondary literature on active learning. Findings suggest that on average active learning reduces the achievement gap for underrepresented students in STEM courses by 33%. Laursen et al. (2014) demonstrated using data from over 100 undergraduate math courses that active learning in the form of IBL helped "level the playing field" for women. (p. 412). Generalizing from this work, researchers and practitioners often treat active learning as a silver bullet for equity in post-secondary classrooms.

However, some scholars have questioned active learning's impact on the experiences of underrepresented students (Henning et al. 2019; Esmonde, 2009; Takeuchi et al., 2019). At the post-secondary level, Johnson et al. (2020) found that male students outperformed females on a content assessment test when inquiry-oriented instruction was used in abstract algebra. Henning et al.'s (2019) work suggests that during peer engagement there may be a "heightened awareness of social identities" which can impact underrepresented students' participation, STEM self-efficacy, and sense of belonging (p. 1).

Active learning emphasizes communicating mathematically and participating in the classroom (Moschkovich, 2002). Students in active learning classrooms are also expected to regularly interact with their peers and make sense of mathematics collectively. Given this emphasis on communication and peer interaction, there is a need to better understand active learning's impact on classroom equity in language diverse spaces.

At the undergraduate level, a lack of research exists exploring this need. However, at the K-12 level, math education scholars have advocated for active learning – specifically group learning – as a tool for supporting students with diverse language needs (Boaler & Stapes, 2008; Gutiérrez, 2002; Cohen & Lotan, 2014). For example, Complex Instruction suggests that placing students in mixed language-ability groups supports the language development of emerging bilingual students through interactions with native speakers (Cohen & Lotan, 2014). Gutiérrez (2002) also demonstrates how group work enriched learning for high school English language learners by utilizing their home language.

At the same time, some K-12 researchers have documented inequities that bilingual students experienced under more active approaches to teaching (Civil 2014; Takeuchi et al., 2019; Takeuchi, 2016). For example, Planas and Setati (2009) describe how immigrant students in Barcelona took on identities as active doers of mathematics during small group discussions, however they generally adopted more "passive listener" identities in whole class discussions (p. 41).

Theoretical Framework

This paper adopts a sociopolitical perspective (Gutiérrez, 2013), by centralizing issues of power and identity. This perspective highlights the ways that power and other sociopolitical structures privilege certain identities in the math classroom, while marginalizing others (Langer-Osuna and Esmonde, 2007). In active learning settings, classroom interactions have the potential to facilitate learning, but must also be understood as existing in and being shaped by classroom power structures. This has implications on how students are positioned and their opportunities for learning (Adiredja & Andrews-Larsen, 2018). In this sense, power can be made visible by examining the ways that students position themselves or are positioned by others in the classroom (Martin-Beltran, 2013).

A sociopolitical perspective also views language as political, as some languages – like English – are assigned "higher status" over others (Civil, 2008). For instance, English is often seen as the language of "access and power" (Setati & Adler, 2000, p. 247), whereas Spanish is often used as a marker of poverty (Moschkovich, 2007). Because of this politicization of language, it is also inextricably connected to who is afforded power and access to participation in the classroom. This can be seen in Takeuchi (2016). This study documents different power imbalances that arise when bilingual students are assigned to groups with monolingual students. For instance, bilingual students were less likely to participate and had less access to being positioned as an expert or leader when they were placed in teacher selected groups.

To think about the role of language and power in the classroom, Planas and Civil (2013) presented the language-as-resource, language-as-political framework. This framework recognizes that on one hand, language is a resource for students. That is, the metaphor language-as-resource represents the potential that language has to facilitate mathematical learning. On the other hand, language-as-political recognizes that not all languages carry the same status in the classroom and can operate to privilege some students while marginalizing others. Planas and

Civil (2013) demonstrated how students were impacted by dominant language norms in the classroom which impacted their participation.

By leveraging the work that has been done at the K-12 level and by viewing language through a sociopolitical lens, this paper focuses on exploring the experiences of bilingual students in active learning post-secondary math classrooms. In better understanding students' experiences, this papers also explores to what extent active learning served as an equitable teaching approach in language diverse classrooms.

Research Question

This paper addresses the following research question: *How did bilingual students experience active learning in undergraduate math classrooms?*

Methods

Data Source

The data presented here are part of a larger, mixed-methods dissertation study which explores the experiences of bilingual students in undergraduate pre-calculus and calculus courses. This study took place at a large, public, research university that has been designated as a Hispanic-Serving Institution. For the qualitative part of the study, semi-structured interviews were conducted with twenty-eight bilingual students for whom English is an additional language. Nineteen of these students were international students. The languages that were represented among the student participants included: Arabic, Bangla, Chinese, Farsi, Hindi, Korean, Spanish, Uzbek, and Vietnamese.

Each interview lasted between 60-90 minutes. The interviews focused on understanding students' general experiences in college math courses, and their experiences with active learning and group work. This data was collected during the Covid-19 pandemic. As such, students attended different modes of instruction, i.e., students were either enrolled in in-person courses, online courses, or hybrid courses. In online course settings, group work was facilitated through breakout rooms. During the interviews, students in online courses often reflected about their experiences with group work over Zoom and their experiences in in-person courses the previous year.

Analysis

All interviews were transcribed in full and pseudonyms were given to each participant. Although interviews were transcribed verbatim, the quotes presented in this paper have been modified slightly for clarity. No modification impacted the meaning or feel of any of the sentences in the quote. The transcripts were then carefully studied and coded using open and axial coding as part of thematic analysis (Braun & Clark, 2006). This analysis first focused on identifying themes pertaining to students' experiences in active learning (e.g., experiencing microaggressions, not having your ideas understood). These themes were then further analyzed and compared to gain greater, more nuanced understanding of student's experiences.

Results

Three students in this study reported having a positive experience with active learning and group work. One student attributed this to her ability to advocate for herself while working with peers. The other two students found group work to be a less intimidating space for seeking help rather than going to the instructor. However, most participants in this study described the challenges and inequities they experienced in active learning environments as a student with a diverse language background. This often resulted in students participating less in the classroom even though they were actively engaged in the mathematics. For example, Juzhen, an international student from China, shared his experience trying to participate in group discussions in his calculus II course:

> I can understand what they're saying. I just can't join in the speaking. When they talk, if I want to make a response, I have to come up with a sentence in my brain and then speak it, but the native speakers, they will just talk without hesitation /…/ I can understand the conversation but sometimes, maybe it's kind of hard to join the conversation.

From my analysis of student interviews, four themes emerged regarding the inequities that students experienced in active learning classrooms: (1) feeling that they were not understood by classmates because of language, (2) experiencing microaggressions while working with others, (3) being positioned as a peripheral or marginalized member of the group, and (4) not being able to use their home language as a resource in their learning. First, many students reported feeling like their peers were not as good at understanding "what they were trying to convey" during mathematical discussions compared to their instructors. They felt that students often lacked "experience communicating with international students" and "people whose first language was not English". Second, because active learning opened the classroom space up for students to interact, several students reported experiencing microaggressions during these interactions. These microaggressions were based on their country of origin or their accent in English. In this paper, I will focus my discussion on (3) and (4).

Student Positioning During Group Work

Analysis of the data suggests that students in this study were often positioned as peripheral or marginalized members of their groups. First, several students shared stories of being positioned as passive listeners in their groups, rather than as an intellectual authority or leader. For instance, Anayeli, whose first language is Spanish, described how her groupmates were "not really willing to listen to [her] input". She recalled one instance during an in-class activity where she knew how to solve a problem because she had encountered something similar before. However, the student who was positioned as the group's leader was not receptive to Anayeli's ideas. Instead, he decided that the group should use his method of solving the problem, which did not end up leading to a correct solution. This left Anayeli feeling "frustrated that people don't listen to [her]". When asked what role Anayeli typically takes up during group work, she explained:

> They tell me, oh, we should probably solve it like this and then I'll try it that way. And then if it doesn't work, I'll suggest a different way. I think that sometimes I would also like to kind of lead. But it's just not always possible, you know.

This quote highlights a mismatch in the way Anayeli would like to be positioned, as an intellectual authority in the group, and the positioning that she had access to, as someone who takes directives from others.

In the interview, Anayeli described her classroom as being predominately composed of male students. Later in the interview, I asked her if she thought that being a woman impacted the experiences in group work. Anayeli explained “Well like there's the other girl in my group. And she also kind of just disregarded my ideas. So, really, it could probably be like the fact that I have an accent, maybe, because she doesn’t have an accent.” Here, Anayeli identifies having an accent as a reason she felt that her ideas were devalued by her group members. Therefore, the language background that Anayeli brought into the classroom impacted her experiences during group work and caused her to be marginalized by her peers.

Several students were also positioned as inhibiting the group’s productivity. This often occurred when instructors created incentives for students to engage in group work. For example, this can be seen in the case of Jason, who is a native Chinese speaker from Trinidad and Tobago. In his math class, students were allowed to leave class early when the group finished their work. Jason describes the pressure he felt to make sure he could explain his group’s solution because he did not want to inhibit them from leaving early.

> I just feel kind of ashamed when we doing a question and I'm like one of the person in that group that doesn't really engage much /…/ And I’m just their getting the answers, and just listening, and when it comes to the explanation, they're like, oh, make sure you understand this. That’s what’s going through my head like, make sure I understand this and I can explain it so we can leave \...\ I felt like I was kind of a burden.

Similarly, Carina, a student from Guatemala, was continually positioned as “slowing down” her group during in-class activities. She attributed this to the fact that the activities were graded and worth a significant amount of points. Carina describes numerous experiences where her classmates were rude and belittling to her when she asked questions. Below are two examples of this:

> I would be in a group, sometimes I wouldn't know how to say a word. And so sometimes my English would go like really bad, like where they wouldn't know what I was talking about. And they're like, I'm sorry I don't understand what you're trying to say. And they're like okay, well just maybe forget your question and let's just actually get to the problem. And I'm like well I am trying to go to the problem, but I don't know how to phrase my words to explain the problem.

> Sometimes one student was like I'm sorry but we really need to get going but some others were like, dude, stop, we can't do this. And then that time I would feel like I'm so worthless.

These quotes depict the ways that Carina was marginalized from her group for asking questions. Rather than engaging with her questions, her peers positioned the questions as distractions or not relevant to the task. Carina described her groupmates as “selfish” and “uninterested” in understanding her or helping her learning. In reflecting on her experiences as a bilingual student, Carina shared: “I am glad I’m a Spanish speaker but sometimes I'm not when students or people feel that they have the upper hand.” This quote highlights how language is political in the classroom, positioning some students as having the “upper hand” because they speak English.

Using Students’ Home Language as a Resource

Another theme that emerged from the data was that students were not able to use their home language as a resource in the active learning classroom. The majority of students in this study reported leveraging their home language to make sense of mathematics outside of the classroom, i.e., forming study groups with peers that share a common home language, finding resources in their home language, etc. However, inside the classroom, students expressed the need to only use English to "go with the status quo".

For example, Gabriela, an international student from Peru, connected with another Spanish speaker in her class. They often worked on math together outside of class using both English and Spanish. The use of both languages helped facilitate their learning. However, when Gabriela was placed in a group with her friend during class, they only spoke English: "When I'm in a group of three, me, my friend and someone else, we have to speak in English to make them feel included, so it's not like an option for us." Making sure group members are included is a valid concern. However, for Gabriela, there is little room for her to leverage her linguistic resources, as an aspect of both her past experiences and current classroom suggest to her that only English should be used.

To further illustrate, Anthony is a domestic student whose first language and the language he prefers to do math in is Spanish. When asked to describe his experience in the classroom as a bilingual student, he first responded "Well, first I have to pretend I'm monolingual". This quote suggests that a part of Anthony's identity as a bilingual student is not being affirmed in the classroom.

Furthermore, when asked if he was ever paired with group mates that spoke Spanish in his math course, he responded:

> *Interviewer:* So, do you ever get grouped with Spanish speakers when you work in groups in math?
> *Anthony:* Yeah. I've had that happen, but they don't want to speak Spanish.
> *Interviewer:* Why is that?
> Anthony: I don't know, I feel like they have that thing about like that you should be only speaking English. If not, they're going to see you as a weird person or something. So, at the beginning of my university life, I tried to speak Spanish with other people, but I noticed that nobody wants to speak Spanish. So, then I just started doing the same thing. I was like okay I'm not speaking Spanish. So, even though we knew each other speaks Spanish we just pretend to be fully English speakers.

This exchange also captures the tension between language-as-resource and language-as-political in the classroom. For Anthony, Spanish is an important tool for checking his mathematical understanding: "When I'm really thinking about something [in math], I tend to go back to Spanish as a way to verify what I'm thinking in English is correct". However, because students felt stigmatized when speaking Spanish, Anthony was unable to activate this resources during group work.

Discussion and Implications

Most bilingual students in this study did not have equitable experiences in the active learning undergraduate math classroom. In particular, the data suggests that group work generally did not facilitate equitable opportunities for participation and learning. Results indicated that bilingual students reported participating less in group discussions, not being positioned as legitimate members of the group, and not having their ideas taken up by peers. Furthermore, active learning spaces often did not affirm students' bilingual identities and allow them to use their native language as a tool in mathematical sensemaking. During interviews, students identified their language background or their accent in English as reasons they felt marginalized. This exemplifies the political nature of language in the classroom, which can serve to privilege some students by marginalizing others. In this study, viewing language as political allowed for a deeper understanding of classroom equity in active learning spaces.

Although students generally did not have positive experiences, the argument of this paper is not that active learning should be abandoned in multilingual classrooms. Nor is the argument that active learning is not an equitable teaching strategy. Findings do suggest, however, the need for more research on effectively implementing active learning in these spaces. This research should examine how active learning can be implemented so that it is more humanizing, affirming, and allows bilingual students to leverage the resources that they bring.

Students in this study provided suggestions for improving the implementation of active learning. For example, as discussed in the previous section, some instructor's used incentives to encourage student engagement and active participation in group work (i.e., allowing students to leave early, assigning points, etc.). However, this had the unintentional outcome of negatively impacting the group dynamics, as the group's goals shifted from group learning to group productivity (Webb, 1995). Students described having better experiences with group work when the tasks were low stakes. Students suggested making group activities for participation points only. Other suggestions from my dissertation data include having students stay in the same group for longer periods of time. Students expressed that this helped them feel more comfortable communicating. Students also preferred to be paired with other international or language diverse students. The shared experience of having a language diverse background helped make group work a more affirming environment.

Finally, I argue that this paper makes a contributions to the field in the following ways: (1) It addresses the lack of research on bilingual students' experiences in undergraduate math classrooms. (2) It examines the impact of active learning on historically marginalized students. (3) It illustrates the ways that language is political in the undergraduate classroom. (4) Finally, it provides a few recommendations for more effectually implementing active learning to affirm and support bilingual students in undergraduate mathematics.

Instructor Beliefs and Practices at the Periphery of STEM

Elizabeth Roan
Texas State University

Jennifer Czocher
Texas State University

As a practice, modeling is beneficial for students. For students to have the opportunity to do modeling, instructors must choose to incorporate it into their courses, a decision based on the instructors' beliefs about modeling in and out of the classroom. To expand applicability and generalizability of results and theories, to expand the focus of mathematics education research to domains trending mathematically, and to work towards incorporating modeling into other classrooms, we interviewed 10 STEM instructors in domains atypical to the current literature base. Analysis indicated this demographic of STEM instructors held beliefs about modeling in and out of the classroom similar and different to those documented about typical STEM instructors. However, similar beliefs are more nuanced than previously reported.

Keywords: Teacher Beliefs, Modeling, Integrated STEM.

Mathematical modeling (hereafter: modeling) is beneficial for students for multiple reasons: from developing general competence towards creative problem solving to helping acquire, learn, and keep mathematical concepts by providing motivation for and relevance of mathematical studies (Blum & Niss, 1991). However, facilitating modeling tasks is challenging, and many STEM instructors cannot easily find time in their courses to dedicate to modeling. Because of this, one obstacle in incorporating modeling tasks into STEM students' coursework is persuading STEM instructors that doing so is achievable and worthwhile.

In general, instructors' judgements about their pedagogical practices arise from their beliefs (Pajares, 1993), a link that has been documented by many researchers in many contexts.: k-12 science (Haney, Lumpe, Czerniak, & Egan, 2002), K-12 mathematics (Bray, 2011; Clark et al., 2014; Jacobson, 2017; Yurekli, Stein, Correnti, & Kisa, 2020), college sciences (Gibbons et al., 2018; Pelch & McConnell, 2016), and engineering (Borrego et al., 2013). The first step in addressing STEM instructor's beliefs about a topic, such as modeling, is to first document their differing beliefs about the construct (Nathan et al, 2010). Thus, a better understanding of modeling's place might be in the curriculum, can inform efforts to persuade STEM instructors that teaching with modeling is an achievable objective.

Across STEM fields, research has documented instructors' beliefs about modeling (as a professional and educational activity), the integration of mathematics into their courses, and the characteristics of successful STEM students where STEM was typically taken to mean physical sciences, engineering, and computer science. However, other fields, such as psychology, biology, and economics, are becoming more mathematical. For fields whose roots are not mathematical, or even statistical, there is still much to be learned about the how these professionals conceptualize modeling, and how they view the role of modeling in their course work. Articulating an inclusive, and empirically informed, account of what constitutes modeling can provide novel perspectives about modeling instruction absent from the literature. Such perspectives can better inform the teaching and learning of modeling by expanding the contexts in which modeling is studied and potentially include a demographics of students not currently accounted for in literature. That is to say, their perspectives are important to include because they are STEM professionals who teach STEM students. Indeed, even the NSF classifies anthropology, psychology, and economics as STEM fields (NCSES, 2014).

This study lays the groundwork for describing an inclusive view of STEM instructors' beliefs about modeling. The goal of this paper is to extend what is known about STEM instructor's beliefs about modeling in STEM majors course work by providing the perspective of STEM instructors not currently accounted for in the current literature base.

Literature Review

Some studies exposed the contrasting views held by STEM instructors with regards to their field's relationship to mathematics which insinuate a instructor's conceptions about modeling's place in their courses. Holmberg and Bernhard (2017) interviewed 22 university instructors who taught content related to Laplace transforms. Some instructors believed that mathematics, physics, and technology are inseparable; others verbalized the opposite view, that these fields are not related at all. Nathan et al. (2010) developed a measure of STEM instructor's beliefs about engineering students' success. They studied differences in beliefs and practices between STEM high school instructors with masters' degrees and instructors using an integrated curriculum. Instructors with master's degrees were least likely to identify sources for engineering support, least likely to claim their class was integrated with STEM, and more likely to agree that students needed to be high achieving to be successful in a STEM career. Bergsten, Engelbrecht, and Kågesten (2015) interviewed two professional engineers about their views of conceptual and procedural mathematics skills in engineering education and practice. One engineer, Robert, from Sweden worked in technical physics and electrical engineering. The other engineer, Ben, was a civil engineer from South Africa. Both engineers held that conceptual mathematics skills are the most important for engineering education. However, Robert emphasized the connection between conceptual and procedural actions, while Ben stated that procedural mathematics skills are not necessary. Bergsten et al. (2015) conjectured that this difference was due to the engineers' differing fields and backgrounds. These studies empirically showcase two ideas about modeling and curriculum present in Kaiser (2017), the idea that different fields view applied mathematics and pure mathematics as either separate and should be taught separately or inseparable from the subject and was an inherent part of other sciences and should not be taught separately.

Other literature focuses on STEM instructors' beliefs about characteristics of successful STEM students, particularly their beliefs about their students as learners of science, mathematics, and, the intersection, modeling. Faulkner and Herman (2016) interviewed engineering and computer science instructors about the skills students needed to be considered mathematically mature. Results indicated that the instructors valued algebraic fluency, quick computations, symbol sense, ability to use online tools to solve mathematics problems, confidence, and other modeling skills are necessary for a student to be called mathematically mature. Similarly, Gandhi-Lee et al., (2015) interviewed biology, chemistry, computer science, engineering, geoscience, health science, mathematics, and physics instructors. Their participants held that to be successful, students must be curious, independent problem solvers, with positive attitudes. Additionally, these instructors identified mathematics overall as a roadblock to success, and specifically identified algebra as the minimum requirement for success.

The field has also documented how professional engineers, and instructors of engineering and mathematics view modeling as a construct (see Drakes, 2012; Frejd & Bergsten, 2018; Gainsburg, 2013). Instructors in these fields, as well as secondary and post-secondary science teachers, have not reached consensus when describing the role of mathematics in their classes. STEM instructors more broadly, including computer science, health and geo sciences, biology, and chemistry have well-considered characterizations for student qualities they believed contributed to success. The field has yet to learn how disciplines at the periphery of the definition of STEM, such as geography, psychology, anthropology, and economics, conceptualize modeling and how those STEM instructors view the role modeling plays in the education of their STEM students. It is thus unknown whether these results generalize to the broader population. Attending to the beliefs and perceptions of the peripheral STEM disciplines will strengthen applicability and generalizability of results and theories expressed in the current literature, will expand the focus of mathematics education research to incorporate domains that are trending mathematical, and will work toward meeting a societal need by getting more modeling into these other classrooms. With these goals in mind, the purpose of this study is to answer the question: what is the role of modeling in the education of undergraduate STEM majors, according to non-traditional STEM instructors and how do their accounts comport with existing research on traditional STEM instructors?

Instructors' beliefs have commonly been studied using a combination of qualitative and quantitative methods (see Bray, 2011; Gibbons et al., 2018; Haney et al., 2002; Nathan et al., 2010; Pelch & McConnell, 2016). Typically, observations are analyzed qualitatively to study instructor practices while instructors' beliefs are measured using surveys and statistical models are used to test associations between beliefs and practices (Philipp, 2007). This approach has been critiqued in the broader higher-education literature for the underlying assumption that there is a clear causal relationship among instructors' conceptions, practices, and student learning (Devlin, 2006). Thus, qualitative methods, such as thematic analysis, are preferred when studying individuals' beliefs (e.g., Bergsten et al., 2015; Drakes, 2012; Faulkner & Herman, 2016; Frejd & Bergsten, 2018; Holmberg & Bernhard, 2017). However, a balance must be struck; overly broad characterizations lose descriptive power necessary for explaining individuals' instructional choices. Consequently, studying the relationship between teacher beliefs and instructor practices necessitates a fine grain size to allow for local causal models that are consistent within participants and their circumstances (Speer, 2008).

Theoretical-Methodological Lens

We adopt the stance that a person's identity, personality, desires, and importantly, their beliefs are embedded within the stories they tell, an assumption of narrative inquiry (Loong, 2019). Following Pajares (1993), we take beliefs to be knowledge a person holds that is either descriptive, evaluative, prescriptive, or any combination of the three (Pajares, 1993). Following Polkinghorn (1995), we constitute a story as a narrative preserving "the complexity of human action with its interrelationship of temporal sequence, human motivation, chance happenings, and changing interpersonal and environmental contexts." (p.4). Thus, a story is more than a description of what happened at a point in time, it has also an underlying structure connecting the events through choices made by the storyteller. The structure, or plot, aids in identifying how individuals connect the events in their lives as precursors for and consequences of the choices they make. This orientation affords a view of STEM instructors' stories as embedding their beliefs about the role of modeling in the education of STEM majors, as follows:

A STEM instructor has beliefs about modeling (even if they do not use the label "modeling"), which include beliefs about modeling in all contexts including their research, their industry jobs (if applicable), and their teaching. An instructor can have an experience, a notable instance salient to them, that may affect their beliefs about modeling. Consequently, analyzing the stories STEM instructors tell about their experiences with modeling in their personal-professional lives and their teaching will afford inferences as to the nature of those beliefs. Descriptive-analytic accounts of the instructors' stories also articulate explanatory mechanisms for how individuals came to hold their beliefs, data useful waypoint for future research.

Methods

We conducted this study at a large southwestern university in the USA. We selected instructors from fields that the NSF (NCSES, 2014) has identified as STEM fields yet are not typically represented in modeling or mathematics education literature: economics, anthropology, geography, and psychology. After identifying majors associated with these fields, we recruited instructors who had recently taught courses for those majors. The population has two advantages for addressing the research questions. First, STEM instructors who are professionals are more likely to have experience with modeling in their undergraduate studies, graduate studies, research work, or industry job. Second, insisting the STEM instructor primarily teaches STEM majors increases the likelihood that the instructor has considered the role of modeling in the education of majors in their classes. In total, the 10 participants of this study were: two economists, two anthropologists, three geographers, and three psychologists.

Data were collected through episodic narrative interviews (Mueller, 2019) conducted over zoom. The episodic narrative interview is a fusion of three other qualitative methods: semi-structured interviews, narrative interviews, and episodic interviews. This approach enabled cross-participant comparisons, provided a strategy for looking at experience-focused narratives which allowed for the participants' views of salience to be prioritized, and allowed for exploration of the target phenomenon (Mueller, 2019). In this way, experience-centered narratives of research and teaching were prioritized while also targeting the scope of each interview toward instructors' beliefs about modeling, generally, and in the classroom through their own salient experiences. Then the salient-to-participants aspects could be inferred and compared across cases and to the extant literature.

In episodic interviews, the interviewer typically starts the interview by asking a question that defines the phenomenon of interest, and then follows with a question to elicit an episode from the interviewee's everyday life in where the phenomenon of interest would take place. The interviewer then asks questions about the phenomenon of interest within that evoked situation (e.g., Romaioli & Contarello, 2019). Similarly, episodic narrative interviews are constructed to funnel the interviewee's story towards the phenomenon of interest (Mueller, 2019). We organized the interview around two sub-stories, building one cohesive story to state and explains the instructors' beliefs about modeling in their classrooms. The first sub-story focused on the professor experiences with modeling outside of teaching. The second sub-story focused on the instructors' experiences with modeling while teaching.

We used analytic techniques informed by narrative inquiry (rather than the more common coding techniques that are appropriate when a pertinent, codified framework exists, which our review of the literature did not reveal). We began with thematic analysis to identify major themes, understood to be patterns within the data (Braun & Clarke, 2006) salient to the participants. We then used emplotment analysis (Polkinghorn, 1995) to probe and then reconstruct the data. Questions such as how does modeling fit into your class as a whole? and How does modeling fit into your students' major (course)work? elicited responses that intimated the instructors' beliefs about the role modeling in the education of STEM majors.

The data were analyzed at the latent level (Braun & Clarke, 2006) with the grain size of analysis being finished thoughts. A finished thought was one or multiple statements about the same topic. A new thought was started when there is a turn in topic of the interview. As informed by Braun and Clarke (2006), the analysis was conducted in five phases: becoming familiar with the data, generating initial codes, looking for themes within the initial codes, reviewing those themes for refinement, and defining the themes. This analysis produced a list of major themes that emerged from the data when focusing on the participants conceptions of modeling in and out of the classroom and curricula. The results of this part of analysis gave a group of codes providing overarching ideas about modeling in and out of the classroom. For example, one idea about modeling was modeling is statistical, and an idea about modeling in the classroom was students are not mathematically prepared for it. To personalize a participant's particular set of beliefs, we identified each participants' core beliefs, where core beliefs are the set of beliefs held by a person that was showcased through multiple instances. This was done to get a nuanced view of the participants beliefs, as a participant could have answered an interview question with a polite response and not necessarily their truly held beliefs. This was done by using the Max Maps feature in the qualitative data software MAXQA. The feature visualized the highest-frequency codes present in a single interview. Codes were transferred to the participants' maps only when they were at least partially constitutive of a core belief.

To account for important background information, significant experiences with modeling in daily life, and significant experiences with modeling while teaching, we used ideas from emplotment from narrative analysis to construct individual narratives about each professor. The first step in emplotment is to identify the end goal. In this analysis, the end goal was each participants' set of core beliefs. The next step is to hypothesize a plot which is then tested against the data. This is done by asking questions like: do any of the major events conflict with this current plot structure? If a major event from the data does conflict, then changes are made to the plot to accommodate and the new revised plot is tested against the data again. While testing the plot against the data, one must ask if each event is pertinent. If an event is not pertinent to the plot, that data is culled from the story in a process called narrative smoothing (Kaasila, 2007; Polkinghorn, 1995). This process is undertaken until a cogent plot emerges that considers all of the pertinent events, this forms the plot outline. This plot outline is then filled in with data elements to form the final coherent story (Kaasila, 2007; Polkinghorn, 1995).

This analysis produced individualized narratives for each participant that tie their core beliefs with important background, and significant experiences with modeling both in daily life and while teaching. It is important to note that the beliefs about modeling in and out of the classroom highlighted by this analysis are not the only ideas about modeling held by the participants in this study. For the purpose of this paper, we present the most salient beliefs about modeling in and out of the classroom at the time of the interview. This helps with identifying beliefs that are most important to the participants but does not identify all the beliefs the instructor might hold. After the construction of these individual narratives, we reanalyzed the narratives, again using techniques from thematic analysis (Braun & Clarke, 2006), to look for overlap between the themes we identified and those present in the literature. This analysis allowed us to make broad-stroke comparisons of our participants' beliefs and the existing literature.

Results

The literature suggests there are differing ideas about the role of mathematics, and thus of modeling, in science, technology, and engineering (STE) courses. The two big ideas about the role of mathematics in STE is that of inseparability (STE cannot be taught without also teaching mathematics) and isolation (STE and mathematics are taught in their own courses). Both sentiments were also found among the core beliefs of our participants. Karter, an economist, and River, a geologist, were insistent that mathematics was inseparable from their courses' content. For example, Karter said

Karter: I tell them [his students] economics and mathematics are inseparable. So, there is no way. If you come to this class and you think that I'm just going to chit chat and not write an equation or any numbers on the board, and then you better drop out of this classroom. I let them know, they know what is coming ahead of them. But, then I motivate them.

In contrast, Phoenix, an anthropologist, talked about mathematics as a tool to be taught in another class.

Phoenix: Well, I'm very glad to have them [economics majors] in my class, but it's really for the economics program to teach them that part of it [the mathematics behind some theories]. Like I said, anthropology is a high-level discipline meaning it's at a high level of abstraction. If they want to do economics, they really do need to learn, they need economic analysis classes. But that's not my job. That's not my job and truthfully, I'm not really qualified to do it.

We do not claim that differing conceptions of STEM integration originate in the participants' fields. The contrasts seem to be rooted in the instructors' salient experiences with mathematics and modeling in their professional lives and teaching. For example, Karter told a compelling story of studying mathematics in his youth and explicated many examples of using modeling in his career. In contrast, Phoenix did not share any salient experiences with modeling in his research or while teaching.

Gandhi-Lee et al. (2015) and Faulkner and Herman (2016) showcased how STEM instructors believed that mathematics proficiency was important for students in STEM fields. More specifically, Gandhi-Lee et al. (2015)'s participants talked about mathematics as a roadblock, and how algebra was the minimum for mathematical preparedness. Almost all participants (9 of 10) in our study explicitly voiced a similar sentiment, that mathematical preparedness of students was a roadblock to implementing modeling tasks in the classroom. One anthropologist, called Phoenix, did not hold this core belief, did not communicate salient examples of using modeling or any mathematics in the classroom. While almost all voiced level of mathematical preparedness as a roadblock to including modeling in their courses, we observed a level of idiosyncrasy in how each participant operationalized preparedness. Predictably, some instructors operationalized mathematical preparedness to mean algebraic fluency or a certain level of proficiency in calculus. For example, Quinn, a psychologist, explained that he had to scale back the difficulty of the mathematical analysis in an in-class experiment.

Quinn: I, over the years, I still do that in the class but I've kind of scaled back the complexity and difficulty of the exercises. I've found that I just needed to and the main reason… Where a math problem that I thought should be pretty simple if you've just taken college level, I don't know, algebra for example. It wasn't anything too crazy that I gave the students. Even then some students had difficulty with it. Not all, some students did just great but I felt that I needed to kind of scale back the complexity of those problems over time but still using them.

Haven, a psychologist, suggested that mathematical preparedness meant fluency with graphical representations and their meanings. She recounted a conversation with one of her graduate students working on a research problem. The student was having difficulty labeling the scatter plot that would illustrate their hypothesis for statistical testing. While recalling this conversation, Haven lamented that students, more generally, were not skilled with graphical representations. She explained that graphical expressions were most important for her students because specifics about what statistical models to run could be looked up later.

Haven: If you can't figure out what's the label on our scatter plot, if you can't figure out what the Y and X axis should be labeled, take a step back and think through what you're doing. I guess that's not an issue of what buttons to click or what the test is called. I was like, "I can tell you what the test is called." Once you get that to me, that's the work I want to see you doing is thinking through graphically how to depict the data. Once you do that work, then you also know what to Google.

Both psychologists teach STEM majors in a psychology department. However, their operationalization of mathematical preparedness was quite different. This is partially due to the courses they teach. Quinn's classes tend to lend themselves more to mathematical exploration than Haven's. This might also be partially due to their differing backgrounds. Both have experience studying mathematics as students themselves, but the types of mathematics are vastly different. Haven spoke mostly of studying mathematics in her statistics and methods courses, while Quinn studied mathematics and physics at both the undergraduate and graduate level. Overall, there was broad consensus that mathematics was a roadblock for students, and that this roadblock was common in their fields. However, when delving deeper, there was no clear pattern of what was meant by mathematical preparedness based on discipline.

Discussion

Our study builds on and extends a synthesis of literature describing beliefs held by STEM instructors about modeling in the classroom through documenting perspectives of instructors from STEM fields not typically included in the literature. This work was necessary as more fields on the periphery of STEM come to rely more heavily on mathematics and statistics.

Overall, there were sentiments held in common about modeling in and out of the classroom shared among these non-traditional STEM instructors and traditional STEM instructors, such as mathematics knowledge being a barrier to implementing modeling in the classroom. However, what is meant as mathematical preparedness seems to be idiosyncratic to the individual professor and partially dependent upon the specific course content. This implies that discipline-level analysis may not be an appropriate grain size for investigating the mathematical barriers students face. We do not claim that there are no differences according to discipline, but we observed differences within disciplines indicating that using discipline to differentiate participants may be too broad. Future research endeavors to uncover instructors' beliefs and practices about modeling in STEM may wish to be cautious when constituting discipline as an independent variable because idiosyncrasies of the instructor's beliefs imply idiosyncrasy of instructional decisions. Additionally, beliefs about mathematics' role in instruction was also as mixed as it was in Traditional-Stem focused literature (Holmberg & Bernhard, 2017; Kaiser, 2017; Nathan et al., 2010). Because instructor's beliefs influence their pedagogical decisions, this differing view of mathematics' role in instruction must be accounted for in future work on persuading STEM instructors modeling is a doable and worthwhile endeavor, but we do not recommend accounting for it at a discipline-based level.

The Influence of Graduate Student Instructors' Mathematical Meanings for Teaching Sine Function on their Enacted Teaching Practices

Abby Rocha
Arizona State University

Prior research suggests that a teacher's mathematical meanings for an idea constitute their image of the mathematics they teach (Thompson, 2013), their pedagogical decisions, and the language they use to cultivate similar images in students' thinking (Thompson & Thompson, 1996). As such, it seems reasonable that there is a link between teachers' meanings for the ideas they teach and their instruction, including teachers' instructional goals, choice of tasks, and the questions they pose to students. This report presents results from clinical interviews that illustrate the relationship between graduate student instructors' (GSIs) mathematical meanings for teaching (MMT) and their enacted teaching practices. More specifically, these results reveal and contrast two GSIs': i) meanings for sine function; ii) goals for students' learning of sine function; and iii) tasks for supporting students' learning of sine function.

Keywords: Mathematical Meanings for Teaching, Teaching Practices, Quantitative Reasoning

Introduction and Review of Literature

In 2016, Thompson proposed using the construct *Mathematical Meanings for Teaching (MMT)* rather than *Mathematical Knowledge for Teaching (MKT)* to make explicit that he was using the word *knowledge* in the sense of Piaget. To Piaget, knowledge and meaning were largely synonymous and grounded in the knower's schemes (Montangero & Maurice-Naville, 1997). Thompson also proposed using the word meaning since a meaning is attributed to a person and knowledge is less personal and disjoint from the knower (Thompson, 2016). Investigations into teachers' meanings (Carlson & Bas Ader, 2019; Thompson, 2013) rather than teachers' declarative knowledge (Schilling, Blunk, & Hill, 2007) provide math educators with insight into teachers' image of the mathematics they teach and intend students to learn and ultimately what they might say or do while teaching (Thompson, 2013; 2016). The affordances of attending to teachers' meanings vs. teachers' knowledge may be best described through an example. If two teachers, Teacher A and Teacher B, were asked to determine the value of sin θ in *Figure 1* below, both Teacher A and Teacher B may correctly answer $sin\ (\theta) = \frac{1.78}{3.96} = 0.45$, indicating that they know how to answer this question. However, this correct answer provides math educators with limited insight into the thinking the teachers used to determine their answers and how the teachers might convey this idea to students.

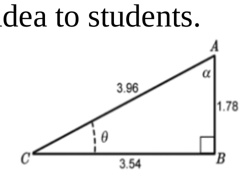

Figure 1. The value of Sine

Instead, a shift in focus to what teachers mean by $sin\ (\theta)\ =\ 0.45$ can uncover what a teacher might say or do in a classroom, and thus, the meaning that a student might construct. For instance, imagine that Teacher A uses the commonly applied trig ratios (SOHCAHTOA) to answer this question. With this way of thinking, Teacher A might convey a meaning to students that $sin\ (\theta)$ is not a function of θ, rather a ratio of sides of a triangle. In contrast, imagine that

Teacher B's meaning for $sin\ (\theta)$ is a function grounded in quantitative reasoning (see next section for example). Regardless of the nature of a teacher's meaning for sine function, they will likely have the goal to convey their meanings to students (Silverman & Thompson, 2008). As such, uncovering teachers' meanings for an idea is essential for understanding a teacher's instructional goals. Although attention to teachers' mathematical meanings for teaching has been repeatedly called for (Byerley & Thompson, 2017; Musgrave & Carlson, 2016, Thompson, 2013, 2016, Tallman & Frank, 2018), few researchers have investigated teachers' MMT. This report addresses the following question: In what ways does a teacher's MMT sine function influence their choice of tasks to be used in class and their goals for students' learning?

Theoretical Perspective

Quantitative reasoning- the analysis of a situation into a quantitative structure, a network of quantities and quantitative relationships (Thompson, 1990, 1993, 2011), has been identified as a critical way of thinking that supports students' development of coherent meanings for angle measure and trigonometric functions (Hertel & Cullen, 2011; Moore, 2012, 2014; Tallman, 2015; Thompson, 2008). A quantity is a quality of something that one has conceived as admitting some measurement process (Thompson, 1990). Quantities exist in the mind of the individual conceiving them. To comprehend a quantity, an individual's conception of "something" must be elaborated to the point that they "see" characteristics of the object that are admissible to the process of quantification (ibid). Quantification is a process of direct or indirect measurement which results in a value. A quantity's value is the numerical result of a quantification process. Numerical operations are used to calculate a quantity's value; however, numerical operations differ from quantitative operations. A quantitative operation is the conception of two quantities taken to produce a new quantity. Put another way, a quantitative operation is a description of how quantities come to exist (ibid).

A Quantitative Meaning for Sine Function

Moore (2014) described a productive meaning for sine grounded in quantitative reasoning. Namely, sine is a function that relates the measure of an angle (measured from the 3 o'clock position) and the vertical distance (of the terminal point of the angle) above the horizontal diameter measured in radii. As such, the value of $\sin(\theta)$ represents how many times as large the vertical distance of a terminal point above the horizontal diameter is compared to the circle's radius when the terminal ray of an angle is rotated to the point that is θ radians counterclockwise from the 3 o'clock position. Thus, for example (see *Figure 2)*, the point (0.8, $sin\ (0.8) \approx 0.717$) conveys that for an arc length of 0.8 radii counterclockwise from the 3 o'clock position on any circle, the terminal point's corresponding vertical distance above the circle's horizontal diameter is $sin\ (0.8)$ or 0.717 times as large as that circle's radius.

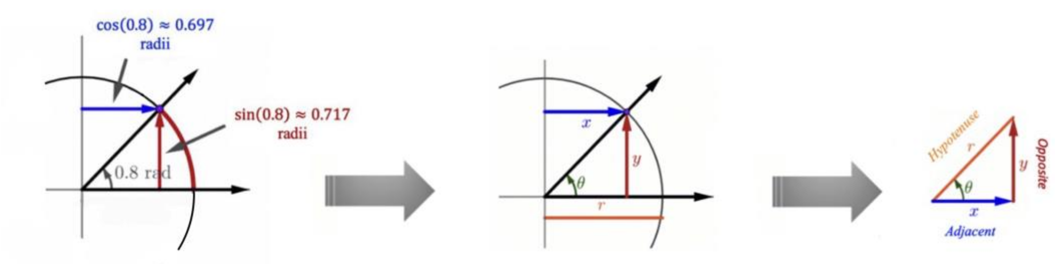

Figure 2. Relating unit circle trig to right triangle trig- Adapted from the Pathways Precalculus Curriculum

A coherent meaning for the sine function involves coordinating two varying quantities' values while attending to how the quantities' values vary in tandem. Moreover, when a student or teacher attends to how the value of $\sin(\theta)$ changes as the angle measure, θ varies, they are engaging in covariational reasoning (Carlson et al., 2002). A coherent meaning for trigonometric functions also includes robust connections between right triangle trigonometry and unit circle trigonometry. The commonly used trigonometric ratios (SOHCAHTOA) can be viewed as using the hypotenuse (radius) as a unit of measure for the legs of the right triangle. As one example, the output of the sine function can be viewed as the length of the triangle's leg opposite the angle whose measure is input to the sine function, measured in units of the hypotenuse (see *Figure 2*).

Methods: Subjects, Data Collection, and Analysis

This study's purpose is twofold (1) to explore GSIs' mathematical meanings for teaching sine and cosine function and (2) to investigate the impact of GSIs' MMT on their enacted teaching practices. To accomplish this goal, the first author conducted clinical interviews (Clement, 2000) with two GSIs who were in their first year of teaching using research-based Pathways Precalculus curriculum materials at a large, public, PhD-granting university in the United States. The purpose of the clinical interview was to investigate the instructors' MMT sine function, including each instructor's goals for students' learning, images of key ways of thinking they wanted students to engage in, and choice of tasks. Before the first clinical interview, each GSI was asked to select a task they considered vital to discuss with students during their sine and cosine function lesson. During the interview, each participant was asked to describe the task they selected, their goals for student learning (relative to a lesson they would be teaching on sine and cosine function), and their image of a coherent understanding for sine and cosine function. Each GSI was also asked to respond to two mathematical tasks designed to elicit their meanings for sine and cosine function.

The analysis of the clinical interviews occurred in three phases, as described in Simon (2019). The first phase involved listening to the interviews to generate hypotheses about the teachers' ways of thinking. The second phase involved a more in-depth, line-by-line conceptual analysis (Thompson, 2008) to describe aspects of the teachers' MMT for sine and cosine. The third and final phase of this analysis involved identifying themes in the conceptual analysis to characterize the teachers' MMT sine and cosine.

Results

During the first clinical interview, the participants, Razi and Wilma, were asked to complete two tasks designed to elicit their meanings for sine and cosine. The estimation task shown in *Figure 3* was posed to the GSIs to reveal the nature of their meanings for sine and cosine function and the degree to which they engage in and value quantitative reasoning. To answer the estimation task, the instructors needed to reason about the meaning of the measure of $\sin(\theta)$ and $\cos(\theta)$ rather than solely performing a computation. As described earlier, one conceptualizes the sine function quantitatively if she conceives of sine as a function that relates the measure of an angle (measured from the 3 o'clock position) and the relative size of the vertical distance of the terminal point to the radius of the circle.

Wilma's response to the estimation task revealed her meaning for the sine function as the "terminal point's vertical distance above the horizontal diameter, measured in radius lengths." She estimated the value of sine function for the angle measure θ to be 0.8 (see Figure 3). Wilma also expressed that 0.8 means that the “orange line is 0.8 times as big as a radius” or “the orange line is 80% of a radius”.

During class you ask students to estimate the value of sin(θ) and cos(θ) using the diagram below. Gabriel, a student in your class, tells you that it isn’t possible to answer the question since there are no numbers. Is this student correct? How will you respond?

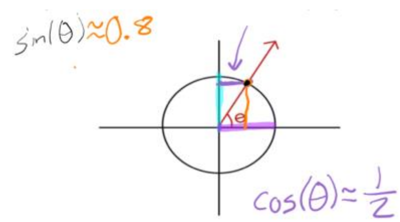

Figure 3. Wilma’s solution to the estimation task

I interpret Wilma’s meaning for sine to be grounded in quantitative reasoning. When describing the sine function, she initially identified the attribute of a circle to measure (the vertical distance of the terminal point above the horizontal diameter), a unit of measure (radius length), and a measurement process (multiplicatively comparing the length of the orange line to the length of the radius). Wilma’s description of 0.8 as a measure of how many times as large the orange line is compared to the radius indicates that her meaning for sine entails a quantitative operation. Wilma’s approach of multiplicatively comparing the vertical distance of the terminal point above the horizontal diameter to the radius resulted in a measure of a quantity in an identified unit (the terminal point’s vertical distance measured in radius lengths). Moreover, Wilma’s response to the *Estimation Task* suggests that she conceptualized the value of the sine function for a particular angle measure as the relative size of the terminal point’s vertical distance above the horizontal diameter to the length of the circle’s radius.

In contrast to Wilma’s stable meaning, Razi expressed multiple meanings for the sine function throughout the clinical interview. As one example, Razi described the value of the sine function as a *y*-coordinate on the unit circle, the proportion of the y-coordinate to the radius, opposite over hypotenuse, and a height. In his response to the estimation task, Razi expressed the former two meanings and described the value of sine as "the length of the y-coordinate in terms of the radius length".

At first glance, one might interpret Razi’s description of sine as “the length of the y-coordinate in terms of the radius length” as conveying a quantitative meaning for the sine function. However, a closer analysis of Razi’s response to the estimation task suggests that Razi was not thinking about measuring quantities. In particular, Razi described his estimate for the value of sine as “a proportion” and “the ratio between the y-coordinate on the circle and the radius”. In this instance, I interpreted Razi’s meaning for the value of the sine function to be that of a numerical operation since Razi appeared to be comparing numerical values rather than the relative size of two quantities. The interview continued by the researcher, prompting him to explain how the idea of proportion was related to his meaning for sine function.

Razi: Oh, I get tongue tied in this all the time, I mean the amount that I have to multiply the denominator by in order to get the numerator.

Interviewer: Okay, so is that what you want students to think about when you say proportion?

Razi: Another thing I like to think about is how many times does the denominator go into the numerator. That’s the classic. Umm… yeah, those two ones. Those are the ones I rely on.

Interviewer: So, do you want students to think of sine as the number you have to multiply the denominator by to get the numerator?

Razi: No, no, I said this earlier I want students to think that sine of an angle corresponds to a place on the unit circle. Which at the same time could be considered a proportion, but I think the unit circle with the x-y coordinate is more important.

Razi's description in the above excerpt provides further evidence that he conceptualized the value of sine as the result of a numerical operation. Razi's description for proportion focused on multiplicatively comparing the numerator and denominator of a ratio. However, it does not appear as though Razi conceptualized the values in the numerator and denominator as measures of quantities. Moreover, Razi's expression "that sine of an angle corresponds to a place on the unit circle" indicates that Razi was thinking about the value of sine as a location rather than a measure of vertical distance.

Razi and Wilma's Goals for Students' Learning of Sine and Cosine

During the interview, Wilma repeatedly stated that she wanted her students to think about quantities and how the quantities values changed together when reasoning about the sine and cosine functions. Wilma's goals for students' learning, as expressed during the first interview (see excerpt below) represent the ways of thinking she wanted her students to use. Wilma expressed that she wanted her students to think about how the vertical distance (blue vertical line in *Figure 4*) and horizontal distance (red horizontal line in *Figure 4*) of the terminal point varies as the measure of the angle "swept out" varies.

Wilma: So, I think…goals for students learning umm I guess like I talked about before, imagining the covariation of the angle measure and either the horizontal distance or vertical distance. Like, as the angle measure changes, or as that terminal ray sweeps out more of the circle, how do the blue line and the red line change? Umm… because I feel like that is a really helpful way to think about sine and cosine.

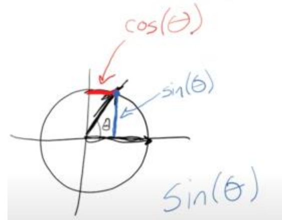

Figure 4. Wilma's Description of Sine and Cosine

When prompted to explain her goals for her students' learning, Wilma conveyed that she wanted her students to conceptualize the values of the sine and cosine functions as measures of distance. It is noteworthy that her goal for student thinking aligned with the thinking she used to respond to the estimation task. Similarly, Razi's description of his goals for students' learning (see excerpt below) was consistent with the meanings he expressed for the sine function. Razi explained that he wanted students to think of the value of the sine function as a coordinate on the unit circle.

Razi: I want them to think that like if I input an angle that it corresponds to or if I have a angle on the unit circle or something that it should have an x,y coordinate in the plane that it corresponds to. And if I want to find out information about any of those points the cosine and sine function are pretty good tools.

Interviewer: Okay

Razi: I honestly think that if they understand that, that the angle corresponds to a point on the circle then that's the pretty big one.

Razi and Wilma's Choice of Tasks to be Used During a Lesson on Sine and Cosine

During the first clinical interview, each instructor was asked to present a task they felt was most important to discuss with students during an upcoming lesson on sine and cosine function. This section displays the tasks and discusses the meaning the instructors intended students to construct while interacting with the task(s). During the interview, Wilma presented the *Bug on a Fan* task (see Table 1) appearing in the Pathways Precalculus curriculum materials (Carlson & Oehrtman, 2010). The first part of the task prompted students to identify quantities that vary as the fan blade rotates. The prompt was followed by a request to explain how the bug's vertical distance above the horizontal diameter changes as the bug travels through various positions around the circle (i.e., from the 3 o'clock position to the 12 o'clock position). This task concludes with the students creating a graph to illustrate how the bug's vertical distance above the horizontal diameter covaries with the measure of the angle, θ, swept out by the bug's fan blade.

Table 1. A table showing Wilma and Razi's Chosen Task(s)

A bug sits on the end of a fan blade as the blade rotates in the counterclockwise direction. The bug is 2.6 feet from the center of the fan and is located at the 3 o'clock position as the blade begins to turn.	Kristin boards a Ferris wheel at the 3 o'clock position and rides the Ferris wheel for one full rotation (as shown below). The radius of the Ferris wheel is 14 meters. Let *s* represent the varying number of meters Kristin has traveled along the circular path sine the ride started.	The vertex of the angle below is at (0,0) and a circle with a radius of *r* units is centered at the vertex of the angle. The angle has a measure of θ radians. What are the coordinates of the terminal point, (x, y)? (Your answers should be expressions in terms of r and θ.
		Wilma's Chosen Task	Razi's Chosen Task 1	Razi's Chosen Task 2

Wilma's discussion of the Bug on a Fan task primarily focused on her plan to ask students to attend to the quantities involved in the task and how the quantities vary together. Wilma expressed that she wanted to provide students with ample time to think about what quantities they could measure to track the bug's position on the fan. During the interview, Wilma also expressed that she intended to use an animation during her discussion of this task to provide students with an image of how the bug's vertical distance above the horizontal diameter changes as the bug travels around the fan.

The tasks Razi chose are also shown in Table 1. The Ferris Wheel task also included three parts. In the first part, students were asked to write an expression in terms of s to represent the number of radians Kristin swept out since the ride started. The remaining two parts of the Ferris Wheel task asked students to write an expression in terms of s to represent Kristin's height above the center of the Ferris wheel measured in radius lengths or meters, respectively. It is noteworthy that the Ferris Wheel Task included an animation of Kristin traveling along the Ferris Wheel; however, Razi did not express a plan to use the animation in class.

Razi's descriptions of the two tasks he intended to use in class (shown in Table 1) were primarily focused on describing how to determine the coordinates of a point on a circle and converting the values of those points when the radius of the circle was not one. It is noteworthy that Razi initially expressed that the value of the sine function represents a height in radians. However, when Razi was asked about the critical ways of thinking he wanted his students to engage in, he expressed a goal for students to "use the sine function to get information about wherever I am on the circle".

Discussion and Conclusions

The results of this study illustrate the influence of an instructor's MMT sine function on their goals for student learning and choice of tasks. During the clinical interview, Razi and Wilma expressed different meanings for the sine function. Wilma described the sine function as a function that relates angle measures to the vertical distance of a ray's terminal point above the horizontal diameter measured in radii. Wilma also expressed that the value of sine represents how many times as large the vertical distance of the terminal point is to the radius. When reasoning about the sine function, Wilma also consistently described how the vertical distance of the terminal point varied as the measure of the angle of interest varied. As such, it appears as though Wilma's meaning for sine function is grounded in quantitative and covariational reasoning.

In contrast, Razi consistently expressed that sine was a function that relates an angle measure from the unit circle to the y-coordinate on the unit circle. Although Razi consistently expressed that sin(θ) gives a y-coordinate on the unit circle, he was inconsistent in describing what the y-coordinate represents. For instance, when the radius of a circle is one, Razi expressed that the value of the sine function is the y-coordinate on the unit circle. However, when discussing tasks in which the radius of a circle was not one, Razi described the value of sine as representing (1) a ratio between the y-coordinate of the terminal point and the radius of the circle, or (2) "opposite over hypotenuse" (in reference to the commonly applied right triangle trig ratios SOHCAHTOA). It is noteworthy that Razi's meaning for sine included trigonometric ratios; however, he consistently referred to the sine function as relating an angle measure on the unit circle and a location in the cartesian plane (y-coordinate on the unit circle).

Both instructors' meanings for sine function were germane to the tasks they chose to discuss in class, their image of the meanings they wanted to elicit from students when discussing the tasks, and their goals for student learning. For example, when Wilma was prompted to describe her goals for students' learning, she expressed that she wanted students to think about quantities and how the vertical distance of the terminal point varied as the measure of an angle varied. In alignment with her goals and meanings for the sine function, the tasks Wilma used when teaching prompted students to engage in these ways of thinking. Similarly, Razi expressed that he wanted students to think about the sine function as a function that inputs an angle measure on the unit circle and outputs the y-coordinate on a circle. In alignment with his goals and meanings for the sine function, Razi selected tasks that prompted students to determine the location of a point on a circle. The influence of both teachers' meanings on their goals for student learning and choice of tasks is not surprising as it supports other's findings that teachers' MMT includes their image of how an idea is learned and tasks they envision for achieving this learning (Silverman & Thompson, 2008; Tallman 2015; Thompson 2013; 2016).

Active-Learning Strategies That Suggest Ingresses for Math Graduate Student Instructors' Use of Student-Centered Teaching

Kimberly Cervello Rogers
Bowling Green State University

Thomas Galvin
Bowling Green State University

Sean P. Yee
University of South Carolina

In the context of a peer-mentoring program for graduate student instructors (GSIs) who were teaching during their first year as instructor of record, we examined what active-learning (AL) strategies could provide ingresses for mathematics GSIs' use of student-centered teaching. Mentors observed Novices approximately six times during their first-year teaching, collected observation data including a standardized list of AL strategies, and conducted critical feedback conversations with each Novice after every observation. Data includes the number of AL strategies observed and discussed as well as pre- and post-survey data from Novices and Mentors on their perceived use of AL strategies. We found that Novice GSIs were primarily observed implementing Quick Polls, Think-Pair-Share, and Conceptually-Based Teacher Questioning. Each of these strategies were utilized by Novices differently throughout their first-year teaching. Our results provide insights for PD facilitators who work with GSIs, and for novice collegiate mathematics instructors.

Keywords: Active-Learning Strategies, Mathematics Graduate Student Instructors, Student-Centered Teaching

In collegiate mathematics classrooms, the instructor and their students interact around mathematics content in a fast-paced, (not entirely) predictable manner. The instructor is expected to make quick decisions about facilitating mathematics discussions, when/how to ask and answer questions, and how to utilize the class time to support students' progress. In this setting, our intention is to explore ways to provide professional development (PD) and support for novice college mathematics instructors encouraging their effective use of active-learning (AL) strategies. However, implementing AL strategies can seem overwhelming, especially for novice instructors during teaching. Thus, we endeavor to help a specific subset of novice college mathematics instructors, namely graduate student instructors (GSIs)[1], to efficiently navigate their use of instructional practices. This often-overlooked subset of instructors is a vital workforce, tasked with teaching hundreds of thousands of undergraduate students in foundational mathematics courses each year (Belnap & Allred, 2009). College mathematics instructors often have their first experience teaching as instructors of record as GSIs, with little or no pedagogical education, while being provided minimal support structures (Speer et al., 2005). As such, in our project, PD facilitators[2] work with peer mentors to help GSIs learn *when and how* to use AL strategies among other best teaching practices for collegiate mathematics teaching. It can be challenging as AL strategies often include teaching approaches that GSIs may have little-to-no experience utilizing or observing in their own learning experiences. Focusing on this subset of best teaching practices, we consider, what specific AL strategies provide natural paths for GSIs to improve their undergraduate mathematics teaching? Moreover, *how* can we cultivate AL strategies with GSIs for their future teaching?

---

[1] GSI is used instead of TA (Teaching Assistant) because GSI specifically means graduate students who are instructors of record: responsible for every day classroom decisions and assessments in math courses.
[2] Mathematics faculty members who support GSIs in their learning to teach.

To summarize, we provide the following analogy. Since GSIs may need to learn about AL strategies in tandem with their first teaching assignment, we envision the vast collection of possible AL strategies that one could choose from as contained in an *AL Sea*. A role of a coach (e.g., a PD facilitator or mentor), in this analogy, is to help GSIs get comfortable kayaking tributaries so they can access the AL Sea, navigating it effectively. To access the AL Sea, GSIs could begin by kayaking along tributaries aligned with a specific AL strategy. Coaches could guide GSIs in navigating these tributaries, if they knew which of the tributaries may be most accessible to a majority of GSIs (e.g., easy to implement, not a steep learning curve, potentially applicable to a range of undergraduate mathematics learning environments or goals). GSIs kayaking along a tributary can begin getting comfortable in the water of AL strategies while getting closer to accessing a wealth of strategies in the AL Sea. We propose that these tributaries (specific AL strategies) could serve as natural *ingresses* for GSIs to begin navigating their AL strategy journey, leading to the potential use of additional strategies and more effective use of current strategies that foster improved student learning outcomes. Throughout this paper we consider, "what specific AL strategies provide natural ingresses for GSIs into the use of student-centered teaching?"

To identify the natural AL ingresses, we implemented a peer-mentoring program for novice GSIs[3], hereafter referred to as *Novices*, at three universities over five-years (Cite Grants Here). Through this peer-mentoring program, Mentor GSIs[4], hereafter referred to as *Mentors,* guided Novices during their first year teaching undergraduate mathematics and statistics courses. From observation data, follow up conversations between the Novice and Mentor after each observation, and survey data, we address our overarching research question, *what specific AL strategies provided natural ingresses into student-centered teaching for Novices?* To unpack this overarching question, we considered the following subquestions:

RQ1: What AL strategies did Mentors frequently observe and discuss with Novices?

RQ2: What type and frequency of AL strategies did Novices and Mentors report using?

To answer RQ1, we identified which AL strategies Mentors documented when observing Novices' classes, and which AL strategies Mentors discussed with Novices during post-observation conversations. We also analyzed the times during the academic year when AL strategies were observed and discussed. To answer RQ2, we analyzed responses to a self-reported survey from Novices and Mentors about their use of AL strategies.

Related Literature

Active Learning in Research

One foundational axiom across most AL definitions is that an AL strategy actively engages students in the content (Freeman, 2014; Anthony, 1996, Laursen & Rasmussen, 2019). Contextualizing the verb "engage" is where definitions diverge. Fundamentally, how a teacher engages students is content-specific, but most AL definitions lean heavily on contrasting AL with traditional lecture (Laursen et al., 2014; Freeman, 2014). In other words, the antithesis of engagement has been articulated as traditional lecture. Although it can be helpful to unpack non-examples when defining something, as Dewey (1938) argued one cannot define an educational approach simply by saying it is not another. Kyriacou and Marshall (1989) argued that there are two independent dimensions of AL (1) learning activities promoting collaboration and autonomy

[3] Defined as mathematics and statistics GSIs in their first or second year of teaching.

[4] Defined as GSIs who taught for at least 2yrs, and who were trained to mentor Novices.

and (2) meaningful learning experience for each student. Further, they said that the structure of an activity does not guarantee mental engagement: An AL "activity can foster either an active mental experience or a passive mental experience, just as a passive learning activity can foster either an active mental experience by passive or active learning activities, must be necessarily constructive (p. 350)." Thus, generating activities alone is not sufficient to avoid the passive mental experience that is often assumed to be the major shortcoming of the traditional lecture.

Context of Study

We consider the PD facilitator to be a seasoned kayaker who teaches newer but not completely novice kayakers (Mentors), who then teach the Novices, providing them with the information and support needed for beginners to learn the necessary basic knowledge and skills to enable them to navigate their craft safely and effectively. We implemented and facilitated the peer-mentoring program at three universities to support Novices and generate *communities of practice* (Wenger et al., 2002) among the GSIs. The peer-mentoring program prepared experienced GSIs to become Mentors through a semester-long professional development with the PD Facilitator that met for 15hrs over the course of a semester (Yee et al., 2021).

Mentors used a GSI observation protocol (GSIOP: Rogers et al., 2019) to observe each Novice teach (3x per semester) in foundational mathematics course (e.g., PreCalculus, Quantitative Reasoning, Introductory Statistics, and Calculus); Novices were mentored for two semesters. The GSIOP informed Mentors' feedback for the Novices (Yee et al., 2021) and focused Mentors' attention on AL strategies for the Novices to consider integrating into their teaching practices. Mentors submitted the number and types of AL strategies they observed, and those that they discussed at follow-up meetings with their Novices. In addition, Mentors and Novices responded to beginning- and end-of-academic-year surveys that included items regarding their perceptions of their use of AL strategies (14 strategies compiled by the Eberly Center from Carnegie Mellon University & higher education researchers; Faust & Paulson, 1998; Meyers & Jones, 1993). We provided both Mentors and Novices with guidance and examples of each of the 14 AL strategies (named in Table 1). Some terms were adjusted to make them more understandable to mathematics GSIs who may not be familiar with the educational vernacular. For example, instead of listing a broad category like "inquiry-based learning" we focused specifically on "conceptually-based teacher questioning" (C-BTQ) because it operationalized a classroom practice that Mentors could observe. It is important to note here that teacher questioning alone is not an AL strategy (Faust & Paulson, 1998). We included C-BTQ so that Mentors could concretely see examples of inquiry-based learning used with C-BTQ, where Novices elicited responses from all students.

Data Collection & Analysis

Data from two years at three universities included 293 total observations. We coded the observations by the semester in which they took place (first or second), and the timing in which they took place (beginning, middle, or end of semester). An AL strategy was *observed* if Mentors noticed it being used during the class period. Frequency of a single AL strategy used in a single class was not recorded (frequency of use did not imply improved quality). An AL strategy was *discussed* if the Mentor and Novice talked about the method during 1-on-1 follow-up conversations (e.g., ways to improve the use of an observed AL strategy or suggestions for future AL strategy use). To answer RQ2, we considered Novices' and Mentors' self-perceived use of the AL strategies and the observation data. We analyzed pre-post survey data where we asked three questions about the AL strategies: (1) their familiarity with the strategies, (2) how useful they perceived them to be, and (3) how often they used them in their own teaching. We report on our analysis of responses to the third survey question, triangulating our RQ1 findings.

Findings

Across the 293 observations, Mentors noted 278 instances of AL strategies in use. In 127 cases (43.3%) no AL strategies were observed. In the remaining 166 cases, Mentors observed an average of 1.63 AL strategies. Mentors and Novices discussed potential use of AL strategies 403 times, an average of about 1.4 strategies per follow-up meeting. Our findings elevate three of the fourteen AL Strategies studied, described as follows: *Think-Pair-Share*—students answer a question individually, synthesize a joint solution with a partner, and then share/discuss it with the class. *Quick Poll*—all students vote in response to a question. Votes can be tallied using technology or quickly by counting. *C-BTQ*—GSIs' questions are used in tandem with tasks for students to investigate, discover and/or apply concepts for themselves.

RQ1: Observed and Discussed AL Strategies

Table 1. Observed and Discussed AL strategies Descriptive Statistics

AL Strategy	Number Observed	Percent Observed	Number Discussed	Percent Discussed	Observed to Discussed Ratio
C-BTQ	68	24.46%	51	12.66%	1.3333
Quick Poll	64	23.02%	116	28.78%	0.5517
Think-Pair-Share	45	16.19%	108	26.80%	0.4167
Peer Review	20	7.19%	16	3.97%	1.2500
Self-Assessment Quiz	16	5.76%	18	4.47%	0.8889
Set It Up	16	5.76%	24	5.96%	0.6667
Brainstorming	14	5.04%	29	7.20%	0.4828
Minute Paper	9	3.24%	8	1.99%	1.1250
Jigsaw	2	0.72%	5	1.24%	0.4000
Muddiest Point	1	0.36%	17	4.22%	0.0588
Concept Maps	1	0.36%	7	1.74%	0.1429
Case Studies	1	0.36%	1	0.25%	1.0000
Other Strategies	21	7.55%	3	0.74%	7.0000

Note: *Other Strategies* means places where Mentors wrote in a Strategy that was not on our original list. Also, two AL Strategies (*Application Card* & *Role Playing*) from our original list were not observed or discussed.

Table 1 presents the number of times each AL strategy was observed and discussed, arranged in descending order of observed. We note that such limited use of 80% of the 14 strategies may indicate further training is needed for such techniques or that they are not natural ingresses for novices implementing AL strategies in collegiate math courses. To compare the data, we created a percentage from each strategy observed (or discussed) out of the total number of strategies observed (or discussed) for that period of mentoring. The right-most column (Table 1) shows some AL strategies were observed more often than they were discussed (ratio > 1), while others were discussed more often than observed (ratio < 1). The *Muddiest Point* strategy was observed only once but discussed 17 times (ratio of 0.0588), suggesting it may be a more difficult strategy for Novices to implement without further guidance. In a more even ratio, we see *Minute Papers* were observed being used 9 times and discussed 8 times (ratio of 1.125) and *C-BTQ* was observed four times to every three times it was discussed (ratio of 1.3333). Recall, *C-BTQ* required more than *teacher questioning*, but conceptual questions engaging students in a task.

The three most frequently observed AL strategies (*C-BTQ* 24.46%, *Quick Poll* 23.02%, *Think-Pair-Share* 16.19%) were the same three most frequently discussed (*Quick Poll* 28.78%, *Think-Pair-Share* 26.80%, *C-BTQ* 12.66%). They were not in the same order, but there is a 55% drop in use for the fourth most-observed strategy, *Peer Review*, (7.19%) and a 43% drop in use for fourth highest discussed strategy, *Brainstorming* (7.20%). Hence, the three observed and discussed AL strategies form a cluster and are separated noticeably from the remaining AL strategies. These results suggest the top three observed and discussed AL strategies require further analysis as they are likely to be viable ingresses for Novices. Based on these findings, we wondered if there was a connection between those methods discussed by Mentors after an initial observation and those observed subsequently. To investigate this latter possibility, we analyzed relationships between the discussion of these three strategies and their use in observations.

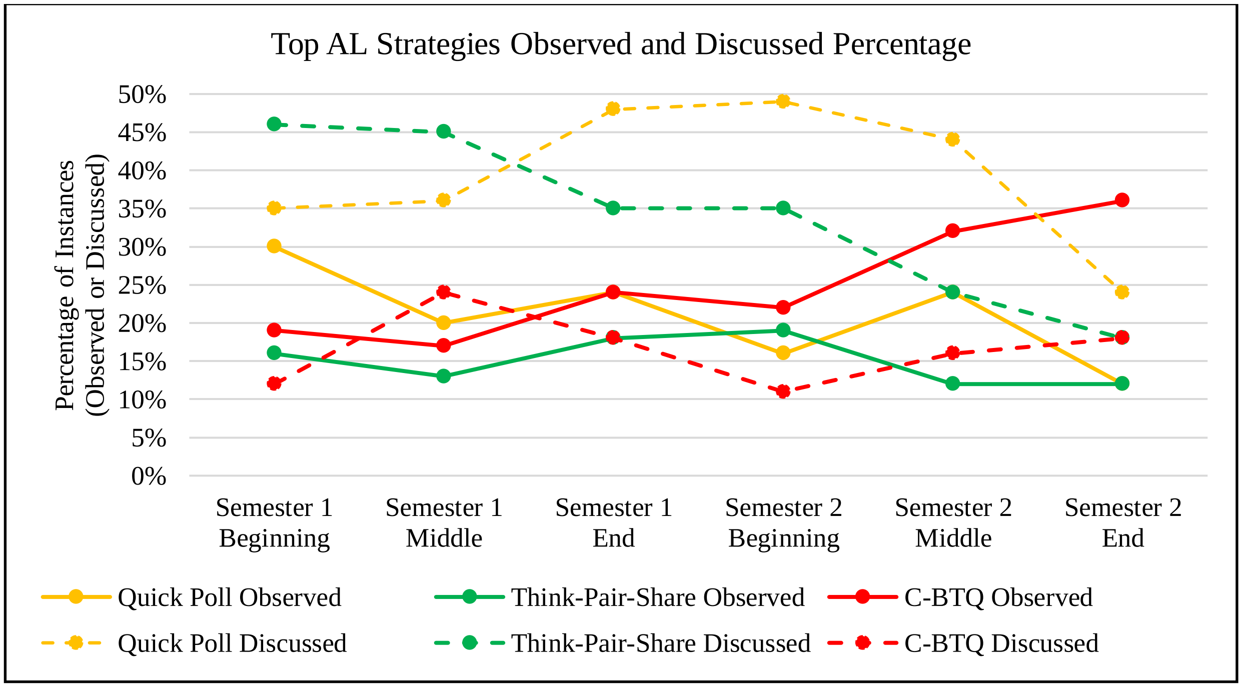

Figure 1: Top three Active Learning strategies by percent of time frame's method

For each of the strategies, we divided the data by when in the semesters the observations were conducted. We then computed the percentage of instances where the strategies were observed or discussed (Figure 1). We did not expect that discussed strategies would be implemented in a subsequent observation because there were weeks between subsequent observations during which time different learning objectives and instructional goals would also affect the Novices' choices of strategies. We were curious if there would be an increased likelihood that Novices would use strategies that had been discussed by their Mentors.

Looking across time (Figure 1), *Quick Poll* and *Think-Pair-Share* had discussed percentages consistently higher than observed. *Think-Pair-Share* had the largest differential between discussed and observed percentages at the beginning of first semester, while *Quick Poll* had the largest difference between observed and discussed percentages at the start of second semester. However, *C-BTQ* had observed percentages greater than discussed most semesters with the largest difference at the end of second semester, where *C-BTQ* observed percentage continued to increase. Thus, *Think-Pair-Share* had the greatest percentile difference with discussed greater than observed at the beginning of first semester, *Quick Poll* had the greatest percentile difference with discussed greater than observed at the beginning of second semester, and *C-BTQ* had the greatest percentile difference with observed greater than discussed at the end of second semester.

RQ2: AL Strategies and Survey Data

Of the 66 Novices and 16 Mentors who participated over 2 years, survey response rates were 56% and 100% from Novices and Mentors, respectively. These GSIs indicated their use of AL strategies by selecting Never, 1-2 times per semester, 3-6 times per semester, 7-12 times per semester, and Almost Every Class Session. We classified *regular use* if a GSI selected 7-12 times per semester or Almost Every Class Session (use of a strategy 7 or more times per semester translated to an average of at least once per two-week period). We defined the *most regularly used* AL strategies as those used at least once every two weeks by at least 50% of the respondents. Because we asked GSIs to indicate how frequently they used each of AL strategy, we compiled their responses to consider which strategies they reported using most often. This data supplements the observation data by capturing semester-long data. Table 2 shows which AL strategies at least 50% of the respondents said they used at least once every two weeks (*regular use*) and Mentors' Pre-Survey responses were comparable to Novices' Post-Survey responses.

Table 2. AL Strategies Novices and Mentors Cited Using Regularly

Novices' Pre-Survey	Novices' Post- & Mentors' Pre-Survey	Mentors Post-Survey		
1. Think-Pair-Share 2. Quick Poll	1. C-BTQ 2. Quick Poll 3. Think-Pair-Share	1. Quick Poll 2. C-BTQ 3. Set It Up	4. Think-Pair-Share 5. Brainstorming 6. Muddiest Point	7. Self-Assessment Quiz 8. Peer Review

We note that 50% or more of Mentors said they regularly used eight AL strategies, a four-fold increase from Novices' pre-survey responses. Table 2 also shows 50% or more of beginning Novices said they regularly used only two AL strategies (*Think-Pair-Share*, *Quick Poll*). By the end of their first-year teaching, Novices cited three strategies (adding *C-BTQ*). These three AL strategies were also the most frequently observed and discussed (*Quick Poll*, *Think-Pair-Share*, *C-BTQ*, Table 3). Thus, the pre-post survey findings (Table 2) corroborate the most frequented AL strategies observed and discussed by the Mentors (Table 1).

Discussion

Table 3. Summary of Findings for AL Ingresses for Novices GSIs

AL Ingress	**Observed: Discussed (Table 1)**	**AL Self-Report (Table 2)**	**Observed AL Trends (Figure 1)**	**Discussed AL Trends (Figure 1)**
Quick Poll	0.5517 (More discussed)	Novices reported using it right away	Initially observed often, and dipped down until middle of 2nd semester	Initially, consistently ~30%; highest in middle of 2nd semester
Think-Pair-Share	0.4167 (More discussed)	Novices reported using it right away	Consistently observed through both semesters	Discussed at beginning of each semester; decreased from there
C-BTQ	1.3333 (More observed)	Reported used more often 2nd semester	Nearly doubled observed use by mid 2nd semester	Not often discussed until middle of 2nd semester

We identified and triangulated three AL strategies (*Quick Poll*, *Think-Pair-Share*, and *C-BTQ*) to answer our over-arching question, *what specific AL strategies provided natural ingresses for*

GSIs into student-centered teaching? Our results provide a path for PD facilitators who work with GSIs, and for novice collegiate mathematics instructors. In the context of a peer-mentoring program utilizing regular observations and post-observation feedback (Rogers et al., 2019; Yee et al., 2021), we found that Novices were primarily observed implementing *Quick Polls, Think-Pair-Share*, and *C-BTQ*. Each of these strategies were utilized by Novices differently throughout their first-year teaching (as summarized in Table 3).

Implications

Our results build upon prior work when examining instructors' use of Muddiest Point Simpson-Beck (2011) argued that studying only one AL strategy may yield misleading results. In our study the *Muddiest Point* was observed only once but recommended 17 times. We interpret this result to mean that the *Muddiest Point* may not be a viable ingress for these Novices. Moreover, Angelo, and Cross (1993) argued AL strategies need to appeal to your intuition, should not be a burden, and provide benefits to you and your students, aligning with the role of Novices' natural ingresses. Among the 14 AL strategies we trained Mentors to observe and discuss, three rose to the top, and each AL strategy had unique characteristics in its observed and discussed use by Mentors (Table 3), suggesting that future studies could be designed examine longitudinal use of these three strategies and potential connections to student-learning outcomes.

One strategy, *C-BTQ* provided insights into a specific timeframe we should expect for its use to burgeon. Unlike *Quick Poll* and *Think-Pair-Share*, the ability to implement *C-BTQ* is likely a reflection of teaching skill and experience, rather than a teaching technique. *C-BTQ* requires a deeper understanding of the curriculum and pedagogical content knowledge (Shulman, 1986). To know what significant questions to pose (and how) for discovery and task-oriented learning, the instructor must be anticipating what significant topics are coming up. Thus, it was not surprising that the use of *C-BTQ* was often observed more in Novices' second semester teaching. This result could imply that PD programs interested in increasing collegiate mathematics instructors' use of *C-BTQ* may need to plan for more than one semester to support Novices' PD.

Conclusion

Initially, we asked how can PD providers cultivate AL strategies with GSIs for future teaching? We found one method that demonstrated growth in frequently observed and discussed AL strategies was providing time and ongoing PD via peer mentoring during that first critical year of teaching. Due to the variety of intentions and resources for mathematics departmental programs to educate current and future GSIs, there is inequity in PD opportunities because novice GSIs do not have equal access to the pedagogical support for using "best practices" as listed within the Instructional Practices Guide (MAA, 2018). Combating this inequity, we examined what natural ingresses Novices can first navigate with the support of a peer mentor to gain access to the larger set of AL strategies (the AL Sea). Of the three ingresses we identified, how and when they are used by Novices varies and so our findings provide guidance within each ingress differently. Ideally, these ingresses will provide a means for GSIs to access and have positive experiences using AL strategies, resulting in student-centered instruction to foster GSIs' long-term PD.

Using Concept Images as a Framework for the Concept of Confidence Intervals

Kristen E. Roland
Appalachian State University

Jennifer J. Kaplan
Middle Tennessee State University

Both the American Psychological Association (APA) and American Statistical Association (ASA) recommend that researchers move toward reporting interval estimates, such as confidence intervals. While previous literature in psychology and statistics education has documented many non-normative conceptions about confidence intervals, little is known about how individuals construct knowledge of confidence intervals nor what constitutes robust understanding of the concept of confidence intervals. This paper defines a formal concept image for the concept of a confidence interval. The formal concept image is based on the underlying statistical theory for deriving a confidence interval. The statistical theory is followed by a presentation of a formal concept image for confidence intervals and the interpretation of the interval and its level. The paper concludes with a brief statement of the affordances and limitations of the formal concept image.

Keywords: Statistics, Confidence Intervals, Concept Image

While a number of misconception studies[1] inform statistics education research about *what* individuals can communicate about interpretations and meanings of confidence intervals, little is known about *how* individuals construct their knowledge of confidence intervals. For example, previous studies have explored the knowledge retained about interpretations of confidence intervals (e.g., Belia et al., 2005; Crooks, 2014; Crooks et al., 2019; Fidler, 2005), interpretations of confidence intervals by learners (e.g., Andrade et al., 2014; Andrade & Fernández, 2016; Fidler, 2005; Grant & Nathan, 2008; Henriques, 2016; Kalinowski et al., 2018), and aids for instruction of confidence intervals (e.g., Bertie & Farrington, 2003; Gordon & Gordon, 2020; Hagtvedt et al., 2008). These studies included a diverse group of students (pre-service teachers, psychology undergraduate and graduate students, and general population undergraduate students) at different levels of statistical experience, with the aim of identifying common misconceptions subjects had about confidence intervals, but little work had been done to understand how these misconceptions form. As a result, there is no existing theoretical framework describing the required knowledge and understanding for a well-developed and connected understanding of confidence intervals – including how to interpret the necessary components. This paper describes a framework, in the form of a formal concept image, that can be used to elicit and study the conceptual knowledge of confidence intervals and uncover, from a cognitive perspective, the concepts and connections individuals have developed around the concept of confidence intervals.

Theoretical Perspective

This paper defines a formal concept image for the concept of a confidence interval based on the underlying statistical theory for deriving a confidence interval, and the interpretation of the interval and its level. A *concept image* is defined as the complete cognitive structure associated with a concept, including all mental pictures and associated properties and processes (Tall & Vinner, 1981, p. 152). This definition resulted from the difficulty in "[distinguishing] between

[1] The authors prefer the words *conception* or *resource* to *misconception*. The authors use the word misconception to reflect the intentions and meanings of the original studies cited.

the mathematical concepts as formally defined and the cognitive processes by which they are conceived" (Tall & Vinner, 1981, p. 151). In particular, Tall and Vinner discussed the difference between formally defined mathematical concepts (*formal concept definition*) and an individual's definition of mathematical concepts (*personal concept definition*). An individual's personal concept definition may deviate from a formal concept definition, and may vary because of a particular *evoked concept image*: "a portion of the concept image which is activated at a particular time" (Tall & Vinner, 1981, p. 152). This paper presents a formal concept image for the concept of CIs to be used as a foundation to analyze individuals' personal concept images. It is the authors' hope that the formal concept image defined here will be a foundational framework for future research.

Statistical Theory

The formal concept image describing the cognitive structures underlying understanding of confidence intervals was developed from the statistical theory for deriving confidence intervals and the related curricular concepts. A condensed summary of the statistical theory used as the basis for the formal concept image is provided in this section. Formally, *confidence intervals*[2] are defined as "interval estimators, together with a measure of confidence (usually a confidence coefficient)" (Casella & Berger, 2002, p. 419). In statistics, an *estimator* is a function, $T(x_1, x_2 \ldots x_n)$, of a random variable used to estimate an unknown value of a parameter, θ. In the case of a point *estimator*, this is represented by a single function of a random variable from a yet-to-be-collected sample. In the case of an interval *estimator*, this is constructed through two functions of a sample, $L(x_1, \ldots, x_n)$ and $U(x_1, \ldots, x_n)$, that satisfy $L(\boldsymbol{x}) \leq U(\boldsymbol{x})$, for all $\boldsymbol{x} \in \mathcal{X}$, the random interval $[L(\boldsymbol{x}), U(\boldsymbol{x})]$. A confidence interval, however, takes the idea of an interval estimator one step further by defining a *coverage probability*, $(1-\alpha)$, which is a term used for the probability that the random will contain the unknown value of the parameter, $P_\theta(\theta \in [L(\boldsymbol{x}), U(\boldsymbol{x})]) = (1-\alpha)$ or $P([L(\boldsymbol{x}), U(\boldsymbol{x})]|\theta) = (1-\alpha)$. The formula for the confidence interval estimator for a confidence interval for the population mean, μ, with an unknown population variance σ^2

$$\bar{X} \pm t_{n-1,\alpha/2} * \frac{s}{\sqrt{n}} \tag{1}$$

is derived an example of this statistical theory. Given that certain conditions are met, Equation 1 is derived starting with the *pivotal quantity*, T, which allows the researcher to model the probabilities associated with the estimators ($\bar{X}$, the sample mean, and *s*, the sample standard deviation) with known distributions not determined by either of the unknown parameters (μ and σ^2):

$$T = \frac{\bar{X}-\mu}{s/\sqrt{n}} \sim t_{n-1} \tag{2}$$

Using the *t*-distribution, find the endpoints of the region of the distribution that would satisfy the specified coverage probability (1 - α):

$$P\left(-t_{\alpha/2,n-1} < T < t_{\alpha/2,n-1}\right) = 1-\alpha \tag{3}$$

Substituting Equation 2 into Equation 3 and solving for μ, the confidence interval estimator is derived in a way that ensures, probabilistically, the desired coverage probability is achieved:

$$P\left(\bar{X} - t_{\alpha/2,n-1} * {S}/{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/2,n-1} * {S}/{\sqrt{n}}\right) = 1-\alpha \tag{4}$$

[2] The theory of confidence intervals discussed from the frequentist perspective, referring to the belief that probabilities represent long-run frequencies of repeated random experiments.

Thus, Equation 1 is derived from functions of random variables: meaning Equation 1 represents a random interval.

When using Equation 1 in practice, however, the researcher has already collected (or is planning to collect) a sample. Once a sample has been collected, Equation 1 no longer represents a random interval because $\bar{X}$ and s are no longer estimators. Instead, $\bar{X}$ and s are point *estimates* as they are now a realized value of a function of a random variable used to estimate the unknown value of the parameter, μ. Since $\bar{X}$ and s are now fixed values from an actualized sample from a random variable, the probability statement represented by Equation 4 is no longer true because there are no longer any random values to which probability can be assigned. The difference in an *estimate* and *estimator* determines how and why a confidence interval is interpreted.

As an estimate, Equation 4 is either true or false: the value of the parameter, μ, is either in the interval (probability of occurrence is 1) or is not in the interval (probability of occurrence is 0). Since the value of the parameter is unknown, the individual calculating the interval cannot know whether the interval is one of the $100(1-\alpha)\%$ that captures the value of the parameter or one of the $100(\alpha)\%$ that does not capture the value of the parameter. Therefore, there was confidence level *probability* that the value of the parameter would be within the random interval, but there is confidence level *confidence* that the value of the parameter is within the actualized interval. *Confidence* refers to the probability associated with the random process – not the probability that the value of unknown parameter is within the actualized interval. Thus, in communicating the meanings of a constructed confidence interval, interpretations need to be clear about the difference between the process that was used to derive the *estimator* for the confidence interval and the *estimate* that has been calculated.

Formal Concept Image for Confidence Intervals

The theoretical underpinnings of a confidence interval presented above require learners to simultaneously coordinate meanings and ways of thinking across multiple curricular concepts in statistics. This section contains a description of a formal concept image for confidence intervals along with two of the "sub"-formal concept images that make up the larger formal concept image for confidence intervals. The goal is to provide a formal framework based on necessary cognitive structures from which individuals' personal concept definitions of the concept of confidence interval, of the interpretation of a confidence interval, and of the interpretation of a confidence level can be understood. This formal concept image is not intended to serve as a learning progression for concept of confidence intervals, rather as a guide to understand current knowledge based on prior learning, rather than a framework to analyze current learning.

Hypothesized concept clusters

It is hypothesized that individuals need to coordinate many statistics curricular concepts[3] when they construct their personal concept image for the concept of confidence intervals. Specifically, the model contains five concept clusters representing the pre-requisite and co-requisite knowledge needed for a robust understanding of the concept of confidence intervals: 1) parameter/statistic, 2) random process, 3) estimator/estimate, 4) sampling distribution, and 5) coverage probability. Requisite curricular concepts for statistical inference start with understanding the underlying purpose of inference: to use information provided in a sample to learn more about a characteristic or attribute of a population. The information typically derived

[3] The following descriptions are a brief summary of the curricular concepts within each concept cluster, for those seeking formal definitions of each of the statistics terms see AUTHOR (2020).

from a sample is summarized into a statistic, which should be an unbiased estimator of the unknown value of a parameter (a summarization of information gathered from a population).

Parameter/Statistic. Within this concept cluster, individuals need to understand the difference between the unknown value of the parameter, which is a summarization of a characteristic of the population, and the *actualized value of the statistic*, which is the point estimate calculated from a collected sample. Before an individual can begin to formalize conceptions of parameter and statistic, the individual must understand the difference between a population and a sample. Furthermore, the individual needs to coordinate information about 1) the population to which results can be generalized, 2) a sample, 3) a statistic, and 4) a parameter. Thus, the statistics curricular concepts within this cluster are: (a) observational unit, (b) datum, (c) variable, (d) types of variables, (e) population, (f) parameter, (g) sample, and (h) statistic.

Random Process. The concept cluster, *Random Process*, encompasses understanding the random process. A random process is a process that can be repeated many times under identical conditions for which any one instance is unknown, but for which the proportion of times a particular outcome occurs in the long run can be predicted (Tintle et al., 2021). This process helps explain the variability that exists in the population and sample data and can aid in developing a model for the long-run probabilities of particular outcomes. Understanding the difference between the assignment of probability to the model of the outcomes of a random variable generated from a random process and the lack of probability associated with collected data (a particular instance of the random process) is pivotal in understanding the idea of random process. The purpose of this concept cluster is to describe the ideas of probability and random processes (models designed to explain a real-world situation) that underlie the field of statistics. The following curricular concepts may require simultaneous or prior development of the Parameter/Statistic concept cluster: (a) random variable, (b) random process, (c) outcome, (d) relative frequency, (e) independence, (f) probability, and (g) sampling methods.

Estimator/Estimate. Understanding the interpretation of an actualized confidence interval is reliant on distinguishing between random variables and fixed (but unknown) values, which forms the basis of the concept cluster, *Estimator/Estimate*. A common conception of a confidence interval is the belief that the confidence level is the probability that the fixed, but unknown, actual value of the parameter is between the endpoints of the interval. This interpretation implies the random interval is a fixed interval and the fixed actual value of the parameter a random value of the parameter. Both are incorrect. The endpoints of the interval are random values based on the random statistic, which is based on the model of a random process from real-world situations. The actual value of the parameter is not known to the researcher, which explains the reason for inference, but the parameter of interest is defined. Understanding the distinction between the fixed unknown parameter and the random endpoints of the interval is not trivial and difficulties with this distinction may exist due to incorrect or incomplete knowledge of probability and random processes. Thus, the concepts being coordinated within this concept cluster are: (a) random variable, (b) actualized variable, (c) estimator, and (d) estimate. In addition to these formal concept image-specific concepts, an individual needs to coordinate the Parameter/Statistic and Random Process concept clusters.

Sampling Distribution. The *Sampling Distribution* concept cluster encompasses many concepts including the sampling distribution. The connection between confidence intervals and sampling distributions is very complex. The sampling distribution models the natural variability in statistics from samples generated by repeated sampling from a population (or repeated instances of a random process). The natural variability of the random statistics can be modeled by either theoretically-defined or simulated models, both of which provide a structure to understand how statistics generated by repeated sampling vary with respect to the associated parameter. This model forms the basis of the theoretical derivation of the formulas for confidence intervals. The Sampling Distribution concept cluster may incorporate: 1) properties of distributions (measures of center, measures of variability, shape, probability); 2) differences between distributions of populations, distributions of sample, and distributions of statistics (sampling distributions); and 3) characteristics of sampling variability (i.e. between-sample variability). Thus, the concepts that are being coordinated within this concept cluster are: (a) mean, (b) variability, (c) standard deviation, (d) distribution of a population and a sample, (e) theoretical and empirical probability distributions, (f) shape of a distribution, (g) sampling distribution of a statistic (including the mean, standard deviation, and standard error of the sampling distribution for a statistic), and (h) sample size.

Coverage probability. The *Coverage Probability* concept cluster is the foundation of the theory of a confidence interval. Within this concept cluster, the individual is hypothesized to be coordinating the ideas of Parameter/Statistic, Sampling Distribution, Random Process, and Estimator/Estimate but specifically within the context of a confidence interval. The Coverage Probability concept cluster is hypothesized to contain the ideas of confidence level, the confidence interval estimator, and the confidence interval estimate. Therefore, the specific concepts that an individual may be coordinating are: (a) confidence interval estimator, (b) coverage probability, (c) confidence level, and (d) confidence interval estimate.

Formal Concept Image for Confidence Intervals

The formal concept image for confidence intervals appears to have sub-formal concept images (gray diamonds, Figure 1), only two of which are described in this paper: interpretation of a confidence interval and interpretation of a confidence level. The curricular concept clusters discussed previously combine in different ways to create the sub-formal concept images (tan hexagons, Figure 1). Note that some of the curricular clusters are hypothesized to be dependent on each other, but those connections are not shown in the figure.

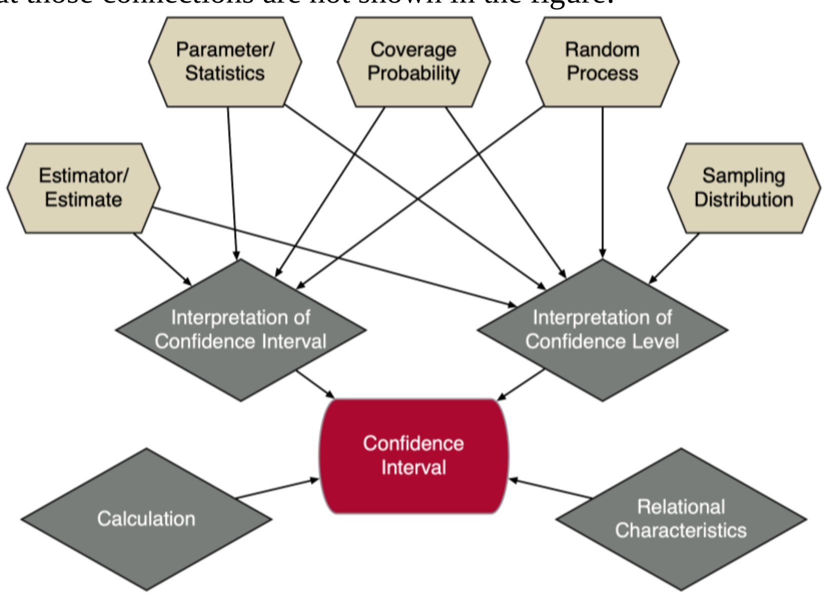

Figure 1: Formal Concept Image for the concept of Confidence Intervals

Formal Concept Image for Interpreting a Confidence Interval. The commonly accepted *interpretation of the confidence interval*[4] is: "We are 100(1-α)% confident that the calculated interval contains the true value of the parameter." *Confident* in this sentence implies that the user is confident in the random process of sampling and calculating confidence intervals rather than the probability that any one actualized confidence interval contained the value of the unknown parameter. An individual needs to coordinate several concept clusters in order to unpack the meaning of this sentence:

- $\mathbf{100(1-\alpha)\%}$ refers to the coverage probability that the interval estimator will capture the unknown value of the parameter of interest and requires the Coverage Probability concept cluster.
- **Confident** refers to the random process and coverage probability used to derive the confidence interval and requires the Random Process and Coverage Probability concept clusters.
- **Parameter** refers to a fixed, but unknown, value that summarizes a variable of interest (or attribute) within a population and is contained within the Parameter/Statistic concept clusters.
- **Between** is used to denote the actual value of the parameter is fixed and the interval "captured" the unknown value of the parameter not that the unknown value of the parameter was moving (see for more information: Callaert, 2007; Foster, 2014). This requires understanding the Estimator/Estimate and Random Process concept clusters.
- **(Lower limit) and (Upper limit)** are possible values for the unknown value of the parameter which requires the Parameter/Statistic and Estimator/Estimate concept clusters.

Formal Concept Image for Interpreting a Confidence Level. Traditionally, the interpretation of the confidence level is "Approximately $100(1-\alpha)\%$ of all samples of size n from a given population are expected to produce $100(1-\alpha)\%$ confidence intervals that will contain the actual value of the parameter of interest." Like the interpretation of a confidence interval, this interpretation is hiding several concepts that need to be unpacked:

- **Approximately** refers to the long-run probability derived from an estimated sampling distribution and the difference between theoretical and empirical distributions. This requires the concept clusters Sampling Distribution and Random Process.
- $\mathbf{100(1-\alpha)\%}$ refers to the Coverage Probability concept cluster of the given confidence interval.
- **All samples of size n from a given population** requires the concept clusters Parameter/Statistic, Sampling Distribution, and Random Process to understand the ideas of gathering all of the samples possible from a population.
- **Will produce** refers to the Random Process and Estimator/Estimate concept clusters, which allow an individual to understand the difference between an estimator and an estimate.

[4] The interpretation of a confidence interval is not without its own set of controversies. Morey et al. (2016) argued that the frequentist assumptions of traditional (Neyman) confidence intervals do not lend themselves to interpretation once an actualized interval has been created. While Morey et al. identified a difficult aspect of the interpretation of a confidence interval, the general consensus of the textbooks sampled appeared to side with some form of the interpretation: "We are 100(1-α)% confident that the calculated interval contains the true value of the parameter" (e.g., Agresti et al., 2017; De Veaux et al., 2018; Larson & Farber, 2019; McClave & Sincich, 2017; Triola & Iossi, 2018).

- $\mathbf{100(1-\alpha)\%}$ **confidence intervals** refers to the specific confidence interval of a given confidence level that had been constructed from each sample. This requires the Random Process and Estimator/Estimate concept clusters.
- **Will contain** refers to the ideas that the actual value of the parameter is fixed, and the interval is random. This requires the Estimator/Estimate concept cluster.
- **Parameter of interest** requires the Parameter/Statistic concept cluster.

The final part of the sentence that requires unpacking is the "$100(1-\alpha)\%$ of all samples … $100(1-\alpha)\%$ confidence intervals." These two percentages should be the same for the sentence to hold true. It is still a true sentence if the first "$100(1-\alpha)\%$" was larger than the second "$100(1-\alpha)\%$": "approximately 98% of all samples of size n from a given population will construct 95% confidence intervals that will contain the actual value of the parameter of interest." In this case, the researcher has overestimated the proportion of samples (98% instead of 95%) that should produce 95% confidence intervals that contain the actual value of the parameter of interest.

Affordances and Limitations

The formal concept image presented in this paper provided a theoretical framework for a foundational study into the cognitive structures required for a robust understanding of confidence intervals, allowing the analysis of the study data to be grounded in statistical content. A limitation of this formal concept image as an analytic framework was its specificity and focus on curricular concepts. The results from the study demonstrated that student personal concept images about interpretations of confidence interval and confidence level are more connected than defined through the formal concept image. Future iterations of a formal concept image for the concept of confidence intervals may need to demonstrate connections among the concept clusters prior to the development of "sub"-formal concept images for the interpretation of the confidence interval and the interpretation of the confidence level. Further research into applying the formal concept image to individuals' personal concept image for the concept of confidence intervals and into how individuals' personal concept images affect their knowledge of a confidence interval, interpretation of a confidence interval, and interpretation of a confidence level.

The Implications of the Difference Between Estimators and Estimates in the Meaning of Confidence Intervals: Brody and the Jamie's Colleague Task

Kristen E. Roland
Appalachian State University

Jennifer J. Kaplan
Middle Tennessee State University

Recently professional associations have called for increased use of confidence intervals in reporting inferential results. Little is known, however, about the knowledge structures necessary for a robust understanding of confidence intervals (CIs). This paper presents a case that demonstrates an important connection within a formal concept image for the concept of CIs. Understanding the interpretations of CIs and confidence levels (C-Lvls) requires understanding the probabilistic difference in a CI estimator and a CI estimate. Several tasks were developed to explore participants' demonstrated knowledge of this difference and its connection to the interpretations of CIs and C-Lvls. The case provides evidence of 1) the necessity of a hypothesized curricular concept cluster including the concepts of CI estimator/ estimate and 2) the importance of its connection to both the interpretation of CIs and C-Lvls.

Keywords: Statistics, Confidence Intervals, Confidence Levels, Estimator/Estimate, Case Study

News reporting of data and models reached unprecedented levels in 2020 as the world battled the coronavirus pandemic. Making sense of this information requires global citizens to be knowledgeable consumers of data and results of statistical inference. The two main frequentist[1] statistical inference techniques are hypothesis testing and confidence intervals (CIs). Of these, hypothesis testing and in particular, the use of the *p*-value cutoff, $p < 0.05$ for publication of scientific results, is ubiquitous (Hubbard, 2016, 2019). Both the American Statistical Association and the American Psychological Association, however, have issued statements cautioning against the over-reliance of *p*-values in scientific research (see: Wasserstein & Lazar, 2016; Wilkinson, 1999) and strongly suggest reporting point and interval estimates and/or effect sizes accompanied by a measure of uncertainty, such as a standard error or interval (Wasserstein et al., 2019). In fact, scientists already use interval estimates in reporting of modeling: for example, in predictions about the path and intensity of a storm or the spread of a disease or a contaminant spilled into a water source.

Communicating and understanding the uncertainty associated with CIs requires a robust understanding of the interpretation of 1. the CI and 2. the confidence level (C-Lvl). Complicating matters, the idea of CIs is a highly complex set of concepts within statistical inference requiring an individual to understand fine details in the derivation of the confidence interval procedure. In essence, there is a fundamental difference between an *estimator*, a function of a random variable used to estimate an unknown value of a parameter, and an *estimate*, a realized value of a function of a random variable (i.e. a value calculated from a collected sample) used to estimate an unknown value of a parameter. Probabilities lie with the estimator and become fixed when an estimate has been calculated. This is the theoretical underpinning of the interpretation of CIs. The authors hypothesize that developing a deep understanding of the difference in the estimator and estimate, particularly with respect to CIs, will help individuals be better consumers and producers of statistics. This paper presents an interesting case, selected from a larger study, that

[1] This paper discusses only frequentist CIs. Future work should study Bayesian credible intervals and bootstrap percentile intervals.

provides evidence of the high-level of connections among concepts necessary for a robust understanding of CIs presented in a hypothesized concept image for the concept of CIs. In particular, the participant discussed in this paper was the only participant in the larger study (n=11) to show development of knowledge associated with differentiating between an *estimator* and an *estimate*.

At present, the authors are unaware of research about students' knowledge of the difference between an *estimator* and an *estimate*. Current research has explored the knowledge retained about interpretations of CIs (e.g., Belia et al., 2005; Crooks et al., 2019) and interpretations of the conclusion and p-values from hypothesis testing (see: Castro Sotos et al., 2007). These studies illuminated what they call misconceptions[2], but little work had been done to understand how these conceptions form[3].

Theoretical Perspective

The theoretical perspective and underlying framework for this case study is based in the development of a concept image for the concept of confidence intervals. A *concept image* is "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (Tall & Vinner, 1981, p. 152) The construct of a concept image helps researchers distinguish between formally defined mathematical concepts, *formal concept images*, and a *personal concept image*, an individual's interpretation and coordination of concepts and images, which may or may not align with the formal concept definition (Tall & Vinner, 1981, p. 151). Roland and Kaplan (2022) present a formal concept image for the concept of confidence intervals. They hypothesize that the concept of a CI requires a complex coordination of several "sub" concept images and statistical concept clusters. This formal concept image was derived from the formal statistical definitions and curricular concepts required to understand the formal definitions. Roland and Kaplan created *statistical concept clusters* to describe the potential clusters of statistics curricular concepts. Since this theoretical framework is grounded in the statistical theory, a brief review of the necessary statistical theory will be discussed prior to describing the concept image of the concept of confidence interval.

Statistical Theoretical Background

There are two typical expressions of the frequentist *interpretation of the confidence level*: 1) approximately 100(1-α)% of all possible 100(1-α)% CIs should capture the unknown value of the parameter and/or 2) prior to collecting data, the probability of a 100(1-α)% CI capturing the value of the unknown parameter was 100(1-α)%. These interpretations are fairly straightforward because both describe the coverage probability either in terms of long-run probability or the probability associated with a random sample from a random variable. The commonly accepted frequentist *interpretation of the confidence interval*[4] is "We are 100(1 -α)% confident that the calculated interval contains the true value of the parameter." *Confident* in this sentence implies

[2] The authors prefer the words *conception* or *resource* to *misconception*. The authors use the word misconception to reflect the intentions and meanings of the original studies cited.

[3] For current literature on how learners conceptualize CIs see Andrade et al. (2014), Andrade and Fernández (2016), Fidler (2005), Grant and Nathan (2008), and Henriques (2016).

[4] While Morey et al. (2016) make a reasonable argument that the frequentist assumptions of traditional (Neyman) CIs do not lend themselves to interpretation once an actualized interval has been created, the general consensus of textbooks appears to include interpretations similar to that presented here (e.g., Agresti et al., 2017; De Veaux et al., 2018; Larson & Farber, 2019; McClave & Sincich, 2017; Triola & Iossi, 2018).

that we are confident in the random process of sampling and calculating CIs rather than the probability that any one actualized CI contains the value of the unknown parameter.

The derivation of a CI is based on the assumption of the existence of random components (point *estimators*, such as $\bar{X}$ and *s*) and fixed, but unknown components (parameters, such as μ and σ). The use of point estimators allows the researcher to leverage theoretical probability models to create an interval *estimator* (specifically, a confidence interval *estimator*) with random endpoints. The width of the interval estimator corresponds to the probability the CI estimator will capture the true parameter, which is called the *coverage probability* $(1-\alpha)$. Roland and Kaplan (2022) provide a detailed example, a CI for the population mean (μ) with an unknown population variance (σ^2), to demonstrate this statistical theory. Summarizing the example, the endpoints of the region of the distribution that would satisfy the desired coverage probability (1 - α) and solving for μ, the confidence interval estimator is derived ensuring, probabilistically, the coverage probability:

$$P\left(\bar{X} - t_{\alpha/_{2},n-1} * {}^{S}/_{\sqrt{n}} < \mu < \bar{X} + t_{\alpha/_{2},n-1} * {}^{S}/_{\sqrt{n}}\right) = 1-\alpha \tag{1}$$

Recall that $\bar{X}$ and *s* are functions of random variables, meaning the equation represents a random interval with an associated coverage probability, called the confidence level (C-Lvl). Since $\bar{X}$ and *s* are now considered *estimates*, however, the equation no longer has meaning because there are no random components in the equation. As an interval estimate, the statement is either true or false: the value of the parameter, μ, is either in the interval (P(parameter) = 1) or is not in the interval (P(parameter) = 0). Since the value of the parameter is unknown, the individual calculating the interval cannot know whether the interval is one of the $100(1-\alpha)\%$ that captures the value of the parameter or one of the $100(\alpha)\%$ that does not capture the value of the parameter. Therefore, there was C-Lvl *probability* that the value of the parameter would be within the random interval, but there is C-Lvl *confidence* that the value of the parameter is within the actualized interval (the interval estimate based on the collected sample data).

The Formal Concept Image of the Concept of Confidence Interval

There are five statistical concept clusters (tan hexagons in Figure 1) defined in Roland and Kaplan (2022): 1) Parameter/Statistic, 2) Random Process, 3) Sampling Distribution, 4) Coverage Probability, and 5) Estimator/Estimate. Figure 1 summarizes part of the overall formal concept image of a confidence interval (red box), including two "sub"-concept images (gray diamonds): 1) interpretation of a CI and 2) interpretation of a C-Lvl. This case study explores the evidence for the existence of the Estimator/Estimate concept cluster, and its connection to the interpretations of a CI and C-Lvl.

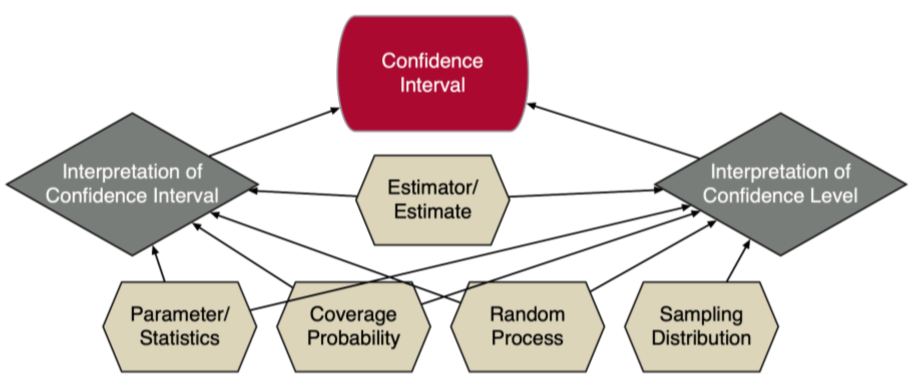

Figure 1: Modified Concept Image for the Concept of Confidence Intervals

The statistical concept cluster, Estimator/Estimate describes the statistical curricular concepts needed to understand the difference between the estimator and the estimate and the implications of the differences in the interpretation of an actualized CI and the confidence level. Thus, the concepts being coordinated within this concept cluster are: (a) random variable, (b) actualized variable, (c) estimator, and (d) estimate. To demonstrate knowledge within the Estimator/ Estimate concept cluster, an individual should be able to explain how the difference between the estimator and the estimate affects the interpretation of the CI and the interpretation of the C-Lvl. Using the case of Brody as an example, this paper demonstrates the connections between the interpretation of the CI and CL reliant on the Estimator/Estimate cluster within the formal concept image of the concept of confidence intervals.

Methods

Brody[5] is an interesting case from a larger study. He, along with the other participants, were students at a large research-focused institution in the Southeastern part of the United States. Brody was a senior undergraduate dual major in statistics and theology enrolled in the statistics capstone course in the Fall 2019 semester, when data were collected. The senior capstone course for statistics majors is 3-credit year-long seminar course centered around a data-based project. Brody also reported he had completed most of the requirements for his degree in statistics, including a 2-semester mathematical statistics sequence.

Brody engaged in three clinical interviews each of approximately one hour in length over the course of the semester. The first two interviews consisted of open-middle tasks (Bell & Burkhardt, 2002; Yeo, 2017), all with correct answers. The interviews were mostly conversational in nature and were designed to elicit, among other things, the conceptualizations participants had about the interpretation of CI and interpretation of the C-Lvl. The third interview piloted an activity designed to introduce students to the concept of CIs by developing deep connections between the C-Lvl and the derivation of CIs. The data presented in this paper center around the curricular concepts within the Estimator/Estimate concept cluster. When asked to define the word *confident* in the interpretation of a CI in the first interview, several participants explained that confident did not mean probability with a statement exhibiting the fundamental difference between the estimator and the estimate: *there is no longer 95% probability, the interval either contains the parameter or it does not*. Based on these statements, the authors created three tasks to explore the concept cluster:

1. *Task Statement 1*: There is a 93% probability that the actual mean monthly rent for students at HTSU is within the interval $\bar{x} \pm \left(t^*_{n-1}\frac{s}{\sqrt{n}}\right)$.
2. *Task Statement 2*: The process used to generate confidence intervals will capture the actual mean monthly rent for students at HTSU approximately 93% of the time.
3. *Jamie's Colleague*: Jamie[6] talked to a fellow reporter about constructing 93% confidence intervals. Jamie's colleague said that prior to collecting his sample, there is a 93% probability that the confidence interval will capture the actual mean monthly rent of all HTSU students. The colleague continued the explanation by saying that once Jamie collected a sample, the probability of the interval ($705, $793) actually containing the mean monthly rent of all HTSU students is now either 0 or 1.

---

[5] a pseudonym, demographic information and preferred pronouns were not gathered at the time of the study, the use of the gendered pronoun is based on the researcher's assumption of outward projection of gender

[6] In the previous task, Jamie, a recurring character in the interview, had constructed a 93% CI for the mean monthly rent for students at a fictional university, Hill Top State University and was found to be ($705, $793).

Task Statement 1 is a true statement about the CI estimator presented in a non-traditional way. The sentence is Equation 1 in narrative form. Task Statement 2 is a true statement about the interpretation of the C-Lvl, also in a non-traditional way. As it is not the typical statement used to interpret the C-Lvl, participants may not have seen it before. These statements set up the ideas summarized in the *Jamie's Colleague* task. The colleague is correct in identifying that probability does exists prior to collecting data (discussing the CI estimator), but does not once a sample has been collected (discussing the CI estimate). This task describes the reason why the statement provided by participants in the first interview is correct. Since little was known about the connections students make when conceptualizing and reasoning about CIs, a *generative* research approach, defined by Clement as "generat[ing] new observation categories and new elements of a theoretical model in the form of descriptions of mental structures or processes that can explain the data" (2000, pp. 332–333) was used. Methods proposed by Powell et al. (2003), which are similar to grounded theory-inspired methods, were used as a guide to analyze the task-based clinical interviews.

Results

In the first interview, Brody said the statement of the interpretation of a CI typically taught is "formulaic." He continued his critique of this interpretation explaining the incorrect conceptualization people often make: understanding this sentence as reference to a probability that the parameter is within the CI. Brody used the explanation that the probability of the actualized interval either capturing (1) or not capturing (0) the actual value of the parameter to explain how the interpretation of the [actualized] interval does not a include probability. He saw the word confident as indicating a CI was used and was quite clear that confident did not mean probability. While this is correct, Brody was very uncomfortable with any use of the word "probability" with respect to interpreting the CI. Brody initially rejected Task Statement 1 as incorrect. When questioned about difference between whether the sample has or has not already been collected, Brody was able to make the distinction:

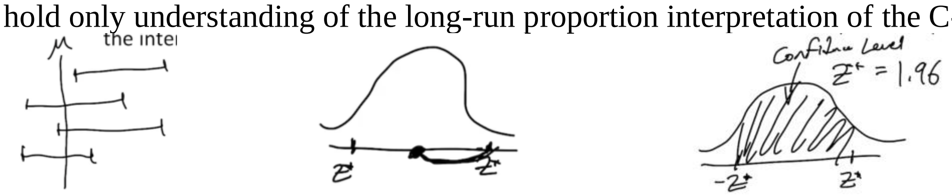
> Yes, in that if you've already collected it, then … the $\bar{x}$ is no longer a random or it would still be a random variable, but you know the value of it. Whereas with if you haven't done yet, obviously, you don't know the value.

He was, however, still uncomfortable with the use of the word probability. He continued by saying "You could look at probability differently on what is the probability of obtaining a sample monthly rent. …But I don't think it changes the probability for the actual mean monthly rent."

Brody was also able to articulate the interpretation of the C-Lvl clearly. He seemed to prefer the use of visuals with his explanations and drew many different pictures to demonstrate his depth of knowledge of the concept of CIs. Over the course of the first and second interviews, Brody drew an image that is a common display used to demonstrate the long-run proportion of C-Lvl% CIs that capture the parameter, similar to Figure 2a. This particular drawing was used to illustrate Task Statement 2. He described that 93% of the confidence intervals (the horizontal lines) would capture (indicated by the horizontal lines that cross the vertical line) the parameter (the vertical line labeled μ). He continued this explanation by drawing Figure 2b. Previously in the interview, Brody drew Figure 2c, which visualizes the region in the theoretical sampling distribution where 95% of the statistics calculated from repeated sampling from the same population are within a given critical value ($\pm z^*$in Figure 2c) of the unknown value of the parameter. Having already discussed Figure 2c, Brody explained:

I think of how we look at the distribution, we'd expect …93% [of the statistics to fall] within these like these like z^* or t^*[7]. And we'll have a margin of error that's this long [drawing the line connecting the dot with the z^*]. And so 93% of the sample values will include whatever is at the center [pointing to the dot], right? And, obviously, approximately, if we do anything less than infinite sampling, and we're not going to get an exact representation.

These visualizations and explanations demonstrate the interpretation of the C-Lvl, but only describe the long-run behavior and the lack of probability of capturing the parameter for an actualized CI. This imagery does not make a connection between the long-run proportion and the theoretical reason for its truth: the difference in the estimator (and associated coverage probability) and the estimate. Brody had not discussed any connection between the estimates and the probability associated with the estimator. Brody's response to the inclusion of the word probability, as discussed above, indicates that his explanation of the interpretation of C-Lvl did not include knowledge of the difference between an estimator and an estimate. Rather, Brody seemed to hold only understanding of the long-run proportion interpretation of the C-Lvl.



a b c

Figure 2: Brody's drawings used to explain the interpretation of a confidence level

Brody had demonstrated his isolated knowledge about the interpretation of the CI and interpretation of the C-Lvl, separate from any probability implications. At the end of his discussion about Task Statement 1, Brody began to make connections between his interpretations of a CI and a C-Lvl and the idea that probability could be discussed prior to collecting a sample.

In approaching the *Jamie's Colleague* task, Brody stated, "It's actually kind of makes sense. And I don't know if it's just because the way I was taught, I think, is that like, instinctively you go, it's like, oh, like it has to be 0 or 1." To punctuate this point, Brody said,

So, I guess it would be true that it's not until you set those parameters [Brody's gesture indicates he means the bounds of the interval, not statistical parameters] that it either is or it isn't. … But if we haven't taken our sample yet, there is still a chance that it could be or that could not be and so I think your colleagues right. I don't know. This is the most in depth I've actually explored this, I haven't really thought about it. … Because I've always been taught that like, it's not a probability because it's set already and that like that's true. … But when it's not set, I think this [referring to *Jamie's Colleague* task] is correct.

Brody acknowledged this as a new thought process and different from his statements after Task Statement 2. By directing him back to Figure 2c and reminding him of his previous statements about Figure 2c, Brody continued:

If 95% of these are in this range, that means 95% would give me intervals that include the true parameter. And since this is the sampling distribution for a sample mean of size, whatever we're using, there's a 95% chance that a random value chosen from this distribution would be on the interval [referring to the area in the sampling distribution that contains central 95% of the statistics]. And so yeah, there is a 95% chance that my

---

[7] Brody had already demonstrated he knew the context required the *t*-distribution. He tended to use the standard normal since he already knew (without calculation) the critical values.

> sample yields a confidence interval that includes the true proportion, or true mean… But we can only say that before we do the sample.

At the conclusion of this task, Brody was able to connect the long-run proportion of CIs that capture the parameter (Figure 2a) with the percentage of statistics within a given region of the sampling distribution (Figures 2b and c) with the Estimator/Estimate concept cluster. Thus, the *Jamie's Colleague* task ultimately helped Brody develop and demonstrate the missing connection between the concept cluster Estimator/Estimate and the sub-concept images for the interpretation of the confidence interval and the interpretation of the confidence level.

Conclusion

Brody was the only participant in the larger study who demonstrated robust conceptualizations of the concept of a CI, the concept of the interpretation of a CI, and the concept of the interpretation of a C-Lvl. From his first interview, it was clear Brody had a deep conceptual understanding of the concept of CIs, the concept of the interpretation of a CI, and the concept of the interpretation of the C-Lvl. These conceptualizations, however, seemed to be isolated: there did not appear to be connections between the concept of a CI and how to interpret the C-Lvl and the CI. Brody used visualizations to demonstrate his knowledge of these concepts and often used imagery that are standard textbook practice for explaining interpretations of CIs and C-Lvls. As Brody demonstrated, these images and statement like "confidence does not refer to probability because the parameter is either in the interval or it is not in the interval" when discussing or explaining the interpretation of a CI do not necessarily aid in helping students develop the necessary connections for robust understanding. The is/is not in the interval statement requires just as much unpacking as do the correct interpretation of the CI and the C-Lvl. In fact, the meaning of the is/is not statement is perhaps more difficult to unpack than either of the interpretations studied. The face-value interpretation of this statement is fairly easy to explain:

> If I were to toss a coin, there is a 50% chance that it lands on heads. Once I toss the coin, even without revealing the outcome, there is no longer a 50% chance it landed on heads. It either landed on heads (P(head) = 1) or it landed on tails (P(head) = 0).

Unfortunately, this explanation does not clarify the underlying theoretical connections between the is/is not statement and the difference between the estimator and the estimate. Many participants in the larger study made statements similar to the is/is not statement, but it was unclear from their demonstrated knowledge whether they fully understood this statement. *Jamie's Colleague* was invented to determine the strength of the connections. Brody was the only participant who was able to make the necessary connections.

The use of the *Jamie's Colleague* task helped Brody make important connections among his well-developed conceptualizations of the interpretations of CIs and C-Lvls. This final connection, described by the curricular concept cluster Estimator/Estimate was needed to solidify the distinction between the use of *confident* rather than *probability* in the interpretation of CIs. Further, this provides conceptual understanding of the theoretical derivation of the confidence interval estimator, particularly with respect to the coverage probability. The long-run proportion of CIs that capture a parameter Generally, Brody's demonstrated conceptualizations were unusual in the larger study, even among peers who had taken the same courses. Finding more students with his level of conceptualization and identifying how they generated their robust understanding of CIs will aid future instruction of CIs.

Values and Norms of Mathematical Definitions

Rachel Rupnow
Northern Illinois University

Brooke Randazzo
Northern Illinois University

Definitions play an important role in mathematics by stipulating objects of interest to mathematicians in order to facilitate theory building. Nevertheless, limited research has examined how mathematicians approach writing definitions or the values they seek to uphold through definitions. Based on interviews with nine mathematicians, we highlight key mathematical values upheld through definitions as well as values related to defining that mathematicians do and do not attempt to emphasize through their instruction.

Keywords: Definitions, Norms, Values, Mathematical Culture

Definitions are central to mathematical activity (Edwards & Ward, 2004) as they specify objects used for proof activity. Nevertheless, limited research has directly examined how mathematicians approach writing definitions or how mathematicians view the role of definitions in perpetuating mathematical norms and upholding mathematical values. We examine these aspects as well as consider how these norms and values relate to instruction of definitions.

Literature Review

Extensive research has examined various facets of proof understanding and instruction. Examples include examining the purpose of proofs (e.g., Weber, 2002), the logic of proofs (e.g., Selden & Selden, 1995), formats of instruction (e.g., Weber, 2004), differences in proof-production in different disciplines (Dawkins & Karunakaran, 2016), how students understand proofs (e.g., Stylianides & Stylianides, 2009) and differences in students' and mathematicians' approaches to proof (e.g., Weber & Alcock, 2004). However, limited research has focused specifically on the role of definitions in proof or mathematics more generally.

Most literature on definitions has focused on students' difficulties. Edwards and Ward (2004; 2008) highlighted students' reliance on extracted definitions, where students tried to work from examples to create a definition for themselves rather than work with the stipulated definitions (written to define a concept) that they were given, as well as students' tendency to act as though their concept image was more important than the concept definition. Similarly, Alcock and Simpson (2011) highlighted students' inconsistency in applying given stipulated definitions for increasing and decreasing to particular sequences. Implicit in these works is the mathematical community's belief in the importance of stipulating definitions appropriately. Nevertheless, work directly asking mathematicians about their process for making or teaching definitions is limited.

Theoretical Perspective

In order to examine how mathematicians' views of definitions align with their broader views of mathematics, we used the theoretical lens of mathematical values created by Dawkins and Weber (2017) in the context of proof. In their paper, they highlighted four mathematical values upheld by norms of proof as addressed in the literature. These values were:

1. Mathematical truth is a priori
2. Mathematical knowledge and justification should be independent of (non-mathematical) contexts, including time and author
3. Proofs should increase mathematicians' understanding

4. Mathematicians desire a consistent set of norms and practices

While Values 1 and 2 are related, Value 1 emphasizes the logical and objective nature of mathematics, while Value 2 especially focuses on the role of the author being irrelevant to final presentations of mathematical knowledge. For our purposes, we are modifying Value 3 to say *definitions* should increase mathematicians' understanding, with the idea that definitions also contribute to how mathematicians understand theory. Value 4 highlights the notion of a shared mathematical culture that views mathematical knowledge as possessing a standard form. We used this framework to organize norms of definitions as described by participants to see whether these four values (or others) were supported by mathematicians' views of the role of definitions.

Methods

Data was collected from interviews conducted remotely with nine mathematicians. These participants were a subset of those recruited for a previous study targeting mathematicians who had taught at least one abstract algebra or category theory course in the last five years. (All names are gender-neutral pseudonyms.) For this paper, the first two interview questions about how they approach writing a new definition and the purpose of definitions in math are the most relevant, although some participants made relevant comments about definitions later in the interview when discussing isomorphism and homomorphism, which were also coded.

Two independent researchers used thematic analysis (Braun & Clarke, 2006) which included multiple iterations of coding (Anfara, Brown, & Mangione, 2002). First, two transcripts were open-coded using descriptive coding (Saldaña, 2016), noting themes about the construction or use of mathematical definitions highlighted by participants. Then, the two researchers discussed the open codes and produced a first round of focused codes, which were created by grouping the original open codes into categories. Next, all nine transcripts were coded with these focused codes and additional codes were developed for any relevant themes appearing more than once in later transcripts. Any discrepancies in coding were discussed by the researchers until agreement was reached. The focused codes were then examined to come up with axial codes, which led to the adoption of the theoretical framework from Dawkins and Weber (2017) for categorizing codes. Finally, focused and axial codes were revised and transcripts were recoded as necessary.

Results

Following the norms and values of proof laid out in Dawkins and Weber (2017), our themes (axial codes) are grouped into four similar values with focused codes (italicized) as evidence.

Value 1: Mathematical truth is a priori

In order for mathematics to be rigorous, proof must be based on stipulated definitions that are unambiguous (Dawkins & Weber, 2017; Edwards & Ward, 2008). These codes are related to this norm of proof in that they highlight that there is a norm of precision in writing mathematical definitions and that this precision is necessary for using definitions to support arguments.

Mathematical communication norm of precision. The code *axiomatic system/work with definitions* was given to five participants who referred to definitions as part of the axiomatic method or as the building blocks of a particular theory in mathematics. Avery said:

> And definitions [are] a critical part of the axiomatic method. This last spring, I taught my students an axiomatic geometry course, and so the first couple of weeks is pretty heavy on just the structure of logic. Day two, we defined the axiomatic method. We have our

> undefined terms. We have our axioms. We have our definitions…the definitions are those things we define for this theory because we're going to talk about them all the time.

Like others given this code, Avery believes mathematical definitions are important to the axiomatic method and students need to understand how to work with them for this reason.

Eight participants highlighted the norm of mathematical definitions being unambiguous (*clarity/no ambiguity in communication*). Several of these participants emphasized this lack of ambiguity is important for communicating with other mathematicians. For instance, Greer said:

> I think fundamentally the purpose [of definitions] is to make clear what you're talking about. I do have trouble conversing with mathematicians who don't make precise definitions because I can't understand their arguments because I don't have this precise set of rules I'm allowed to work by.

Other participants tended to use similar language when talking about this topic, describing definitions as an agreement of rules between the author and the reader. Five participants noted the norm of rigor in definitions, often without clarifying exactly what that means in a math setting, and were given the code *rigor/precision*. This included phrases like "it would be defined properly, rigorously" (Avery) or "it's fundamental for rigorous mathematics to use clearly stated definitions" (Dallas). These participants may have chosen not to elaborate because they assumed the interviewer, as a member of the mathematical community, would know what was meant.

Norms perpetuated through teaching. The code *norm of precision perpetuated through teaching* arose in all nine interviews. Here, Emerson described their approach to teaching definitions in proof courses such as abstract algebra:

> I think the … right place to start proof in formal methods is to talk about definitions. And so I spend the first couple of days just practicing definitions. So why is this definition good or bad? You don't want to define something in terms of what it's not. You should define it in terms of what it is. It needs to be unambiguous. And it should be something that you can use. If it's not clear enough from what you call a definition, how you're going to be able to use this quote "definition" in a proof then it's not a good definition.

Notice Emerson believes that a proper understanding of what a good definition is aids discussing the role of definitions, which then supports teaching proof.

Value 2: Mathematical knowledge and justification should be independent of (non-mathematical) contexts, including time and author

The second value of proof in Dawkins and Weber (2017) is that mathematical knowledge and justification should be independent of non-mathematical contexts. Related to Value 1, many participants spoke about being "on the same page" (Cameron) with regards to definitions. However, only Avery was explicit that definitions should be written in a way that avoids multiple interpretations based on the readers' experience:

> As different people have sort of different personal, cultural connotations that they have, we do have to make sure that we are talking about the same things. So we need a rigorous definition because, I mean, if you take a word like group…that has a very specific meaning in mathematics, but just in standard English, there are lots of ways you could use that word, sometimes good, sometimes bad…And that's the thing is we have to be prepared that someone's life experience might have prepared them to hate a certain word, and therefore, we need to make sure that we see exactly what it is.

Notice Avery focused on personal, context-dependent ways of interpreting mathematical definitions as being excluded by writing a proper definition.

Value 2.5: Mathematical knowledge and justification are generated by people with agency

We propose an addition to Dawkins and Weber's framework that highlights that definitions are specifically chosen by mathematicians both to communicate results effectively and for purposes of exploration in research.

Definitions written purposefully by people. All nine participants stressed that definitions are written by people who have agency and actively choose how to frame the definition. This idea was given the code *people make definitions*. For example, Hayden said:

> I mean, often, I guess I'm working in something for a while before some of the definitions are crystallized. The ones that become the sort of bones on which I want to sort of build the story.… I think of them as part of building a story rather than something that exists a priori.

This is in contrast to Dawkins and Weber's Value 1 that mathematical truth is a priori, although still compatible since the emphasis is on a tool for discovering truth rather than the conclusion. Many quotes coded in this way emphasized that mathematical definitions are actually quite flexible and are crafted specifically for a purpose. The latter idea was coded as *write definitions purposefully for utility,* which also occurred in all nine interviews. For example, Greer said, "I was trained to think of the definition as the set of properties needed to prove a theorem" and then later when talking about students, "It's hard to get into this conversation with students about [alternate] definitions because I think of them as so flexible because I think of them as just designed to make the theorems true." Again, we see that mathematical definitions are often written in such a way that makes them easy to use in particular results, though Greer acknowledges that this idea is not necessarily easy to communicate to students.

Definitions created to explore in research. Many participants pointed out the importance of writing definitions to aid the research process, whether through generalizing examples or homing in on a particular topic. Blair was given the broad code of *definitions as a way to explore* for saying things like "When you're originally mapping out areas that you're not even necessarily sure what consequences are going to look like, definitions are ways of focusing on particular areas of that map and then being able to explore the territory around you." Blair clearly invoked an exploration metaphor, though the manner of exploration was not explicit.

Others were clearer about mechanisms for exploration. Seven participants talked about the fact that *definitions arise from/relate to examples* in their research. For instance, Finley said:

> I guess it comes about in the way that it would for most mathematicians—that you have some examples in mind and you recognize that they have common features. And at some point, you try to write down those common features, and those become the definition.

Seven participants similarly mentioned that *definitions permit inspection of relevant features*, often noting the separable axioms embedded in definitions. For instance, Blair noted:

> So when you're researching different ideas and different structures within existing frameworks, certain adjectives and hypotheses and settings begin to present themselves as being useful of specifically naming and studying. And so as those come up, you go back and create definitions that pull out the relevant features from whatever you're thinking about so that you can explore just those structures with those features.

These codes all highlight the idea that while mathematical definitions may arise from existing mathematical objects or examples, they are specifically constructed by mathematicians.

Value 3: Definitions should increase mathematicians' understanding

This value is a slight reframing of that in Dawkins and Weber (2017) in order to center on definitions. While this value emphasizes mathematicians' understanding, we found that the norms that served to uphold this value focused specifically on characteristics of good communication.

Good mathematical communication helps explain concepts. This norm centers on ways that definitions are written to aid understanding and positioned to enhance clarity. Five participants highlighted students' need for more than memorized definitions to understand a concept—rather they expected students to have intuition or use multiple representations (*need more than definitions to understand concepts*). Dallas gave a number of ways students should be able to engage with a concept:

> A lot of the goal with teaching, …you want to help them to kind of build an intuition for these different concepts. Certainly, …they need to understand the formal definition, be able to work with it. But…[I] also want to kind of convey how do we actually think about what does it mean when two groups are isomorphic or two rings are isomorphic. And here, kind of the sameness concept is… part of the—sort of, the intuition.

Notice Dallas expects students to have some sense of what isomorphism is besides reciting a definition, though being able to recall some version of the definition is implicitly important.

Similarly, six participants viewed undergraduates as requiring scaffolding and more intuitive explanations of definitions than graduate students or mathematicians (*definitions scaffolded for undergrads*). Reasons for this included students' unfamiliarity with notation or being conceptually unready for rigorous definitions to be used without explanation. Indy said:

> For graduate students, … [y]ou don't have to necessarily motivate the definitions as much so you can just say, "We're going to consider this kind of definition or this definition." Or you could just say, "Because we're going to get some really nice results, and then, we'll see cases where that applies." … Whereas, with the undergraduates, I think you really have to sort of motivate things a little bit more.

Indy suggests that more explanations are necessary for undergraduates because they are less familiar with why mathematicians work the way that they do.

Formatting and notation choices aid communication. This norm focuses on ways that mathematicians utilize standard formatting and notation for definitions to make communication easier. Five participants addressed standards of written mathematical communication, such as the layout of research papers, and their norms for formatting and ordering (*norms of mathematical communication through formatting choices*). Avery emphasized the use of different typefaces for showcasing important definitions:

> For the important definitions…I take…a textbook approach, in which case you will have "Definition 1.3", we'll write it out, the word or words that are sort of the focus here, they'll be bolded…Other terms that aren't as important, I'll…take a less formal approach that perhaps in the prose there'll be a sentence that describes it, and then I'll maybe italicize the word…to kind of emphasize that we're trying to define this word right now.

Thus, changes in text style facilitate the reader's understanding by highlighting what's important.

*Conventions between mathematicians***,** noted by six participants, addressed mathematicians' adoption of conventions in their papers and when teaching; specifically, choices need to be clearly communicated, especially when multiple choices could be made. For instance, Blair noted their choice of a different convention on whether rings had to be commutative:

> In a class, I'll try to pick a convention and have it stick consistently through that class. And ideally, it will be the same conventions that the textbook shows…if I really disagree with the textbook, I will either not choose that textbook, …or I'll go out of my way to constantly saying like, "Author of textbook, definition" every time I talk about that and

> then, versus, "Our definition" of something…I did do that in my last abstract algebra class. I wanted to talk about rings not necessarily being commutative. And I believe, in the textbook we were using, very quickly, the rings all became commutative with unity.

Notice the choice of definitional convention influences the types of assumptions that can be made, which can influence students' understanding of the concepts.

Eight participants emphasized efficient communication through the norm *definitions as shorthand*. For instance, Emerson contrasted naming a property "*" with having a word name:

> A name just gives you—just makes the paper shorter because then you can refer back to this thing every time, rather than having to say you have some condition you call star [(*)]. …It's a lot nicer to read and easier on the brain if you have a word for it.

Similarly, Finley focused on how encapsulating a concept with a standard definition makes it easier to process new information: "I mean, it's just kind of a way of preserving space in your working memory, I guess." This seems to suggest that definitions make easier building blocks for arguments than unencapsulated, multifaceted concepts.

Value 4: Mathematicians desire a consistent set of norms and practices

The norms discussed here related to norms of communication within mathematics and how communication differs with people outside that community. Three participants highlighted the norm that *mathematical communication has consistency*, which focused on mathematicians having a standard way of communicating that should not be changed lightly. Avery gave an example of someone trying to defy this norm:

> I regrettably…got involved in some stupid social media debate on ResearchGate where people were talking about, are the rational numbers bigger than the integers…one author sort of had the argument that…rational numbers are like infinity times infinity. And we're trying to convince them that's still infinity…They wouldn't accept that the question was closed because they were, in their essence, trying to change what cardinality meant, without actually saying that.

This participant was focused on how definitions, once defined and accepted, should not be redefined at will; new concepts should be described with new terms. Implicitly, defying this norm would cause communication problems because people would not know which meaning was intended. This also demonstrates that violations of norms can clarify the form of norms. This idea arose indirectly through instances of violations like the failure of consistency noted above. However, it also arose more explicitly with the four participants given the code *norms irrelevant to laypeople*, which occurred in discussions about how to explain isomorphism and/or homomorphism to a layperson. For instance, Dallas said "So if I were trying to describe isomorphism to say someone in a different department… I might just be really vague and say they're roughly the same," suggesting that ambiguity was acceptable for laypeople, which was quite different from the typical mathematical norm of precision in communication.

Discussion and Conclusions

This study aimed to determine mathematicians' norms of mathematical definitions, both in the writing of definitions and their use, and how these norms relate to their values. Analysis of interviews showed these norms largely aligned with the four values upheld by norms of proof conjectured by Dawkins and Weber (2017), with the exception that mathematical definitions showcase mathematicians' agency more than a-contextual knowledge. Specifically, the mathematical norm of precision (Value 1), various aspects of clear communication (Value 3), and a desire for consistent norms (Value 4) all parallel ways that proof upholds these same values. However, participants focused less on definitions as a-contextual objects (Value 2) and more on the (changeable) context that leads to their generation (Value 2.5). Indeed, participants noted definitions are written purposefully for known or exploratory purposes. Thus, while mathematical truth is a priori, the definitions one chooses to get at this truth are not. This is not a contradiction to Value 2 of Dawkins and Weber–the purpose of definitions merely relates better to a different mathematical value, that of mathematical agency.

Of special note, while we might naturally think about precision as a norm in mathematics and expect it to be cited by mathematicians, the range of ways in which communication was centered was illuminating. In particular, definitions encapsulate a large amount of information and thus can be used as a shorthand in both writing and in memory. However, while experts seem to view these definitions as enhancing their ability to work with new ideas, it is less clear whether they expect students to able to use definitions in the same way. Research suggests students may not automatically have those skills (Weber & Alcock, 2004). Even while highlighting this important role of definitions, many participants noted that students and researchers need more than just definitions to understand a concept, such as specific examples or multiple intuitive representations.

Many norms found in these interviews are critical to doing good mathematical research and to communicating mathematical results. Thus, it is important that these norms are communicated to students, and many of those interviewed mentioned that they try to do so. For instance, all nine participants indicated that they communicate the norm of precision to students. This included encouraging clear and explanatory writing, talking about how definitions are situated in an axiomatic system, and discussing what makes a good mathematical definition. They also seemed to attend to aspects of communication in teaching, such as noting the need for more than definitions to understand concepts and for additional scaffolding to understand mathematical definitions. Some attempted to provide this scaffolding through examples and intuitive explanations, though future research should examine more details of how this scaffolding is provided. In contrast, there was limited emphasis in the interviews on communicating to students the norm of agency in creating definitions. Some participants mentioned adopting conventions in class that are different from those in the textbook, and that this difference must be clearly communicated to students. However, others indicated that students are likely unaware of the fact that mathematicians choose definitions and the flexibility that results from this. Furthermore, they seemed less likely to try to communicate this norm to their students, which may skew students' view of what mathematicians do. Edwards and Ward (2004) noted that some upper-level undergraduate students do not always categorize mathematical definitions as stipulated but rather see them as extracted from what we know about a concept, suggesting a perceived lack of agency for mathematicians. Future research should examine how, if at all, students' views of math and mathematicians might be impacted by explicit conversations around mathematical agency or when such interventions would be most impactful for students considering advanced mathematical study.

College Algebra Students' Definitions of 'Simple Mistakes' Through A Causal Attribution Lens

Megan Ryals
University of Virginia

Sloan Hill-Lindsay
San Diego State University

Mary E. Pilgrim
San Diego State University

Linda Burks
Santa Clara University

Mathematics students sometimes refer to making "simple mistakes" in analyzing or explaining their past performance. We interviewed eight college algebra students to learn whether they classified their mistakes on a first test as simple or not-simple and how they would direct their studying efforts in the future based on these classifications. Using Attribution Theory, we created categories of students based on how their causal attributions impacted their definition of a simple mistake.

Keywords: Error Analysis, Simple Mistakes, College Algebra, Attribution Theory

We know too little of how mathematical learning for college students happens outside the classroom and how it might be influenced. We do know that study habits, study attitudes, and study motivation, which are underdeveloped when students arrive to their first college math course, are strongly correlated with collegiate academic performance and can predict collegiate performance at a rate comparable to test scores and prior grades (Crede & Kuncel, 2008). Some authors have called for instructors to explicitly help students learn how to study math while teaching math itself, but this is not common practice (Lewis, 2014; Mireles et al., 2011), and attempts to do this have not always led to significant results (Bogardus, 2007; Hight, 1993).

Changing student behavior requires students to see a need for change and understand the change will be worth the effort. This is of primary importance in first-year college math courses, since these students are more likely to be struggling with confidence in mathematics and questioning whether to persist (Brainard & Carlin, 1998; Ellis et al., 2016; Seymour & Hunter, 2019). This study was motivated by our prior research in using self-reflective activities in the College Algebra classroom to help students process how their efforts leading up to an exam may have impacted their performance. On one self-reflection, multiple students indicated they were not satisfied with a recent exam score (50-70%) because they made "simple mistakes" (Ryals, Hill-Lindsay, Burks, & Pilgrim, 2000). We define a "simple mistake" as one that could be made accidentally, would likely not be repeated, or violates a mathematical convention rather than a rule while a "not-simple mistake" arises from a lack of conceptual understanding (Ryals et al., 2000). We hypothesize that 1) students' definitions may not agree with ours and 2) their definitions and their classifications of their mistakes may provide evidence for why and how they do or do not modify their future study behavior. Therefore, we posed the following research questions:

1. What are the different student distinctions between simple and not-simple mistakes?
2. How do those distinctions compare from student to student and to the researchers' distinction?

3. How do students say they will change their behavior after identifying their mistakes as simple or not-simple?

Literature and Analytic Framework

Math educators have long studied the impact of students' beliefs about the nature of mathematics (Carlson et al., 1999; Carter & Norwood, 1997; Kloosterman et al., 1996; Schoenfeld, 1989; Suthar et al., 2010), but the impact of students' beliefs about their own characteristics and behavior on performance and persistence in mathematics has been given less attention. Instructors and researchers may ask "why" do students perform well or poorly, but their interpretation of causes do not necessarily agree with students' perceived causes, or causal attributions. Causal attributions are explanations or reasons for behaviors or outcomes (Heider, 1958; Weiner, 1972). Motivation is closely tied to these attributions (Borkowski et al., 1990), and the potential exists for instructors to impact attributions, thereby changing students' effort allocations and persistence in mathematics (Perry & Hamm, 2017). Causal attributions are directly linked to affect and future expectations, significantly impacting future behavior (Kelley & Michela, 1980). For example, a student who attributes failure on a test to a lack of ability may experience shame or hopelessness, may expect similar results on future exams, and be unlikely to change their approach to the course; whereas a student attributing failure to a lack of effort may study more or seek help in the future with the expectation they can change future outcomes. Ability and effort have been commonly viewed as dominant attributions (Graham, 1991), but Weiner and others have expanded the list of common attributions to include variables such as task difficulty, luck, and strategy (Watkins & Astilla, 1984; Weiner, 2000).

Weiner theorizes that each attribution has three dimensions, locus (internal/external), stability (stable/unstable), and control (controllable/uncontrollable), which are underlying properties of the attributions that can help explain how that attribution will impact affect and behavior. The attributions effort and ability, for example, are both internal, while task difficulty, something determined by the instructor, is external. Individuals are more likely to attribute success to internal factors and failure to external factors (Wolleat et al., 1980). While both effort and ability are internal attributions, ability is typically perceived as stable, or at least more stable than effort. Stable attributions for failure can lead to hopelessness because they indicate past failures are likely to be repeated. While external factors are inherently uncontrollable by the student, internal factors, particularly those that are unstable, can be perceived to be either controllable or uncontrollable. Effort, for example, is perceived to be controllable, while ability often is not.

We have several decades of research linking attributions and causal dimensions to performance, behavior, or affect. High performance is consistently associated with not attributing failure to low ability (Bempechat et al., 1996; Shores & Smith, 2010) which is supported by a well-established link between self-efficacy and mathematics performance (Hackett & Betz, 1989). Confidence in one's potential to succeed in the long-run can increase effort and persistence in the face of failure (Pajares & Kranzler, 1995; Stevens et al., 2004). Shores and Smith (2010) note that attributions to unstable or controllable factors can lead students to believe that past failure does not dictate future performance. In contrast, attributing failure to stable, uncontrollable factors, such as low ability, often results in reduced effort in the short term and a lack of persistence in mathematics (DeBoer, 1985; Shores & Smith, 2010; Weiner, 2010). There is a difference between confidence in overall mathematical ability, which can improve with effort and/or assistance, and confidence in the ability to complete a particular mathematical task in the moment (Hackett & Betz, 1989; Bandura, 1986). Over-confidence in the ability to complete a particular task can lead to insufficient effort, decreasing performance.

Methods

Data Collection

Study participants were enrolled in College Algebra for STEM-intending students at a large public institution and were also enrolled in a co-course designed for students whom the university identified through multiple measures as having weaker prerequisite backgrounds. We invited all students present in class to participate in a 30-minute interview after the first test was graded and returned. Eight students signed up and were interviewed. In the interviews, students were asked about each error they made (not just each problem they missed). We asked them to identify the type of error (such as a copy error or arithmetic mistake) and then classify it as simple or not-simple and explain. After all errors were addressed, students were asked for their overall definitions of simple and not-simple mistakes and were asked how they would modify their study behavior if the majority of mistakes on a failed test were simple versus not-simple.

Analysis

In order to address Research Questions 1 and 2, we first inductively coded for students' definitions of simple mistakes. We went from error to error on each student's transcript and used the constant comparative method (Glaser, 1965) to develop new codes and refine existing ones. When coding a particular error, we considered student's comments about their other errors to help interpret their meaning. After coding all eight transcripts, we wrote a description of the defining characteristics between simple and not-simple for each student. We did not rely solely on the student's overall definition of a simple mistake because they often omitted some of the attributions they had made for individual errors in these overall statements, likely due to availability bias and relying more heavily on recently discussed errors (Tversky and Kahneman, 1973).

We were surprised by how often students referred to some cause of the error rather than the type of error and also by their emotional response to the error; we had not explicitly asked about causes or emotions. This led to the choice of attribution theory as an analytical framework. We began coding for student's *perceived* causal attributions, starting with Weiner's four main attributions (ability, effort, task difficulty, and luck), and added other distinct attributions (anxiety, running out of time) or created subcategories (study effort, metacognitive effort during test) as they emerged from the data. We noticed specific attributions were not always consistently described on the control and stability dimensions, a phenomena Weiner uses to justify shifting focus to the three dimensions rather than the causes themselves (2012). Therefore, we began coding for the three causal dimensions: controllability, stability, and locus, rather than focusing on the specific attribution.

For each student, we compared our codes for the simple versus not-simple distinction and the attributions. We looked for patterns across the errors and summarized each student's pattern of attributions for simple and not-simple mistakes. We then did a cross-case analysis. We used a matrix to compare and contrast these summaries for each pair of students. From this arose the major themes we will discuss in the results below.

For Research Question 3, we coded the behaviors mentioned in responses to the final interview questions and compared these behaviors across students to determine if there was any pattern between categorizing past errors as simple and modifications to future study behavior.

Results

We will first address Research Questions 1 & 2 together and end by answering Question 3 separately, as there were separate prompts in our interview protocol addressing Question 3.

Relationship between Stability and Control

For a majority of participants, there was a strong link between unstable and controllable attributions. These students did not attribute their errors to unstable, external causes like bad luck or the teacher choosing a particularly difficult test problem. For these students, some aspect of control was a distinguishing factor of their definition of a simple mistake.

Control during the test. Of the students that addressed controllability, TY, R, and MM defined simple mistakes as those that were controllable on the test (i.e. an in-the-moment error due to lack of metacognitive effort during the test) and not necessarily controllable prior to the test (i.e. an error in understanding due to lack of study effort). TY explained, “simple is more like when like you know what you’re doing and how to do it but like you kind of just like mess up in that moment.” This conception of a simple mistake was most consistent with ours.

This group of students associated not-simple mistakes very closely with a fundamental lack of understanding (as opposed to not knowing how to perform a procedure or not having something memorized). One problem asked students to rationalize a denominator. Multiple students, including MM, remembered they were supposed to multiply by the conjugate, but used the same, rather than the opposite sign. MM called this a not-simple error, explaining, “I didn’t really understand how to do that. Like, it wasn’t such a small error in my mind, even though it is on paper. But to me it was not a small error.” On the only problem with an error that R classified as not-simple, he had still received 7 out of 8 points. While missing a single point would be considered a simple error for other students, R was very critical of the fact he had had to attempt this problem multiple times before finding a correct approach. He believed that not knowing immediately which strategy to use implied he did not understand the material, and therefore it was not a simple mistake.

Control at any point in time. Where TY, R, and MM saw simple mistakes as attributable to factors that were controllable during the test, two other students, AY and RG, classified mistakes as simple if they were attributed to controllable factors at any point in time, including before and after the test. RG classified all nine of his mistakes as simple. He suggested some simple mistakes could have been prevented *during the test*, such as when he lost points for not showing his work. He also often suggested a mistake was simple if he could now understand his mistake and solve the problem *during the interview*: “I feel like if I was to do [the] problem again, now I learned. We went over it. You told me. Not really the kind of mistake that I would make twice.” (This is despite the fact that the instructor had gone through this type of problem immediately prior to the test, and he did make this error twice on the test.) We contrast this with TY, who called a particular mistake not-simple, saying, “I remember doing like this problem right before like doing the test but I remember like going over it but like when I did it on the test I just forgot." RG also attributed other simple mistakes to a lack of effort *prior to the test*: "If I would have looked at these questions again other than the one time I did it...I probably would have got that one right." We noticed a frequency of what we termed "if/coulda" language that was common for RG and AY, such as "If I had" or "I could have." This language alludes ultimately to the perceived unstable nature of their errors and hope for the future, and specifically for RG and AY, indicates a belief they ultimately have control over the outcome.

Both RG and AY downplayed the amount of effort that would have been required to be successful and associated simple mistakes with minimal additional effort. RG stated explicitly, "I think that a simple mistake is something that can be fixed without a, without a, uh, large amount of time devoted to fixing the problem." AY suggested that simple mistakes are due to a lack of memorization. She never mentioned studying explicitly, and we suspect she equates studying mathematics with memorization. When discussing a problem where she incorrectly added exponents rather than multiplying them, she explained, "I know there's some instances where you're supposed to add them but I don't remember which instances...I feel like [my mistake is] simple because it's memorizing rules of exponents."

Did not address control. We now discuss those students for whom control was not a distinguishing factor between simple and not-simple mistakes, J and C. Similar to RG and AY, C and J frequently used "if/coulda" language, but in contrast, when using this language, C and J did not necessarily indicate they believed these possibilities were within their control, unlike RG and AY. C frequently said "If I had studied..." or "If I had practiced…," attributing multiple errors to a lack of practice or lack of memorizing, but some of these errors she labeled simple and others not-simple. On the surface, these appear to be effort attributions (controllable), but she began and ended the interview explicitly stating she doesn't "know how to study for math, so [she] didn't study" indicating (uncontrollable) lack of ability. C missed a problem asking solely about vocabulary. She explained that she did study the definitions, but didn't know how to study them correctly. "I think I did go over them but there's different like, um, definitions so I was like, 'What? These are not the definitions I studied.' And I Googled the definitions. I didn't get it from this course, so it's probably different."

While the large majority of attributions made by all participants were internal, C and J used "if/coulda" language frequently with external attributions. C classified one error as simple, saying "for these like I guess I just feel like if I like had more time…" It was common for the external attributions to be associated with the frequency of exposure to certain types of problems (as part of course activities). C justified classifying one error as not-simple saying, "Yeah, like I feel like - like I don't really remember seeing that, like, in the homework, or it probably was but it wasn't as common [as another problem where she classified a similar error as simple]." Similarly, she had classified two seemingly similar mistakes differently, and when prompted to explain the difference, she said "When I was studying, I did problems from, like, number 3, but...I didn't do problems that would be square root times square root." We contrast this with TY, who did not consider how frequently or recently she had practiced a problem essential to her definition of a simple mistake. TY classified a mistake as not-simple and explained: "I remember doing this problem right before like doing the test...but when I did it on the test I just forgot."

For both C and J, the distinction between simple and not-simple mistakes is not primarily about control but about the complexity of the problem itself and the student's perceived probability of being able to solve it correctly or at least more completely in the future. C explained her reason for classifying a particular error as simple: "It was a simple, like question. It wasn't, it didn't ask me to do much." C made the same sign error MM made when attempting to rationalize a denominator, but C classified her error as simple, explaining "...if I would have remembered like that it's the opposite like that, I would have gotten it right." To C, this is something she could have corrected fairly easily, and could, with little effort, remember in the future, and therefore it is a simple mistake. J had multiple similar attributions for errors she classified as simple, such as "cause if I just read it correctly I would have gotten it right." On a different problem, J said her error was simple "because if I would have remembered the equation and then remembered the steps, it would have been simple." We note that she did not remember during the test, but she still classified this error as simple, reiterating the importance of this "if/coulda" influence on her simple/not-simple distinction. J and C labeled any error as simple that may not have occurred if any reasonable changes to circumstances, whether within or beyond their control, could have prevented the error.

Control changes depending on time frame. MF was the only participant whose simple mistake definition did not reflect patterns in causal attributions. Regardless of whether the mistake was simple or not, she framed her mistakes as uncontrollable in the past, yet controllable in the future. For example, she claims some errors were made because she did not know what to study, but speaks hopefully about the future when stating how she will change her future behavior to prevent similar mistakes: "I mean, it's just memorizing just definitions of terms, and then on the test, it wasn't the correct form that I was looking for, but, um, hopefully for the next test, I'll definitely look at the vocabulary more, and then that way I won't have this issue again".

Like C and J, MF's simple mistake distinction was based on the likelihood of making that mistake again in the future. For example, if the problem required only one or two steps or if the mistake could have been caught with minimal monitoring, then she believed it was likely she would not make that mistake again, and therefore it was a simple mistake.

Modifications to Study Behavior

At the end of the interview, students were asked how they might modify their studying in response to two hypothetical situations. In the first, they missed 50% of a test's problems due primarily to simple mistakes, and the second, they missed 50% due primarily to not-simple mistakes. Five of the students explained that making a lot of not-simple mistakes would mean they needed to seek outside help (such as from a tutor or their instructor during office hours), but that they could learn to prevent simple mistakes on their own. There was an important difference, however, in the goal of seeking outside help. Some described a need for procedural assistance, such as J. She explained she would need to ask for help at the learning center because "it's like I don't know how to do it at all." In contrast, some students would seek outside assistance to deepen their conceptual understanding. TY said that if she was making a lot of not-simple mistakes, it's because "I'm not understanding something in it." Though R did not indicate he would seek outside help for not-simple mistakes, he said "I would work on harder problems. Or I would like work on like fewer problems but like understanding like in depth every step and like what you're actually doing in the step."

A common approach to address simple mistakes was repetition or a revisiting of problems they had already worked and believed they already knew how to solve. For some, this repetition was closely associated with memory. This was especially true for the students who did not limit simple mistakes to those that could be controlled during the test. RG, for example, said that to avoid simple mistakes, he needed “familiarization I guess. Lookin’ over the stuff.” For J, direct memorization of formulas was a strategy to combat simple mistakes. C and MF suggested they needed to actually work and “write down” more problems (as opposed to avoiding practicing particularly challenging problems and/or only relying on studying provided solutions).

Discussion and Implications

Our analysis uncovered clear distinctions between students’ definitions of simple mistakes when compared to our definition or other students’ definitions. While we see a simple mistake as something made once, in-the-moment, some of our participants have a much wider umbrella for simple mistakes. Some include any mistake on problems they believe they previously knew or currently know how to solve, and others also include problems they believe they could or would have a decent probability of solving, if just one of many possible variables was or had been different. To some, the distinction between simple and not-simple mistakes has more to do with the amount of effort required to learn to solve the problem or the perceived difficulty of the problem itself. In practice, this means that instructors and tutors cannot assume that students attributing their underperformance to “simple mistakes” means the student made a bunch of copy errors. It is quite possible that those “simple mistakes” were made on problems that the student cannot solve and/or never knew how to solve.

What is more consistent across these different groups is an approach for how to prevent certain types of mistakes in the future. Most students argued they can address simple mistakes on their own, with more repetition, practice, or memorization, versus needing assistance with problems on which they made not-simple mistakes. This is crucial for instructors and tutors to consider when assisting a student in making changes to their study approach. Some of our participants had a wide net for simple mistakes, but did not indicate a need to seek help or deepen their conceptual understanding in the future when trying to avoid these mistakes.

We posit that students whose definition of a simple mistake was limited to those controllable during the test (R, TY, MM) are the most adaptive, as they recognize mistakes due to flawed studying or misunderstandings are not-simple. Students such as RG and AY, who consider a mistake simple if they knew how to solve the problem prior to or after the test, are not motivated to understand why they made the mistake during the test and do not think critically about how to prevent these types of errors in the future. Finally, students like C and J, who do not use control to distinguish simple mistakes, are at a distinct disadvantage. Their focus is on the perceived instability of their simple mistakes and their hope is that circumstances, possibly beyond their control, will change in the future and lead to their improved performance even without making changes to their future behavior. We recommend instructors challenge the last two groups of students to compare results across tests, highlighting inconsistencies between expectations and outcomes from one test to the next. Interventions aimed at retraining students’ causal styles towards controllable, unstable causes have been shown to increase performance and persistence (Perry & Hamm, 2017), and we suspect classroom discussions surrounding simple mistakes could be an effective intervention to help move students toward controllable, unstable causes.

Department's Openness to Change. A Study from Calculus Instructors' Perceptions

Brigitte Johana Sánchez Robayo
Virginia Tech

I studied factors that predict the department's openness to change (DOC). I used survey data collected from STEM instructors using the Survey of Climate for Instructional Improvement (SCII) instrument. Using Mathematics Instructors' responses, I first conducted an exploratory factor analysis. I extracted six factors, including DOC. Then, considering the components of the SCII, the extracted factors, and the elements that influence change according to the literature, I conducted a multiple regression analysis assuming collegiality, leadership, and participation in professional development could be predictors of DOC. Based on the literature and the extracted factors, I also added self-efficacy as a possible predictor. In this analysis, leadership is the strongest predictor, followed by collegiality and self-efficacy. Professional development is not a predictor of DOC.

Keywords: change, collegiality, leadership, self-efficacy, and professional development.

Change in STEM higher education has been a focus of study over the last decades (Henderson et al., 2011; Reinholz et al., 2020, 2021). There are mainly significant efforts for supporting instructors (Kezar et al., 2015; Reinholz et al., 2021; Tirosh & Graeber, 2003). Furthermore, different perspectives of change (Corbo et al., 2016; Kezar, 2013) have called for also considering contextual factors that may influence instructional practices.

Academic departments are critical sites for change, and more research on changes in the mathematics department is needed (Reinholz et al., 2020). Research in mathematics departments would contribute to understanding unique aspects of change in these settings and contexts (Reinholz & Andrews, 2020). Also, studying departmental culture for change is essential since faculty are highly impacted by their department (Corbo et al., 2016; Henderson et al., 2011). As part of the efforts for understanding how change occurs in departments, Walter et al. (2016, 2021) designed and applied the Survey of Climate for Instructional Improvement (SCII) to elicit "organizational climate for instructional practices" (2016, p. 411).

The SCII's design assumes that culture and climate are different, although commonly, they have been referenced indistinctively (Walter et al., 2016, 2021; Wang & Degol, 2016). Whereas culture refers to values, beliefs, and rituals; climate refers to "shared, subjective experiences of organizational members that have consequences for organizational functioning and performance" (Walter et al., 2021, p. 167). Furthermore, climate includes the atmosphere of the organization, it is multidimensional (Wang & Degol, 2016), and it is "more malleable to change than culture" (Walter et al., 2021, p. 167). In this way, as an instrument that gathers information about organizational climate, the SCII is applied to collect instructors' perceptions of the organization they belong to according to seven components: rewards, resources, professional development (PD), collegiality, academic freedom, and autonomy, leadership, and shared perceptions about students and teaching.

Viewing departments as crucial units of change (Quardokus & Henderson, 2015; Reinholz & Apkarian, 2018), I concentrated my study on the mathematics department's openness to change (DOC). In any change process, openness to change and resistance to change are considered essential factors (Hussain et al., 2018). Commonly openness to change has been considered the individual's willingness to accept and implement a specific change (Sinval et al., 2021; Wanberg

& Banas, 2000). In the organizational context, this idea can be transferred to consider, for instance, the department's acceptance to change or the department instructors' willingness to implement changes. The SCII includes questions regarding the department chair's, the department instructors', and the department's willingness or flexibility to implement different strategies for improving teaching. Thus, this study started with the assumption that the SCII could also be used for studying DOC. Using the instructors' perceptions, I looked to understand the extent to which some factors predict the openness or willingness of the mathematics department to improve teaching by implementing different strategies or providing various resources to instructors.

Here I focus on three components of the SCII, collegiality, leadership, and professional development, that are also commonly cited factors for instructional change (Berebitsky & Andrews-Larson, 2017; Kilinc et al., 2020; Melo Moreno et al., 2020; Sleegers et al., 2014). Thus, the research question was: to what extent do collegiality, leadership, and PD predict DOC? While not part of the SCII, the survey did include some items on the instructor's self-efficacy. As some literature does point to this being an important factor that may influence change (Tschannen-Moran & Woolfolk Hoy, 2001; Wheatley, 2002), secondary analysis added instructor's self-efficacy into the primary model.

Framework

In the SCII, collegiality is defined as the instructors' feelings of belongingness to a community of colleagues (Walter et al., 2016, 2021). As part of the community, an instructor can have different types of interactions with their colleagues that will help to improve their practice (Males et al., 2010). Those interactions and the sense of community between colleagues may positively influence DOC. Solid interactions between colleagues are essential for different approaches to changing mathematics teaching practices in K-12 education, such as lesson study or collaborative action research (Sánchez Robayo, 2020). In high education, Reinholz et al. (2021) found that Communities of Practice was the most common theory used in research about change in STEM. In particular, communities of practice have been used to design theories of change for specific attempts of change (Reinholz & Andrews, 2020). Communities of practice refer to groups of people (communities) with a common goal, a mutual compromise, share a concern, and belong to a specific enterprise (Wenger, 1998). In this way, participating in the community gains a particular connotation and represents individual learning and community strengthening.

Collegiality can take place as part of a formal learning opportunity or as an on-the-job learning opportunity. As an on-the-job learning opportunity, interactions between colleagues can vary from low to a high depth depending on the focus of the conversation (Cobb & Jackson, 2011; Coburn et al., 2012). For instance, a low-depth interaction is a quick exchange about a deadline, whereas a high-depth interaction could be a conversation about the nature of student learning (Coburn et al., 2012). Walter et al. (2021) found that experienced faculty build stronger and more diverse networks of colleagues, facilitating instructional improvement in higher education. Similarly, instructors who belong to a social network with strong ties, deep interactions, and more experienced teachers develop a flexible instructional approach to adjust it to changing conditions (Berebitsky & Andrews-Larson, 2017; Coburn et al., 2012).

The idea of leadership has been extended, and currently, there are types of leadership such as distributed leadership (Sleegers et al., 2014) or shared or collective leadership (Kezar, 2013) in high education. In general, these variations assume leadership beyond the scope of an individual. For instance, leadership is a property of a group, network, or community rather than of an individual in the case of the distributed version (Bianchini et al., 2014). However, generally, leadership has been considered an individual enterprise, in which the leader influences a group of people to achieve a common goal (Hussain et al., 2018). In the SCII, leadership is defined as "policies, actions, or expectations established by the formal leader of the department that communicate the value of teaching and instructional improvement" (Walter et al., 2021, p. 171). In particular, Walter et al. (2021) consider leadership a catalyst of change in higher education, and they found that department chairs are essential for instructional improvement. In this way, the leader's actions and perceptions may determine the department's willingness to implement different approaches or resources.

PD refers to a set of activities designed to train staff members to improve their performance in their role through learning about their profession (Ball & Bass, 2002; Ball & Cohen, 1999; Ball & Forzani, 2010; Desimone, 2009; Korthagen, 2017; Opfer & Pedder, 2011; Osman & Warner, 2020; Shabani, 2016; Silver, 2009; Tirosh & Graeber, 2003; Walter et al., 2021). At different educational levels, PD is considered a driver for change in instructional practices (Ainley & Carstens, 2018; Ball & Cohen, 1999; Ball & Even, 2009; Durksen et al., 2017; Frank et al., 2011; Franklin, 2015; Guskey, 2002; Osman & Warner, 2020). In addition, through PD, instructors can extend their knowledge and skills to address challenges (Walter et al., 2021). Thus, department instructors' participation in PD may influence the department's flexibility at the moment to implement some change.

Self-efficacy is defined as one's perceptions of their capabilities to perform a task (Ainley & Carstens, 2018; Skaalvik & Bong, 2003; Skaalvik & Skaalvik, 2007). It is a belief about what the person can do rather than their attributes; thus, self-efficacy is more about what individuals believe they can do independently of their skills and abilities. Teacher self-efficacy refers to teachers' beliefs of their ability to influence student learning, to provide effective learning environments, or to enact a teaching behavior (Agudelo-Valderrama et al., 2007; Ainley & Carstens, 2018; Fackler & Malmberg, 2016; Rodríguez et al., 2009; Skaalvik & Skaalvik, 2007; Tschannen-Moran & Woolfolk Hoy, 2001; Wheatley, 2002). Instructors with high self-efficacy are more receptive and more likely to implement changes (Bellibaş et al., 2020; Guskey, 1988; Piwowarski, 2010); thus, instructors with high self-efficacy in the same department may shape a receptive department for change.

Methods

The data came from the SCII applied to different STEM instructors from different colleges in the US. Along the design and validation process, the designers confirmed five factors to study organizational climate: leadership, resources, collegiality, respect for teaching, and organizational support. Although the survey also included questions about change; change and precisely the department's openness to change was not considered a factor. Thus, I started conducting an exploratory factor analysis.

The exploratory factor analysis

First, I restricted the dataset selecting only mathematics instructors and keeping survey items related to department climate and context, instructors' self-efficacy questions, frequency of different actions related to teaching, and participation in PD.

I transferred the data from excel to SPSS, and once I manage the missing values, I did all the analysis in SPSS. First, I confirmed the sample had an acceptable Kaiser-Meyen-Olkin measure of sample adequacy (KMO= 0.915) and a significant Barlett's Test of Sphericity ($\chi^2(528)$=14403.938; *p=.000*). Since data were not normally distributed, I followed Samuels'

(2016) advice of using Principal Axis Factoring as the extraction method since I intended to deal with the data for further analysis rather than developing an instrument. I also used Promax rotation as the recommended rotation method for correlated factors (Osborne, 2015). According to Samuels (2016), the threshold for the commonalities is 0.2; thus, I removed items with lower commonalities. Over the process, I removed 14 items because they had low commonalities. Six factors were extracted and retained once I compared them using parallel analysis (https://analytics.gonzaga.edu/parallelengine/). **Error! Reference source not found.** shows the final factors with their reliability (Cronbach's alpha measure).

Table 1. Factors from EFA

Factor	Eigenvalue (% variance)	Reliability	Number of items	Representative item
Leadership	8.890 (26.939%)	0.921	7	The department chair is receptive to ideas about how to improve teaching in the department
Instructors' self-efficacy	4.194 (12.709%)	0.858	9	How confident are you in ability to ask open, stimulating questions?
Departmental openness to change	1.969 (5.966%)	0.807	5	Instructors in my department value teaching development services available on campus as a way to improve their teaching.
Organizational support	1.905 (5.772%)	0.797	5	Instructors in my department have adequate departmental funding to support teaching improvement.
Collegiality	1.683 (5.101%)	0.884	3	Instructors in my department frequently talk with one another about their teaching
Participation in PD	1.321 (4.003%)	0.692	3	Have you ever participated in half-day workshop(s)?

Although participation in PD had low reliability, I decided to keep that factor in the model because the literature highlights it as one of the strongest mechanisms for change.

The multiple regression analysis

Once I got those factors, I conducted a multiple linear regression to predict departmental openness to change based on leadership, collegiality, and participation in PD. Following is the model:

$$DOC = \beta_0 + \beta_1 C + \beta_2 L + \beta_3 PD + \varepsilon$$

Where

DOC is the department's openness to change

C is collegiality

L is leadership

PD is participation in PD

For running the model, I found the mean of the questions that belong to the same factor. In the case of PD, I recoded the answers as follows:

Table 2. New codes for questions about PD

Question	Original value	New code

Have you ever participated in any of the following types of teaching-related professional development?	2- yes	
Half-day workshop(s)	2	1
Full-day or longer workshop(s)	2	2
Attending a teaching-focused conference	2	3

In all the cases, the answer "no" had the original value '1' and was recoded as '0'. Using these new codes, I summed up the values of the questions for the factor PD.

Once I run the model, I included the factor self-efficacy in the model. Then, as I did with the other factors (*DOC*, *C*, *L*), I calculated the mean of the questions that composed that factor.

Results

Since the research question is focused on a predictive relationship, I will focus the results in the multiple regression analysis calculated to predict the department's openness to change. Table 3 shows the means of instructors' responses to the items of each factor (*DOC*, *C*, and *L*). The items were Likert scale questions ranged from one to six, with one being the lowest positive score, and six being the highest from strongly disagree to strongly agree. The table also shows the mean of the sum of PD values after recoding.

Table 3. Descriptive Statistics

	Mean	Std. Deviation	N
DOC	3.8857	1.07173	1084
sumPD	4.2583	2.17381	1084
Mean_leadership	4.4040	1.09169	1084
Mean_Collegiality	4.8495	1.01377	1084

A backward multiple regression analysis was conducted to identify predictive variables based on their contribution to the model. Pearson correlation revealed no correlation between *DOC* and *PD* ($r(1082)=0.063$, $p=0.020$). *PD* was removed during the multiple regression analysis obtaining a significant regression equation for two predictors: *L* and *C*. Table 4 shows beta coefficients for these two variables that were statistically significant related to *DOC*, *L* ($r(1082)=0.712$, $p=0.000$), and *C* ($r(1082)=0.569$, $p=0.000$).

Table 4. Multiple regression coefficients

Variables	β coefficients	Std. error	t	Sig
(Constant)	-.056	.112	-.501	.616
Leadership	.559	.023	24.865	<.001
Collegiality	.305	.024	12.579	<.001

A significant regression equation was found ($F(2,1081)=715.210$, $p<0.001$) with $R=.755$, $R^2=.570$, and 57% of variance explained (adjusted $R^2=.569$). A subsequent stepwise multiple regression analysis starting with the predictor leadership yielded the same regression equation.

Overall, leadership is the best predictor of *DOC*. It is an expected result since leadership has been considered as one of the strongest facilitators for change in higher education, and leaders are seen as change agents (Kezar, 2013) in particular, in top-down changes. This means leaders are considered the ones who promote and lead changes initiated by the top of the organization's hierarchy and attempt to affect faculty. In particular, this result confirms the essential role of department chairs in the department climate for change (Henderson et al., 2011; Walter et al., 2016, 2021). However, as Knaub et al. (2018) highlight, not everyone can be a leader, particularly in the context of change. Organizations need individuals who can adapt easily to change (Wanberg & Banas, 2000). In particular, leaders as change agents should know how to create conditions for a change initiative and work with others (Quardokus & Henderson, 2015). Based on the questions that compose the leadership factor, department chairs who: are flexible, view changes in teaching positively, accept the possible struggles that come with change, recognize possibilities for improvement, and acknowledge the potentialities of the department in that process will have a significant role to set a department that is prepared for implementing change.

Collegiality is also a predictor of *DOC,* although it is not the strongest. As a collective stance, the community and its relationships are a strong influential element in determining how the collectivity will scope challenges. In this case, the opportunity to discuss with colleagues about teaching, the use of different resources, or challenges that arise in classrooms seem to influence the department's willingness to accept different strategies in teaching. In particular, collegiality as an on-the-job learning opportunity creates the scenario for having a mathematics department willing to introduce different teaching strategies or resources.

Surprisingly, *PD* is not a predictor of *DOC*. Since *PD* is an approach that seeks instructional improvement viewing the instructor as a learner, it is expected this factor influences the instructor, their practice, and the department on a broader level. However, some authors have reported that PD has a very limited impact on teaching practices (Cobb & Jackson, 2011; Guskey, 2002) and unsuccessful results on teacher change (Parise & Spillane, 2010; Simon, 2013). Thus, although the impact of PD in teacher learning is undeniable, there is a doubt about the effect of PD on change at the instructional and departmental levels.

Additionally, a backward multiple regression was conducted to identify if instructors' self-efficacy was also a predictor of DOC. In this case, also a significant regression equation was found (F(3, 1086)=498.123, p<0.001) with R=.761, R^2=.579, and 58% of variance explained (adjusted R^2=.578). The following table shows the coefficients:

Table 5, Multiple regression coefficients including SE variable

Variables	β coefficients	Std. error	t	Sig
(Constant)	-.660	.165	-3.998	<.001
Leadership	.548	.022	24.601	<.001
Collegiality	.304	.024	12.724	<.001
Self-efficacy	.201	.041	4.949	<.001

Self-efficacy is a significant predictor of *DOC* (p<.001). Although not in high proportion, the model increases the percentage of variance explained, which means self-efficacy as a predictor improves the regression equation.

Discussion

The SCII proved to be a useful tool for investigating the extent to which faculty view their departments as open to change. In addition to the factors already identified within the SCII (Walter et al., 2016, 2021), the EFA conducted here demonstrated that the SCII has a considerable potential to study even more specific factors than those considered in the instrument's design. For instance, the factor DOC arose with high reliability (α=0.807).

Commonly, the study of change in educational settings has concentrated on the process of implementation or afterward; the SCII and, in particular, the idea of DOC would enable to identify the grounds for studying change not just during the implementation but also before. Investigating DOC allowed to identify specific elements as part of the department climate to analyze the state of a department to implement new strategies or resources to improve teaching. In this way, I found three significant predictors: leadership, collegiality, and self-efficacy. As the type of individual leadership, it lies in the department chair. The study reveals that an open-minded department chair willing to manage the difficulties that could come with changes in teaching strategies or with the introduction of different sources could increment DOC. Meanwhile, collegiality is an expected predictor since it shapes the interactions between the community members. Finally, self-efficacy has a subjective nature and predicts DOC, maybe by increasing the instructors' trustiness in their ability to face challenges.

Although this study confirmed the influence of individual leadership in a change in the department, particularly in DOC, for future work, it could be worthy to identify since a descriptive view, how the individual leadership may influence DOC. Similarly, other types of leadership, such as shared leadership (Kezar, 2013), seem to have great potential to influence DOC. Inquiring how these collective views of leadership influence change would also bring essential steps to understand change phenomena.

There is an open question regarding the influence of PD in DOC. On one way, PD is one of the components of the SCII. Also, many studies in K-12 education focus on the relationship between PD and instructional improvement; some of them included characteristics of effectiveness to produce deep and significant changes in mathematics teaching practices (e.g., Boström & Palm, 2020). On the other way, the relationship between PD and change in teaching practices is not clearly defined. Although that result could sound striking, it is important to recall the finding from Opfer and Pedder (2011). They establish that the literature about PD's effects has the epistemological fallacy of assuming some measures of teacher change as teacher learning.

There is also another open question about how self-efficacy, which is a variable with an individual nature, influences DOC. One possibility could rely on what has been called teachers' collective efficacy, which refers to teachers' beliefs about their collective capacity to do a task (Klassen et al., 2011; Skaalvik & Skaalvik, 2007). Instructors' self-efficacy could influence their confidence as a collective producing a better disposition to implement a change in the department.

Acknowledgments

I thank professor Estrella Johnson from Virginia Tech for allowing me to do this project, providing me the data, and helping me during all the process. I also thank my colleague Alexander Moore from the same University for his help when I was stuck.

Teacher Actions to Foster Creativity in Calculus

V. Rani Satyam
Virginia Commonwealth University

Miloš Savić
University of Oklahoma

Gail Tang
University of La Verne

Houssein El Turkey
University of New Haven

Gulden Karakok
University of Northern Colorado

Fostering mathematical creativity in the classroom requires intentional actions on the part of the instructor. We examine the teaching actions that students in a creativity-based Calculus I course report as contributing to their sense of creativity. Based on interview data, we found the four overall types of teaching actions: Task-Related, Teaching-Centered, Inquiry Teaching, and Holistic Teaching. We discuss subtypes as well as concrete actions, to provide actionable steps practitioners can take to foster students' creativity.

Keywords: creativity, Calculus I, teacher actions

Educational efforts to prepare students for Science, Technology, Engineering, and Mathematics (STEM) related jobs need to be furthered to prepare the STEM workforce to tackle ill-defined problems with no clear solution paths (Wilson et al., 2017). Fostering creativity in mathematics classrooms help develops this (Leikin, 2014), but at the tertiary level such classroom experiences are often restricted to pre-service teachers (Shriki, 2010) or mathematics majors in upper-level courses beyond Calculus I (Zazkis & Holton, 2009). By the time mathematics is exposed as a creative subject, we have lost many potential STEM majors, due to the ways in which calculus serves as a gateway course (Moreno & Muller, 1999). We argue that creativity must be fostered as early as Calculus I.

The role of teachers in fostering students' mathematical creativity is crucial. Moore-Russo and Demler (2019), citing Aiken (1973) stated that "teachers [are] the keys to unlocking creativity in the classroom" (p. 1). This is furthered by Hershkovitz, Peled, and Littler's (2009) statement: "creativity in mathematics classroom[s] can be improved through appropriate teaching methods" (p. 255). However, most discussion of how to foster creativity has been theoretical and/or at the K-12 level (e.g., Levenson, 2011, 2013). There is a need for actions tertiary instructors can take that are grounded in empirical data. In this paper, we explore teacher actions, as reported by undergraduate students, that fostered their sense of creativity in a creativity-based Calculus I course. Using qualitative coding, we present types and subtypes of actions that students discussed in interviews to provide practical actions that instructors can take.

Conceptual Framework & Background Literature

Creativity

We take a stance that mathematical creativity is relative to the student (Liljedahl & Sriraman, 2006; Zazkis & Holton, 2009); if any item (process or product) is new to the student then that is an act of creativity. This perspective differs from absolute creativity, which requires an item to be new to the field of mathematics (Kaufman & Beghetto, 2013; Leikin, 2009) to be considered creative. This discussion of relative versus absolute creativity is also reflected in the psychological literature, discussed as Big-C creativity (absolute) versus little-c creativity (relative) (Beghetto & Kaufman, 2007; Levenson, 2011). In educational settings, where the goal is to support students, relative creativity may be most relevant. We therefore take a developmental perspective on creativity: that a person's creativity can and does develop over time (not fixed). The main focus of investigation then is a person's process and actions, as opposed to the product created (Kozbelt, Beghetto, & Runco, 2010). Given that a person's creativity can change, this implies creativity can be honed by an instructor's processes and actions.

Teacher Actions

We consider a teaching action to be any act (physical, written, or verbal) in or out of the classroom that can be attributed directly to the teacher. Teaching actions share similarities to teaching practices (e.g. Ponte & Chapman, 2006). According to Ponte and Quaresma (2016), these actions can be "framed by two basic elements: the tasks proposed to the students, and the communication processes that take place in the classroom" (p. 52). Teacher actions have been one of the important constructs of research studies within inquiry-based and inquiry-oriented teaching. For example, Kuster et al. (2018) identified "four primary components of inquiry-oriented instruction: 1) generating student ways of reasoning, 2) building on student contributions, 3) developing a shared understanding, and 4) connecting to standard mathematical language and notation" (p. 2). For each component, Kuster et al. provided examples of instructional actions. For instance, when generating student ways of reasoning, Kuster et al. stated a description in action, including: "The teacher explicitly asks students to share their approaches to the tasks and the reasoning the students used to complete those tasks" (p. 6). In this paper, we follow a similar trajectory of categorizing creativity-oriented instruction through providing specific and explicit actions as reported by students that fostered their mathematical creativity.

Actions to Foster Creativity: K-12 & Tertiary

Actions to foster mathematical creativity proposed in the literature at the tertiary level are largely theoretical or conjectural (Sriraman, 2005). At the lower grades, Levenson (2011, 2013) explored fostering mathematical creativity at the 5th and 6th grades. Levenson (2013) found concrete actions that fostered creativity: "choosing appropriate tasks, fostering a safe environment where students can challenge norms without fear of repercussion; playing the role of expert participant by providing a breakdown of the mathematics behind a process; and setting the pace, allowing for incubation" (p. 273). Both Sriraman's theoretical principles and Levenson's empirical findings agree with some of the educational psychology literature, including Cropley's (1997, 2018) nine categories of fostering creativity. Levenson (2011, 2013) is one of the few that identified concrete actions grounded in data of fostering creativity.

In the context of tertiary education, Zazkis and Holton (2009) spoke about one crucial aspect of fostering creativity: "for a student to be creative, the instructor has to provide a problem where creativity can be shown" (p. 346). They included tasks in specific topics (e.g., graph and number theory). The authors suggested other tasks, including Watson and Mason's (2005) learner-generated examples, Leikin's (2013) multiple-solution tasks, and Shriki's (2008) explicitly valuing creating new mathematical concepts. They concluded with some teaching actions that "attend to the 'flow' of students' thinking, rather than setting the boundaries of formal mathematical curriculum" (p. 361). Shriki (2010), focusing on pre-service teacher education, furthered the research by allowing students to create new geometrical concepts and questions over the course of six weeks. They starkly stated, "Refraining from development of creativity in the classroom conveys the impression that mathematics is merely a set of skills and rules to memorize, and in doing so, many students' natural curiosity and enthusiasm for mathematics might vanish" (2010, p. 161-162).

We aim to complement these existing, mostly theoretical or conjectural work, by supplying ways of fostering creativity through practical actions that instructors could apply in their tertiary Calculus I courses. Given the need for actions grounded in data, coupled with the need for more creativity in calculus (Ryals & Keene, 2017), our research question is: *What are the teaching actions that calculus students have reported as fostering their sense of creativity?*

Methods

Participants were 34 undergraduates enrolled in Calculus I courses across various institutions in the United States. This study is part of a larger NSF-sponsored research project investigating fostering mathematical creativity in calculus. Participants were spread across two cohorts: Spring 2019 (C1) and Spring 2020 (C2). Twenty-four students identified as female (four bi-racial, five Latina, four Black, two AAPI, one Persian, eight White), nine as male (one bi-racial, one AAPI, one Latino/Hispanic, six White), and one as non-binary (White).

Instructors who taught these courses took part in a weekly online professional development about fostering creativity in Calculus I as part of a larger NSF-funded grant, where they designed and implemented at least six creativity-based tasks (El Turkey et al., 2020) and used a reflection rubric for creativity (Karakok et al., 2020) in their classroom.

Data Collection, Sources, & Analysis

We conducted semi-structured interviews with all participants. Interviews lasted 45-90 minutes long and took place over video conferencing software. The researcher asked questions such as "Did you feel creative in this course?", "Why and when do think you were creative?", "What have you learned about your mathematical creativity from this course?", and "What aspects of this course contributed to your or your classmates' creativity in the course?" Interviews were transcribed using a third-party transcription service and uploaded to the software nVivo™ for further analysis.

Because our theoretical stance was students' relative mathematical creativity, we examined each student's response to "Did you feel creative in your Calculus 1 course?" If they answered "yes," we looked at the reasons they gave for why they felt creative. If they answered "no," we looked at actions stated in the follow-up questions about their peers' creativity in the classroom. This was to account for students who did not see themselves or may not have felt comfortable stating they were creative during the interview but perceived a fellow classmate as creative. Two authors used holistic coding (Saldaña, 2016, p. 142) to identify (1) teacher actions: any student utterance about what the teacher did in reference to themselves or the class as a whole and (2) instances of creativity: any specific mention of creativity or answers to questions pertaining to mathematical creativity. In doing so, we identified teacher actions that fostered creativity.

For the first round of coding, we looked at the intersection of creativity and teacher actions, specifically if a student referenced a teaching action when talking about their own creativity. Two authors created teaching action nodes using a combination of descriptive and in vivo coding (Saldaña, 2016) and created 40 nodes. From those nodes, we used the process of theming (Saldaña, 2016) and organized them into five initial types based on emerging themes: *Task-Related, Assessment-Related, Teacher-Centered, Inquiry Teaching,* and *Holistic Teaching*. Within each of these types, we then read over all 211 instances of teaching actions mentioned and identified further sub-types. Due to the low number of instances and similarities in theme, we subsumed *Assessment-Related* under *Task-Related* as a subtype, resulting in four types.

Results

We created four overall types of teaching actions from analyzed student utterances related to fostering their own creativity. These types are separated into two overall categories, as inspired by Ponte and Quaresma (2016): actions that are part of the design of tasks and assessments, and actions that are part of the implementation of those tasks in class (See Table 1). These are teaching actions that the students reported as fostering their mathematical creativity in calculus; this does not consider teachers' perceptions of fostering creativity.

Table 1. Teacher actions reported to foster creativity, by type and frequency.

Type		Subtypes (with excerpts of teaching actions)
Design	Task-Related (76)	*Design High-Cognitive Tasks:* assign create new definitions, theorems, functions, and problems; assign solve created problems; assign problems that require making connections; give higher-order-thinking tasks
		Include Meta-Task Properties: provide group-worthy tasks, assign writing assignments such as journaling/reflections, revising homework
		Assessment-Related: assess open-ended questions, assess journaling assignments, assess creating new theorems, assess purposefully, de-emphasize correctness in assessment, does not assess drafts
Implementation	Teacher-Centered (18)	*Teacher Answers:* give different ways to solve problems, use online lecture videos, teach how topics are connected, review material
		Teacher Guides: foster understanding, persist to foster understanding, guide to correct answer, allow students to quietly work
	Inquiry Teaching (50)	*Allow for Discussion:* allow for discussion in class, allow for students to build (on other's thinking), divide class into groups
		Allow to Present: allow to present in class
		Teacher Active Listening: be aware of students' actions, encourage participation, inquire into students' thinking

Holistic Teaching (67)	*Encourage Mathematical Behavior:* prompt and encourage different approaches or divergent thinking; de-emphasize correctness in class; allow students freedom of time; use of the Creativity-in-Progress Rubric on Problem Solving tool (Karakok et al., 2020)
	Attend to Emotional Space: explicitly encourage students in their creativity, show excitement after student contributions, respect differences in the classroom

Within our dataset, the most frequently reported types were *Task-Related*, *Inquiry Teaching*, and *Holistic Teaching*. We focus our results on these three, as each had over 50 reported instances (out of 211). *Teacher-Centered* had the fewest: 18 instances. We defined *Teacher-Centered* as any action that was mostly focused on the instructor, whether it be verifying correctness or connecting topics. Given the low number and that they primarily consisted of typical teaching actions that many instructors already undertake, we do not expand on it here.

Task-Related

We defined *Task-Related* as any action that mentions properties of a mathematical content task that were (re-)designed, evaluated, or assessed by the instructor. Actions of this type were split into three subtypes. The first sub-type, *Design High-Cognitive Demand Tasks*, were made of teacher actions that were essentially about designing tasks with high cognitive demand (Stein & Smith, 1998). For example, Abbie (White woman, C1) discussed problem posing as fostering her creativity: "We had to create and solve most of our own problems based on problems in the textbook." Bryan (White woman, C1) also talked about the choice of assigning word problems that provide a "need to understand the concept in order to solve the problem." She went on to talk about making a connection with "information we've already learned in previous things and applying it here or just being very um inventive and creative about how to solve the problem."

The next sub-type, *Include Meta-Task Properties*, were about overall properties of the task itself that were not necessarily part of high-cognitive demand tasks. These tasks were not content-focused, but rather prompted the students to think about their problem-solving processes or reflect on how others thought about content. For example, Sal (Biracial Filipina American woman, C2) stated that "I know we had one class about thinking creatively and how to approach a math problem in a creative situation or asking, are there? Is it possible to approach a problem with a different mindset or different mannerisms?" This also involved re-evaluating homework or getting together in groups to discuss homework that had been done, in order to "understand how we went through the process to get our answer" (Breezy, Mexican man, C2).

The last sub-type, *Assessment-Related*, consisted of any mentions of how an assignment was graded or of tasks on quizzes or exams. For example, Bryan shared how homework was graded on a complete/incomplete scale. Murphy (White woman, C1) also said that the instructor would "give them [problems] back to us with like a little bit more notes on it just saying like oh that's interesting. Like the way that you found that and if you like you could have done this or this and that was good." We note that there were very few reported instances of Assessment-Related actions (11). Moreover, most of the instances (7) were in reference to one instructor. We explore what this lack of students reporting Assessment-related actions could mean in the Discussion.

Inquiry Teaching

Inquiry Teaching was defined as any action that can be linked to inquiry-oriented (or -based) instruction. We center the definition of active learning on two previous studies: Shultz and Herbst (2020) and Kuster et al. (2018). Shultz and Herbst (2020) created the INQUIRE (inquiry-oriented instruction review) instrument with four constructs about in-class teacher instruction: "interactive lecture, hinting without telling, group work, and student presentations" (p. 532). With these understandings of inquiry-oriented instruction, we saw the following three sub-types in our coding: *Allow for Discussion, Allow to Present* and *Teacher Active Listening*.

Allow for Discussion actions were about student discussion and characterized by group work, including actions as basic as *divide the class into groups* for deeper attention to student thinking such as *allow for students to build knowledge.* JCRU (Black woman, C2), in response to what contributed to her creativity, stated: "we all are able to learn from each other and build off of other people's ideas. Or take it and add a little something or maybe change it a little bit to make it work and make sense for us."

Allow to Present actions were also about student discourse but in front of the whole class. For example, interactive lecture was one way that Amelia (White woman, C2) reported her instructor contributed to her sense of creativity. The instructor "would always ask, like, how someone solved something. And then she would ask if someone solved it in a different way. And so she kind of wanted us to think differently and have different solutions."

Teacher Active Listening actions were where the teacher attended seriously to student voices. Aon (Black woman, C2) said her professor was aware of students' actions in the classroom:

> We did the problem, but we did it in a different way. And she compared the two ways and told me, "what's good about this way? What's good about this way?" So I feel that right there, her showing us, the students, different ways to do different problems showed her creativity and showed how, like she's able to adapt to everyone's learning style, learning that everyone won't be able to learn something as quickly in one way.

Holistic Teaching

Holistic Teaching consists of any teaching actions that do not require a response from students yet psychologically build an environment for fostering creativity. Within this type, there were two subtypes: *Encourage Mathematical Behavior*, which encourages mathematical behaviors that lead to creativity, as well as *Attend to Emotional Space* which attends to the student's affect. For example, Jmenard (White man, C2) shared the impact of his instructor promoting students' different responses on the growth of his sense of creativity:

> We spent like a whole 10 minutes, just everybody coming up with their own, you know, thoughts of what are different examples and then we went through them all together and she didn't tell anyone that they were wrong. She was just like, 'Well, I don't think that is one. Can you try to prove me wrong' or, 'Yeah, that is one. Can you prove [to] me why you're right.' Or, you know, so and so forth. So you're not in a situation where there's only one and one acceptable answer…So then that's where the creativity side gets in, because you're not worried about just doing a bunch of homework and applying the formula and just essentially robotic type learning. To where it's so I can actually learn the material, get comfortable with it. And then when it comes time to applying it, I can apply it any which way I want. And as long as I can convince the teacher that I'm right, then I'm right, you know?

Attend to Emotional Space actions attended to students' emotional states, by including supportive actions. As an example, Jennifer (White woman, C2) discussed how her instructor encouraged creativity: "He always tried to show the different ways that we would solve stuff, because he knew that some of us did do it that way and some of us did this way. So he always encouraged that even if it wasn't the most conventional method to use he would always encourage everyone's methods." She also shared that "he would always get excited whenever we would answer the questions and everything. And that whenever we would be understanding [the content]. So, it was just nice to see that he was rooting for us, (laughing) I guess all the time."

Holistic Teaching was made up of actions where instructors relinquished some control of the classroom. Some of the creativity-fostering actions reported involved uncertainty in solutions or understanding and acknowledging that teachers can learn from students. For example, Frost (Native American/Latinx/white man, C1) stated:

> [T]here's never…any negative outcome whenever you try and fail with him. It's like 'Oh you tried this. That's a good idea. But maybe next time like or what else could you do in this situation?' and he'll make you think through it and then eventually you'll solve it yourself.

This shows the impact of how students feeling there are no negative impacts to their attempts can lead to positive attitudes and mathematical practices that feed into feeling creative.

Discussion

In summary, we themed teaching actions that Calculus I students reported fostered their sense of creativity: *Task-Related, Teacher-Centered, Inquiry Teaching,* and *Holistic Teaching*. We further split these into subtypes, to show the breadth of actions teachers can take to foster students' creativity. We provided practical actions, as examples within these types and sub-types, to provide actionable recommendations for instructors looking to further creativity in their Calculus I classrooms. We note that these actions are from the students' (not instructor) perspective. We did not corroborate whether instructors in fact did these actions. Given our lens of creativity and that the individual themselves is the ultimate judge of whether they felt creative (independent of their reporting of it to us), students' judgments of what their instructor did that actively contributed to their sense of creativity are most valuable.

A number of the *Task-Related* teaching actions corroborate findings within the mathematical creativity literature (e.g., Levenson, 2013) and our own previous findings regarding creativity task features (El Turkey et al., 2020), e.g., different approaches leading to one answer, posing problems and questions, allows for originality/novelty, and uncertainty. That these are reflected in what students report back (versus the instructor/task designer perspective) and that moreover stand out in memory for them confirms that students are noticing their importance.

Our work confirms Hassi and Laursen's (2015) findings that "…inquiry, collaborative problem solving, and class discussions seemed to foster students' creativity and flexibility, growth that also improved their learning in other classes, and in everyday life" (p. 17). Next steps include exploring the further impact of these teaching actions on students, namely on their affect. We will link specific teaching actions to specific affective or other desired outcomes, so that instructors can choose which teaching actions to focus on, given their classroom goals. Another step is to use the themes from this paper to analyze classroom video data to identify what the teachers in fact did. This work may serve as a basis for developing a Creativity-Fostering Teaching Guide for practitioners. Our results suggest that teaching to foster creativity does not require a complete redesign of a class but can be done in little changes by incorporating some of the actions listed here.

Students' Conceptual Understanding of Normalization of Vectors from $\mathbb{R}^2$ to $\mathbb{C}^2$

Benjamin P. Schermerhorn
Virginia Tech

Megan Wawro
Virginia Tech

Interdisciplinary studies illuminate ways mathematics is incorporated into core STEM courses. Vector normalization is a crosscutting idea that appears in several mathematics and physics courses. The research question pursued in this study is: how do quantum physics students reason about normalization of vectors from $\mathbb{R}^2$ and $\mathbb{C}^2$, before and after quantum mechanics instruction? The data are analyzed using the theory of coordination classes (diSessa & Sherin, 1998). Results focus on students' thinking as they normalize different types of vectors: (A) a real vector and (B) a complex vector before instruction; and (C) a complex vector after instruction. Analysis identifies the ideas students coordinate when problem solving, which problem aspects students attend to, and how students take up or disregard ideas while they problem solve.

Keywords: linear algebra, quantum mechanics, normalization, coordination class theory.

Interdisciplinary studies have a significant role within mathematics education research because they illuminate the ways mathematics is incorporated into core science, technology, engineering, and mathematics (STEM) courses. For example, many physics programs require students to take mathematics courses in integral and vector calculus, differential equations, and linear algebra. In these courses, problem solving and reasoning involve a coordination of discipline-specific and mathematical knowledge (e.g., Christensen & Thompson, 2012; Hu & Rebello, 2013; Uhden et al., 2012; Wagner et al., 2011; Wittman & Black, 2015).

Physics and mathematics education researchers have started investigating student thinking around how linear algebra concepts are used in quantum mechanics. These areas of research include eignetheory (Dreyfus et al. 2017; Her & Loverude, 2020; Wawro et al., 2019), notation (Gire & Price, 2015; Wawro et al., 2020), expectation values (Schermerhorn et al., 2019), basis and change of basis (Serbin, et al., 2021; Close et al., 2013), and boundary conditions (Ryan & Schermerhorn, 2020). One mathematical concept that is essential to quantum mechanics is vector normalization, a crosscutting idea that also appears in several other mathematics and physics courses. Despite students encountering normalization several times in their undergraduate studies, students' understanding of normalization has been relatively uninvestigated. In this study, we pursue the research question: *how do quantum physics students reason about normalization of vectors from $\mathbb{R}^2$ and $\mathbb{C}^2$, before and after quantum mechanics instruction?*

Literature Review

Research on students' understanding of norms and normalization at the undergraduate level is sparse. There is some education literature where these ideas are relevant, such as student understanding of unit vectors. Barniol and Zavala (2011) asked physics students at a Mexican university to draw a unit vector in the direction of a vector drawn from the origin to the point (2,2) on the Cartesian plane. 22% of students gave a correct answer, 25% drew a vector from the origin to the point (1,1), and 14% drew the component vectors $2\hat{\imath}$ and $2\hat{\jmath}$; these findings were confirmed in a subsequent study (Barniol & Zavala, 2014). Vega et al. (2016) investigated students' abilities to draw unit vectors representing the motion of a particle moving in a two-dimensional plane, where the unit vectors were in terms of polar unit vectors $\hat{r}$ and $\hat{\theta}$. Many students drew vectors that did not satisfy the definition of a unit vector. The authors found four fundamental ideas to correctly solve this problem, namely that unit vectors: are vectors, have a length or magnitude of one, point in the increasing direction of the corresponding coordinate, and are dimensionless. This shows that finding a unit vector (i.e., normalizing) is not trivial.

Theoretical perspective

We analyze the data using the theory of coordination classes (diSessa & Sherin, 1998). Derived from a knowledge-in-pieces perspective (diSessa, 1993), a coordination class (CC) is a model for student understanding of a concept based on a networked system (or coordination) of context-specific knowledge elements. The theory of CC was developed as a means to define conceptual understanding and conceptual change (diSessa & Sherin, 1998) for the analysis of thinking and learning. To account for how information is determined from observation and from inference, a CC is divided into two parts: readout strategies and a causal net.

The first component of a CC, Readout strategies, relates to how information is observed from the surrounding world, while the second component, a causal net, deals with inferences. Readout strategies are the processes by which the information is drawn out from the external source. diSessa and Sherin note that for many quantities in physics, the readout strategies mostly involve determining the value of the quantity in a given situation (1998). A readout strategy for a CC around the concept of “fastness” could mean attending to what is more (Parnafes, 2007).

The second structural component of the CC, the causal net, represents the network of knowledge elements that connect observation to targeted information. This network can include small elements such as phenomenological primitives (diSessa, 1993) or more complex resources (Buteler & Coleoni, 2016; Wittmann, 2002). The causal net is often intertwined with the readout strategies. How students read information out of a given task can determine which elements are invoked and/or the causal net might influence strategies for answering a question.

In addition to usefulness in describing conceptual understanding, CC theory was designed to map conceptual change as new information is integrated into understanding or previously held ideas are deemed inapplicable. Incorporation is the process of recruiting knowledge elements in a CC. New CCs can be constructed by an individual through reorganizing and extending existing readout strategies and causal nets from known CCs and other prior knowledge (diSessa & Sherin, 1998). Complimentary to incorporation, displacement is the acknowledgement that certain elements or ideas are not applicable or helpful in a particular context.

Methods

To analyze the impact of a quantum mechanics course on the ways students conceptualize normalization, interviews[1] were conducted at two universities identified as University A and University C. Both universities offered a spins-first approach following the textbook *Quantum Mechanics: A Paradigms Approach* (McIntyre et al., 2012) and incorporated student-centered activities which encouraged discussion in the classroom. University A is a large, public, research-intensive university in the northwestern United States. The course enrolled 35 students and met seven hours a week for three weeks after a week-long preface on matrix methods. Linear algebra was a prerequisite course. University C is a medium-sized, public, research university in the northeastern US. The course met three hours a week for 15 weeks and enrolled 17 students. Following the textbook, eigentheory was first introduced in the context of spins before learning about wave functions in a continuous positions space. The second round of interviews was

[1] All interviews were conducted in-person prior to the COVID-19 global pandemic.

conducted within a few weeks of the conclusion of the spins content. As the prerequisite, students could take differential equations and linear algebra as one combined or two separate courses, and students saw some linear algebra in a mathematical methods for physics course.

Both the pre-interview and post-interview were semi-structured (Bernard, 1988), containing targeted questions related to thinking about normalization. Interviews were conducted using a think-aloud protocol and students were encouraged to discuss their choices when problem solving. The main stem for the interview questions are given in Figure 1. In the first interview (pre-interview), students were given two different vectors. Each was written on a piece of paper with the statement "Normalize the following vector." The first vector did not include any complex terms. After students completed the normalization, they were asked what it means to normalize and why they chose that procedure to normalize v. Students were then presented with a second vector included complex terms in both components. This vector was changed at University C to align with a physics convention of having real-valued first components and complex-valued second components. Additionally, the vector components were chosen so that students who did not use the complex conjugate[2] would arrive at $\|w\| = 0$ and need to reconcile the connection of length with normalization. The second interview (post-interview) focused on a vector in $\mathbb{C}^2$. Students were asked out loud to "Normalize a vector whose components are 3 and 2i" so they could choose the representation of the vector. Students were again asked about their meaning for normalization and about their procedure.

At University A, interviews were conducted with nine and eight students during the preface and at the course's end, respectively; six students participated in both interviews. At University C, eight and nine students were interviewed in the first and eighth weeks, respectively; seven students participated in both interviews. All interviews were videotaped and transcribed. Written work was collected and scanned. Participants were assigned pseudonyms "A#" or "C#" to identify them from a roster of all students in the courses. Students were not asked for their pronouns, so we use the gender-neutral singular pronoun "they" throughout the paper.

Data analysis identified the knowledge elements (units of ideas) as students reasoned about normalization. CC theory is used to analyze (a) information students invoke when normalizing vectors and describing normalization, and (b) compare snapshots of students' CCs to determine how the CCs are impacted by learning quantum mechanics. The second focus places interest on how knowledge of complex terms is incorporated into a student's conceptual framework.

Interview transcriptions were analyzed synchronously with the video data to account for students' written work. Analysis specifically attended to ways students conceptualized or

	University A	University C
Pre-interview	Normalize the following vector: $v = \begin{bmatrix}5\\2\end{bmatrix}$	
	Normalize the following vector: $w = \begin{bmatrix}3+2i\\4-i\end{bmatrix}$	Normalize the following vector: $w = \begin{bmatrix}3\\3i\end{bmatrix}$
Post-interview	Please normalize a vector whose components are 3 and 2i.	

Figure 1: Overview of interview questions presented at University A and University C. The questions given during the first week of the course were written out on paper. The question given post-spins content was asked verbally.

[2]For $v = [v_1\ v_2]\epsilon\mathbb{R}^2$, $\|v\| = \sqrt{\langle v|v\rangle} = \sqrt{v \cdot v} = \sqrt{v_1^2 + v_2^2}$, but for vectors $w = [w_1\ w_2]\epsilon\mathbb{C}^2$, $\|w\| = \sqrt{\langle w|w\rangle} = \sqrt{w_1\overline{w}_1 + w_2\overline{w}_2}$. The conjugation in the inner product for $\mathbb{C}^2$ produces nonnegative magnitudes in $\mathbb{R}$ for $w \neq 0$.

characterized vectors, vector representation, complex quantities, mathematical norms, and normalization. We performed inductive open coding (Miles et al., 2013) to identify knowledge elements, which were student ideas (complete thoughts or utterances expressing an idea), representational choices, or procedural choices.

The initial coding of the knowledge elements incorporated the language used by students. For example, the two student utterances *"*that will give us the length, and we can divide that length to normalize the vector*"* and *"*So, I'm just going to divide *v* by the magnitude of *v"* resulted in two similar codes: "Dividing a vector by its length normalizes the vector" and "Normalization is vector divided by its magnitude," varying only by the concepts of magnitude and length. Codes based on representational choices or calculation were also framed around student statements. A student who said "I'm going to do this in Dirac Notation" and a student who rewrote the vector in Dirac notation[3] would both be coded as "A vector can be expressed using Dirac notation." To interpret students' readout strategies, the initial review of the transcripts involved identifying what elements or aspects students attended to when problem solving.

Results

We present students' coordination classes as they normalize different types of vectors: (A) a real vector and (B) a complex vector during pre-interviews; and (C) a complex vector during post-interviews. Using a CC perspective, we identify the ideas students coordinate (causal net), which aspects of the problem statement students attend to (readouts), and the ways in which students take up or disregard ideas while they problem solve (incorporation and displacement).

Pre-interviews for normalizing a real vector

Overall, students were successful in normalizing a real vector. All but one student read out the coefficients of the vector and coordinated that the coefficients were squared and added. Four of seventeen students explicitly identified the dot product. Others bypassed the dot product by directly correlating magnitude or length with the square root of the sum of squared components.

We first present the CC established by A11 to highlight the method of data analysis, then expand discussion to other students. A11 correctly approached the procedure for normalization:

> ***A11:*** Normalize the following vector. Uh, well, we just, we solve for the dot product, which is v-dot-v, which would be five-squared plus two-squared. And we want to square root that, and divide by it. So, you'd have v divided by the square root of v-dot-v.

A11 immediately connected normalization and the dot product. We identify a knowledge element "Normalization involves a dot product." They then coordinated this element with their reading out of the components, an element we label "Dot product adds the components squared." Lastly, they take the result of the calculation and divide it into the original vector, which is identified by the element "Normalization involves dividing by the square root of the dot product." The progression of ideas in the causal net is shown by (1)-(3) in Figure 2.

When asked to "explain why you chose that process," A11 introduced the idea of magnitude and unit vectors, and reiterates several of the earlier connections.

> ***A11:*** Oh, so, to find the magnitude of v, square root of that [v-dot-v] … To normalize it, I took v and I divided by the magnitude of v. It's taking the vector and dividing by its length. ... What's the symbol for a unit vector? … [the] hat kinda tells you it's normalized.

Figure 2 shows the causal net with the elements from the student's additional explanation. Since the student references the dot product they wrote in their initial calculation, we can draw a

[3] Dirac notation uses bras, $\langle v|$, and kets, $|v\rangle$, to represent row and column vectors, respectively.

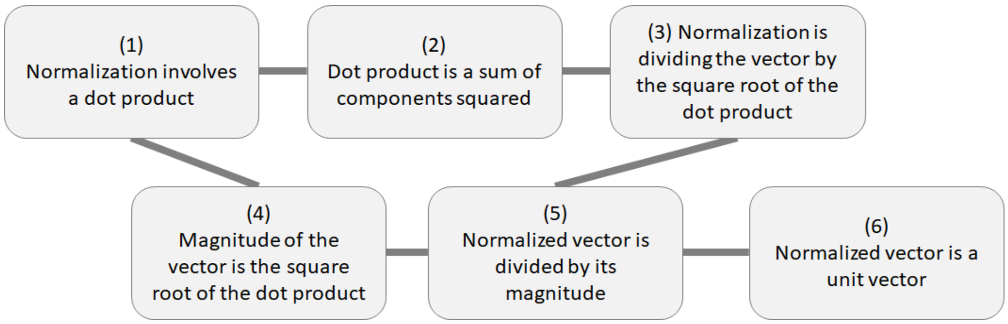

Figure 2. A depiction of A11 CC after they are asked to explain their process. Elements 1-3 were part of their original solution., while the remaining elements appear during further explanation.

connection between their first element and "Magnitude is the square root of the dot product." They coordinate this information with the element "Normalized vector is divided by its [magnitude/length]." The subsequent discussion of division, as the student finalizes their response, is why we connect this element with their initial element (3) in Figure 2.

Our analysis of A11's initial solution provides a look at the sequence of knowledge elements that led from the observed prompt to the determined output. As the student explained their process in response to the interviewer, other elements were identified ((4)-(6) in Figure 2).

Three students approached normalization geometrically, either through graphing on a set of Cartesian axes or by representing a triangle, as exemplified by C7 below.

> ***C7:*** 5 units along one basis vector and two units along the other basis vector which is orthogonal. [draws triangle] … the magnitude of this entire vector would be 5^2 plus 2^2.

C7 coordinated an earlier element "Normalization makes magnitude 1" with elements: "Vector forms a triangle," "Components are amounts along basis directions" and "Magnitude is sum of components squared." Reading out the components as a number of units, C7 identified the magnitude in a physicalized space, albeit incorrectly since they did not include a square root.

C7 was the only student in the pre-interviews to invoke the use of an arbitrary constant.

> ***C7 (continued)***: But we need to normalize that so if I say constant C times 5^2 plus 2^2 equals... C times 29 is one. … So, C is equal to 1 [over] 29, that way it is equal to one. [Adds 1/29 to expanded vector] But then how do I get// Oh, I could say that's 5 over the sqrt of 29 all of that squared plus 2 over the sqrt of 29. All that squared equals one.

A traditional physics approach is to include a *normalization constant* within a given vector and then solve $v \cdot v = 1$ to determine the constant. Inconsistent with the physics approach, C7 applied a constant after the dot product was calculated (Figure 3). We identify a coordination between "Normalize involves multiplying by a constant" and "Constant times the magnitude is one." These connections result in the determination of the constant and a normalized vector.

Three other students read out "normalize" from the question statement, and activate a CC for finding the normal vector. Two of these students end up displacing the incorrect elements by separating the ideas of finding a normal vector and normalization as involving magnitude.

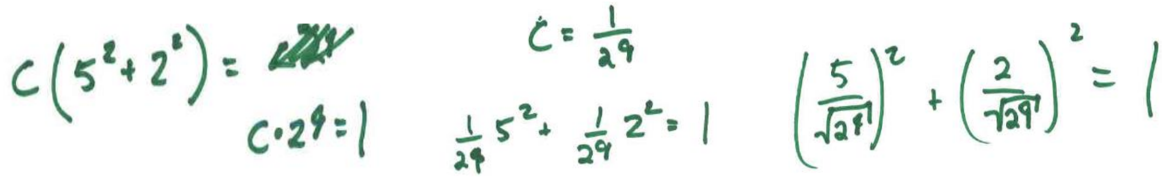

Figure 3. C7's written work where they multiply a constant by the result of their dot product. They then solve for the constant as part of finding the normalized vector.

Pre-interviews for normalizing a complex vector

The additional readout of an imaginary number requires a shift in thinking to include complex conjugates. Most commonly, 10 of 16 students[4] did not incorporate elements for complex vectors. The causal nets were similar to those for the first task. Students commonly invoked the summation of squared components and the division by the square root. As an example, A11 applies the same strategy as with the real vector.

> ***A11:*** So, you do 3 + 2i squared, uh, plus 4 - i squared, square root of that. That's going to equal the w magnitude. [Calculates to $\sqrt{20+20i}$] … divide by that.

A11 begins the same process of summing the components squared as they did with the dot product for the initial vector. They take the square root and identify the result as the magnitude, consistent with the knowledge element "Magnitude of the vector is the square root of the dot product." Lastly, they divide the vector, w, by the magnitude. Figure 4 shows the relevant knowledge elements that were identified overlapping with the student's initial causal net.

Six students identify the imaginary component and change their strategies to incorporate the idea of a dot product of the vector with its complex conjugate, as shown by C7 below.

> ***C7:*** I think I am going to be using a complex conjugate but I am not sure. So first of all, to get the magnitude of w, I am going to do w vector times w vector star. … that is 3+3i times 3-3i right. That is equal to ... 18 and then I have got to square root the whole thing.

After being presented with a complex vector, C7 identified the need for a complex conjugate, w^*. They changed the sign of the i term and carried out a dot product between w and w^*. They determined the magnitude as the result of the calculation, the square root of 18. The elements used by C7 up to this point are consistent with other students' causal nets for incorporating complex terms. However, C7 went on to use a constant and again invoked the elements "Normalized vector has a magnitude of one" and "Constant times multiplied vectors is one."

Post-Interviews with a complex vector

Following instruction in quantum mechanics, all students invoked the complex conjugate and only one of seventeen students incorrectly normalized the vector. The majority carry out normalization by independently finding the magnitude of the vector and then dividing by it.

The most common method was calculating the inner product of a vector with its complex conjugate, then dividing by the square root of the result. A11 now exemplifies this process.

> ***A11:*** Ok, so normalize it. ... v dot v ... would be, uh, 3^2 plus negative $(2i)^2$ [laughs] because now, we know how to do that, and that's 9 plus 4 and that's going to be 13. So, you're going to have v normalized, is going to be 1 over root 13, … you take v, and you multiply by its complex conjugate, ... so this would be 3 times 3 plus 2i times negative 2i.

In addition to elements related to the dot product, A11 referenced the complex conjugate in their

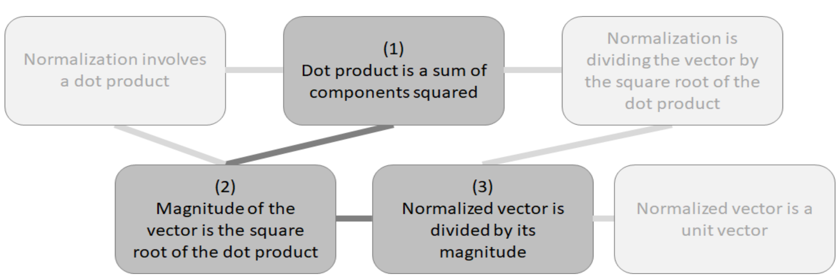

FIGURE 4. A11's causal net for normalizing a complex vector, which incorporates the same knowledge elements.

[4] One student did not get the question with the complex vector, since they did not complete the first task.

explanation. Here, we identify “Dot product is between vector and complex conjugate” and “Complex conjugate adds a negative sign to the imaginary term.”

Three of the four students using Dirac notation were also among the four to apply a normalization constant. As part of the post-interviews, C7 accurately applied the constant to the vector (not the dot product), consistent with other students who applied this method.

> ***C7:*** Now, to normalize … there needs to be some scalar times these two [kets] such that when I square the components of them and add them together, I'll get a total of one. ... v bra times v ket is equal to one, alright? So complex conjugate times [writing]. All that times the normal thing [initial vector]. So, C 3 up ket plus C 2i minus ket. (Figure 5)

In C7’s work, we identify the elements “Normalization involves a scalar” and “Multiplying by scalar means sum of the components squared is 1.” C7 then sets the Dirac inner product equal to one and writes out both the bra and ket in terms of the basis vectors as shown in Figure 5. They then invoke elements “Bra is the complex conjugate,” consistent with the application of Dirac notation in physics, and “Complex conjugate changes the sign of the imaginary terms.”

Discussion

Vector normalization is a cross-cutting concept that spans both mathematics and physics instruction. This work informs on physics students' conceptualizations of normalization of both real and complex vectors. The use of interviews before and after relevant instruction explore the way the concept of normalization changes following instruction in quantum mechanics.

Pre-interviews establish a baseline for thinking about normalization, in which all but one student normalized the vector correctly. Students commonly coordinated elements related to dot products, the sum of squared components, dividing by a square root, and magnitude or length of a vector. The transition to the complex vector resulted in about two-thirds of students invoking the same knowledge elements, and thereby utilizing the same CC. Students that correctly normalized, incorporated additional elements related to complex vectors into their causal net, such as needing a dot product of the vector with its complex conjugate.

In the post-interviews, all but one student correctly normalized the complex vector. By the end of quantum mechanics, students successfully incorporated elements related to complex vectors into their causal nets. The identified CC became more consistent with the standard approaches for normalization within both physics and mathematics.

The results provide information to mathematics instructors about how mathematics is applied in a physics course. For example, the use of a constant to normalize a vector is a common practice in quantum mechanics that is taken up by students following quantum instruction. This research further reports common knowledge elements used by students to construct a process for normalization by way of coordination class theory from physics education research.

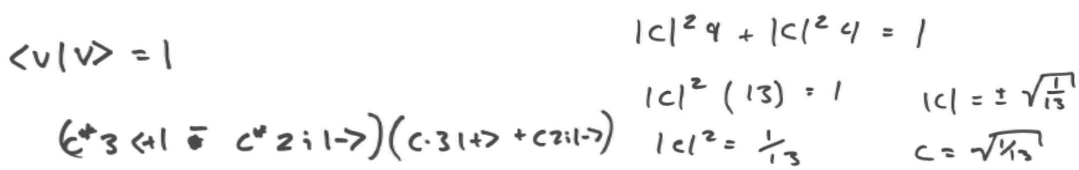

Figure 5. C7’s work using a normalization constant. C7 applies C with the complex conjugate vector but later choose C to be real and positive, consistent with physics conventions.*

Ways that Student Reasoning about Linear Algebra Concepts Can Support Flexibility in Solving Quantum Mechanics Problems

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Megan Wawro
Virginia Tech

Reasoning with mathematics plays an important role in solving quantum mechanics problems. In addition to understanding mathematical concepts and procedures, physics students often connect the content areas by mathematizing physical constructs in terms of their associated mathematical structures and by interpreting mathematical entities in terms of the physical context. In this study, we investigate undergraduate physics students' reasoning about linear algebra in two quantum mechanics problems. Through analysis of interview data from twelve students, results show that student reasoning about orthonormal bases, change of basis, and inner products informed their flexibility in choosing problem-solving approaches. We illustrate the results with student reasoning examples and provide directions for future research.

Keywords: Linear algebra, Quantum mechanics, Student reasoning, Flexibility, Problem-solving

Mathematics and physics have an interconnected, reflexive relationship. Physical problems motivated the origins of several mathematics concepts, and the mathematization of physical phenomena often enables the development of physical theory. According to Uhden et al. (2012), "the role of mathematics in physics has multiple aspects: it serves as a tool (pragmatic perspective), it acts as a language (communicative function) and it provides a way of logical deductive reasoning (structural function)" (p. 486). Due to the entangled nature of mathematics and physics, it is essential for undergraduate physics students to reason with mathematics as they solve physical problems. They often make connections between concepts and procedures learned in mathematics and physics courses, and these sometimes vary between the two disciplines.

In this paper, we examine undergraduate physics students' mathematical reasoning used as they solve two probability problems in the context of quantum mechanics (see Figure 1). We address the following research question: *How do undergraduate physics students reason with mathematical concepts and procedures as they solve quantum mechanics problems?* In particular, our research goal was to investigate what linear algebra reasoning students leveraged in their solutions and explanations regarding the quantum mechanics problems shown in Figure 1. Our results demonstrate how students draw on their understanding of linear algebra to inform their flexibility in choosing an appropriate problem-solving approach.

Consider the quantum state vector $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$.

a) Calculate the probabilities that the spin component is up or down along the z-axis.
b) Calculate the probabilities that the spin component is up or down along the y-axis.

Figure 1. The quantum mechanics problems addressed in this study.

Brief Physics Background

To assist the reader in following student work, we summarize relevant content. Spin is a measure of a particle's intrinsic angular momentum. This observable is mathematically represented by an operator such as S_z (where the z indicates the particle's axis of rotation). Each state of the physical system is associated with a vector, denoted as a ket $|\psi\rangle$. The eigenstates corresponding to possible measurements of an observable create an orthonormal basis for the associated Hilbert space. The eigenstates for the spin-½ operator S_z are $|+\rangle$ and $|-\rangle$, which correspond to the measurements $\hbar/2$ and $-\hbar/2$, respectively. Any quantum state $|\psi\rangle$ in this system is a linear combination of the eigenstates $|\psi\rangle = a|+\rangle + b|-\rangle$ for $a, b \in \mathbb{C}$. The complex conjugate transpose of a ket $|\psi\rangle$ is a bra symbolized as $\langle\psi| = a^*\langle+| + b^*\langle-|$. The probabilistic interpretation of superposition in quantum mechanics implies $|\psi\rangle$ will sometimes have attributes that resemble those of either $|+\rangle$ and sometimes those of $|-\rangle$. If the particle is in a state $|\psi\rangle$, the measurement of its spin along the *z*-axis will yield one of the eigenvalues $\hbar/2$ and $-\hbar/2$ with probability proportional to the modulus square of the projection of $|\psi\rangle$ along the eigenvector $|+\rangle$ or $|-\rangle$, respectively. The state changes from $|\psi\rangle$ to $|+\rangle$ or $|-\rangle$ as a result of the measurement.

Problem A (Figure 1) asks for the probability of obtaining $\hbar/2$ or $-\hbar/2$ in a measurement of observable S_z on a system in state $|\psi\rangle$. The solution is calculated by $P_{\pm} = |\langle\pm|\psi\rangle|^2$, where $\langle\pm|\psi\rangle$ is an inner product of one of the *z*-basis vectors and psi. The solution for problem B (see Figure 1) is calculated by $P_{\pm,y} = |{}_y\langle\pm|\psi\rangle|^2$, where ${}_y\langle\pm|\psi\rangle$ is an inner product between one of the *y*-basis vectors and psi. To complete problem B, a change of basis is involved because $|\psi\rangle$ is written in terms of the *z*-basis, but the prompt asks for the probability that the spin component is up or down along the *y*-axis. The two main approaches are to either change $|\psi\rangle$ to be written in terms of the *y*-basis (denoted $|\pm\rangle_y$) and calculate $P_{\pm,y} = |{}_y\langle\pm|\psi\rangle|^2$, or change the *y*-basis vectors to be written in terms of the *z*-basis and calculate $P_{\pm,y} = \left|\left((1/\sqrt{2}\langle+| \mp (i/\sqrt{2}\langle-|\right)|\psi\rangle\right|^2$. In either approach, one would need to utilize the equations $|\pm\rangle_y = (1/\sqrt{2}\,|+\rangle \pm (i/\sqrt{2}|-\rangle$.

Literature Review and Theoretical Framework

Although some research does exist on student understanding of relevant linear algebra concepts such as basis and change of basis (e.g., Adiredja & Zandieh, 2017; Bagley & Rabin, 2016; Hillel, 2000; Stewart & Thomas, 2010), the more pertinent literature for this study is the relationship between mathematics and physics and how students reason about that interplay (e.g., Christensen & Thompson, 2012; Karakok, 2019; Redish, 2006). For example, Schermerhorn et al. (2019) investigated physics students' reasoning about basis and change of basis in the context of calculating expectation value problems. They found that a challenge for most students was choosing an appropriate basis in which to express the matrices and vectors involved in the calculation. Wan et al. (2019) discussed how structural features of quantum notations can foster or hinder students' reasoning about inner products and quantum probabilities. They found that Dirac notation brackets helped students make sense of inner products of energy eigenstates and state vectors. In examining metarepresentational competence, Wawro et al. (2020) found that "students' rich understanding of linear algebra and quantum mechanics includes and is aided by their understanding and flexible use of different notational systems" (p. 020112-2).

As Caballero et al. (2015) noted, researchers have documented that reasoning about mathematics in physics contexts can be a complex endeavor for students. This complexity is partly due to the need to connect mathematics and physics via mathematizing and interpreting. Karam (2014) defined *mathematizing* as the "process of constructing a mathematical representation for a physical situation (in the broad sense). This process can be seen as a translation from the physical world (e.g., observations and experiments) into mathematical structures (e.g., numbers, functions, and vectors)" (p. 5-6, parentheses in original). The notion of *interpreting* involves making sense of mathematical symbols and structures in terms of the physical phenomena they represent or correspond to (Uhden et al., 2012). Mathematization and interpretation are central aspects of Uhden et al.'s (2012) model for the use of mathematics in physics, in which one structures physical phenomena, performs varying degrees of mathematization, uses technical skills to reason with mathematics, and interprets mathematical structures in terms of the corresponding physical phenomena. We draw on Uhden et al.'s theory as it highlights the entanglement of mathematics and physics that students navigate.

We use Uhden et al.'s and Karam's (2014) technical and structural skills to analyze students' mathematical reasoning on quantum mechanics problems and illustrate how their structural and technical skills support their flexibility in choosing problem-solving approaches. *Technical skills* involve using knowledge of mathematical concepts and procedures as a tool to solve physics problems; this use of mathematical skills is independent of connections to physics. Karam (2014) elucidated two types of technical skills: procedural and conceptual. *Technical-procedural skills* involve using mathematics to perform manipulations or procedures. This is akin to procedural knowledge (Hiebert & Lefevre, 1986; Star, 2005) encompassing "knowledge of procedures that is associated with comprehension, flexibility, and critical judgment" (Star, 2005, p. 408). We focus on the aspect of *flexibility,* a central facet of students' decision-making when choosing a particular problem-solving approach. It "incorporates knowledge of multiple ways to solve problems and when to use them" (Rittle-Johnson & Star, 2007, p. 562). *Technical-conceptual skills* involve giving conceptual explanations of mathematical rules and procedures, akin to Hiebert and Lefevre's (1986) conceptual knowledge. *Structural skills* incorporate reasoning about the interconnectedness of mathematics and physics and are "based on the capacity of employing the mathematical knowledge for structuring physical situations" (Pietrocola, 2008, p. 7). *Structural-mathematizing skills* involve translating from the physical world to mathematical structures and formulas, and this "involves not only a significant understanding of mathematical concepts and theories, but also the ability of abstracting, idealizing and modelling physical phenomena" (Karam et al., 2010, p. 2). *Structural-interpreting skills* involve making sense of mathematical structures in terms of the physical phenomena with which they correspond.

Methods

The participants were 12 undergraduate physics students, of which eight (pseudonyms A#) were enrolled in a junior-level Quantum Mechanics course at University A, a large research institution in the Northwest US. The other four participants (pseudonyms C#) were enrolled in a senior-level Quantum Mechanics course at University C, a medium-sized research institution in the Northeast US. Semi-structured interviews (Bernard, 1988) with each participant were conducted with the broad goal of gaining insight into how students reason with linear algebra concepts in quantum mechanics contexts. The interviews were recorded, transcribed, and written work was retained. We analyzed the participants' responses to the problems shown in Figure 1.

We performed inductive open coding (Miles et al., 2013) on each transcript, capturing what knowledge or skill the student implicitly used or explicitly described as they engaged with the problems. The authors independently coded four students' transcripts, compared, and created a primary code list, which the first author used to code the remaining transcripts. When new codes emerged from interpreting the remaining transcripts, they were added to the original list. The transcripts were coded again to ensure that no segments were missed or miscoded. We then performed deductive coding by assigning the codes one of four a priori parent codes: structural-mathematizing, structural-interpreting, technical-conceptual, or technical-procedural, which derive from Uhden et al.'s (2012) and Karam's (2014) structural and technical skills, as well as Hiebert and Lefevre's (1986) and Star's (2005) conceptual and procedural knowledge.

We explored the students' reasoning behind their decisions to use certain problem-solving approaches. To perform this analysis, we identified segments of the transcripts where the student justified their choice in using a particular approach and assigned those segments the code, "Flexibility in Choosing Approach." We aggregated all the transcript segments labeled with this code and identified which part of the problems the students were working on as they decided which approach to use. We identified three[1] such places in the students' work: calculating $|\langle\pm|\psi\rangle|^2$, $|_y\langle+|\psi\rangle|^2$, and $|_y\langle-|\psi\rangle|^2$. To see which technical and structural skills the students used as they chose their problem-solving approach or reflected on their choice, we identified all the other codes that were assigned to those transcript segments. We then decided which coded technical and structural skills were relevant to the students' flexibility in choosing an approach.

Results

Our primary finding was that students' technical and structural skills related to reasoning about linear algebra concepts supported their flexibility in choosing an appropriate approach to the problems. Particularly, (1) students' technical and structural skills related to reasoning with inner products and orthonormal bases supported their flexibility in choosing an approach for calculating $|\langle\pm|\psi\rangle|^2$, and (2) their technical and structural skills related to reasoning with basis and change of basis supported their flexibility in choosing an approach for calculating $|_y\langle+|\psi\rangle|^2$.

Students' Technical and Structural Skills Related to Reasoning with Inner Products and Orthonormal Bases Supported their Flexibility in their Problem-solving Approaches

For Problem A, there are two main approaches that could be used to calculate the probability that the spin component of angular momentum was up or down along the *z*-axis: that is, to compute $P_\pm = |\langle\pm|\psi\rangle|^2$. The first approach involved calculating $P_+ = |\langle+|\psi\rangle|^2$ by substituting $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$ into the inner product to get $P_+ = \left|\langle+|(\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle)\right|^2$, using the distributive and commutative properties to find $P_+ = \left|\frac{3}{\sqrt{13}}\langle+|+\rangle + \frac{2i}{\sqrt{13}}\langle+|-\rangle\right|^2$, using known properties $\langle+|+\rangle = 1$ and $\langle+|-\rangle = 0$ to reduce the equation to $P_+ = \left|3/\sqrt{13}\right|^2$, and simplifying to $P_+ = 9/13$. The procedure for determining the complementary probability $P_- = |\langle-|\psi\rangle|^2$ can be performed similarly to conclude that $P_- = \left|2i/\sqrt{13}\right|^2 = 4/13$. Alternatively, the second approach allows students to skip most of the procedures in the former approach: students could square the norm of the coefficient of $|+\rangle$ or $|-\rangle$, respectively, in $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$ to find P_+ and P_-. We include this description of the approaches that the students considered using because their reasoning here includes the acts of considering various options and using their understandings of the mathematical or physical concepts to decide on an approach.

First, students' technical and structural skills related to *inner products* supported their flexibility in choosing this problem-solving approach. For instance, A8 explained:

> Because this is written along the *z*-axis, I'm assuming that we're working in the *z*-basis here, standard representation. Then you do… norm squared of plus with psi [$|\langle+|\psi\rangle|^2$], and by the same rule I talked about earlier, about how we have this just plus plus minus minus equals 1 [$\langle\pm|\pm\rangle$ =1], then all you get here is plus and minus. Literally just pull out these same coefficients, so you get 3 over root 13 squared and 2 over root 13 squared.

A8's technical-conceptual skill of knowing that the vectors in the inner product were expressed in terms of the same basis allowed them to take advantage of properties of the *z*-basis. To be able to skip the steps in the first approach of evaluating the inner product, $\langle+|(\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle)$, students first used the structural skill of interpreting the mathematical symbols to recognize that

[1] For brevity, we only discuss the first two instances in this paper. They correspond to the two Results subsections.

the vectors in the inner product were linear combinations of vectors from the same basis. Their technical-conceptual skill of recognizing that vectors in an inner product must be in terms of the same basis then allowed them to use the inner products of *z*-basis vectors.

Second, the students' technical and structural skills related to *properties of orthonormal bases* supported their flexibility in choosing to use the second efficient approach to solving problem A. The students used structural-mathematizing skills to recognize that $|+\rangle$ and $|-\rangle$ comprise an orthonormal basis which allowed them to use technical skills involved in using the inner products of orthogonal basis vectors: $\langle\pm|\pm\rangle = 1, \langle\pm|\mp\rangle = 0$. For example, when asked about how they found their answer, A11 explained their reasoning about this idea:

> Since this is a basis, uh, plus with a plus is equal to 1 [$\langle+|+\rangle = 1$], whereas plus with a minus is equal to 0 [$\langle+|-\rangle = 0$]. So, if I was to distribute a plus [$\langle+|$] out to all of these, this would give us zero automatically because they're orthogonal. This would go to 1, so I square that. Same thing with the other way, because minus plus [$\langle-|+\rangle$] is equal to 0.

Reasoning about orthonormal bases, namely that $\langle\pm|\pm\rangle = 1$ and $\langle\pm|\mp\rangle = 0$, allowed students to anticipate that evaluating inner products by distributing $\langle+|$ to $(\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle)$ and $\langle-|$ to $(\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle)$ would leave only the coefficient of $|+\rangle$ and $|-\rangle$, respectively. This allowed them to skip these steps and instead calculate the probabilities by squaring the norm of the coefficients of $|+\rangle$ and $|-\rangle$. Overall, students' technical and structural skills related to reasoning with inner products and orthonormality supported their flexibility for calculating $P_\pm = |\langle\pm|\psi\rangle|^2$.

Students' Technical and Structural Skills Related to Reasoning with Basis and Change of Basis Supported their Flexibility in their Problem-Solving Approaches

To calculate $|_y\langle+|\psi\rangle|^2$, the students recognized a need to perform a change of basis, and they had the choice to either change $|\psi\rangle = \frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$ to be written in terms of the *y*-basis or change $|+\rangle_y$ to be written in terms of the *z*-basis. The students' technical and structural skills supported their decision in choosing their problem-solving approach. In particular, the students' technical and structural skills related to reasoning about the *basis that the vectors in the inner product were expressed in terms of* and about the *properties of orthonormal bases* supported their choice to perform a change of basis. Their technical and structural skills also supported their flexibility in deciding which of the two aforementioned change of basis approaches to use.

The students' technical and structural skills related to reasoning with basis and inner products supported their choice to perform a change of basis. For example, A13 explained:

> You'd either have to change this [$|\psi\rangle$] to *y*-basis to fit this, which would not be fun probably, or change your *y*-basis to *z*-basis… psi is in a completely different basis, so you can't just multiply out in- when they're in different bases, so you have to switch bases.

As exemplified in A13's reasoning, the students used their structural skill of interpreting that "psi is in a completely different basis." They recognized that $|\psi\rangle$ is a linear combination of *z*-basis vectors, which does not match the basis expression of $_y\langle+|$, the other vector in the inner product. The students then used their technical-conceptual skills to recognize that the vectors in the inner product needed to be expressed in terms of the same basis for them to be able to perform the inner product. For instance, C6 claimed, "you can't do anything until you're in the same basis." The students then used the structural-mathematizing skill of recognizing that a change of basis is necessary to be able to perform that inner product. Thus, the students' technical and structural skills related to reasoning about the basis of the vectors in the inner product supported their choice to perform a change of basis.

Reasoning about the orthonormality of the bases and the associated inner product values also supported their choice to perform a change of basis. Some students discussed how changing basis made the calculations simpler due to orthonormality of the bases. For instance, A21 said:

> I wanna be able to read off those coefficients really easily and do this in bra-ket notation if these are in the same uh basis. If I'm expressing plus y [${}_y\langle +|$] in the *z*-basis then I can make all those assumptions about one, you know, the pluses and the minuses, the cross terms are gonna be zero. But if I were to do this in the *y*-basis… like write this out as like let's say y plus, but against all of this [$\frac{3}{\sqrt{13}}|+\rangle + \frac{2i}{\sqrt{13}}|-\rangle$], then I can't make any assumptions about that, so I don't really know how to calculate that in bra-ket language.

A21 claimed it was necessary to change basis to make assumptions about the inner products of the various (orthonormal) basis elements, such as $\langle \pm|\mp\rangle = 0$. A21 suggested that leaving the inner product with the vectors expressed in terms of different bases would not allow them to use $\langle \pm|\mp\rangle = 0$. Thus, the need to use the orthonormality property informed their choice to perform a change of basis. C5 also claimed a change of basis was necessary for "inner products to be nice:"

> Because my state vector was given in the *z*-basis, if I'm doing the inner product of the positive *y* with that, I need that to be written in the *z*-basis, or to do those inner products to be nice. So I guess the plus and plus gives you one. The plus and minus gives you zero.

Taking advantage of the orthonormal basis properties motivated the students' selection of the change of basis approach. The students used their structural-mathematizing and technical-conceptual skills to leverage that the *y*-basis and the *z*-basis are both orthonormal. These structural and technical skills informed their choice of approach and therefore their flexibility.

In addition to informing their decision to perform a change of basis, the students' structural and technical skills also supported their flexibility in choosing a change of basis approach: either changing $|\psi\rangle$ to be a linear combination of *y*-basis vectors or changing ${}_y\langle +|$ to be a linear combination of *z*-basis vectors. A8 performed the former after acknowledging both approaches:

> There are two ways to go about it, um, one of them is to put this vector in some phi prime that's in the *y*-basis, and then just do y plus phi prime y [${}_y\langle +|\psi'\rangle_y$]…it follows the same rules as this. Um, the other possibility is to do, is to take the spin up *y* and go to whatever it is in the *z*-basis, cause we have this in the *z*-basis. Um, they're both equivalent.

Expressing $|\psi\rangle$ as a linear combination of *y*-basis kets allowed A8 to square the norms of coefficients of *y*-basis kets. A8 recognized that both methods were "equivalent" and yielded the same probability result. A8 reflected on their choice of approach and compared the efficiency of the two methods: "The other method is probably faster if you think of it. Actually, I don't know if it's really faster. You just save so much time on this side, if you do it this way." In summary, A8's structural-mathematizing and interpreting skills supported their flexibility in recognizing the two approaches, comparing their efficiency, and choosing one for solving the problem.

Most students chose to use the approach of changing ${}_y\langle +|$ to be a linear combination of *z*-basis vectors, and their structural and technical skills supported their flexibility in doing so. Some students chose this one due to computational ease. For instance, A6 explained:

> You can't do anything until you're in the same basis…I needed plus *y* in the *z* basis, because this was in the *z* basis. If I really wanted to, I could have changed [$|\psi\rangle$] to the *y* basis. Um, this [${}_y\langle +|$] is a lot easier because we had the spins sheet, so I changed this from the *y* basis to the *z* basis here, so then both of them were in the *z* basis.

Students could use the equation $|+\rangle_y = \frac{1}{\sqrt{2}}|+\rangle + \frac{1}{\sqrt{2}}i|-\rangle$, which made the change of basis procedure "a lot easier," only involving substitution and not the solution of a system of equations. Students' technical-procedural skills of using substitution and given equations supported their flexibility by allowing them to compare the efficiency of possible approaches. A13 also acknowledged that changing $|\psi\rangle$ to be in terms of the *y*-basis vectors "would not be fun probably," so they chose to change the basis that ${}_y\langle+|$ was expressed in terms of, instead. A11 similarly recognized that changing $|\psi\rangle$ to be in terms of the *y*-basis vectors would involve more work, explaining, "I didn't really want to have to deal with that math." These students' structural-mathematizing skill of recognizing that changing ${}_y\langle+|$ to be in terms of the *z*-basis vectors was easier than changing $|\psi\rangle$ to be in terms of the *y*-basis vectors supported their flexibility in choosing a way to change basis. Overall, the students' structural and technical skills related to reasoning about change of basis via substituting and using equations supported their flexibility.

Discussion

Given the entanglement of mathematics and physics, it is essential for undergraduate physics students to learn to reason with mathematics as they address physical problems. This is complex for students as it involves connecting their mathematics and physics reasoning via interpreting and mathematizing. We leveraged Uhden et al.'s (2012) and Karam's (2014) framework of students' technical (conceptual and procedural) and structural (mathematizing and interpreting) skills to investigate the flexibility of physics students' reasoning about mathematics in relation to physics content addressed in two quantum mechanics problems. Through our analysis of interview data from twelve physics students, we found that the students' technical and structural skills related to reasoning about linear algebra concepts supported their flexibility in choosing a problem-solving approach. Flexibility is an essential aspect of problem-solving, as it involves being aware of multiple approaches to solve a problem and choosing an appropriate one. Other researchers have demonstrated how conceptual knowledge can support procedural flexibility (e.g., Rittle-Johnson et al., 2015). This finding is furthered in our study. When students draw on their mathematical knowledge to inform their approach for solving these quantum mechanical problems, it relies on their understanding of how the mathematics and physics concepts are intertwined. Students' use of conceptual understanding in their work on these problems is more complex than just reasoning about mathematical concepts and procedures because students must reason about them in relation to their corresponding physical concepts. Thus, not only are physics and mathematics are entangled; students' reasoning about them is also entangled.

With respect to teaching implications, our research helps raise the mathematics community's awareness of what concepts from mathematics courses are used and in what way by students in physics courses. Our study revealed the centrality of: basis, orthogonality, normality, change of basis, algebraic substitution, simplification of vector equations or system of equations, and inner product in the solution process for a quantum mechanical problem. While those are core to a linear algebra course, additional mathematical concepts were central, namely the probabilistic relationship of mutually exclusive events, distribution, and operations with complex numbers. These concepts are relevant for larger systems, as well as other quantum mechanical observables. Future research can address how students use their understanding of linear algebra in quantum mechanical contexts in which the mathematical concepts correspond to physical phenomena.

Prospective Teachers Connecting Group Axioms with the Structure of the Identity Function

Kaitlyn Stephens Serbin
The University of Texas Rio Grande Valley

I examined the development of three Prospective Secondary Mathematics Teachers' (PSMTs) understandings of connections between concepts in abstract algebra and secondary algebra. I investigated how PSMTs deepened their understanding of the identity function and unified various identities under the overarching identity structure as they engaged in a Mathematics for Secondary Teachers course. Analysis revealed that one PSMT conceptualized the identity function as both a function that leaves its input alone and the result of composing inverse functions. The other two conceptualized the identity function as x, the output of $f(f^{-1}(x))$, instead of a function. The PSMTs unified the additive identity, multiplicative identity, and identity function as instantiations of the same overarching concept by reflecting on the group axioms. I discuss the opportunities given to the PSMTs during instruction that contributed to their development of these understandings. I conclude with implications for PSMT preparation.

Keywords: Abstract algebra, Prospective teachers, Mathematical knowledge for teaching

Abstract Algebra is an almost universally required course for prospective secondary mathematics teachers (PSMTs, Blair et al., 2013), but teachers might not perceive connections between properties of algebraic structures in secondary algebra and abstract algebra contexts (e.g., Cofer, 2015; Wasserman, 2017). Thus, there is a need to make more explicit the ways in which teachers use their knowledge of abstract algebra to better understand the algebra content they teach. Wasserman (2018) theorized that for knowledge of abstract algebra to be useful in teachers' instruction, it must first help reshape the teacher's understanding of the content they teach. Thus, this study examines the reshaping of PSMTs' mathematical understandings that occurs as they reason about content connections between secondary algebra and abstract algebra.

Teachers' knowledge of abstract algebra could potentially influence their instruction on inverses (Wasserman, 2016). The structure of inverses is derived from that of a group. An *identity element* e in a group $(G,*)$ satisfies the property that $a * e = e * a = a$ for any element a in G (referred to as the identity group axiom). In a group, there exists an *inverse element* a^{-1} for every element $a \in G$, such that $a * a^{-1} = a^{-1} * a = e$ (referred to as the inverse group axiom). Some groups commonly found in secondary contexts include $(\mathbb{Z},+)$, $(\mathbb{Q}^*,\cdot)$, and the set of invertible functions (with domain restrictions) under function composition. Understanding the structure of a group might help one make sense of the structure of additive, multiplicative, and function inverses, as well as the structure of various identities. Each type of inverse is an inverse element from a group and is associated with an identity and binary operation. Thus, every element f of the group of invertible functions under composition has an inverse f^{-1} such that $f \circ f^{-1}(x) = f^{-1} \circ f(x) = i(x)$, where i is the *identity function* defined as $i: X \to X$ such that $i(x) = x$. The application of group axioms is involved in the algebraic cancellation used in equation solving, which illustrates content connections in secondary and abstract algebra. These content connections were covered in a Mathematics for Secondary Teachers course. In this study, I explore how PSMTs in that course reasoned about the group axioms to make connections among the additive, multiplicative, and compositional identities. I address the research questions: (1) *How do PSMTs reason about the structure of the additive identity, multiplicative identity, and identity function? (2) What aspects of the course helped them develop those understandings?*

Literature Review and Theoretical Background

Several studies have addressed teachers' or undergraduate students' understandings of inverses, focusing on their attention to the corresponding binary operation and identity. Zazkis and Kontorovich (2016) explored prospective teachers' explanations of the superscript -1, which is the same notation used for inverse functions and multiplicative inverses (reciprocals). Most PSMTs in their study perceived the superscript -1 as a symbol that refers to different unrelated meanings that are context-dependent. They did not use their knowledge of group structure to reason about the similar inverse meanings implied by the superscript -1. Furthermore, Bagley et al. (2015) found all ten of their participating undergraduate students "said the result of composition of a function and its inverse should be 1" (p. 36), implying they associated inverse functions with the multiplicative identity. They found that when students resolved that inaccurate idea, they used "do-nothing function reasoning" or "net-do nothing function reasoning," which respectively involve understanding the composition of inverse functions as a function that does nothing to its input argument (i.e., the identity function) or as a process of an inverse function undoing what a function does to an input. They suggested these were productive ways of reasoning about the composition of inverse functions. Wasserman's (2017) study also focused on teachers' attention to the binary operation and identity that was associated with inverse functions. He investigated how secondary teachers, who had recently taken Abstract Algebra, situated inverse functions within their group structure by attending to the identity function and composition; only two of seven teachers could do so. These studies illustrate the complexities teachers may experience in distinguishing inverses by reasoning about their associated identity.

This study is framed by Wasserman's (2018) theory of Knowledge of Nonlocal Mathematics for Teaching. Wasserman (2018) distinguished types of mathematics as local or nonlocal, relative to the mathematics one teaches and used this distinction to consider how teachers' understanding of nonlocal (advanced) mathematics influences their understanding and teaching of local mathematics. Wasserman argued for teachers' understanding of nonlocal mathematics (e.g, abstract algebra) to influence their instruction, the teachers need to first make connections between the nonlocal and local content that *reshape* their understanding of the mathematics they teach. I conceptualize this reshaping of knowledge according to Lee's (2018) construct of a transformative transition which involves *extending* the contexts in which one's understanding is situated, *deepening* one's understanding of a concept, *unifying* disparate concepts under an overarching concept, and *strengthening* the connections between their existing understandings of multiple mathematical concepts. I use the deepening and unifying categories to analyze how PSMTs reshape their understandings of identities used in secondary algebra.

For documenting this increase in depth of students' understandings, Lee (2018) used Action-Process-Object-Schema (APOS) theory (Arnon et al., 2014), which provides a lens for how students can deepen their understanding of a concept through transitioning from having an action to a process to an object level conception. As students begin to understand a mathematical concept, they manipulate either physical objects or previously constructed mental objects to form actions. A student first performs an action explicitly and then repeats and reflects on this action. Once a student can mentally imagine the steps of this action without having to explicitly carry out all of the steps of the action, the student has interiorized the action into a process. A student then encapsulates a process into an object by performing actions on the process as if the process was a static object. A schema is a collection of actions, processes, and objects and the connections between those structures. I focus on the PSMTs' development of Identity Schemas, which comprise conceptions of additive, multiplicative, and compositional identities and the relations among them. I use Lee's (2018) construct of unifying to analyze the development of this schema in which the connections between identities become more coherent. A learner can unify their existing understandings under an overarching mathematical object by increasing the extent to which seemingly unrelated mathematical concepts become more coherent. This reshaping of a mental schema can be analyzed using Piaget and Garcia's (1983/1989) triad. At the intra-object level of unifying, the learner focuses on constructs in their mind individually in isolation from each other. The inter-object level of unifying involves finding similarities between some of the concepts but not articulating the overarching idea that the concepts embody. The trans-object level of unifying is characterized by the learner recognizing the concepts all as instantiations of the same overarching idea and thus connecting the concepts into a coherent schema. In this paper, I use these deepening and unifying categories in Lee's (2018) Extend-Deepen-Unify-Strengthen (EDUS) framework as mechanisms to document how PSMTs' understandings of identities are reshaped in a Mathematics for Secondary Teachers course.

Methods

Data were collected in a senior-level Mathematics for Secondary Teachers course at a large research university in the eastern US. The class consisted of four PSMTs, of which three (Amelia, Christina, and Derek) participated in this study. The participants had previously taken an introductory undergraduate course in Abstract Algebra. Clinical interviews (Clement, 2000) were conducted with each participant before and after instructional units covering ring and group axioms in relation to inverses and equation solving. These interviews elicited evidence of the PSMTs' understandings of inverses, identities, binary operations, and the relations between them. These interviews had a pre-post format, so I could observe changes in their understanding.

To address research question (1), I used Lee's (2018) EDUS framework to analyze changes in each participant's understanding of inverse, identity, and binary operation. I characterized the depth of the students' understanding of a single concept (e.g., identity function) using the levels of Action, Process, and Object. A student with an action conception can compose two inverse functions and get x as the resulting output but does not perceive the identity function's identity structure. A student with a process conception can compose two inverse functions and anticipate the resulting output to be the identity function internally in their mind. A student with an object conception can perceive the identity function as a function in its own right and can act on it via function composition. I also classified the extent to which their understandings of different types of the same concept (e.g., additive, multiplicative, and function identities) were unified into a coherent schema using Piaget and Garcia's (1983/1989) triad of schema development. At the intra-object level, a student focuses on additive, multiplicative, and function identities in isolation from each other and does not recognize similarities among them. At the inter-object level, a student can articulate some similarities between the identities. At the trans-object level, a student can articulate the identity structure shared by these different identities, i.e., that two inverse elements operated together equals the identity or that an element operated with an identity equals that element. I documented changes in these classified levels of the PSMTs' understanding between the pre- and post-interviews to find how they were deepened or unified.

To address research question (2), I collected video and audio data of each class from the two instructional units. I analyzed class episodes in which the PSMTs had opportunities to deepen or unify their understandings of identities as they received instruction on abstract algebra concepts and their connections to secondary mathematics. Through this analysis, I identified aspects of instruction (e.g., the instructor's discussion prompts or tasks) in the Mathematics for Secondary Teachers course that supported the PSMTs' in deepening and unifying their understandings.

Results

The PSMTs Deepened Their Understanding of the Identity Function

The PSMTs deepened their understanding of the identity function during the Mathematics for Secondary Teachers course, although to different depths. During the pre-interviews, Amelia and Derek described the composition of inverse functions as one or zero and thus had not yet constructed a conception of the identity function. For example, Amelia anticipated the composition of inverse functions to be 0 and was surprised when the composition yielded x. She explained because "they negate each other, it would make sense for it to be zero." She thus related the composition of inverse functions with the additive identity.

Amelia, Christina, and Derek then developed Action conceptions (Arnon et al., 2014) of the identity function as they verified that two given functions were inverses of each other. Once they reflected on x as the result of the composition of inverse functions, they could anticipate that result in subsequent tasks and use that to determine whether a pair of functions were inverses of each other. They thus developed a Process (Arnon et al., 2014) understanding of the identity function as the result of composing inverse functions. For example, Derek constructed a Process conception of the identity function during a pre-interview. After Derek found the inverse of a given function, the interviewer asked follow-up questions:

Interviewer: How does this inverse relate to the inverse definition you gave?

Derek: … so in functions, your like, I guess the thing you're doing is composition of functions … and $f(x) = x$ is kind of your identity in functions. So when they're put together, you want it to be equal to the identity, which would be x. So you want to get the equation $f(x) = x$ when you do those two things together…

Interviewer: Why, again, do we want it to be equal to x there?

Derek: That's the identity function, that we've referred to as the identity of functions is just y equals x, so we want to have that kind of form when we do the composition of functions.

Derek's responses demonstrated his Process conception of identity function as the result of composing inverse functions, as he could mentally anticipate the result of the composition. Derek also developed an Object conception (Arnon et al., 2014) of the identity function, as he could perform actions, such as composition, on the identity function as if it were a static entity. Derek demonstrated an understanding of the structure of the identity function as the function that maps an input to the same output, as well as the function that is the result of a composition of inverse functions. For example, Derek said, "The identity function is just a function that equals x, so it's something that if we plug in, it just doesn't change the function, I guess, so if we like plug in an x, we just pop out y, which it happens to be x, so it just like leaves it alone." He described that if one plugs an input into the identity function, the identity function does not change it and "leaves it alone," meaning the input of the function is the same as the output.

Amelia and Christina developed a process conception of the identity function as the result of composing inverse functions. They conceptualized the identity function as a variable x rather than a function, which seemed to inhibit them from constructing an Object conception of the identity function because they were unsure of how to compose it with other functions. Whenever they reasoned about why x was the identity function, they related it to the property that it was the resulting output of the composition of inverse functions ($f(f^{-1}(x)) = x$). For example, Amelia described the identity of the set of invertible functions, saying "For invertible functions with composition, plugging them into each other would give you back x as the identity… when you compose them with one another you get out x, so if f inverse is actually the right inverse for f, then you'd get out an x." She thus demonstrated a Process conception, but she did not show evidence of having constructed an Object conception of the identity function by the post-interviews. She expressed uncertainty about whether the identity x was a function or a variable. She tried to show that the identity function satisfied the definition of identity, explaining:

Amelia: The inverse would just be f inverse and the identity would just be x, the identity function, since it is under composition, and so we know, f, f inverse, x. But I'm not really sure. Like going back to the definition of an identity, because earlier, I would do it like a plus 0 equals 0 plus a, which equals a. I'm not sure how that would work like with the definition similar to that for functions and composition of functions.

Interviewer: Okay, so the identity x, is that just like the variable, or is that a function?

Amelia: It's the variable, or it is a function. I'm not sure.

Amelia tried to relate the additive identity structure ($a + 0 = 0 + a = a$) to the structure of the identity function, but she was unsure of how to do that. Thus, she did not know how to show that the identity function satisfied the definition of identity that for any function f in the given group, $f \circ i = i \circ f = f$, where i is the identity function defined as $i(x) = x$. Given that she consistently referred to the identity function as just x, she conceptualized the identity function as the variable x, not a function. Christina similarly expressed uncertainty regarding the identity function, explaining, "I think identity might not be the function. I think it's the variable." Amelia and Christina did not know how to compose the identity function with another function. Thus, they had not yet constructed an Object conception of the identity function.

In summary, Amelia and Christina developed process conceptions of the identity function as the result of composing inverse functions, but they did not recognize how the identity function satisfied the definition of identity that for any function f in the given group, $f \circ i = i \circ f = f$, where i is the identity function defined as $i(x) = x$. They thus conceptualized the identity as x, the resulting output of $f(f^{-1}(x))$, instead of the function $i(x) = x$, while Derek conceptualized the identity as a function itself. He could articulate how it satisfied the identity group axiom and the inverse group axiom that the identity function equals the composition of inverse functions.

The PSMTs Unified Additive, Multiplicative, and Function Identities

Amelia, Christina, and Derek all unified additive, multiplicative, and function identities under the same overarching identity concept throughout the semester. They originally exhibited an inter-object level understanding of the connections among the additive and multiplicative identities, but they conflated the multiplicative identity and the identity function, particularly when composing inverse functions. For example, Derek explained his reasoning about $e^{\ln(2)}$ as "e to the natural log cancels out, and that just essentially becomes one, and same with natural log of e is just one…I guess multiplicatively they're inverses because if you multiply… they come back to an identity of one." Derek reasoned about the structure of operating inverse elements together to get the identity, so he connected the idea of "e to the natural log canceling out" to the idea of multiplicative inverses "coming back to like an identity of one" instead of the identity function. He thus confused the multiplicative identity with the identity function. Derek had not yet mentally constructed the concept of the identity function, so he could not yet form connections between it and the multiplicative identity to develop a coherent schema of identities. Overall, the students' Identity Schemas were not yet coherent during the pre-interviews because they had not yet unified the identities as instantiations of the same concept.

Once the students each developed a conception of the identity function, they recognized the structure of the identity function as the result of composing inverse functions and perceived it as similar to the structure of the additive and multiplicative identities. For instance, when Amelia defined an inverse during the post-interviews, she said, "An inverse is an operation or a function that when computed will bring that portion of like the equation *to the identity… for a function it would be the identity function, or like the additive identity, or the multiplicative identity.*" Christina similarly could identify the identities of various groups. For the groups $(Q^*,\cdot)$, $(\mathbb{Z},+)$, and the set of invertible functions with the same domain and range under the operation of function composition, she identified their respective identities as 1, 0, and x. Furthermore, after Derek mentally constructed the identity function during Interview 2, he could identify the similar structure of different types of identities. For example, when Derek compared multiplicative and function inverses, he identified similarities in the structure of their corresponding identities, explaining, "they're similar in the sense that they take it back to the identity… if we had a and it was operated with a inverse, it'd give you back to identity in that set, and f inverse does the same for f." Derek recognized that the multiplicative identity and the identity function are both the result of an element of a set being operated with its inverse. He made connections between the different identities associated with different inverses by reasoning about their similar structure of being the result of operating inverse elements together. Once Derek recognized that the identity associated with inverse functions was $i(x) = x$, he could unify $0, 1,$ and $i(x) = x$ as instantiations of the same overarching concept. Overall, these students recognized $0, 1,$ and the identity function as instantiations of the same overarching identity concept. They could articulate the shared identity structure of the additive, multiplicative, and compositional identities as the result of operating two inverse elements in a group together, which is indicative of a trans-object level (Piaget & Garcia, 1983/1989) understanding of these identities. Thus, the PSMTs all unified their understandings of these different types of identities under the overarching identity concept and thereby developed a more connected and coherent Identity Schema.

How Instruction in the Course Supported the PSMTs in Developing these Understandings

The PSMTs had opportunities to develop these understandings of the identity function during class. The instructor led class discussions about the inverse group axiom and the identity group axiom to lead the PSMTs to reason about the structure of the identity function. Reasoning about the structure of operating inverses together to get the identity (i.e., $f^{-1}\big(f(x)\big) = f^{-1}\big(f(x)\big) = x$) first led the PSMTs to conceptualize x as the identity that resulted from the composition of inverse functions. The class later proved that the identity function defined by $i(x) = x$ satisfied the inverse group axiom, (i.e., $f \circ f^{-1} = f^{-1} \circ f = i$), by showing these three functions had the same output for each input. Thus, the class discussed the identity function as an actual function. The instructor often referred to "getting back to the identity function" after composing a function with its inverse. This likely contributed to the PSMTs' development of a Process conception of the identity function as the result of composing inverse functions. The class also discussed how the identity function satisfied the identity group axiom, "i is the identity if for all f in some set S, $i \circ f = f \circ i = f$," by showing that $(i \circ f)(x) = i\big(f(x)\big) = f(x)$. This likely supported Derek in developing an Object conception of the identity function, and this might have supported Amelia and Christina in transitioning toward their development of an Object conception, as well.

The PSMTs had opportunities to unify the additive identity, multiplicative identity, and identity function as they reflected on their shared identity structure during class. They reasoned about their identity structure as the result of operating two inverses together, particularly in the context of equation solving. The instructor led the PSMTs to consider the motion of crossing out while solving equations and had them identify what structures were used that allowed them to cross terms out. Discussing how "getting rid of" terms while solving equations involves the use of the additive identity, multiplicative identity, or identity function gave the PSMTs an opportunity to identify similarities in the structure of the identities corresponding to different binary operations. The instructor often juxtaposed the identity function with the additive and multiplicative identities to lead the PSMTs to think about the identity was associated with inverse functions. This gave the PSMTs an opportunity to recognize the similar structure of the various identities as the result of operating two inverse elements together. The PSMTs' development of the connections among these concepts during class involved reasoning about the inverse group axiom and reflecting on the similar structure of each of the identities, $0, 1$, and $i(x) = x$. This likely helped the PSMTs recognize $0, 1$, and $i(x) = x$ as instantiations of the same identity concept and unify them into a coherent Identity Schema.

Discussion

Wasserman (2018) suggested that teachers' abstract algebra knowledge can potentially become useful for teaching if it helps reshape their understandings of the algebra content they teach. Drawing on Lee's (2018) extend-deepen-unify-strengthen framework, I explored this reshaping of PSMTs' understandings as they reflected on connections between group axioms and the structure of the identity function. I examined how PSMTs deepened their understanding of the identity function and unified various identities under the overarching identity structure as they engaged in a Mathematics for Secondary Teachers course. The first finding revealed that the PSMTs deepened their understandings of the identity function from not having a conception of it to developing process or object conceptions. One PSMT conceptualized the identity function as a function that leaves its input alone and as the result of composing inverse functions. The other two conceptualized the identity function as x, the output of $f(f^{-1}(x))$, instead of a function. The participants' conceptions of the identity function are similar to the do-nothing function (DNF) reasoning or net do-nothing function (net-DNF) reasoning documented by Bagley et al. (2015). These authors claimed, "the process of pushing an arbitrary element through the function and its inverse and observing that the net result is no change… can allow students to come to see the result of composition of a function… and its inverse as a function…in its own right" (p. 45). Derek was successful in reflecting on the result of composing inverse functions to develop an Object conception of the identity function (i.e., do-nothing function). However, Amelia and Christina reflected on the result of composing inverse functions and demonstrated net-DNF reasoning, but they conceptualized the output x as the identity instead. Thus, the findings of this study provide additional insight into students' conceptions of the identity resulting from a composition of functions as the function $f \circ f^{-1} = i$ or the output $f\left(f^{-1}(x)\right) = x$. Future research can address how students transition from Process to Object conceptions of the identity function.

Another finding was that the PSMTs unified the additive identity, multiplicative identity, and identity function as instantiations of the same overarching concept by reasoning with the group axioms. They all could identify that the different identities were the result of operating two inverse elements together with the group's corresponding binary operation. Reasoning about how the inverse group axiom applied to various inverses and identities in secondary algebra contexts allowed them to make these connections among the different identities and thereby develop a more coherent Identity Schema. The PSMTs had opportunities in their course to develop this understanding. Implementing class discussions of how the cancellation procedure in equation solving involves the use of the various identities helped the PSMTs identify similarities in their structure. I, therefore, suggest that teacher educators should ask PSMTs to explicitly identify which properties from abstract algebraic structures are used in each step solving an equation.

Epistemological Tensions in Applying Culturally Relevant Pedagogy to Undergraduate Mathematics

Nissen Education Research and Design

Communities of practice are rich places to learn new practices and refine existing practices. Mathematics schooling has been racialized and inequitable to minoritized groups and learning how to teach mathematics in culturally relevant ways is one potential way to address the needs of students who have been systemically ignored. We found from analysis of ten interviews with mathematics instructors at Hispanic-Serving institutions that two central barriers to enacting culturally relevant pedagogy in undergraduate mathematics instruction are a lack of communicating about students' identities and holding epistemologies that mathematics is a culture-free discipline. For the community of mathematics instructors to incorporate more culturally relevant pedagogy, first, it needs to become safer to talk about students' racial and gendered identities and, second, culturally relevant tasks that leverage mathematical tools in nontrivial ways need to be developed.

Keywords: Hispanic-Serving Institutions, Professional obligations

Mathematics has been given a high-status position as an academic subject in the United States school curriculum (Berry et al., 2014; Schoenfeld, 2004). Students' mathematical performances have influence over their future academic and economic opportunities (U.S. Department of Education, 2008) and their social access and mobility (Schoenfeld, 2004), and can be interpreted as an indication of one's intelligence (Shah, 2013). Scholarship in mathematics education has revealed how K-16 mathematics education is inherently racialized and inequitable and has a long history of ignoring the needs of minoritized groups (Berry et al. 2014; Gutiérrez, 2017; Martin, 2019). Mathematics functioning as an important subject for access and social status, yet systematically discriminating based on race, is a toxic combination. Given this perpetuated inequity, *Culturally Relevant Pedagogy* (CRP; Ladson-Billings, 1995; 2014) has been regarded by education researchers as a way to empower minoritized students and update the mathematics curriculum (Brown-Jeffy & Cooper, 2011; Morrison et al., 2008).

Ladson-Billings (2014) described CRP as teaching that helps students achieve three outcomes: (1) *academic success*, "the intellectual growth that students experience as a result of classroom instruction and learning experiences"; (2) *cultural competence*, "the ability to help students appreciate and celebrate their cultures of origin while gaining knowledge of and fluency in at least one other culture"; and (3) *sociopolitical consciousness,* "the ability to take learning beyond the confines of the classroom using school knowledge and skills to identify, analyze, and solve real-world problems" (p. 75). These are also known as the three *tenets* of CRP. She explained that undertaking this way of teaching is a long-term commitment to give students the education they deserve and to create the future society we want to live in (Ladson-Billings, 2006).

Enacting all three tenets of CRP requires attention to students' cultures and identities. For example, helping students understand how mathematics relates to their own culture and real-world situations relevant to them requires that the instructor knows what cultures students identify with and what sociopolitical issues are relevant to them. Identity research in mathematics education has drastically increased in recent years (Darraugh, 2016). However, it has largely been split into research done on the identities of learners and on the identities of instructors (Darraugh, 2016; Graven & Heyd-Metzuyanim, 2019), without much attention to how instructors are thinking about or incorporating student identities in their practice. We contend that understanding of how instructors consider student identities in their instruction is key to understanding if or why they enact CRP. We do not define identity ourselves, but explore how instructors at Hispanic-serving institutions (HSIs) perceive identity as playing a role in their instruction.

Instructors at HSIs are well-positioned to serve a critical mass of historically underserved students but can also replicate the existing inequities if they rely on their disciplinary enculturation to shape their pedagogical choices. Institutions with at least 25% Hispanic full time student populations can apply for HSI status (U.S. Department of Education, 2021). Hubbard and Stage (2009) found few differences between HSI faculty and their faculty counterparts at predominantly White institutions in terms of perceptions and attitudes towards teaching and students. It is unclear whether or how instructors are attempting to serve their increasingly diverse student populations. Shifts in demographics (Laden, 2004) have left many institutions without clear direction about the implications of being an HSI. This study investigates CRP enactment at HSIs and what barriers might currently exist to its implementation in mathematics classrooms.

Theoretical Framing

An integral part of changing and developing one's teaching practices is involvement in a *community of practice* (Wenger, 1998). We employ this framework to give a lens as to how mathematics instructors might change their practice to incorporate more CRP, or what might be preventing such change. The community of practice framework begins with the premise that learning is fundamentally a social activity that involves participation in the context of a given community. Wenger (1998) continues that communities of practice are not only places for individuals to learn but are especially rich places for new insights to be transformed into knowledge. Participants can bring their own unique experiences to generate the creation of knowledge within a community: "A history of mutual engagement around a joint enterprise is an ideal context for this kind of leading-edge learning" (Wenger, 1998, p. 214). As instructors become increasingly aware of their shifting student populations and the inequities that students experience, there is an opportunity to learn (as communities of mathematics instructors) new ways to serve those populations. However, little is known about if or how mathematics instructors at HSIs think about students' cultures and identities.

With this community of practice framing of learning, we ask the following research questions: (1) *To what extent are the three tenets of CRP being used by mathematics instructors at HSIs?* and (2) *What barriers might communities of mathematics instructors at HSIs face to enacting CRP?*

In a community of practice, meaning is negotiated in two primary ways. First, community members make meaning through *participation* by taking part in the actions and interactions associated with the social community and, second, through *reifications* of those participatory actions. Participation happens by doing, acting, teaching, and interacting, while reification refers to the product of giving concrete form to the shared experiences. For example, a lesson plan, a definition of CRP, or an abstract formula could all be reifications. Reifications are like the tip of the iceberg, where the iceberg represents what the community counts as meaningful. For change to happen in a community of practice, the way meaning is negotiated must change. We suspect that two substantial barriers in the community of undergraduate mathematics instructors correspond to the duality of participation and reification.

Ignoring Culture in Identities and Mathematics Reifications

Discussions around some aspects of identity can be inadequate to nonexistent. This is not unique to mathematics or even education, but deeply ingrained in history. In the United States, legal documents used the language of "colorblindness", intending to indicate that they treated humans as equal regardless of their color (Annamma et al., 2015). While initially intended to portray that the policies should be applied equally *regardless* of race, the language began to be used to indicate that the policies should instead *ignore* race (Annamma et al., 2015). In education, this color-evasiveness[1] in school policies has led to policies at odds with factors that center on race such as where students go to school, access to resources, and categorization into certain academic programs (Wells, 2014). The extent to which instructors currently recognize or ignore racial identities seems like valuable information for HSIs to better serve the large percentage of Hispanic and other minoritized student populations.

The second potential difficulty is how the mathematics community's reifications reflect an abstractness that some mathematicians see as culture-free. Non-applied mathematics, or 'pure' mathematics, is often about removing context and finding the most generalizable universal rules. In doing higher level pure mathematics, not only do mathematicians remove the real-world application of the problem, they also generalize to other non-Euclidean spaces (e.g., hyperbolic geometry). Framed by topology, a coffee cup and a donut have identical properties. Rabin et al. (2021) facilitated a collaboration between chemistry, biology, physics, and mathematics instructors to try to streamline how mathematics is presented and applied in sciences. Doing the work, the science instructors noted that "mathematicians' thinking is too abstract, context-free, or ungrounded in reality" (Rabin et al., 2021, p. 8). Thus, there could be a tension between the context-free reifications of mathematics problems and focusing on students' contexts to teach the mathematics that would be applicable to issues relevant to their lives.

Methods

We used a stratified random sampling technique to identify the institutions we invited to participate in this study. This paper is based on a larger study of 40 interviews with STEM instructors, ten of them with mathematics instructors from eight different HSIs. Participants represent a range of institution categories (associate's=4, master's=1, doctoral=5) and locations (East=1, Midwest=1, Southeast=1, Southwest=5, and West=2). The mathematics instructors

[1] Preferable term to color-blindness, which equates a form of racism to an unavoidable disability (Annamma et al., 2015).

self-identified their gender (women=6, men=4) and race (Caucasian=2, Indian=1, Latin White=1, Latina=1, South Korean=1, White[2]=4).

We coded the transcripts for enactments of the three tenets of CRP (academic success, cultural competence, and sociopolitical consciousness), evidence that identity did or did not play a role in their practice, and evidence of the epistemology that their field was culture-free, as defined in Table 1.

Table 1. Code names, descriptions, % agreement, and kappa scores (Cohen, 1960).

Code	Description	% Agreement	κ
CRP: Academic Success	Expresses the intent or willingness to take into account students' backgrounds, cultures or identity to set them up for academic success.	82.2%	0.63
CRP: Cultural Competence	Expresses the intent or willingness to set students up to understand things relevant to their own or other students' cultures.	93.3%	0.37
CRP: Sociopolitical Consciousness	Expresses the intent or willingness to help students use the discipline to develop the skills to critically "identify, analyze, and solve real-world problems" that tie to sociopolitical issues that directly impact the students being taught.	100%	undefined
Culture of no culture	Evidence that they believe that culture is somehow absent or neutral in their discipline.	93.5%	0.66
Identity: YES	There exists evidence that they intend or would like to take into account student identity in their teaching practice. Identity was operationalized as how instructors' interpreted it.	50.2%	0.42
Identity: NO	Considers student identity as not playing a role in their practice.	84.4%	0.61

The first author coded the full set of interviews. The codes largely applied to responses to the questions, "Do the identities of students who enroll in that course influence your approach or the way you teach it? If so, how?" and, "How would you describe the culture or climate for students in your department in terms of supporting their identities?" To check reliability, the two remaining authors coded responses to those two questions for 20 of the 40 interviews. Our agreement was at least moderate for all codes (Landis & Koch, 1977) except CRP: Sociopolitical consciousness and CRP: Cultural competence because there were so few instances.

Results

[2] In this publication, we capitalize all races, including White, emphasizing that there is no default race and that they are all social constructs with associated sets of cultural practices.

Instructing with Culturally Relevant Pedagogy

We coded these examples of academic success as CRP only when instructors specified that they did them on account of students' backgrounds, cultures, or identities. For example, altering assessment for all students would not be considered enactment of CRP. The instructor said he changed how he viewed and conducted assessment while explaining that his students are 50% Hispanic and often parents. As an example of how he changed assessment practices, instead of giving a poor participation grade to a student who kept missing class, he instead tried to proactively reach out to the student and communicate about what was going on. He made this change after switching from a non-HSI to an HSI.

We found that, of the ten mathematics instructors we interviewed, eight enacted CRP in ways consistent with the academic success tenet, two with the cultural competence tenet, and one with the sociopolitical consciousness tenet (see Table 2). The tenet of academic success was enacted through speaking to students in Spanish, making sure they had resources available (e.g., textbooks, calculators, online materials), maintaining high academic standards, taking personal responsibility for students' success, directing students to extra tutoring, reviewing more background content, recording lectures and making class notes available, modifying examples to be more inclusive, changing assessment, and making sure that minority students' voices were heard.

Table 2. Percentage (and number) of participants that gave evidence of enacting tenets of CRP.

Evidence of	Mathematics (*n*=10)	Total (*n*=40)
Culturally relevant pedagogy: Academic Success	80% (8)	75% (30)
Culturally relevant pedagogy: Cultural Competence	20% (2)	23% (9)
Culturally relevant pedagogy: Sociopolitical Consciousness	10% (1)	3% (1)

The two examples of the cultural competence tenet were showing the film Hidden Figures to familiarize students with more representation and talking about how politics spilled over into class. The example of the sociopolitical consciousness tenet came from a mathematics for future teachers course in which students read a special education article with the goal of helping them think critically about how what they were learning would apply differently to a marginalized group of people.

Barriers to Cultural Competency and Sociopolitical Consciousness

We found two main barriers to undergraduate mathematics instructors learning to teach with CRP, especially pertaining to the cultural competency and sociopolitical consciousness tenets: (1) lack of communication around student identity and (2) limited perspectives on what the mathematical community counts as disciplinary knowledge.

Barrier 1: Communication around student identity. For communities of practice to learn, they need to negotiate meanings with each other. However, we found a cautiousness around the language needed to communicate about race. When asked, six out of ten instructors stated explicitly that student identity does not play a role in their teaching. Yet we found evidence that seven of the ten instructors did incorporate identity in their teaching. Three of the instructors did so while explicitly denying it.

The only three student identities instructors explicitly said *do not* impact their teaching were gender, race, and nationality. Some instructors did say or show that gender and race influenced their teaching, but for many instructors, it seemed like they had a concern with making assumptions based on race and gender and preferred labels that had more direct implications. Other labels instructors used when they explained ways they changed their teaching on account of students' identities included first generation, English-language learner, international student, socioeconomic status, mathematics experience, caregiver, and age. For example, an instructor said, "I think of them as individuals, but not necessarily as identities, if that makes sense. So given the fact as far as you know, their color, their gender or anything else, you know, it's all the same to me in a sense when I teach." Moments later, however, she explained how if students were not native English language speakers it would impact how much work students would have to do to decipher the context of statistics problems.

Even when instructors said race played a role, they also emphasized the importance of not making assumptions based on these labels. Samuel, a mathematics educator, said, "Things like race, gender identity, first generation, they all sort of get boiled into building this relationship with the individual students. I don't want to [...] assume that because they're a first-generation student, they're gonna struggle with X, Y, Z." He did not want to make assumptions about the student based on the community that student might belong to, because he did not know how that individual had experienced the things associated with that community.

Barrier 2: Mathematics as culture-free. Two of the ten mathematics instructors viewed mathematics as a culture-free discipline. Instructors were never explicitly asked about their opinions on whether their discipline was culture-free or not, so it is possible that more instructors felt similarly. One other instructor expressed that, while she believed mathematics was culture-dependent, other instructors in her department did not. To instructors with this culture-free epistemology, mathematical knowledge could be viewed independent of race and gender. For example, Francesca said, "We don't see a color or sex or anything. We see a raw being that you can teach mathematics to. Mathematics has no color." She continued, "You look at something like the ocean and the color currents in it. And you know that those are all governed by mathematics. And, you know, many, many forces. And that's just nothing about ethnicity in it." Kyung Joon similarly expressed that the sciences are more neutral than other subjects.

Holding this culture-free epistemology does not appear to be wholly incompatible with enacting CRP or incorporating student identity into their teaching. Both instructors that expressed culture-free epistemological beliefs concerning mathematics also enacted the academic success tenet of CRP. Francesca held high academic standards for students especially when she taught racially diverse students and took personal responsibility for each students' success. Kyung Joon did extra review of background content for students who were struggling financially or had poor high school preparation. We found evidence that Francesca incorporated student identity into her teaching while we did not for Kyung Joon. Francesca said that students of different ethnicities had minds that understood things differently and all were capable of understanding - it was a matter of finding the right way to explain it so a student would be able to understand.

However, instructors holding culture-free epistemologies might be more hesitant to enact the cultural competence and sociopolitical consciousness tenets of CRP. Neither Francesca or Kyung

Joon found it necessary to enact any aspects of those two tenets. Kyung Joon explained, “If the math professor used K-pop as an example, or some Korean barbecue, they wouldn't make the math problem easier or more understandable. To me it's not really that relevant in math courses.” He said that not only is it not relevant to use such cultural examples, but also it can come off as insulting. Thus, we found that if instructors believed mathematics is culture-free, they did not see a need to teach how the content is relevant to students’ individual cultures nor how mathematics might be used as a tool to critique or solve sociopolitical issues relevant to students.

Implications and Conclusion

We found evidence that many practitioners in the community of mathematics instructors at HSIs already enact the academic success tenet of CRP, and there are two primary barriers to enacting the other two tenets. First, to communicate about students’ cultural contexts in a community of practice, conversations about aspects of identity must become more normalized. That instructors have difficulty talking about students’ racial identities is not evidence that instructors do not care about the cultural context of their students. Rather, it is a misguided but well-intentioned color-evasiveness or a desire to avoid essentialization of students (Gutiérrez, 2013). Race is politically charged, and we live in an era where the wrong publicly stated comment can ruin careers (Ronson, 2016). The implication for the mathematics community is that it must become a lower-risk place to talk about race and the role it has in doing mathematics. Dr. Loretta Ross advocates for calling people in rather than calling them out (Bennett, 2020). She proposes the idea that publicly shaming is a toxic, non-productive response. Instead, she advocates leaning into the discomfort of having a conversation and talking to the person directly with compassion and assuming they bring good intentions.

The second barrier to enacting CRP was perceiving mathematics as culture-free, corresponding to the issue that reifications of mathematics often reinforce that mathematics is free of culture. While holding these culture-free epistemologies did not prevent enacting the CRP tenet of supporting students’ academic success, the two instructors did not see reason to teach how mathematics could be relevant or applicable to students’ cultures or to sociopolitical issues relevant to them. For instructors like Kjung Joon who only could think of cultural applications that were surface-level, content-specific resources might make a difference in their enactment of CRP.

The findings suggest three implications for communities to start creating and sharing culturally relevant content that goes beyond helping students achieve in traditional ways. First, mathematics instructors can improve communication with each other about students’ racialized and gendered identities. Doing so is messy and political, so when instructors, departments, and universities inevitably say problematic things, they need to learn how to teach each other rather than shame each other. Second, if mathematics instructors are more comfortable talking about more concrete student characteristics (e.g., first generation, low socio-economic status), those identifiers could still be useful for understanding what issues might be culturally relevant. For example, calculus can be used to understand issues of minimum wage, student loans, or COVID growth/decline rates; these are nontrivial applications that can be taught before instructors work to communicate about gender and race. Moreover, if mathematics instructors would like to avoid making assumptions about a given individual, instructors can design teaching that is culturally relevant for a population of students in their course without assuming anything about the identity or culture of any specific student. For example, something related to Hispanic culture broadly would contribute to the cultural relevance of the course for everyone, whether they identify with the aspect of Hispanic culture involved. Third, a community effort must go into developing content that is relevant to both the students' lives and the mathematical tools learned in standard courses like the calculus series. With the practical time constraints on full- and part-time faculty, it would be unrealistic to expect everyone to create materials to enact CRP on their own.

Key Aspects in the Development of a Quantitative Understanding of Definite Integrals

Courtney Simmons
Florida State University

This work draws on the framework of Emergent Quantitative Models to identify how calculus students might develop a quantitative understanding of definite integrals that supports them in modeling activity when the differential from is not a multiplicative product between a rate of change and a differential quantity (e.g. gravitational force). To characterize the mental activity that supports the productive development of a quantitative understanding of definite integrals I engaged students in an eight-week teaching experiment.

Keywords: emergent models, quantitative reasoning, calculus, definite integrals

Introduction

Research has shown the majority of students primarily reason about the definite integral in terms of either prototypical imagery (e.g. area beneath a function, above an x-axis, and between two boundary lines at $x = a$ and $x = b$), or purely algorithmic and non-quantitative ways (e.g. antiderivative). Over the past two decades, a growing body of research has identified that connecting definite integrals to Riemann sums and quantitative reasoning provides students with robust ways to reason about contextual tasks (e. g. Merrideth and Marongelle, 2008; Jones, 2015; Sealey, 2014). These studies have primarily focused on constructs in which the differential form is a local Riemann product—a multiplicative product between a rate of change and a differential quantity. However, limiting students' definite integral reasoning to local Riemann product structures has been identified as potentially inadequate for a successful transition to other STEM coursework in which the integrand does not naturally decompose into a rate of change or density, such as gravitational force (Oehrtman, 2015). This study aims to contribute to the mathematics education field by offering insight into the question:

> *How can calculus students develop an understanding of definite integration that supports the quantitative reasoning necessary to productively engage in definite integral tasks in which the differential form does not naturally decompose into a local Riemann Product?*

Literature Review & Frameworks

Quantitative reasoning encompasses the mental actions in the conceptualization of quantities and relationships between quantities. By quantities, I mean the measurable qualities of objects which are formed by individuals engaging in a dialectic between an object, an attribute of that object which is of interest, and a way in which to measure that attribute to solve a problem (Thompson, 1990, 2012). As part of the experimental design, I drew on Realistic Mathematics Education which views modeling as an integral aspect of what it means to do mathematics and sees "mathematics as a human activity" where experientially real problems play a crucial role. Realistic Mathematics Education is a domain-specific instructional theory originating out of the Netherlands with three central design heuristics: guided reinvention (Freudenthal, 1973), didactical phenomenology (Freudenthal, 1986), and emergent models (Gravemeijer, 1999).

In line with Gravemeijer's approach to modeling as an emergent process, Simmons and Oehrtman (2017, 2019) described an Emergent Quantitative Models framework for students' reasoning about definite integrals. This framework extends previous characterizations of students' reasoning about definite integrals when the differential form does not naturally decompose into local Riemann Product and can be utilized to understand, for example, how students reason about physics-based tasks. The framework relies on three conceptual models, basic, local, and global, which students draw on when reasoning about definite integrals.

> The basic model represents the quantitative relationship which would apply to the situation if the quantities involved were constant values, the local model is a localized version of the basic model applied to a sub region of the original situation (typically within a partition), and the global model is derived from an accumulation process applied to the local model, whose underlying quantitative reasoning is encoded in the differential form (Simmons & Oehrtman, 2019).

Through an analysis of students' emergent models while productively engaging with physics-based integration tasks, Simmons & Oehrtman characterized a *Quantitatively Based Summation* (QBS) symbolic form (Sherin, 2001; Jones, 2013) for the definite integral. This symbolic form associates the symbolic template $\int_{[A]}^{[\boldsymbol{B}]}[C]$ with an underlying conceptual schema in which A and B are the values representing the beginning and end of the measure for the quantity defined to be the differential respectively and C represents an algebraic representation of the local model which shares a quantitative structure with the basic model of the desired quantity. The construction of the symbolic template for the differential form $[C]$ involves a recognition that variation of a quantity makes the basic model inappropriate, a partitioning and accumulation process based on a parts of a whole symbolic form, and coordinates of the accuracy of global and local models as dependent upon the magnitude of a differential quantity.

Methodology

The epistemological underpinning of this study is that of Piaget's genetic epistemology (1972; Piaget & Duckworth, 1970). From this perspective, knowledge is an adaptive construct of human minds which is actively created consistent within an individual's conceptual structure through interactions with the outside world. Because the QBS symbolic form was identified as productive for students' reasoning for contextual integration tasks, this study aimed to engender the development of this conception through an eight-week teaching experiment (Steffe & Thompson, 2000). Unlike a clinical interview, where the goal is to capture students' understanding at a particular instant in time, the goal of a teaching experiment is to characterize the development of students' schemes as those understandings evolve to test hypothesized learning trajectories.

For the teaching experiment, I recruited six freshman students during their first-semester calculus course at a large southwestern university. The interviews began two weeks before the introduction of Riemann sums. Due to the longitudinal nature of planned follow-up studies, I requested all Fall 2020 introductory calculus instructors submit recommendations for students appropriate for a year-long study based on the engagement in the course. Due to the large time commitment, students were compensated $20 per hour for participation. Students were matched into groups of two based on availability.

Due to social distancing restrictions in Fall 2020, I interviewed and recorded study participants through the Zoom platform. There were two types of interviews throughout the eight-week teaching experiment: paired (approximately one hour) and individual (approximately a half-hour). Both types of interviews were planned to take place twice a week for a total of 3 hours per week in interviews per participant resulting in over 70 hours of video recordings. Most weeks all interviews took place as planned. At the end of the teaching experiment, I engaged participants in a series of task-based clinical interviews in which they were asked to model physics-based tasks in which the differential form was not a Riemann product. During paired interviews participants worked on tasks while talking with one another through zoom and writing on a collaborative online whiteboard, AWWApp.com. I asked clarifying and directive questions while transitioning between responsive/intuitive and analytical interactions as the students progressed through the tasks.

The data was analyzed in two phases: ongoing and retrospective. After each interview, I refined my models of the participants' understandings. This involved taking notes during and after each group interview, noting significant interactions, and reviewing clips before conducting the follow-up individual interviews. Follow-up interviews provided an opportunity to test my hypothesized models of participants' reasoning, build a more coherent image of their evolving schemes, and let students elaborate on constructs they might not have provided enough detail on in group interviews. When I developed specific hypotheses regarding students' reasoning that would not be investigated through the normal course of the hypothetical learning trajectory, I designed and introduced supplementary prompts and tasks which I provided to groups and/or individuals on an as-needed basis. After the teaching experiment, I reanalyzed all data using constant comparative analysis (Clement, 2000) with the MaxQDA analytic software. This analysis included refining the hypothetical learning trajectory and conceptual analysis based on additional passes through the teaching experiment data which characterized participants' emergent quantitative models. Follow-up reviews of the dataset were performed to identify episodes that supported, or refuted, my evolving image of the participants' schemes until I felt that the data was no longer able to provide additional nuance. I concluded with a cross-comparison between the emergent quantitative models of the different groups to identify commonalities and distinctions between participants.

As part of the data collection, there were limitations to conducting the teaching experiment online. First, the need for participants to have access to a computer, high-speed internet, and a web camera placed a potential handicap to the generalizability of the results. Participants needed to have access to a private computer with internet access for at least three hours a week which means it is likely participants in this study were of above-average socioeconomic status. Online interviews also limited the ways I could capture students' reasoning that would normally be evident in gestures, demeanor, and written work. By only viewing students' upper bodies I often missed out on slight hand movements, fidgeting, and quick scribbles made as they were problem-solving. Additionally, slow internet connections sometimes resulted in choppiness in videos and an inability to clearly identify what the participant was relaying. Finally, due to recruitment, it is possible the participants in might not be an accurate representation of the general calculus population. These students were handpicked by their professors as being highly engaged and likely to succeed through to the next calculus course. There also may have been implicit biases in the instructors' recommendations which affected the outcome of the final participant population.

Results

For brevity, this paper will focus on the key aspects of the conceptual development of quantitative understanding of definite integrals for a single group, Ashley and Adam, over the first two major tasks of the six-task teaching experiment sequence which adds nuance to the Emergent Models framework as participants' emergent models were in development.

Ashley was a Caucasian female statistics major pursuing a minor in music. Adam was a Caucasian male architectural engineering major. Both Ashley and Adam took a calculus course in high school and agreed that it felt like they had "missed the last half of calculus" due to

COVID which included integration topics. They both demonstrated an inclination to rely on procedural knowledge without giving much thought to the underlying mechanics in their initial clinical interviews. Ashley and Adam worked well together and were open about their thinking throughout the teaching experiment. As a result, I developed a detailed image of the precise development of their basic, local, and global models (and relationships between models) as they constructed a quantitative understanding of definite integrals.

The Development of a Gross Basic Model and Global Model

In the Curiosity Rover task, students were presented with the goal-orientated activity, in four parts, of identifying whether a rover would complete its mission on Mars. The task provided specific readings for rates of dust accumulation at different geographic locations and had a limitation that the rover could not continue operating when it had over 400 mg of dust on its solar cells. Students were provided a GeoGebra applet with a slider that presented data for specific sites which included location, total distance along the path from the landing site, composition of the Martian surface, and the corresponding rate of dust accumulation. The Curiosity Rover task was chosen and adapted due to its ability to provide a meaningful context which motivated the need to identify an overestimate using an accumulation of local estimates. The conception the Curiosity Rover task aimed to engender most closely represents a finite Riemann Sum, however, no formal summation notation or language was introduced.

I presented Ashley and Adam with prompts requesting rates of dust accumulation at different sites, the measured distance between sites, and how one could identifying the approximate amount of dust on the rover's solar cells as it traveled between sites. Early in the task, I prompted Ashley and Adam to identify an overestimate for the amount of dust that would accumulate on the rover as it traveled between two neighboring locations which did not share identical rates of dust accumulation. As they were discussing the task Ashley observed,

> *Ashley:* So, if we're traveling. The rover is traveling. And, at the beginning, it's kind of getting dust at six milligrams per kilometer, but slowly, by the end of it, it's only getting dust at 3.5 milligrams per kilometer. So, this rate is going to be decreasing. Like, if we were to draw a graph. You know what I'm saying? So, I think it's wanting us to overestimate. Like, for example, a gigantic overestimate for this problem would be 6 times 30. If we just say, well, it just keeps the 6 milligrams rate the entire time it travels, times 30, which is the kilometers, you know, we would get like, what 180? That would be like a massive overestimate because we know it changes because the soil changes. And then like, obviously, an underestimate would be the opposite to do it by 30 times 3.5.

That is, Ashley extended her basic model of [rate of dust accumulation]·[distance]=[total amount of dust] to what I describe as a *gross basic model*. A gross basic model represents directly applying a quantitative relationship that holds for constant quantities (a basic model) to a quantitative relationship in which one, or more, of the quantities is varying. An important aspect of a gross basic model is the recognition that the quantity obtained is only an approximation, and that the varying quantity within the gross basic model must be bounded (either above or below depending on the desired approximation).

From here, Ashley was able to construct a global model for the total dust on the rover along longer paths through the additive accumulation of gross basic models; "So basically, we can take from Darwin to Cooperstown [the next segment along the rover's path], find our overestimate of that, and then add it," and Adam agreed "yeah, it's just a bunch of intervals."

Increasing the Accuracy of a Global Model Through Refinement

A key aspect of the hypothetical learning trajectory was to have students construct their conception of a definite integral as a tool that would aid in precise approximation when one, or more, quantities of a basic model is varying. To that end, the Curiosity Rover task was designed so that additional data points provided more accurate underestimates and overestimates of the total dust obtained along the rover's journey. The initial applet displayed data for 7 major sites, a subsequent applet adjustment allowed students to see data for the midpoints between sites, and a final applet, with an accompanying spreadsheet, provided additional readings every 2.5 kilometers for a total of 65 data points. Until the third applet, it would remain unclear if the rover would be able to complete its journey on Mars.

After Ashley and Adam computed overestimates and underestimates for the initial 7 data points, resulting in a range of 295.75mg to 471.25mg of dust on the solar panels, they reported that they would not feel safe sending the rover to Mars. In response, I provided the second applet with a comment that an intern managed to obtained more data. When asked if this would help, Adam suggested that it would because they could calculate "another set of intervals… how we did intervals last time, right. Yeah, it's the exact same thing, just with more of them, because we can use the midpoints." Ashley added, "yeah, we could make an even more precise over and underestimate, and see how far away from 400 that is… to see how much our recommendations need to change." This anticipation that the difference between the overestimate and underestimate could be reduced by additional data would serve as a crucial component of Ashley and Adam's development of a local model in the next major task.

The anticipation of an increasingly more accurate global model through additional datapoints was put to the test when a computational error resulted in a larger overestimate value than 471.25mg. Adam was dissatisfied because the increase in the number of partitions "didn't really narrow the interval [difference between the underestimate and overestimate]" and that "the smaller value [the underestimate] should have gotten a bit bigger and the bigger value [the overestimate] should have gotten smaller." That is, Adam was already operating with the expectation that more intervals equate to a more accurate result and that this phenomenon should act "kind of like limits that should approach the actual [value]." After writing out the expression on the shared whiteboard, Ashley identified Adam's error and they moved on to the final phase of the Curiosity Rover task. To make quick computations Ashley and Adam multiplied each rate of dust accumulation by 2.5km (the distance between each reading) and added those values together to obtain a single answer of 381.7mg. Adam conjectured, "All right, so that is, umm. Is that just an estimate of the actual?...Yeah, cause that's not an over-under." However, because the question prompts continued to situate students' goal-oriented activity toward identifying both an under and overestimate, Ashley remained perturbed. Drawing on her earlier correction of Adam's overestimate, she recognized that the last term in their computations would represent an underestimate for the total amount of dust on the rover if it only traveled the last 2.5 km of the journey. She explained,

> *Ashley:* Because if we add up, okay, let's see, two minus, okay 65. Because 65 times 2.5 is 162.5, and see, we have 65 cells here and our total distance is only 160. So, whenever we just look at this, this is too much distance. That's why you have to subtract one or the other to get your over and underestimate….So the underestimate is gonna be 364.7, and the over will be 381.25. Since we've narrowed it to that interval, we know that the rover

should be able to handle the load of the milligrams of dust.… That's exciting! This is exciting, our rover works! At least according to our spreadsheet math.

The Development of a Local Model from a Gross Basic Model

In the second major task of the teaching experiment I tasked Ashley and Adam with identifying over and underestimates for the total fluid force exerted on both rectangular and trapezoidal dams. The Fluid Force on a Dam task was situated so that identifying over and underestimates was in service of providing parameters that allowed a superior to minimize the total cost of the dam. I included this task early in the teaching experiment sequence because (1) it provided students an opportunity to reason about non-Riemann product quantitative structures as their basic-local-global models were in development, and (2) provide a challenge to those students who may have already constructed a scheme for integration that was based in antidifferentiation or consistent with schemes for the differential as a Riemann product.

After engaging Ashley and Adam with a supplementary activity aimed at familiarizing them with the basic models involved in fluid force, I prompted them to identify estimates for the total fluid force that would be exerted on a rectangular dam. Unsurprisingly, Ashley and Adam directly applied a gross basic model to the entire dam to obtain over and underestimate values. Following this, I requested Ashley and Adam improve their estimations based on a supervisor's feedback to partition the dam into two pieces. This prompt was aimed at extending Ashley and Adam' gross basic models from discrete to continuous data in which they perform the partitioning and measurement process. That is, this prompt encouraged Ashley and Adam to explicitly construct a local model to measure the force on each half of the dam which required them to reason about the quantitative relationships involved in their basic and global models. After dividing the dam into two, Adam attempted to add the overestimate of the fluid force on the top half of the dam, to the overestimate for the fluid force on the entire dam. However, with an expectation of the global model being more accurate with more data and upper bound provided by the gross basic model estimate, Ashley observed, "If we add the same thing [the value of the whole dam] it [the total force] gets bigger instead of smaller." This expectation positioned Ashley to determine that the overestimate for local models should only reflect the largest pressure multiplied by the local elements area.

The Development of a Generalized Local Model

After correctly identifying overestimates and underestimates Adam actively anticipated the next steps in the sequence, commenting, "So, I guess just to kind of look ahead. Are we just going to keep breaking this up into smaller parts and adding these together to get narrower?... We did that before." In response, I had Ashley and Adam identify over and underestimates for a partition with 5 elements, before asking them to find the number of pieces they would need to break the dam into to identify estimates within 50,000 Newtons of the actual value. This request would require a significant shift in reasoning, as the correct answer was well over 8000 peices. Intuitively, Adam recognized that it would "be an insane amount of intervals to add" and went on to suggest, "I was thinking, I guess if there's some way to relate depth and force kind of like we already have but an equation, then we could use that equation to kind of get a more accurate feel for the estimations," and Ashley asked, "Do you want to write a formula… using a tool to compute it?" As Ashley and Adam began trying to construct a formula Ashley observed, "we know we're just multiplying area times depth times 9800, right? And then we're adding that again. We're just going to keep going for each interval that we decide to do." That is, Ashley recognized that each element within a global model shared the same quantitative structure. I provided Ashley and Adam a GeoGebra applet to compute their desired sum using their local model expression. During their initial 'guesses' Adam and Ashley explicitly worked out the value for area before wondering aloud if there was a way to automatically compute height, I informed them that the calculator was designed to accept Δx as the height. The timing of the introduction of this notation allowed Ashley and Adam to coordinate that the Δx element within a local model was a quantity that remained constant across elements of a global model, but whose magnitude was dependent upon the number of elements within the global model (i.e. the value varies across different partitionings). I characterized this mental activity of generalizing quantitative structure across elements of a global model as a *generalized local model*.

The most obvious outside behavior Ashley and Adam engage in as part of their development of a generalized local model was the algebraic representation of this activity. However, as a generalized local model become a more engrained aspect of their emergent model system, they drew on this same mental activity to anticipate the applicability of a partition for a global model. That is, in later tasks within the teaching experiment, if they could not notice meaningful variation across a fixed partition quantity, then they looked for alternative partitionings.

Discussion

As a result of this teaching experiment, I contribute two constructs to the Emergent Quantitative Models framework, which offer explanatory power and instructional implications for the development of a QBS conception of integration. I created the *gross basic model* as a part of the experimental task design to engender students' goal-oriented activity towards identifying estimations for a whole through the direct application of a basic model. In support of generating a global model as an accumulation of elements of the same quantitative type as the basic model, I engaged students in the act of progressive addition of gross basic models to create a global whole. This positioned students to create a local model, as a new construct, through an accommodation of applying a gross basic estimate to a partitioned element of a global model.

A *generalized local model* is a result of the mental activity students engage in as they generalize the structure of a local model across elements of their global model and was identified as a critical element in the evolution of students' emergent models. This construct is a result of the mental activity students engage in as they make comparisons across elements of their global model to coordinate which quantitative components vary and which remain fixed. In this study, the genesis of a generalized local model emerged from students' need to create an explicit formula for their local (or global) model which would allow them to identify the value of any element of a partition, for any size partition, in service of identifying the number of partitions necessary to be within a given tolerance. The mental activity required for such an activity is cognitively distinct from that of computing explicit values for partitions through a measurement process and is at the crux of the difficulty in students' ability to productively model complex quantitative situations using definite integrals.

Robert Ely
University of Idaho

This work is drawn from a larger study on student conceptions in a Calculus course designed to promote quantitative understandings of definite integrals. For one student, we investigate the evolution of conceptions of definite integral applications. We pay particular attention to quantitative and non-quantitative interpretations of the differential as they emerge or disappear in unexpected ways. Implications for instruction and future research are considered.

Keywords: calculus, definite integral, differential, quantitative reasoning

Introduction & Literature Review

Students' reasoning about differentials has been of continued interest to mathematics and physics education research due to its importance in the fundamental understanding of derivative and integral concepts in STEM. In the area of integration particular interest has been paid to whether students interpret differentials as simply a cue for an antiderivative process (e.g. Merrideth and Marrongelle, 2008; Jones, 2013), as an infinitesimal quantity (Ely, 2017), as a width of a representative rectangle used in identifying graphical area (e.g. Jones, 2013), or as a physical quantity (e.g. Thompson & Silverman, 2008; Merrideth and Marrongelle, 2008; Sealey, 2014; Author, 2017, 2019). Physics education researchers Von Korff and Rebello distinguished different categories for differentials based on size, macro (Δx) and micro (infinitesimals dx) (2012), as well as different types of differentials, change and amount (2014). Amount differentials are distinct from a typical $x_2 - x_1$ computational change approach due to some quantities not being productively conceived of in terms of changes, such as mass.

In most learning trajectories and textbook curricula, definite integral applications are initially limited to position-velocity-acceleration contexts, and other meaningful quantitative interpretations are placed well after learning the fundamental theorem of calculus and computational methods. This promotes the dominance of antiderivative and area under a curve conceptions amongst calculus students. Based on evidence promoting the productivity of quantitative interpretations of the differential form (e.g. Jones, 2015; Wagner, 2018; Author, under review), in recent years, emphasis has been placed on the study and development of calculus curricula which promotes a quantitative understanding of differentials, leading us to an obvious research question;

RQ: How do students reason about the differential after engaging in curriculum designed to produce a quantitative understanding of the definite integral?

Theoretical Perspective and Methods

Six students were recruited from an accelerated eight-week asynchronous online introductory calculus course at a large southwestern university. The learning trajectory for the calculus course was designed to engage students in the mental activity of developing a quantitative understanding of definite integrals distinct from area under a curve and antiderivative conceptions (Author, under review). To that end, modeling using accumulation with summations and definite integrals was covered early in the coursework, while topics related to antiderivatives and computational practices were not covered until the final two weeks (Table 1).

Drawing upon the heuristics of Realistic Mathematics Education (Gravemeijer, 1994, 1999), the course materials were designed to engage students in experientially real tasks which extended beyond simple reproductions of instructor examples, called "Your Turn" activities. Each week students were provided with approximately 3 hours of lecture videos. Within these lecture videos there were embedded "Your Turn" activities that accounted for approximately 60% of the course material. These activities were required to be turned in weekly as a part of their course grade. "Your Turn" activities were routinely referenced when new topics were introduced to allow students to reflect on their previous problem-solving activity as they learned new skills (e.g. Recall Your Turn X.X). For example, the lecture videos introduced the concept of using a definite integral to model work against gravity for building a cement column, and students were tasked with identifying the work against gravity to build a pyramid or to lift a chain to the top of the building. Once students learned the fundamental theorem of calculus they revisited all tasks from the accumulation section to rework those solutions by hand.

Table 1. Course learning trajectory topics broken down by week covered.

Week 1	Some Basics: Introduction, Quantities, and The Spread of Disease Accumulation: Introduction to Accumulation, Approximations using Sums.
Week 2	Accumulation: Continuously Varying Rates, Limits, Modeling with Definite Integrals – Geometry

Week 4	Rates of Change: The Derivative Rules, Techniques
Week 5	Rates of Change: Modeling - Basic Applications, Related Rates, Limiting Values, Differential Equations
Week 6	Rates of Change: Modeling: Extreme Values, IVT and Monotonicity, Concavity, Drawing Graphs, Applied Optimization.
Week 7	Bringing It All Together: Fundamental Theorem of Calculus Part 1, Antiderivatives, Fundamental Theorem of Calculus Part 2
Week 8	Bringing It All Together: Accumulation Functions

Data collected for this study included an introductory questionnaire which identified a baseline for students' understandings for calculus concepts, all written notes for the course (including "Your Turns"), quizzes, exams, written homework, hour-long task-based clinical interviews mid-semester (immediately following the accumulation section in Week 3), and a series of task-based clinical interviews post-final exam. The interviews were conducted through Zoom using an online collaborative whiteboard. Additionally, there were 25 required short surveys throughout the semester, one at the end of each subsection module, in which students provided immediate feedback regarding their evolving understanding of calculus constructs. Students who participated in the study were offered extra credit in the course, worth 1% of the course grade, as well as a chance to win a $10 gift card. Data was analyzed using the constant comparative method to construct a model of the participants' image of definite integrals at various stages of the course (Clement, 2000). Particular attention was paid to the mid-semester, and post-final exam task-based clinical interviews as these interactions provided the most nuanced data to inform our models of students evolving schemes for the definite integral and differential quantity.

Results

In this paper, we focus on a single student, John, from the larger dataset. John was a white, male, sophomore Chemical Engineering major who reported having taken at least half a semester of university calculus before enrolling in the Summer 2020 course. John reported that low quiz scores prevented him from achieving a satisfactory grade. In John's preliminary survey he did not provide quantitative interpretations of the definite integral notation, including the differential (Figure 1).

What does the expression $\int_3^7 f(x)dx$ mean?

the interval of the derivative of f(x) where x =3, 4, 5, 6, 7.

In the expression $\int_3^7 f(x)dx$, what does the dx stand for?

the derivative of

In the expression $\int_3^7 f(x)dx$, what does the $f(x)dx$ stand for?

the derivative of f(x) in relation to x

Figure 1: John's preliminary calculus survey responses.

During his mid-semester interview, John was presented with four tasks. The first task was posed as a general inquiry to explore John's image of definite integrals in the abstract, while questions 2-4 situated definite integral tasks within specific contexts. Throughout John's mid-semester interview he repeatedly demonstrated that his primary conception of a definite integral is an area under a curve. John viewed a definite integral as an infinite summation of rectangles with height the function value at a particular point, and width an infinitesimally small width of the horizontal axis. The aim of this summation was to identify a 'really good' approximation for the total area under the rate function. John's view of infinitesimally thin rectangles coordinated values for differentials that could be considered smaller than the size of a single atom with a non-finite summation process. For John the differential form $f(x) \cdot dx$ represented the height times the width of a single rectangle and when asked if you could leave off the differential off the differential form, John objected, "Oh no. Because that would just tell you, let's see $f(x)$ on the interval a to b… that would just be talking about the height of the rectangles, which you can see by the graph. You don't calculate area without having these widths here."

Watson is filling a huge beaker with water from a faucet. He is playfully turning the faucet up and down, so that the water's flow rate is continually changing. There is a flow meter on the faucet that tells him this flow rate $r(t)$, in ounces/sec, where t is measured in seconds after Watson first turns on the faucet.

What does $\int_3^8 r(t)dt$ mean?

Figure 2: Mid-semester task 2 – flow rate.

When presented with the Flow Rate task (Figure 2), John quickly identified that the definite integral measured the total ounces of water in the beaker which accumulated between 3 and 8 seconds. John justified his conclusion through a graphical area interpretation, stating,

> *John:* The area under the curve, which is the rate that the beaker is filling up with water and ounces per second, if we take the area underneath that, that tells us the total amount of ounces put into the beaker over the interval of three seconds to eight seconds after turning the faucet on.

John went on to describe that he was able to identify what the definite integral was computing through unit cancelation that he had learned in Organic Chemistry. In particular, $r(t)$ was measured in units of oz/sec and dt was "just seconds," so their product, $r(t) \cdot dt$, must be a measurement of oz. That is, John was intentional with regards to assigning the differential (dt) a quantitative interpretation, the width of a rectangle, as well as its associated unit which corresponded to the independent variable of time.

During the school year, the population density of a certain college town can be measured as a radial density,

$$\rho(r) = \frac{25}{\sqrt{1+r^2}} \ (in\ thousands\ of\ people\ per\ mile^2)$$

where r represents the distance (in miles) from the University. Write a definite integral that will identify how many people live within 4 miles of the University.

Figure 3: Mid-semester task 4 – population density.

In the following task, which required the construction of a linear rate of change function in service of writing a definite integral, John continued to associate an appropriate unit to the differential quantity while reasoning through a graphical area interpretation of the context. Task 4 of the mid-semester interview (Figure 3) was chosen because in prior studies, students with a primarily area under a curve or antiderivative conception of the definite integral were often unsuccessful in productively producing a correct definite integral expression due to the radial density function being provided in terms of a radial length, while the natural differential quantity for a Riemann product structure would be in terms of area. In this task, John was asked to identify the total number of people within 4 miles of a university center when provided a two-dimensional, one-variable population density function. John's initial strategy for solving Task 4 was to write an integral of the form

$$\int_0^4 \rho(r) \cdot \pi r^2 \cdot dr = \int_{[no\ radius]}^{[4\ miles]} [radial\ density] \cdot [area\ at\ radius\ r] \cdot dr$$

Notably, when not reasoning in terms of area under a curve, John's associated schemes for the summative properties of a definite integral were transferred to the integrand rather than the entire differential form. When writing out the units associated with each term John ascribed $\rho(r)$ the units $people/mi^2$, πr^2 the units mi^2, and the differential term dr no units. When the interviewer brought John's attention to the fact that in his solutions to the previous three prompts he had ascribed a unit to the differential quantity, John immediately correlated the differential quantity with a width of a rectangle;

> *John:* That's 100% correct… so if I'm going to be consistent. That should just be the width of like, er yeah, the width of how much it should be. So why did I put πr^2 there? This is a thinker. I believe what I wrote is correct but.… Okay, I'm sticking by what I said before, dr is definitely the width of the rectangle for the area underneath a curve.

However, John had not initially reasoned about this task in terms of area under a curve which caused him to reevaluate his differential form. When attempting to reinterpret the context with an image of the differential quantity as a width of a rectangle, John scratched out the πr^2 leaving just the radial density to act as the height of the rectangles. Although bothered by the fact that the units in his new expression, $\int_0^4 \rho(r)dr$, still did not produce 'people' as expected, John was unable to make further headway on the task.

Approximately two months later (two weeks into his next calculus course) John participated in a set of 3 post-semester interviews in which he was presented with additional contextual definite integral tasks. The first task asked participants to identify the total fluid force acting on a dam, while the second centered on finding the total kinetic energy of a rotating rod. Despite John's inclusion of a differential during his mid-semester interview, his post-semester interview solutions did not include such a quantity. It was hypothesized that the physical contexts of the tasks were in opposition to John's tendency to ascribe to the differential the quantitative interpretation of 'rectangle's width' impeding the need for its inclusion within the differential form. At the end of the second interview, the interviewer directly asked about the omission of the differential. John observed that "there should definitely be a dr," and attached the notation to the end of his definite integral expression. When asked if there should be units attached to the dr John replied "I don't think so. I think it's just telling the person looking at it that it's with respect to r," and then hedged "or it adopts the unit of whatever variable it is." When asked to explain John continued,

> *John:* I've never thought of it as having a unit. That would mess with our units at the end. I've never seen it do that. But the other train of thought I was thinking was because it's with respect to r, and r has a unit of meters… but I've never seen it mess with units before.

John's reversal of units being associated with a differential was unexpected. To investigate further, the interviewer provided John a much simpler context of distance as an integral of velocity over time, which could be more readily adapted to an area under a curve interpretation (Figure 4).

When fully wound, a toy car will travel in a straight line for just over 17 seconds. Its speed t seconds after it is released is $v(t) = 3\sin\left(\frac{t^2}{100}\right)$ m/s. What distance will the car travel during the first 10 seconds?

Figure 4: Post-semester task 3 – toy car.

Once again, John left off the differential quantity when writing a definite integral expression to the toy car task, initially providing the solution $\int_0^{10} 3\sin\left(\frac{t^2}{100}\right) t$. The inclusion of the extra t in the differential form was "because otherwise we'd just get velocity if we didn't multiply by another *t*." When asked to describe how the definite integral was able to use the expression in the differential form to find the total distance traveled, John noted "there definitely should be a *dt* there," appending the notation to the end of his expression. Like in the previous post-semester interviews John did not ascribe a quantitative meaning to the differential, even when the interviewer presented him with a graphical representation of the velocity function.

Looking for an indication as to why John no longer considered *dt* to be a quantity, even if just the width of a rectangle, the interviewer related the notation of the differential with the derivative language of 'change in *t*', and associated notation df/dt, which prompted John to re-associate the notation with the "size of the partition" that was the Δt in the summation representation of accumulation. Attempting to reconcile both meanings John reflected,

> *John:* That's just a wicked small number…. I've always just negated it. Because, I remember thinking about it this summer, about how it does have some effect but not really much. On like computing it at least.

Discussion

The case of John provides a glimpse into an unexpected outcome of engaging in curriculum designed to engender a quantitative understanding of the definite integral. Although during the mid-semester interviews John did not demonstrate a fully formed quantitative conception of definite integrals, he provided clear quantitative interpretations for the differential form as an area of a rectangle and ascribed units of measurement associated with each quantity of that product. When these infinitesimally thin rectangles were accumulated they would provide the area beneath a rate of change curve. That is, during the mid-semester interview John demonstrated a consistent area under a curve conception along with an image of computing the area using a Riemann sum approach which was reinforced by his organic chemistry unital analysis. For tasks that did not naturally lend themselves to a graphical interpretation (e.g. radial density) John was unsuccessful in constructing a definite integral which would model the situation. Because the course curriculum de-emphasized the correlation between area under a curve and definite integrals, only briefly covering the topic at the end of the accumulation section as motivation to transition to investigating rates of change, it is safe to assume that John entered the course with some pre-existing schemes for the definite integral as area under a curve.

The most interesting aspect of John's development was the lack of inclusion, or meaning, given to the differential at the conclusion of the semester even when directly presented with a graphical curve. John's recorded coursework notes did not provide enough detail into how his image of definite integrals and differentials adapted over time or when he began to negate any quantitative meaning for the differential quantity. Additionally, due to the asynchronous nature of the course and John's free admittance to relying heavily on an outside tutor throughout the semester, it was not possible to pinpoint the precise source of his conceptions. Even with these limitations, John's case provides potential instructional and research implications. First, similar to other studies, John's reliance on graphical imagery to reason about definite integrals limited his ability to reason about quantitative situations in which the integrand is not inherently a rate of change. Second, John's decision to 'negate' the differential because it is such a small number leads to implications for students reasoning about differentials as infinitesimal quantities. If students interpret phrases such as "negligible" as "unimportant" or "infinitesimal" as "insignificant" then they might be prone to disregarding the differential as having a quantitative interpretation which could prevent them from being successful in constructing definite integral expressions.

In John's case, even with a heavy emphasis on modeling using definite integrals in his course curriculum, an area under a curve conception remained persistent through his mid-semester interview, potentially hindering his ability to adapt to a more general quantitative interpretation of the definite integral. By John's post-semester interviews he only demonstrated reasoning about the differential as a meaningful quantity when interpreting the differential in terms of a macro-sized change differential through an interviewer's direct intervention. With the continued rise of students who take calculus courses in high school, before retaking the course in university, such a finding suggests that more research be conducted to identify how coursework designed to engage students in quantitative understandings of calculus concepts interplays with the primarily procedural and computational skills learned in their secondary education.

Constructing Linear Systems with Particular Kinds of Solution Sets

Jessica L. Smith
Florida State University

Inyoung Lee
Arizona State University

Michelle Zandieh
Arizona State University

Christine Andrews-Larson
Florida State University

Systems of equations are a core topic in linear algebra courses. Solving systems with no or infinitely many solutions tends to be less intuitive for students. In this study, we examined two students' reasoning about the relationship between the structure of a system of linear equations and its solution set, particularly when creating systems with a certain number of equations and unknowns. Using data from a paired teaching experiment, we found that both students favored the notion of parallel planes, geometrically and numerically, in the case of a system having no solution or infinitely many solutions. We also found that algebraic or numerical approaches were used as the main way of developing systems with a unique solution, especially in systems with more than two equations and two unknowns. Throughout the tasks, one student generally used geometric approaches and the other toward algebraic and numerical approaches.

Keywords: solution sets, linear systems of equations, Realistic Mathematics Education, paired teaching experiment, linear algebra

Systems of linear (SLE)equations are a fundamental topic of introductory linear algebra courses. Systems are one way to model relationships among multiple quantities (Smith & Thompson, 2007). Students from applied science, technology, engineering, and mathematics make up a dominant portion of those enrolled in linear algebra in the U.S. and Canada, and applications related to linear systems are an important component of their learning in this course (Andrews-Larson et al., in press). In applied contexts, SLE often do not have a unique solution, so in this work we focus on students' reasoning about SLE with non-unique solutions.

Students at a variety of levels have exhibited greater levels of success solving systems of linear equations with unique solutions as compared to solving inconsistent systems or systems with an infinite number of solutions (Harel, 2017; Huntley et al., 2007; Oktaç, 2018), and this has been linked to procedural and rule-based approaches to students' solving processes. Oktaç (2018), for example, found that interpreting the result "x=x" was not intuitive for students. Such approaches tend to be unhelpful to students when linking algebraic and geometric representations of systems and their solution sets. It has more recently been documented that, in the context of introductory linear algebra, though students are relatively successful at rewriting systems as augmented matrices and row reducing with technological assistance, many students experience a disconnect in reinterpreting solutions in relation to the original system (Zandieh & Andrews-Larson, 2019). In this paper, we identify resources in students' reasoning that may help address this disconnect, drawing on data from a teaching experiment. Our research question is: How did students reason about the relationship between the structure of a system of linear equations and its solution set, including their reasoning about the graphical representation of the solution set?

Theoretical Framing

In this paper we focus on how students symbolize systems of linear equations that have one, infinitely many or no solutions, and how the students relate their symbolizations to various graphical representations. In doing this we follow Larson and Zandieh (2013) who describe a system of equations as one way to symbolize a relationship between variables and scalars. They compare and contrast this symbolization to others such as a vector equation (a linear combination of vectors equaling another vector) or a linear transformation stated in function notation. Collectively they refer to these as interpretations of the matrix equation $A\vec{x}=\vec{b}$. Paired with these symbolic expressions are different graphical representations. For example, a system of two equations with two unknowns is depicted graphically as two lines with the intersection of the lines denoting the solution. In contrast a linear combination graphically is indicated by scalars stretching each of two vectors with the vectors being added in a tip to tail manner.

In a later paper, Zandieh and Andrews-Larson (2019) extend their work to symbolizations of augmented matrices and discuss how the solution(s) to a system of equations may be expressed using both implicit and explicit notation. For example, the statement of a system of equations to be solved is already an implicit description of the solution space. In this paper we focus on two students' growing recognition of how the components of the symbolic expression that implicitly describes the solution set (i.e., the system of linear equations) relates to the graphical inscriptions that illustrate the solution space.

Methods

This proposal reports findings from a paired teaching experiment (PTE) conducted as part of a larger NSF-funded project aimed at extending inquiry-oriented curricula in linear algebra. The task sequence was designed to support students' reinvention of ways to reason about solution sets to systems of linear equations (SLE). We conducted a task-based PTE with two students for four consecutive days on Zoom to see how students reason about solutions to SLE related to the task and how their reasoning evolved throughout the sequence of tasks (Steffe & Thompson, 2000). The participants we call Student R and Student L were undergraduate math majors also studying to be secondary teachers; one was a white woman and one a white man, respectively. They had no experience with linear algebra but had taken Calculus I at the time of the PTE. Two authors conducted the PTE with one leading the interview and the other taking notes and asking clarifying questions. We present findings from the last day of the PTE, in which students started working individually on the given tasks and shared their initial thoughts with each other. The leading interviewer prompted with questions about their thinking in the moment and leveraged their ideas to help them advance their mathematical thinking. While this proposal emphasizes the last day of the PTE, relevant results from the first three days are included in the task description to give readers the basic context of the instructional sequence.

The Day 1 and 2 tasks were designed to support students in reinventing the notion of large or infinite solution sets corresponding to a SLE. On Day 1, the students worked with a constraint of meal plans that included three variables, B, L, D (# of breakfasts, lunches, and dinners), where B+L+D=210. They used ordered *n-tuples* to organize a large set of solutions satisfying the constraint. On Day 2, the students made predictions about how the set of solutions to B+L+D=210 and 5B+7L+10D=1500 (an added meal plan constraint) would look geometrically. The students agreed the graphs of the two equations would intersect more than once because they found several solutions to both equations (for more details, see Smith et al., 2021b). Day 3 focused on graphing the two meal plan constraints in GeoGebra. This was the first time the students used GeoGebra in the PTE. Based on this work they concluded that each constraint constitutes a plane and the solutions found on Day 2 are on the same line where the two planes intersect. They were guided to the next task called "Intersections of Three Planes" (Wawro et al., 2013). Given the new SLE where the third equation is the sum of the first two equations, the students were asked to find the closest graphic from options (a) through (f), focusing on the intersection of the three planes. At first, they were not allowed to do any calculations nor use GeoGebra. The options consisted of graphics such as three planes having no intersection and intersecting at a point, line, or plane, as shown in Figure 1. Results from these tasks will be discussed in the next section.

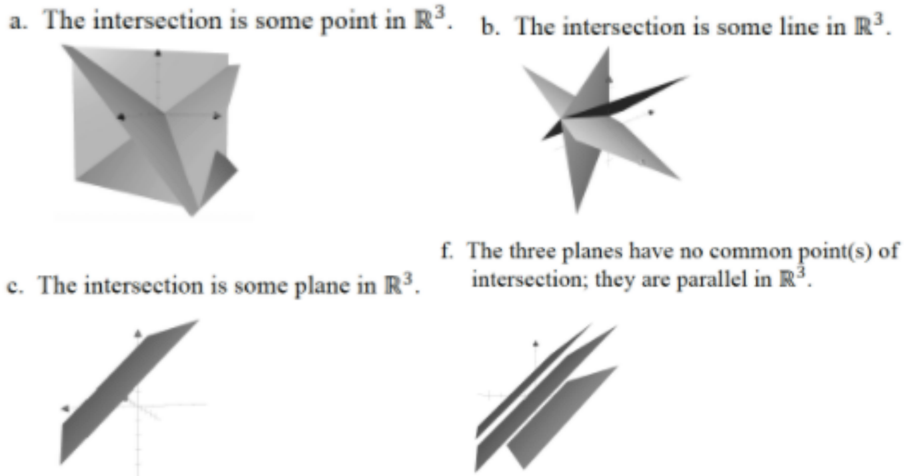

Figure 1. Examples of options in the Intersections of Three Planes task (Wawro et al., 2013).

On Day 4, the students continued to work on the Intersection of Three Planes task with a different approach. Using GeoGebra as an aid, they engaged in the activity to construct a SLE that looks like one of the options' graphics. The students started manipulating the given SLE (where the third equation is the sum of the first two) to satisfy the graphics. The students then worked on a task involving creating SLE that met a specified number of equations, unknowns, and solutions described in a table, called the Example Generation task. In this paper, we use abbreviations to report these more succinctly. For example, 2E2U refers to 2 equations and 2 unknowns and 3E2U refers to 3 equations and 2 unknowns. This task also included a prompt to make generalizations about SLE regarding the number of solutions, equations, and unknowns.

Our data sources include Zoom video recordings, students' written work, and field notes. The Day 3 and 4 video recordings were transcribed in spreadsheets. Two of the authors watched and reviewed the videos and transcripts and created reflective notes focusing on the students' reasoning about creating SLE with specific solution sets using an emergent coding method (Glaser & Strauss, 2017). We paid special attention to what students were referring to when reasoning about solutions, including students' attention to specific traits of the SLE as written and traits of its graph. We discussed the students' quotes and gestures that offered insight into their mathematical reasoning about SLE. Based on the findings, we were able to describe the differences and similarities between students' reasoning about SLE in relation to specified solution sets.

Findings

We found that Student R and Student L developed geometric and numeric strategies, respectively, for reasoning about parallel planes, and leveraged these strategies heavily in constructing systems of linear equations with specific types of solution sets. In this section, we illustrate how this strategy emerged from students' efforts to construct a system with particular visual characteristics in GeoGebra and provide evidence regarding how students leveraged these strategies to construct systems with no solution, unique solution, and infinite solutions -- even as the numbers of equations and unknowns in these systems varied.

Intersections of Three Planes Task

When working on the modified version of the Intersections of Three Planes task, students looked at scenario (a) in which three planes intersect at a point and initially noted that they did not think it was possible. Student R drew on her knowledge of systems of line equations by drawing three lines as a way to represent three planes to see if they could intersect in a point.

R: I didn't even think (a) was possible at first, but I drew out a picture of what I thought it could be. And I was like, maybe, I guess it is possible for planes to intersect in a point. But I thought only lines could intersect in a point.

Int (interviewer): Can you show what you drew? [Student R shows Figure 2] ... Tell me how you were thinking about what you drew.

R: I thought, these are lines technically, but I was like, even if they were extending, if they were all going different directions, then I just drew three random lines that all intersected only in the middle.

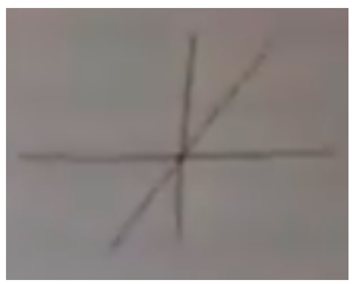

Figure 2. Student R's two-dimensional reasoning about three planes intersecting at a point.

Student (R) drew on her prior knowledge to make sense of a new type of intersection. She conjectured, through the lens of intersecting lines as shown in Figure 2, that it could be possible for three planes to intersect at a point. Both students revisited this idea in the Example Generation task.

The rest of this section will highlight students' initial reasoning with parallel planes that they used later in the Example Generation task. When starting the modified Intersections of Three Planes task, Student R stated that she initially thought the parallel option *"would be easier because… if you just double the values, then it'll be the same plane. But maybe if you manipulate the number that it's set equal to, to not be double, if you doubled the coefficients of the variables… [then] I think we can make the planes parallel."* She pointed out that every value cannot be multiplied by the same number, but parallel planes might be achievable by changing the constant by a different factor from the coefficients. While working on making three parallel planes, Student R referred to the "slopes" of the equations in terms of the coefficients in each. She reasoned that to make parallel lines they needed to create equivalent slopes in the equations, then expanded that reasoning to planes.

Int: So why do you think you have to make them the same for all of them?

R: If we want the slope to be the same, they all have to be multiplied by the same. I can't think of the words… We want the slopes to be there's a word that I can't think of, related…

L: Parallel. Yeah, related.

R: So like, if you change the coefficient of one number, it's no longer gonna be parallel because then the slopes of the equations aren't the same anymore.

Int: So like, what if your original equation was x plus three y plus z and you're trying to make one parallel by changing the coefficients? [Referring to L's eq7: x+3y+z=6]

L: ... like 2x+6y+2z is equal to like, whatever. I believe that would make it as well… Then, so then 2x+6y+2z=6.

Int: So you doubled one side but not the other. So it kept the slope the same.

L: Right. Exactly.

Both students reasoned that all the coefficients in an equation must be multiplied by the same number to have the same "slope" as the original equation. They said that if one coefficient is not multiplied, then the plane will no longer be parallel to the original. Once again, it was mentioned that the 'right side' (or constant) cannot be changed by the same amount as the coefficients.

The students used the parallel planes they had just developed to recreate a system consisting of two parallel planes with a third plane intersecting both. When asked about the number of solutions to the SLE, Student R relied on the fact that two of the planes are parallel and said "*Zero. Because two of the planes are parallel. And those are never going to have a solution that makes them both true.*" Student L came to the same conclusion but by reasoning numerically, stating, "*And also because you have x+y+z is two, and x+y+z is eight. So that doesn't really make sense either, because you can't have three numbers that equal two and also equal eight, when you add them together.*"

Overall, we found that students' previous knowledge regarding systems was essential to students' development of SLE in relation to graphical representations. Students wondered about the possibility of a unique solution for a system with three planes. Because they had never seen it previously, they explored this possibility by drawing on their knowledge of a system of equations in a 2-dimensional setting. The students developed initial reasoning for parallel planes, seemingly relying on what they knew about parallel lines. This reasoning about parallel lines and planes became a way for students to reason about systems with infinitely many and no solutions.

Example Generation Task

Constructing systems with no solutions. In this section, we will describe our findings regarding students' reasoning while creating SLE with no solutions. The students' work on the example generation task began in the context of 2E2U (two equations and two unknowns). In this case, the students started with one equation, x+y=3, and created another equation by multiplying each coefficient by two to get, 2x+2y=3. As they explained with planes in the previous task, the constant cannot be multiplied by the same number as the coefficients, or else the second equation is actually the same line as the first. When students subsequently worked to construct an example of a system with 3E2U with no solution, they added another parallel line to their previous example. The interviewer probed on whether this was the only way a SLE with no solution could be constructed.

Int: So would it have to be parallel?

R: I guess not. We could do like we just did with the last one we did with three variables. Maybe. That also has no solutions.

L: If it wasn't parallel, wouldn't they eventually come to a point or something?

R: Well, equation one and equation two are parallel. But if I change the third equation, instead of it being parallel as well, if I make it not parallel, then it's kind of like what we just did. How there's no solution because these two lines are parallel.

Student R mentioned their previous example in which there were two parallel planes and one plane intersecting the two, except with lines this time. The students used similar thinking to create a system of 3E3U with no solution with parallel planes.

Constructing systems with infinitely many solutions. When constructing systems of equations with infinitely many solutions, the pair began by working on the case with 2E2U. Student R created two copies of the same line by multiplying x+y=3 (equation one) by 2 and explaining, "*If we wanted infinitely many solutions, we can just do like 2x+2y=6 with equation one. And then they're the exact same line.*" The students used a similar process to construct a system of 3E2U and voiced that multiplying the second and third equations by some value is the only way they understand creating a system of lines with infinitely many solutions. Student L wondered, "*Is there? I'm not sure if there's another way to have infinitely many solutions*." When shifting to the cases with 2E3U and 3E3U, the pair leveraged their previous work, and created equations representing the same planes.

Constructing systems with unique solutions. In working to construct a system of 2E2U with a unique solution, Student L used a heavily numeric approach and started with one equation, found a viable solution to that equation, then created a second equation in which the previously viable solution satisfies. In other words, Student L started with the equation x+y=3 and a solution of x=2, y=1 and developed 2x+y=5 as a second equation. He explained, *"So I just used x+y is equal to three. And then I said, okay, x is equal to two y is equal to one. So, then I was just like, well, two times two is four plus that one is five. So that should give us the one solution. It'll be two, one."* The students only referenced the geometry of this SLE by describing (2, 1) as the point of intersection. In moving to 3E2U, Student L did something similar by building another equation based on a selected solution that satisfies the two originally developed equations: *"Just like how we did it with the, the two equations and two unknowns. I was just thinking, well, we have x+y is equal to three. And then if x is two, y is one. So then, in 2x+y, it would make it five. And then if you were to add like another one to just like another coefficient to that x, it would make it 3x+y. And now you just go to seven."* Once again, neither student explicitly referenced geometry as they built this SLE.

In shifting to the case with 2E3U, student L stuck with his numerical approach, presumably because it had been successful previously. Student R thought more geometrically, arguing that it was impossible for the system to have a single solution because two planes cannot intersect at a single point. She explained, "*When we were doing the algebra part of it, I was more like maybe there is only one solution. But because when you look at it, it's hard to just tell from the numbers. There's no way just to look at it and be like there's a million solutions. I know what they all are. But when you look at the graph, it becomes clear that there's no way that these two planes are going to ever intersect in just a point because they're planes. And there's only two of them."* Student L tried a guess-and-check method, but he later accepted Student R's justification because he could not find a system that had only one solution. In the case of 3E3U, the students questioned whether it was possible to have a single solution, thus revisiting their previous query. Their intuition told them that it was possible. They constructed the SLE in GeoGebra by creating two planes that intersect in a line and then added a plane that intersected that line at one point.

Making Generalizations

At the end of the interview, the interviewer asked students for generalizations about systems and their solutions. We found that both students attended to ideas they developed when reasoning about parallel planes, such as looking at coefficients and constants.

R: I would say pay attention to the **coefficients** and maybe look for like **how the equations could be maybe parallel… or how they're intersecting**… Parallel will tell you that there would be no solutions for the system.

L: I would also say, make sure to pay attention to the **constant**. So like whatever you're setting it equal to, x+y is equal to three. So for instance, it had no solutions, we know that the constant is just going to stay the same, because the lines are going to be parallel… The constant is going to change based on how the other equations change.

Student R eventually came to reason about the number of equations and unknowns, something that had not been deeply discussed previously. She stated, *"In the beginning, we were trying to find a solution to that system of equations that had only two equations and three unknowns. Now I know in the future, don't waste your time looking, doing substitution. It's not gonna work… Maybe because there's* ***more unknowns than equations****, you don't have enough information to use substitution or anything because there's not going to be a single solution. I don't know if that's true."* It could be that the design of the Example Generation task led Student R to connect that the reason two planes could not have one solution was because there were fewer equations than unknowns (along with her geometric reasoning), leading her to conjecture that there can never be one solution to a system with that trait.

Discussion

On Day 4 of the PTE, Student R generally oriented her reasoning around a geometric approach to make sense of no, unique, and infinitely many solutions. She predicted how the graphs of solutions would look as she modified the coefficients in the SLE and used the same strategy when constructing SLE in the Example Generation Task. On the other hand, Student L leveraged a numerical approach to reason about solutions to various SLE. He began by choosing specific tuples satisfying a first equation or concluded no solution by examining the coefficients and constants in equations. Then, the parallel graphics became sensible to him. The two students' different ways of reasoning seemed to reflect their interpretation of solution to SLE: It is the intersection of graphs [R] and the point(s) in the intersections of graphs that satisfies all equations in the SLE [L]. In the case of 2E3U, Student R's geometric approach allowed her to conclude that this type of system can never have a unique solution. She subsequently conjectured that this might be true in all cases where the number of equations is less than the number of variables. Throughout the task sequence, Student R's geometric reasoning was more useful in some cases, and Student L's numerical reasoning in other cases, but both students relied on their understanding of parallel lines and planes in many of the infinitely many and no solutions cases. This study demonstrates ways students can reason about solutions to SLE without having learned row reduction, pointing out potential areas for connections between students' prior knowledge and what is to be learned.

Function Metaphors Seen in Undergraduate-Mathematics Sign Language

Kaki Smith
Arizona State University

Michelle Zandieh
Arizona State University

In this study, two Deaf instructors and two American Sign Language (ASL) interpreters sign undergraduate mathematics terms and definitions. This study characterizes the types of metaphors present when the participants signed about the notion of function. We used a theoretical framework for characterizing the metaphor clusters students used in the unified notion for function to categorize the signed metaphors. We found the Mapping cluster to be the most common metaphor cluster used, and compared the different uses of an indicative sign of this cluster, MATCH, to show the differently conveyed meanings.

Keywords: deaf, sign language, metaphor, function

Deaf students are overlooked in many equity-based research projects along with other students with different abilities, specifically in STEM Education and Mathematics Education research (Schneiderwind & Johnson, 2020). American Sign Language (ASL) is the native language of the Deaf Community in the United States and most of Canada. It is not a one-to-one translation of the English language and maintains its own grammar structures and cultural significance (Lepic, 2015). Because of this, ASL is an important area to investigate in order to further the goals of increasing equitable research with regards to d/Deaf and Hard of Hearing (DHH) students. ASL also has regional differences throughout the states.

The structure of ASL lends itself to different affordances than spoken language because of its three-dimensional modality (Lepic, 2015). Thus, the study of ASL communication in mathematics not only has potential benefits for DHH students, but it also has potential benefits for non-DHH education in expanding our insight into language use and communication issues about mathematical concepts. In this paper we draw on research into metaphor in spoken English language and consider how these constructs might apply to ASL. This has overlap with other research on iconicity of signs in mathematics contexts.
