Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-fifth annual Conference on Research in Undergraduate Mathematics Education in Omaha, Nebraska from February 23 - February 25, 2023.

The 25th RUME Conference enabled presenters and attendees the option to participate fully online such that travel was not a requirement, approximately 25% of participants were online.

The program included plenary addresses by Dr. Warren Christensen, Dr. Natasha Speer, and Dr. Hortensia Soto and the presentation of 151 contributed, preliminary, and theoretical research reports and 69 posters. The conference was organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in undergraduate mathematics education, each underwent a rigorous review by three or more reviewers:

- Contributed Research Reports describe completed research studies
- Preliminary Research Reports describe ongoing research in early stages of analysis
- Theoretical Research Reports describe new theoretical perspectives for research
- Posters may fall into any of Contributed, Preliminary, or Theoretical and were presented in poster format. Authors contributed the poster itself, a summary of the work, or both.

The conference was hosted by the University of Nebraska – Omaha's Department of Mathematical and Statistical Sciences. Many members of the RUME community volunteered for the Program Committee where they reviewed many submissions such that every submission was reviewed by at least one member of the Program Committee. The Program Committee aided us in putting together this program and their hard work is greatly appreciated. The Local Organizing Committee were responsible for the smooth running of the presentations and on-site activities, which would not have been possible without the help of many volunteers, and we thank them for their tireless efforts to host a conference that runs smoothly.

Thank you to all of the researchers who submitted such strong proposals and ultimately made the conference a fun and joyous event.

Applying Proof Frameworks Is Harder for Students than We Think

In order to overcome difficulties many students in mathematics and computer science face with rigorous proofs, some higher education institutes present a "Mathematical Reasoning" or "Transition-to-Proof" course. In this paper, we analyzed data from the exams of 310 students in such a course, focusing on the way they approach a proof regarding set inclusion, and whether they use a particular "proof framework" that we taught them when doing so. We found that the students are able to use the proof framework, and that using it is beneficial to them, but that a surprisingly large percentage of them fail to use it consistently.

Keywords: Transition-to-proof courses, Proof frameworks, Operable interpretations of definitions

Introduction

One of the challenges mathematics instructors face is teaching their students to write correct rigorous proofs and to use the definitions properly. Between 1990 and 1999, more than 100 papers have been published on this subject (Hanna, 2000). The question of how students engage with proof and proving is continuously being studied (Reid and Knipping, 2011). These studies have suggested various explanations for the root of the problem, and proposed a variety of methods for addressing it, which have been tested with varying degrees of success. One common conclusion is that the transition from an intuitive answer to the rigorous formulation is one of the students' main sources of difficulty. Vinner (1991), for instance, claims that students tend to ignore the definitions necessary for a rigorous proof, preferring an intuitive "general explanation" answer. Moore (1994) supports this assertion, noting that, while attempting to write formal proofs, students do not necessarily understand the content of relevant definitions or how to use them.

One of the ways institutes deal with this issue is by having students take an "introduction to proof" course. Most such courses emphasize helping students learn the proof construction process (see in particular, Selden, Benkhalti and Selden, 2014 and Moore, 1994). This paper presents data collected in the context of the course "Mathematical Reasoning" - a mandatory course for first year computer science undergraduates. Specifically, our study focuses on the manner and extent to which undergraduate students employ - or fail to employ - a "proof framework" while proving a theorem. The concept of the proof framework was first introduced by Selden and Selden, 1995, and later expanded upon (2014). Similar ideas were presented by Scheinerman, 2013, who refers to it as a "proof template," and Hammack, 2013. In this paper we focus on one specific framework, used for proving set inclusion according to the definition. We analyzed 310 students' answers to questions that require this proof and discovered that a large percentage did not consistently use the proof framework, even when they had presented the ability to apply a very similar proof framework in an earlier part of the question, and despite the fact that this was the only technique they had learned for dealing with a question of that sort.

Proof Framework

Selden, Selden and Bankhalti (2018) define *proof frameworks* as "a way of structuring a proof, in which the student begins by writing the first and last lines of a proof and works towards the middle. It often consists of a first level, in which a student unpacks the logical structure of the theorem statement to write the first and last lines of the proof, and a second level, in which a student unpacks the definitions involved in the conclusion to write the second and second-to-last lines of the proof" (Selden, Selden and Bankhalti , 2018 p.4). To illustrate this point, they provide a sample proof framework for an elementary set theory theorem, which we have copied in its entirety here:

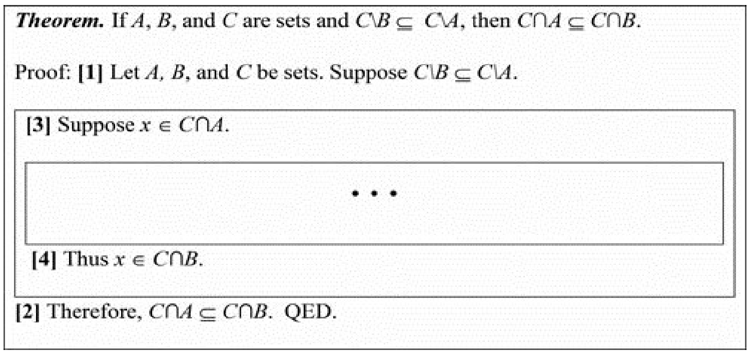

Fig. 1. Proof framework of set inclusion

Clearly, a theorem regarding set inclusion should start with an element that belongs to the included set, and by a sequence of steps ends with the result that the element belongs to the including set. In their study, Selden, McKee, and Selden, 2010 discuss the habits of mind that appear to drive many mental actions in the proving process, and discuss the way feelings can help cause mental actions and also arise from them. They offer the following example of a wrong "proof," in the form of Sofia's answer to the following theorem.

Theorem: *For any sets* A, B, C *if* $A \subseteq B$ *then* $(A \cap C) \subseteq (B \cap C)$.
Sofia's Proof: (Selden et al., 2010, p.13) Let A, B, C be sets
Suppose $x \notin A, x \in B$ *and* $x \in C$
Then $x \notin (A \cap C)$, but $x \in (B \cap C)$
Therefore $(A \cap C) \subseteq (B \cap C)$

We were curious **how common** the approach presented by Sofia might be - namely starting wrong, such that it is impossible to produce a proof from that starting point. These authors' study presented insightful qualitative findings, based on a deep analysis of a small sample. Our study is based on an analysis of hundreds of students' exams, which allowed us to produce, in addition to qualitative findings, some interesting quantitative results. Our primary goal was to understand whether students who fail to present a rigorous proof do so because they do not use the proof framework that we teach them, or because they use it incorrectly.

This information is important in order to improve teaching: Should we be placing more emphasis on the use of the proof framework (i.e. encouraging the students to use it), or putting more effort into the details of the framework itself (making sure that the students use the framework correctly)? It is also interesting to check whether students who do not use the framework (i.e. students who use other proof techniques) are doing well. If we see that using the proof framework does not result in better proofs, compared to other techniques, this might indicate that the effort invested in sticking to a proof framework is redundant, or even harmful.

Our Course

Much like other Transition-to-Proof courses elsewhere (e.g. Selden, Selden and Bankhalti , 2018), our reasoning course is based on students practicing the act of proving. We cover basic classical mathematical concepts and proving methods: The role of definitions, quantifiers, proof by contradiction, dealing with cases, and induction. We rehearse these concepts and methods throughout the course. The course contains only elementary mathematical concepts: arithmetic, basic set operations, and basic linear algebra. It consists of 3 hours of weekly lectures, with an emphasis on independent practice and homework. In every lesson, we solve the homework given in the previous lesson. The students are encouraged to present their proofs in class, and get feedback from the teacher. This usually takes the first half of the lesson, and the second half is dedicated to a method of proving, explained and followed by many examples. The students are first year, first semester, computer science undergraduate students, and the course is designed to help them develop the skill of proving, which is needed in later courses such as Linear Algebra, Calculus, Data Structures and Algorithms. In each genre of proof, we introduce the students to a proof framework (see Section II for details) as a way of getting started writing proofs.

The Study

We teach in one of the largest colleges in the country, and our students have high grades in the acceptance exam and in the matriculation exam in mathematics (significantly higher than the average).

Around 300 students are enrolled in the "Mathematical Reasoning" course every year. When dealing with **basic set theory** we stress that:

1. When proving $A \subseteq B$ one should start with 'Let $x \in A$' and end with 'then $x \in B$'.
2. When proving $A = B$ the technique is to prove that $A \subseteq B$ and that $B \subseteq A$, using the framework of set inclusion.

We chose a non-covid cohort, where all lectures and the exams were frontal (i.e. not via zoom). The class took place between October 2019 and January 2020 and was divided into 5 groups of around 60 students. We analyzed the students' responses to a multi-part question on basic set theory given in the course's final exam. Our goal was to analyze the use of the proof framework in students' answers, specifically: did students use the proof framework that we taught them? If so - did they use it correctly or did they merely write something that looks like the framework but is actually totally wrong? If not - were they able to present a rigorous and correct proof without depending on the proof framework?

The exam question that we analyzed began with a "definitions" section requiring the students to present definitions that were taught during the semester. Specifically, we were interested in the correct definitions of inclusion and equality of sets. The "definitions" section was followed by two "proof" sections, in which the students were asked to prove or disprove certain claims (that were actually both true). We will later refer to the two proof sections as the "first" and "second" proofs. Here is the question (summarized, for brevity):

1. (10 pts) For A, B sets define $A \backslash B,\ A \cap B,\ A \cup B,\ A \subseteq B,\ A = B$
2. (12 pts) Prove or disprove according to the definitions:
   For sets A, B, C, $(A \backslash B) \backslash C = (A \backslash C) \backslash (B \cup C)$
3. (12 pts) Prove or disprove according to the definitions:
   For sets A, B, C, $C \subseteq A$ if and only if $(A \cap B) \cup C = A \cap (B \cup C)$

The "definitions" section is important as it requires the students to recall the correct definitions needed in the proof sections. In the analysis, we set aside the exams of those who did not write the definitions correctly, based on the assumption that we cannot expect students who are not able to present the definition of inclusion correctly to prove inclusion correctly (only a handful of students failed to correctly answer the definitions section, likely because this section is repeated every year).

The first proof is a set equality. This requires, by definition, a bi-directional inclusion. We expected the students to use the proof framework twice, once for each inclusion. The first starts with $x \in (A\backslash B)\backslash C$ and ends with the conclusion that $x \in (A\backslash C)\backslash(B \cup C)$, and the second does the same, but in the opposite direction. Since the question required the students to prove by definition, using set identities was not allowed. However, the students *could* also legitimately prove each of the directions by contradiction.

The second proof is an "if and only if" claim. One direction of the proof required students to prove an inclusion, and the other required them to prove a set equality. We expected the students to use the proof framework three times. Here, as well, proof by contradiction is considered "according to definitions", and was accepted as a correct answer, although it is not based on the proof framework. Note that there are altogether *five* inclusions to be proved: two of them for proving the first proof, and three for proving the second. The students saw at least four examples of very similar questions in class and solved five more similar questions in their homework assignments, which were solved in class after submission. In addition, every exam in the course from past years contained a question of that sort. When analyzing students' answers for the first and second proofs, we first focused on whether the student implemented the proof framework in the answer, to determine the extent of the phenomenon of students not applying the framework. We categorized the students' answers according to the following taxonomy:

1. **Correct use:** The student followed the proof framework correctly.
2. **Misuse:** Presenting incorrect use of the proof framework, (i.e., starting the proof of inclusion by inspecting an element which does not belong to the included set).
3. **No use - right:** Not following the framework and using another technique, however the solution was correct (e.g., proof by contradiction).
4. **No use - wrong:** The student did not follow the framework and used another technique, and the solution was incorrect.

If the student skipped the proof sections of the question or tried to disprove it (for both proof sections, the correct answer was proving), we marked this as well.

Findings

We analyzed 310 exams. We focused on the students who wrote the definitions correctly, meaning they knew that the definition of inclusion $A \subseteq B$ is that every $x \in A$ holds that $x \in B$, and that the definition of $A = B$ is that $A \subseteq B$ and $B \subseteq A$. 10 students failed to write the definitions correctly and were filtered out of the study. A perfect usage of the proof framework consisted of 5 uses, as the first proof required two inclusions to prove an equality and the second proof was an iff proof that required proving three inclusions. Therefore, within a single exam, it was possible for each student to sometimes use the framework right, sometimes use it wrong, and sometimes not use it at all. We started our analysis of the proof sections by inspecting the first proof, which asked the students to prove or disprove an equality (see Table I).

The results seemed promising. A large percentage of the students indeed used the framework we had taught them, and a very large percentage out of those received all the points for that part. It is interesting to note that only two students tried to prove by contradiction, which is allowed (it is considered as proving "according to the definitions"). However, their overall answer was not perfect and they did not receive all the points.

TABLE I
SUCCESS RATE FIRST PROOF

	Num	percentage
Failed on the definition part (out of)	10 (310)	3.2%
Disproved or wrote nothing	2 (310)	0.6%
Correct definition and attempted to prove	298 (310)	96.1%
Two correct uses	274 (298)	91.9%
Received all points (two correct uses)	224 (274)	81.7%

There were two conclusions we could draw right away:

1. Almost all students are **familiar** with the framework for set inclusion.
2. Almost all students know how to prove an equality between sets.

Having established that, and encouraged by the students' success in the first proof, we continued to check the second proof, where we found a drastic drop in framework use. Recall that the second proof is an iff claim with one side being an equality and the other side a single inclusion. Hence, we expected the proof to contain three inclusions. However, fewer than half of the students met this expectation by using the framework three times, as shown in Table II.

TABLE II
SUCCESS RATE SECOND PROOF

	Num	Percentage
Failed on the definition part (out of)	10 (310)	3.2%
Disproved or wrote nothing	26 (310)	8.3%
Correct definition and attempted to prove	274 (310)	88.3%
Three correct uses	125 (274)	45.6%
Received all points (three correct uses)	72 (125)	57.6%
At least one by-contradiction (no-use-right)	34 (274)	12.4%
Received all points	12 (34)	35.3%

The results were surprising. We expected that students who were able to use the proof framework correctly in the first proof could do that again in the second proof as well. It is important to note that the numbers clearly show that using the proof framework is potentially beneficial, with a success rate of 81.7% for part one for those who used the framework (compared to 0% for those who did not use it), and a success rate of 57.6% for those who used the framework in part two (compared to 35.3% for those who did not use the proof framework in the second proof). Having noticed the difference in the percentage of framework use between the two proofs, we proceeded to count the number of students who had shown familiarity with the framework (i.e., used it at least once), but who did not use it all the way through the exam. This finding is presented in the first row of Table III. Then we counted the number of students who used the framework perfectly on the first proof (two "correct use"), but made at least one misuse in the second proof, starting with an element belonging to the set in the hypothesis rather than an element in the included set. This finding appears in the second row of Table III. Both numbers (33.5% and 28.5% respectively) seem to be very high, and point to a difficulty in assimilating and implementing the proof framework, even when you have shown that you know how to use it.

TABLE III
CORRECT AND INCORRECT USES

	Num	percentage
At least one correct use and at least one mistake (out of)	100 (298)	33.5%
Two correct uses in first part and at least one misuse in second	78 (274)	28.5%

TABLE IV
MISTAKES IN BOTH PROOFS

	Num	percentage
First proof At least one misuse (out of)	3 (298)	1%
At least one no-use-wrong (out of)	20 (298)	6.7%
Second proof At least one misuse (out of)	85 (274)	31%
At least one no-use-wrong (out of)	39 (274)	14.2%

The large difference in the number of correct usages of the framework between the first proof and the second is especially striking, as can be seen in the differences between Table I and Table II. This overwhelming difference drove us to look deeper into the answers to the second proof. Two findings arose from that inspection:

1. We first ruled out the effect of the "iff". It turned out that **all** the students who attempted to prove the second part but did not follow the framework wrote that there are two directions to be proved. This means that they correctly addressed the iff part of this proof.
2. The second proof, as opposed to the first one, had a hypothesis. Many students began their answer with an element belonging to the set in the hypothesis rather than to an element in the included set. This was found to be the most common "misuse" of the framework.

In order to conjecture about the reasons for the difference between the two proof sections, we asked ourselves how many students made the mistake of using the framework wrong ("misuse") or not using it at all ("no-use-wrong"). The results are presented in Table IV. The type of "misuse" employed by many students in the second part, which included a hypothesis, reflects a problem described in Selden et al., 2010 as "*Students who focus too soon on the hypothesis.*" There can be several explanations for this common phenomenon. Our conjecture is that the students have not yet acquired the habit of relying on the proof framework, and it does not come naturally to them, so they were distracted by the existence of a hypothesis. Another possibility is that the effort of being strict while solving the first proof was followed by a "loosening" later in the exam. The evident conclusion, however, is that whatever the reasons, applying the framework is harder for many students than we may think.

Examples

In this section, we present snippets from actual exams, focusing on the approach taken.

A. Adam

Adam's answer demonstrates a **correct use** of the framework, 5 times as expected:

1. Prove / disprove according to the definitions: For sets A, B, C, $(A\setminus B)\setminus C = (A\setminus C)\setminus(B \cup C)$.
   We will show a bi-directional inclusion. Let $x \in (A\setminus B)\setminus C$ [...] then $x \in (A\setminus C)\setminus(B \cup C)$.
   Now let $x \in (A\setminus C)\setminus(B \cup C)$ [...] so $x \in (A\setminus B)\setminus C$.
2. Prove / disprove according to the definitions: For sets A, B, C, $C \subseteq A$ if and only if $(A \cap B) \cup C = A \cap (B \cup C)$
   We will prove the two claims.
   - First, assume that $(A \cap B) \cup C = A \cap (B \cup C)$ and we will prove that $C \subseteq A$. Let $x \in C$ [...] and also $x \in A$.

- Second, assume that $C \subseteq A$. To prove $(A \cap B) \cup C = A \cap (B \cup C)$ we will prove bi-directional inclusion [...]
  - First, let $x \in A \cap (B \cup C)$ [...] it holds that $x \in (A \cap B) \cup C$.
  - Second, assume that $x \in (A \cap B) \cup C)$ [...] so $x \in A \cap (B \cup C)$.

We proved bi-directional inclusion so by the definition of set equality it holds that $(A \cap B) \cup C = A \cap (B \cup C)$. We proved both iff directions so this completed the proof.

B. Liam

Liam's proof for the first part was perfect, but in the second part, trying to prove equality between sets, he *focuses too soon on the hypothesis*. This is an example of a **misuse**.

[...] Let us prove that if $C \subseteq A$ then $(A \cap B) \cup C = A \cap (B \cup C)$.
According to the definition of equality we will show a bi-directional inclusions.

1. We prove that $(A \cap B) \cup C \subseteq A \cap (B \cup C)$ -- Let $x \in C$ [...]
2. We prove that $A \cap (B \cup C) \subseteq (A \cap B) \cup C$ -- Let $x \in C$ [...]

C. Sean

Sean, like many others, knew that to prove inclusion he should start with an element that belongs to the included set (he did this perfectly in the first part). However, instead of starting with $x \in C$ he started with an x that belongs to one of the sets in the hypothesis:

[...] Assume $(A \cap B) \cup C = A \cap (B \cup C)$ and prove that $C \subseteq A$. Let $x \in (A \cap B) \cup C$ [...]

D. Rita

Rita's proof of the first part was also perfect. However, in the second part she omitted the framework altogether. Her answer is an example of **no use - wrong**:

Let A, B, C be sets. We want to prove that if $C \subseteq A$ then $(A \cap B) \cup C = A \cap (B \cup C)$. By the hypothesis that $C \subseteq A$ it holds that every element that belongs to C also belongs to A. Let us look at the set $(A \cap B) \cup C$ the set of elements that belong to A and also to B, or belong to C. Now let us look at the set $A \cap (B \cup C)$ This set contains the elements that belong to A and to B or the elements that belong to A and to C. Combining the two, and according to the hypothesis, it holds that $(A \cap B) \cup C = A \cap (B \cup C)$.

Conclusions

Our examination showed that most students are able to use a proof framework correctly and that using a proof framework is potentially beneficial (i.e., significantly raises the chances of presenting a correct answer). However, we also discovered that students who were able to present a correct use of the proof framework in one question suddenly failed to use the same framework in a subsequent question. Analyzing examples of answers, we saw that many students neglected the framework that they had been using in the previous question, while others continued to use it, but incorrectly (starting with an element that belongs to the wrong set). This can be attributed to several reasons. At first glance it may seem that the 'iff' added a measure of difficulty to the question, but our analysis suggests that this was not the actual obstacle. Other possible explanations may be that the heavier "load" of the second proof caused students to lose their way, or perhaps they tired as they progressed through the test, thereby dropping the framework and going back to their bad "natural" habits. Finally, when a question contains a hypothesis, it may distract the students, who focus on it too soon. Making recommendations on how to better make use of proof frameworks may be premature at this preliminary stage. However, we can say that employing proof frameworks can indeed be beneficial for students, but that doing so consistently is harder than it may first appear. It appears that additional practice of the framework's more complicated usage scenarios is required. It may also help to present students with actual mistakes to avoid. It is clear, however, that students are able to apply proof frameworks, and we should aim to help them do so in the more complicated proofs.

Planting Seeds through Embodiment to Teach Formal Concepts of Abstract Algebra

Jessi Lajos, Hortensia Soto, & Alissa Romero
Colorado State University

In this descriptive case study, we explored how a mathematics educator integrated embodiment into a first semester abstract algebra course. We found that, in addition to gesture, the instructor encouraged students to interact with physical materials and simulate mathematics using their bodies. Our results offer practical implications by illustrating examples of how embodiment can be incorporated in an abstract algebra classroom.

Keywords: Cosets, Embodied Cognition; Equivalence relation, Factor Group, Homomorphism

Introduction and Literature Review

The purpose of this work is to contribute to the literature on how embodiment, beyond gesture, can be integrated in the teaching of collegiate mathematics. Nathan (2022) defines embodiments as the use of "body-based resources to make meaning and connect new ideas and representations to prior experiences" (p. 4). In this case study, we addressed the research question: In what ways does a mathematics educator, who is knowledgeable about embodiment, integrate embodiment to support students' learning of abstract algebra concepts? We found that instructor-led embodied activities planted seeds for formal definitions, theorems, and proofs. Additionally, our results indicate that embodiment served as a tool to disambiguate referents of students' speech, to position students' contributions as legitimate, to strengthen the classroom community, and to include students who were not yet fluent in formal language.

A majority of the research related to embodiment intersects gesture and K-12 mathematics teaching. Studies show that teachers use gestures to convey mathematical ideas (Alibali & Nathan, 2012; Font et al., 2010), scaffold material (Alibali & Nathan, 2007), or establish common ground (Alibali, et al., 2013). In some of their more recent work, Alibali et al. (2019) found that teachers sometimes repeated students' verbal utterances and added gestures or made gestures, without speaking, in correspondence with students' verbal utterances towards referents. Gestures appeared to highlight students' verbal utterances, correct students' verbiage, or develop shared understanding in the classroom. Research at the intersection of embodiment and collegiate mathematics teaching is sparce and primarily attends to gesture (Lee et al., 2009; Stewart et al., 2019; Weinberg et al., 2015; Wheeler & Champion, 2013). For example, Lee et al. described how a differential equations instructor used pointing gestures to connect a mathematical problem with inscriptions. Wheeler and Champion portrayed an instructor's gesture to represent mapping of a function in abstract algebra. Weinberg et al. highlighted how an abstract algebra instructor's speech, writing, and gestures took on meaning in relation to each other. Beyond gesture, Stewart et al. explored how a linear algebra instructor navigated between embodied, symbolic, and formal instruction. Stewart et al. found that the instructor often used embodied explanations before moving to symbolic or formal instruction. For example, after defining span, the instructor asked the students to "imagine beginning with a new empty set and including a new vector in the set, one at a time" (p. 1257) and then imagine the span of the set. This was an attempt to help students experience linear independence before formally defining it.

Theoretical Framework

For this research study, we drew upon Nathan's (2022) four types of embodiments that he claims are useful for educational settings as the framework. The first type, *body form, movement,* and *perception,* make up our primary experiences, as we exist in "a body that has form and movement as well as specific perceptual capacities" (Nathan, p. 87). The second type, *gesture,* entails "movements of our hands and arms, as well as other body parts, that we make spontaneously as we talk with others and think to ourselves, including pointing and tracing actions" (p. 89). Nathan defines *simulations* as mental events that "enable us to extend the cognitive processes we have for things that are present and familiar so that we can think about possible things and unfamiliar ideas" (p. 90). The last category, *materials*, refers to how "we use physical objects and material in the world to perform epistemic operations" (p. 93). Nathan also describes four ways that embodiment supports student learning. First, *grounding* connects abstract ideas to concrete experiences to facilitate making meaning. *Offloading* leverages "external resources to manage highly constrained cognitive and attentional resources" (p. 99). *Cognitive-sensorimotor transduction* occurs when intellectual processes and sensorimotor processes interact and support learning unconsciously. Finally, *participation* entails communities of practice where newcomers become old timers (Lave & Wenger, 1991). Nathan believes communities of practice support learning "because they develop effective and efficient ways to collaborate, use cultural tools, and application-specific discourse practices" (p. 106).

Methods

The second author served a dual role of instructor (participant) and researcher. She has almost 30 years of teaching experience, has taught abstract algebra numerous times, and her research area centers on undergraduate mathematics education where she adopts an embodied cognition lens (e.g. Soto & Oehrtman, 2022; Soto-Johnson & Hancock, 2019; Soto-Johnson & Troup, 2014). She tends to follow Tall's (2013) three worlds to navigate between embodiment, symbolism, and formalism while teaching. She encourages students to use their bodies, tangible materials, and technology to learn mathematics (e.g. Dittman et al., 2016; Soto, 2021, 2022; Soto-Johnson & Troup, 2014). She values community and requires her students to work with their peers throughout the semester. For the course, the instructor adopted the text *A Book of Abstract Algebra* (Pinter, 1990) because as an undergraduate she used this text to learn abstract algebra and, as a mathematics educator, she appreciates its constructivist format.

The first author attended each lecture, had weekly conversations with the instructor on the role of embodied cognition in her teaching, audio- and video- recorded six weeks of class, and kept field notes. To capture recorded data, the first author set up two cameras. One stationary camera framed the front of the room, and the second hand-held camera was used to focus on the instructor or students. After the course, the first author and the instructor met twice a week to review recorded classroom data, which was divided into seven- and ten-minute segments. The two authors time-stamped instances when the instructor integrated embodiment, took descriptive notes on those instances, and summarized major themes from each segment. Themes included: regesturing students' gestures, delaying formal language until students understood relevant concrete examples, and transforming students' contributions into inscriptions.

After reviewing classroom data, the research team selected video segments that exemplified the instructor's use of embodiment. We fully coded and analyzed four episodes, but for the sake of brevity, we only discuss the episode related to acting out conjugation, showing a subgroup is normal, and the Fundamental Homomorphism Theorem (FHT). The two non-instructor research members re-watched the selected video segments and coded the types of embodiments as well as how each embodiment type appeared to support students' learning per Nathan's (2022) framework. They then used the codes to write descriptive results (using pseudo names for students) on how the instructor integrated embodiment. The instructor reviewed written results and the entire team engaged in round table discussions to ensure the accuracy and validity of the results, which served as member-checking (Merriam & Tisdell, 2015).

Results

In this section, we summarize how the instructor introduced conjugation, normal subgroups, and the FHT by leveraging all four types of embodiments, which appeared to support students' learning in each of the four ways described by Nathan (2022). Table 1 is a summary of these findings.

Table 1. Instances of embodiment in exploring conjugation, normal subgroups and the FHT

Forms of learning→ Types of embodiments	Grounding	Offloading	Cognitive-sensorimotor transduction	Participation
Body form, movement and perception	Vocabulary "to the right of" and "to the left of"		Described conjugation in terms of direction	
Gesture	Held imaginary group elements to gesture the action of conjugation			Gesture to establish common ground Orchestration of conjugation
Simulation	Students acted out conjugation on a normal subgroup to develop embodied meaning			Students searching for other students to help them conjugate
Materialist epistemology		Paddy paper to represent of D_4		

The instructor created a simulation in which she assigned students to act as elements of $\langle \mathbb{Z}_8, + \rangle$ and $\langle \mathbb{Z}_4, + \rangle$. She asked students to perform a homomorphism from $\langle \mathbb{Z}_8, + \rangle$ to $\langle \mathbb{Z}_4, + \rangle$; she assigned certain students from $\mathbb{Z}_8$ to map to specific elements of $\mathbb{Z}_4$. Students chose to touch the shoulder of the appropriate student to represent mapping. Together, the class verified that the kernel (K) of the homomorphism formed a subgroup. Then, without using the term conjugation, the instructor explained how to act out conjugation on the subgroup $K = \{Margaret, Cam\}$ of $\mathbb{Z}_8$ by stating, "Margaret [or Cam] is going to be in the middle and is going to be operated on the left-hand side by the inverse and on the right-hand side by the element." While describing conjugation in terms of the simulation, the instructor gestured to "hold" Margaret in the middle, “hold” an element’s inverse on the left, and “hold” the element itself on the right, which encouraged her students to imagine conjugation (see Figure 1). The instructor’s gesture grounded her explanation of conjugation within the students’ performance. Additionally, gesture supported participation because it positioned students as central rather than peripheral participants. Students then created their own sign for conjugation in which Margaret (the identity) stood in the middle, Julie ($5 \in Z_8$) stood on the right, and Jim ($5^{-1} \in Z_8$) stood on the left (see Figure 2).

Figure 1. Gesturing Conjugation of the Kernel

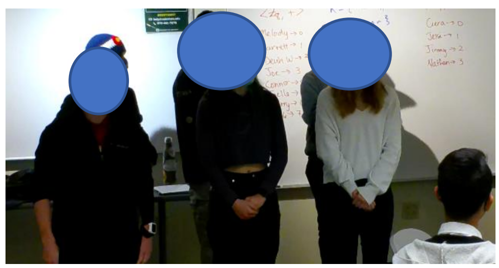

Figure 2. Julie and Jim simulating the action of conjugation on Margaret

The informal language “to the right of” and “to the left of” to describe conjugation is an example of the instructor using body form to support students’ learning because spatial relationships *grounded* conjugation in a primary aspect of the human experience – direction. Body form also supported student learning via *cognitive-sensorimotor transduction* because it reversed the complex notion of conjugation in terms of students’ physical position in space. Given Margaret was the identity element, the class noticed that the action of conjugation by an element (a student) and its inverse (another student) on Margaret always returned Margaret. Then, by acting out conjugation on Cam, students showed that every element-inverse pair in $\mathbb{Z}_8$ returned Cam under conjugation (see Figure 3).

Overall, simulation served as a tool that helped the instructor guide her students in showing that $K = \{Margaret, Cam\}$ was a normal subgroup. The instructor’s use of simulation grounded conjugation and normal subgroup in a meaningful experience before she introduced formal definitions. Moreover, simulation supported student learning via participation. For example, when Patrick conjugated Cam, he looked for his needed classmate (element) to help him perform the operation and students at their desks helped their peers find their inverses, which strengthened the classroom community.

Figure 3. Conjugating Cam by elements of Z_8

After the class (unknowingly) showed that K formed a normal subgroup, the instructor intentionally gestured to recap the simulation. She reminded the class that they began with two groups and "plucked out" a subgroup which generated cosets. Then, via pointing gestures, she emphasized that the two elements in the subgroup they "plucked out" both mapped to the identity in $\mathbb{Z}_4$ (see Figure 4). She also emphasized that the map was a homomorphism and not an isomorphism, which was new to the class. Finally, she emphasized normality of the kernel by stating, "if I take these two elements right **here** [Margaret and Cam] and I operate them by an element from the group and its inverse I somehow end up getting Margaret or Cam." The instructor used gesture to establish common ground because she made sure the class knew that the importance of the simulation was to see an example of a map that was a homomorphism, but not an isomorphism and that the kernel, K, satisfied interesting new properties, i.e., normality.

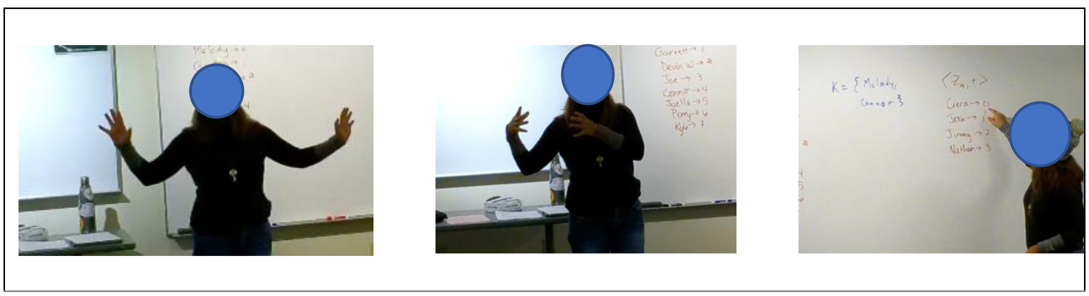

Figure 4. Two groups, pluck out two elements, these elements map to the identity

Following the FHT simulation involving conjugation, the instructor asked the class to complete a problem set related to the group D_4. In conjunction with the problem set, the instructor employed materialist epistemology by holding up a paddy paper and helping the class recall that D_4 represents the symmetries of a square. After distributing paddy paper to each student, she reminded students that all the rotational symmetries keep the square "on the same side." When she noticed Karen flip her square over, the instructor said, "tell me what you just did Karen." Karen replied that she performed a reflection of the square. It seemed that the geometric behavior of the square served to offload information because rather than write down each element of D_4 symbolically, the students could visualize the group D_4 in the material world.

Following this, the instructor encouraged students to look at the Cayley table for D_4 in *Group Explorer* (Carter, 2006), to find patterns in the table, and to reflect on the meaning of the simulation they had just completed. As the students worked in groups, David realized that, looking at this [D_4 Cayley table] … you got your warm and your cool colors here. And earlier in class, … we were talking about, … the cool ones are almost subgroups, but they're not because they don't contain the identity. … now we are realizing that if they have the same number of things like they are kind of subsets, but not subgroups [cosets]. Then that's how you construct a homomorphism to your subgroups or subsets [cosets] … and the homomorphism [image] is isomorphic to S_2 (see Figure 5a).

It appeared that David visualized the FHT. Then, Cam also excitedly changed tabs in his browser to visually show a case of the FHT in a map from $\mathbb{Z}_3 \times \mathbb{Z}_3$ to $\mathbb{Z}_3$ because "you can cut it [$\mathbb{Z}_3 \times \mathbb{Z}_3$] into the nine squares and there is a homomorphism to this one [$\mathbb{Z}_3$]" (see Figure 5b).

Figure 5a. D_4 is homomorphic to S_2

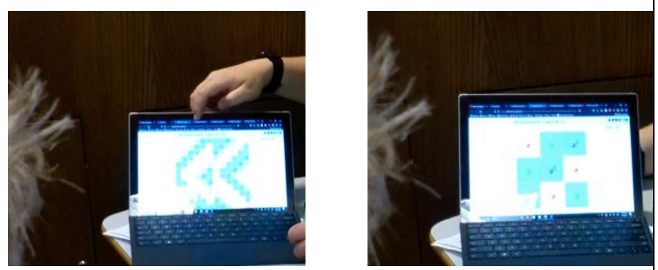

Figure 5b. $Z_3 \times Z_3$ is homomorphic to Z_3

Discussion and Implications

We situate our findings within existing approaches for the teaching of abstract algebra and discuss how gesture, along with other embodiment types, supported shared classroom understandings and helped strengthen the classroom community.

Early instructional design research in abstract algebra was based on actions, processes, objects, and schemas theory (Dubinsky et al., 2001) and the activities, classroom-discussions, and exercises cycle (Asiala et al., 1997). More recently, an inquiry-oriented curriculum was developed by the *Teaching of Abstract Algebra for Understanding* research program, which adheres to the principles of guided reinvention and realistic mathematics education (Gravemeijer & Doorman, 1999; Larsen, et al, 2013; Larsen & Lockwood, 2013). Similar to existing approaches on the teaching of abstract algebra, the instructor in this research study facilitated informal activities before presenting formal definitions, theorems, and proofs. Her approach is novel because she integrated all four types of embodiments described by Nathan's (2022) framework, which also appeared to support student learning in the four ways Nathan described.

Alibali, et al. (2019) drew from a compilation of their research to describe three cases illustrating how teacher gestures can create common ground and support students' contributions. In the first case, students sat at their desks so that they were "physically distant from the referents of their utterances," while the middle school teacher was "proximal to those referents" (p. 350). The teacher regestured and revoiced the student's verbal utterances by pointing at symbolic referents to ensure their interpretation was consistent with the student's intentions before moving on. In the second case, Alibali et al. (2019) identified a variation of gesture by a high school geometry teacher who silently gestured over inscriptions located at the board as a student spoke from their desk to "amplify certain voices" (p. 356). In the third case, both the college teacher and student were within arm’s reach of the referent (an electrical breadboard). Here, the teacher pointed to connect the students’ gestural actions on the electrical breadboard to symbols in a truth table. The instructor from our research study used gesture to establish common ground and support students’ contributions in ways that overlap with and extend Alibali et al.’s (2019) three cases. Specifically, the instructor used various types of gesture (besides pointing), she combined gesture with simulation, and her gestures supported student participation.

The instructor’s gestures that described conjugation by “holding” group elements (students) to the left, right, and center in relation to each other differed from the three cases described in Alibali et al.’s (2019) work on establishing common ground. Compared to the teachers from Alibali et al., this instructor did not sole use pointing gestures; she also used representational gestures, while describing conjugation. Alibali and Nathan (2012) refer to the merging of iconic and metaphorical gestures as representational gestures. McNeill (2005) categorized metaphoric gestures as those which indicate images of an abstract concept such as holding a function in one’s hand and iconic gestures as those which “present images of concrete entities and/or actions” (p. 39). The instructors’ gestures along with simulation closed the distance between students and referents because students were the referents of the instructors’ gestures. Students responded to her gestural description of conjugation by creating a sign: physically standing to the sides of one another. The instructors’ representational gestures, thus, created common ground because students responded with the physical action of standing beside each other and the instructor could ensure that her students understood what she meant by checking that their embodied sign aligned with her knowledge of the conjugation operation.

Nathan (2022) believes communities are helpful for learning because they leverage cultural tools and practices as a means of collaboration. The way that students followed the instructors’ descriptive gesture of conjugation by developing their own tool (the sign of standing beside each other to conjugate) is an example of how gesture can strengthen a classroom community and, thus, establish common ground. Through creating and implementing their own sign, students’ ideas were positioned as significant and actively used by each other to communicate and work as a team. The entanglement of gesture and simulation illustrates how gesture along with other embodiment types can help establish common ground because the entire class adopted a shared sign, which naturally prompted and reinforced shared understandings.

After the simulation ended, the whole class sat at their desks and the instructor stated, “lets recap what we just did.” Unlike the cases described in Alibali et. al.’s (2019) findings on how gesture is implicitly used by teachers to create common ground, this instructor explicitly stated that establishing common ground was her purpose for regesturing. This made the instructors’ intentions clear to her class. The instructor used both pointing and representational gestures to review the significance of the simulation. During her recap, students asked why the order of the kernel divides the order of the group. Student questions suggest that when the instructor explicitly stated that her goal in gesturing was to review, she invited students to engage in reflective practices and students felt that they could ask for help establishing common ground.

Our study provides examples of how embodiment could be integrated in abstract algebra classrooms. In response to Johnson et al. (2020), we believe incorporating embodiment can facilitate understanding and has the potential to lead to equitable outcomes where students’ contributions are supported. Future research may entail creating an embodied curriculum (Wang & Zheng, 2018) and developing embodied simulation activities for abstract algebra using unrefined human experiences, genuine relationships and collaborations, adjustments tailored to the students’ interests and instructors’ expertise, and scenarios that embody real-life experiences.

Students mathematical working styles and perception of immediate feedback in a digital assessment system

Siri Ovedal-Hakestad
University of Agder, Norway

The use of digital formative assessment in higher education mathematics is increasing throughout the world. Digital tools come with features such as endless ways of creating tasks and assessing in different ways. However, there is a need of research that focuses on what students do when working with digital tasks and how immediate feedback influence their learning process. This study examines students working styles and immediate feedback in STACK (The System for Teaching and Assessment using a Computer Algebra Kernel). The study reports on interviews with five first-year pre-service teachers who had completed a STACK-test for the first time, in order to get information regarding their working styles and perception of immediate feedback. The results indicate that students have issues regarding mathematical representations in a digital environment and a preference for line-by-line solutions in the feedback.

Keywords: Digital assessment, Feedback, Workings Styles, Syntax

Tools for digital teaching as well as digital assessment have become widespread and accessible in mathematics education (Drijvers, 2018). This was accelerated by the Covid-19 pandemic, and now we have reached a point where computer aided assessment is, in some countries, a part of university mathematics. In addition, previous studies (Faber et al., 2017 (Haelermans et al., 2015; Sung et al., 2016) have shown that using digital learning tools for formative assessment may have positive impact on students' achievement. Drijvers (2020) work show that mathematics students' use of digital tools, in addition to pen and paper, lead to new opportunities and constraints. There can also be room for exploration that may lead to explorative and productive activities, whereas the constraints such as syntactical ones, may lead to frustration (Drijvers, 2020). Therefore, research on students' working styles, where they have opportunities to exploit the opportunities and deal with the constraints a digital tool provides, is essential. The aim of this paper is to explore how students work a digital assessment system and how they approach digital mathematical tasks.

In this paper, working styles is used in line with Weigand and Weller (2001) in their report on changes in students' working styles when they worked with mathematical tasks on computers. Working styles were described in three ways, on tool level, representation level and object level. Their research showed that students worked more experimentally and used more search strategies than expected. However, their study also showed that students did not get a better understanding, but a different understanding of the concept of functions. This study will contain observations of how students use the computer and pen and paper, hence tool level. And how students write mathematics using a keyboard, which is related to representation level.

In the study reported from here, the participants worked with tasks in STACK (the System for Teaching and Assessment using a Computer Algebra Kernel). STACK is designed for formative assessment in mathematics, it is internet-based, and the interactions are through a web-browser (Sangwin, 2013). A distinguishing feature of STACK is the opportunity to create detailed and appropriate feedback for each situation (Sangwin, 2015). In STACK, students enter an algebraic expression into a computer using linear syntax. An option within STACK is validating answers, which means invalid answers are rejected and that students confirm their answer is interpreted correctly by the system before submitting.

This is a qualitative study based on interviews with five pre-service teachers who, before the interview, completed STACK-tests within the mathematical topic of algebra. Students were asked about their working styles and perception of feedback in the interviews, and the aim was to answer the following research questions:

1. What working styles do students in higher education use when working with digital tasks in mathematics?
2. How do students perceive immediate feedback in a digital assessment system?

Conceptual framework

To analyse how students in higher education work with mathematical tasks in STACK and get their view on immediate feedback, the concept of "working styles" was operationalised. The concept of mathematical working styles used by Weigand and Weller (2001) is described in three ways:

> First, it has to be seen on the tool level, e.g., whether one works with tools like paper and pencil, computers, or physical models; second, on the representation level, that describes working with representations like symbols, graphs, tablets, diagrams or pictures, and third, on a mathematical object level, where we see a working style as a sequence of actions that operate on objects and transform these objects. (p. 88)

An object can be an equation, an action can be multiplying, and sometimes one step of this sequence involves several sub-steps (Weigand & Weller, 2001). According to Thies and Weigand (2001), the relationship between object and representation is that the mental objects and their real representations are connected inseparably. In this way, operating with objects on the computer is the same as operating with mathematical objects.

The tool in this study is a computer, which entails special mathematical notations for the objects, and mouse-driven or key commands for different actions. This allows a person to work, for some in new ways, with objects or the representations of objects on the screen (Thies & Weigand, 2001). In this study, the concept of working styles will be used to explain how students work with tasks in STACK, and because of the scope of this paper, only the tool and the representation level are emphasised.

On tool level students had to make their answers using a keyboard. However, they had full access to pencil and paper to write notes. Therefore, it is interesting to observe how they use the tools. On representation level, students work with representations of mathematical symbols on a computer and had to use a keyboard and therefore computational notation to give their answer.

Assessment and feedback

Black and Wiliam (2009) define digital formative assessment as a close view of the teacher, technology, and student interaction within a learning process and their functions. Formative assessment may positively impact learning, and teachers, peers, and students are all actors in formative assessment (Dalby & Swan, 2019). Formative feedback is a key element of formative assessment because it provides the learner with information about their current state of knowledge and their learning goals (Narciss et al., 2014). This research conceptualises formative feedback in line with the definition by Black and Wiliam (1998) which "refers to all those activities undertaken by teachers- and by their students in assessing themselves- that provide information to be used as feedback to modify teaching and learning activities" (p. 82).

Digital learning tools might be an essential aspect of formative assessment in higher education. Technology can be used to improve the quality of the feedback received by students during their formative assessment, especially when considering the following three factors according to (Cosi et al., 2020). First, while using a technological tool, the time factor is immediate. Second, students can receive feedback in different formats such as text, video, audio etc., which enrich the message. And third, facilitation of a range of complementary resources is available on the internet.

According to Kulhavy and Stock (1989), the content of the feedback message should comprise two separate components, verification and elaboration. Verification is a judgement of whether the initial response is right or wrong, while the elaborated component consists of more information than just right or wrong. In this study, there were two different STACK-tests. The first one contained a verification component only, which indicated to the students if their response was right or wrong. The second STACK-test contained both a verification and an elaboration component, where the students also got information about the right response.

Methods

Data collection

The participants in this study were first-year student teachers for grades 5–10 at a university in Norway. All participants had deliberately chosen mathematics as their future subject to teach and the data were collected during their first mathematics course. The first lecture, I informed about the project and offered all students to participate in a two-hour working session every week, where they could choose to work with weekly tasks provided by their lecturer or digital tests created in STACK. The students were reminded of this working session each week. The STACK-tests were in addition to the students' regular work and was created as a supplement to their work towards the final exam. The topic of the STACK-test was algebra, which was part of the course content.

In total, 30 students completed the STACK tests, 13 students agreed to participate in the study, and 5 students participated in an in-depth interview. Early in the semester, three students completed the first STACK test and volunteered for interviews. Later in the semester, two more students volunteered after completing the second STACK test. The participants are, in this paper, named Oliver, Roger, Daniel, Harry, and Jack. It is accidental that all participants are male, because in class there was approximately fifty percent female and fifty percent male. Daniel, Harry, and Jack conducted individual interviews and completed the first STACK test, while Oliver and Roger participated in a group interview and completed the second STACK test.

The STACK-tests

STACK uses the computer algebra system Maxima to interpret students typed algebraic expressions and assign outcomes such as feedback and marks (Sangwin, 2019). STACK is equipped with algebraic equivalence, which makes multiple solutions, as long as they are equivalent, correct. STACK has a built-in interpretation of the students' answers; this means that the students' writing is shown interpreted mathematically before the students give their final answers. Regarding students input in STACK, there are six different options for inserting stars (*). In both tests the option of don't insert starts automatically was selected. This means that if there are any pattern identified the result will be an invalid expression.

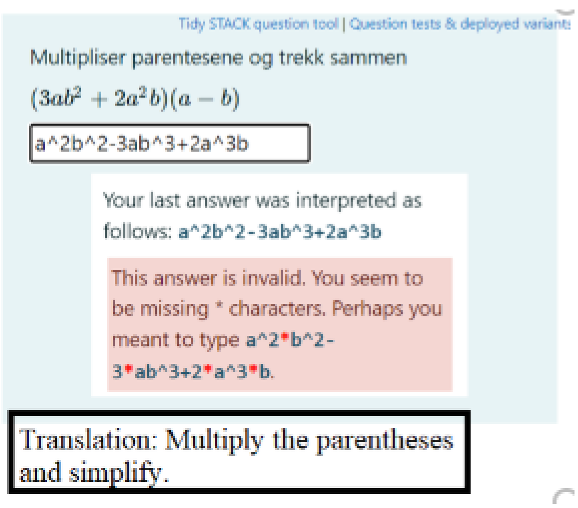

Figure 1. A picture of question 3 which show STACKs interpretations of an invalid expression.

The two tests had 9 similar tasks, and the second test consisted of 6 additional tasks. The first task in both tests concerned acceptance of participation in this study, and students had to actively decide whether to engage or not in this study. The difference between the two tests was primarily the feedback, where the first test had feedback as verification, and the second test had feedback including verification and elaboration. In addition to a difference in verification where the first test a verification was given after each reply, but in the second test, the students didn't get the result until all tasks were answered. All tasks were in the mathematical field of algebra, which was one of the students' mathematical topics this semester.

Because of space limitations and the relevance of this study, not all tasks will be recalled. The aim is to look at what working styles students had in this digital environment and how they wrote the answers into STACK.

Data analysis

To be able to answer the research questions, the interviews were transcribed in their entirety. Afterwards, the transcripts were coded in a process inspired by grounded theory. First, the transcripts were broken into discrete parts, closely examined, and compared for similarities and differences, which Saldaña (2021) refers to as the initial coding process. The transcripts were read statement by statement, and notes were taken on the side. This process created a starting point, which led to further exploration. Some of the notes after this initial process were: improvements, more organized approach to tasks, learning outcome, mastery, multiplication sign, step-by-step response, notation of tasks, and earlier experience.

After preliminary analysis codes that was overarching and related were created (Swanborn, 2018). This led me to two categories which will be elaborated on in this paper: working styles and feedback.

Results

First, I present the findings related to the first research question, addressing working styles students use when solving digital mathematical tasks. Second, findings related to feedback will be presented. Both parts will mainly consist of reproduction of the five interviews with Oliver, Roger, Harry, Daniel and Jack.

Working styles

In this section, ways of working with mathematical tasks digitally are reported. Oliver says that he always writes down each task on his tablet (similar to pen and paper) and calculates line by line. He had a similar approach to the STACK tasks, where he wrote line-by-line what he did in each task. This is a working style he always uses when approaching a mathematical task involving algebra. Oliver says that this way of approaching tasks give him a good overview of what needs to be done in order to solve the task. Roger explains that he tried to calculate in his mind first because he saw some of the tasks to be straightforward. If there were tasks, he could not calculate in his mind, he wrote down some notations to get back on the right track. These notations contained steps he knew how to solve but could not calculate it in his head. He explains that he enjoyed especially a task about quadratic identities, because he immediately saw that this was the case. In that task he had to understand how to calculate with parentheses, which he knew how to do, it became a practice on routine. Roger used STACK to check if his calculations were correct. Harry perceives algebra as a topic he manages well and explains that he did most of the calculations in his mind. He used STACK to guess and check his if the calculations done in his head was correct. If he did not know the answer, he guessed something, in order to look at the right answer after completing the task. He emphasized that since this was an assessment with no impact on his grade, the guessing and checking approach worked fine. If the test had an impact in his grade he would use a different approach, where he would have written down each task and made line-by-line calculations. He had high expectations of his work, especially work that had an impact on his grade. Daniel also explains that since this was a digital test with no impact on his grade, and the level of the tasks was not that high, he did most of the calculations in his mind. He used pen and paper to do small calculations he could not complete in his head. He reports that in this test, and digital tests in general, he does more calculations in his mind and uses the assessment system as a way to check if his answers are correct. Oliver used his tablet, Roger and Daniel used pen and paper in addition to the computer as tools. Harry did use any tool in addition to write notation in this test.

Using STACK for the first time requires writing mathematics with the use of a keyboard. All five students made comments regarding the multiplication (*) sign. The tests were programmed with an option where the program did not insert * characters automatically. Daniel said that remembering to write this sign everywhere because I know it is there. And since we do not usually write it, he forgot to write it in each task. In the interview with Oliver and Roger, a discussion about the multiplication sign occurred because Roger emphasized the importance of knowing that $4a$ actually is 4 times a. However, Oliver said that since he already knows that the sign is there, it is a waste of time to write it every time. The had different views on the importance of this * sign. Oliver was clearly frustrated about this sign, while Roger saw it as a way of writing mathematics digitally. Harry faced a challenge when he was going to write the power of a number. He did not know which symbol belonged to the right mathematical meaning. After spending some time thinking about it, he remembered using GeoGebra in upper secondary school and remembered what key it was. Jack also had some challenges with finding the power of a number. His approach was to write the wrong answer and then look at the right answer in the feedback. Then he could use this to remember which key it was if another similar task appeared. Another challenge Harry reported was that in one task, he wrote the wrong mathematical symbol and got the wrong answer. He said that he did not remember what this symbol was and that this mistake would never happen if he had written these tasks on pen and paper. This shows that students had different approach to finding the right symbol to a mathematical meaning. It is clear that this challenge would not happen if this test was created on paper, and the students were required to write the answers on paper. They knew what the mathematical meaning was, and how to write it on paper, but not the transition to a computer keyboard was difficult. If this test would have had an impact on their grade, Jack would have gotten the wrong answer if he deliberately answered wrong to look at the symbol. It is worth knowing that this can be challenging, because students mark may not reflect their knowledge.

Feedback

Feedback was given differently in the two tests. The first test had a verification component, and feedback was given immediately after each task. In the second test, feedback contained a verification component and details about the correct answer and was given after all tasks were answered. Jack, Roger, and Oliver explained that they would like a step-by-step solution after completing each task. They all agreed that this would help them in the learning process. Oliver and Roger emphasized that it will be easier to know if you are on the right path if you get a response after each task. Oliver said that, in this case, if you have to go through 15 tasks without any feedback, you had no way of knowing you were on the right track. However, if you got feedback earlier, you would know that you were doing right. Jack explains that in some of the tasks he was close to the correct solution, and if he got a line-by-line solution as feedback, he would quickly understand his mistakes. If a similar task would appear, then he could use the feedback in a different situation. He also explains that tasks he did not know how to approach, just by viewing the right answer in the feedback, he would not know how to do it in a similar situation. Daniel elaborated that a line-by-line solution given as feedback would help him figure out exactly where his mistakes were. And that a right answer and a line-by-line solution would help his mathematical understanding and development.

Discussion

This work sheds light on students' own report on working styles and how they perceive immediate feedback in a digital environment. In the case of working styles, the students consider writing mathematics on a computer to be challenging. The students had to use the computer as a tool to communicate mathematics. They also had access to paper and pencil or tablet to write notes during the tests. On tool level, Roger, Daniel, and Harry compared their work done in STACK with mathematical work they usually do on paper. The three of them agreed that if this test were on paper, they would write down more detailed line-by-line calculations on paper. As Usiskin (2004) points out, we have turned to paper and pencil for the last 400 years regarding transformational activities in algebra and arithmetic. Daniel, Harry, and Roger reported that they did most of the calculations in their mind. There are some explanations why this might be the case. First of all, this test had no impact on the students' grades. There might be no incentive for the students to complete all calculations as thorough as they would in a grading situation. Second, there was an opportunity to guess the answers and look at the feedback to see if they were on the right track.

There were some issues on the representation level because the notation used on a keyboard is sometimes different compared to the notation using pencil and paper or a tablet. Some students reported their frustration regarding finding right mathematical meaning, and some experience frustration regarding the multiplication sign, however, using the computer as a tool seemed like something the students are used to in different settings. Harry, Jack, and Daniel report that they have trouble finding the right key on the keyboard that belongs to the right mathematical meaning. The keyboard is the basic interaction with a computer, and according to Sangwin (2013), assigning definite meanings to individual symbols is a problem that needs to be solved.

Since this is the students first meeting with STACK in a test, and with no knowledge about the student's prior experience with writing mathematics digitally, these results were expected.

Students in this study also reported that they forgot to write the multiplication sign in places in line with the regular syntax of mathematics. There is an option in STACK to remove this function; however, as students become teachers, it is fundamentally important to know that the multiplication sign is there. While this issue frustrated Oliver and Roger, Jack saw it as a reminder of the difference between number and variable. This type of syntax error is not interpreted as a wrong result in STACK, but purely a technical error (Sangwin & Ramsden, 2007). A question to be raised for further use of STACK is whether to have this function switched on or off because it might lead to less frustrated students if you remove this function. On the other hand, this function is important, especially for pre-service teachers.

Oliver and Roger completed the second STACK test, where feedback was given after completing all tasks, while Jack, Daniel, and Harry completed the first STACK test where feedback was given after each task. Jack, Daniel, and Roger reported that they would value a step-by-step solution after each task. They all reported they would value more information than just verification or justification and the right answer. Kluger and DeNisi (1996) found that task-level feedback often emphasizes one solution, or strategy, and might therefore be a hinder for the transition to more complex tasks. If a solution to a task is presented to the students, they might lock their future work to only this way of solving a similar task and may therefore not help the students to think about other ways of solving a task. This issue needs more research because what the students want and what they will learn most from is debated.

A report from Shute (2008) says that step-by-step feedback is often more effective than presenting all feedback together. Given a summary after completing the whole test might be perceived as overwhelming, and as a result, students may reject all feedback given. This is in line with what the students in this study report.

Conclusion

Typographical errors can easily be missed by students, resulting in wrong answers. This might lead to frustrated students and should be avoided if possible. There are simple things lecturers can do to avert this problem when introducing STACK to students. When STACK as an assessment system is implemented, students should be taught the usual pitfalls, such as the multiplication sign (if this function is on) and learn which key to push for the most common mathematical operations and meanings. Spending time in class on mathematical representations used in a mathematical digital environment may help the students from spending time on finding the right key for the right mathematical symbol.

Students also report that they would appreciate a line-by-line solution as a part of their feedback. However, previous research is not clear that this is the best for their learning outcome. This study lacks data to conclude about students' learning outcome regarding feedback.

In this study, several students report that they calculated without using written notation. This also raises questions for further investigations. Is this a common case for students when they use computer as a tool to write mathematics? Is this a representations level case? Is this a result only in this study, or are the students working in a digital environment more into guessing and checking? More work needs to be done in order to answer these questions.

Variation in Students' Thinking about Sameness and Comparisons to Mathematicians

Rachel Rupnow	Rosaura Uscanga	Annie Bergman
Northern Illinois University	Mercy College	Fort Lewis College

Sameness is a topic threaded throughout all levels of mathematics and yet it has not received much focus from the mathematics education research community. Our work categorizes the dimensions of variation that students highlighted when asked to describe sameness using a recent framework on sameness in mathematics. We captured students' ideas about sameness through a pair of open response surveys at multiple doctoral-granting institutions across the United States. In this presentation, we report on the variation found in the student surveys and also compare our findings to a prior study of surveyed mathematicians.

Keywords: Sameness, Dimensions of Variation, Example Space, Advanced Mathematics

Introduction and Background

The concept of equivalence is fundamental in mathematics (Asghari, 2009; 2019). Students are introduced early in their schooling to a specific type of equivalence, mathematical equality, and continue to use equality throughout their mathematics courses (e.g., National Governors Association Center for Best Practices, 2010). Despite their familiarity with the concept, students do not always develop a robust conceptual understanding of equality, which can hinder their ability to engage with middle school algebra topics like solving equations (e.g., Alibali et al., 2007; Kieran, 1981). In undergraduate mathematics courses, students encounter more complex ideas of equivalence like the notion of isomorphism in abstract algebra. Studies have shown that students, professors, and researchers all associate isomorphism and sameness (e.g., Dubinsky et al., 1994; Leron et al., 1995; Rupnow, 2019; 2021; Weber & Alcock, 2004).

Early work on students' understanding of mathematical sameness focused on alternative interpretations of operations and objects from those of the researchers (Melhuish & Czocher, 2020). Still, little is known about how undergraduate and graduate students understand sameness. Recent studies focused on mathematicians' understandings of sameness have categorized notions of sameness according to salient features and examined norms while interpreting sameness (Rupnow et al., 2022; Rupnow & Sassman, 2022). While mathematicians are able to recognize and distinguish between types of sameness, it remains unknown whether students do so in similar ways or what aspects they attend to.

Furthermore, math education research has benefited from comparing experts' understandings to those of students, such as in the context of example usage (Lockwood et al., 2016; Lynch & Lockwood, 2019) and proof production (Weber & Alcock, 2004). These types of studies provide opportunities to leverage mathematicians' expertise to find potentially productive connections and ways of thinking to teach students. In this paper we examine the ways in which mathematics undergraduate and graduate students describe the notion of sameness and how these compare to mathematicians.

Theoretical Perspective

In this study, we employed the notion of example space (e.g., Watson & Mason, 2005) to characterize how undergraduate and graduate students view mathematical sameness. Example spaces are the collections of examples that are associated with a particular concept and include the ways of making such examples. The structure of an example space can be described in terms of dimensions of possible variation, which refers to the aspects that are allowed to vary, and the range of variation of a particular topic, which involves the different options in the dimensions (Watson & Mason, 2005). In particular, we drew on the community example space created from a survey of mathematicians, largely algebraists (Rupnow et al., 2022), which characterized dimensions of variation of sameness used and range within those dimensions. Rupnow and colleagues (2022) highlighted five dimensions of variation: universes of discourse, concepts, objects, properties, and qualities. We adopted this framework to analyze our student data. In so doing, we provide a community example space for undergraduate and graduate students to highlight dimensions and range of variation of mathematical sameness. We also explore the differences and similarities between students' descriptions of sameness and those of mathematicians. In particular, we address the following research questions:

1. Which dimensions of variation did students highlight when describing mathematical sameness?
2. In what ways were the examples and characterizations of sameness provided by our students similar and different to those provided by algebraists?

Methods

Data Collection

We conducted a pair of open response surveys at doctoral-granting institutions across the United States. Each survey consisted of fifteen questions aimed to capture students' ideas about sameness. The first survey, Survey-A, invited actively registered abstract algebra students at three different institutions. A member of the research team visited each of the three courses to personally invite students to participate. During data collection, each of the courses offered at the selected institutions were cross-listed; that is, the courses were listed in the course catalogs as available to both undergraduate and graduate students. Therefore, the 15 students who provided responses to Survey-A were either undergraduate or master's students currently enrolled in abstract algebra. The follow up survey, Survey-G, was also conducted at three doctoral-granting institutions across the United States and invited any current master's or doctoral student in mathematics. For Survey-G, students were emailed an invitation through departmental lists of graduate students, there were 12 responses in total. Responses to both Survey-A and Survey-G serve as the dataset, consisting of 27 total student responses.

While both surveys asked how students think about sameness in general and in specific contexts, the wording of the questions was slightly different. The questions we chose as most relevant for analysis are as follows:

- (Q2) What does it mean to be the same in a math context? (both)
- (Q4) How do you know two things are the same in abstract algebra? Is this the same or different from other classes? (Survey A)
- (Q4a) How do you know two things are the same in abstract algebra? (Survey G)
- (Q4b) How is sameness in abstract algebra similar or different from sameness in other branches of mathematics? (Survey G)

Data Analysis

The research team, consisting of abstract algebra education researchers, analyzed the student responses. We used Rupnow and colleagues' (2022) sameness framework describing the various contexts, concepts, objects, properties, and qualities related to sameness. Each member individually coded all student responses to the survey questions provided above. Together, the team compared coding, discussed any discrepancies, and came to group consensus, resulting in total inter-coder agreement. To compare our findings to those of the mathematicians, we considered the differences in prevalence of each dimension.

Results

The results that follow report the universes of discourse, concepts, objects, properties, and qualities used by students when describing sameness. See Rupnow and colleagues (2022) for a detailed definition for each code found in Tables 1-5. Within each table, the frequency ordering of the mathematician paper is maintained to permit comparison of relative frequencies between the mathematicians and students. Following each table, we also provide illustrative examples of common student responses to better characterize the findings.

Table 1. Universe of discourse for sameness

Context[a]	Survey-A	Survey-G	% of total
Linear Algebra	0	4	15%
Topology	2	7	33%
Geometry	0	2	7%
Discrete Math	0	3	11%
Calculus[b]	-	-	-
Arithmetic/pre-university algebra[b]	-	-	-
Analysis	0	5	19%
Category Theory	0	3	11%
Other	0	2	7%
Set Theory	1	2	11%

[a]Some questions prompted consideration of or comparisons to abstract algebra so we do not report frequencies for abstract algebra, but we do discuss ways that discussion of abstract algebra was positioned below.
[b]Not present in graduate student responses

In Table 1, we focus on descriptions of each universe of discourse (context) for discussions about sameness. Among our student participants, topology was the most common context. Some responses broadly noted similarities and differences between abstract algebra and topology: "Another branch of mathematics where I think about sameness is topology. I think sameness in abstract algebra is both similar to and different from sameness in topology." Others linked contexts with particular concepts: "For instance, in topology, we have homeomorphisms that establish the 'sameness' of topological spaces."

Other responses made use of linear algebra and analysis contexts. For instance, a participant focused on co-existence in the same vector space as characterized by the span: "A vector v in a vector space identified with all of its nonzero scalar multiples. In other words, v is the 'same' as w if v = a.w[1] for some nonzero scalar a." Analysis contexts included oblique references to sameness of functions equal almost everywhere (a.e.): "In a more elaborate sense, one can argue that usually in algebra the homomorphisms are bijections whereas in analysis (measure theory) often time ignores sets that are very small."

In general, we note that the prevalence of each universe of discourse roughly mirrors the mathematicians, though our students did not allude to arithmetic or calculus to make points about

[1] We interpret v = a.w as the product $\mathbf{v} = a\mathbf{w}$.

sameness, nor did many use geometry examples. We further note that the preponderance of instances are grounded in areas of math outside abstract algebra and the variety in contexts was driven by the graduate students in the second survey.

Table 2. Concept conveying a type of sameness

Concept	Survey-A	Survey-G	% of total
Isomorphism	9	11	74%
Equality	6	6	44%
Other (e.g., categorical equivalence)	1	4	19%
Equivalence Relation	5	1	22%
Congruence	1	1	7%
Homomorphism	1	4	19%
Homeomorphism	2	6	30%
Diffeomorphism/Homotopy equivalence	0	1	4%
Similar (geometry)	0	1	4%
Linear transformation[a]	-	-	-

[a]Not present in graduate student responses

Table 2 highlights concepts conveying a type of sameness. Among our participants, isomorphism was the most common concept conveying sameness, followed by equality and homeomorphism. Discussions about isomorphism generally were positioned within abstract algebra and emphasized sameness of underlying structures: "We know two things are the same in abstract algebra when we can construct an isomorphism between the two structures. That is, the two structures may not look the same, but they have the same properties." While some references to equality occurred in isolation, many references were used to contrast with isomorphism:

> The meaning of "same" in a math context is a vague one. We can say two groups are the same if there exists an isomorphism between them, but the elements of the respective groups may be different. We may also say things are equal which is a different meaning than isomorphism but also implies a form of sameness.

While this participant's characterization of isomorphism is more specific than that of equality, we believe it is noteworthy that they used multiple concepts to characterize sameness. Similarly, in keeping with the large number of responses (especially in the second survey) positioning discussion in topology, we observed a number of instances of homeomorphism, especially in contrast with isomorphism. For instance:

> They are the same if there is an isomorphism between them. It may be an isomorphism of groups, rings or modules…The sameness in algebra means that the relationships between elements in one structure is the same as the relationships between the elements of the other structure with respect to the underlying operations. In other situations in math, this may not hold true, but two things might be considered the same if they share some property in common or if there is some special bijective function between them. For example, topological equivalence means there is a homeomorphism between the two sets. They can be considered the same in the sense that one can be molded into the other as opposed to algebraic sameness where the underlying mechanics of two sets are the same but they are labeled differently.

Specifically, while we recognize that questions asking about sameness in abstract algebra likely drove the high number of references to isomorphism, we were encouraged by the number of responses that characterized sameness using more than one concept (6 of 15 in the first survey, 11 of 12 in the second survey). We also observe that while there was a higher percentage of references to homeomorphism and fewer to congruence in this survey than the mathematicians, isomorphism and equality were the most commonly discussed in both settings.

Table 3. Objects to which sameness is applied

Object	Survey-A	Survey-G	% of total
Group	4	6	37%
Ring	2	5	26%
Other (e.g., categories, modules)	3	9	44%
Vector Space	0	4	15%
Set	2	8	37%
Number	1	2	11%
Function	0	2	7%
Field	0	1	4%
Quotients	1	0	4%
Elements	3	3	22%
Triangle	0	1	4%

Table 3 highlights objects that could be 'the same'. In addition to references to groups and rings (similar to the mathematicians), our student participants centered sets and elements as well as a variety of Other objects (e.g., categories, graphs, modules, manifolds). Respondents often listed multiple examples of structures and sometimes used these lists to contrast with sets:

> Most areas of mathematics have a notion of isomorphism between the objects of interest. Exact equality is almost always a much too strong condition to be of any significance when studying mathematical objects. In topology, homeomorphic spaces are looked at as "the same"; in graph theory there is a notion of isomorphic graphs; in analysis one usually studies spaces up to an isometric isomorphism; and even in category theory there is a notion of equivalent categories. This does contrast with set theory where in many cases one does care about exact equality of sets and not just a bijection between them.

Others used lists to contrast whole objects with elements, such as:

> In my experience in linear algebra, the "things" that you'd deal with are structures (groups, rings, fields, modules, ...) and their elements. The elements of the same structure are the same if and only if removing both of them is the same as removing one of them (sameness in the sense of set elements). Two structures are equal if they are isomorphic. This guarantees that they share the same algebraic properties. This will mean that sameness is [an] equivalen[ce] relation with equivalence classes.

We again observe, most of the variety in objects, both in the Other category and generally, were driven by responses to the second survey.

Table 4. Properties conveying sameness or a lack of sameness

Properties	Survey-A	Survey-G	% of total
Cardinality / Bijection	3	8	41%
Representation	1	4	19%
Other (e.g., commutativity, generators)	2	5	26%
Dimension	0	1	4%

Table 4 highlights properties of objects that should be shared for objects to be the same or that could vary and still allow the objects to be the same. Similar choices of properties arose in this survey as in the mathematicians' survey. There were numerous references to bijections, especially as they related to understanding concepts listed above, like isomorphism and homeomorphism. Other properties that students noted included orders of elements within a group, commutativity, and topological invariants. One participant highlighting multiple properties wrote:

> Two isomorphic groups that are essentially the same have similar properties (like the same order of the group or the same orders of its elements) and behave in similar ways with respect to how elements are operated together (e.g., there is a homomorphism between the groups, and the generators of one group correspond to the generators of another group).

Note this participant commented on cardinality (orders of groups) as well as Other properties of orders of elements and relationships between generators.

Table 5. Qualities of sameness

Qualities	Survey-A	Survey-G	% of total
Levels of Sameness	5	5	37%
Computability / Construction	2	2	15%
Logical equivalence	1	2	11%

Table 5 highlights qualities of sameness, namely ways to compare the types of sameness conveyed by specific concepts. For instance, the following response received a levels of sameness code:

> Two things are exactly the same if, and only if, all of their properties have the same value. We often discuss sameness without meaning, "exactly the same". Here, we reduce our scope to specific properties and check to see if two things have these specific properties in common. Then we call them the same in some sense. Other times, if two things have exceptionally close property values we might call them (knowing that it is strictly untrue) the same. So, in a math context, when one declares two things to be the same, one may mean they are exactly the same. See above. Or, one may mean only some of their properties are the same. This is almost always intuited, or explicitly given, in context.

This segment, which came at the end of an extended response in which five axioms and six definitions were provided to carefully characterize sameness, highlights a distinction between being "exactly the same" and having many properties be the same, which is often sufficient to be called the same in a particular context.

The computability/construction code and logical equivalence code captured ways of demonstrating sameness of object. Computability/construction focused on creating specific mappings (e.g., "We know two things are the same in abstract algebra when we can construct an isomorphism between the two structures."), whereas logical equivalence focused on the use or existence of theorems that can be used to draw the same conclusions, such as the following:

> Often times in mathematics some results appear to be equivalent to some other result although their proof might be completely different. For example, the axiom of choice is equivalent to Zorn's lemma, Tychonoff's theorem, the Well ordering principle, and a whole lot of results in different fields of mathematics.

Unlike the other dimensions, we saw similar frequencies in the descriptions of qualities from both surveys and these frequencies occurred in a similar ordering to that of the mathematicians.

Discussion

In this paper, we have observed many similarities between the students of our data set and previous work with mathematicians (Rupnow et al., 2022). All dimensions of sameness (contexts, concepts, objects, properties, and qualities) in the mathematician study arose in the student data. Many of the particular examples of each dimension, that together comprise the range of variation for each dimension, were also cited. When aggregating across our students, we see similarities to the mathematicians in the ordering of examples cited, including emphasis on isomorphism and equality as concepts conveying sameness, bijections/same cardinality being an important property for sameness, and nuance in qualities of sameness such as the existence of different levels of sameness. Some differences are explainable by the participants' backgrounds, such as frequent emphasis on abstract algebra and algebraic objects (groups, rings) among the mathematicians, who were largely algebraists. Whereas students, some of whom did research in applied math or analysis, gave more emphasis to analysis and other non-algebraic objects.

Examining the data in closer detail, however, it may not be fair to lump together our two student samples. The respondents to Survey-A were students in an abstract algebra course, which included both undergraduates and first-year graduate students in math education. The respondents to Survey-G were exclusively graduate students and included students farther into their programs. We also see some differences in the range of variation discussed. Much of the range in each dimension of variation, which mirrored the mathematicians, was driven by the Survey-G respondents. Except for the concept *equivalence relation* and object *quotient,* the same or more participants in the second sample provided each example within each dimension of variation, despite fewer participants. Thus in this sample, the Survey-G respondents discussed a greater range of topics per person than students responding to Survey-A.

While we recognize this is a small data set, we believe the differences between our two student samples spark questions warranting further research. In particular, it is possible that some formative experiences happen in early graduate school that lead graduate students to write and act more like mathematicians beyond simply taking more courses. Research might examine the impact of studying for preliminary/comprehensive exams on graduate students' perceptions of mathematics and abilities to make connections across their coursework. It is also possible that students who make stronger connections across courses are more likely to want to pursue graduate work in mathematics; thus, some weeding process may occur before graduate school. Other experiences or mechanisms may also be important to graduate students' development of nuanced views of sameness. While RUME is focused on undergraduates' experiences, we nevertheless encourage such work on the transition from undergraduate to graduate students to be included in the RUME community because of the potential impact on understanding what motivates undergraduates for higher study.

How do instructors understand unequal representation in STEM?

Naneh Apkarian
Arizona State University

Estrella Johnson
Virginia Tech

Alexandra Claire Lau
American Physical Society

Melissa H. Dancy
Western Michigan University

Charles Henderson
Western Michigan University

While trends over the last few decades show increases in women and non-white scholars in STEM fields, there remains disparate attrition at different transition points within academia. The underrepresentation of certain demographic groups in STEM is broadly understood as rooted in systematic historical oppression and exclusion which continue their presence in various ways – but it is not clear how understood this is by faculty at large. To better understand faculty beliefs related to the (dis)advantagement of race-gender groups in STEM, we conducted a Latent Class Analysis on 945 responses from instructors of introductory chemistry, physics, and calculus courses at a variety of institutions across the United States. We then looked to see how those views relate to faculty support of policies and activities which might advance diversity and equity in postsecondary STEM education. Four clear patterns are discussed.

Keywords: Equity, instructor beliefs, DEI, STEM instructors

One symptom of the systemic inequities plaguing our society is that the race-gender demographics of STEM fields in the United States are markedly dissimilar from those of the country and the undergraduate student population. Though representational diversity is not equivalent to equity or justice, the persistent discrepancies in representation are certainly indicators of a larger problem. Trends over the last few decades show increases in women and scholars of color[1], with variation between different STEM fields (NCSES, 2021). However, there continue to be disparate attrition for women (Shaw & Stanton, 2012) and non-white (Shaw et al., 2021) scholars at different transition points within academia.

The underrepresentation of certain demographic groups is broadly understood as rooted in systematic historical oppression and exclusion which, while now ostensibly outlawed, continue their presence in various ways – but it is not clear how understood this is by most faculty. Current faculty are key actors within the broader educational system: they interact regularly with students, make decisions about who to mentor (and how), and have some say in policy decisions within their academic units. How they engage in these activities has the potential to impact recruitment and retention. While instructors may occupy a role in which they can support diversification of the fields and a shift toward more equitable systems, they may not be aware of this potential (Gandhi-Lee et al., 2017) or even the need for change – and in some cases may push back against efforts to advance diversity, equity, and inclusion. In order to better recruit faculty to the cause of advancing equity in higher education, we must better understand their current views and the organizational culture(s) in which they exist – parallel to the work our field has done to recruit instructors to use research-based instructional practices (e.g., Apkarian et al.,

[1] We note that gender is not a wo/man binary, that race is a fluid and complex social construct which should not be reduced to simplistic categorizations, and the intersectional nature of identity. However, we are limited in some respects by how these terms are used generally in society, federal databases, and prior research.

2021; Chowdhury et al., 2021; Johnson et al., 2018, 2019; Reinholz & Apkarian, 2018; Yik et al., 2022). This study takes a first step toward that end, reporting on a subset of:

1. *Classes (or patterns) of instructor beliefs related to the (dis)advantagement of race-gender groups in STEM which exist among current instructors; and*
2. *Relationships between class membership and support for activities in support of advancing DEI in postsecondary STEM contexts.*

Theoretical Background & Relevant Literature

We take the position that equity is a moral imperative, and that STEM, education, and academia are currently inequitable systems which need to undergo systemic cultural change. Faced with institutional inertia as well as complex logistical, economic, and political considerations, we look in the short-term to the role of faculty to support students and shift disciplinary culture to be more inclusive and equitable. In essence, faculty act as the ultimate gatekeepers of the disciplines, and their actions – influenced by their beliefs – have great power to support or constrain efforts toward diversifying and making equitable the STEM fields.

Among the indicators of inequity in STEM higher education is the race-gender imbalance in representation (Apkarian, in press; NCSES, 2021). Some of the immediate factors impacting students' intention to pursue STEM (e.g., recruitment) include existing interest in STEM, positive math and/or science identity, and academic preparation (Cribbs et al., 2015; Gandhi-Lee et al., 2017; Graven & Heyd-Metzuyanim, 2019; Langer-Osuna & Esmonde, 2017); of course, these are not equally accessible to, nor cultivated in, all students. Beyond recruitment, there are disparate rates of retention at various junctions along the path to a STEM career (Ellis et al., 2016; Hatfield et al., 2022; NCSES, 2021; Shaw et al., 2021; Shaw & Stanton, 2012; Wapman et al., 2022). Additionally, there are cultural systems, specific to mathematics and science. These include a racialized hierarchy of mathematical ability which generally manifests as an expectation that Asian (men) are 'too good' while those who are not White or Asian are 'not good enough' at mathematics (Martin, 2003; McGee & Martin, 2011; Shah, 2017, 2019). There are additional gendered norms and expectations, which often take the form of suggesting that women are not as capable of mathematical or scientific thought as men (Handley et al., 2015; Hottinger, 2016; Leyva et al., 2016). Of course, these are intersecting systems which produce intersectional experiences (Castro & Collins, 2021; Cech, 2022; Covarrubias, 2011; Gholson & Martin, 2019; Williams et al., 2014). These, and additional systems of inequity such as ableism (e.g., Annamma et al., 2013; Bettencourt et al., 2018; Taylor & Shallish, 2019) are often hidden behind a belief that STEM is insulated from racism and sexism, and is instead a true meritocracy (Au, 2013; Cislak et al., 2018; Handley et al., 2015; Liu, 2011; Sobuwa & McKenna, 2019).

While there exist a number of strategies employed by higher education institutions to try to acknowledge, mitigate, and/or address aspects of system inequity (e.g., affirmative action, and similar, policies for student admissions and faculty hiring; diversity statements), these are not uniformly supported by faculty nor is there unanimous consensus among STEM faculty that they have a personal responsibility to address inequities in their disciplines (Johnson et al. 2022). We take support for, and engagement with, policies and efforts to diversify STEM fields as aspects of faculty professional practice and, just as with other aspects of professional practice (e.g., instructional practice) we see faculty beliefs as both a key influence and a necessity for change.

Participants & Data Collection

Data come from a web-based survey of postsecondary instructors distributed in Fall 2020. Participants were instructors of introductory chemistry, physics, and calculus courses at a variety of institutions (including two-year colleges, four-year colleges, and universities). Each had completed a survey in 2019 regarding their instructional practices and factors impacting their pedagogical choices as part of a larger project; they were then invited to participate in this follow-up regarding their experiences with, and attitudes toward, DEI issues and initiatives in higher education. For the follow-up survey, we received 1064 responses from the 2229 invited to participate (47.7% response rate).

We focus this analysis on a series of questions related to beliefs about different race-gender groups and STEM. These items were designed to gauge whether instructors recognize the systemic advantages and disadvantages related to race and gender in the sciences as well as to gauge instructors' beliefs about various explanations for under-representation of demographic groups compared to white cisgender men. Previous analysis (Johnson et al., 2022) showed that, in the aggregate, many STEM instructors recognize relative systemic (dis)advantages based on racial and gender characteristics; few suggested variation in aptitude for STEM; responses were more mixed with regards to the distribution of opportunity and interest in the disciplines. It also revealed that instructors were more likely to support statements in support of DEI than affirmative action style policies. This analysis seeks to understand patterns within these responses in order to better understand clusters of attitudes and positions relevant for faculty support to advance equity and inclusion in STEM.

Latent Class Analysis

We employed *latent class analysis* (LCA) to identify potential groups or classes among our participants, which might drive patterns in their responses. LCA is a type of structural equation modeling used to identify groups (called latent classes) in multivariate categorical data. The data used for the LCA is the 22 items about (dis)advantage, opportunity, aptitude, and interest in STEM for different race-gender groups. In the survey items regarding (dis)advantage, respondents were presented with 8 race-gender pairs (Asian Women, Black Women, Hispanic/Latinx Women, White Women, Asian Men, Black Men, Hispanic/Latinx Men, White Men) and asked "From your perspective, do people from each of the following demographic groups receive a net systematic advantage or disadvantage due to their demographic characteristics in [your field]?" For the survey items regarding opportunity, aptitude, and interest in STEM, respondents were asked "More than half of the PhDs awarded in 2017 in mathematics and the physical sciences were received by white men. As compared to the majority group (white men), how much interest, aptitude, and opportunities do you think other groups have in [your field]?". They were prompted to respond with regard to the seven other race-gender pairs. Each of these 22 items had three response options, more/equal/less. We reduced the 1064 responses to 945 complete cases.

Multiple LCA models were built and tested; model selection involved inspection of model fit parameters and diagnostic criteria (Nylund-Gibson & Choi, 2018; Weller et al., 2020). Analysis was performed in RStudio using the poLCA package (Linzer & Lewis, 2011; R Core Team, 2022; RStudio Team, 2022). For $5 \leq k \leq 10$, 10 models of k-classes were generated using Monte Carlo Markov Chain methods. These models were then compared in terms of their model fit statistics, diagnostic criteria, as well as their interpretability considering existing theory and literature, as incongruent fit indices are common with such analyses (see Table 1 for model fit statistics.) This resulted in a choice of the eight-class model, which had the lowest BIC and highest BF. For this eight-class model, the minimum average latent class posterior probability is 0.940, well above the minimal threshold; entropy was 0.96, well above the .80 standard cut off; the smallest class is 2.8% of the sample population (Class 5); this is 26 individuals and may be admitted for analysis with caution.

Table 1. Evaluating class solutions.

Model	LL	AIC	BIC	G^2	X^2	BF
5	-13247.61	27083.22	28509.47	15075.2	4.4e+18	0.000
6	-12899.78	26505.57	28218.04	14379.54	1.6e+18	0.000
7	-12661.73	26147.46	28146.15	13903.44	2.9e+16	0.000
8	-12395.36	25732.71	**28017.62**	13370.69	**3.6e+15**	**>>15.00**
9	-12281.36	25622.73	28193.85	13142.7	8.3e+17	0.000
10	**-12066.67**	**25311.35**	28168.69	**12713.32**	1.16e+15	--

Note: LL – maximum log-likelihood; AIC – Akaike information criterion; BIC – Bayesian information criterion; G^2 – likelihood ratio/deviance statistic; X^2 – Pearson chi-square goodness of fit statistic for fitted vs. observed multiway tables; BF – Bayesian factor.

Model Description

Figure 1 shows the proportion of participants, in each latent class, who responded "more," "equal," or "less" to four key questions (divided by dashed lines) regarding each of the target race-gender groups; that is, the conditional probability of a participant selecting responses given that they are a member of a particular class. Note that the question at the bottom is the only one which includes White Men, because that's the question about net advantage/disadvantage; the others are asked in reference to White Men (the dominant group). Moving upward, the second question related to *interest* to engage in the field; the third to *aptitude* for the field; the fourth (top) to *opportunity* in the field.

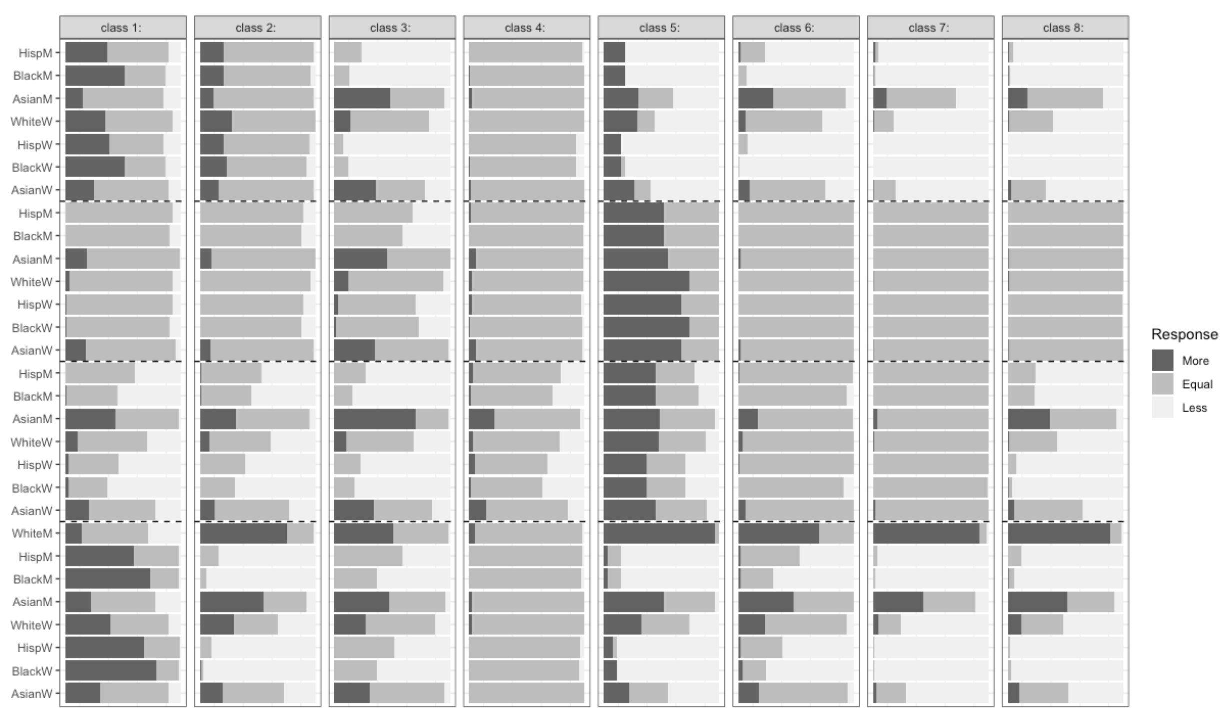

Figure 1. Conditional probabilities of answer choice selection based on class membership.

Model Interpretation

We anticipate that these profiles coincide with beliefs and actions which have direct impact on DEI issues and initiatives in higher education which is of great interest to our work. To that extent, we performed a series of Pearson's Chi-squared tests (with Bonferroni correction). Table 2 reports the results of these tests, as well as the cells in which standardized residuals (*sr*) had magnitude larger than 2, indicating that they are contributing to the statistical significance. This suggests that the model captures some variation in relation to faculty positions on DEI initiatives.

Table 2. Chi-squared tests

	χ^2	df	*p* adj	Contrib.
[A] *Do you, or would you, support AA-style policies in…*				
Student admissions	112.7	14	< 0.001	1, 3, 4, 7
Faculty hiring	132.5	14	< 0.001	1, 4, 7, 8
[A] *Do you, or would you, support DEI statements by…*				
Departments	134.3	14	< 0.001	1, 4, 7, 8
Institutions	135.4	14	< 0.001	1, 4, 7, 8
Professional societies	162.3	14	< 0.001	1, 4, 7
[B] Efforts to increase diversity are […] for my field	187.1	14	< 0.001	1, 3, 4, 7, 8
[C] I have personal responsibility to address DEI	73.01	7	< 0.001	1, 4, 6, 7, 8

N varies across tests by question response rate. All p-values adjusted for repeated testing. [A] Response options were yes; no; no opinion; [B] Response options were beneficial; detrimental; neither. [C] Response options were condensed to Agree (Strongly Agree; Agree); Disagree (Strongly Disagree; Disagree).

Discussion of Results

Classes 1, 4, 7, and 8 contribute the most consistently to associations between latent classes and additional characteristics, account for about 2/3 of the participants, and are easily interpretable within the extant literature. Therefore, we focus on them and suggest that additional, clearer data is needed to understand other patterns of belief. We name these four based on their most distinctive analysis patterns: Class 1 becomes *Advantage to Underrepresented Racial Groups*; Class 4 becomes *Race-Gender Equity in STEM*; Class 7 becomes *Opportunity and Advantage for White and Asian Men*; Class 8 becomes *Opportunity, Interest, and Advantage for White and Asian Men*. We discuss the belief patterns of each group, as well as the relationship between group membership and positions on DEI initiatives.

Class 1: Advantage to Underrepresented Racial Groups

This group of 73 represents 7.8% of the survey respondents. The group presents an inverted pattern of advantage compared to the other groups (see Figure 1); the majority of this group identify Black and Hispanic men and women as having a systemic advantage in STEM and Asian and White men and women as having neither an advantage nor disadvantage. More than a quarter of this group identify White men as *disadvantaged*. As compared to White men, this group suggested that Black men and Women have more opportunity to do science and mathematics, with other groups considered more equal. In terms of aptitude, the majority of this group (as with most groups) viewed everyone as having equal aptitude (though the distribution of the minority is interesting as well). In terms of interest, however, we see that this group believes that some of those least represented are also less *interested* in STEM than White men.

Considering the other questions (Table 2), this group were less likely to support affirmative-action style policies (admissions *sr* = -4.6; hiring *sr* = -5.0) and DEI statements (department *sr* = -7.3, institution *sr* = -7.9, society *sr* = -8.9); more likely to say that efforts to diversify STEM are detrimental for the field (*sr* = 7.8); less likely to say that they have personal responsibility to address inequities (*sr* = -5.7). These responses may reflect some kind of 'reverse discrimination' mentality, in which those with privilege view any reduction in their status (or increase in others' status) as an attack, rather than a leveling.

Class 4: Race-Gender Equality in STEM

This group includes 107 people, or 11.4% of the sample. The vast majority (93-100%) of the members of Class 4 responded that each race-gender group receives *neither a systematic advantage nor disadvantage* due to their demographic characteristics. They report similarly consistent and dominant views that all groups have equal opportunity (91-100%) and aptitude (93-99%). The majority (61-76%) of this group report that all race-gender groups have equal interest in STEM. (See Figure 1).

Like Class 1, members of Class 4 were less likely to support affirmative-action style policies (admissions *sr* = -5.4; hiring *sr* = -6.7) and DEI statements (department *sr* = -5.1, institution *sr* = -4.7, society *sr* = -5.9) and more likely to disagree that they have personal responsibility to address inequities (*sr* = -5.3). They were also less likely to say that efforts to increase diversity are beneficial (*sr* = -7.6), but unlike Class 4 they are more likely to say that these efforts are neither beneficial nor detrimental (*sr* = 8.0) rather than to identify them as detrimental for their field (*sr* < 1).

Class 7: Opportunity and Advantage for White and Asian Men

Class 7 is the largest group of them all, including 283 (30%) of the survey participants. The vast majority (96-100%) of this group indicated that Black and Hispanic/Latinx men and women receive a systemic disadvantage in STEM; a substantial majority indicated that Asian women (71%) and white women (76%) receive a systemic disadvantage. For Asian men, the story was rather split between neutral and advantage. In contrast, 93% of this group indicated that white men receive a systemic advantage. (See Figure 1).

Members of Class 7 were more likely to support affirmative-action style policies (admissions *sr* = 7.6; hiring *sr* = 6.9) and DEI statements by departments (*sr* = 6.9), universities (*sr* = 6.1), and professional societies (*sr* = 5.9); more likely to report that efforts to encourage diversity are beneficial for the field (*sr* = 6.5). In all these responses, members of this group were less likely to hold an opposition *or* neutral stance. This group was also more likely to agree that they have personal responsibility to address inequities (*sr* = 3.9).

Class 8: Opportunity, Interest, and Advantage for White and Asian Men

Class 8 included 158 participants (17% of sample). This group is very similar to Group 7 in their responses to the advantage, opportunity, and aptitude questions, but differs when it comes to the question about interest levels. While members of Group 7 unambiguously noted that all groups have equal interest in STEM, Group 8 is more complicated. Almost all of this group (93-96%) reported that Black and Hispanic women are less interested in STEM than White men; roughly ¾ of the group suggested that Black and Hispanic men are less interested; the majority (57%) suggest that White women are less interested compared with White men. Regarding Asian men and women, we see that the majority (58-59%) report that Asian men and women have the *same* level of interest as White men – but the bulk of the others diverge. A little more than a third (35-37%) of the group thinks that Asian women are less interested, but Asian men are *more* interested than White men. (See Figure 1). This reveals nuance and complexity within instructors' beliefs, evidencing the intersection of racialized and gendered hierarchies in STEM.

Chi-squared testing revealed a bit less about members of Class 8 than Classes 1, 4, and 7. They were less likely to oppose affirmative-action style policies in faculty hiring (*sr* = -2.1), but not more likely to support (*sr* <1); they did not contribute to the significance of responses to affirmative-action in student admissions. Similarly, they were less likely to oppose DEI statements by departments (*sr* = -2.3) and institutions (*sr* = -2.1) but not more likely to support – and they did not contribute to the significance regarding DEI statements by professional societies. They did not contribute to the significance of the personal responsibility question. However, they were strongly overrepresented in saying that efforts to encourage diversity are beneficial (*sr* = 4.1) and were less likely to say these efforts were detrimental (*sr* = -2.1) or not to have an opinion (*sr* = -3.4).

Concluding Remarks

This report is a very brief investigation of STEM instructors' views related to race and gender in STEM, as well how those views relate to activities which might advance diversity and equity in postsecondary STEM education. We detected eight profiles within our sample of 945 faculty. The four detailed here suggest that there are differing views on systemic advantages in relation to race and gender; there are also differing views of potential causes.

The prevailing response pattern found in Class 1 appears to aligns with beliefs that reparative efforts are 'unfair,' which have manifested in court cases opposing affirmative action[2] and may reflect how a loss of privilege can feel like oppression (Klein, 2020; Murrell & Jones, 1996; Yosso et al., 2004). The belief pattern reported by Class 4 is consistent with (inaccurate) beliefs about STEM and academia as race-gender-neutral spaces which function as meritocracies and do not perpetuate societal inequities. The response distributions in Classes 7 and 8 have similar response patterns with regards to systemic advantages and disadvantages; they also report similar patterns in terms of opportunity and lack thereof. However, while nearly all respondents in Class 7 report that all race-gender groups have equal interest in STEM, respondents in Class 8 indicated that they view the race-gender groups that have been systemically disadvantaged also have *less interest* in STEM.

This kind of nuance, even among those who generally recognize the presence of systemic race-gender inequities in STEM, are indicative of the nuances needed to enact systemic change toward more equitable systems. Additional research is needed to ascertain nuances of belief and how to leverage and/or change those beliefs. For example, how do members of Class 8 come to believe that Black and Hispanic men and women have less interest in STEM than Asian and White men and women – and how might that impact their views on who has opportunities to do STEM and net systemic advantages and disadvantages? There are many limitations to this study, but none which suggest that there are *not* such beliefs among instructors – particularly given the extant literature.

Variations in Grading and Instructor Feedback

Anna Marie Bergman
Fort Lewis College

Andrew Kercher
Simon Fraser University

Although developing proof proficiency is an integral part of undergraduate mathematics, little is known about instructor grading practices and feedback conventions in undergraduate courses in which proof is taught. In recent years, small-scale studies have begun to shed light on how individual instructors at single institutions assign points and provide feedback on proof-related activities. Our study extends this work by describing the results of a large-scale online survey of mathematics educators (n = 86) from multiple institutions. Participants were asked to score and give feedback to hypothetical student submissions of a proof-adjacent assignment; we investigate participants' responses and provide a taxonomy of their feedback.

Keywords: Feedback, Grading, Proof-related activities, Teaching Practices of Mathematicians

Proof is widely agreed to be central to the activity of mathematicians, and therefore argumentation and proof-related activities are an integral part of undergraduate mathematics education. Developing proof proficiency "is often the primary goal of advanced mathematics courses and typically the only means of assessing students' performance," (Weber, 2001, p. 101). In light of this, mathematics educators spend significant time evaluating and responding to students' mathematical arguments—and yet, little is known about instructor grading practices and conventions for feedback (Moore, 2016). In fact, until recently, little has been known about the teaching practices of undergraduate mathematics educators in general (Speer, Smith, & Horvath, 2010). Small scale exploratory investigations have begun to shed light on the criteria professors use to grade proofs (Moore, 2016; $n = 4$ $n = 4$), assign points (Miller et al., 2018; $n = 8$ $n = 8$), and provide feedback (Kontorovich, 2021; $n = 1$ $n = 1$). Findings indicate that proof grading is a complex teaching practice requiring difficult judgements that lead to substantial variation in points assigned and a need for further research.

Our study aims to add to the growing body of literature on undergraduate mathematics teaching practices by investigating the scores and feedback provided to a proof-adjacent activity on a large scale. We conducted an online survey of mathematics educators in which we provided 5 different student submissions analyzing a single mathematical statement. Survey participants were asked to score each submission and provide feedback to the student. Responses to the survey were used to investigate the following research question: *What kinds of feedback accompany different numerical scores on an undergraduate, proof-adjacent mathematics task?*

Background

In general, "feedback is conceptualized as information provided by an agent (e.g., teacher) regarding aspects of one's performance or understanding" (Hattie & Timperley, 2007, p.81). There is an extensive body of research on feedback, including reviews of the literature and meta-studies investigating the effectiveness feedback (Black & William, 1998; Shute 2008; Hattie & Timperley, 2007). Many of these studies span disciplines and provide frameworks for describing particular features and functions of feedback. For example, Shute (2008) compiles several frameworks in her review differentiating *directive* feedback which tells the student what to fix; from, *facilitative* feedback which provides comments or suggestions without explicit direction (Black & Wiliam, 1998, as cited in Shute, 2008). Feedback can also contain elements of both *verification* and *elaboration*. Verification acknowledges whether or not the work is correct, whereas elaboration is a description of the work designed to lead the student to a better answer (Kulhavy & Stock, 1989, as cited in Shute, 2008). While many of these frameworks offer general ideas about feedback, they are often drawn from studies based in secondary or primary school settings and feature participants who are engaged in well-defined tasks or well-structured problems. Literature on feedback in undergraduate settings that features ill-structured or open-ended tasks with multiple solution strategies is needed.

Methods

Data Collection

We conducted an online survey of mathematics educators in which we provided 5 different student submissions to the assignment pictured in Figure 1.

For the following statement, indicate whether it is mathematically true or false. If you claim that the statement is false, refute it with a counterexample. Explain the relevance of your example to the statement and how it disproves the statement. If you claim that the statement is true, prove it.

There exist four different prime numbers the sum of which is prime.

Figure 1. The assignment that engendered the student submissions featured in the online survey.

Survey participants were prompted to "Imagine that you were teaching a math class, and you received the following five homework submissions as an argument or justification for whether the statement ['There exist four different prime numbers the sum of which is prime'] is true or false." For each submission, participants were asked to score it out of 10 possible points and to also provide written feedback for the student. No scoring rubric was provided. The student submissions in question are pictured in Table 1.

Table 1. The five student submissions assessed by participants in the study.

Participant	Submission
Alpha	True. In order to prove this exists we only have to show one valid example of the statement. *a, b, c, d, e* in "primes" $a + b + c + d = e$ Example: 2 + 5 + 7 + 17 = 31 2, 5, 7, 17, and 31 are all primes. Therefore, there does exist a case where four distinct/ different primes sum to equal a prime number.
Beta	True. For example, consider the sum of prime numbers 2 + 3 + 7 + 11 = 23 which proves that there exists four different prime numbers the sum of which is prime. But there also exists four different prime numbers the sum of which is not prime. For example, 2 + 5 + 7 + 11 = 25.
Gamma	True. 2, 3, 5, and 7 are all different positive primes. Their sum, 2 + 3 + 5 + 7 = 17, is also a prime number. This example proves the initial statement that there exists a (at least one) solution. Note that 2 must be one of the primes in the sum: 2 is the only even prime number, so if none of the four primes is 2, then we have odd + odd + odd + odd = (2a + 1) + (2b +1) + (2c + 1) + (2d + 1) = 2(a + b + c + d + 2) = 2k

	where k is an integer, hence the result is even and cannot be prime (unless k = 2, except all odd primes are greater than 2, so the sum will be greater than 2 making this not possible).
Delta	True, 2 + 3 + 5 + 7 = 17, all primes.
Epsilon	This statement is true. Proving by contradiction, let us assume that this statement is false, then it becomes, "There don't exist four different prime (positive) numbers the sum of which is prime." We can disprove this with a single example, such as 2, 5, 7, and 17, which sum to 31, a prime number. As the inverse statement is false, we can see that the original statement, that there exists at least one group of prime numbers that sum to a prime, is true.

The student submissions in Table 1 were inspired by real student work and only slightly re-worded for clarity. These particular submissions were chosen because they all correctly identified the statement as true and provided the necessary example. However, they also represented a variety of different, sometimes non-standard approaches to mathematical proving.

In total, 86 participants provided at least a numerical score to each of the 5 student submissions. Of the 430 individual numerical scores, 69 had no accompanying written feedback. Therefore, in total, we analyzed 361 individual *complete responses* in the sense that they contained both a numerical score and accompanying written feedback. Delta received the fewest complete responses (n = 69), whereas Gamma received the most (n = 74). The other student submissions each received 72 complete responses.

Participant Demographics

Two populations of mathematics educators were invited to participate in the online survey through email invitations distributed via listserv. The first population was comprised of mathematics educators and mathematics education graduate students at an R1 institution in Canada; the second population was an international group of professionals who were subscribed to a listserv dedicated to promoting research in undergraduate mathematics education. Participants were only asked demographic questions related to their education and teaching experience. More specifically, participants described the highest levels at which they had taken courses in mathematics and mathematics education. They also provided the highest levels at which they had taught courses in mathematics and mathematics education (see Table 2).

Table 2. Participants' experience as students and instructors of mathematics and mathematics education.

	Graduate	Undergrad.	Secondary	Primary	None of these
Experience as a student:					
Mathematics	71	15	-	-	-
Math Education	62	6	-	-	18
Experience as an instructor:					
Mathematics	25	46	15	-	-
Math Education	43	14	-	1	30

Data Analysis

To analyze the content of the complete responses, they were subjected to two rounds of coding. In the first round, each researcher used open-coding techniques to apply many descriptive codes (Saldaña, 2016) to the data; these codes sought to comprehensively capture the variety and nuance within the data from multiple perspectives and along several axes. The research team then came together to discuss the variety found in the content. Together, they organized their independently generated codes into a unified set of codes that captured the types of feedback given to the student characters. In a second round of coding, each researcher independently recoded the entirety of the dataset, this time using the newly created codebook. Discrepancies between these codes were discussed on a response-by-response basis until consensus was obtained and complete intercoder reliability was achieved.

In this report, we present a subset of feedbacks that the research team recognized as *actionable feedbacks*. We interpreted feedback as actionable if the student to whom it was directed could interpret that feedback as suggesting a course of action that would bring the submission closer to an implied mathematical standard for proof-writing.

Findings

We identified 62% of written feedback as containing an actionable element. At the broadest level, we categorized actionable feedback as either *prompting an addition, prompting a reduction*, or *prompting a change*. Note that these three types of feedback (and each of their respective subcategories, described in the following sections) are not treated by the research team as mutually exclusive categories. In this study, however, overlap was observed to be minimal.

Feedback Prompting an Addition

Feedback prompting an addition recommends, implicitly or explicitly, that something be added to the student's submission to improve its overall quality. Within this type of feedback, four prominent subcategories arose. First, and most broadly, some feedback that prompted an addition simply asked the student to add more without any specific direction about what type of addition would be appropriate; this was a general prompt.

When the feedback prompting an addition made a specific recommendation to the student, it fell into one of the three remaining subcategories. The addition could be an *epistemological justification*; this was a common suggestion when the participant did not feel that the student submission adequately demonstrated why the proposed statement was in fact true. The addition might instead be a *structural justification*, which (in the eyes of the participant providing the feedback) would lead to a submission that had clearer internal logical structure and purpose. Finally, some participants directed the students to provide *additional insight*—that is, the feedback suggested that the submission would be improved if the student added details of their problem solving, examined related corollaries, or demonstrated a deeper understanding of the mathematics than might be required to establish the truth of the statement. Examples of each type of feedback prompting an addition are provided in Table 2.

Table 2. The types of feedback prompting an addition.

Feedback Type	n	Example
General	6	"You should explain a bit more."
Epistemological Justification	24	"Why is it sufficient for you to identify just a single example to establish the statement as true?"
Structural Justification	33	"The argumentation is correct but you should express it through a discourse, and make logical relationships clearer."
Additional Insight	69	"You have answered the question correctly. Can you expand by giving another three examples? What do all of your examples have in common?"

Feedback Prompting a Reduction

Feedback prompting a reduction pinpointed a particular area in which the student's submission could be cut down in some way, rather than expanded. This type of feedback manifested in two ways. First, the reduction might target *excess information*; this type of feedback can be interpreted as the antithesis of feedback prompting the addition of additional insight. That is, whereas some participants posed questions in their feedback that solicited mathematical details that did not directly contribute to a proof of the statement at hand, other participants specifically requested that students remove such details. Second, the reduction might require removing *excess machinery*. In this type of feedback, the respondent typically felt that the information presented in the student submission was relevant but that the proof structure or level of mathematical formalism used to convey that information was unnecessary and could be reduced. Examples of each type of feedback prompting a reduction are provided in Table 3.

Table 3. The types of feedback prompting a reduction.

Feedback Type	n	Example
Excess Information	44	"It suffices to show that one case exists. It's not necessary to show that there are sums of primes for which the property does not hold."
Excess Machinery	51	"Your proof is correct, but it's unnecessarily cumbersome. The original statement is a claim about a single case existing. The most direct proof then just gives an example. The extra layer of disproving the negation is a bit confusing for a reader."

Feedback Prompting a Change

Finally, feedback prompting a change suggested that some already existing aspect of the work was relevant, and thus should not be removed, but instead should in some way be modified. Feedback prompting a change typically targets one of two types of perceived shortcomings. On one hand, the reviewer may have felt that the mathematical content of the student's submission needed to be changed. This type of feedback typically attended to a student's misuse of mathematical vocabulary or symbols; often, it pointed out what the respondent perceived to be a "typo" on the part of the student. On the other hand, the reviewer may have called attention to a way in which the organizational or grammatical formatting of the submission was inadequate. Examples of each type of feedback prompting a change are provided in Table 4.

Table 4. The types of feedback prompting a change.

Feedback Type	n	Example
Mathematical Content	34	"Terse and correct except for the error in mathematical grammar. The equation is a true assertion about primes, but an equation is not a prime."
Formatting	9	"Nice addition. In the future, please separate the proof from additional insight, and mark the proof as such."

Frequency of Actionable Feedback Types

In Table 5, we present the frequency with which of each type of actionable feedback was provided to each student submission. In this table, we also coordinate the type of actionable feedback with whether or not the participant awarded the student submission in question with a full or partial score (FS and PS, respectively). For example, of the 19 feedbacks that prompted Alpha to include additional insight, 9 of these still awarded his submission a full score; another 10 awarded him less than a full score.

Table 5. The frequency of each type of actionable feedback given to each student submission.

Feedback Type	Student									
	Alpha		Beta		Gamma		Delta		Epsilon	
	FS	PS	FS	PS	FS	PS	FS	PS	FS	PS
Prompting an Addition										
General	-	-	-	-	-	-	-	6	-	-
Epist. Justification	1	1	1	3	-	-	2	15	-	1
Str. Justification	2	1	4	3	1	1	1	12	-	8
Additional Insight	9	10	6	9	7	3	6	9	4	6
Prompting a Reduction										
Excess Information	-	-	16	16	8	4	-	-	-	-
Excess Machinery	3	1	-	-	-	-	-	-	25	22
Prompting a Change										
Math Content	3	5	-	1	7	3	-	3	-	12
Formatting	1	1	2	-	2	-	-	3	-	-

Discussion

Miller (2018) observed that, when instructors allotted scores to student-submitted proofs, "the points that they assigned was dependent upon their perceptions of participants' understanding of the proof that they submitted" (p. 30). As seen in Table 5, certain types of actionable feedback are more likely to be attached to partial numerical scores; prompts for additional epistemological justification, for additional structural information, and for a change in mathematical content. These types of actionable feedback appeared 83%, 76%, and 71% of the time (respectively) with a partial numerical score. In light of Miller's finding, the association of these types of feedback with partial scores could indicate which types of errors instructors tend to recognize as indicative of a fundamental misunderstandings on the part of the student author.

On the other hand, actionable feedback prompting a reduction of excess information or machinery did not clearly correlate to either a full or partial score. Respondents in our study did not clearly agree on whether or not "too much" of something demonstrated that the student fundamentally misunderstood the underlying mathematical logic. Beta and Epsilon received prompts for a reduction in information and machinery (respectively) more than any other student submission received any other type of feedback. However, despite how frequently respondents provided these types of feedback, they did not clearly correspond to a partial score.

We note that prompts for additional insight were also more common on partially scored submissions, but only slightly (at 54%)—and this trend was reversed in the case of Gamma's feedback. In fact, because of Gamma's overall high scores, this was not the only trend they reversed. Gamma's submission was the only student's work to receive mostly full scores even in the presence of a prompt for a change in mathematical content which, as discussed in the previous paragraph, was often attached to partial scores. As described in Moore (2016), some instructors, when grading proof-like student submissions, do not deduct points for each error; instead, they attempt to assign a score "by judging the overall quality of the proof" (p. 263). Thus, while Gamma's mathematical typo generated a number of feedbacks prompting a change in mathematical content, they still often received full credit because respondents perceived that Gamma understood the underlying mathematics of the proof.

Prompts for additional insight comprised a large and especially nuanced portion of feedback. This type of actionable feedback occurred more often than any other, and in 30 of its 69 instantiations, it was the only type of actionable feedback offered to a student who received a partial score. Of these 30 feedbacks, 6 are very open-ended prompts (e.g., "Can you dig deeper?"). The rest are guiding questions that ask the hypothetical student to consider or provide material that is beyond the scope of the original prompt (e.g., "What are the reasons of the choice of your primes?"). Occasionally, the respondent instead presents their prompt for additional feedback in the form of an observation; for example, one feedback explains that "this [Delta's submission] is correct but it offers very little in the way of showing where your numbers come from or telling me how you understand this must be true."

Miller (2018) found that, by some instructors' standards, "correct proofs would not necessarily receive full credit" (p. 29). Our study corroborates this finding. Student submissions were chosen for this study on the basis that they each correctly attended to the task at hand. As Miller observed, however, "correctness is not the only criterion that is used by mathematicians for grading proofs" (ibid, p. 30); the student submissions in this study were also often scored based on how well respondents felt they demonstrated the student authors' understanding of why their work was sufficient and correct. Sometimes, this is clear in the accompanying written feedback—see the example of feedback requesting additional structural justification in Table 2.

Conclusion and Limitations

Our main contribution is a taxonomy of the feedback mathematics educators provided to students in proof-adjacent activities. Beyond a more detailed description of the feedback presented above, the presentation will also explore a type of feedback adjacent to the actionable feedback described in this report: that is, when no actionable written feedback is provided and yet the student submission is only awarded a partial score. We wonder, when instructors provide such feedback, what socio-mathematical norms (if any) are they attempting to reinforce? A future study could also explore what actions students take in response to actionable feedback.

We would like to recognize two limitations to our study. First, respondents were not allowed to physically grade the student submissions—that is, they weren't provided with submissions that they could "mark up" with non-textual feedback. Spiro et al. (2019) found that annotations such as checkmarks or arrows account for 50% or more of the recorded feedback when professors grade assignments. Our survey required participants to type feedback in the form of sentences, which might be different from their usual method of providing feedback to their students. On the other hand, our study could contribute to a better understanding of how instructors' feedback practices change in an online environment.

Second, we agree with the sentiment expressed by Sommerhoff & Ufer, who argue that "the generalizability of results in the context of proofs are always questionable, as they rely on local socio-mathematical norms" (2019, p. 729). From that perspective, our study was limited by the decontextualization of the student work from a greater classroom culture. In fact, some respondents indicated that their treatment of student submissions would depend on the socio-mathematical norms that had been established in the classroom. The feedback given by these participants may not be representative of their actual feedback practices.

Multivariable Calculus Instructors' Reports of Resource Use: Resources Used and Reasons for Their Use

Rafael Martínez-Planell
University of Puerto Rico, Mayagüez

Deborah Moore-Russo
University of Oklahoma

Given the challenge of visualizing the main constructs of two-variable functions and their differential and integral calculus, it is important to consider the use and perceived potential of resources to contribute to students' understanding of multivariable calculus. This case study considers how four instructors attempt to utilize resources in their multivariable calculus teaching and their motivations to do so. We study how these instructors think about the digital and non-digital resources that they use to foment students' understanding. We also look at their reporting of the ways that instructors, students, and resources interact in multivariable calculus to determine if resource use is meant to facilitate visualization, reasoning, or communication. With this, the study proposes to contribute to the discussion of resource use in multivariable calculus.

Keywords: multivariable calculus, digital resources, visualization

Introduction

Multivariable calculus is an important tool for modeling phenomena in science, technology, engineering, mathematics, and other fields of knowledge. There is a growing research base on the teaching and learning of two-variable functions that includes the study of related definitions, basic ideas, and geometric understanding (e.g., Martínez-Planell & Trigueros, 2021; Dorko & Weber, 2014; Martínez-Planell & Trigueros, 2012, 2019; Trigueros & Martínez-Planell, 2010; Weber & Thompson, 2014; Yerushalmy, 1997). There are also studies about the differential calculus of two-variable functions (e.g., Harel, 2021; McGee & Moore-Russo, 2015; Martínez-Planell et al., 2015, 2017; Tall, 1992; Trigueros et al., 2018; Weber, 2015) and their integral calculus (e.g., Jones & Dorko, 2015; McGee & Martínez-Planell, 2014; Martínez-Planell & Trigueros, 2020). All of this is discussed in a survey article on multivariable calculus (Martínez-Planell & Trigueros, 2021). There are some studies on the use of non-digital resources (e.g., McGee et al., 2012, 2015; Sherer et al., 2013; Wangberg et al., 2013, 2020). However, the literature on the use of digital technologies is somewhat sparse (e.g., Alves, 2014; Habre, 2001; Ingar & Silva, 2019; VanDieren et al., 2020).

To further study the use of digital resources, we seek to study how multivariable instructors report that they use resources in their teaching of multivariable calculus. More specifically, we consider how multivariable instructors report that digital, digitally generated, and other resources are used to nurture students' understanding and their reports of how students, instructors, and resources interact in the construction of multivariable calculus understanding. This study attempts to contribute to answering these questions by focusing on four instructors as they discuss the resources they use and the reasons for using them to determine if they are focusing on visualization, reasoning, or communication.

Theoretical Framing

Didactic Triangle and Didactic Tetrahedron

The didactic triangle is a model that can be used to organize and discuss instructional phenomena by considering three key components, the teacher, the students, and the content, as well as interpreting the links between the three components in the context being studied. Observing that "artifacts are not passive resources that teachers and students draw on but 'actively' shape activities," Rezat and Strasser (2012, p. 644) argue to extend the didactic triangle to the model of the didactic tetrahedron (displayed in Figure 1). The idea of the didactic tetrahedron was previously presented by Tall (1986). This seems particularly appropriate in our study since we focus on artifacts used, including both digital and non-digital resources that instructors leverage in their instruction.

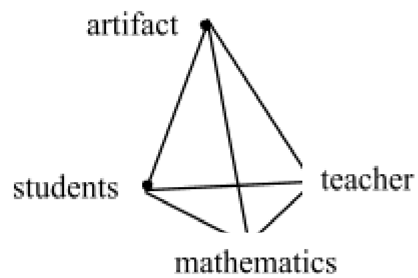

Figure 1: Didactic tetrahedron model (Rezat & Strasser, 2012).

The Teaching Triad

Jaworski's (1994) teaching triad (displayed in Figure 2) may be thought of as an expansion of the "teacher" node in the didactic triangle. It consists of three interrelated elements: sensitivity to students, mathematical challenge, and management of learning (Jaworski et al., 2017). *Sensitivity to students* relates to the teacher-student link. It describes the teacher's knowledge of students and the teacher's attention to affective, cognitive and social student needs. It includes the ways in which the teacher interacts with individuals and how the teacher guides group interactions. *Mathematical challenge* relates to the teacher-mathematics link. It describes the challenges that a teacher offers to students to promote mathematical thinking and activity. It includes the assigned tasks, the posed questions, and any teacher emphasis on metacognitive thinking. The *management of learning* construct extends the didactic triangle to the wider context of the classroom. It describes the teacher's role in the constitution of the classroom learning environment by the teacher and students. It includes, among other things, classroom groupings, instructional planning of tasks and activities, selection and use of instructional resources, and classroom norms that are set. The three components are interrelated.

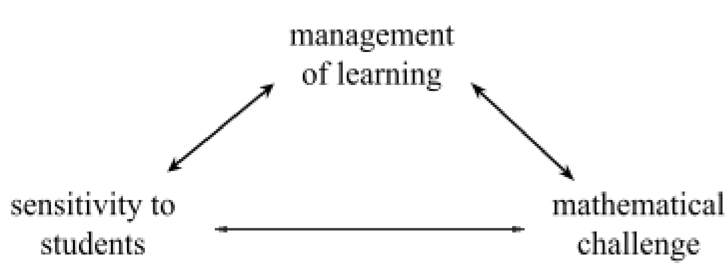

Figure 2: The teaching triad (Jaworski, 1994).

Spatial Literacy

The broader sense of being literate refers to being competent and knowledgeable in a certain area (Moore-Russo & Shanahan, 2014). Spatial literacy includes the abilities to visualize objects in three-dimensional space, to reason about their properties and relations, and to communicate with others about these objects and relations. Moore-Russo and colleagues (2013) introduced a framework that describes spatial literacy in terms of three domains (shown in Figure 3): visualization, reasoning, and communication. *Visualization* is the process of generating cognitive representations of spatial objects through visual images that may or may not be facilitated by external representations or physical actions. For example, a student can internally visualize a paraboloid when looking at a representation of a paraboloid on a computer screen, or when listening to the word “paraboloid”, or when out of habit or by memorization the student imagines the geometrical object given the symbolic representation $z = x^2 + y^2$ without reasoning about or justifying the relationship or communicating about it with others. *Reasoning* is defined as the cognitive processes that individuals use to form conclusions or make judgments from a given set of premises; it is the process of organizing, comparing, or analyzing spatial concepts. For example, a student is reasoning when mentally using transversal sections to justify that the graph of $z = x^2 + y^2$ is a paraboloid. Reasoning may or may not involve geometric imagery, as when using an entirely symbolic mental argument to conclude that $z - x^2 = y^2$ is also a paraboloid. *Communication* is the exchange of information with others using resources such as language, written symbols, gestures, etc. to convey ideas that relate to spatial objects or relationships. For example, a student explaining to another why the graph of $z = x^2 + y^2$ is a paraboloid is engaging in communication. At the same time, the student may or may not be engaged in reasoning and/or visualization depending on the argument in the student’s mind. The different domains overlap as suggested in Figure 3. Although we will not give examples of each possibility, they may be imagined using variations of the above paraboloid examples.

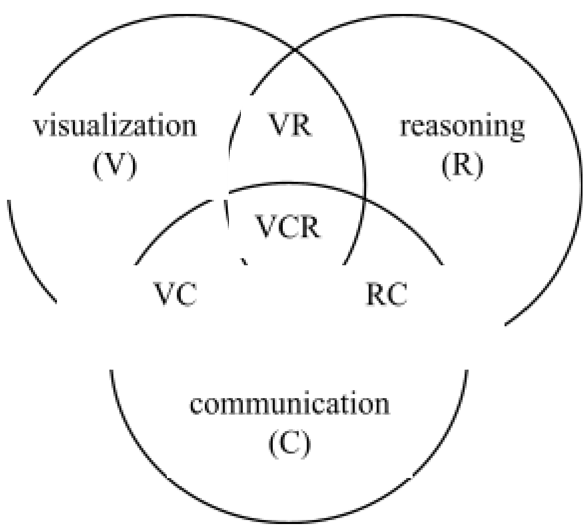

Figure 3: Spatial literacy domains (Moore-Russo et al., 2013)

Research Questions

This case study considers how university instructors reflect on teaching multivariable calculus specifically related to the resources they use. The specific research questions follow.

1. Which **resources** do university mathematics instructors report that they use or have used in the past for teaching multivariable calculus? What reasons do they give for their selections? How do they report that they use the resources?

2. Which, if any, **spatial literacy domains** (i.e., visualization, reasoning, communication) do instructors mention and focus on? Is this the same for all instructors or does it vary by instructor?

Methods

The data reported here are part of a case study that involved four university instructors from four different U.S. universities. We studied written responses to a series of 24 survey questions and present the results of the eight questions that directly address the resources used and the reasons for their use below. The instructors were part of a convenience sample of multivariable calculus professors from four different universities in four different states working on a project whose main purpose was to help students develop a deeper understanding of multivariable calculus concepts through hands-on, physical 3D explorations using guided learning activities and innovative, pedagogically designed 3D-printed surfaces and solids. All four instructors were currently using the digital CalcPlot3D platform (Seeburger, 2018). Since this paper focuses on the instructional decisions that guide the work of teaching, specifically of teaching multivariable calculus, we analyze data from the instructors in regard to their teaching rather than analyzing student thinking, student engagement, or how students make meaning of the content at hand.

An instructor's response to a survey question was considered the unit of analysis. The research team independently reviewed the survey responses multiple times. During their independent review, they marked ideas that appeared frequently. The "bottom-up" analysis yielded possible directions that the analysis could take. The team met to discuss this first pass over the data, comparing their notes. They decided to revisit the data individually while considering possible frameworks that could be used to frame the research. The team met twice to determine the framing of the study and then decided on specific categories to use for the coding. Each team member coded the data set independently before coming together to discuss the coding until a consensus was reached. During this process, the team pulled out representative quotations from the data set. The results were analyzed both in terms of each instructor as well as in terms of general tendencies across the group of four instructors.

Results

We begin by reporting our results for the first series of research questions: Which resources do university mathematics instructors report that they use or have used in the past for teaching multivariable calculus? What reasons do they give for their selections? How do they report that they use the resources? In our discussion, we will refer to the four surveyed instructors as M, P, S, and T, and we consider their use of digital resources then their use of other types of resources.

Instructor M has used CalcPlot3D since initially teaching multivariable calculus. For out-of-class assignment, she tried Survey Monkey and a publisher's online homework system before settling on WeBWorK, since she could embed video lectures and CalcPlot3D labs in that platform. She has also used Jamboard and Flipgrid for more student interaction. She has used Matcha.io as an online, mathematics editor. Instructor P initially used Cabri Geometry and Excel before writing his own Visual Basic, Java, and Java Script applets. CalcPlot3D followed from this. This instructor also used other digital resources like Smartboards, which he used to record lessons and an online custom OER textbook on the LibreTexts platform together with the WeBWorK online homework system and student-produced videos. While some digital textbooks might be what Viglietti and Moore-Russo (2018) call "static resources" (i.e., text-heavy resource that relies on typed text and digital pictures), the custom OER textbook used by P leveraged interactive figures. Instructor S initially used Mathematica and GeoGebra before she adopted

CalcPlot3D. Instructor T initially relied on Mathematica with some incorporation of Desmos and Tikz for two-dimensional plots before he moved to using CalcPlot3D. The reasons given by the four instructors for using digital resources in multivariable calculus and for changing their initial graphing software (which only applied to P, S, and T) are detailed in the next paragraphs.

Even though their initial choices of software varied, their reasons for using digital resources were fairly consistent. The responses from all four instructors showed the importance of *mathematical challenge* to them and the value they placed on students visualizing ideas of multivariable calculus, convinced that doing so would improve student understanding. M mentioned that digital resources "give students a deeper understanding of the material beyond the computational and symbolic which they are used to" stating that digital resources "challenge students to think and reason visually in 3D." P reported that "students need to see the relationships of calculus in motion to develop the kind of intuition for the definitions and constructs involved." S claimed to use digital resources every class "to create illuminating visual demonstrations" and to show students the insights that could be gained through *visualization*. S felt that digital resources help foster "a spatial awareness and understanding that connects to the material they [students] are learning." T felt digital resources helped students "attach geometric meaning to various course concepts."

The reasons that Instructors P, S and T gave for changing from their initial choices of graphing resources to a different digital resource (in this case, CalcPlot3D) also show *sensitivity to students* in their concern for students' affective, cognitive, and social needs. The most cited reasons were that not only is CalcPlot3D free (i.e., students do not incur any cost), but more importantly it requires no specific syntax so that it is easier to use. Instructor P said that he "had to change platforms a number of times to keep my visualizations usable and easier to get students to play with themselves." When explaining why she switched digital resources, S reported that "CalcPlot3D requires no coding syntax, unlike Mathematica, which I have used before for this course. It is more intuitive for users than GeoGebra, which makes it much more accessible to students." She stated, "my students could immediately jump into graphing with the program without any training." Instructor T adopted CalcPlot3D because "the syntax is simple enough that I feel good about having students work with it, and the fact that it's web-based is great."

Issues related to the *management of learning*, that included providing formative feedback, also figure among the reasons given by the instructors for using digital resources. Instructor comments often dealt with software features that allow for the creation and use of in-class instructor demonstrations or independent student work. Instructor M said, "I have embedded video lectures into webwork with 'exit ticket' questions that students answer immediately following watching a video. I also embed CalcPlot3D labs in webwork to give students immediate feedback." Instructor P stated that he would use a scenario presented with CalcPlot3D as a common focus for student discussion board assignments, and he "encouraged students to visually verify their results using CalcPlot3D" during student video presentations. Instructor S reported that she liked "the self-explanatory nature of the [CalcPlot3D] program and the powerful options that are built in to help instructors easily craft in-class demonstrations." Instructor T said, "there are a lot of visualizations I spent hours on creating in Mathematica, only to later realize that CalcPlot3D had already built in…the software is robust enough that I can usually render the objects that I want to render, and I'm calibrating my expectations of what I can ask students to do with the software independently and with how much guidance." T reported using CalcPlot3D as "visuals I include in lectures, assignments, and worksheets."

As for non-digital resources, there was also a wide variety of resources that have been used by three of the instructors including: 1x1x1 blocks (M), Play-Doh (M), paper cylinders to demonstrate parametric curves lying on surfaces and finding tangent planes (M), a hill on campus to explain partial derivatives (S), extendable pointers with arrows (S), a machine-shop-produced tabletop 3D coordinate system (S), coffee stirrers and fishing line (T), giant arrows made from wooden dowels for vectors (T), the K'nex toy pieces for xyz axes (T), various foods that were sliced to represent integration (T), and cardboard sheets for planes (T). The incorporation of such a wide variety of resources shows the instructors' *sensitivity to students*' cognitive needs. These resources shed light on how instructors have changed their *management of learning* for certain topics by bringing what they believed to be the most relevant resources.

The use of 3D-printed surfaces, a non-digital yet digitally generated resource, were reported by all four instructors. This is of particular interest since it is the focus of a project in which the four instructors participate. All four instructors were aware and mentioned that CalcPlot3D has the capability to produce STL files that can be used to print a 3D surface (or curve) model using a 3D printer. The instructors report using 3D-printed surfaces either just a few times a semester or some of the time. The most common reasons given for using 3D-printed surfaces related to *mathematical challenge*; they included their beliefs that: 1) embodied learning is privileged by the potential interactivity and manipulability of the physical object and 2) the 3D model had the potential to bridge the gap between the 2D renderings of a screen and the 3D reality. Instructor M mentioned student engagement when using 3D-printed surfaces, she claimed the engagement came from students being "able to hold and point to them" and believed in the importance of showing "an additional visual representation of the surface beside the 2D version on the screen." Instructor P shared that since a 3D-printed surfaces are "more concrete than the 3D renderings on the 2D computer screen using CalcPlot3D, it can be quite helpful for students, making the surfaces tactile" and "used it to help us confirm our various traces of the surface drawn on the Smartboard." Instructor S mentioned, "I wanted to provide students with a physical object to touch, to hold at various angles, and to point to features as they discuss concepts with their classmates. Having a tactile object removes any ambiguity that could arise from viewing a 3D object on a 2D screen." While Instructor T claimed that both 3D-rendered and 3D-printed objects afford avenues for students to be able to attach geometric meaning, he believed, "3D models have some advantages, like being able to draw on the models; they are easy to handle and view from multiple angles, in a more natural way than computer images." The reasons for using 3D printed surfaces are indicative of the instructors' *sensitivity to students*' cognitive needs. However, there were comments, especially from Instructor T about how they also affect the *management of learning* since there are non-negligible constraints to their use in class (e.g., number of models needed, class time issues in passing out and collecting the models).

We now report our results for the second series of research questions: Which, if any, spatial literacy domains (i.e., *visualization*, *reasoning*, *communication*) do instructors mention and focus on? Is this the same for all instructors or does it vary by instructor? Concerning the spatial literacy domains, the data from all four instructors were similar and provided evidence of a seemingly balanced instructional focus on VR (*visualization-reasoning*) and VC (*visualization-communication*), with some VRC (*visualization-reasoning-communication*) instances.

In the VR overlap, instructor comments focused on issues related to students being able to see the idea and relationships in multivariable calculus as they were trying to make meaning of the topics or trying to solve tasks that had been assigned to them. Instructor M mentioned how "challeng[ing] students to think and reason visually in 3D… gives students a deeper understanding of the material beyond the computational and symbolic which they are used to." Instructor P talked of benefits to student understanding when they are "rotating the surfaces in their hands to gain perspective." S claimed, "Visualization through CalcPlot3D gives students a spatial awareness and understanding that connects to the material they are learning. Instead of going through calculations blindly, students develop a spatial understanding of the concepts."

In the VC overlap, Instructor M related that "Each group got a different model so some students 'connected' with their model referring to it later in the class (e.g., 'Remember in our group's model there was that point that....')." While some of the comments focused on student-to-student *communication*, a number of comments related to instructor-to-student *communication* where instructors used resources in their lectures to help visual clarify the items being presented through demonstrations and examples. Instructor P stated, "I have brought in a couple 3D printed surfaces for students to see and to point out certain features."

The overlap of VRC was also noted, but not as often as comments that involved either VC or VR. As shared earlier, Instructor P encouraged students to use CalcPlot3D as a common anchor that allowed them to visually communicate their arguments in online discussion forum posts as well as in student-produced video presentations. Instructor S observed, "during office hours, students will reach for one of the 3D surfaces in order to ask their question. Likewise, they will reach for a surface to explain the answer to a question that I have posed to them." Instructor T commented that the "models are easy to handle and view from multiple angles (in a more natural way than computer images), and I find they work well for in-class group work" that would naturally involve *communication* among the students and for "office hours" that would involve *communication* between the instructor and a student.

Conclusions

We found that concern for students' learning and the conviction that geometrical understanding is crucial in multivariable calculus, moved the four instructors to consider the use of a variety of resources in their teaching. Three of the instructors started with a graphing resource other than what they were using at the time of the interview (CalcPlot3D). Ease of use for them and for students was the major factor influencing their change in digital technology. It seems that over time (and with more instructor experience) the attention to the use of technology for teaching shifted from being instructor-centered (demonstrations to present in class) to student-centered (activities to engage students and group work). In the spatial literature domains, there was about an equal number of *visualization-reasoning* and *visualization-communication* comments and some which also suggested *visualization-reasoning-communication* activities. The observations resulting from our study suggest that the interviewed instructors were from the start *sensitive to students'* needs and that future faculty adopting digital resources in their teaching could benefit from support in issues dealing with the *management of learning*: the creation of demonstrations and activities using their software of choice, being able to discuss constraints and difficulties using particular software for graphing in multivariable calculus, coordinating the use of graphing software and digital homework systems like WeBWorK, using digital technology in evaluation, sharing materials, and so on. Similarly, the instructors seem to find great potential of digitally generated resources, particularly 3D-printed models, in helping with student *visualization*, *reasoning*, and *communication*. However, the creation and subsequent use of these models in class seems to also require as much support as digital resources.

Instrumental Genesis: For Loop and ‘len()’ as Artifacts

Antonio Estevan Martinez IV
California State University, Long Beach

In this contributed report I present results from a teaching experiment broadly focused on students utilizing machine-based computing as a mediating tool to learn fundamental concepts related to set theory and logic. Specifically, I highlight the mathematical activity of one student and his unique approach to finding the intersection of three sets. To understand how this student leveraged the computer programming environment, I used the analytical framework known as instrumental genesis, which can be utilized to investigate the confluence of an artifact (often a piece of technology) and the human mind to solve a mathematical problem. Results indicate that the student was able to use computational tools such as For Loops and the len(), or "length," function as artifacts in his solution to finding the set intersection.

Keywords: Computing, Programming, Set Theory, Instrumental Genesis

Introduction

In this report I present the results of an investigation into student thinking in which students were tasked with using Python, the text-based computer programming language, to learn fundamental concepts related to set theory and logic. The call for research to investigate the ways in which technology and, more specifically, computers can be used to facilitate the teaching and learning of mathematics is not new (e.g., Fey, 1989; Papert, 1980; Perlis, 1962). However, previous approaches to address this need have varied in the medium through which the technology is used, such as video games (Levine et al., 2020), graphing calculators (Leng, 2011) and virtual reality (Bogusevschi et al., 2020). Also, these areas of technology integration have been a focus at multiple levels throughout the educational system (Ball et al., 2018; Oates, 2011). Moreover, Lockwood and Mørken (2021) explicitly made a call for research in undergraduate mathematics education with a focus on machine-based computing. They define machine-based computing as "the practice of precisely articulating algorithms that may be run on a machine" (p. 2). An important aspect of machine-based computing is the development of an algorithm rather than its performance or implementation alone. This is an important component of machine-based computing that distinguishes it from other forms of computing such as the use of Desmos where one may only be required to input parameters to create a visual representation of a function. Thus, Lockwood and Mørken consider machine-based computing to be a separate construct that includes the use of programmable calculators, writing packages in Geogebra, and using text-based or block-based programming languages. As such, the focus of my study was to introduce machine-based computing (Python) as a mediating tool to work with mathematical ideas in the context of mathematical logic and set theory.

Additionally, I emphasize a need to focus on machine-based computing in the context of mathematics for three main reasons. The first is that data science, and computer science more broadly, are becoming increasingly valuable skills in an age where fields such as artificial intelligence and machine learning are in position to be the most influential drivers of change for our society (World Economic Forum, 2016). The second purpose draws on Lockwood et al.'s (2019) commentary on the relationship between computing and students' mathematical activity in that computing will be a focus for mathematics educators soon to come. By encouraging the use of computational software as a tool for students to learn and connect ideas in undergraduate mathematics, I am encouraging a movement for where mathematics education will be going in the coming decade. Lastly, many areas of mathematics lend themselves to machine-based computing environments, which suggests that the computational environments may serve as useful tools for learning the mathematical content. For this study, I focus on a fine-grain analysis of how programming may influence student reasoning and learning of mathematical set theory and logic. The research question driving this study is the following: *How does Python mediate students' reasoning of important concepts related to set theory and logic?* In the next section I describe a theoretical analysis framework which can be used to document students' mathematical activity while using a piece of technology.

Theoretical Framework

As alluded to in the introduction, programming is starting to become a fundamental aspect of learning undergraduate mathematics. For example, Buteau et al. (2020) investigates how an undergraduate student may use programming to learn both theoretical and applied mathematics. Rather than investigating student work with a particular mathematical concept, the authors articulated the use of a specific theoretical framework to study the use of programming as a tool for learning mathematics. The framework is known as the *instrumental approach* (Artigue, 2002; Guin & Trouche, 1998; Trouche, 2004). Importantly, Buteau et al. (2020) highlight that the instrumental approach has been used in the past for various artifacts such as graphing calculators, spreadsheets, applets, etc. but has not yet been used in the case where a programming language was considered as the artifact. They do provide illustrative examples of the relationship between mathematical inquiry and programming through the lens of an instrumental approach, but they do not provide an in-depth analysis of one specific mathematical concept. Therefore, to investigate how Python supports students' learning and advancing mathematical activity related to set theory and logic, I utilize the instrumental approach.

The description of the instrumental framework starts with the distinction between *artifacts* and *instruments*. An artifact may be a physical object, such as a graphing calculator, but also may be a formula, graph, or other objects that are central to a certain mathematical task (Roorda et al., 2016). Once the artifact has been determined, the integration of the artifact into a learner's mathematical activity is known as the instrument. This includes the use of the artifact to problem solve and as Trouche (2004) describes it, "an instrument can be considered as an extension of the body, a functional organ made up of an artifact component...and a psychological component" (p. 285). In the context of this study, the artifact is the computer programming environment, Python. As mentioned, programming environments have previously been utilized with this framework in mathematics education, but never with a focus on students' advancing mathematical activity in relation to set theory and logic.

The development of the instrument is known as *instrumental genesis* (Artigue, 2002) and is tied directly to the artifact and to the mental actions of the learner in their use of the artifact to carry out a given task. This means that the learner may be afforded particular lines of reasoning but also may be constrained in their mental activity given the particular features of the artifact itself. This psychological component, the mental processes of the learner to carry out a particular task, is referred to as an *instrumented action scheme* (Trouche, 2004). The idea of a student's scheme draws on the theory of constructivism and is described by Vergnaud (2009) as "the invariant organization of activity for a certain class of situations" (p. 88). To clarify, this definition encompasses the assimilation of familiar situations which learners respond to with their learned rules or already-established ways of understanding as well as addresses the adjustments necessary to address novel situations in which a learner is required to adapt, modify or reorganize their psychological thought processes. In the literature regarding the instrumental approach, schemes are defined as consisting of four main features (Trouche, 2004; Vergnaud, 2009). These features are summarized well by Buteau et al. (2020) as:

1. The goal of the activity, with sub-goals and expectations.
2. Rules of action: stable behaviors of the subject.
3. Operational invariants, which can be theorems-in-action (propositions considered as true) or concepts-in-action (concepts considered as relevant).
4. Possibilities of inferences. These possibilities are essential for the adaptation of the scheme to the specific features of the situation. (p. 1026)

As Buteau et al. (2020) state, the rules of action and operational invariants may present themselves through students' mathematical activity in a situation where a student says "When I want to do this [aim of the activity] … I always act like this [rule of action] … because I think that [operational invariant]" (p. 1027). The rules of action are stable methods of activity that the student will rely on to accomplish a task, based on the belief or conceptual understanding (operational invariant) of how something works. The operational invariants are broken down into two categories, theorems-in-action and concepts-in-action. The theorems-in-action are constructed ways of understanding how something works. The concepts-in-action are the related mathematical concepts that are pertinent to the goal of the activity. For example, if a student was asked to use a graphing calculator to find the local max and min of a function given a certain domain, an example of a rule of action would be 'enter the function in the calculator'. A concept-in-action might be 'zero slope at local min and max,' and a theorem-in-action might be 'the window display of the graphing calculator must capture the specific domain that is asked in the problem in order to be sure of the local max and min.' Lastly, the possibilities of inference would be situations in which the student encounters a problem that might result in new rules of action and operational invariants. In accordance with constructivism, technically these schemes are constructed within the learner's mind and thus are not directly observable, however, they can be inferred by an instructor or researcher based on the "regularities and patterns in students' activities" (Drijvers et al., 2013, p. 27). That is, for the purposes of this study, a "scheme" is a model that I construct based on the actions of the student.

As Roorda et al. (2016) highlight, at the core of the instrumental approach is the relationship between one's scheme and their *technique*, or actions in response to a given situation. In contrast to a student's scheme, the technique consists of the observable actions that are carried out by the student. It is important to highlight that while the observable actions inform the researcher's interpretation of the learner's scheme, their actions may also contradict the scheme that was originally developed based on previous actions. So, the student's techniques are in-the-moment observable actions of the student that may or may not coincide with the student's scheme. The student's techniques are linked with conceptual elements that help frame an understanding for the student's scheme. To capture the idea of instrumental genesis in more detail, it is broken into two subcomponents, instrumentalization and instrumentation, each describing a distinct directional relationship between the artifact and the learner (Artigue, 2002; Trouche, 2004). *Instrumentalization* is the reshaping of the artifact in the learner's mind as to what the artifact can do to accomplish a certain task. Instrumentalization occurs through the use of the artifact and develops over time as the learner understands the functionality of the artifact and its capabilities. This includes the use of an artifact by the learner in unexpected or unintended ways. An example of this could include a learner storing mathematical results and theorems in their graphing calculator as a memory aid for future use. *Instrumentation* works in the opposite direction in which the artifact itself, with its built-in constraints and potential uses, is shaping the ways in which the learner conducts their mathematical activity. In Table 1 I provide a hypothetical example of what a student's subset scheme might look like from an instrumental genesis perspective using the framework provided by Roorda et al. (2016).

Table 1: Hypothetical Example of a Student's Subset Scheme

Instrumentation Scheme	Techniques	Conceptual Elements	Technical Elements
Subset Scheme	Draw a Venn Diagram	To determine if a set is a subset, one must conclude that every element of the set is an element of the other set	Write a For Loop to check that each element is an element of the larger set

Roorda et al. (2016) provide examples of how an artifact may shape a learner's mathematical activity in their description of a student named Andy's schemes regarding the concept of the derivative. One specific example is Andy's use of the dy/dx-option on the graphing calculator to calculate the steepness of a graph at a particular point. Andy used this option in other examples throughout the longitudinal study when they needed to find instantaneous rate of change and did not coordinate between the dy/dx-option on the calculator and the symbolic representations that were covered in class. The authors conclude that while Andy's graphical and numerical representations of the derivative were strong, these representations were being developed independent of Andy's symbolic representations, a negative consequence of Andy's overreliance and strong use of the graphing calculator. Trouche (2004) comments that both instrumentalization and instrumentation work together in tandem as part of the instrumental genesis process, and thus refers to a learner's scheme as the instrumented action scheme as opposed to other terms such as *instrumentation scheme* as used by Roorda et al. (2016). For the purposes of this manuscript, I will adhere to Trouche's approach to the development of a learner's scheme (as perceived by the researcher) and refer to it as an instrumented action scheme or just scheme for short.

Methods

Participants were recruited from a four-year Hispanic-Serving Institution and were purposefully selected (Patton, 1990) in that they had already taken, or are currently enrolled in differential or integral calculus and not enrolled in an Introduction to Proofs course. Thus, the students in this study were not familiar with mathematical logic or set theory. Additionally, the students had little-to-no prior experience programming. The design of the study was a conjecture-driven teaching experiment (Confrey & Lachance, 2000) in which the conjecture was the following: *programming can serve as an experientially real context in which students will be able to connect mathematical logic and set theory.* There were 10 students that participated in the study divided into four groups with two to three students in each group. Due to the ongoing COVID-19 pandemic, the teaching experiment sessions were conducted and recorded via Zoom. For each session, I shared my screen which displayed two windows. The first window was a Jamboard[1] slide deck to present the tasks to the students, and to capture their ideas and diagrams.

[1] Jamboard is a Google interface that serves as a collaborative and interactive canvas.

In a window next to Jamboard, I had an Integrated Development Environment that was used to run Python code.

For analysis, I utilized Roorda et al.'s (2016) framework for identifying the techniques, conceptual elements, and technical elements as the basis for developing the students' instrumented action schemes. Recording the conceptual elements was done through the identification of the mathematical concepts that the students were learning. In analyzing the techniques used by the students (e.g., the output students produced, diagrams they drew, logical statements they considered), I watched the Zoom video recordings to document what exactly the students were producing in relation to conceptual elements. To document the technical elements (e.g., the code the students typed, the mathematics they wrote in Jamboard), I analyzed the Zoom video recordings to document what the students typed and when they typed it. This analysis was done by tagging the audio transcriptions using MAXQDA with Concepts, Techniques, Tech-Elements as the main codes for analysis. If a student typed something without saying out loud what they had typed, I used the 'memo' feature within MAXQDA to document what the student typed. This way I was able to analyze all three aspects of the students' instrumented action schemes within MAXQDA. By coding the techniques, conceptual elements and technical elements, I was then able to construct each students' instrumented action schemes. Importantly, the students' schemes were constructed with the four features as described by Trouche (2004) and Vergnaud (2009) which included the goals, rules, operational invariants and the possibilities for inference. Due to the page length constraints, I highlight the results for only one of the students on one problem within the larger teaching experiment. Additionally, the data presented here came from the fourth session out of five total sessions with this group of students.

Results

In this section I present the work of Alonso (pseudonym), a participant in Group 4 as they worked on a problem in which they were asked to "find the common elements across all three sets." The three sets, A, B, and C were given to the students in the study and contained both strings and integers. The students were also asked to "draw a diagram of what this set relationship might look like first before you write any code." I highlight Alonso's work due to the unique nature of his approach to solving this task. No other student in my study attempted to solve the task in the same way that Alonso did. First, I will briefly present some information that will be pertinent to understanding Alonso's solution method. First, repeated elements in a set, in Python and in mathematics in general, are not counted multiple times for the total number of elements that belong to the set. For example, if we define A = {1, 2, 3, 4, 5, 5}, the number of elements that belong to A, otherwise known as the *cardinality* of A, is five. Second, the cardinality of a set can be determined in Python using the 'len()' function. This function finds the length, or the number of items in the iterable data object. Also, it is important to note that before drawing the diagram, Alonso wanted to clarify what I meant by "diagram." I told him that I would "leave it up for interpretation." Figure 1 is a screenshot of Alonso's diagram, which he used as an opportunity to write pseudocode, a step-by-step process outlining an algorithm that would solve the problem. Of the ten students in the study, Alonso and his partner were the only two to write pseudocode. The other students either drew Venn diagrams, circled certain elements in the sets, or did some type of representation of what the intersection process might look like.

The first process in Alonso's pseudocode was to iterate through all the values, or elements, in A and add those elements to the set B and the set C. This step is fairly straightforward but requires a little interpretation as to what is meant by 'set B and C' in the second line. One could interpret this to mean the logical operator 'and,' because he refers to it as a 'set' instead of 'sets,' and would thus possibly imply the intersection of the two sets B and C. However, in his description of the pseudocode, Alonso clarified this line when he said, “So, if you had set A, you would add it to both set B, and C. So that all the values from set A get cycled through the two sets.” This confirms to me that Alonso was referring to two separate sets, set B and set C.

```
Step through values in set A

add value to set B and C

Check to see if length has changed

if it has not changed add value to set D

Step through values in set B

add value to set A and C

Check to see if length has changed

if it has not changed add value to set D

Step through values in set C

add value to set B and A

Check to see if length has changed

if it has not changed add value to set D
```

Figure 1. Alonso’s Pseudocode for Set Intersection

The next step in Alonso’s pseudocode was to check the cardinality of the two sets B and C. As Alonso described it, “With each iteration you check to see if the length has increased. If the length has not increased, then you know that there has been a repeat.” I am interpreting this statement as a process of adding each element from A to both sets B and C. One then finds the cardinality of the sets B and C. If there is a change in the cardinality from before the element in A is added to the sets B and C, then one can determine that this element is not shared with the set. For example, let $A = \{1, 2, 3\}$ and $B = \{4, 5, 6\}$. If we add the element 2 to B, then the cardinality of the set B would change from three to four since 2 is not an element of B. The next step in Alonso’s pseudocode is to add the element to a new set, D, only if the cardinality does not change when added to sets B and C. An overview of the whole computational process is described by Alonso in the following way:

> This would require three For Loops and at the end you would just print the length of D and you would get the number of common elements. Or you could just print D to get which elements are in common.

The three For Loops that Alonso mentioned represent three iterative processes to add all the elements from each of the three sets to the other two remaining sets. Of course, three For Loops are not required. We did not go through the process of writing out Alonso’s code as we were running close to the end of time during the session and we still needed to hear from Alonso's partner about his diagram, but given that Alonso's method was so detailed, my hypothesis is that having the actual code would not change anything about his scheme or his conception of finding the intersection of multiple sets.

Due to Alonso's solution method, I refer to his scheme as the *Monitor Change in Cardinality Scheme.* As for his scheme, it is evident that the goal is to find the intersection of the three sets. I see two rules-of-action for Alonso. First, '*Construct an algorithm that would select each element in all sets'* and second, '*verify whether or not each element existed in each of the other sets*.' One theorem-in-action would be, '*Using a For Loop, one can iterate through every element of a defined set in Python.*' A second theorem-of-action is, '*One can determine the existence of common elements by monitoring any change in the cardinality of a set once an element has been added to the set.*' These theorems in action led Alonso to the solution method presented in his pseudocode. Given that this is just one problem from the larger teaching experiment, there is no identification of a possibility of inference for Alonso. A summary of Alonso's scheme can be found in Table 4.4.

Table 2: Alonso's Monitor Change in Cardinality Scheme

Instrumentation Scheme	Techniques	Conceptual Elements	Technical Elements
Determine Set Intersection by Monitoring Change in the Cardinality	Add an element to a set and calculate the cardinality of the set	The cardinality of a set changes when a new, non-repeated element is added	By writing a For Loop, one can pass through every element in a set. These elements are added to the other sets and the cardinalities of the other sets are calculated. If there is no change in the cardinality from before the element was added to after, for all sets, then the element is a repeated element and can be added to a new set.

Conclusion

Without Python, it is unlikely that Alonso would have come to that solution method to determining the set intersection of three sets, which is evidence on its own that Alonso constructed an instrument. Moreover, one important realization from analyzing these results was that Alonso used the For Loop and the 'len()' function as the artifacts in the construction of an instrument to solve a problem. That is, For Loops and functions are computational tools that were not originally designed to find the intersection of sets, but were co-opted by Alonso to solve the mathematical task of finding the intersection of three sets. This is a nuanced elaboration of how I initially interpreted the role of Python as the primary artifact when I designed this study. Specifically, when I originally conceptualized this study, I considered Python itself as the primary artifact in the students' instrument development. I was thinking about text-based code in general, not specific computational tools like For Loops and functions, which is what emerged through Alonso's work. The brief example presented in this manuscript illustrates that it is possible to understand how machine-based computing can be used to develop and enhance one's understanding of a mathematical idea.

Mathematics Learning Assistantships and Undergraduate Students’ Identity Development

Paula Jakopovic, Ph.D.
University of Nebraska at Omaha

Kelly Gomez Johnson, Ed.D.
University of Nebraska at Omaha

Increasing the participation and achievement of students in science, technology, engineering, and mathematics (STEM) in PK-16 education continues to be a focal area of educational transformation and research. Faculty members at Institutions of Higher Education (IHE) plan, implement, and investigate how program structures can support the development, retention, and overall success of undergraduate students in STEM. Active learning classrooms, especially in mathematics, are one way IHE are reforming student learning experiences, and also provide a unique opportunity to engage undergraduate learning assistants with faculty to support near-peer students and deepen their own learning. This report examines the role of learning assistantships in developing undergraduate preservice teachers' identity while participating in a Noyce Scholarship program. Findings from this study show that preservice teacher participants gained competence in a variety of forms and developed their identity as a teacher through their experience as learning assistants in active learning classrooms.

Keywords: Teacher Preparation, Mathematics Education, Learning Assistants

Teacher attrition rates in the United States (U.S.) are approximately 8% annually. However, the highest rate of teacher attrition takes place in high-needs schools and turnover rates for mathematics and science teachers are nearly 70% greater in low socioeconomic schools (Carver-Thomas & Darling-Hammond, 2019). In 2017, 47 states and Washington D.C. identified shortages in qualified mathematics teachers (U.S. Department of Education Office of Postsecondary Education). Additionally, enrollment in teacher preparation programs has declined by more than one third since 2010 (Partelow, 2019). These factors not only contribute to the teacher shortage, but also to a lack of highly qualified, experienced teachers in classrooms. Kini and Podolsky (2016) found that teacher experience is associated with increased student achievement, highlighting the importance of teacher retention. Conversely, recruitment and retention challenges result in approximately 40% of new STEM (science, technology, engineering, mathematics) teachers entering the profession underprepared, yet they are the most likely to teach in high-needs schools, serving a majority of historically marginalized populations of students (Carver-Thomas, 2018; Carver-Thomas & Darling-Hammond, 2019; Sutcher et al., 2016). Teachers who receive less pedagogical training are more likely to leave teaching—especially in mathematics and science (Ingersoll et al., 2012).

This report examines an effort made by a mid-sized, urban university to recruit, train, and retain highly qualified secondary mathematics teachers. The project, supported by a National Science Foundation Noyce Track 1 grant (# 1852908), engages undergraduate dual-major mathematics and secondary education preservice teachers (PSTs). Within the program model, students serve as learning assistants (LAs) in active learning mathematics courses with the support of faculty mentors. In this research report, we utilize Chickering’s Seven Vectors of Identity Development framework (Chickering, 1969; Chickering & Reisser, 1993) to answer the following research question: How do learning assistantships in active-learning mathematics courses develop undergraduate students’ identities as future mathematics teachers?

Literature Review

The development of undergraduate student identity has been recognized as an essential factor impacting students' knowledge/competence, habits, attitudes, dispositions, and emotions (e.g., Allen & Schnell, 2016; Grootenboer & Zevenbergen, 2008). For example, identity development in mathematics begins in early childhood education where dispositions and deeply held beliefs about a student's ability to participate and perform in areas such as mathematics is established (Aguirre et al., 2013). Factors influencing STEM identity development include content competence, the ability to showcase learning to others (performance), and recognition of competence and ability in STEM by others (e.g., Carlone & Johnson, 2007; Herrera et al., 2012). These factors reveal the multifaceted and complex nature of identity development (competence, performance, and recognition) and the interwoven nature of interpersonal interactions involved in developing individuals' social and cultural identities (Herrera et al., 2012).

For undergraduate students interested in STEM education, an entirely new PST identity formation is needed to build upon their background knowledge and experiences, dispositions, roles, and responsibilities as future teachers (Beijaard et al., 2004; Slavit et al., 2016). For example, Ball et al. (2008) posit that effective mathematics teaching requires knowledge within six different domains that encompass both subject matter and pedagogical content knowledge. Not only must teachers deeply understand mathematics content, they must also be familiar with specialized mathematical content knowledge required for teaching and be able to employ effective teaching practices, both content and non-content specific. The K-12 teacher identity literature based across grade bands and contexts are well represented (e.g., Flores & Day, 2006; Friesen & Besley, 2013; Obenchain et al., 2016); however, STEM teacher identity development is still a growing area of educational research due to the increasing workforce demands and changing instructional expectations of STEM teachers to more actively engage students.

Classroom-based practicum experiences have been shown to strengthen some aspects of teacher preparation, yet many key qualities of effective teachers need to be addressed beyond PSTs' technical knowledge of content and for teaching (Banks et al., 2005). PSTs must have "wider-professional experiences" (WPEs) that allow them to consciously grapple and engage with their own attitudes and expectations on teaching and learning and to develop, enact, and reflect on their own professional knowledge in new contexts (Darling-Hammond & Bransford, 2005; Sleeter, 2018). For example, 21st century STEM teachers are called to create active learning environments where students engage deeply with content and collaborate with peers, as instructors uplift student thinking in an equitable learning space (Laursen & Rasmussen, 2019). Despite this aspiration, memorization and lecture-based instruction are still cited as the most commonly used approaches in STEM classrooms (Eurydice, 2015). Preparing PSTs to implement student-centered, active learning environments on their own requires them to experience learning and reflect on these environments through college coursework, field experiences, etc. (McDonnough & Matkins, 2010). Developing awareness through practicum and WPEs helps PSTs see what active learning looks like and how student engagement and learning can be impacted. Research has shown that undergraduates serving as learning assistants (LAs) in active learning classrooms not only shifted their understanding from unawareness to awareness of active teaching practices (Hall, 1974; Tunks & Weller, 2009), but also improved their own development of content understanding and identity, as well as enhanced their communication skills (Close et al., 2016; Goff & Lahme, 2003). Further, LAs recruited to K-12 teaching have demonstrated greater use of reform-based practices than their peers (Gray et al., 2016). While there is growing interest in exploring the processes and outcomes of embedding learning assistantships into undergraduate programs (e.g., Gomez Johnson et al., 2021; Vandergrift et al., 2020), connecting these experiences to PST development is an area of investigation that is needed to develop and retain future teachers.

Theoretical Framework

Undergraduate students undergo substantial changes in the way they think, act, and relate to others and to self during this pivotal time in their lives. Beyond cognitive development through academics, undergraduate education can be enriched by specific learning experiences and interactions in and outside of the classroom (Quinlan, 2011). Seminal work by Chickering & Reisser (1993) integrated undergraduate students' cognitive and psychosocial development theory into a model illustrating the fluid nature of student development along seven core areas, called vectors. The vectors are: developing competence, managing emotion, moving through autonomy toward interdependence, developing mature interpersonal relationships, establishing identity, developing purpose, and developing integrity. These vectors aim to define identity development as a cyclical continuation rather than a linear developmental path, later illustrated by Leggette and Jarvis (2015) as spokes on a wagon wheel to illustrate the interconnectedness of the developmental vectors. Chickering and Reisser's call to higher education institutions is to create environments that foster broad developmental practices and policies to support human talent and potential. By advancing strengths and skills along each vector, students are better equipped to overcome barriers and unexpected challenges through increased cognitive and psychosocial versatility (Chickering 1969; Chickering & Reisser 1993; Evans et al., 2010).

Research Methodology

This study investigates the ways in which engaging secondary mathematics PSTs as LAs in active learning undergraduate mathematics courses influences their development along Chickering's vectors of development. Understanding the lived experiences of the participants is well suited to qualitative research design, as we are able to collect rich and descriptive data (Charmaz, 2008; Yin, 2018) to glean how student participants "interpret their experiences and…[assign] meaning they attribute to their experiences" (Merriam, 2009, p. 5).

Context and Participants

Faculty from the institution's mathematics and teacher education departments developed a program funded by a five-year National Science Foundation Robert Noyce Teacher Scholarship Program aimed at recruiting and retaining high quality secondary mathematics teachers. Undergraduate students participating in the project are paired with a faculty mentor with whom they engage as LAs for active learning mathematics courses. Participants for this study include nine undergraduate students who participated in the program in Fall 2021. Five of the nine participants identify as female and four as male. Five out of the nine participants are upperclassmen (juniors or seniors) who have had at least one practicum experience within their traditional teacher preparation program. Fall 2021 piloted the LA experience in active learning mathematics courses uniformly with all participants.

Data Collection and Analysis

Participants completed a total of ten reflective journal entries across a 16-week semester in Fall 2021. The reflection prompts were open-ended in nature but asked the students to frame their responses around potential implications for them as future teachers. Participants agree at the onset of their acceptance to the program to allow these journals as data collection to inform the research and evaluation requirements of the program. In addition to the written reflections, the participants also take part in a focus group at the end of the fall semester. The following interview prompts were used to facilitate the semi-structured interview with the group:

1. Describe your learning assistant experience.
2. What, if anything, have you learned about mathematics? Did anything surprise you?
3. What, if anything, have you learned about teaching mathematics? Did anything surprise you?
4. What, if anything, have you learned about learners? Did anything surprise you?
5. What, if anything, have you learned about yourself after serving as a learning assistant/teaching assistant?
6. Is there anything you would change to improve your experience as a learning assistant? What advice do you have?

We used Chickering's Theory of Identity Development (Chickering, 1969; Chickering & Reisser, 1993), which is framed around seven vectors, to create a codebook. We used the codebook to engage in deductive, first round coding (Saldaña, 2021), and we added descriptive examples to the codebook to ensure the stabilization of subsequent coding across the data (MacQueen et al., 1998; Roberts, et al., 2019). We read through and coded excerpts from the participants' reflections and the focus group interview that identified moments where students referred to vector-aligned experiences/opportunities, which are: 1) developing competence, 2) managing emotions, 3) moving through autonomy toward interdependence, 4) developing mature interpersonal relationships, 5) establishing identity, 6) developing purpose, and 7) developing integrity. As we coded the data, we identified an additional, emergent code of "self-awareness," which we inductively added to our list of codes (Miles et al., 2020). In a second round of coding, we parsed out sub-codes within the parent codes to help us better understand the aspects of each vector that students self-reported experiencing. To increase the validity and reliability of our results, we coded all data sources together, allowing us to reconcile in the moment any potential differences in coding. The following section presents preliminary findings from our analysis.

Results

Identifying which vectors participants experienced in their role as LAs is an important first step to developing a richer understanding of how wider professional learning experiences can influence PST development. As such, we were interested in the codes that were most highly saturated in the data. Moving through autonomy toward interdependence, developing mature interpersonal relationships, developing purpose, managing emotions, and developing integrity were each coded less than 25 times. Of the seven vectors, the remaining two codes, developing competence (coded 85 times) and establishing identity (coded 41 times) surfaced as the most highly saturated codes in our data, so we sought to further examine what it was about these codes that participants identified surfacing within their LA experiences to better understand how we might leverage such experiences to maximize identity development.

Developing Competence as Future Teachers: Mastering Content, Pedagogy, and Relationships

Chickering sub-divides the vector "developing competence" into several components, two of which surfaced regularly in our data: intellectual competence and interpersonal competence.

Intellectual competence is defined as including the ability to master content, develop sophistication related to intellect and aesthetic, and build a wide range of skills, whereas interpersonal competence involves the acquisition of communication skills such as listening, cooperating, and communicating and responding effectively (Chickering, 1969; Chickering & Reisser, 1993). These sub-codes were the most frequent in our data, with 63 instances of intellectual competence and 22 instances of interpersonal coded, thus we wanted to tease out the aspects of participants' experiences as LAs that resulted in their sense of gained competence.

Intellectual competence. We uncovered several common themes in our analysis of the sub-code of intellectual competence. First, multiple participants described development of their ability to recognize (and sometimes employ) effective strategies for engaging learners in the classroom. One participant reflected on their experiences in an active learning classroom, stating,

> As a LA I have an opportunity to, it's a very interactive class and so I'm having one on one conversations with students or having group conversations with this group and learning a lot about how to guide students' thinking without giving them the answer. I think that's been a big takeaway from the LA experience (Focus Group Interview).

For several of the participants, this was their first-time experiencing mathematics instruction in an active learning environment, as either a learner or a teacher, and it pushed them to rethink their understanding of the structure of a mathematics lesson at the undergraduate level.

This led into our second observation that multiple participants discussed the ways in which observing their mentor teachers' teaching style influenced their thinking about mathematics instruction. They identified specific teaching structures and strategies their mentors utilized, as well as the impact it had on students in their classroom. Participant A explained it thus,

> I have been trying to analyze and pick apart [my mentor's] teaching style… because he is a phenomenal teacher and I want to be the same for my students. One big thing I have noticed is that he… tells the students to do something alone for a couple minutes, then discuss with their partner for a minute, then their group for another minute. He does this everyday… Everything he does is consistent, and it reflects on the students' engagement and learning. (Learning Assistant A).

In addition to thinking about how content is delivered, participants also reflected on the depth of mathematics content knowledge they would be required to have as future mathematics teachers and how to make mathematical connections obvious for their students. A participant described one instance of this he experienced while observing, saying,

> I am going to reach out to my mentor that I am teaching with and ask if they would share the lesson plan ahead of time. This way I can study up on the mathematics I know but forget due to the length of time it has been since I learned or used it. Just because I learned it before, does not mean that it is permanently retained. More practice and re-learning can solidify the mathematics in my brain though (Learning Assistant B).

These recurring themes around intellectual competence illustrate the potential power of using learning assistantships to help students develop mathematical content and pedagogical knowledge for teaching (Ball et al., 2008). As participants continue in their preparation program and future practicum experiences, having the opportunity to recall these WPEs as LAs can help them be more conscious of their teacher actions and leverage their own experiences to help their students learn (e.g., Darling-Hammond & Bransford, 2005; Sleeter, 2018).

Interpersonal competence. In addition to developing intellectual competence, participants also reflected on how their experiences as LAs influenced growth in their interpersonal competence, or their ability to communicate and collaborate effectively, in approximately one-fourth of segments coded for this vector. As participants engaged in conversations with their mentors and with the students in the mathematics courses they assisted as LAs in, they reflected on how these opportunities allowed them to develop their capabilities to engage with colleagues and students.

One aspect of this competence arose through comments that indicated the LAs' learning about the importance of fostering positive relationships with the students in their classes. Receiving advice about how to do this in mathematics courses from veteran instructors can help to develop this vector in preservice teachers. Providing additional and early access through LA experiences can offer these novice teachers more chances to reflect on this. As one LA shared,

> This past week I was able to get to know my mentor teacher…we discussed… her past experiences as a teacher and what I had experienced so far as a future teacher… Her biggest piece of advice was to try and build relationships and trust with the students I will work with… I know that I will have to find my own way here, but hearing examples of what has worked for others helps a bit (Learning Assistant C).

Recognizing the potential impact that the trust and rapport that comes of this relationship building can have on student engagement in mathematics courses was uplifted by another participant, who said, "I want to get to the point where the students become comfortable with explaining their thought process through the work to me. My goal is to increase the student's ability to discuss ideas and their confidence in math" (Learning Assistant D).

Another aspect of interpersonal competence that arose in the data was the idea of vulnerability in front of students as a way to build trust. One participant described this by saying,

> I have gotten more confidence in myself ironically when I'm able to admit when I'm not confident. We were learning about [a math strategy] ... I had never really seen before and… just being real with the students and saying, hey listen, this is not how I learned it when I took this class… and I think the students actually really appreciated that because a lot of them found it really confusing as well. So, I think just, I learned about myself to be more open and straightforward with the students (Learning Assistant E).

This notion of "humanizing" mathematics and the faculty who teach mathematics courses is perhaps a novel revelation for PSTs, who may historically think of the teacher as being the "expert" in all aspects of their field, especially STEM areas (Aguirre et al., 2013; Allen & Schnell, 2016). Taken together, participants recognized that being a "good" mathematics teacher involves more than knowing content, it also requires them to know their students and vice-versa.

Establishing Identity as Future Teachers: Developing a Professional Identity

Establishing Identity was the second most saturated code in our data, with this parent code identified a total of 41 times across the data. Within the larger code of establishing identity, we nested several sub-codes: professional/teaching identity, social or group identity, personal identity, and identity threats. Of these, professional/teaching identity was overwhelmingly the most often coded in the data with a total of 25 counts coded, or just over 60% of the segments (social group and identity threats coded only six times each, personal identity coded only 4 times). A crucial part of helping undergraduate students make the shift from their identity as "student" to their identity as "teacher" is providing them opportunities to gain knowledge of the praxis of teaching and strategies, and also to gain authentic experiences to implement such skills and strategies in real-time. Although most teacher preparation programs offer field experiences where PSTs work in classrooms with students, there is no guarantee that all field placements are with experienced mathematics teachers who incorporate research informed teaching practices, such as active learning and teaching through inquiry. Supplementing these more traditional teaching apprenticeships with learning assistantships can offer PSTs in mathematics rich opportunities to develop not only their praxis, but their self-image as a teacher practitioner.

Participants recognized the importance of this, as well as the impact of engaging as LAs on their professional identities as future teachers. One LA summarized this by saying,

> Additionally, it helps us grow our "teacher voices," which has been my biggest growth. When I presented my first proof to the class, I was nervous to talk in front of others. Now, with my most recent presentation, I was much more confident, was able to face the class and present from the board and engaged with my peers. I noticed my voice was more confident… (my "teacher voice"!). I believe I am more confident now because I have found my 'place' in the class and have gotten to know my peers and professor more, which helps me understand what type of presentation and engagement I should do (Participant F).

Our findings support previous research finding that learning assistantships develop both content understanding and their identity as a future professional (Hall, 1974; Tunks & Weller, 2009). In part, our data show that participants' ability to find their voice, communicate their thinking, and work with others helped them see themselves more as teachers and leaders in the classroom (Close et al., 2016; Goff & Lahme, 2003).

Applications to/implications for teaching practice or further research

Findings from this study support that learning assistantships are advantageous WPE that support the development of PSTs competence and professional identity as second mathematics teachers. In particular, these early program and full semester LA experiences are unique factors of this program design that have the potential to accelerate PSTs development. These LA experiences also provide intentional mentor pairing that are often challenging to control in traditional teacher preparation programs. The sample size and data set presented here are small and lack diverse representation of student participants. However, this study indicates the need for research on the impact of LA opportunities on PST development in mathematics and other STEM areas. This work does add to the body of existing research in this area and presents elements of this apprenticeship model that are important to focus on in future studies:

- leveraging learning assistantships to develop PSTs content and pedagogical knowledge of teaching secondary mathematics using active learning strategies;
- utilizing learning assistantships as models for how to foster positive, trusting relationships with students and allowing LAs to examine its impact on student engagement and achievement; and
- providing additional structured, scaffolded experiences teaching mathematics to facilitate PSTs' sense of "teacher self."

Future work has the potential to extend to other STEM education content areas, which can help to generalize the benefits and challenges of using learning assistantships to develop undergraduate PST identity and support the learning outcomes of mathematics students learning side-by-side with their near-peers as guides.

Goals, Orientations, and Social Support Offered by a Mathematics Graduate Teaching Assistant

Brittany Johnson
University of Nebraska-Lincoln

Research suggests that support offered by an instructor can significantly impact student experiences and that there are different types of support that instructors can offer (e.g., emotional support, informational support, etc.). This case study examines the goals and beliefs of a first-year Mathematics Graduate Teaching Assistant (MGTA) in an attempt to explain their in-the-moment classroom decisions about offering different kinds of support to their students. This study found that the MGTA's beliefs about the nature of mathematics and how mathematics problems are solved were critical in understanding their tendency to offer a particular type of support. Understanding the ways that MGTAs support their students can initiate a valuable discussion surrounding novice mathematics instructors and their professional development.

Keywords: Graduate Teaching Assistants, Social Support, Goals, Beliefs, Decision-Making

In recent years, education researchers have become more concerned with teacher-student relationships and the impact these relationships can have on student experiences. Teachers are no longer considered couriers of knowledge as they have been in the past. Several studies from the past 20 years provide evidence that a positive teacher-student relationship correlates to increased engagement, motivation, effort, achievement, and overall well-being for students (Furrer & Skinner, 2003; Niehaus et al., 2012; Tennant et al., 2014). The present study is concerned with one specific facet of the teacher-student relationship: social support. *Social support* refers to any action intended to alleviate or prevent negative emotions that someone might experience (House, 1981). Numerous studies have explored social support in the classroom, including the kinds of social support that students receive, student perceptions of social support, and the effects of social support on student experiences (Federici & Skaalvik, 2013; Tennant et al., 2014). However, little research has explored social support from the perspective of the teacher, including the decision-making process behind offering different kinds of support. Tardy (1985) claims that the direction of social support (i.e., the distinction between the giver and receiver) is one of the most important characteristics of social support but acknowledges that the receiver is usually the focus of research.

Since research suggests that social support has the potential to positively benefit students and that different kinds of social support affect students in different ways, it is important to understand the elements that contribute to decisions to provide different kinds of support. While much of this decision process occurs subconsciously, research suggests that the decision-making process is determined by things that one can become aware of (Schoenfeld, 2011). An awareness of the decision-making process and the elements that it draws upon can better inform such a decision and lead to more intentional, productive support being offered.

The purpose of this study is to explore how Mathematics Graduate Teaching Assistants (MGTAs) choose the types of support they offer their students in first-year math courses by exploring their goals and orientations about teaching (*orientations* refers to one's beliefs and values) (Schoenfeld, 2011). MGTAs comprise a consequential portion of the teaching force behind undergraduate mathematics education, teaching 17% to 21% of mathematics courses at doctoral institutions (Blair et al., 2013). The long-term intent of this research is to better understand the decision-making process behind offering support, enabling MGTAs to become more aware of the ways they offer support and in turn better serve their students. Such an understanding has the potential to contribute to professional development for all educators, not just graduate students, as making decisions about social support is a ubiquitous part of teaching (Schoenfeld, 2011).

This paper is a part of a larger, semester-long study that explored the ways that six MGTAs conceptualize the types of social support that they offer, as well as the goals and orientations that influence their decisions to offer social support in particular ways. Due to space limitations, this paper focuses on one MGTA and the findings related to the following questions:

RQ1: What goals and orientations are present when MGTAs offer social support to their students?

RQ2: How can MGTAs' goals and orientations be used to explain the types of social support that they offer their students?

Literature Review

This study was designed around two separate frameworks, the first being House's categorizations of social support (1981). House asserts that all examples of social support can be categorized as emotional, informational, instrumental, and/or appraisal support. *Emotional support* is defined as support in which the negative emotion itself is being combatted, such as a teacher providing validation to a student experiencing self-doubt. *Informational support* is that in which resources are provided to combat a negative emotion indirectly. For instance, a teacher referring a student struggling with a homework problem to a helpful example in the textbook would be considered informational support. The other two categories are not discussed in this paper, and therefore will not be addressed due to space limitations. Despite being written more than four decades ago, House's framework is still referenced today and more recent frameworks for categorizing social support are comparable to House's (Wu et al., 2020; Feeney and Collins, 2015; Federici & Skaalvik, 2014).

The second framework around which this study was designed is Schoenfeld's "resources-orientations-goals" framework for in-the-moment decision-making (henceforth referred to as the ROG framework) (2011). Orientations include one's beliefs, values, and other related concepts, while goals are "something that an individual wants to achieve, even if simply in the service of other goals" (Schoenfeld, 2011, p. 21). According to the framework, one's in-the-moment decisions are shaped by these constructs, and if you know enough about one's resources, orientations, and goals, you can understand and ultimately explain the decisions they make (Schoenfeld, 2011). The present study was conducted in a convened course in which lesson plans, student workbooks, and assessments were constant across all participants and were therefore excluded from consideration.

Methods and Procedures

Methodological Approach

This study used a qualitative case study methodology, defined as "an empirical inquiry that investigates a contemporary phenomenon… in depth and within its real-world context" (Yin, 2014, p.16). This methodology is appropriate for this study because the research questions are less focused on the general phenomenon (the decision-making process behind MGTAs offering social support) and more concerned with the individual cases. Each case is an individual MGTA teaching a calculus recitation during their first semester as a PhD student at a large Midwestern public university. A descriptive case study design gives each participant an opportunity to have their story be told in order to “develop a complete, detailed portrayal of [the] phenomenon” (Schwandt & Gates, 2017, p. 346).

Participants

Only MGTAs teaching a recitation for either Calculus I or II were considered for this study. MGTAs were excluded if they were doing doctoral research in mathematics education or if they had significant teaching experience prior to matriculation, as they were not representative of a typical graduate student. This paper focuses on one first-year MGTA in the study, Blake (pseudonymized).

Data Collection

Data was collected in three stages. First, MGTAs were interviewed to explore their goals and orientations related to teaching. Secondly, each MGTA was observed teaching for four 75-minute class meetings; these lessons were audio-recorded while the researcher took note of examples of social support that they noticed the instructor offer. The observations were followed by a second semi-structured interview to discuss a selection of the observed examples of social support. Here, MGTAs were asked to reflect on their motivations and decision-making behind each example and asked to categorize each example within the social support categorization framework (House, 1981).

Data Analysis

A pilot study indicated that multiple coding methods would be needed to analyze the data through the lenses of the different research questions. The purpose of the first phase of coding was to address RQ1 by focusing on the goals and orientations of each participant; this phase used both structural and provisional coding to develop parent and child codes, respectively. *Structural coding* refers to the use of codes relating data to specific research questions; this method allows one to categorize excerpts related to similar topics before moving on to further coding and analysis (MacQueen et al., 2008; Saldana, 2016). In this study, parent codes were used to categorize data related to goals, orientations, and social support, allowing for simultaneous coding. In *provisional coding*, a codebook is developed prior to data collection, but can be “revised, modified, deleted, or expanded to include new codes” (Saldana, 2016, p. 168). Child codes were developed based on the literature review and experiential data (both from the pilot study and the researcher’s familiarity with the data) to capture different types of goals and orientations that participants might express; child codes included things like “Goals – Student Performance” and “Orientations – Nature of Mathematics”. The flexibility of provisional coding allowed the researcher to continuously add codes as new goals and orientations arose. Each interview was coded multiple times to ensure that no codes or excerpts were missed.

A second phase of coding utilized hypothesis coding. In *hypothesis coding*, codes are generated “specifically to assess a researcher-generated hypothesis” (Saldana, 2016, p. 171). The researcher developed specific theories for each participant based on the first cycle of coding, memos that were taken throughout the study thus far, and peer debriefing. An individualized codebook was then developed for each participant to assess the researcher’s hypotheses, and coding was repeated until no new themes emerged.

Findings

What follows is a discussion of Blake. Of the six participants in the larger study, Blake’s case exemplifies how the ROG framework (Schoenfeld, 2011) can be used to relate MGTAs’ goals, orientations, and social support actions. Blake's case ultimately forms the foundation that the rest of the cases expand upon.

A Brief Introduction to Blake

Blake is a first-year MGTA whose enthusiasm for teaching was immediately evident during data collection. When talking about their reasons for coming to a doctoral program, Blake said,

> I want to learn more about math, but then on top of that, I want to become the best math educator that I can be. So teaching for me is extremely important… I find joy in teaching these topics, leading students through problems, helping them understand, and just also in general just helping them enjoy mathematics.

Prior to graduate school, Blake sought out various opportunities to teach in informal settings (such as tutoring) and continued to seek out opportunities to improve their teaching throughout their first semester of graduate school. Blake puts a great deal of energy into their teaching, including developing rapport with their students. Throughout this study, it was evident that Blake knew and cared about their students.

During the observations, Blake gravitated towards offering informational support over the other categories of social support (House, 1981). During data analysis, two compelling themes emerged that could explain Blake's tendency towards informational support: their perspectives on what mathematics is and how math problems should be solved. What follows is a description of Blake's goals and orientations related to these themes and an explanation of how they are reflected in Blake's social support actions.

Goals and Orientations Related to the Nature of Mathematics

When reflecting on what mathematics is and what it means to solve math problems, Blake regularly made comparisons to solving a puzzle. When asked about their goals, Blake said, "I always think of it [math] as a puzzle, so hopefully I can transfer that to them [my students]. Like this is like a fun puzzle, here are the rules that you can use". They went on say that, like a puzzle, much of their enjoyment in math comes from the sense of accomplishment one gets after completing a problem:

> *I* [emphasized by speaker] enjoy doing math, like mathematics is fun to me. It's frustrating, it's annoying, sometimes it's heartbreaking… But I'm here in a PhD program because I enjoy doing and teaching and just like, being a part of mathematics. And so if I can get my students to then feel some of that same enjoyment… If they did a thousand-piece puzzle and like a really cool [math] problem, like if I can get the idea in their head that that is possible? Then I've already won. I've done most of what I want to do.

These ideas—that math is like a puzzle and that it is more enjoyable if it is challenging—are personal beliefs of Blake's that present as goals that they have for their students and are frequently reflected in their day-to-day teaching practices. For example, Blake often encouraged students to try problems that the students may find challenging. Blake suggested different problems for different groups depending on the capabilities of each group (e.g., Blake suggested challenging problems to groups who appeared to have mastered the content for that day while suggesting more standard or introductory problems to groups who seemed to need more practice before attempting the challenging problems). This suggests that Blake was not only aware of the capabilities of individual students and groups, but also that they had a sense of what degree of difficulty would be both challenging and rewarding for different students.

Goals and Orientations Related to Solving Mathematics Problems

Blake frequently referenced a metaphorical "toolbox" full of "tools" that students possess to approach different kinds of mathematical problems. For example, Blake described the process of problem solving in a calculus class as, "You took this set of tools, you applied it to a problem, and then you got to a solution". In the second interview, Blake said,

> We have our bag of tools and then a bunch of math is just figuring out in what ways we can use them, in what ways can we combine them, what are some of the limitations, but also [what] are some of the like further stuff that we can use with these tools?

This belief is reflected in Blake's teaching practices. For instance, during the observed classes, Blake wrote important theorems and definitions on the board before class started; when class began, they encouraged students to refer to these resources as they worked through problems. When asked why they chose to start class this way, Blake said,

> Few things suck and bring up as many negative feelings in math as when you don't even know where the heck to start. So to have at least the definition… You can't work with tools if you don't know what's in your toolbox. So I guess in my case, at the very least everyone has the same set of starting tools and so they can at least get started.

In fact, when helping students one-on-one in class, Blake often explicitly asked students what "tools" they had in their "toolboxes" and asked them which tools they might be able to use.

Blake's Use of Informational Support

Blake's beliefs about mathematics being like a puzzle that can be solved using "tools" from one's "toolbox" are not only present in their goals and orientations but in the social support actions that they offer in the classroom. Blake tends to use informational support more than any of the other categories proposed by House (1981). Table 1 outlines some of the examples of informational support offered by Blake during observations and offers a brief explanation of why informational support is the best categorization for them.

Table 1. Examples of Informational Support Offered by Blake

Example of Informational Support	Justification for Categorization
Before class (and as students started to work individually and in small groups), Blake wrote all the major theorems/rules/definitions that were needed for today's lesson up on the board.	Blake was providing a resource that was not inherently helpful to any particular problem that students were working on; students were responsible for identifying the tool that would be helpful and determine how to use that tool effectively.
While Blake was helping a student, the student kept flipping through their notebook searching for a rule. Blake encouraged them to make a list with all the rules they'd learned recently so that they'd all be in one place.	Advising the student to create a reference page is informational support because Blake is not providing them with something helpful but is suggesting something that would be helpful if the student were to follow through.
Blake checked in with a student who had missed two weeks of class; during that conversation, Blake reminded the student of their office hours and of the tutoring center.	Blake gave this student the tools to seek out help, but it was up to the student to get help if they needed it.

algebraic computations. When the students told Blake they'd decided to skip this problem, Blake made light of it, even going as far as to laugh along with the students when one of them jokingly crossed the entire problem out of their workbook. The researcher categorized this example as emotional support because Blake was empathizing with the students and validating their frustrations with the problem by implicitly giving them permission to skip the frustrating problem. However, Blake interpreted this action as informational support. Blake argued that by encouraging the students to skip the problem after struggling with it for a long time, they were indirectly giving the students information that they could benefit from (in particular, that this problem was not "standard" and that their frustration was probably coming from long computations and not the calculus itself). When categorizing this example, Blake said,

> I want to put it into informational support again because like… I'm not telling them to skip the problem… If you don't think that this is going to be productive use of your time, I'm going to agree with that. And then you should move on to something else. So I'm not fixing the problem… I'm validating their… intuition on like "I could be doing something more productive". Great. Yes… Maybe now think about why this question is maybe not as helpful as maybe some of the other ones are.

Overall, informational support was the most frequent category of social support that was observed, both for the researcher's initial categorizations and Blake's categorizations during the interviews. Moreover, Blake explicitly identified informational support as the category that they believe they provide the most of. The use of informational support is a repeated in-the-moment decision that Blake makes, and therefore according to the ROG framework (Schoenfeld, 2011), any such decision should reflect their goals and orientations.

Explaining Blake's Use of Informational Support

Many of Blake's social support actions are related to their beliefs about the nature of mathematics and mathematical problem solving; in fact, all the examples of informational support discussed in this paper can be attributed to these beliefs. For example, Blake writing theorems and definitions on the board before class reflects their belief about how math problems should be solved. Blake believes that the best way to approach mathematics problems is to have a "toolbox" of "tools" at one's disposal. As a result, Blake perceives it to be their job as an educator to ensure that students have the tools necessary to solve a particular problem. By writing the relevant definitions and theorems on the board at the start of each class, Blake guarantees that every student at least has the required tools to approach any problem that day.

Even the example of informational support that the researcher and Blake disagreed on the categorization of makes sense when juxtaposed with Blake's beliefs about the nature of mathematics. Blake believes that mathematics is like a puzzle and that enjoyment often comes from overcoming the challenge. In this example, the students were frustrated by the problem because it was mired with tedious computations, not with the calculus itself. Blake's argument is that the students weren't benefitting from doing those computations because that problem was not representative of the skill they were supposed to be practicing. In the context of Blake's perception of mathematics being like a puzzle, this problem was like forcing the students to do the puzzle in the dark: it would be an impressive feat to complete the puzzle, but it would not have been representative of what solving a puzzle really is. This particular problem was in contention with Blake's beliefs about what mathematics should be, so it is understandable that Blake would encourage the students to skip that problem with the hopes that the students would recognize what made the exercise futile.

On a larger scale, Blake's general tendency towards informational support over the other categories is aligned with their beliefs about mathematics and mathematical problem solving as well. Many of Blake's goals and orientations reflect their beliefs that mathematics problems are puzzles to be solved, that the puzzles are more satisfying if they are challenging, and that one needs tools to approach the puzzles in the first place. In terms of social support, these beliefs are reflected in the fact that Blake fosters an environment that values productive struggle and has a teaching philosophy in which students cultivate their own "toolbox" of theorems, rules, and definitions; such attributes are closely aligned with informational support. In fact, research has suggested that in mathematics classrooms, informational support is one of the most beneficial categories of social support for developing problem-solving skills (Cutrona & Russell, 1990). When reflecting on social support in general, Blake said, "I should be providing them hints, clues, telling them that they're doing a great job, and giving them the tools to succeed. I should not be sitting down and doing the problems with them", which is indicative of someone who values the use of informational support.

Discussion

Blake serves as an excellent starting point in understanding how Schoenfeld's ROG framework (2011) can be used to understand MGTAs' use of social support in the classroom, particularly in consideration of both the research questions. RQ1 asks, *What goals and orientations are present when MGTAs offer social support to their students?* While the goals and orientations discussed in this paper are certainly not comprehensive, they paint a vivid picture of who Blake is as an instructor. It cannot be said that every first-year MGTA will have the same goals and orientations as Blake, nor can it be said that a MGTA with the same goals and orientations as Blake would offer social support in the same ways. However, discussing Blake's goals and orientations can serve as a starting point for understanding the ways that novice mathematics instructors conceptualize math and mathematics education.

RQ2 asked, *How can MGTAs' goals and orientations be used to explain the types of social support that they offer their students?* Analysis suggested that Blake's beliefs about the nature of mathematics and how mathematics problems should be solved are not only present when they offer social support to their students, but that they are a driving factor in many of the in-the-moment, day-to-day instructional decisions that Blake makes. All the observed social support actions discussed in this paper were considered informational support and could be traced back to these orientations. While Schoenfeld's ROG framework (2011) cannot be used to predict how Blake would respond in certain situations, this does provide insight into how Blake prioritizes and ultimately makes in-the-moment instructional decisions on a day-to-day basis.

The purpose of this study was not to develop a comprehensive understanding of how MGTAs provide social support in the classroom, but to instead begin a conversation about the goals and orientations that are relevant when making in-the-moment decisions. Since the ways that MGTAs offer social support is so heavily dependent on their personal goals and orientations, the results of this paper cannot and should not be generalized. Instead, the findings may inform professional development efforts as mathematics departments aim to understand how MGTAs support undergraduate students in classrooms.

Student Understanding of Eigenvalue Equations in Quantum Mechanics: Symbolic Forms Analysis

Anthony Pina
University of Maine

Zeynep Topdemir
University of Maine

John R. Thompson
University of Maine

As part of an effort to examine students' mathematical sensemaking (MSM) in a spins-first quantum mechanics (QM) course, students were asked to construct an eigenvalue equation (EE) for a one-dimensional position operator. Sherin's symbolic forms were used in analysis. The data suggest three symbolic forms for an EE, all sharing a single symbol template but with unique conceptual schemata: a transformation which reproduces the original, an operation taking a measurement of state, and a statement about the potential results of measurement. These findings corroborate prior literature on a construction task rather than a comparison or deconstruction task, and with a continuous variable after instruction on discrete variables.

Keywords: Quantum Mechanics, Student Thinking, Eigentheory

Introduction

Quantum mechanics is one of a handful of topics in which every undergraduate physics major will take at least one course due to its pervasiveness in modern research and applications in physics and beyond. Despite the ubiquity of quantum mechanics courses and the significant amount of work that has gone into improving them, the subject has still proven difficult for students. Learning quantum mechanics has been shown to be a non-trivial task across both traditional (functions-first) (Singh and Marshman, 2014a; Singh and Marshman, 2015a; Emigh et al., 2018) and the more novel (spins-first) (Passante et al., 2015a, 2015b) approaches.

Eigentheory is central to the theory of quantum mechanics; it's baked into the second and third postulates of quantum mechanics. McIntyre (2012) presents the first three as follows:

1. The state of a quantum mechanical system, including all of the information you can know about it, is represented mathematically by a normalized ket $|\psi\rangle$.
2. A physical observable is represented by an operator $\hat{A}$ that acts on kets.
3. The only possible result of a measurement of an observable is one of the eigenvalues a_n of the corresponding operator $\hat{A}$.

The first postulate gives the first exposure to Dirac notation. The ket $|\psi\rangle$ is referred to as the state vector and, when projected into a basis, is often represented as either a column vector or a sum of other basis vectors in Dirac notation with appropriate coefficients. In general, any expression in Dirac notation has a direct translation to more standard linear algebra. Dirac notation however explicitly shows what basis the vector is written in, whereas the basis vectors are only implied in linear algebra. In Dirac notation an operator is denoted with a hat ($\hat{A}$); the linear algebra representation of this operator would be a matrix. The eigenvalues of this matrix are the possible results of measurement referenced in the third postulate. Standard in linear algebra, but not written into the postulates, is that each of the eigenvalues, a_n, of the operator $\hat{A}$, has an associated eigenvector, labeled $|a_n\rangle$. Therefore, one could argue that an eigenvalue equation in quantum mechanics has a fundamentally different interpretation than that of an eigenvalue equation in a mathematics context, and while they could be interpreted the same way, there are more productive interpretations for quantum mechanics.

The majority of research on student understanding of eigenvalue equations has come from the research in undergraduate mathematics education (RUME) community. Henderson and colleagues (2010) found that prior to instruction student reasoning about eigenvalue equations fell into one of three categories: superficial algebraic cancellation, correct solutions but an inability to interpret appropriately, and a correct solution with a correct interpretation. The correct interpretation in this case relates to an operation of a matrix acting on a vector resulting in the scaling of that vector by its eigenvalue. Thomas and Stewart (2011) studied student understanding of eigentheory over a two-year span and found that students tended to continue to think about linear algebra as a set of procedures rather than focus on the concepts. They target specific goals for instruction such as shifting focus toward the ideas of sets of eigenvectors and reinforcing a view that students were lacking: a geometric interpretation.

Physics education research (PER) has studied interpretations of the eigenvalue equation, often focusing on the Schrodinger equation or the eigenvalue equation for the Hamiltonian (total energy) operator, $\widehat{H}|\psi_n\rangle = E_n|\psi_n\rangle$, which is a major focus of QM courses, since time evolution of a system is associated with the Hamiltonian operator. In a study focused on resources students use to understand quantum mechanical operators, Gire and Manogue (2008) identified "quantum measurement as an agent," the idea that taking a measurement changes the system. Students also know that operating on a vector generally transforms the vector, which the researchers labeled "operating as agent." Accessing both of these resources in parallel can lead students to the idea that operating represents measuring. Gire and Manogue (2011) followed this up, noting that navigating unfamiliar language in addition to eigentheory presents additional challenges for students. Singh and Marshman (2013) reported student difficulties determining states for which the eigenvalue equation for the Hamiltonian would be true, some students going so far as to say that it is true for all states, including superposition states.

More recently, researchers have looked at how physics students reason about eigenvalue equations in different formats. Wawro, Thompson, and Watson (2020) investigated how students in a quantum mechanics course were thinking about both traditional mathematical eigenvalue equations ($\hat{A}\,\vec{x} = \lambda\vec{x}$) and a quantum mechanical eigenvalue equation ($\hat{S}_x|+\rangle_{\mathrm{x}} = \frac{\hbar}{2}|+\rangle_x$). They found that the mathematical equation typically elicited a scaling model, which carried over to the QM equation in some cases. They also noted that some students thought of the quantum mechanical equation in terms of representing a physical measurement, similar to prior PER findings. A novel finding was that some students used conditional language describing the equation in terms of potential or possible measurements rather than directly linking operating to measurement; this more subtle interpretation is consistent with the expert interpretation of a QM EE. Notably, some students who seemingly initially equated operating with measuring expanded their interpretation to encompass potential measurement.

The primary goal of this study is to identify cognitive resources students access when constructing and reasoning about eigenvalue equations in quantum mechanics (symbolic forms). This was done by analyzing written data from student responses to an eigenvalue equation construction task. We identified three different symbolic forms for an eigenvalue equation in the data. One is consistent with the mathematical interpretation. Another is reflective of a common misconception in quantum mechanics. The third is connected to the interpretation of eigentheory presented in the postulates of quantum mechanics. The primary delineating factor of the first, and other two are the connections the second and third make to the physical systems being modeled.

Symbolic Forms

Symbolic forms (Sherin, 2001) can be seen as an extension of the knowledge in pieces framework for student understanding (diSessa, 1993), developed as a means of examining how students think about (physics) equations. Sherin intentionally modeled this framework after diSessa's phenomenological primitives (p-prims), which were another set of intuitive chunks of knowledge or ideas (diSessa, 1993). These p-prims were each self-contained and relatively simple; small knowledge structures originating from nearly superficial interpretations of reality. By comparison, symbolic forms are larger structures consisting of two pieces: a pattern of symbols in an expression, the symbol template, and the rough idea expressed therein, labeled the conceptual schema. A conceptual schema is intended to have a fairly simple structure and is not inherently connected to any physical system or reasoning. Given that the schema contains all the meaning, it is possible for a single symbol template to be a part of several different symbolic forms, depending on the interpretation and/or context. To make clear the difference between them, some examples can be quickly explored. A common expression for the total energy of a system in intermediate mechanics is $H = T + U$, where T is the total kinetic energy in the system and U is the total potential energy. The sum on the right side is an example of the *parts-of-a-whole* symbolic form, as the individual pieces being summed compose the total energy of the system. In a senior-level quantum mechanics, class this expression would look quite different, $\widehat{H} = \frac{\hat{p}^2}{2m} + V(\hat{r})$ but could be interpreted in much the same way. In both cases here the symbol template is $\square + \square$ and the schema is "elements that combine to make a whole quantity.'"

Given their intended nature as building blocks, it is possible and likely to find more than one symbolic form in a physics equation. In the examples discussed above the focus was on the meaning of the sum, but other symbolic forms could be used to determine the meaning of the different equal signs. Due to the nature of the framework, it has been used in several contexts to analyze the intersection of math and physics. An example of its more traditional implementation is seen in the work of Schermerhorn and Thompson, who used symbolic forms to investigate student construction of differential length elements (Schermerhorn, 2019a).

Dreyfus and colleagues engaged in a theory-building effort meant to use data to illustrate their conjectures and to explore a method for analyzing student mathematical sensemaking in quantum mechanical problem solving (Dreyfus et al., 2017). They also argue the MSM tools learned in introductory physics are necessary but insufficient for MSM in quantum mechanics; this argument would be consistent with the findings of Kuo and colleagues (2013). The third and final claim of Dreyfus and colleagues' paper is that when students do not succeed in MSM in QM it is not because they are not engaging in the process, but that they are not using particular cognitive machinery (i.e., symbolic forms) needed to engage in expert MSM in QM. They highlight episodes from a study (Bing and Redish, 2012) to illustrate problems students could have interpreting equations with unproductive symbolic.

Dreyfus and colleagues observed two students (electrical engineering (EE) majors) recruited from an upper-level EE course that included a fair bit of quantum mechanics, working on a quantum mechanics tutorial. The researchers identified instances where the mathematics was consequential to the students' reasoning, labeling them as occurrences of potential MSM; they used these instances to conjecture what potential quantum mechanical symbolic forms could be. The primary segment of this interview entails the students reasoning about the time-independent Schrodinger equation or energy eigenvalue equation. The students struggled to determine whether the energy of the ground state of the infinite square well was constant due to the inclusion of the wave function on both sides of equation. The authors suggest that the students were interpreting the energy eigenvalue equation through the *dependence* symbolic form ([...*x*...]; a whole dependent on a quantity associated with an individual symbol) rather than seeing it as an eigenvalue equation, leading to their conceptual difficulties.

These observations were the starting point for the suggestion of new symbolic forms that would be productive for quantum mechanical MSM. The first symbolic form they posit is the *transformation* symbolic form, whose symbol template is $\hat{\square}|\ \rangle$ (an operator acting on a state) and whose conceptual schema is "reshaping" (the idea of stuff getting molded into a different shape). The only other posited symbolic form is the *eigenvector-eigenvalue* symbolic form, whose symbol template is $\hat{\square}|\ \rangle = \mathrm{C}|\ \rangle$, and conceptual schema is "a transformation which reproduces the original". This is a compound symbolic form, containing their *transformation* symbolic form, as well as a new interpretation of the equal sign, and Sherin's *coefficient* symbolic form. In this case the equal sign denotes a relationship between the operator, scalar, and eigenvector, as opposed to other previously proposed meanings of the equal sign (Dreyfus et al., 2017). Expert-level reasoning on quantum mechanical eigenvalue equations adds layers of physical interpretation on top of conceptual understanding, where the operator corresponds to a physical quantity and the solutions are physical states for which that quantity has a definite value, given by the eigenvalue.

Methods

Data were collected in a senior-level, spins-first quantum mechanics course that is required for the completion of physics and engineering physics B.S. degrees at the institution but is also taken by B.A. physics majors, physics minors, and non-physics majors. While not the students' first introduction to quantum mechanics in physics or engineering physics programs, this is the most in-depth study of the topic available to undergraduate students at this institution.

Students were asked to construct an eigenvalue equation for an operator that represents the position of a particle constrained to a one-dimensional system (Fig. 1) as an ungraded quiz. This task falls more in line with the mathematization oriented tasks used to develop the framework, making it better suited to identification of forms than prior, interpretive tasks. An adequate answer to this prompt would use the same symbol template as the *eigenvector-eigenvalue* symbolic form proposed by Dreyfus and colleagues (2017) but specified to the position context.

Consider a quantum mechanical system that is physically constrained to be located along a straight line, as shown below.

Position of object/system constrained to a line

a. Write down an **eigenvalue equation** for an operator that represents the position of this system.
b. Briefly explain what each term in the equation represents.
    i. How do each of these relate to the physical system?
    ii. What, if any, connections exist between the terms in your equation?

Figure 1. Eigenvalue equation construction task.

The authors engaged in collaborative qualitative analysis to refine the codebook until a consensus was reached (Richards, 1981). Student responses to this task were coded with the symbolic forms framework in mind. Due to the nature of the task, most student responses did not fit into existing symbolic forms. As a result, student responses were first coded for a symbol template, and then an associated conceptual schema. The first pass was essentially a binary coding identifying which students provided an expression utilizing the template $\hat{\square}|\cdot\rangle = \mathrm{C}|\cdot\rangle$, where the dots inside the ket symbols indicate identical symbols inside the kets, and thus identical kets. This symbol template is the same as that of the *eigenvector-eigenvalue* symbolic form proposed by Dreyfus and colleagues with the exception that the “empty” kets have been given dots to denote that it must be the same ket on either side of the equal sign.

For those students that used this template, a variety of conceptual schemata were identified, derived from the portions of student responses where they interpreted their expressions. Coding only for expressions that used an eigenvalue equation template proved inadequate however, as a variety of other expressions provided by students did not conform to this symbol template and therefore required additional categorization. Grouping similar student responses by the structure of their equation, and subsequently by ideas presented by the students, resulted in the identification of other potential symbolic forms in addition to those for eigenvalue equations.

Results

Student responses were indicative of three different ways of thinking about eigenvalue equations which are summarized in Table 1. Each of these different symbolic forms shares a single template but has a distinct conceptual schema.

Table 1. Summary of identified symbolic forms for the eigenvalue equation in quantum mechanics.

Symbol Template	Conceptual Schema	Symbolic Form
$\hat{\square}|\cdot\rangle = c|\cdot\rangle$	A transformation which reproduces the original	*Reproductive transformation*
	An operation taking a measurement of state	*Operating as measuring*
	A statement about the potential results of measurement	*Potential measurement outcome*

Reproductive Transformation

The first symbolic form discussed for an eigenvalue equation has the symbol template $\hat{\square}|\cdot\rangle = c|\cdot\rangle$, and the conceptual schema related to a geometric scaling but not rotation of the vector. This is consistent with the traditional mathematical interpretation of the eigenvalue equation (Henderson et al., 2010), and documented in a QM context by Dreyfus and colleagues as the conceptual schema “a transformation which reproduces the original” and labeled *eigenvector-eigenvalue* (Dreyfus et al., 2017). However, because we identify three distinct symbolic forms that all share the eigenvalue equation symbol template, we refer to this form as *reproductive transformation* as opposed to *eigenvector-eigenvalue* for clarity.

These student responses all had the appropriate terms, and some even labeled the elements appropriately (e.g., Fig. 2) but did not provide any physical reasoning or explanation for their expressions. Responses in this group give us insight into the symbol template students are using for eigenvalue equations. These students are showing evidence of the proposed *reproductive transformation* symbol template. Given that this is all some students provided however, it is difficult to determine the exact nature of the schema associated with these students’ understanding of the eigenvalue equation. While they are not demonstrating any additional

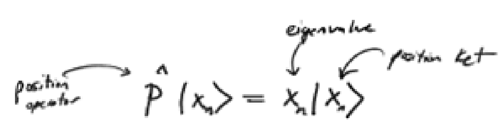

Figure 2. Example student response for reproductive transformation *symbolic form.*

quantum mechanical knowledge in their responses, these students are at least demonstrating that they know that the same ket needs to be on both sides of the equation, consistent with the form.

Operating as Measuring

Some student responses to the eigenvalue equation construction task are indicative of their conflating an operator acting on a state with the taking of a measurement of that state. These students seem to be thinking that the position operator acting on the eigenstate of position represents a measurement of position. While this and *reproductive transformation* share a symbol template, a more appropriate conceptual schema for these students may be “an operator taking a measurement of a state,” which would yield an *operating as measuring* symbolic form for eigenvalue equations.

In one such response and explanation, shown in Figure 3, the student’s expression has all the correct elements, and they are able to appropriately identify the different elements of the expression. However, in addressing how each element of the expression relates to the physical system, the student says that the operator represents “the operation of measuring position,” indicative of *operating as measuring*, a distinct interpretation of an eigenvalue equation.

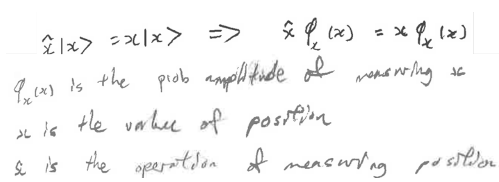

Figure 2. Example of operating as measuring *symbolic form.*

Potential Measurement Outcome

The final interpretation of eigenvalue equations with this symbol template comes from one student. Their eigenvalue equation contained all the correct elements, written as one would expect from convention (Fig. 4a). Figure 4b shows their explanation of what each term represents. When the text alone is read this is a fairly sophisticated statement: “When you measure the position of [the eigenstate] x_i you get x_i.” (The portion in brackets is an addition by the author for coherence, which is supported by the student’s response to the question, “How does each of these relate to the physical system?”, shown in Figure 4c.) This student’s interpretation of an eigenvalue equation goes beyond a geometric interpretation and does not include the notion that operating is the act of taking a measurement. This is indicated by the student’s use of the phrase, “can be measured,” which stands in contrast to the student in Figure 3 who stated that the operator represented “the operation of measuring position.” This is a subtle but important distinction as it separates the idea of taking a measurement from the idea that the operator represents a quantity which can be measured. This student presents a more sophisticated interpretation of the eigenvalue equation than the previous ones shown: that it is a statement about the *possible* outcome of measurement of the position, or more generally, the quantity being represented by the operator. A more concise version for use as a conceptual schema would be “a statement about the potential results of measurement”. This schema is directly connected to the 3rd postulate of quantum mechanics: “The only possible results of measurement of an observable $\hat{A}$ are one of the eigenvalues of the observable a_n” (e.g., McIntyre, 2012). While a single student is not indicative of the greater study population, the sophistication of this student’s response and its alignment with the meaning of a quantum mechanical eigenvalue equation warrant its inclusion as an example of a student-generated expert-level form for an eigenvalue equation.

Discussion and Conclusion

Dreyfus and colleagues posited that there may be symbolic forms specific to quantum mechanics that had yet to be seen in student work. Their eigenvalue equation symbolic form, *reproductive transformation,* which is consistent with the desired outcome of mathematics instruction on eigenvalue equations (Henderson et al., 2010) and a productive conceptualization for students (Wawro, Watson, & Zandieh, 2019), is one of three forms identified that all use the same eigenvalue equation template, which follows the canonical structure.

The other two forms, *operating as measuring* and *potential measurement outcome*, both illuminate the physical meaning of the QM eigenvalue equation rather than a mathematical interpretation. *Operating as measuring* instead focuses on the act of taking a measurement "operator as agent" (Gire and Manogue, 2008, 2011) as a lens for interpreting an eigenvalue equation. Wawro and colleagues observed this conceptualization and proposed an explanation for this form: that physics equations typically represent relationships between physical quantities, documenting covariation among the quantities; *operating as measuring* conceptually reflects this relationship and is consistent with physics students' experience.

The third symbolic form, *potential measurement outcome*, is significantly more relevant to and meaningful for the physical interpretation of a QM eigenvalue equation. One could argue it falls into the expert-like additional layered meaning discussed by Dreyfus and colleagues; however, the student response discussed in relation to this form seems completely void of the ideas that form the schema of *reproductive transformation* (Dreyfus et al., 2017). Students could hold these two forms simultaneously (Wawro et al., 2020), and invoke them as needed or convenient, consistent with evoked concept images or resource activation, but *potential measurement outcome* is a more expert-like interpretation of a QM eigenvalue equation.
The way students mathematize a physics problem has been of interest to the PER community since the introduction of symbolic forms. Student construction of equations meant to describe physical systems, both in this and Sherin's (2001) tasks, provides insight into resources accessed by students in mathematizing physics problems. This analysis also opens the door for mathematical sensemaking analysis (Kuo et al., 2013). Some students explicitly attempt to utilize mathematics from other quantum contexts to generalize to this novel system. It is also noteworthy that both interpreting and constructing eigenvalue equations was not a trivial task for students. Some explicitly wrote about the difficulty of the tasks in their responses, while others showed the non-triviality of the task through their failure to provide a classifiable expression in response to the construction task. These data can provide insight into the ways students are reasoning through the discrete-to-continuous transition in a spins-first quantum mechanics course and will be a topic of further exploration.

Modeling Mathematicians' Playful Engagement in Task-Based Clinical Interviews

Dru Horne	Anna Bloodworth	Amy B. Ellis
University of Georgia	University of Georgia	University of Georgia

Theoretical accounts of mathematicians' disciplinary practice draw similarities to mathematical play, in that it can entail agency and autonomy, open exploration, creativity, imagination, and enjoyment. We analyzed task-based clinical interviews of 13 mathematicians to determine whether their problem-solving activity was playful and found evidence of three aspects of playful math: agency in exploration or goal accomplishment, self-selection of mathematical goals, and a state of immersion, investment, or enjoyment. We present these findings and introduce a form of problem-solving activity, the Explore-Focus Cycle, as one characteristic of playful math.

Keywords: mathematical play, clinical interviews, mathematicians

One goal of undergraduate mathematics education is to support students' development of productive dispositions towards mathematics (Code et al., 2016; Watson, 2008) helping students engage with mathematics in disciplinarily authentic ways (Lim & Selden, 2009). Work examining mathematicians' practices has highlighted activities such as detecting and formalizing patterns, developing and refining definitions, thinking structurally and generally, selecting and applying proof techniques, and refining earlier reasoning (Burton, 2001; Fernández-León et al., 2021; Melhuish et al., 2021; Martín-Molina et al., 2018). Although it is important to not take an overly narrow view of what it means to meaningfully engage in mathematics as an expert (Stillman et al., 2020), researchers nevertheless argue for instruction that supports the habits of mind believed to be similar to mathematicians' practices, such as generating interesting questions, experimenting, conjecturing, and generalizing (e.g., Bass, 2008; Cuoco et al., 1996).

Gresalfi and colleagues (2018) note that the above forms of disciplinary engagement involve many of the same features as play including "exercising personal agency to set and reach goals, exploration, imagination, and joy" (p. 1335). Others agree: For instance, Mason (2019) remarked that "playfulness provides an accurate and apt description of what mathematicians do," and Su, in his MAA Presidential Address at the Joint Mathematics Meetings (2017), stated, "We play with patterns, and within the structure of certain axioms, we exercise freedom in exploring their consequences, joyful at any truths we find." He went on to identify play as a key component of mathematics for human flourishing (Su, 2020). Indeed, offering opportunities to develop a mathematically playful disposition can center student voices, invite agency, and increase equitable access to mathematics (Gresalfi et al., 2018; Widman et al., 2019).

These remarks reflect a robust belief that mathematicians are playful in their engagement, and yet, we have found little empirical evidence demonstrating these claims. Consequently, the motivation for this study is to investigate whether and how mathematicians' disciplinary engagement is playful. In particular, we consider the following research questions: Is mathematicians' problem-solving activity in task-based clinical interviews playful? If so, what are the characteristics of mathematicians' playful engagement?

Theoretical Framework and Background Literature: Defining and Characterizing Mathematical Play and Playful Math

Definitions of play vary, but all entail a sense of agency in (a) choosing to engage in an activity, (b) exploring, (c) selecting goals, and (d) accomplishing goals (Jasien & Horn, 2018). Huizinga (1955), one of the early scholars to define play, remarked that play is voluntary, steps outside the ordinary, is bounded in time and space, is orderly, is governed by rules, and involves tension; the player wants to achieve something but wants to succeed by their own expertise. Dewey (1916/1966) similarly noted that people who play “are trying to do or effect something” (p. 203). Thus, play is goal-driven, but as Featherstone (2000) noted, the goals of play, unlike the goals of work, “are always in some sense ‘inside’ the play, they are real and shape the activity of the players” (p. 15).

Mathematical play is a particular type of play. Holton et al. (2001) described mathematical play as the playful exploration that emerges when learners find themselves in mathematical contexts with open goals, and Williams-Pierce (2019) defined mathematical play as voluntary engagement in cycles of mathematical hypotheses with occurrences of failure. Much of the work on mathematical play investigates the mathematics that can arise from playful settings such as preschool children’s block play (e.g., Brown, 2009), or players’ interactions with videogames (Williams-Pierce, 2019). In contrast, our interest is in how to incorporate play into the school mathematics that occurs in classrooms. We use the term “playful math” rather than “mathematical play” to highlight the potential of “playifying” classroom mathematical activity. Following the traditions of researchers who emphasize agency, we define playful math as a form of mathematical engagement that entails (a) agency in exploration or goal accomplishment, (b) self-selection of mathematical goals, and (c) a state of immersion, investment, and/or enjoyment.

Characteristics of Mathematical Play

Characterizations of mathematical play are typically either situated in studies of young children’s activity or in studies of individuals in informal environments. When they concern the mathematical play of undergraduates or experts, characterizations are often, but not always, theoretical rather than empirical. This is likely due to the fact that when students enter high school and college, discussions of learning seldom reference play (Gresalfi et al., 2018). Indeed, play has increasingly been pushed out of school settings (Jerret, 2015), and undergraduate education in particular has seen a separation of play and learning (James & Nerantzi, 2019). Consequently, little is known about the nature of learners’ playful engagement in advanced mathematics tasks (Gresalfi et al., 2018).

Many scholars have called for supporting and legitimizing play in adult lives (e.g., James & Nerantzi, 2019; Sicart, 2014, Swank, 2012). Concerning playful mathematics in particular, researchers argue for the importance of understanding and fostering students’ playful dispositions as a way to encourage engagement that mirrors the activity of mathematicians. For instance, Featherstone (2000) noted a number of similarities between play and the discipline of mathematics itself in that both focus on theoretical entities, are set apart from daily life, create order, and are rule bound. Mason (2019) explained that “mathematicians play with what is given and with what is sought – extending, varying, simplifying, and complexifying” (p. 95), and other mathematicians have described their own practice as playful (e.g., Lockhart, 2009; Su, 2017).

Descriptions of mathematicians’ playful engagement highlight the presence of two phases of activity. Su (2020), for instance, distinguished between the *inquiry phase* and the *deductive reasoning phase*. In the inquiry phase, one engages in pattern exploration and uses inductive reasoning to build conjectures from specific examples. One shifts to the deductive reasoning phase when a conjecture has been selected and must now be proved or disproved. Holton et al.’s (2001) theoretical analysis of mathematicians’ play makes a similar distinction between two phases. In the first, one produces tentative examples without a clear direction. In the second, one becomes more systematic and intentional in generating particular types of cases. These phases are reminiscent of Cai and Cifarelli’s (2005) examination of undergraduates’ mathematical exploration with open-ended problems. Although not specifically referencing play, they distinguished two types of goal episodes, *primitive* and *refined*. Primitive goal episodes entail trying out preliminary ideas without a specific goal other than to generate empirical results to support further exploration. Refined goal episodes are ones in which the problem solver's activity occurs with a well-defined goal in mind.

Although each of these researchers use different terms, all emphasize two characteristics of the first phase: It is empirical, gathering data to inform the development of a pattern, hypothesis, or direction, and it is not goal oriented, in that one is exploring without pursuing a particular, pre-determined direction. The second phase entails goal-directed activity towards a particular outcome in which one's actions are guided by anticipation. There is some disagreement about whether mathematical play is still happening when one shifts into the goal-directed phase (Holton et al., 2001), but there is broad agreement that mathematicians' playful engagement includes open exploration. We therefore attended to these two phases of activity and sought to determine whether mathematicians demonstrated instances of them in their problem-solving activity as a potential characteristic of playful engagement.

Methods

Our data set consisted of task-based clinical interviews from 13 mathematicians (see Lockwood et al., 2016 for additional details). Twelve mathematicians held a PhD in mathematics, and one held a PhD in computer science. During the interviews, the mathematicians worked on the problems shown in Figure 1. Task 1 was taken from Andreescu et al. (2007), and Task 2 was taken from a Putnam exam. All thirteen mathematicians worked on Task 1, and seven also worked on Task 2. We gave the mathematicians time to work on the tasks and asked them to think out loud as they worked. The interviewer generally only interrupted to ask clarifying questions and to answer the mathematician's questions. Each interview lasted approximately 60 minutes and was audio recorded using Livescribe pens and transcribed.

Interesting Numbers Task
Most positive integers can be expressed as a sum of two or more consecutive integers. For instance, 24 = 7+8+9 and 51 = 25+26. A positive integer that cannot be expressed as the sum of two or more consecutive positive integers is therefore *interesting*. What are all of the interesting numbers?

Selfish Sets Task
Define a selfish set to be a set which has its own cardinality as an element. Find, with proof, the number of subsets of $\{1, 2, \ldots, n\}$ which are minimal selfish sets, that is, selfish sets none of whose proper subsets is selfish.

Figure 1. The Interesting Numbers Task and the Selfish Sets Task.

In analyzing the data, we began with a priori codes based on our three-part definition of playful math: (a) agency in exploration/goal accomplishment, (b) self-selection of mathematical goals, and (c) immersion, investment and/or enjoyment. The first and second authors coded each transcript separately and met weekly to reconcile discrepancies. All three authors then discussed any remaining questions or discrepancies. In addition to coding for playful math, we also analyzed the data for the two phases of activity identified in the literature, which we call *Explore-Focus Cycles* (Ellis et al., 2022). For Mathematician 1, we did this analysis as a whole group. For the remaining mathematicians, the first and second authors conducted their analyses independently, kept notes, and met weekly to discuss and reconcile codes. The project team met weekly to consider discrepancies and finalize codes until the codes had stabilized.

Findings

Playful Math Codes

We found evidence of two out of three playful math codes in all 13 mathematicians' problem-solving activity, and evidence of all three codes in nine of the 13 mathematicians' activity. The first code, *Agency in exploration/goal accomplishment*, occurs whenever a person has the agency within a task to explore their chosen ideas or work towards accomplishing their goals. The mathematicians almost always had agency to explore and accomplish their goals as a result of the open nature of the tasks, the structure of the interviews, and their authority as mathematicians. Even when the interviewer directed mathematicians' actions by asking them, for example, to prove a conjecture, the mathematicians typically retained agency to explore and select their own proof strategies. For example, while working on the Selfish Sets Task, Mathematician 5 (M5) discussed various strategies for answering the problem. She decided between "doing some answers and then prove it inductively" or "try to think about [the task] combinatorially in some way that would help the answer pop out." The interviewer acknowledged these different paths: "Yeah, so there are a lot of different ways that you could go from here" but did not suggest a specific direction. M5 immediately decided to "think about how I'm going to compute this sum". This demonstrated both *Agency in exploration,* as M5 thought through different approaches to solving the problem, as well as *Agency in goal accomplishment,* as she narrowed in on a direction to accomplish the task goal of solving the Selfish Sets Task.

The second code, *Self-selection of goals,* occurs when a person chooses their own goals or sub-goals for a task. These may include exploring the problem, making conjectures, deciding on a strategy, etc. For example, while solving the Interesting Numbers Task, M2 created a generalized algebraic expression for interesting numbers and wondered, "so now the question is what numbers can't be written in that form", which M2 began trying to answer using a parity argument. Similarly, in trying to determine how to prove that the number of selfish sets of $\{1, 2, \ldots, n\}$ is a Fibonacci number, M7 attempted to use a proof by induction on the size of the subsets: "Obviously you've got all the ones before, okay, so the proof would be induction. And, what does this new one add?" She tried to find a recursion but then switched to considering a sum of binomial coefficients. Before stopping the interview, she noted that in order to prove that the sum is a Fibonacci number using induction, she would need to "get a better sense" of the sum. Thus, her self-selected goals included using proof by induction, determining the recursive structure of the problem, and better understanding the sum of binomial coefficients.

The third code, *Immersion, investment, and/or enjoyment,* refers to when a person shows evidence of immersion or investment in the task, or shows that they are enjoying the task. For example, M1 demonstrated investment in the Selfish Sets Task by voluntarily returning to it. He spent 15 minutes on first task, shifted to the Selfish Sets Task for 20 minutes, and then returned to first task. After giving a proof for first task, he noted, "Wait, okay. So now I got a little time to play around with the other one. (Interviewer: Mm-hmm) Might not get it. Sets are not my thing particularly." He expressed an interest in returning to the Selfish Sets Task and attempting to solve it, which indicated investment. Additionally, during the interview, M1 expressed enjoyment with the two tasks, remarking, "These are great problems, by the way." Another indication of immersion or investment is losing track of time, which is one aspect of flow (Csíkszentmihályi, 1990; Liljedahl, 2018). We saw this when M4 was surprised at the time he had spent on the problem: “I've been working on this for 15 minutes, oh my god.” Other mathematicians persisted in solving the problem even when they were given a chance to stop, which indicated enjoyment and investment in the tasks. During M10’s interview, he continued working to solve the problem even when the interviewer provided an opportunity to stop:

Interviewer: Great. And just so you know, so it's been about an hour. So, if you want to stop now, that's fine. But if you want to try...

Mathematician 10: Oh, I'm just getting warmed up.

Interviewer: No please, please do. I just don't, I don't want to take up too much of your time.

Mathematician 10: Okay, no, no problem at all. Okay. Yeah, I should warn you, once I get going, I don't quit.

Thus, M10’s desire to continue working even being provided an opportunity to stop is evidence of investment in the task.

Recall that we found evidence of all three codes for only nine of the 13 mathematicians. For the remaining four mathematicians (M2, M6, M7, and M11), we saw evidence of *Agency in exploration/goal accomplishment* and *Self-selection of goals*, but we did not find evidence of *Immersion, investment, and/or enjoyment.* We found three reasons for the lack of immersion, investment, or enjoyment: (a) problem difficulty, (b) interruptions preventing sustained engagement, and (c) lack of open exploration. M2 was already familiar with the ideas in both problems, and so he was able to achieve solutions to both tasks in about 10 minutes. Thus, the problems were exercises for him rather than problems (Kantowski, 1981). M6 and M7 both experienced multiple interruptions during their interviews, which may have impeded their engagement and the ability to enter a state of flow. Finally, both M6 and M11 had a truncated exploration phase, as they found a viable solution path early on in their exploring. Without the extended exploration, these mathematicians may not have had as many opportunities to become immersed or experience enjoyment. In the next section, we report in more detail on the exploration phase by elaborating the evidence of Explore-Focus cycles in the mathematicians’ problem-solving activity.

Explore/Focus Cycles

We found that Explore-Focus Cycles (Figure 2) occurred in the tasks where mathematicians were playfully engaged. However, the amount of exploring actions versus focusing actions and the amount of time spent on those types of actions varied greatly from mathematician to mathematician. The two mathematicians for whom we found the most evidence of immersion/investment spent a significant amount of time exploring. Additionally, as we noted above, each of the four mathematicians who did not exhibit the immersion/investment code had fewer exploring actions and spent less time in exploration compared to the mathematicians who exhibited immersion, investment, and/or enjoyment. To exemplify the Explore-Focus Cycles, we present one cycle from M1’s engagement with the Interesting Numbers Task (Figure 2).

Within the cycle, mathematicians shift between exploring actions and focusing actions. *Exploring actions* occur when problem-solver(s) either (a) engage in an action with little or no anticipation of an associated outcome, or (b) notice properties of outcomes and wonder about the connection between those outcomes and the actions that led to them. For example, in the two tasks, mathematicians might generate small examples to look for a pattern or notice a general form to help them determine interesting numbers or minimal selfish sets. They may also explore different solution strategies before deciding to try one. A *focusing action* occurs when the action is tied to an anticipated outcome. For example, after generating small examples and noticing a pattern, a mathematician may make a conjecture, and then choose specific examples to test their conjecture. Both conjecturing and choosing examples are focusing actions.

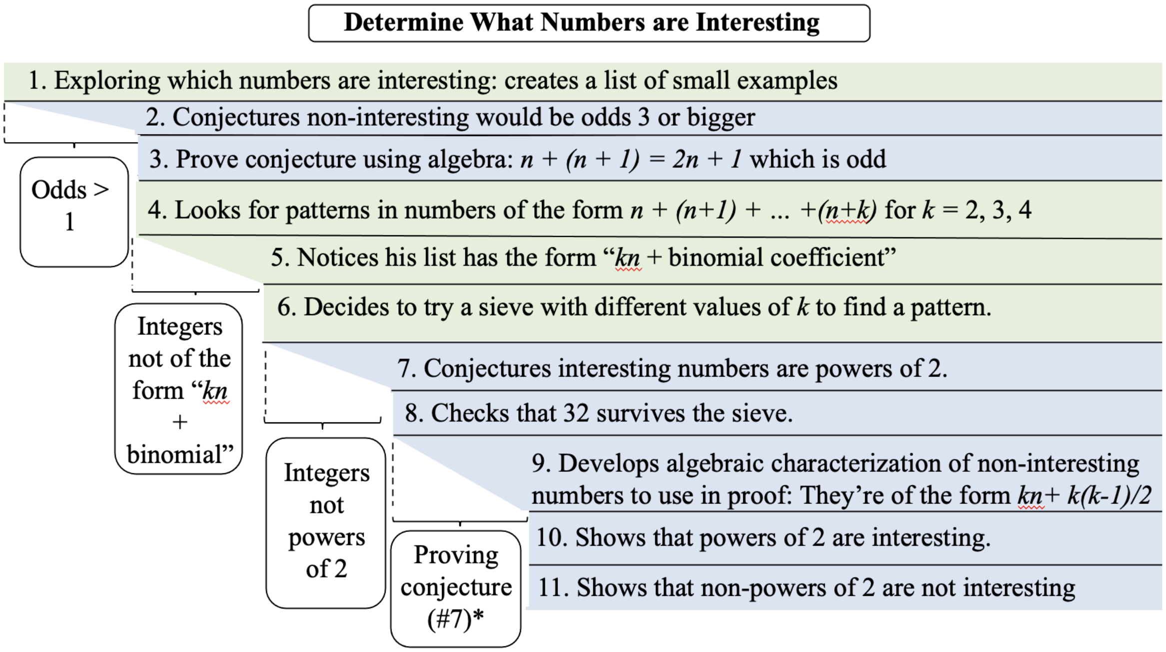

Figure 2. The Explore-Focus Cycle for M1's solution of the Interesting Numbers Task.

In Figure 2, the exploring actions are green and the focusing actions are blue. With our data, the problem space consisted of characterizing the objects specified by the tasks, namely, interesting numbers and minimal selfish sets. Once the mathematicians had a characterization in the form of a conjecture, they shifted to trying to prove their conjecture. The narrowing of the problem space can be seen in Figure 2 as "Odds >1", "integers not of the form kn + binomial coefficient", and "integers not powers of 2". Once M1 had conjectured that interesting numbers are powers of 2 (#7) and checked his conjecture with an example (#8), he shifted to trying to prove his conjecture, which resulted in another narrowing of the problem space. This action is denoted with an asterisk as this narrowing represents a shift from characterizing the interesting numbers to proving his conjecture about interesting numbers.

M1 began the task by exploring the constraints of the problem and generating small numbers (#1). His initial exploration only consisted of sums of two positive integers and led him to conjecture that the non-interesting numbers are odd numbers greater than 1 (#2). During his small example generation, he did not anticipate the form of non-interesting numbers; hence, his engagement was exploratory. He then made a conjecture after generating four examples. At this point, M1 shifted to trying to prove his conjecture, "non-interesting numbers are odd numbers greater than 1." He argued that if we consider two consecutive numbers, x and $x + 1$, then their sum is an odd number of the form $2x+1$ (#4).

At this point, the interviewer redirected M1 to the problem statement, pointing out that non-interesting numbers can be the sum of more than two consecutive integers. This shifted M1 back into a narrower problem space in which he tried to determine which even numbers are interesting (since he had already proved that odd numbers are non-interesting). To do this, he tried small algebraic examples (#4), i.e., he considered numbers of the form $3n + 3$, $4n + 6$, and $5n + 1$, which are the sums of three, four, and five consecutive integers, respectively. He noted that all of these integers are of the form $kn +$ binomial coefficient (#5). While generating these small examples, M1 had not anticipated the general form, nor at this point did he anticipate how it would be useful, thus he was still exploring. Deciding that he wanted to exclude all integers of those forms led him to comment, “this looks a little like the Sieve of Erastothenes … you’re trying to exclude numbers that have certain forms.” M1 then created a list of numbers and systematically eliminated them (#6); in doing so, he realized that the surviving integers are powers of 2 (#7). Although his decision to try a sieve focused his actions, he did not anticipate the outcome of the sieving process, and so we classify it as an exploring action.

At this point, M1 had a conjecture that the interesting numbers were powers of 2. In order to test his conjecture, he continued his sieving process to see if 32 survived the sieve (#8). This was a focusing action because he anticipated that 32 would survive. Having checked that his conjecture held for 32, M1 shifted to trying to prove his conjecture that a number is interesting if and only if it is a power of 2. At first, M1 did not see how to proceed and decided to spend some time with the other task. Once he returned to this task, he reviewed his work and noted that non-interesting numbers can be written in the form $kn + k(k\text{-}1)/2$ (#9). M1 first showed that if a number is a power of 2 then it doesn’t have the form $kn + k(k\text{-}1)/2$ since it would factor as $k/2(2n+k\text{-}1)$ which would be odd (#10). To prove the other direction, he showed that if a number is not a power of 2, then it is not interesting by demonstrating that every odd number can be written in the form $2n+k\text{-}1$ where k is a power of 2 (#11). All of his actions in the proof were focusing actions because he anticipated that they would allow him to reach a logical conclusion and prove his conjecture.

Discussion

Researchers have argued that mathematicians’ disciplinary engagement is playful (e.g., Mason, 2019; Su, 2020). Our study supports these assertions with empirical findings. We found evidence of all three aspects of playful math engagement (agency in exploration or goal accomplishment, self-selection of mathematical goals, and a state of immersion, investment, and/or enjoyment) for nine of our 13 mathematicians and evidence of the first two aspects for all 13 mathematicians. We also found evidence that the mathematicians shifted back and forth between the two types of engagement depicted in theoretical studies (e.g., Holton et al., 2001; Su, 2017), which we call exploring and focusing. Given the constraints present in analyzing task-based interviews, more research is needed to better understand the playful nature of mathematicians’ practice when engaged in their own research activities. Nevertheless, it is encouraging that we were able to verify theoretical claims with our findings.

What is perhaps more interesting is why some of the mathematicians did not demonstrate immersion, investment, or enjoyment. The first two aspects of playful math are ones that are seldom present for students, but we would expect to see in mathematicians. The third aspect, however, appears to be related to not only the ability to maintain engagement without interruption, but also to the level of exploration the mathematicians engaged in. Those whose exploration was truncated may not have found the tasks sufficiently challenging. This finding suggests that an appropriate level of task challenge, one that is within reach but is also not too easy, may be an important factor in fostering flow (e.g., Liljedahl, 2018), and, by extension, playful math engagement.

Students’ and Mathematicians’ Playful Math Engagement

Anna Bloodworth
University of Georgia

Dru Horne
University of Georgia

Amy B. Ellis
University of Georgia

Mathematical play is hypothesized to foster student dispositions that mirror authentic disciplinary engagement, such as exploring, conjecturing, and strategizing. However, most research on mathematical play investigates the mathematics that can emerge from children’s natural play or play in informal spaces. We introduce the term “playful math” to highlight the potential of playifying school mathematics tasks and investigate both students’ and mathematicians’ problem-solving activity through this lens. Drawing on teaching experiments and mathematician interviews, we found evidence of playful engagement in both populations and identified similar activity structures across both groups, which we call Explore-Focus Cycles. We present two such cycles and discuss implications of playful math for student activity.

Keywords: Playful math, cognition, mathematician interviews, teaching experiments

Motivation and engagement are critical factors in supporting students’ abilities to understand, perform, and persist in mathematics (e.g., Durksen et al., 2017). Students’ experiences of self-efficacy can foster motivation, which in turn predicts persistence in the STEM fields (Simon et al., 2015). Despite the importance of these factors, however, studies show ongoing challenges with students’ self-efficacy and positive engagement in mathematics (e.g., Martin & Marsh, 2006). Finding ways to help students experience mathematics as enjoyable and worthwhile is an important part of addressing attrition rates (Wilson et al., 2012).

One way to foster enjoyment is to provide opportunities for students to engage in more authentic disciplinary practice, such as exploring, conjecturing, defining, and proving (Jasien & Horn, 2018). In contrast to school mathematics, which can be procedural and routinized, these practices can be simultaneously challenging, creative, and playful. In fact, much of authentic disciplinary engagement involves many of the same features as play (Gresalfi et al., 2018), and professional mathematicians have been described as engaging in mathematical play as part of their practice (Lockhart, 2009; Mason, 2019; Su, 2020). Mathematical play has the potential to center student voices enabling them to create their own challenges, investigate novel ideas, and develop a disposition for innovation (Barab et al., 2010; Gresalfi et al., 2018).

Mathematical play is, therefore, a promising avenue for fostering productive practices (Mason, 2019). However, the bulk of existing research on mathematical play is situated either in early childhood or in informal spaces such as video games. Less is understood about the potential benefits of incorporating play into school mathematics, particularly for older students. Furthermore, the degree to which “playifying” classroom mathematics fosters engagement that is more similar to that of mathematicians is not well understood. Therefore, this study investigates both mathematicians’ problem-solving activity and middle-school students’ activity in playful math tasks to ask, how does students’ playful math engagement compare to mathematicians’ problem-solving engagement? We use the term “playful math”, rather than “mathematical play”, to highlight the opportunities of “playifiying” classroom mathematics tasks.

Background Literature: The Benefits of Playful Math

Playful math offers both conceptual and affective benefits. Playifying mathematics can favor social interaction and communication (Edo & Deulofeu, 2006) and has been shown to foster increased enjoyment (Plass et al., 2013; Sengupta-Irving & Enyedy, 2015), engagement (Barab et al., 2010), and to engender positive attitudes towards mathematics (Holton et al., 2001). Su (2017) noted that it can also foster connection and community: "It's why the MAA supports programs like the American Mathematics Competitions and the Putnam Competition. We help kids flourish through building hopefulness, perseverance, and community" (p. 486).

Researchers have also identified a number of learning benefits of playful math for children, including increased mathematical fluency (Plass et al., 2013), improved knowledge in geometry (Levine et al., 2012; Sedig, 2008), improved spatial skills (Casey et al., 2008; Levine et al., 2012), and improved number development (Siegler & Ramani, 2008; Wang & Hung, 2010). The degree to which these learning benefits extends to older students is unclear, but researchers have identified a number of ways in which playful math can foster forms of engagement that is thought to more closely mirror mathematicians' disciplinary practice. This includes activities such as abstracting and generalizing (Featherstone, 2000; Melhuish et al., 2021), exploring patterns within axiomatic structures (Fernández-León et al., 2021; Su, 2017), conjecturing (Jasien & Horn, 2018), and "extending, varying, simplifying, and complexifying" (Mason, 2019, p. 95), among others. However, the manner in which this actually occurs, particularly with classroom tasks, is not well understood. Therefore, we sought to better understand both the playful nature of mathematicians' problem-solving activity, as well as the activity of students when engaging in playified tasks.

Theoretical Framework: Defining Playful Math and Principles for Task Design

What makes mathematical engagement playful? Definitions of play vary, but all emphasize the learner's freedom and autonomy (Holton et al., 2001; Su, 2017). Jasien and Horn (2018) described mathematical play as entailing agency in exploration, self-selection of goals, and self-direction in how to accomplish them. Davis (1996) described play as an acceptance of uncertainty and a willingness to move, which is similar to Mason's (2019) depiction of play as trying out actions and exploring consequences. Play is not aimless, but rather, it is goal driven and occurs within a structure (Featherstone, 2000; Huizinga, 1955; Su, 2017). Following these researchers, we define playful math as a particular form of engagement in mathematics, one that entails (a) agency in exploration and goal accomplishment, (b) self-selection of mathematical goals, and (c) a state of immersion, investment, and/or enjoyment.

One common feature of playified tasks is that they are typically goal-free (Kapur, 2015), open-ended problems (Cai & Cifarelli, 2005). In goal-free problems, learners only have to attend to the present state and consider how to make any possible move from that state. This is in contrast to goal-specific problems, in which learners must consider a problem's givens, the pre-determined goal, and how to connect the givens to the goal. Open-ended problems are similar, in that one could construct many different problems and solutions within the given situation. In constructing goal-free and open-ended problems, we followed four design principles for playifying our tasks (Plaxco et al., 2021): (1) allow for free exploration within constraints; (2) allow the student to act as both designer and player; (3) engender anticipating within the task; and (4) provide a method for authentic feedback.

Methods

Study 1: Middle-School Teaching Experiments

We conducted two teaching experiments (TEs) over the course of 5 weeks during the summer of 2020 (Steffe & Thompson, 2000). Sessions for the TEs occurred weekly for approximately one hour; the third author was the teacher-researcher. We video and audio recorded both TEs, with the exception of the second session, when a technical error prevented video collection. We also collected student work at the end of each session. The first TE was with two rising 7th grade students, Stewie and GJ, and the second TE was with three participants, Artemis, a rising 7th grade student, and Apollo and Frances, rising 6th grade students (all students chose their own pseudonyms). The students had limited graphing experience and had received no prior instruction on linear functions.

To investigate students' activity when exploring rates of change within playified tasks, we drew on a set of established research-based linear and quadratic growth tasks (Ellis et al., 2020; Matthews & Ellis, 2018). In these activities, students investigate shapes via dynamic geometry software, determining the rate of change of a shape's area compared to its changing length as it sweeps out from left to right, and then graphing that relationship. In following the above-described four design principles to playify the tasks, we developed a series of activities called *Guess My Shape*, in which the students created secret shapes of their choice (design principles #1, #2), constructed graphs comparing length and area (design principles #2, #3), and then challenged one another or the teacher-researcher to determine the secret shape based on the graph alone (design principles #2, #3, #4). Because playful math describes a form of engagement rather than the task itself, we hypothesized that the playified tasks would encourage playful engagement, but we did not assume that they would. For Session 1, we only used the extant covariation tasks, which we call standard tasks. For Sessions 2 - 5, we used both the standard tasks and the playified math tasks. For each of those sessions, we spent the first two-thirds of the session working with the standard tasks and the last one-third implementing the playful math tasks

Study 2: Mathematician Task-based Interviews

Additionally, we analyzed task-based interviews with 13 mathematicians (see Lockwood et al., 2016 for details). We gave each mathematician one or two tasks and asked them to work on the task(s) while sharing their thinking out loud. The interviewer only interrupted to ask clarifying questions or to address participant questions. We audio recorded the interviews with Livescribe pens, which also captured the mathematicians' written work as they spoke. All mathematicians worked on the *Interesting Numbers* task, and 7 of the mathematicians also worked on the *Selfish Sets* task. The Interesting Numbers tasks asked, "Most positive integers can be expressed as a sum of two or more consecutive integers. For example, 24 = 7 + 8 + 9 and 51 = 25 + 26. A positive integer that cannot be expressed as a sum of two or more consecutive positive integers is therefore *interesting*. What are all the interesting numbers?" The Selfish Sets task asked, "Define a *selfish* set to be a set which has its own cardinality as an element. Find, with proof, the number of subsets of {1, 2, . . . , n} which are minimal selfish sets, that is, selfish sets none of whose proper subsets is selfish."

Analysis

We analyzed the TE data for aspects of playful mathematics using a combination of a priori and emergent codes (Strauss & Corbin, 1990). We drew the a priori codes from our three-part definition of playful math, and we developed emergent codes to address aspects of students' playful engagement that were not captured by the initial set of codes. All three authors coded the transcripts independently and met weekly to refine codes and to adjust and resolve discrepancies. This process continued through ten rounds of adjustments until all codes had stabilized. This analysis of the TEs also produced a cyclic model of exploring and focusing actions (Ellis et al., 2022), which we then used as an analytic tool for the mathematician data. We discuss this Explore-Focus Cycle in more detail in following sections.

We then turned to the mathematician data and analyzed the interviews for playful engagement using the codes we developed from the TE analysis. We also developed descriptive notes and diagrams that described each mathematician's actions in terms of the Explore-Focus Cycles. The first and second author coded the interviews separately and met weekly to resolve discrepancies until the coding scheme had stabilized.

Results

Explore-Focus Cycles

In the Explore-Focus Cycle, one shifts back and forth between exploring actions and focusing actions in order to make sense of a problem and determine a solution path. *Exploring actions* occur when the problem solver either (a) engages in an action with little or no anticipation of an associated outcome or (b) notices properties of outcomes and wonders about the connection between those outcomes and the actions that led to them. As such, exploring actions are empirical; they entail gathering information without a pre-determined aim, in order to develop an idea, direction, or conjecture. In contrast, *focusing actions* are ones that a problem solver makes with a specific anticipated outcome in mind.

For example, in the Interesting Numbers task, many of the mathematicians engaged in exploration by generating examples of interesting and non-interesting numbers in order to see if any useful patterns would emerge. Others explored by generating the algebraic formula for the non-interesting numbers and then seeing if they could identify a useful structure in the algebra. These actions typically resulted in the development of a conjecture that the interesting numbers are the powers of 2. At this point, the mathematicians shifted to focusing actions, pursuing strategies with anticipated outcomes such as an algebraic proof that powers of 2 are interesting.

In examining the students' activity, we also found evidence of Explore-Focus Cycles but only in the playified tasks. In the standard tasks, the students engaged in focusing actions but not exploring actions. In order to exemplify the Explore-Focus Cycles for both the students and the mathematicians, we present a truncated version of one cycle for a trio of students, Apollo, Frances, and Artemis, and for one mathematician, M10. The students' cycle occurred during a Create a Shape playified task, and M10's cycle occurred during the Interesting Numbers task (Figure 1). In the figure, the exploring actions are in the green cells and the focusing actions are in the blue cells.

Let us first consider the mathematician's engagement. M10 began with an exploration of possible approaches in order to determine which approach might be most productive (A1). She did not attempt any of the approaches but just listed and considered which ones might be feasible, and so there was not yet an anticipated outcome. She then focused on one strategy that allowed her to generate an algebraic formula for non-interesting numbers (A2). M10 then switched away from the algebraic form and instead generated and explored examples of non-interesting numbers to "see if it makes sense" (A3). After generating examples, she did not notice any patterns, and so she returned to the algebraic formula (A4). Here, she explored the formula to determine helpful structures that might indicate restriction on non-interesting numbers. From here, she switched again to the generated examples to look for patterns and structures and determines empirically that all odd numbers will not be interesting (A5).

For the *Create a Shape* challenge, the students began by exploring possible shapes to use in making a challenge for the teacher-researcher (TR) (B1). Here, they generated options without considering the associated length/area graph. However, once the options were suggested, they considered the reasonableness of the associated graph. They anticipated that some shapes were beyond their ability to graph and returned to exploring other possible shapes (B2). Apollo suggested a spiral and then a C-shape (B3, B4). Then, they applied a grid structure and a "connect the dots" structure to the C (B5). They were not anticipating the outcome of the graph or measurements but were looking for structures that might help them to do so. Artemis then considered the connect the dots method and suggested the need to number them (B6). Artemis was now anticipating how to use this structure for measurement and thus was engaged in a focusing action. Not included in the diagram below, the girls continued exploring and narrowing in on their chosen shape and ended with creating a "wave" shape and corresponding graph that introduced shapes shifted off the horizontal axis (Figure 2).

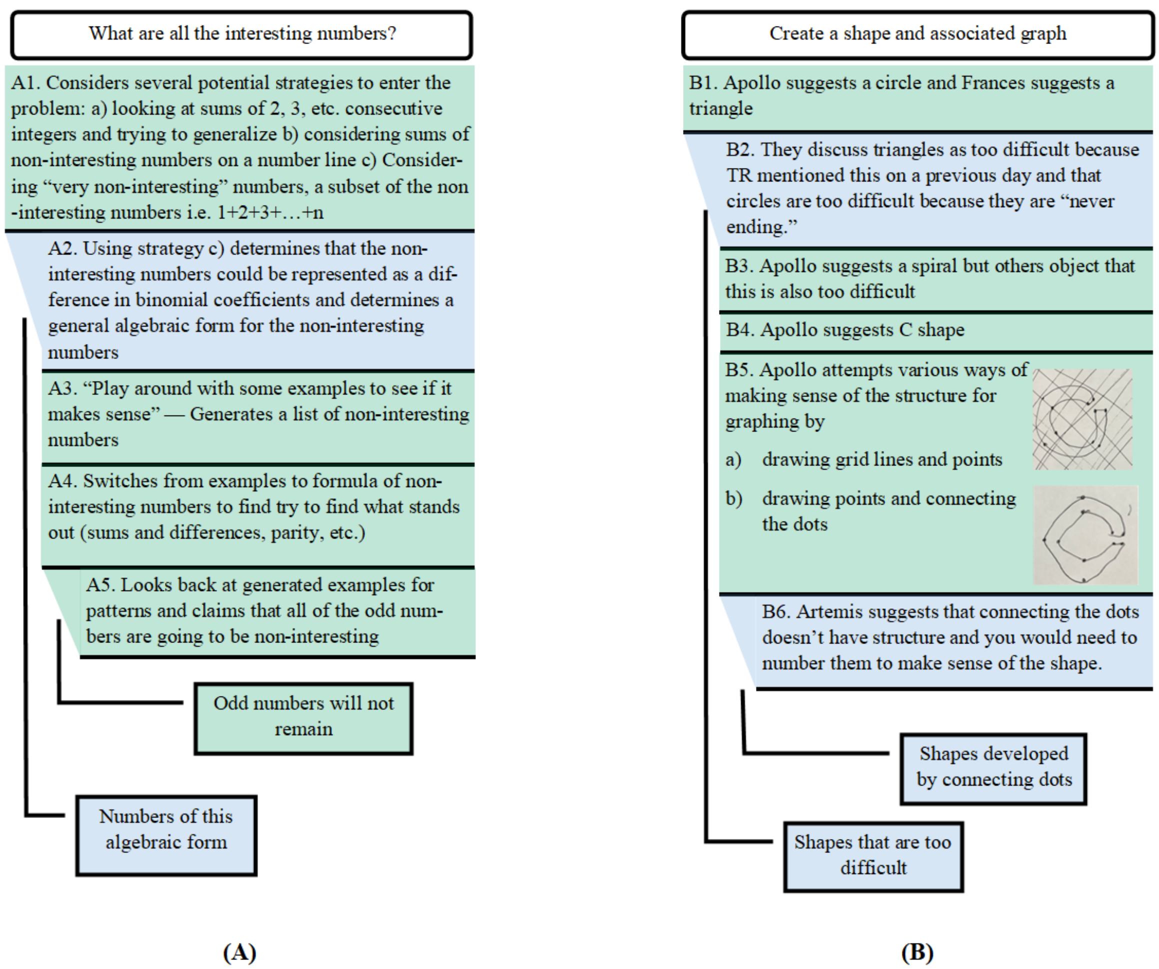

Figure 1. (A)Mathematician Explore-Focus Cycle and (B) Middle-School Explore-Focus Cycle

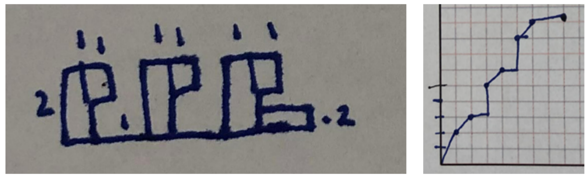

Figure 2. Artemis, Apollo, and Frances's final shape and graph for the Create a Shape Challenge on Day 3

For both the mathematicians and the students, we saw similarity across the presence and the function of exploring actions. Exploring actions can serve to help determine intial goals to begin narrowing in on the problem. M10 began with an exploration of possible approaches in order to determine which approach might be most productive to begin the problem, and then, she focused on one strategy that allowed her to generate information about non-interesting numbers. The exploration allowed her to select an initial strategy. Similarly, the students began by exploring possible shapes to use in their challenge. The exploration of shapes allowed the students to choose a goal for graphing and also helped them focus on the constraints of particular shapes. We saw this when Frances mentioned that triangles were too difficult, and when Artemis suggested, "Circles are never ending and that's impossible to graph a circle." Additionally, we saw that sometimes exploration serves as a way to search for structures. M10 explored structures when looking back at the algebraic formula of non-interesting numbers and when looking across her generated list of non-interesting numbers. The students did this when trying to work with a shape but were unsure of how to graph it. Wanting to graph the C-shape, Apollo tried overlaying a grid and "connecting the dots" between predetermined points. Here, she was trying to make sense of the structure of the C in a way that may be productive for graphing, as using points or grids may be natural ways of creating measureable areas and lengths.

Although similarities exist across the cycles, the cycles only occurred for the students during the playified tasks; whereas, they modeled the mathematicians' engagement across all of the tasks and interviews. One difference in the cycles is the novel, creative, and difficult mathematics that the students created for themselves. In this example, Apollo, Artemis, and Frances had only experienced linear and piecewise linear changes with shapes that were rectangles. However, to make the problem sufficiently challenging for the TR, they worked hard to create something different than what they had seen before, suggesting triangles and curved shapes such as circles, spirals, and the C-shape. Even though they moved on from using curved shapes, the desire to construct something novel and challenging persisted throughout the sessions. The mathematicians did not demonstrate creativity or make the mathematics more challenging, likely because the nature of the tasks did not call for designing or exploring their own questions.

Playful Engagement Codes

Recall that our three-part definition of playful math is (a) agency in exploration and goal accomplishment, (b) self-selection of mathematical goals, and (c) a state of immersion, investment, and/or enjoyment. Three additional codes emerged during our analysis: (d) taking on authority, (e) creative/unusual, and (f) harder math. *Taking on authority* refers to either a shift in authority from the TR to the students, or to an instance of students taking on mathematical authority with one another or with the TR. *Creative/unusual* applies when students have developed an idea, representation, connection, or task that we perceived as creative, novel, or atypical, and *harder math* occurred when students created a goal or task that introduced new challenges for them and represented mathematical ideas that surpassed the TR's intended set of topics or concepts.

Across the 10 sessions of the two TEs, we implemented 40 standard tasks and 9 playified tasks. Students completed one to two playified tasks at the end of each session, beginning with the second session. We coded any evidence of the six codes across both the playified and standard tasks. We then examined the rate of occurrence of each of the codes with respect to task type (Figure 3). For instance, self-selection of goals occurred on average 0.075 times per standard task and 3.11 times per playified task. We found that all six codes occurred with greater frequency on average within the playified tasks compared to the standard tasks. Furthermore, two of our codes, *creative/unusual* and *harder math*, occurred only in the playified tasks.

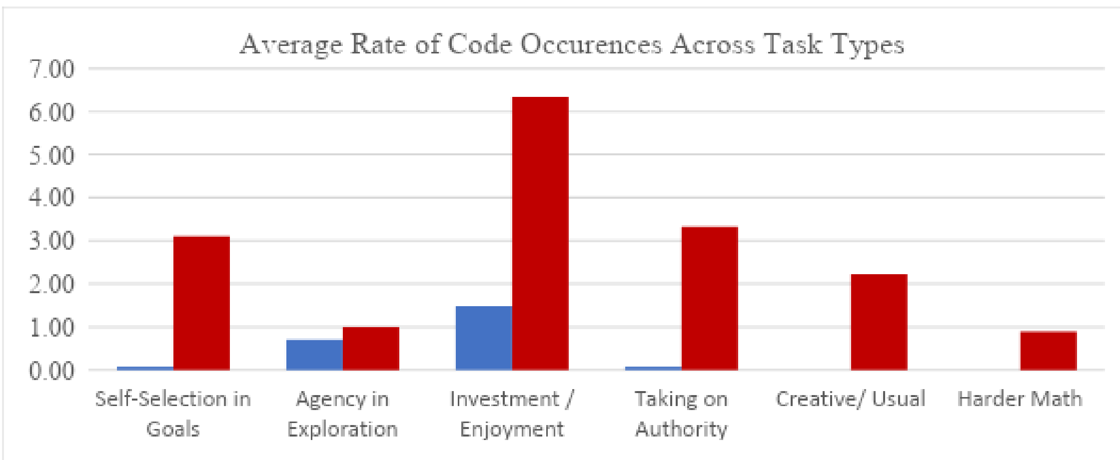

Figure 3. The Average Number of Occurrences of each code per Standard and Playified Task

We also investigated the presence of the playful math codes (a – c) in the mathematician interview data. We did not include the three emergent codes (d – f), as the nature of the interview tasks, unlike more authentic research activity, did not necessitate creative, unusual, or harder math (and the mathematicians already held mathematical authority). We found evidence of (a) *self-selection of goals* and (b) *agency in exploration/goal accomplishment* for all 13 mathematicians, and evidence of (c) *immersion, investment, and/or enjoyment* for nine of the 13 mathematicians. The presence of these codes and the Explore-Focus Cycles in both data sets suggests that playful math can be one way to support the development of productive practices.

Discussion

Playful math is a dispositional stance towards an activity, rather than a description of the activity itself. Thus, we did not know whether our design principles for playifying tasks would necessarily support more playful engagement. We found that they did, and they also supported students' development of novel, creative, and challenging ideas and strategies. It is possible that other open tasks may do the same thing; more research is needed to understand the unique affordances of a play-based approach. Nevertheless, this study offers a proof of concept that playful math can be one fruitful avenue for necessitating (Harel, 2008) more spohisticated concepts and connections.

We also found that mathematicians' problem-solving activity is not only playful, it also entails open exploration, with mathematicians shifting between phases of exploring and focusing. Notably, the students demonstrated similar cycles, but only in the playified tasks.

These findings provide evidence to support theoretical arguments that incorporating playful math into classroom activities can foster forms of engagement similar to mathematicians' activity (e.g., Mason, 2019).

Students Leverage Struggles with Proof to Script Fictional Dialogues about the Rules of Proving

Igor' Kontorovich
The University of Auckland

Nicole Qiusong Liu
Dulwich College Shanghai Pudong

Research has noted that some aspects of proof remain implicit in undergraduate instruction. Accordingly, we propose that direct interaction with the rules of proving (e.g., deductive reasoning, proof-writing conventions) is of didactical value to students transitioning to proof-based mathematics. Using the commognitive framework, we aim to delineate the rules that newcomers to proof find challenging. These were solicited with a scriptwriting task that asked students to create a fictional dialogue about a proof-related mistake that they had experienced. The task was embedded in a homework assignment in an undergraduate course for academically motivated high-schoolers. Thematic analysis of 61 scripts resulted in a range of rules that concerned the use of examples, logical circularity, and proof layout. We discuss these findings in relation to students' instruction and the existing literature on proof.

Keywords: Commognitive framework, proof, rules of proving, scriptwriting, transition to proof

Introduction

Dreyfus (1999), Selden and Selden (2015), and other researchers have argued that many aspects of proof remain implicit in undergraduate teaching and learning. Consistently, the lion's share of proof research can be reframed as students grappling with new mathematical rules that are not as explicit as they could be (e.g., Balacheff, 2008; Harel & Sowder, 2007; Moore, 1994; Selden & Selden, 1987; Weber, 2002). Overall, the shift to proof-based mathematics requires a fundamental change in the rules of argumentation and justification. Kjeldsen and Blomhøj (2011) maintain that developing appropriate rules for activities of this sort is indispensable for mathematics learning. In the context of proof, such rules can be associated with deductive reasoning, propositional calculus, logic, and generally accepted proof-writing conventions. Accordingly, we propose that a direct engagement with the *rules of proving* (*RoP* hereafter) is of didactical value to newcomers to proof-based mathematics. This study comes from a larger project that explores how newcomers articulate, apply, and make sense of RoP while making their first proving steps.

Background

A "solid finding" of mathematics education research is that "many students rely on validation by means of one or several examples to support general statements, [and] this phenomenon is persistent in the sense that many students continue to do so even after explicit instruction about the nature of mathematical proof" (ECEMS, 2011, p. 50). Another occasionally reported issue pertains to logical circularity. In abstract algebra, Selden and Selden (1987) found that some students use one version of the conclusion of the assigned statement to prove an equivalent version of the same conclusion. Additional findings of a similar type have been reported in the literature (e.g., Weber, 2002).

Emerging from cognitive studies, these findings are often framed in terms of students' errors and misconceptions since they have to do with proof validity. We adhere to the social perspective on proof (Stylianides et al., 2017). Within this perspective, the findings can be viewed as students' deviations from the rules that are broadly accepted in professional mathematics communities. And while it is not rare for mathematicians to disagree on proof-related issues (e.g., Lew & Mejía-Ramos, 2020), abiding by such rules as modus ponens and propositional calculus is likely to be expected in all communities that practise proof.

Generating proofs that abide by these rules requires additional rules that are less universal. For instance, Stylianides (2007) argues that in a classroom, a proof uses accepted statements and employs forms of reasoning and expression that are known to, or are within, the conceptual reach of the students. Accordingly, proofs can vary depending on what each classroom renders "accepted," "known," and "within students' reach." Furthermore, guidelines are needed to compile mathematical statements, forms of reasoning and expressions into a proof that the classroom community will endorse. In terms of Yackel and Cobb (1996), RoP of this kind are not very different from sociomathematical norms that determine "what counts as an acceptable mathematical explanation and justification" (p. 461). While using different terms, Dreyfus (1999) discusses instances where students grapple with such community-specific rules in the context of Calculus and Linear Algebra. The instances contain explanations and proofs that Dreyfus describes as insufficient: they present computations without accompanying explanations, draw on theorems without spelling them out, and, overall, do not "go back" enough and do not "go deep" enough.

The findings overviewed in this section come from research where students did not follow RoP that the researchers viewed as conventional. This study endorses an anti-deficit approach that foregrounds productive resources that all students bring to mathematics learning. The approach acknowledges that "learning takes time and imperfect articulations of mathematical ideas and some inconsistencies in the student's current conception are a natural part of the process of learning" (Adiredja, 2019, pp. 416–417). Specifically, we interpret students' deviations from conventional rules as a marker of their ongoing transition to proof-based mathematics. We also see value in encouraging students to notice and reflect on such deviations as a stepping-stone towards the conventional RoP (e.g., CUPS, 2004). This study aims *to delineate RoP that newcomers to proof-based mathematics find challenging*.

Commognitive Framework

We follow in the footsteps of previous studies that mobilized the conceptual and analytical potential of commognition to study university students' engagement with proof (e.g., Brown, 2018 Kontorovich, 2021, Kontorovich & Greenwood, 2022; Kontorovich et al., 2023). Commognition construes mathematics as a *discourse*. Discourses are defined as, "different types of communication, set apart by their objects, the kinds of mediators used, and the rules followed by participants and thus defining different communities of communicating actors" (Sfard 2008, p. 93). Then, *learning* is a process through which one's communication starts abiding by the rules of the target discourse.

Proof and proving concern *endorsable narratives*—narratives that can be rendered as true "according to well-defined rules of the given mathematical discourse" (Sfard, 2008, p. 224). Sfard (2008) acknowledges that "being dependent on what participants find convincing, routines of substantiation are probably the least uniform aspect of mathematical discourses. The very term endorsement may be interpreted differently by different people" (pp. 231–232). Indeed, the mathematics community has been revising these interpretations of what constitutes endorsement throughout history (e.g., Kleiner, 1991). Notwithstanding, Sfard (2008) proposes that "for today's mathematicians, the only admissible type of substantiation consists in manipulation on narratives, and it is thus purely intradiscursive" (p. 232). This manipulation unfolds as a sequence of utterances (or proof components), each either an "accepted fact," or derived according to some generally accepted rules (e.g., modus ponens). In this way, we associate RoP with intradiscursive principles for endorsing true mathematical statements and rejecting false ones. Colloquially speaking, these rules pertain to “when to do what and how to do it” (Bauersfeld, 1993, p. 4).

Commognition distinguishes between *object-level rules* and *meta-discursive rules* (or *metarules* for short). The former rules attest to the properties of mathematical objects and take the form of narratives on these objects (e.g., “the product of rational numbers is rational”). Metarules focus on how discourse participants formulate and substantiate object-level rules. Thus, RoP are meta-discursive by definition. Metarules are often enacted tacitly. Once a rule has been captured in words (i.e. when a *rule-narrative* is generated), commognition refers to it as *endorsed* by the interlocutor (Sfard, 2008). In this study, we scrutinize RoP that newcomers to the discourse of proof-based mathematics endorse.

The Study

Our participants were students in a special program entitled “Mathematics extension and acceleration” in a large New Zealand university. The program is intended for mathematically motivated and academically inclined students (usually 17-year-olds) in their final year of high school. As part of this program, the students take a special semester-long mathematics course that gives them academic credit for a bachelor’s degree in mathematics or engineering.

Proofs play a marginal role in New Zealand school mathematics (Knox & Kontorovich, 2022). The first part of the course ushers students into proving, while leveraging their familiarity with different kinds of numbers. In the first two lectures of the course that we studied, the instructor introduced proof as “an argument that mathematicians use to show that something is true.” Then he presented three true mathematical statements and led a whole-class discussion about what he positioned as “broken proofs.” In the following three lectures, he introduced selected properties of real numbers (e.g., distributivity) and illustrated how these could be used to derive additional properties (e.g., $-a = -1 \cdot a$); the illustrations were discussed as instances of “good proofs.” In these lessons, the instructor shared many proof-related insights and guidelines, including: examples do not prove universal statements, avoid circularity, start with true things, delineate the statement to be proved before proving it, the scope of the introduced variables should be defined, use words to explain the proof (not just formulas), avoid proofs that prove without explaining. In the last section, we draw on these insights and guidelines to reflect on RoP that students endorsed.

A *scriptwriting task* was designed to pursue the aim of this study. In tasks of this sort, students are provided with a thought-provoking prompt and asked to offer a resolution by scripting a fictional dialogue between made-up characters (Zazkis et al., 2013). Research has used scriptwriting to investigate students’ proving (e.g., Gholamazad, 2007). Brown (2018) argued that by making students’ envisioned interactions about a proof public, scriptwriting affords students a way to make their thinking visible and fosters reflection. In turn, researchers get access to proof-related aspects that students render important.

The course instructor and the first author collaboratively developed a scriptwriting task to provide students with opportunities to engage with RoP and collect data (Kontorovich & Bartlett, 2021). Figure 1 presents the task eventually developed. It was embedded in an individual homework assignment together with proof-requiring problems that are typical to transition-to-proof courses.

The second author conducted an initial analysis of students’ submissions (Liu, 2018). The analysis started with an overview of the 74 scripts that were collected to develop a general impression of whether they pertain to RoP. This process converged into 61 submissions, which underwent a thematic analysis (e.g., Braun & Clarke, 2006). The initial themes were iteratively separated and merged to develop general categories and descriptions of rule-narratives that the students generated through the voices of characters that represented them in their scripts (*Student-characters*, hereafter). This process combined deductive and inductive techniques as the initial themes were informed by the literature as well as by the content of students' scripts. When characterizing students' rule-narratives, we distinguished between the *restricting* and the *guiding* version of a rule: the former posited that something should not be done, while the latter offered guidance for how proving should be pursued.

> Writing proofs can be quite difficult, especially when you're new to them! One of the best ways to get better at writing proofs is to **look back** at past mistakes and think about how to fix them. This exercise is meant to help you do this, as follows:
> (a) Come up with a mistake you've made (possibly while working on this assignment!) or seen others make when trying to prove something.
> (b) Write a dialogue between you and an (imaginary) friend, where they make this mistake and you explain what's wrong with that idea and how to fix it: i.e. something like
>
> *Paddy's imaginary friend*: So, I was trying that checkerboard problem above[4], and I figured that if I wrote that I tried three different ways to do it and none of them worked that would totally count as a proof.
>
> *Paddy*: Well, actually it probably doesn't. You see . . .

Figure 1. A scriptwriting task[1]

Findings

This section presents six categories of the most common rules that emerged from analyzing students' scripts. We use rule-like formulations for the first five kinds due to the high consistency of the rule-narratives that the students' generated. Next, we elaborate on each kind and illustrate it with representative examples from students' scripts.

Examples are insufficient to prove a universal statement

This type of rule featured in 16 scripts. There, the students' rule-narratives stressed the insufficiency of drawing on specific examples to prove a universal statement that pertains to infinitely many cases. For example, one script revolved around the statement that the product of two rational numbers is rational. To prove it, "an imaginary friend" multiplied the rational $\frac{3}{4}$ and $\frac{4}{2}$ to obtain $\frac{12}{4}$, which he identified as a rational number. The Student-character did not disagree with the rationality of the product, but he did not accept that this substantiation can be endorsed as a proof. Specifically, the Student-character generated a rule-narrative, stating that "Just because you gave an example where the claim is true, doesn't mean it's always true". In other scripts, the Student-characters explicated the insufficiency of supporting examples by stressing that "a proof cannot be made of citing examples only". Some rule-narratives highlighted that even a large number of supporting examples would not make a proof (e.g., "It doesn't matter how many examples you give […] that would still not be satisfactory enough to say that the claim is true"). Guiding rule-narratives featured in 5 scripts and suggested considering "the full range" and "all possible values" that are relevant for the focal statement.

[1] The task refers to a famous tiling chessboard problem that was part of students' homework assignment.

Failures to produce an example are insufficient to prove a non-existence statement

Six scripts highlighted the insufficiency of failing attempts to exemplify a non-existence statement to be considered as a proof. Consider an excerpt:

Friend- character: When I was attempting the chessboard problem, I tried to manually place rectangles onto the box and fit them in. Since I couldn't solve it, it proves the problem is unsolvable.

Student-character: When you tried to place rectangles on the board, it only proves the specific arrangement doesn't work. But there are many different arrangements which can be attempted, and the result of one cannot be assumed to be the same as all the others.

In this exchange, we see the Student-character generating a rule-narrative, positing that the friend's unsuccess in covering the board does not account for all possible arrangements. Then, her attempts cannot be viewed as a valid proof that the board cannot be covered. In the first part of her submission, the same student wrote this explicitly, "[the specific arrangements] showed that they could not fit, but it did not prove the problem is unsolvable". Another Student-character argued that "no matter how many examples you provide, it's possible for a solution to exist". In this way, other Student-characters also stressed that specific attempts to generate examples for a non-existence statement does not extrapolate to other possibilities. Contradiction-based guiding rules-narratives appeared in three scripts in this category.

Deriving a true claim from a statement does not prove it

This type of rule emerged from seven scripts where "imaginary friends" manipulated the assigned statement until the obtainment of a true claim. Then, it was interpreted as a warrant that the initial statement has been proved. For instance, one "imaginary friend" drew on her deriving that "$0 = 0$" to argue that some initial (and never explicated statement) was true. But the Student-character insisted that "Proofs don't work like that […and] you definitely cannot say $0 = 0$ so it must be true". In what appears as an attempt to replicate this approach, the Student-character wrote "1=2" and multiplied both sides by zero to end up with "$0 = 0$". This move illustrated that a deviation from the focal rule opened the door to the endorsement of false statements. Similar rule-narratives featured in other scripts, arguing that "Assuming the truth of the claim and manipulating it to reach a true conclusion does not prove that it is true." Instead, four scripts contained guiding rules, suggesting one should "start with what you know is truth."

A proof must contain no invalid moves nor false claims

This type of rule grew from 12 scripts where "imaginary friends" conducted a mathematically invalid move to prove a statement. These moves included multiplying both parts of the equation by zero, manipulating with infinity and 0^{-1} like these were real numbers, and building on false assumptions that steered proving towards a problematic course.

To diversify the scope of illustrations, we refer to a script where this rule was enacted silently without being endorsed. There, the 'Imaginary friend' proposed to prove the irrationality of $2^{\frac{1}{\sqrt{2}}}$ by first showing that the exponent is irrational, and then proving that a rational number raised to an irrational power is irrational. The Student-character rejected "that method" by counter-exemplifying the second step. In this way, the scriptwriter implicitly suggested that building on a false assumption disqualifies the proof. Other students were more explicit regarding this rule. In one script, the Student-character posited that "Unfortunately, we can't divide by 0, which kills the whole argument". In another submission, a student shared "I made a false assumption that made the proof false”, which tacitly foregrounds the focal rule. A guiding rule-narrative featured in a single script, and it suggested “always start with something that you know is true!”

A proof should not include circularity

This type of rules emerged from six scripts where an “imaginary friend” drew on the assigned mathematical statement or some variation of it within the proof itself. Then, the Student-character called out this circularity, arguing that it disqualified the proof. For instance, in one script, a “friend” attempted to prove that the sum of irrational numbers is irrational. As part of it, they defined the irrational x and y, and sequentially relied on the irrationality of $x + y + (-x)$ “as claimed” in the original statement. In turn, the Student-character responded with a rule-narrative stating that “you cannot make assumptions based on the claim [since you] are proving the claim to be true”. Additional examples of rule-narratives that the students generated included “using what is required to be shown/proven in the proof (!), which is clearly invalid” and “Well you are trying to prove that the product of two rational numbers is also rational. So how can you say that $a \cdot m$ is rational, since this is the fact you are trying to prove [a and m were previously assumed to be rational]?” Only in one script, a Student-character proposed a guiding rule, calling their fictional peer to “stick to things that you 100% know are true: like our axioms”.

The rules of proof layout

This category emerged from 18 scripts. The rule-narratives that the students generated in these scripts were diverse, and we sub-divided them into four types: (i) the statement to be proved should be explicated, (ii) the numeric sets of the introduced variables should be specified, (iii) the proof moves need to be explained, and (iv) sub-narratives constituting a proof should be proved. Table 1 illustrates each rule with excepts from students’ scripts. Overall, these rules regard the layout of different proof components. Note that all these rules are guiding.

Table 1. Rules of proof layout

Sub-categories of the rules	Excerpts from students’ scripts
(i) The statement to be proved should be explicated	“You must have a claim at the top of your proof so that other readers and markers can understand what you are trying to do. Plus your conclusion may not make much sense without any claim to measure it against”
(ii) The numeric sets of the introduced variables should be specified	“I forgot that when saying something is rational, you say it $= \frac{m}{n}$ where $m, n \in \mathbb{Z}$ you say $n \neq 0$”
(iii) The proof steps need to be explained	“You need to write down your logic and reason step-by-step to backup your proof.”
(iv) Sub-components of a proof should be proved	“We cannot just assume that $\sqrt{8}$ is irrational. You must prove it first, otherwise the rest of the proof is invalid.”

We notice the categorical tone of the rule-narratives in this category, implying that the rules are unambiguous and can be enacted straightforwardly. This appears to be the case for (i) and (ii). Regarding (iii), in some scripts, Student-characters insisted on introducing “math terms” and “explanations” to symbolic substantiations. This afforded students to maintain that a proof that “doesn’t use words” is problematic, without discussing how “wordy” a proof should be.

The issue of ambiguity is also relevant to rule (iv): what mathematical claims can be used without any substantiation, and what claims need to be proved separately? Indeed, one script revolved around the rejection of “the sum of rational numbers is rational.” There, the Student-character criticized a counter-example where $1-\sqrt{2}$ was treated as an irrational number without explicit proof. Then, the same character suggested using $-\sqrt{2}$ instead, arguing that "it's still an irrational number and $\sqrt{2}+-\sqrt{2}=0$". What makes this script interesting is that in the course, neither the irrationality of $-\sqrt{2}$ nor the rationality of 0 were proven, but the student still endorsed these numbers as such.

Summary and Discussion

Building on the literature and the commognitive framework, we argued that direct engagement with RoP is of didactical value to students in transition to proof-based mathematics. To trigger this engagement, we asked students to script a fictional dialogue about a proof-related mistake that they experienced. We used the students' scripts to explore the metarules that newcomers to proof can find challenging.

The analysis resulted in six kinds of rules, none of which are foreign to the mathematics education literature. The innovation is in their epistemological status: while in most studies, the rules emerged from students' infelicitous proof attempts (e.g., Selden & Selden, 1987; Weber, 2002), in our case, the students were the ones to position these rules as something that a mathematical proof must avoid or abide by. Many students went beyond the rule formulation to illustrate, elaborate, and substantiate these rules. Accordingly, a key contribution of our study is in showing that newcomers can not only struggle with proof, but also communicate about it on a meta-level after a relatively short acquaintance period. That said, we acknowledge that our findings come from a special cohort that is hardly representative of a broader student population. Thus, we call for further anti-deficit research into how students learn RoP.

Sceptics may suggest that we should not "read too much" into students' endorsed rules as they could "simply" be drawing on what the course instructor demonstrated. Indeed, the overlap between the instructor's and students' rules cannot be ignored. However, even if the sceptics are correct and this is how students' rules came about, we argue that it is legitimate and even expected. Indeed, Sfard (2008) maintains that transitioning to a new discourse is impossible without a ritual phase, where learners imitate the discourse oldtimers. To do so, the students still needed to craft relevant proof attempts, generate their versions of rule-narratives, and apply them in a different context. Currently, we are developing an analytical framework to distinguish between cases of rigid imitation and agentive application of RoP. Overall, the identified overlap draws attention to the impact of proof instruction on students' communication about proof.

Each RoP can be captured in a guiding or in a restricting form. However, most of our participants adhered to the latter rather than the former. This result may be a side-effect of the assigned task: asking about a mistake may have nudged students to emphasize what is not supposed to happen in a proof. Alternatively, many guiding rules are based on deductive reasoning, communication about which requires a special vocabulary that the students may not yet possess. Accordingly, it could be interesting to explore whether students' capabilities to generate guiding and restricting rules develop in parallel.

We must be cautious when offering implications based on this exploratory study. Yet, we hope that its findings will encourage instructors to consider locating RoP at the center of their proof teaching. Furthermore, scriptwriting tasks may offer valuable information about students' emerging RoP: a carefully designed task can mirror the rules that students find challenging or ambigous, and can also point at the rules that currently escape students' attention.

Teaching Assistants' Use of Students' Work When Planning How to Address Misconceptions Inferred from It

Jungeun Park

Douglas Rizzolo
University of Delaware

Given the crucial role that the graduate teaching assistants (TAs) play in undergraduate mathematics education, this study investigated how TAs interpret students' work and plan to address students' work in teaching. We analyzed TAs' interpretations and plans according to approaches towards addressing students' misconceptions discussed in the literature: viewing them as simply incorrect regardless of students' thinking behind them, viewing them as a reflection of students' flawed ideas to be confronted and replaced, and viewing them as resources for future learning. Our analysis shows that while TAs' interpretations were often sufficiently rich to support using student misconceptions as resources for future learning, none of their plans used them in this way. Rather, most TAs' plans were aligned with the confront-and-replace approach. Our results suggest that professional development could be designed to help TAs convert their rich interpretations into plans for using student misconceptions as resources for future learning.

Keywords: Graduate Teaching Assistants, Use of Student Work in Teaching, Interpretation of Student Work

Introduction

There has been growing interest in the role that graduate teaching assistants (TAs) play in undergraduate mathematics education (Kung & Speer, 2009; Speer et al., 2005). TAs have direct impact on their current undergraduate students' learning of mathematics by teaching classes, holding office hours, and working in tutoring centers (Kim, 2014; Ellis, 2014) and also will have long-term impact on mathematics education at the university level as the next generation of instructors (Ellis, 2014; Kim, 2014; Musgrave & Carlson, 2017). Recently there have been calls for more research especially about TAs' teaching (American Association for the Advancement of Science (AAAS), 2019). The current study addresses an important aspect of TAs' teaching: how TAs interpret and address their students' work. How teachers interpret students' work and plan to address errors has been studied intensively in K-12 teacher education literature (see the review by Stahnke et al., 2016). However, in comparison, we as a field still have limited understanding of whether and how TAs' interpretations of students' work relate to their instructional decisions. To understand how TAs make instructional decisions based on students' work we conducted a study where TAs analyzed students' written work on non-routine problems and planned to address the issues that they identified. The following research question guided our study:

> How do TAs use students' written work in planning how to address with the students any misconceptions reflected in that work?

Our question focuses on misconceptions because we will consider TAs inference of student understanding from written work and whether/how such inferences are related to their plans to address errors. To address this question, we adopted three ways to view students' misconceptions that we identified in the existing literature on how to use student errors or misconceptions in teaching, which we will detail in the following section.

Theoretical Background

Views on Misconceptions

Three different views of students' misconceptions that we identified in the literature (Smith et al., 1993; Li & Schoenfeld, 2019; Rake & Ronau, 2018) guided our analysis of TAs' interpretation of students' work: viewing misconceptions as simply incorrect regardless of students' thinking behind them, viewing them as a reflection of students' flawed ideas or thinking that need to be replaced, and viewing them as resources for future learning. The differences between these views of misconceptions are significant because they suggest different instructional approaches for dealing with misconceptions, such as simply reteaching the content that students showed the error for, confronting the error and replacing it with the expert counterpart, and providing context to reorganize and refine students' existing knowledge. We analyzed TAs' plans to address students' misconceptions in terms of these three instructional approaches. As summarized in Smith et al. (1993), studies that viewed students' misconceptions as "flawed ideas that are strongly held, that interfere with learning, and that instruction must confront and replace" (p. 115) represented a "fundamental advance from previous approaches that essentially divided student responses into two categories, correct and incorrect" by focusing "attention on what students actually say and do in a wide variety of mathematical and scientific domains" (p. 117). However, they also pointed out that "confront and replace" is problematic in practice because "misconceptions continue to appear even after the correct approach has been taught" (pp. 120-121). Smith et al. (1993) provided a constructivist view of "learning that interprets students' prior conceptions as resources for cognitive growth within a complex system of knowledge" (pp. 115-116) and suggested that refinement of students' existing knowledge for learning was more effective than replacement. Specifically, they argued that "instruction should help students reflect on their present commitments, find new productive contexts for existing knowledge, and refine parts of their knowledge for specific scientific and mathematical purposes" (p. 150). This reconceived view of misconceptions has been advocated for in recent approaches emphasizing sense-making in mathematics and understanding (Li & Schoenfeld, 2019) and in empirical studies investigating student reasoning behind incorrect responses (e.g., Makonye, 2012; Rake & Ronau, 2019). It should be noted that, from this view, errors or error patterns are different from misconceptions. Smith et al. (1993) used misconception as "a student conception that produces a systematic pattern of errors" and differentiated it from "simply designat[ing] a pattern of errors" (p. 119).

Given that our TAs sometimes just noticed errors or error patterns from student work samples (and/or connected it to error patterns that they noticed from their previous teaching experience) and proceeded with their plan to address the errors without providing interpretations, in our current study, we analyzed TAs' interpretation of students' errors or misconceptions in terms of the three views described above, focusing on whether it was viewed as a flawed idea to be replaced or a reflection of their knowledge to be used as a resource of learning, and whether and how it was reflected in TAs' planning of how to address the students' errors or misconceptions, i.e., reteaching, confronting-and-replacing, or reorganizing and refining.

Perceiving, interpreting, and responding to students' thinking

Addressing students' misconceptions starts with perceiving and understanding those misconceptions. Given that TAs spend a lot of time trying to make sense of students' written work while they are grading or during small group work in class, our study design adopted a setting where TAs would have opportunities to read written students' work samples, interpret what is written, and devise plans for their next instructional moves. Several existing studies have similarly adopted this setting; they involved student work samples, most of which included errors, that were developed, based on, or adopted from, existing research (e.g., Son, 2013; Cooper, 2010). As noted in the recent review by Stahnke et al. (2016), most such studies focus on content at the elementary level, such as proportional reasoning (Hines & McMahon, 2005; Son, 2013), geometry (Son & Sinclair, 2010), fractions (Jakobsen et al., 2013), algebraic or numeric computations (Cooper, 2010; Magiera et al., 2013) and have involved preservice teachers (PSTs). Stahnke et al. (2016) made common observations based on the results of these studies: (a) "pre-service teachers had difficulties in perceiving and interpreting" among other things "common misconceptions and student errors", and (b) teachers' own "difficulties with mathematics tasks influenced their perception and interpretation" (p. 14). They also showed that (c) teachers' proposed approaches to addressing students' misconceptions or errors were either '"reteaching' (Cooper, 2009) or showing students' how to do it correctly (Son, 2013)" (p. 14). Moreover, a large number of PSTs did not use student work at all in their response to the students, other than to say that the student's method is wrong or they briefly mentioned it as "a stepping-stone" to correct the student error (33 and 13 out of 75, respectively, Son, 2013, p. 62). Although these studies did not explicitly adopt the views and approaches towards misconceptions we discussed above, the approaches to student misconceptions that PSTs adopted that are in the literature are aligned with "reteaching" or "confront-and-replace" approaches to misconceptions, rather than with using student misconceptions as a resource for reorganizing and refining students' existing knowledge, and are connected to PSTs' difficulties with interpreting students' errors in terms of the students' thinking reflected in their written work.

Research Methods

Research Setting, Participants, and PD

We conducted our study in a single-variable calculus course, Calculus I for STEM majors, at a mid-sized public U.S. university. At the institution, Calculus I is offered as large coordinated lectures with 100-150 students taught by faculty instructors, and with discussion sections for 25-30 students taught by TAs. In the discussion sections, TAs mainly solved textbook problems based on questions from students. At the time of the study, 16 TAs at the institution taught discussion sections. We invited all 16 TAs to participate in our study. From these, five TAs volunteered. Those TAs were considered overall "strong" PhD students in the department, four were in their 3rd-4th year in the program with years of experience teaching calculus discussion sections and one was in the second semester of their first year in the program and also with experience teaching discussion sections. The TAs also participated in a bigger study that included classroom observation, collection of students' work, and interviews, as well as professional development (PD). However, we will only focus on the PD in this proposal. The authors (one mathematics educator, and one mathematician who has also conducted mathematics education research) conducted four 75-minute PD sessions that were one or two-weeks apart. Each session centered around one worksheet (with non-routine problems) and started with one of the TAs presenting their solutions to the problems as a prompt for discussion about how to make the solution better mathematically, or friendlier to students, or about their own difficulties when they tried to solve the problems. Then, the PD analyzed 2-4 student written solutions to the worksheet problems that we collected from the previous years. The student work samples we chose were examples of common misconceptions based on what is reported in the existing literature on students' thinking about calculus, and included evidence of student's reasoning (based on the researchers' determinations). Based on their analysis, TAs wrote responses to the following three prompts: "Please describe in detail what you think each student did in response to this problem," "Please explain what you learned about these students' understandings", and "Pretend that you are the TA of the student. What questions/problems might you pose next? Why?" There were also additional verbal prompts from the facilitators, such as "where may they be coming from?" and "why do you think the student answered that way?". Then, they discussed their noticing, interpreting, and planning with other TAs. These prompts were adopted from the noticing literature (Jacobs et al., 2010) to collect what TAs' were attending to, how they were interpreting student work, and their plan to address what they noticed and interpreted. In this proposal, we will focus on the observations we made about the TAs interpretations and plans.

Analysis

The data we used was the TAs' written responses to the three prompts and their discussions during the PD. We first transcribed the TAs discussions during the PD and typed out their written responses. Then, we classified chunks of written responses or verbal participation in the PD (divided by who spoke and the misconceptions or errors that were addressed) into noticing, interpreting, and planning. Then, the two authors categorized the chunks into several codes based on open coding (Strauss & Corbin, 1998). Once we came up with all the codes that were descriptive of the data, we again coded about 20% of the chunks, chosen randomly from each TA and from each PD session, to check inter-coder reliability. Our results matched except for a few chunks for which we discussed and revised the description of the codes until we reached agreement. Note that we analyzed all of the interpretations and plans proposed during PD, not only the ones that TAs eventually settled on by the end of the PD sessions.

Results

TAs' interpretation of student work

We analyzed TAs' interpretations in terms of the three views towards misconception discussed earlier: incorrect regardless of student reasoning behind it, reflection of student's flawed ideas or thinking that needs to be replaced with the right one, or reflection of student's existing knowledge that can be refined and reorganized to accommodate new concepts/context to learn. In our analysis, we first identified types of TAs' interpretations that indicated they considered students' work as a reflection of students' mathematical thinking. Our analysis indicated that in most chunks of interpreting student work (83 among 107), TAs interpretations indicate that they considered the students' work as a reflection of the students' mathematical thinking. Among these 83 chunks, 35 interpretations regarded a student's thinking about a concept, relation, theorem, or procedure as being different from what is mathematically accepted, 35 interpretations regarded a student's application of knowledge as in an inappropriate context, and 13 regarded a student's thinking as taking an approach deemed correct but with mistakes or as not carrying the approach out to its conclusion. The remaining 24 chunks, where TAs interpretations did not indicate that they considered the students' work as a reflection of their mathematical thinking, included interpretations such as that the student is just guessing, that they are computing without thinking, and that students' work is unclear, with no further interpretation.

The 35 interpretations regarding a student's application of knowledge in an inappropriate context are particularly important for promoting instruction that helps "students reflect on their present commitments, find new productive contexts for existing knowledge, and refine parts of their knowledge for specific scientific and mathematical purposes" (Smith et. al. 1993, p. 150) because of the straightforward way such interpretations can be translated into plans to help students understand the appropriate context for their approaches and how the present context is different. For example, three TAs interpreted the following student work (Figure 1) as an example of applying limit laws in an inappropriate context.

1. Find $f^{'}(0)$ if $f(x) = \{g(x)sin\left(\frac{1}{x}\right), \quad if\ x \neq 0\ 0, \qquad if\ x = 0$, and $g(0) = g^{'}(0) = 0.$

$$\lim_{x \to 0} f(x) = 0 \times \lim_{x \to 0} \sin\left(\frac{1}{x}\right) = 0 = f(0)$$

Figure 1. Part of Student Work Sample that TAs Interpreted as Unwarranted Generalization

One TA said, "the student tried to distribute the limit symbol over products while the limit does not exist for one of the factors. This also reflects reliance on memory rather than understanding," and another TA elaborated further by saying "they don't know limit when h goes to 0, that $sin(\frac{1}{h})$ does not exist. So, they assume that it exists and 0 times something that is 0." Here, the TA's interpretations indicates that the student's application of the limit law in this context was incorrect, but also notes contexts where their method would have worked (i.e., when the limit of each factors exists). Translating this interpretation into an instructional plan that uses the student's misconception as a resource for new learning to promote knowledge refinement could happen if the TA planned to discuss types of limit problems where the student method of distributing the limit worked, and specifying the difference between those problems and the current problem as a rationale for why the method is not applicable any more. This way, the student's existing knowledge will be refined with boundaries of where that particular method is "correct" and new ways of approaching a similar-looking but different context can be learned in comparison to the old way. In next section, we will discuss whether and how TAs' plans were in line with such a view of considering students' misconception as resource of new learning.

TAs' plans to address students' work

To understand what TAs planned to do to address student misconceptions, we first coded each TA's plan, and categorized them based on the conceptualization of how to use student work: reteaching without using it, confront the misconception that the error is showing and replace it with the correct counterpart, and using it as resource for learning. As we discussed, the most productive use of students' error in this regard would be using students' misconceptions as resource for student learning. Our analysis shows that most TAs' plans involved confronting students with their errors while none of the TAs plans used students' misconceptions as a resource for student learning. Three main instructional approaches were (a) giving students opportunities to realize their error (52 plans), (b) pointing out the error and have them fix it or teach them how to fix it without giving such opportunities (12 plans), and (c) solving the problem without addressing students' errors and starting with a simpler problem, giving hints, or scaffolding them with small steps (7 plans). Plans included in (b) and (c) are clearly aligned with "confront-and-replace" and "reteach" approaches. Plans included in (a) could potentially align with using students' misconceptions as resources for learning and knowledge refinement, but further investigation of these plans showed that they did not.

The plans included in (a) could be categorized into several further subcategories, the most prominent of which were (i) asking students to explain the part of their answer that includes an error (11 plans), (ii) providing students opportunities to check if their answer has the desired properties, hypotheses that their answer is assuming when students applied a theorem, or consistency within their answer (16 plans), and (iii) giving students counter examples to their methods/responses or providing examples or tasks for students to realize the error (13 plans). Seven plans involved a combination of these approaches, and the remaining plans combined these with some additional guidance on a next step assuming that the error was fixed by students.

A common feature of most of these plans is that they stop with the student realizing their error. Only a small number of plans included next steps after students realized their errors and most of these next steps were about restarting the problem by scaffolding students with small steps or having the student try a simpler problem than the originally given problems. Therefore, these plans confront a student with their error and either leave the student to try again or give steps to replace the student's incorrect method with a correct one, but do not use the student's misconception as a resource for refining their mathematical thinking. An example of this can be seen from the discussion in PD of the student work sample in Figure 2.

Suppose for some function $h(x)$, we know that $h(0) = 2$ and that $h'(x) = \left(1 + x^3\right)^{\frac{1}{3}}$. Draw the graph of $h(x)$.

$h'(x) = (1+x^3)^{1/3}$ $\quad f(x) = (x)^{1/3}$ $\quad g(x) = 1 + x^3$

$\quad\quad\quad\quad \downarrow \quad\quad\quad\quad\quad \downarrow$

$\quad\quad\quad \frac{3}{4}(x)^{4/3} \quad\quad x + \frac{x^4}{4}$

$$h(x) = \frac{3}{4}(1+x^3)^{4/3} \cdot x + \frac{x^4}{4}$$

$$\boxed{h(x) = \frac{3x(1+x^3)^{4/3} + x^4}{4}}$$

Figure 2. Student work sample TAs plan to address by asking the student to check if their answer has the desired property.

The following excerpt shows one TA's response to one of the researchers' questions about next steps, after the TA presented their plan of having the student differentiate their answer to show that it would not result in the derivative originally included in the problem (Figure 2):

Researcher 1: Let's say you know they…took the derivative and they got the wrong answer and they got confused, what would you do?

TA E: Both integration and differentiation to them is just a bunch of following. They don't understand really why the nuts and bolts of why this exists. So I would just be like if you have learned this, you have learned it the wrong way, this formula does not exist and one way to clearly see that is the derivative is not the derivative that we want it to be. But if you want to know why it's actually wrong then take an analysis course or something.

In this excerpt, the TA re-emphasized why the contradiction should tell them that what they did was wrong, and this excerpt exemplifies that TAs often do not have explicit plans to use students' misconceptions as a resource for learning. In fact, all plans to the problem in Figure 2 involved starting over by asking what they know about the original function given the derivative without attempting to "integrate". An approach that uses the student's misconception as a resource for learning could use some of the TAs' interpretations of the work in Figure 2 as an "unwarranted" generalization of a differentiation rule (i.e., chain rule) to integration. The plan could focus on how to properly implement the student's idea of "going backwards" with a differentiation rule (in this case, integration by u-substitution) and discuss the differences between contexts where that works and the given problem. Then, one could start navigating the different methods to accommodate the new, similar looking, but different context. However, we did not see any plans that take this type of approach for any student work samples in our data.

Discussion and Conclusion

Our analysis of TAs' plans to address students' misconceptions showed that their plans mainly focus on addressing what student did wrong in the solution by providing students opportunities to realize their errors and potentially fix them, or by directly teaching how to fix the errors. These results are more positive than just "reteaching" the concepts or procedures without addressing students' errors, which was one of the main approaches PSTs adopted in some of the existing studies in K-12 literature (Cooper, 2010; Son, 2013). However, TAs' plans were mainly aligned with the "confront-and-replace" view of misconceptions, which has been criticized in the existing literature. Moreover, in most of their plans, TAs did not include any plans to provide alternatives after giving students opportunities to realize their error, other than just starting over the problem in a mathematically correct way. With these approaches, students will have opportunities to learn that what they did is wrong, but are not helped to understand what problems in their thinking led to such a wrong answer. Thus, this way of addressing student errors is not supporting learning as expanding students' thinking (Smith et al., 1993).

In contrast to their planning, a significant number of TAs' interpretations of students' misconceptions were aligned with a desirable view of misconceptions based on the literature, which is as a resource of new learning. In these interpretations, TAs identified the methods that students may have adopted, and the contexts where their method might have worked in the past, although it did not work for the problems that were given to them at the time. Although we did not see any evidence from our data that this way of interpreting misconceptions was reflected in TAs' planning of addressing students' errors, we found that there is potential to expand this view to their planning. Since our TAs have ability to identify where the students' methods would have worked in the past, they could share that with their students to acknowledge that their attempt to solve the problem had a rationale that was supported by their learning in the past, and then help them realize the differences between the contexts where their methods worked and the current problem context. This way, students' previous knowledge about the concept or procedure would be refined and reorganized in their learning of new way of addressing the problem. We anticipate that this way of planning that is aligned with what is recommended by mathematics education literature on how to address student misconceptions as resource of learning (Smith et al., 1993; Li & Schoenfeld, 2019; Rake & Ronau, 2018) could be promoted in PD for TAs. The TAs in our study were capable of and showed a tendency to attribute potential reasons for students' "wrong" choice of methods to the problem to their past "successful" experiences of using them. PD could promote this way of interpreting when applicable and provide opportunities to think about how to incorporate such interpretations in their planning to address students' misconceptions. This type of PD has the benefit of helping TAs learn about an approach to teaching that is broadly applicable and could be used in a variety of courses regardless of their content and focus.

A Design-Based Research Approach to Addressing Epistemological Obstacles in Introductory Proofs Courses

Vladislav Kokushkin
Virginia Tech

Matthew Park
Virginia Tech

Rachel Arnold
Virginia Tech

Anderson Norton
Virginia Tech

As has been well-documented, the epistemological obstacles associated with teaching and learning mathematical proofs persist despite research-based instruction. We describe the ongoing design process of our NSF-funded project aimed at understanding and addressing those obstacles in introductory proofs courses, using proof by mathematical induction as an anchor. Our process is framed by two cycles of designed-based research. The first cycle corresponds to designing and implementing research-based instruction on mathematical induction, whereas the second cycle broadens the scope of our research to other introductory proofs topics. This paper reports on the outcomes of the first cycle, the transition between the first and second cycles, and the project's end products.

Keywords: designed-based research, epistemological obstacles, proofs, proof by mathematical induction, quantifiers.

There is a wide recognition among researchers and practitioners that proofs and proving are of vital importance in students' learning of mathematics at all levels of education (NCTM, 2000). At the same time, a growing body of research has identified numerous challenges associated with teaching and learning proofs (e.g., Brousseau, 1997; Brown, 2008; Dawkins & Weber, 2017; Hanna & de Villiers, 2012; Harel & Sowder, 2007; Shipman, 2016; Sierpińska, 1987; Stylianides, 2014, 2016). Sierpińska (1987) and Brousseau (1997) have conceptualized the necessary challenges in students' mathematical development in terms of epistemological obstacles (EOs). EOs in teaching and learning mathematical proofs are the primary focus of this project.

Here, we frame EOs as cognitive challenges that persist even in response to research-based instruction. Thus, EOs can be experienced both by students and teachers during instructional interactions. When instructors experience EOs, there is a tension between the desire to circumvent them and the need to provide students with opportunities to develop logical structures that are fundamental for proving. However, as it has been pointed out by Brousseau (2002), addressing an obstacle head on is essential for overcoming it because "it will resist being rejected and, as it must, it will try to adapt itself locally, to modify itself at the least cost, to optimize itself in a reduced field, following a well-known process of accommodation" (p. 85). As such, because EOs are persistent, students must internalize an intellectual need for the underlying concepts to motivate, persevere, and successfully overcome the obstacles.

Therefore, the overarching goals of our project are to 1) identify the EOs associated with teaching and learning mathematical proofs and 2) design instructional tools for evoking and addressing these obstacles. The research questions guiding our study are as follows:

1. What are the EOs associated with teaching and learning mathematical proofs?
2. What instructional tools are suitable for evoking and addressing these EOs?

In answering these questions, we employ a cyclic design-based research approach (Anderson & Shattuck, 2012; Bakker & Van Eerde, 2015; Cobb et al., 2003; Gravemeijer & Cobb, 2006). The first cycle was conducted in Spring 2018, when the third and fourth authors implemented research-based instruction on proof by mathematical induction (PMI) in their classrooms. The results are presented in Norton et al. (2022). We use PMI as an anchor for broadening the scope of our research. During the second cycle, the same teachers will use the designed instructional materials in their respective Introduction to Proofs classes – one in Fall 2022 and one in Spring 2023. This paper reports on the outcomes of the first cycle, the transition between the first and second cycles, and the project's end products (see Figure 1).

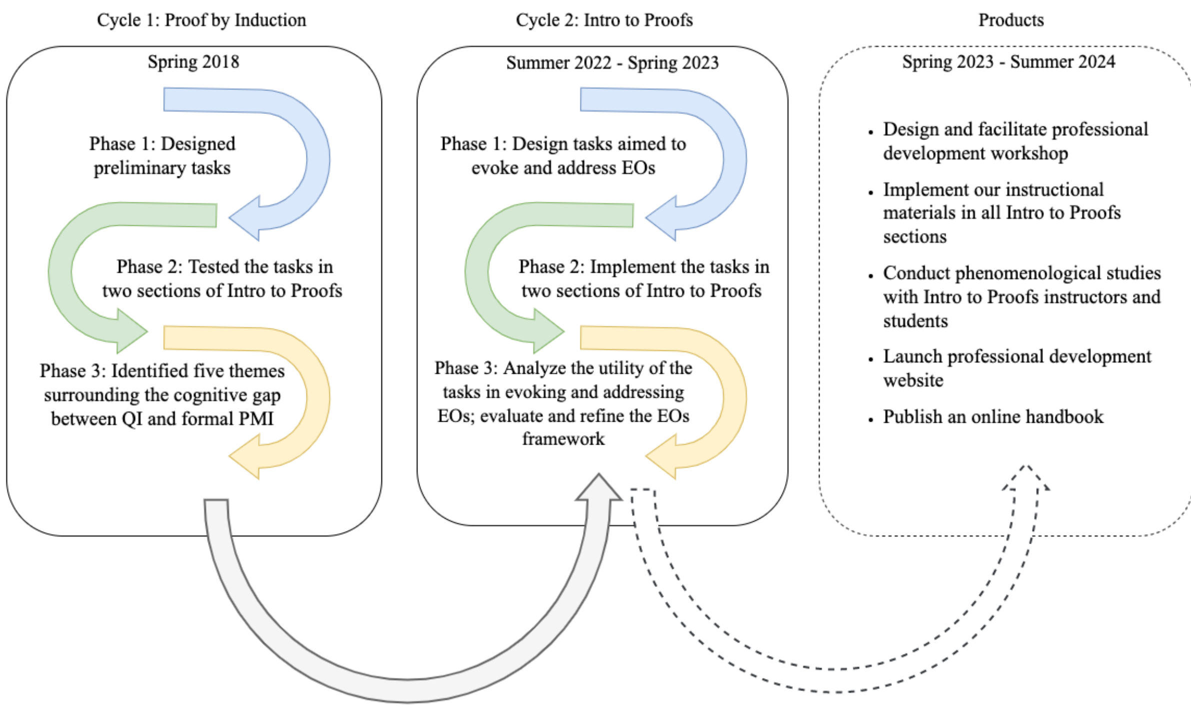

Figure 1: Two cycles and the end products of the project.

Literature Review and Theoretical Framework

Prior research has documented EOs on a variety of concepts studied in proofs-based courses. The following challenges have been associated with students' mastery of PMI: understanding the role of the base case (Baker, 1996; Ernst, 1984; Ron & Dreyfus, 2004; Stylianides et al., 2007), treating logical implication as an invariant relationship (Dubinsky, 1986, 1991; Norton & Arnold, 2017, 2019), discerning between the truth of the conjecture and the inductive hypothesis (Movshovirz-Hadar, 1993), attending to (hidden) quantifiers (Shipman, 2016) and the proper use of related language (Ernst, 1984; Movshovitz-Hadar, 1993; Stylianides et al., 2007), and having domain-specific knowledge particular to the conjecture (Dubinsky, 1991). Many of these challenges, especially quantification, extend well beyond PMI (Dawkins & Roh, 2020; Lew & Mejía-Ramos, 2019).

Instructional Approaches for Addressing EOs

Awareness of EOs should inform the design of instructional approaches to introductory proofs topics. Traditional instructional approaches may be insufficient in addressing these obstacles, necessitating the development of alternative instructional techniques that support student learning.

In the case of PMI, traditional instruction introduces the technique as a three-step procedure: (1) prove the base case, (2) assume the inductive hypothesis, and (3) prove the inductive step. However, this procedure can inadvertently cause learners to bypass the logic of PMI, ultimately circumventing experiencing necessary challenges (Harel, 2002).

An alternative approach that combines procedure with logical structure was first suggested by Avital and Libeskind (1978) and then further elaborated by Harel (2002) as "quasi-induction." A student who uses this method shows that $P(1)$ is true and that $P(1) \rightarrow P(2)$, $P(2) \rightarrow P(3)$, and so on. This leads to the plausible conclusion that eventually $P(n-1) \rightarrow P(n)$. Although formal PMI may be considered to be a natural generalization of quasi-induction, there is a significant cognitive gap between the two (Harel, 2002). Norton et al. (2022) implemented research-based instruction to address and better understand this gap.

Design-Based Research

Design-based research (DBR) is an interventionist approach aimed at weaving together educational practice and theory (Bakker & Van Eerde, 2015). DBR is typically used to develop educational materials and accompanying theoretical insights into how these materials can be used in practice.

Gravemeijer and Cobb (2006) framed DBR in terms of three interrelated phases: 1) preparing for the experiment, 2) experimenting in the classroom, and 3) conducting retrospective analysis. These phases occur in repeated cycles in which the last phase of the previous cycle informs the first phase of the following cycle, and so on. During the first phase, researchers scrutinize the problem of interest, synthesize the available research literature, curricula, and textbooks, and articulate the learning objectives and theoretical intents of the experiment. In the second phase, the experiment is conducted using the designed instructional materials as a guideline for teaching and observing. Data collection and preliminary data analysis also takes place during this phase. Once the experiment is complete and the data has been collected, the retrospective analysis begins in phase three. The comprehensive data sets must be analyzed systematically while simultaneously documenting the grounds for the subsequent cycle. As such, the retrospective analysis should examine the utility of the designed instructional materials and spark ideas for how they might be refined and complemented.

Cycle 1 (Spring 2018)

As aforementioned, prior research indicates a number of EOs experienced by introductory proofs students and suggests fruitful instructional approaches for supporting students in overcoming these obstacles. In particular, the method of quasi-induction (QI) has been validated as accessible to students and beneficial for their mastery of PMI (Cusi & Malara, 2008; Harel, 2002). However, a cognitive gap remains in transitioning between QI and formal PMI. Therefore, Cycle 1 centered around understanding the factors contributing to this gap and designing instructional materials that help students address it.

Preparing for the Experiment

Informed by prior research, we designed a set of scenarios about an unspecified proposition $P(n)$ (Table 1). For each scenario, students are tasked to decide whether the given information is sufficient to prove that $P(n)$ is true for all positive integers n. The tasks are independent of mathematical content. They are built from students' conceptualizations of logical implication, and they aim to bridge the gap between QI and PMI. We first validated these tasks in Arnold and Norton (2017) and Norton and Arnold (2017) via clinical interviews with students from an introductory proofs course, and we further refined them in a follow-up study (Norton & Arnold, 2019).

Table 1. Cycle 1 tasks.

Suppose $P(n)$ is a statement about a positive integer n, and we want to prove the claim that $P(n)$ is true for all positive integers n. For each scenario, decide whether the given information is enough to prove $P(n)$ for all positive integers n.	
A	$P(1)$ is true; for all integers $k \geq 1, P(k)$ is true.
B	$P(1)$ is true; there is an integer $k \geq 1$ such that $P(k)$ is true.
C	$P(1)$ is true; there is an integer $k \geq 1$ such that $P(k) \rightarrow P(k+1)$.
D	$P(1)$ is true; for all integers $k \geq 1$, $P(k) \rightarrow P(k+1)$.
E	For all integers $k \geq 1$, $P(k) \rightarrow P(k+1)$.
F	For all integers $k \geq 1$, $P(k)$ and $P(k+1)$ are true.
G	$P(1)$ is true; for all integers $k \geq 2$, $P(k) \rightarrow P(k+1)$.

Conducting the Experiment

We implemented research-based instruction in two sections of Introduction to Proofs at a large public university in the southeastern United States. The third author used the tasks within an informal pre-assessment. The fourth author used them to generate class discussion. Following these approaches, both instructors sought to promote the inductive implication as an invariant relationship between the inductive assumption and the inductive step (rather than treating the inductive assumption and step as separate components), and to explicitly address the issues of quantification. All classes associated with instruction on PMI were recorded. The third author had three class meetings, 50 minutes each. The fourth author held three meetings, 75 minutes each. Recordings captured the instructors' activity, the notes and PowerPoint slides displayed on the overhead projector, and students' interactions.

Retrospective Analysis

We performed two rounds of retrospective analysis of classroom data. During the first round, we coded the data using a set of codes informed by existing literature on students' struggles with PMI. They included base case (B), quantifiers (Q), inductive implication (I), domain knowledge (D), and conflation (C) between the inductive hypothesis, implication, or proposition. As new themes emerged for which we did not have an existing code, a new code was created. In this case, we reviewed and re-coded the prior data, using a constant comparative method (Glaser, 1965). This iterative process repeated until the codebook stabilized. The new codes included reducing the problem to computational setting (R_c), “why k, not n?” (K), effects of formal instruction (F), and the cognitive gap (G).[1]

We conducted the second round of analysis with an emphasis on the cognitive gap. Specifically, we reanalyzed the data to document how each code was related to the gap. As a byproduct of this analysis, two more codes emerged – intellectual need (N), and the use of language for communicating the intended logic (L).

The analysis revealed five themes describing the relationships between the cognitive gap and other challenges, depicted in Figure 2. Students must develop an intellectual need to generalize the logic involved in building the quasi-inductive chain of inferences (Theme 1). However, even when students have an intellectual need for formal PMI, issues with quantification arise (Theme 2). These challenges include careful quantification of the inductive implication and a shift in the language for quantifying the inductive assumption when proving the implication. As a consequence, students require new language to support the distinctions they make in quantifying the inductive assumption, the inductive implication, and the proposition they must prove (Theme 3). Finally, we found that a shift in notation from n to k when denoting the inductive implication seemed unnecessary to students. Students did not demonstrate the intellectual need for it in either class (Theme 5), nor for the use of proper language for quantifying n and k (Theme 4).

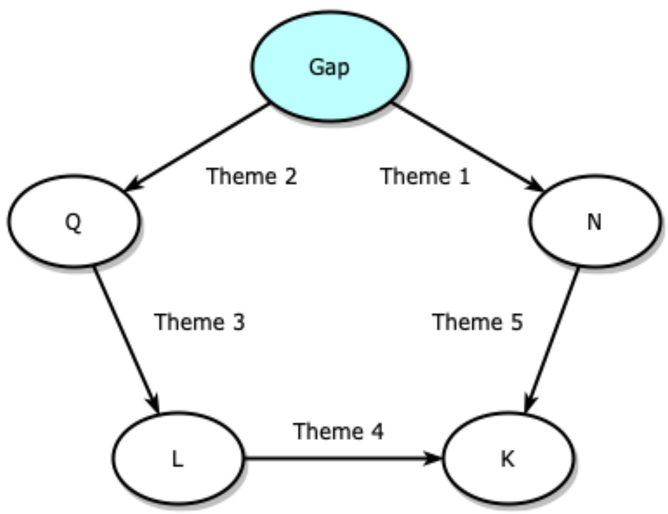

Figure 2. Five themes emerged from Cycle 1.

Cycle 2 (Summer 2022-Spring 2023)

Cycle 2 is ongoing. Its purpose is to broaden the scope of our study to the fundamental topics traditionally studied in introductory proofs courses, such as mathematical statements, logical implications and their transformations, quantifiers, and functions.

Preparing for the Experiment

Cycle 2 began with an advisory board meeting in June 2022. The advisory board members included three widely recognized experts in research on PMI, quantifiers, and logical reasoning. We relied on their expertise, on the previous research findings, and on the results from Cycle 1,

[1] A detailed description of the codes can be found in Norton et al. (2022).

to 1) identify the EOs associated with teaching and learning proofs, and 2) design instructional tasks aimed at evoking, addressing, and assessing the discussed EOs.

In particular, as one of the outcomes of Cycle 1, we found that students' apparent treatment of inductive implication is closely linked with a language issue inherent in quantifying an implication. On the one hand, the implication $P(k) \rightarrow P(k+1)$ must be proved *for all* values of k. On the other hand, the proof of the implication requires one to assume $P(k)$ is true *for some fixed but arbitrary* value of k. Ignoring the former quantification leads to an incomplete argument. Ignoring the latter quantification leads to circular reasoning. Similar issues with language in quantifying mathematical objects have been documented in prior research (Dawkins & Roh, 2020; Lew & Mejía-Ramos, 2019).

To evoke and address challenges related to teaching and learning quantifiers, we designed six multiply quantified statements about a linear equation $mx + b = 0$ (see Table 2). The statements exhaust all combinations of ordering explicit quantifiers and their attached variables that make sense geometrically. Statement 2 is the only false statement. The variety of statements will allow students to compare and contrast the quantifiers in a different order, and, as a result, understand the role of quantifiers in mathematical statements.

Table 2. A sample Cycle 2 task.

Below are six statements about real numbers *m, x,* and *b.*
TASK 1: give a geometric interpretation to each of these statements. One of them is not true. Which one? Explain why this statement is false.
TASK 2: Match the true statements with the following proofs:

Statement	Proof
The exist real numbers *m,b,* and *x,* such that $mx + b = 0$.	Let $b = 0, m = 1$, and $x = 0$. Therefore, $mx + b = 1 \cdot 0 + 0$.
For all real numbers *m,b,* and *x,* $mx + b = 0$.	N/A
There exists a real number *m,* such that for all real numbers *b,* there exists a real number *x,* such that $mx + b = 0$.	Let $m = 1$. Then, for any real number *b,* take $x = -b$. Therefore, $mx + b = 1 \cdot (-b) + b = -b + b = 0$.
There exists a real number *m,* such that for all real numbers x, there exists a real number *b,* such that $mx + b = 0$.	Let $m = 1$. Then, for any real number *x,* take $b = -x$. Therefore, $mx + b = 1 \cdot (-x) + x = -x + x = 0$.
There exists a real number *b,* and there exists a real number *m,* such that for all real numbers *x,* $mx + b = 0$.	Fix an arbitrary *x.* Let $b = 0$. Observe that, when $m = 0$, $mx + b = 0 \cdot (-x) + 0 = 0 + 0 = 0$.
There exists a real number *b,* and there exists a real number *x,* such that for all real numbers *m,* $mx + b = 0$.	Let $b = 0$. Observe that, when $x = 0$, $mx + b = m \cdot 0 + 0 = 0 + 0 = 0$ for any real number *m.*

Conducting the Experiment

As in Cycle 1, the third and the fourth authors will implement research-based instruction in their respective Introduction to Proofs classes: one in Fall 2022 and one in Spring 2023. The classroom interactions pertaining to the aforementioned topics will be video and audio recorded.

Retrospective Analysis

We will qualitatively analyze the complex student-teacher and student-student interactions. The analysis will be reminiscent of the procedures we used in Cycle 1, involving the elements of constant comparative method (Glaser, 1965). To present the data in a comprehensive and feasible fashion, we will create a graph of connected codes, in which the nodes and edges will respectively represent the key codes that pertain to answering the research questions and the relationships between these codes, respectively.

Implications and Products

We will use the results of the first two cycles of our project to deepen our understanding of the EOs and disseminate research findings. Specifically, throughout the research-based instruction, we will collect data for a phenomenographic study to gain more nuanced insights into how students experience EOs during instructional interactions. In parallel with Cycle 2 data analysis, we will recruit instructors teaching Introduction to Proofs courses in Fall 2023 who are willing to participate in a week-long workshop preceding the fall semester and implement the proposed instruction. The workshop will be organized by the authors and will include selected videos of instructional interactions from Cycles 1 and 2. We will also conduct a phenomenographic study to see how the instructors experience the proposed EOs.

On the basis of the data collected in Cycles 1 and 2, we will compile an online handbook documenting the instructional interactions surrounding the EOs. The handbook will include our modified instructional tasks designed for evoking these interactions, as well as video clips of classroom interactions from the Introduction to Proofs classes taught by the third and fourth authors. The handbook is intended to increase instructors' pedagogical content knowledge on foundational topics of the course. In addition to serving as an instructional guide for bridging research and practice, the handbook will also provide instructional videos that can be shared directly with students.

To bolster the broader impacts of our project, we will create a "Train-the-Trainers" style professional development website. This website will transform and extend the training activities of our workshop (organized in the summer of 2023) into professional development activities that can be hosted and facilitated by any university wishing to implement the instructional tools resulting from this project. Each activity will be accompanied by a facilitator's guide for empowering and equipping members of other universities to conduct their own in-house training workshop for the instructors of their introductory proofs courses.

Exploring Geometric Reasoning with Function Composition

Yuxi Chen	Nicholas H. Wasserman	Teo Paoletti
Columbia University	Columbia University	University of Delaware

Students learn about function composition, $(g \circ f)(x)$, in secondary school. From two given equations, one might identify the composite function algebraically via substitution, $g(f(x))$. But what about when functions are given as graphs? This study aims to explore how students were able to reason geometrically about composing functions. We identify common types of resultant graphs participants generated in trying to sketch the composition of various graphically-depicted functions, and the common types of reasoning we infer those participants engaged in while doing so. The results generate both questions, and hypotheses, about how best to support students' development of deep – and diverse – meanings for composing functions.

Keywords: function composition; graphs; geometric reasoning

Students are exposed to function composition in secondary school (cf., CCSSM, 2010). Primarily, they are taught that $(g \circ f)(x) = g(f(x))$ – meaning, for two functions defined by equations, one can procedurally determine the composite function via algebraic substitution. Additionally, in the context of inverse functions, secondary school students are taught that $(f^{-1} \circ f)(x) = (f \circ f^{-1})(x) = x$. Yet, such algebraic approaches are limited in their ability to develop sufficiently deep mathematical understandings of function composition. In this study, we try to explore the ways students' reason geometrically about the composition of two functions.

Background and Framework

In this study, we seek to answer the following research question: *In what ways do students graphically respond to function composition tasks?*

Function and Function Composition in Extant Literature

Much literature in mathematics education has been devoted to the function concept. This has included characterizing its essential abstract features (e.g., Freudenthal, 1983) and debating them (Mirin et al., 2021), considering its place in the school curriculum (e.g., McCallum, 2019; Paoletti & Moore, 2018), the notation we use for it (e.g., Paoletti et al., 2018; Thompson & Milner, 2019; Zazkis & Kontorovich, 2016), and studying how students and teachers understand and conceptualize it – including inverse functions (e.g., Breidenbach et al., 1992; Even, 1990; 1992). Scholars have also explored students' conceptions about real-valued functions (from $\mathbb{R}$ to $\mathbb{R}$) through the notion of covariational reasoning (e.g., Paoletti & Moore, 2017). In this context, a deep understanding of function demands students understand how quantities co-vary together – meaning, how changes in one quantity correspond to changes in the other quantity. However, studies have shown that students have difficulties in understanding the relationship between co-varying quantities and their graphs (e.g., Carlson et al., 2002; Schoenfeld, 1985). It can be concluded that there is a rich literature base for functions – including inverse functions.

Yet when it comes to function composition, very little exists. Much of the literature about composition of functions is in relation to calculating derivatives via the chain rule (e.g., Clark et al., 1997). In terms of covariational reasoning, function composition requires students understand how the quantity represented by the variable x covaries with the doubly-transformed output

$g(f(x))$, but this has been a minimal focus in terms of research (e.g., Moore & Bowling, 2008). Perhaps the study most closely related to function composition, on its own, was Ayers et al.'s (1988) exploration of using computer programming to help students develop the notion of function composition. In sum, there is a dearth of literature on function composition (especially in comparison to that about the function concept) – and none of it has considered it through a geometric lens. The study in this report aims to address this gap in the literature.

Geometric and Algebraic reasoning

A key premise underlying this research is that algebraic and geometric reasonings are different, where each provide distinct conceptions that are complementary for developing deep mathematical meanings. Broadly speaking, algebra is a mathematical field that examines particular structures, based on a set of objects (e.g., $\mathbb{R}$), and a binary operation(s) defined on them (e.g., $+$). Whereas geometry explores spaces that are related with distance, shape, and size (e.g., the Euclidean plane). To highlight this difference, a function, algebraically, is often characterized by its equation, e.g., $f(x) = 2x + 1$ (i.e., the structure of the set of points included in the relation); whereas, geometrically, we depict a function as its graph (typically in the Euclidean plane), e.g., $f(x)$ is a line. Moreover, not only do these fields explore different things, but key ways of reasoning differ between them. Driscoll et al. (1999; 2007), for example, differentiated Algebraic from Geometric "habits of mind." In our context, for simplistic purposes, we use *geometric reasoning* to mean reasoning that relies on figures and shapes in the plane and their properties; *algebraic reasoning*, by contrast, would rely on equations.

Beyond just the ways we might think about functions from school algebra, abstract algebra provides yet another point of connection to function composition. A primary connection for prospective teachers between abstract algebra and school mathematics is recognizing how functions and inverse functions are situated within their group structure (Wasserman, 2016). Notably, this structure is related through an operation on functions – namely, function composition. That is to say, in order for teachers to genuinely understand this mathematical connection between their university studies and the mathematics they will teach, they need to view composition as an "operation" in the same way that they view, for example, multiplication as an operation. They need intuitions, tools, ways of reasoning, and so forth, in order to be able to consider what the "result" of that operation of composition would be for two particular functions – even if those functions are given as graphs. Dreyfus and Eisenberg (1983) pointed out that without a formula, the graphical representation of function has very little meaning for most students entering calculus. This can be challenging, even for the mathematically adept.

Methodology and Data Sources

As a way to explore how students reason geometrically about function composition, we had (n = 143) university students in two mathematics and mathematics education programs (primarily from precalculus classes) sketch what they thought the composite function $(g \circ f)(x)$ would look like, primarily based on two given graphs of functions.

Task Design

On Desmos, participants were asked to sketch, using digital tools and within a limited timeframe (30 seconds, to capture their intuitions and reasonings), the composite function $(g \circ f)(x)$ for six pairs of functions. The majority of these pairs were represented only graphically (Figure 1 displays an example Desmos page; Figure 2 displays the other 5 tasks). The purpose in providing participants with somewhat unusual, and non-algebraic forms of the functions, was to deter them from immediately converting to an algebraic equation to complete the composition. Doing so increased the likelihood that students would have to try to reason about function composition geometrically based on the shapes of the graphs. In the last two tasks, functions were given as an equation, and as a table, as a point of comparison. In the complete study, participants: i) give an initial sketch within 30 seconds; ii) provide a written explanation for how, and why, they sketched the composite function the way they did; and iii) had a final opportunity to go back and modify any of their original sketches. In this paper, we analyze just their initial sketches. We do not include the "correct" composition $g(f(x))$ for the tasks in this paper, in part because it was uncommon for participants to sketch the correct graph but also to point out the genuine challenges of reasoning geometrically about function composition to the reader.

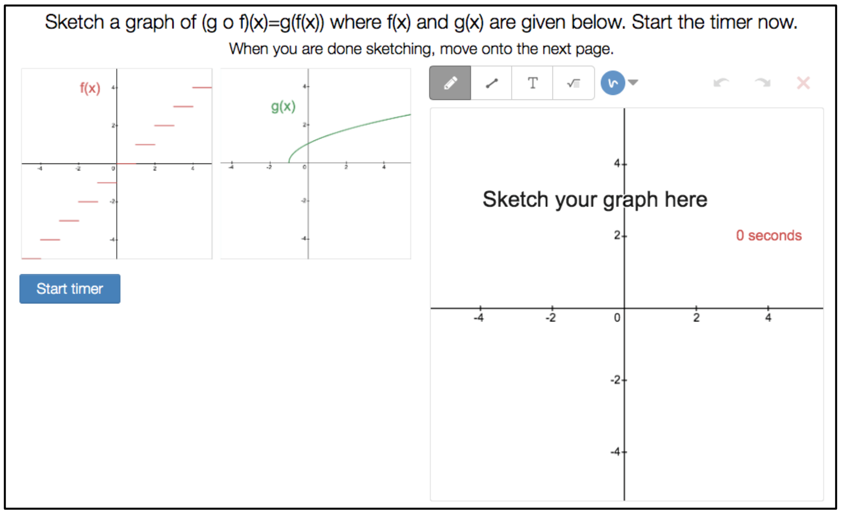

Figure 1. Task 2 in Desmos

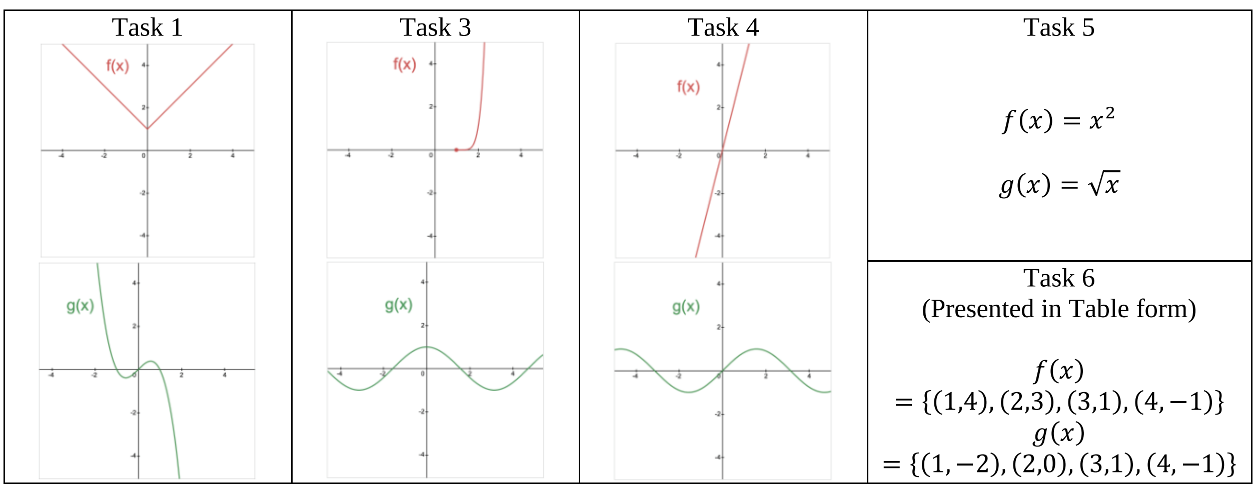

Figure 2. Given functions for Tasks 1, 3, 4, 5, 6

Analysis and Coding

Our analysis identified normative types of graphs, and processes for sketching those graphs, that were shared across participants. Notably, we aimed to create categories that could be applied across the entire set of tasks, although a few categories were specific to particular tasks. We anticipated these to include both incorrect and correct resultant graphs of composite functions, and a diverse range of reasoning students may have used to approach this sketching. We generated and refined all categories of coding as a group; when there were uncertainties in how to code a graph, we resolved such cases together and made refinements to categories as needed. As a rule of thumb, given that these were sketches, using a digital tool, we were reasonably lenient in trying to give students appropriate credit for their resultant graphs.

Due to space constraints, we do not include all codes used in our analysis. However, Table 1 provides codes and definitions for the majority of codes – and, in particular, those we report on in this paper. Clarifying examples are given in the results section.

Table 1. Codes for analyzing data

Code	Description of the composite function $g(f(x))$ sketched
BLANK	No graph
DOUBLE	Both graphs on top of each other
ONE	One of the graphs
ONE-T	One of the graphs, but with some basic transformation
MIXED HALF	Half of one graph put together with half of other graph
MIXED PROP	One graph put together with property of other graph
INVERTED	Correct graph of $f(g(x))$
CORRECT	Correct graph of $g(f(x))$
Y=X	Graphed the line $y = x$
OTHER	Some other graph

Results

Table 2 provides an overarching summary of students' initial ways of reasoning about sketching the composite function on the six tasks. Notably, we only report on the codes given in Table 1, so most, but not all (n = 143), of students' responses are present. Then, we look more carefully at results from the three types of tasks: (i) given graphs (Tasks 1-4), (ii) given equations (Task 5), and (iii) given tables (Task 6).

Table 2. Summary of data on Tasks 1-6

Code	Task 1	Task 2	Task 3	Task 4	Task 5	Task 6
BLANK	20	24	26	25	24	33
DOUBLE	26	22	31	34	19	26
ONE	10	12	10	15	10	26
ONE-T	31	16	17	19	5	0
MIXED HALF	2	6	12	8	4	1
MIXED PROP	9	26	12	12	0	0
INVERTED	1	0	0	2	3	0
CORRECT	7	5	1	4	27	3
Y=X	0	0	0	0	25	0
OTHER	27	27	30	20	24	48

Given Graphs

In Tasks 1-4, students were given *graphs* of $f(x)$ and $g(x)$ and asked to sketch the composite function. Although there are some differences between the four tasks, for the most part, we observed consistent themes in the different ways students approached these tasks. As a primary, overall result, students had very limited success in reasoning geometrically to produce a correct composite function. Only 3% of the responses (17 of 572) were correct, whereas roughly 35% were left "blank" or given some "other" unusual response. (All percentages given in this section are across all responses to Tasks 1-4.)

More interesting are the results for the different ways students appeared to reason geometrically about the result of composing two given graphs. Although we saw both DOUBLE and ONE codes on the tasks with given equations and tables, these were prominent ways of reasoning geometrically as well; and the transformation of one (ONE-T), and the mixing of both graphs (MIXED HALF, and MIXED PROP) were almost entirely observed in the graphical context.

The DOUBLE category was reasonably common (20% of responses) – meaning, participants frequently understood how function composition "combines" two graphs to be simply "put both functions on the same graph." Participants also opted to just graph ONE of the graphs in about 10% of responses. Figure 3 gives a characteristic image for both of these from Task 2.

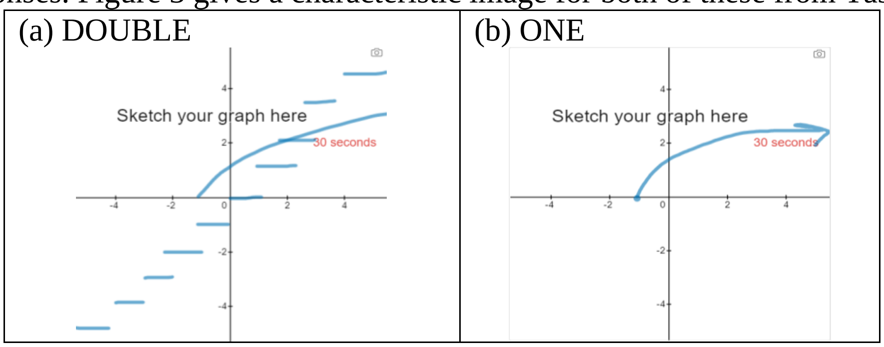

Figure 3. Examples from Task 2 of (a) "double" reasoning, and (b) "one" reasoning

Other common responses – and, in this case, ones there were mostly particular to the functions being given as graphs (Tasks 1-4) – had to do with modifying one or both functions in some way based on graphical features. This sort of geometric reasoning was how students interpreted "combining" two functions (via composition) given as graphs. For the ONE-T code (15% of responses), some students took one function as the base and then applied some transformation to it. Figure 4a shows one example, from Task 2, where a student took the initial $g(x)$ function (approximately square root) and then translated it by a vector of approximately $\langle 1,1 \rangle$, likely inspired by the step function going over one and up one. Although this is one example, there was quite a variety of different sorts of transformations included in this category – sometimes reflections, rotations, etc. For the MIXED HALF code (5% of responses), rather than graphing both functions at once, some students took half of one and combined it with half of the other to create a function – generally, a "left" and a "right" half. Figure 4b shows an example (also from Task 2). The MIXED PROP code (10% of responses) was one in which students applied a property of one function to the other function. As an example (from Task 2), Figure 4c shows one student who took the "disconnected dash" property of the step function $f(x)$, and applied it to the $g(x)$ function (approximately square root), to create a dashed square root graph. Again, there was a lot of diversity in the property being applied within this category – e.g., the domain of one was applied to the other, the pointiness of an absolute value function applied to the curves of the other, and so forth.

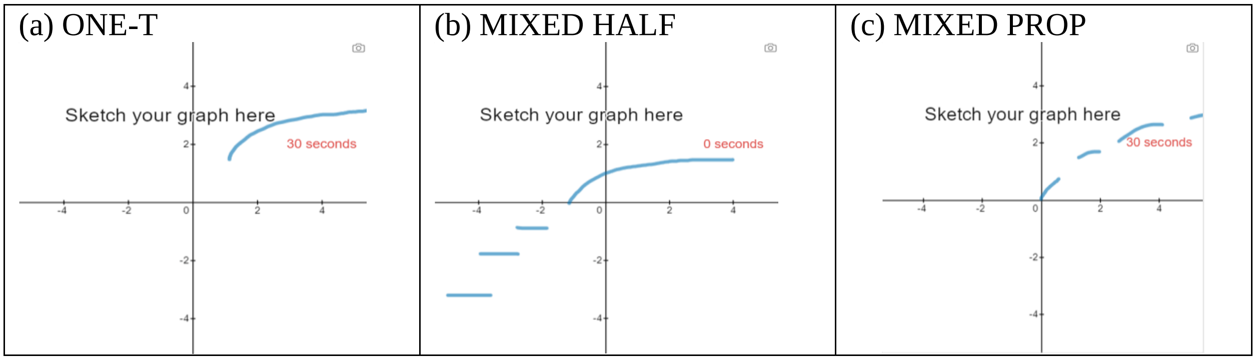

Figure 4. Examples from Task 2 of (a) "one-t" reasoning, (b) "mixed half" reasoning, and (c) "mixed property" reasoning

Given Equations

For Task 5, with two given *equations*, we point out two major results. Participants had the most success correctly plotting the composition of two functions given their equations (19%), which was significantly more than on any other task. One of the unique aspects of Task 5 was that the two functions would also have been known to be inverse functions. This may have simplified the task somewhat, as the output should be the function $i(x) = x$. But a particular nuance of this task is that the correct answer for the composite function is $g(f(x)) = |x|$ – it is $y = x$ only on a restricted domain ($x \geq 0$), and then with the reflective symmetry of the squaring function applied to it. Hence, these participants likely did more than just algebraic substitution to come up with their sketch. Another 18% of responses just graphed the line $y = x$, likely drawing on just their algebraic sensibilities. (This Y=X code was unique to this Task, as inverse functions were not given in any of the other tasks.)

Given Tables

We initially hypothesized that giving two functions in *table* form (Task 6) might facilitate students' ability to compute the composition of two functions; starting with one value, and then doubly-transforming it through f and then g can be readily accomplished with tables of values. This did not bear out in the data. Students struggled to find the composition, with about 33% of responses being some "other" unusual graph–almost twice as many of this category as on each of the other five tasks.

Conclusions and Implications

In this section, we summarize some of the important conclusions and discussion points based on the data. We highlight three important takeaways for the reader.

First, as an answer to the research question about the ways in which students reason geometrically about function composition, the data suggest students had significant difficulties sketching the correct composite function. We reiterate, on tasks where participants were given graphs (and tables), almost no students were able to give correct sketches. More were successful given equations, but even still, roughly the same number of participants gave correct responses as left it blank. This finding suggests that students are not being provided sufficient opportunities to learn about sketching composite functions overall, and especially from graphs and tables. Moreover, in the results, we described the five primary ways students tried to reason geometrically about what "combining" two functions (via composition) would look. These were: both graphs (DOUBLE), one graph (ONE), transforming one graph (ONE-T), half of one and half of the other (MIXED HALF), and applying a property of one to the other (MIXED PROP). Combined, these forms of reasoning accounted for approximately 70% of non-blank responses (58% of total responses).

Second, and perhaps unsurprisingly, students seem to be most familiar with composing functions in the context of two given equations – in particular, familiar functions, and whose composition they knew how to graph. This is the task in which students had the most success. Even still, we saw some of the challenges and limitations of algebraic reasoning in terms of producing a completely correct composite function – i.e., simplifying $\sqrt{x^2}$ to be x. This suggests the importance of having other ways to reason about function composition, specifically including geometric ways of reasoning from the graphs and their properties, which might be a useful way to avoid such oversimplifications. Although the input-output nature of functions may be on full display with tables, it was interesting to observe that students struggled with composing functions when given two tables. This generated some possible hypotheses as to why students struggled to make sense of the composite function being given tables: i) students experiences learning about composition were so strongly grounded in algebraic equations that they do not maintain ways of reasoning for composition in other contexts; ii) the discrete nature of the tables posed difficulties – because the collections of points, and their composition, would be disconnected (or possibly even undefined) on a graph; and iii) the quantified nature of the variable x in functions, where, unlike substituting the expression $f(x)$ into $g(x)$ *once*, the table form requires that students complete *multiple* substitutions – for *each* a in the domain of f, *each* of the $f(a)$ values needs to be substituted into $g(x)$ to obtain the composite collection of points.

Third, as a final point, we elaborate on why we think these particular findings are important. One reason is that the study data collected here document the genuine challenges students face in sketching the composition of two functions – in almost any form they are given, but especially graphically and tabularly. This finding provides a basis upon which to build future work. It suggests students have not been provided opportunities to develop the intuitions, ways of reasoning, and tools needed to develop a robust concept of function composition; in particular, a way to understand function composition as an operation – something that, in some way, "combines" two given functions. A second reason these findings are important is because they document the various ways that students might try to reason geometrically about function composition. Although most of these are non-normative, and would not result in a graph of the actual composite function, they provide a launching point on which instructors can build more normative conceptions. Notably, composite functions often do resemble their initial parent functions – taking, in some form, some aspect of the shape or properties of those initial functions. Third, the findings here point to both the challenges, as well as the unexplored opportunities, to identify ways to advance and enrich students' conceptions of function composition. More work is needed to identify productive intuitions and way of reasoning that might be helpful to build on, and to explore representations and digital tools that might afford learners an opportunity to develop a rich conception of function composition. In the same way that students develop meaningful ways to think about arithmetic operations like addition and multiplication, developing ways to recognize function composition as an "operation" in a similar manner is an important aim in mathematics education – in large part because of the universality of the function concept, and the utility of this operation of composing them.

Using Latent Profile Analysis to Assess Teaching Change

Timothy J.Weston	Sandra L. Laursen	Charles N. Hayward
University of Colorado	University of Colorado	University of Colorado

Teaching observations can be used in multiple ways to describe and assess instruction. We addressed the challenge of measuring instructional change with observational protocols, data that often do not lend themselves easily to statistical comparisons. We first grouped 790 mathematics classes using Latent Profile Analysis and found four reliable categories of classes. Based on the grouping we proposed a proportional measure called Proportion Non-Didactic Lecture (PND). The measure is the proportion of interactive to lecture classes for each instructor. The PND worked in simple hypothesis tests but lacked some statistical power due to possible scaler ceiling effects. The measure correlated highly with a dependent measure derived from the Reformed Teaching Observation Protocol (RTOP), a holistic observational measure. The PND also provided effective descriptions and visualizations of instructional approaches and how these changed from pre to post.

Keywords: Structured Observations, Undergraduate STEM Teaching,

Introduction

Numerous studies show that active, engaging, and collaborative classrooms help students learn and persist in college, but adoption of new teaching practices has been slow (American Association for the Advancement of Science, 2013; Laursen et al., 2019; Matz et al., 2018). In a recent study, observations of 2008 STEM classes at 24 institutions found that most courses were primarily lecture-based, with only a small proportion of classes incorporating significant amounts of student-centered learning (Stains et al., 2018). Professional development programs are one tool intended to help instructors implement new teaching methods and change the status quo in STEM undergraduate teaching (Laursen et al., 2019; Manduca et al., 2017). But learning whether or not these programs change teaching practices is challenging because typical means of measurement, such as surveys, student testing, and classroom observations, all have methodological shortcomings and may be difficult to implement (AAAS, 2013; Ebert-May et al., 2011; Weston et al., 2021).

While observation data are often perceived as more objective than self-report data from surveys or interviews (AAAS, 2013), data derived from observational studies pose particular challenges when used in statistical tests, thus complicating the ability to make claims about the efficacy of professional development and other interventions (Bell et al., 2012). Some observational systems also may lack clarity in their descriptions of teacher and student activities, making it difficult to learn how instruction has changed over time and what exactly changed in the teaching practices of participants (Lund et al., 2015). Because observation is resource-intensive, investigators often observe only a small number of sessions, which may not provide a representative sample of teaching practices across an entire course (Weston et al., 2021).

Shortcomings of Segmented Observational Protocols as Dependent Measures

Segmented observational protocols such as the COPUS and TDOP are employed in comparative research designs but pose measurement challenges. Typically, these instruments code each 2-minute segment of class time for instructor and student behaviors such as lecture or group work. Difficulties arise in using segmented observational protocols in research studies for several reasons. First, the use of single observation codes (such as the proportion of class time devoted to lecture) can result in poor and incomplete representation of the complex underlying instructional styles occurring in the classroom (Bell et al., 2012). In effect, this can oversimplify what is occurring the classroom. Data drawn from a segmented protocol may also have unwieldy distributional characteristics. The distributions of many relatively low-frequency codes are dramatically skewed, with high numbers of zero observations for any given classroom, and skewed distributions are also common when aggregated over multiple classrooms and instructors (Tomkin et al., 2019). The distributional properties of segmented observational data may necessitate the use of non-parametric tests, which in turn cause possible loss of statistical power (Dwivedi et al., 2017). Another concern is the high number of codes generated by segmented protocols compared to a holistic protocol's single aggregate score or few sub-scale scores. When multiple hypothesis tests (e.g., multiple t-tests) are made in the same study, the true probability of making Type-I errors (saying there is a difference when one doesn't exist) increases substantially (Abdi, 2007), which can lead to false claims about the efficacy of an intervention.

Shortcomings of Holistic Observational Protocols as Dependent Measures

Many studies that employ observational data to assess change use the Research Teaching Observation Protocol (RTOP), a holistic observational measure (Sawada et al., 2002). Holistic instruments ask observers to rate elements of a class such as "The lesson promoted strongly coherent conceptual understanding." These types of instruments often ask for more expert judgments of teaching quality versus observations of behaviors (Hora& Ferrare, 2013). While the measures derived from the RTOP have high internal reliability and some criterion validity, the measure seemed to lack structural score validity in that its proposed sub-scales did not form separate factors in the original validity study (Piburn et al., 2000). Those using the measure also seem limited in their ability to extrapolate from scores to more concrete descriptions of teaching. This is partly caused by the somewhat vague wording of some score range categories that are presented in early RTOP validity documents (Sawada et al., 2003) and studies using the RTOP for outcome comparisons (Ebert-May et al., 2011). An example would be the score range category "46-60 Significant student engagement with some minds-on as well as hands-on involvement," which provides little guidance on what instructors and students are doing in the classroom. This lack of descriptive utility for the RTOP was discussed by Lund et al. (2015), who noted that the same score ranges can describe classes with very different instructional practices, and teaching descriptions varied even more widely from study to study.

Rationale for Study & Research Questions

In the current study, we consider two protocols, TAMI-OP and RTOP, evaluating their characteristics as measures on their own merits while also recognizing them as typical examples of segmented and holistic protocols. These protocols are also distinguished by their descriptive and evaluative approaches. In our current study, we worked from a large dataset that included observations scored with both the TAMI-OP and the RTOP. We asked if a simplified measure formed from a segmented observational protocol, TAMI-OP, could be used with common statistical tests and avoid multiple comparisons while maintaining score validity. Research questions include:

1) What are the characteristics of profile groups for classes that can be derived from our TAMI-OP observational dataset of mathematics instructors?

2) What dependent measures can be derived from the TAMI-OP?
3) How do the RTOP aggregate dependent measure and the segmented TAMI-OP dependent measure function with statistical tests?
4) How can the segmented TAMI-OP dependent measure be extrapolated to provide descriptions of teaching and teaching change?

Methods

Instruments

We developed segmented observational protocol called the Toolkit for Assessing Mathematics Instruction-Observation Protocol (TAMI-OP) (Hayward et al., 2018). At two-minute intervals during the class, observers coded for the presence (yes/no) of 11 student behaviors and 9 instructor behaviors. We called these categories *activity codes* or more generally, observation *items*, including codes for Lecture, Student Questions, Group Work and Student Presentation among other activities. We also completed the RTOP for a subset of 484 of the same classes observed with the TAMI-OP. Both the TAMI-OP and RTOP had adequate interrater reliability, generalizability and internal reliability.

Sample

Our full dataset contained 790 observations of full classes by 74 teachers, gathered from three different research studies related to professional development in mathematics teaching. The observation sample from this study includes 15 instructors who taught 278 classes, some pre- and some post-intervention. The results for these instructors are used as an example of how these measures characterize teaching change but are not meant to offer a formal assessment of that program. All data were collected with human subjects approval.

The instructors in the combined data set taught a range of mathematics courses at different undergraduate levels. Classes included Calculus 1 and 2, Geometry, general education mathematics, statistics, and upper division courses for math majors (see Table 3 for full description). Class sizes ranged from 30 or less (65%), 31 to 75 (25%) to over 100 (10%). The instructors included women and men, experienced and early-career instructors; they taught at a variety of types of institutions distributed across the US and used a variety of teaching practices.

Latent Profile Analysis

Latent Profile Analysis (LPA) is a statistical classification technique that identifies subpopulations or groups within a population based on a set of continuous variables (Spurk et al., 2020). LPA is similar but preferable to traditional cluster analysis because it offers the ability to assess the ideal number of groups in a solution and generate probabilities of group membership, which provide estimates of how close any given case is to a profile exemplar (Ferguson et al., 2020).

The software R-Studio 3.5.0 was used to conduct a Latent Profile Analysis of the 790 classes in our database. The component variables for analysis all used class-level proportions of activity codes. While these variables are continuous, most did not form normal univariate distributions. We used a Maximum Likelihood (ME) estimation, and tested models with different constraints on variance and covariance. Best fitting models used estimation with equal variances and covariance equal to zero. No outliers were found or removed from the data, and there were no missing data.

Results

We found four reliable profiles that characterized the 790 mathematics classes in our sample. We determined the ideal number of profiles through a balance of quantitative fit indexes and the logical coherence of the resulting groupings. We named profiles for the variables that best differentiated between groups, resulting in profiles named *Didactic Lecture, Student Presentation and Review, Interactive Lecture,* and *Group Work*. Figure 1 presents the individual averages for each observation code for each profile.

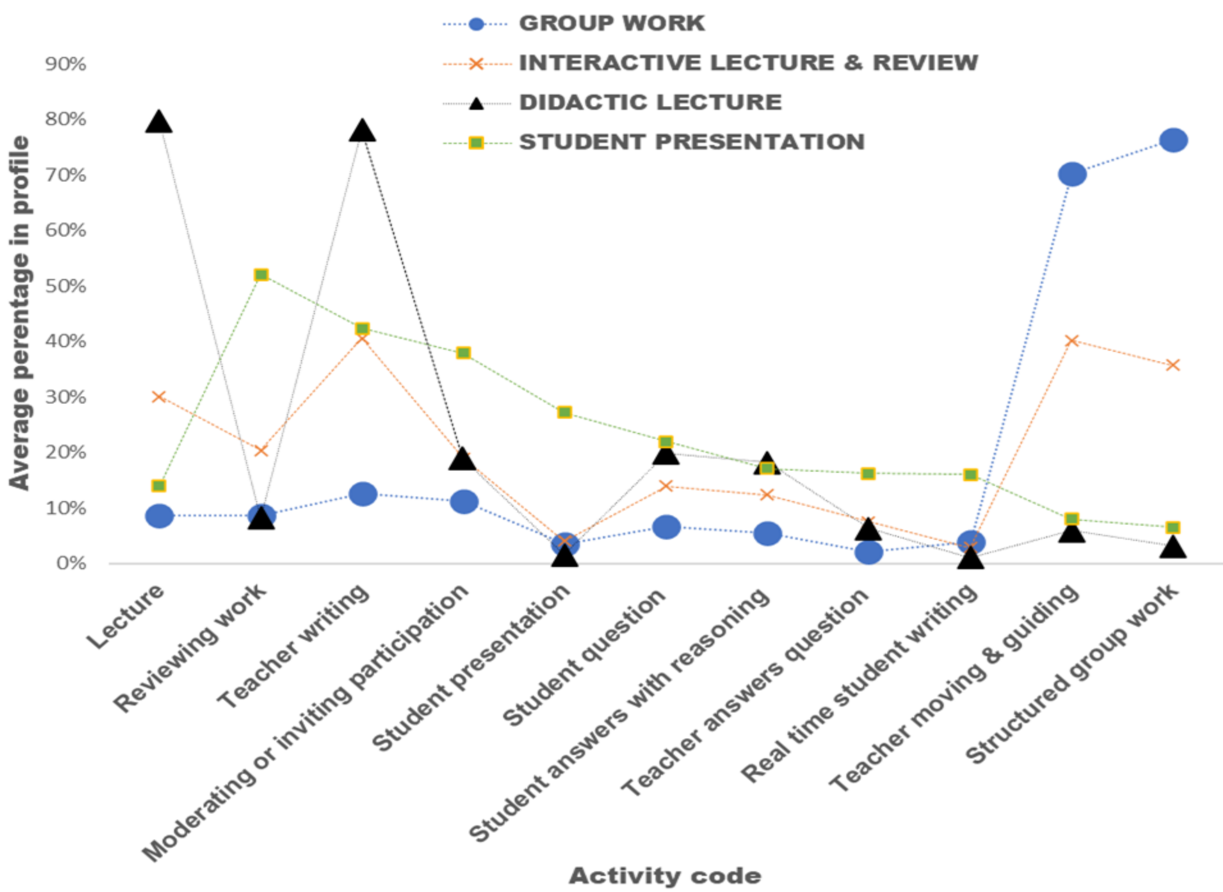

Figure 1. Individual averages for each observation code for each profile.

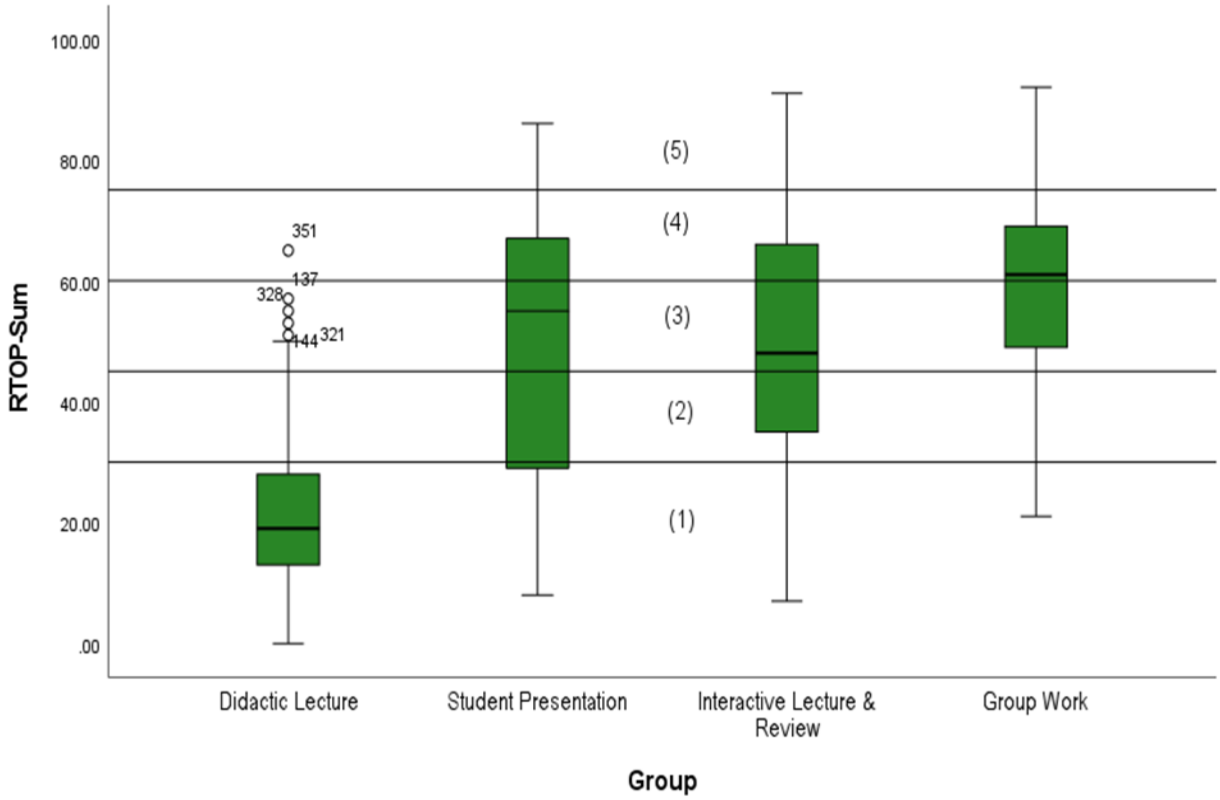
We first attempted to derive outcome measures based on the TAMI-OP with factor analysis but found resulting dependent measures were not reliable enough to use in analyses. A viable outcome measure derived from the LPA was the simple proportion of non-didactic lecture classes used by each teacher: *Proportion Non-Didactic Lecture* (PND). This is a teacher level measure that is the number of Non-Didactic classes divided by total class observed for the each instructor. For example, the observation data set for a particular teacher may have six out of eight classes that fit the profile for the *Didactic Lecture* profile and two that do not, resulting in a proportion of non-didactic classes of PND = 0.25.

We also examined some of the psychometric qualities of the RTOP-Sum, the dependent measure derived from a total of 25 RTOP numerical ratings. The resulting measure showed high

internal reliability ($\alpha = 0.97$), and the RTOP-Sum and the PND had a very high correlation at r=0.81. Attempted Exploratory and Confirmatory Factor Analyses did not find that proposed RTOP subscales presented as item blocks in the instrument formed separate factors.
The relationship between the four latent profiles found with LPA and RTOP-Sum scores can be seen in figure 2.



Note: Numbers in parentheses correspond to RTOP categories: (1) straight lecture, (2) lecture with some demonstration and minor student participation, (3) significant student engagement with some minds-on as well as hands-on involvement, (4) active student participation in the critique as well as carrying out of experiments, (5) active student involvement in open-ended inquiry, resulting in alternative hypotheses and critical reflection. Boxplot lines mark the mean RTOP score for each profile.

Figure 2. individual averages for each observation code for each profile.

We applied these measures to a sample data set of 15 teachers and 278 classes that included both pre and post observations for the same group of teachers, each of whom provided data from the same or similar courses taught before and after a professional development intervention. To learn how the PND functioned with basic statistical tests, we conducted a parametric Paired Sample t-test and a non-parametric Marginal Homogeneity test comparing pre and post values for the PND and RTOP-Sum. We also calculated effect sizes for pre/post gains. The results presented in Table 1 show statistically significant results for change in both the RTOP and PND measures. While both measures detect significant differences in a pre/post comparison study, the RTOP-Sum has a bigger effect size and lower p-value than the PND, indicating that the RTOP-Sum has greater statistical power in this study.

Table 1: Test statistics for the RTOP-Sum and PND measures for pre/post comparison

Test	RTOP-Sum (Scale 0 – 100)	PND (Scale 0 – 1)
Paired t-test (one-sided)	Mean difference = 17 SD = 14.5 Correlation pre/post = 0.63 Standard error = 3.76 t = 4.56, df = 14, p <0.001***	Mean difference = 0.22 SD = 0.27 Correlation pre/post = 0.58 Standard error = 0.07 t = 3.1, df = 14, p <0.004***

The descriptive utility of the PND is linked to its derivation from component Latent Profile Analysis groups. The separate activity codes and global variables used to form groups were also graphed to learn which activities changed from pre to post (not shown here due to space considerations). Most codes changed in ways consistent with the goals of the professional development in which they participated, with lecture and teacher writing decreasing, and group work and student presentation increasing. The average number of activities and balance among activities also increased.

Discussion

Profiles of classes created from Latent Profile Analysis provided four groups, which we labeled *Didactic Lecture, Interactive Lecture and Review*, *Student Presentation* and *Group Work*. The grouping method was reliable, and we believe these groups represent different underlying styles of teaching and learning present in our observations of 790 mathematics classrooms. In the *Didactic Lecture* group, instructors averaged 80% of their time lecturing, usually with little question and answer. This contrasted with the three non-lecture groups where students participated in more interactive activities such as group work (usually working though problem sets), presenting problems on the board, or participating in more back-and-forth dialogue with the instructor during lecture and review. Instructors for classes in the three non-didactic lecture groups also engaged in more activities in their classrooms and tended to have more balance in time devoted to each activity.

From the LPA results we created a measure called the Proportion of Non-Didactic Lecture (PND) that represented the proportion of more interactive classes, contrasted to didactic lecture classes, for each instructor. The value of a measure lies in its ability to summarize data from multiple activity codes and other variables into one measure while avoiding the pitfalls of poor construct representation, strict reliance on non-parametric tests, and multiple comparisons found in many studies that use segmented data (Tomkin et al., 2019). We found that the PND measure had some shortcomings caused by its reliance on proportional frequency data. In our wider dataset the PND had a significant number of “1” values, which created the possibility of ceiling effects and lacked distributional normality. While most statistical tests are robust to non-normality (Glass and Hopkins, 1996), comparisons made with small numbers like ours (i.e., the pre/post subset of 15 instructors) have less statistical power. In fact, the pre/post statistical comparison conducted with the measure showed less statistical power than did comparison with the RTOP-Sum, but in our case provided similar statistical inferences as the RTOP about pre-post change.

There are several other critical caveats to the use of a measure based on LPA or any other clustering technique. The final categorization of classes is dependent on both the sample used and the variables included in the model. The ultimate category where classes end up can vary given the characteristics of the initial pool of classes and the specification of the model (Williams and Kibowski, 2016). Any project also needs a relatively large pool of classes to make cluster or profile methods viable. In their overview of LPA studies, Spurk and coauthors (2020) found a median sample size near 500; in our study we were fortunate to have a collection of nearly 800 classes. It is possible to leverage the earlier work of others; those using the COPUS can take advantage of the COPUS Analyzer (Harshman and Stains, 2020) an online method for profiling observational data. We also can categorize new classes based on the original clustering algorithm. While it may seem obvious, pre and post or participant/comparison groupings (for any clustering technique) must be made at the same time and from the same model. Also, the creation of an LPA model should be done independently from, and before any type of statistical comparison is made. Shopping for the model that creates the largest effect for a comparison would constitute a breach of research ethics.

Deriving a proportional measure from segmented observational data is also limited by several important assumptions. First, there must be enough classes observed for each teacher to form a reliable measure, a number that is usually higher than is found in most research studies (Weston et al., 2021), and observing enough classes for a reliable measure is resource intensive. Related to this are possible interactions between the number of classes sampled for each instructor and the probability that rarer classes will show up in the classes sampled. If greater or fewer classes for each teacher are sampled from pre to post this can create bias in estimates of teaching change. Unequal sampling occurred in our small study because of logistical concerns, ideally pre and post samples should be balanced. Second, profiling or clustering solutions must conform to a continuum from didactic to interactive instruction. This seems to be a common finding for profile studies where a large proportion of classes are didactic lecture (Denaro et al., 2021; Lund et al., 2015; Stains et al., 2018). The main limiting factor for some studies may be the small number of truly interactive classes observed; in Stains et al. (2018) approximately 25% of classes were student-centered, although mathematics classes had the highest percentage of these courses (~35%).

Lessons Learned using *FullProof*, a Digital Proof Platform, in a Geometry for Teachers Course

Orly Buchbinder, University of New Hampshire
Sharon Vestal, South Dakota State University
Tuyin An, Georgia Southern University

Proof-writing is a core practice of mathematicians and a crucial skill every future teacher and mathematics major needs to acquire. A proof-based geometry course is a fruitful ground for developing proof-writing skills. Despite recent pedagogical and technological advances, proof remains challenging to learn and teach. We conducted a pilot study to explore potential advantages of an innovative digital proof platform, FullProof, which aims to advance students' proof-writing skills in Euclidean Geometry. We integrated FullProof in three Geometry for Teachers (GeT) courses at three universities. We report on the findings pertaining to students' interactions with FullProof, their perceptions of the usefulness of this tool to their proof-writing skills, and the lessons learned from the FullProof integration from an instructor perspective.

Keywords: Geometry, Proof, Prospective Secondary Teachers, Automated Proof Writing

Introduction and Theoretical Perspectives

Proof-writing is a core disciplinary practice of mathematicians, and a crucial skill all mathematics majors and future mathematics teachers need to acquire. Developing undergraduate students' facility and comfort with proofs are among the main objectives of many mathematics courses, including geometry. While geometry courses may be either required or elected for mathematics and other STEM majors, they are usually required for mathematics education majors. Hereafter we refer to such courses as GeT- Geometry for Teachers (An et al., in press; Grover & Connor, 2000). GeT courses are essential for cultivating robust and flexible knowledge and skills such as writing, analyzing, and critiquing proofs that will allow prospective secondary teachers (PSTs) to support their students' learning of geometry (AMTE, 2017; González & Herbst, 2006; NCTM, 2000; NGA & CCSSO, 2010).

Technology plays an important role in supporting PSTs' engagement with proof. Dynamic Geometry Environments (DGE) like *GeoGebra, Geometer's Sketchpad* and others have been essential in providing opportunities to explore geometrical properties, make and test conjectures (Jones, 2000; Mariotti & Baccaglini-Frank, 2018). These tools have also been beneficial for fostering PSTs' attitudes towards proof and comfort with proof and teaching it to secondary students (Abdelfatah, 2011; Kardelen & Menekse, 2017). However, DGEs offer little support for the most critical component of mathematics exploration - the *writing* of a deductive proof of a conjecture or a theorem. Recent advancements in artificial intelligence and machine learning offer new tools that support automated and interactive proof writing and verification (e.g., Lodder et al., 2021; Matsuda & VanLehn, 2005; Wang & Su, 2017), and give new opportunities for innovative research in the educational applications of these tools (Hanna et al., 2019).

FullProof is a digital platform that was developed to advance students' proof-writing skills in Euclidean Geometry. In this tool, students write a complete step-by-step proof, using an interactive diagram, an equation editor, and a library of theorems and definitions. Students can choose their own proof paths. The software checks the proof and provides feedback and/or hints to improve their work. Our project aimed to explore the potential advantages of the *FullProof* digital tool for GeT students. Our overarching research question was: *How and to what extent does engaging GeT students with the FullProof software affect their confidence with and attitudes toward geometry proofs?*

Research Setting and Methods

In Fall 2021, we conducted an exploratory study in which we integrated *FullProof* in three GeT courses in three US public universities in the Southeast, Northeast, and Midwest (See Table 1 for course and participant info). In each course, a large portion of the curriculum was devoted to Euclidean Geometry from a synthetic perspective. All instructors had experience with teaching the GeT course. To familiarize students with the platform, the instructors introduced *FullProof* during class and worked together with students to solve several proofs.

Table 1. Course and Participant Information

University Type	University A Southeast, large public	University B Northeast, large public	University C Midwest, medium public
Student population	~ 20 students: PSTs and STEM majors	~15 students: PSTs and STEM majors	~ 6-18 students: PSTs only
Course focus and modality	Content focused Hybrid	Content focused Face-to-face	Mixed content and pedagogy. Face-to-face
No. of students	14	10	6

The instructors integrated the *FullProof* platform into the courses as a support system for writing proofs, both in class and in homework. Each instructor used about 20 proof problems, from *FullProof* 's vast collection of problems on various topics from Euclidean geometry, at three levels of difficulty: high, medium, and low. Figure 1 shows a screen capture of a sample problem (medium difficulty) about triangle midsegments. Given DE is a midsegment of the triangle ABC. F is a point of BC such that BF=(1/2)FC. The segment AF intersects DE at point G and the segment BE at point O. Prove that BO≅EO.

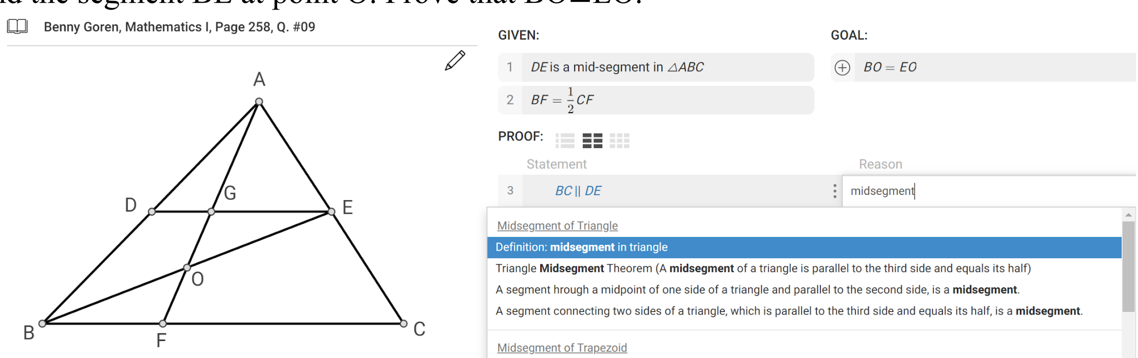

Figure 1. Sample proof problem

While the figure itself cannot be dynamically manipulated, each segment, point, and angle in the figure become highlighted when pointed to. Angles and segments can be marked, color-coded, and named as shown in Fig. 2. The right side of the screen shows the givens and the statement to be proven. The students write the proof by typing statements in the numbered lines and justifying them. The justifications can be searched by keywords, as shown in Fig. 1, or by browsing through the *FullProof* justification library. Despite the two-column format, *FullProof* allows for variation in proof strategies and the order of steps. For example, the problem in Fig. 1 can be solved with congruent triangles or properties of centroid.

The students may ask for a hint by clicking the hint button. The system will produce hints in order of increased specificity from a vague "try using triangle congruence," to suggesting a certain theorem to use, or even proposing a particular step, like "try proving ΔBFO ≅ ΔEGO". Once finished, the students click the "check" button, and in a few seconds, the algorithm checks the proof and provides feedback. Correct proof lines get a green check mark. Incorrect or partially correct lines are marked down with an explanation of the mistake. Fig. 2 shows a solution with two mistakes – a missing proof step and a missing justification for the last step. Clicking on these notifications will show a student what the missing step was (here ΔBFO ≅ ΔEGO by angle-side-angle theorem).

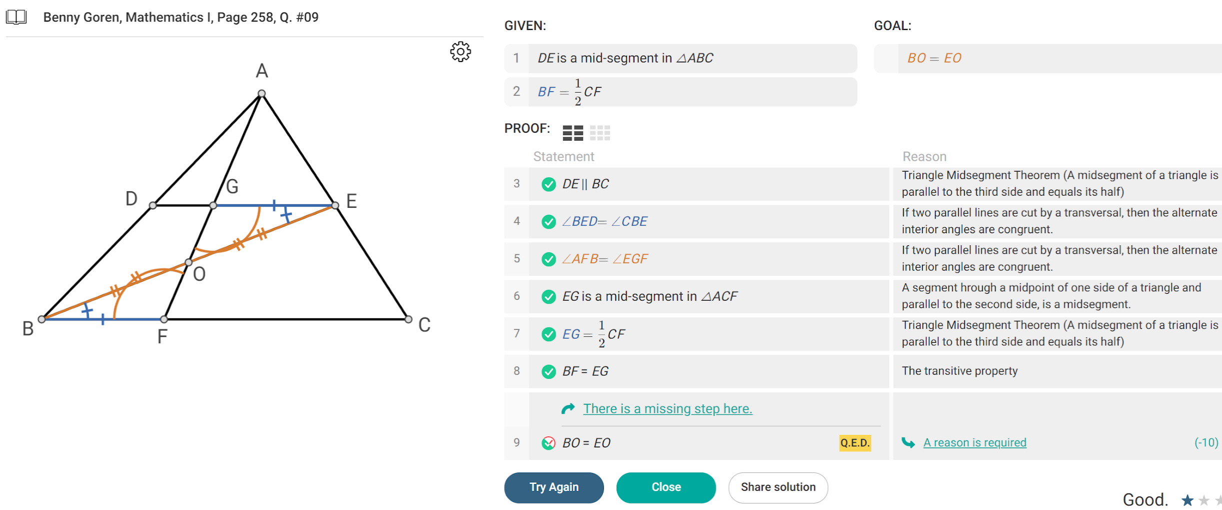

Figure 2: Sample solution in FullProof and the feedback provided by the software.

Clicking the "try again" button allows a student to improve their work, submit a corrected solution and receive more feedback. The number of hints and submissions is unlimited, allowing the students to achieve a perfect score eventually. The information about the number of hints and submission attempts is stored in the system. The instructor's interface contains information about all students in the class – which of the assigned problems they solved, how many hints and attempts they used, and can see the last submitted solution (Fig. 3).

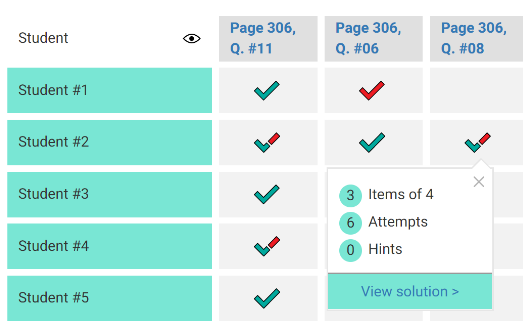

Figure 3: Excerpt of instructor interface in FullProof.

Data Collection and Analysis

To respond to our research question, we administered pre- and post-survey via Qualtrics. We focused on the results of two sets of Likert-type questions about attitudes toward proof, and comfort level with writing proofs (see Fig. 4 for sample items). The items were adapted from the relevant instruments in the literature (e.g., Kaspersen & Ytterhaug, 2020; Stylianou et al., 2015). The Likert-scale for proof-related attitudes was: *Never/Almost never (1), Sometimes (2), Often (3), Always/almost always (4)*; and for comfort-level was: *Strongly Disagree (1), Disagree (2), Agree (3), Strongly Agree (4).*

Attitudes towards Proof questions (20 items). Examples:

1. I take the initiative to learn more about proof writing than what is required in this course.
3. **When I learn a new proof, I try to think of situations when it wouldn't work.**
13. **When I face a proof problem, I consider different possible ways I can prove it.**
18. **I can explain why my solutions are correct.**
20. If I immediately do not understand what to do, I keep trying.

Comfort with proof (10 items). Examples:

1. I feel comfortable when I prove mathematical theorems in the *FullProof* platform.
2. **I feel confident in my ability to prove mathematical results using the *FullProof* platform.**
3. **I am familiar with different proof techniques using the *FullProof* platform.**
4. **I am confident about my ability to teach proof using the *FullProof* platform.**
6. I believe I can learn to read and write proofs if I put enough effort into it.

Figure 4. Selected Likert Items from the FullProof *Survey.*

Twenty-nine students responded to the pre-survey while only 20 responded to the post-survey. To analyze Likert-scale data, we initially used the chi-squared test of independence, which is appropriate for categorical data, but since some of the categories had less than five data points, the chi-square test is unreliable. To address this challenge and to avoid discarding unpaired observations by using a paired sample *t*-test, we used a new statistical test–developed by Ben Derrick, University of the West of England, which allows analyzing observations taken at two points in time, where the population membership changes over time but retains some common members (Derrick, 2020).

The post-survey also contained seven open-ended questions, developed by the researchers, about student perceptions of the *FullProof* platform (Fig. 5). We analyzed the data qualitatively, using open coding and thematic analysis (Patton, 2002) to reveal recurring themes in students' responses, specifically the types of positive and negative appraisals of *FullProof*. Each appraisal is defined as a statement that has a relatively complete and independent meaning. To capture all themes, comments that included multiple ideas were coded multiple times.

1. How much experience did you have writing proofs before using this tool?
2. **Has this tool changed the way you write proofs? If yes, explain in what way.**
3. **What are some of the successes/challenges you have had in proof writing when using this tool?**
4. **How has this tool changed your understanding of reasoning and proof?**
5. **Would you use this tool in your future geometry classroom? Why? How? If not, explain why not.**
6. What other features would you like to see in this tool?
7. **What is your overall impression of the FullProof tool?**

Figure 5. Open-ended Items from the FullProof *Survey.*

In addition to the survey, we analyzed student solutions to a few problems assigned in all three GeT courses to examine the types of proof approaches utilized by the students, and the types of mistakes they made. Due to space constraints, we do not report on this analysis here.

Results

Survey Results

Attitudes toward proof. Fig. 6 shows the statistical test results for three of the survey questions related to proof attitudes. These questions were selected since their Derrick test *p*-values were relatively close to 0.05, indicating that the results are statistically significant.

Question	When I learn a new proof, I try to think of situations when it wouldn't work.	When I face a proof problem, I consider different possible ways I can prove it.	I can explain why my solutions are correct.
Box plot			Derrick test	0.0431	0.0713	0.0438

Figure 6. Sample Survey Results about Mathematical Identity.

While the pre-post changes for the questions in Fig. 6 are significant, the results are not necessarily in the intended direction. For example, the boxplots for the first two questions show a decrease in participants' tendency to think about situations in which a proof wouldn't work or consider different proof paths. With respect to the first question, the results may be reflective of the nature of geometry proof problems, like the one in Fig. 1, as opposed to proofs of theorems; and the static nature of the FullProof figures, as opposed to DGE. These features of *FullProof* are indeed less likely to invoke one's thinking about situations where the proof is inapplicable. The decrease in considering various solution methods was surprising to us since *FullProof* allows for much flexibility in proof approaches that instructors always encouraged. However, the hints from the software may lead students to a certain approach. One explanation for this result is that students' responses at the end of the semester reflect a pragmatic preference for one correct solution that guarantees a good grade, rather than exploring multiple solutions. It is also possible that students' confidence at the beginning of the semester decreased due to the course being harder than they anticipated. The results for the third question are encouraging, with students' increased confidence in their ability to explain their correct solutions at the end of the semester.

Comfort-level with proof. Fig. 7 shows results related to using the *FullProof* platform.

Question	I feel confident in my ability to prove mathematical results using the *FullProof* platform.	I am familiar with different proof techniques using the *FullProof* platform.	I am confident in my ability to teach proof using the *FullProof* platform.
Box plot			Derrick test:	0.0009	0.000136	0.003014

Figure 7. Sample Survey Results about Comfort Level with Proof.

These questions had the lowest p-values, indicating significant pre-to-post changes, which is not surprising since the students had never used *FullProof* prior to the course. Still, we are encouraged by the positive direction and amount of change. For example, in the first two questions in Fig. 7, 75% of the post-survey responses were higher than the pre-survey responses. These results indicate significant increases in students' familiarity with various proof techniques and increased confidence in their ability to write proofs and even teach proofs with the *FullProof* platform. The increased familiarity with different proof techniques in *FullProof* (question 2, Fig. 7) suggests that students' lack of consideration of multiple proving approaches (question 2, Fig. 6) occurred despite increased knowledge of these techniques. This may support our assumption about pragmatic reasons for not considering multiple ways of proving. The analysis of open-ended questions sheds additional light on these results.

Student Appraisals of the *FullProof* Platform

Nineteen students responded to the six open questions about *FullProof*. There was a total of 84 appraisals, 61 (73%) positive and 23 (27%) negative. "Appraisal" is a thematic unit, such that a single written comment may contain both positive and negative appraisals, or more than one appraisal of the same type. Six out of 19 students provided positive appraisals only, others shared a combination of both. One interesting pattern in the data was: when asked to describe some of the successes and challenges they had with *FullProof* (#3, Fig. 5), 65% of comments described challenges as opposed to 35% of successes. However, the overall impressions of *FullProof* (# 7, Fig. 5) were very positive with 73% of comments containing positive reviews.

Three main themes emerged among the positive appraisals. The largest category (41%) described the *affordances of FullProof for supporting students' writing and understanding of proofs*. These included the searchability of reasons for proof steps, clear structure that supports communication and comprehension, interactive feedback, and the ability to pursue multiple solution paths. One student wrote, "*FullProof* has helped me a lot when writing proofs. I like how I can search for reasons if I am not completely sure about a reason/theorem." Another student wrote: "*FullProof* made writing proofs easier not only to write, but also to understand."

The second theme (26%) described the *advantageous technical features of FullProof,* such as hints which help them move forward if one is stuck, interactive feedback pointing to errors, visual clarity, and color-coded elements of a diagram. The third theme (33%) described the affordances of *FullProof* as a pedagogical tool for teaching others. In this theme, the participants highlighted the elements of the software that would support them as teachers in a geometry classroom. Students wrote that *FullProof* presents "a good instructional strategy to implement in the classroom," and the platform "Makes it easier for the students to see what their errors were."

The 23 negative appraisals were distributed rather uniformly across five themes. The main critique (7 out of 23 appraisals, 30%) concerned the discrepancy between the wording of the theorems in the *FullProof* platform and in GeT course. For example, *FullProof* does not have the angle-angle-side triangle congruence theorem, so students need to complete an extra proof step to use the angle-side-angle congruence theorem. Another category of critiques (22%) described the variation in standards of rigor employed by *FullProof* vs. GeT instructors. The students wrote that the software allowed them to skip steps and earn full points for their solution, while the students were aware that their instructor would have likely deducted points. One student wrote: "It allows some things to slide, that should be wrong." Other types of critiques concerned some minor technical issues like the lack of an undo button (17%). Three students admitted having personal struggles with technology, in general (13%). Finally, some students wished to break out from the two-column structure altogether to write paragraph-style proofs (17%).

Additional patterns emerged from the analysis of specific questions. When asked "Has *FullProof* changed the way you write proofs?" the responses split almost evenly between *yes* and *no*. But 83% of the accompanying written comments for this question were positive regarding *FullProof*. A similar pattern was observed in a question: "How has *FullProof* changed your understanding of reasoning and proof?" Sixty-one percent of students wrote that *FullProof* positively influenced their understanding, but interestingly, 91% of their comments contained some specific description of the positive effect of *FullProof*. In response to the question "Would you use *FullProof* in your future classrooms," 14 out of 17 students who answered this question responded positively, citing the advantages of the platform.

Discussion

Overall, the quantitative analysis shows little impact of the use of *FullProof* on student attitude towards proof and comfort level with proof writing, since pre-post changes on most survey questions were not statistically significant at the 0.05 level (as indicated by large p-values on Derrick's test). Yet, there were some questions showing significant changes using the Derrick test. While there is still some risk of a Type I error when using the partially overlapping sample t-test, Derrick's research indicates that this is "the recommended test for analyzing data recorded on an ordinal scale when partially overlapping samples are present and is particularly useful when sample sizes are small" (Derrick, p. 147).

We are also aware of the limitation of our quasi-experimental research design. Due to the lack of randomization and a single experimental group in the research setting, potential confounding variables were not controlled (Johnson & Christensen, 2012). Each course was taught by a different instructor, with no common curriculum or textbook across the institutions. There was also some variation in how instructors used *FullProof* in their courses. Finally, because of the Covid-19 pandemic, one institution required the instructor to accommodate hybrid teaching modality, which affected course pedagogy, including the use of the *FullProof* platform.

Because of these variations, our study design emulates natural conditions of how instructors might use any technological tool within the unique constraints of their institutional environments. Against this backdrop, we find it encouraging that the qualitative analysis showed more positive appraisals than negative appraisals about using the platform, which indicates the overall positive impact of using *FullProof* in GeT courses. The significance of this result is due to our analyses not distinguishing between students of different majors - mathematics education or not - meaning that potential advantages of *FullProof* apply to all GeT students.

As instructors, we note several advantages to using *FullProof* in our GeT courses. Due to the availability of multiple proof problems at various difficulty levels, and the feedback provided by the *FullProof* platform, we were able to assign a greater number of problems and more challenging problems, compared to the past. Since *FullProof* offers hints and multiple submissions, students were able to get assistance from the software itself. However, this also presented a challenge, when some students abused this functionality to get hints on every step of the proof. In the future, we plan to limit the number of hints and submission attempts. Another limitation of *FullProof,* also noted by the students, is that there are some discrepancies in the standards of rigor with the GeT courses. However, this can be leveraged to engage students in analyzing and critiquing proofs, which is an important learning objective of GeT courses (An, et al., in press). Based on the results of our exploratory study, we revised our research instruments and protocols, to use in the next round of the study. Future studies should expand the scope of research questions to include an examination of cognitive and meta-cognitive processes afforded by *FullProof*.

Graphical Resources: Different Types of Knowledge Elements Used in Graphical Reasoning

Steven R. Jones
Brigham Young University

Jon-Marc G. Rodriguez
University of Wisconsin - Madison

In broad terms, much of the research on graphical reasoning can be characterized as focusing on misconceptions, covariational and quantitative reasoning, and graphing as a social practice. In contrast, other research has focused on graphing as a cognitive process, emphasizing the fine-grained knowledge elements related to graphing, with a focus on characterizing ideas students associate with graphical patterns (i.e., graphical forms). This paper moves beyond graphical forms to characterize other categories of fine-grained knowledge – "graphical resources" – that are activated and used in concert when constructing and interpreting graphs. In this study, we identified six categories of graphical resources: graphical forms resources, framing resources, ontological resources, convention resources, quantitative resources, and function resources. We posit that holistically considering different categories of fine-grained graph-related knowledge resources can connect various bodies of research on graphing.

Keywords: graphs and graphing, knowledge resources, student reasoning, graphical forms

Graphical reasoning is a central and critical competency within mathematics and across many disciplinary fields (National Council of Teachers of Mathematics, 2006, 2009; National Research Council, 2012). Much of the education research work to date on graphing has focused on taking one large-scale item at a time and examining it, such as examining misconceptions (Aspinwall et al., 1997; Beichner, 1994; McDermott et al., 1987), covariational and quantitative reasoning (Carlson et al., 2002; Thompson & Carlson, 2017), and viewing graphing as a social practice (Roth & Bowen, 2001, 2003) with community-specific conventions (Moore & Silverman, 2015; Moore et al., 2019). More recently, some researchers have begun to take a finer-grained approach to student graphical reasoning, framing graphical activity as a cognitive process (Elby, 2000; Eshach, 2013; Rodriguez et al., 2019a; Rodriguez et al., 2019b). Fine-grained approaches place emphasis on the productive, intuitive ideas students draw on to guide many aspects of their graphing activity (Rodriguez & Jones, in preparation). In fact, a fine-grained view of knowledge structure may provide a more predictive and explanatory account of students' reasoning.

Rodriguez et al. (2019a) examined one key type of intuitive knowledge, called "graphical forms," which are simple ideas associated with a graphical pattern. As a basic example, a student might associate a graph's steepness with the idea of rate, a graphical form aptly named *steepness as rate*. However, this work has focused only on a sub-category of graphical knowledge elements, namely intuitive associations with the graph (curve) itself. In our work, we began to realize there were other types of such knowledge, beyond only graphical forms, making up a significant portion of students' graphing activity. These resources also seemed related to other phenomena identified in the literature, such as misconceptions, covariation, and conventions, suggesting that such fine-grained knowledge plays a significant role across all of students' graphical reasoning. We consequently directed our attention to the research question: What are various types of knowledge resources students use when constructing or interpreting graphs?

Theoretical Framing

We align with the *knowledge in pieces* (KiP) paradigm (diSessa, 1988; diSessa & Sherin, 1998), which moves away from viewing knowledge as consisting of large unitary objects toward viewing knowledge as a complex system of individual elements (diSessa et al., 2016, p. 30). We call such individual knowledge elements "resources" (Hammer, 2000). Resources can be very simple and intuitive, such as diSessa's examples from physics of *force as mover* or *more effort begets more result* (1988, p. 53). These resources can work together to direct thinking, and the context directly influences which resources are employed (diSessa, 2004). That is, not all resources associated with a given idea are activated in all situations (diSessa & Wagner, 2005). In fact, KiP would view an important part of gaining expertise as reorganizing resources and learning to appropriately apply them in the right contexts (diSessa, 2002).

Sherin (2001) applied the KiP paradigm to students' understanding of equations and mathematical expressions. He called resources that pair a conceptual idea with a specific symbol structure a "symbolic form." Some examples are pairing the structure [] + [] with the idea of *parts of a whole*, or the structure [] – [] with the idea of *competition*. Rodriguez et al. (2019a) then took the idea of symbolic forms and extended it to graphs, called "graphical forms", with a similar idea of pairing a conceptual idea with a specific aspect of a graph. Some graphical forms identified in the literature are *steepness as rate*, *straight means constant rate*, *curve means changing rate*, and *intersection means same* (Elby, 2000; Rodriguez et al., 2019a; Rodriguez et al., 2019b; Rodriguez et al., 2020). A longer library of 26 graphical forms can be found in (Rodriguez & Jones, 2021), and include forms related to points (e.g., *point as instance*), cardinal directions (e.g., *horizontal as constant value*), trends (e.g., *plateau as leveling off*), smoothness (e.g., *curved means realistic*), local features (e.g., *jump discontinuity means sudden*), position (e.g., *displacement as difference*), and pairs of graphs (e.g., *transformation as same*).

Yet, graphical forms may not be the only type of fine-grained knowledge resource students use. In fact, we believe various types of small-scale resources may relate to many of the larger-scale phenomena seen in prior research. In our work documenting graphical forms, we began to identify other types of resources that seemed important for how students constructed or interpreted graphs. This paper contributes by presenting these other types of resources (which we generally call "graphical resources") and attending to how our graphical resources categories relate to other research on graphing, including misconceptions, covariation, and conventions.

Methods

To examine students as they constructed and interpreted graphs, we created two separate task-based interviews (Goldin, 1997). In the first interview, students were given four different contexts involving real-world quantities and were asked to construct a graph of one quantity as a function of another. In the second interview, students were shown various graphs representing mostly real-world contexts and were asked to discuss what the graphs indicated about the contexts. Figure 1 (top of the next page) contains very brief summaries of the tasks used in the two interviews. Some graphs were taken from or based on a common calculus textbook (Stewart et al., 2021), and others were taken from or based on graphs used in past research (Carlson et al., 2002). Two of the "construction" tasks used time-based graphs, while two used non-time-based graphs because of the research showing students' potential overreliance on time (Bowen et al., 1999; Jones, 2017; Rodriguez et al., 2020).

We interviewed students in pairs to permit discussion between them and to help make their thinking visible. We recruited 12 students from two different universities, resulting in six pairs. All pairs participated in both interviews, with the two interviews separated by a few days. We recruited students from first-semester calculus courses, to ensure they had familiarity with graphs and graphing (Patton, 2002). We gave the students pseudonyms that suggest their pairings: Anna/Aria, Berto/Blaine, Cindy/Caleb, Donato/Demyan, Ellie/Eric, and Fiona/Felicity.

Brief Summaries of Interview 1 Tasks (Construction)			
1. Graph temperature of a frozen pizza that is thawed and baked as a function of time.	2. Graph the grass height of a lawn as a function of time over the summer.	3. Graph the volume of soda in a bottle as a function of the soda height.	4. Graph the distance a puck would travel as a function of the surface's friction.
Brief Summaries of Interview 2 Tasks (Interpretation)			
1. Graph of runners in a race over time. 	2. Graph of position of a remote controlled car over time. 	3. Graph representing temperature at different elevations. 	4. [Various mathematical graphs from a textbook were given. Students were asked to compare and contrast them.]

Figure 1. Brief summaries of the tasks given to students in the two interviews

We analyzed the data as follows. We first divided the interviews into "units of meaning" (Campbell et al., 2013) based on the focus of the students' statements, writing, gestures. This is distinct from dividing interviews based on speaking turns or pauses because it retains the focus on keeping a student's explanation intact. These units were bounded based on discussion turning to a different idea or moving in a different direction. Within each bounded episode, we identified candidate knowledge resources. We inferred these resources by what the student said, gestured, and wrote, while keeping the context of that bounded episode in mind. Our focus was on inductive thematic saturation (Saunders et al., 2018), which emphasizes the generation of new codes. Thus, we were initially very inclusive regarding the list of resources we created. Once we had generated this large list of potential resources, our next analytic action was to refine this list by identifying resources that were largely the same (and combining them) or occasionally recognizing that a candidate resource actually contained two separate ideas (and separating them). We then took our refined list and created larger-scale themes (Braun & Clarke, 2006) that categorized the final list of resources into different graphical resource types. Because the category *graphical forms* already existed, we used that category as an a priori category, but five other categories emerged inductively through our analysis, for a total of six categories.

Results

The six categories of graphical resources we identified were: (1) *graphical forms resources*, (2) *framing resources*, (3) *convention resources*, (4) *ontological resources*, (5) *quantitative resources*, and (6) *function resources*. Because *graphical forms* have been discussed in detail in the literature (see Theoretical Framing section), we do not focus on them in this paper.

Framing Resources

The first category, called *framing resources*, involved resources that paired a simple idea with any aspect of a visual graphical image that was not the graph curve itself, such as the axes, the origin, or blank sections. *Framing resources* are important because they reflect ideas related to aspects of the representation that cue the reader into the context of interest, while also physically encasing (or literally "framing") the graphical curve. To illustrate a few resources in this category, consider Cindy and Caleb, who had started the pizza temperature context by drawing axes. Caleb at first labelled the major waypoints of being thawed, baked, cooled off, and placed back in the fridge (Figure 2). However, Cindy countered with the following:

Cindy: I don't know if this is the best way to represent it, but I feel like you should have some way to represent that the intervals of time aren't the same in between thawing [Th], baking [B], and other stuff like that [C and F].

Figure 2. Caleb's uniform spacing that Cindy felt indicated equal times

Here, Cindy expressed that the equal spacings on an axis indicated equal amounts of time. We call this resource *spacing means duration*. To illustrate another framing resources that, by contrast, dealt with the origin, consider Anna and Aria, working with the same pizza context, who were discussing where to start their graph.

Aria: I just feel, I like starting at the corner [i.e., the origin] … When I start at zero [i.e., the origin], I know that I can like, just go from there. I see it as a starting point.

Aria appeared to draw on a resource we call *origin as starting point*. Interestingly, she and Anna later decided they did not know enough about the Celsius scale (which has freezing point at 0ºC), and chose to use a Fahrenheit scale instead. In this case, rather than starting at the origin, they started at a point on the *y*-axis, in a similar resource we call *y-axis as starting point*.

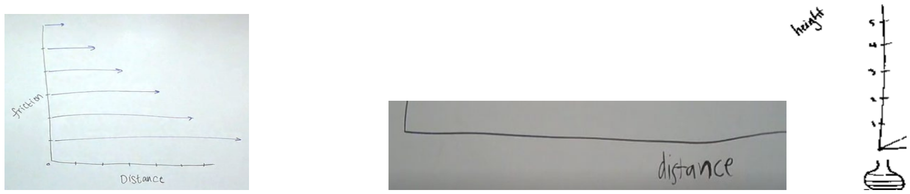
Overall, we found many of these *framing* graphical resources, including some we called *axes need labels, axes need scaling, squiggle means skip*, *y-axis maps to key moment, negative means backward, "+/–" as opposites,* and *axis arrows as continuation*.

Two Types of "Belief" Resources

In our analysis looking for fine-grained resources students used, we identified two separate categories of intuitive "belief-based" resources, regarding implicit assumptions about graphs.

Ontological Resources. The first category of belief-based graphical resources dealt with intuitive beliefs about the very nature of graphs themselves. Thus, we chose to call these *ontological resources*. In fact, one major item in the graphing literature, *graphs as pictures* (Beichner, 1994; Elby, 2000; McDermott et al., 1987), could be reinterpreted as a particularly common and oft-used ontological resource. Here, students believe a graphical image should reflect a picture of the situation. Relevant to our work, we assert that characterizing this as a stable misconception does not adequately capture nuances in students' reasoning and the ways in which this could reflect productive decisions in certain contexts for constructing graphs. Figure 6a below, which is the graph Anna and Aria initially produced for the friction-distance task, shows an example of this ontological resource in action. They claimed that each arrow was one sliding puck at a given friction level. For these students, this reflected an accessible graphing approach that visually resembles the physical scenario while illustrating the expected observation that higher friction (vertical axes) is associated with a shorter distance (horizontal axes).

However, our analysis also revealed a softer version of this ontological resource, in which a graph preserves only a specific visual stimulus. For example, Figure 6b shows the placement of "distance" in the friction task on the horizontal axis and Figure 6c shows the placement of "height" in the bottle task on the vertical axis. While these are certainly fine, mathematically, it did conflict with other student beliefs (see next section) that the independent variable needs to be on the horizontal axis. This result suggests that maintaining visual similarity between the graph and the physical scenario may have a particularly high cueing priority (see diSessa, 1993).



(a) (b) (c)

Figure 6. (a) graph as picture; (b) and (c) preservation of key visual stimulus

While *graphs as pictures* and the softer *graphs preserve visual features* were common, they were not the only ontological resources. For example, when Cindy was interpreting the graph in the atmosphere task, she explained,

> *Cindy*: You can kind of narrate the graph. So, you could be like, as you go up in the troposphere then the temperature… steadily decreases … And then once you get to the stratosphere, then it stays relatively the same for about 10 kilometers…

Cindy drew on a ontological resource we call *graph as a story*. Students held other ontological resources, too, such as *graphs as collections of points*, *graphs as connect-the-dots*, or *graph continuation* (which dealt with the assumption that graphs persist outside the viewing window).

Convention resources. The second type of "beliefs-based" resource were more about fine-grained beliefs about what students considered appropriate graphical practice. That is, rather than being about the *nature* of a graph, these dealt with common social practices (i.e., conventions) (see Moore et al., 2019). Thus, we call these *convention resources*. In fact, based on our work, we believe that much of the convention literature could be reframed to fit within a KiP paradigm. In the following excerpt, Ellie and Eric were working on the bottle task and explained their choice to put volume on the vertical axis and height on the horizontal axis.

> *Eric*: From like the reading of it, 'cause it says as a function of the height. That makes me assume that the height is your independent variable, which is on your *x*-axis [points to horizontal axis] and your volume is on your *y*-axis, because it's the dependent variable.

This excerpt contains evidence of three different convention resources. The first is a very common one already described in the literature, where it is believed the independent variable must be on the horizontal axis (Moore et al., 2014). A second related resource is that the *other* variable (ostensibly, the "dependent" variable) must be on the vertical axis. A third, and new, convention resource seen in this excerpt is that the horizontal axis *is* the "*x*-axis" and the vertical axis *is* the "*y*-axis." That is, "*x*" and "*y*" are essentially the names of the two axes.

Other convention resources dealt with axis direction and scaling. In the pizza task, Anna said,

> *Anna*: Time's going to increase this way [slides hand rightward along horizontal axis]. Temperature, I'm assuming we're going to say it increases [slides hand upward along vertical axis].

Here we can see the simple intuitive idea that *right means increase* along the horizontal axis and *up means increase* along the vertical axes. Note that this is not a graphical form, because the intuitive idea is not coupled with the graph itself, but is rather about the axes. Also, we call these convention resources, because it is not necessary for those directions to mean "increase." In fact, during the friction task, Caleb decided to have the horizontal axis represent *decreasing* friction:

> *Caleb*: 'All' friction to me is zero (i.e., at the origin) … It's weird, I know. But regardless … 'all' friction to me is zero. To me, the x-axis is the amount of friction that is *not* present.

The convention resource Caleb appeared to draw on was *direction is relative*, allowing him to decide that he could control which direction meant "increasing." Thus, convention resources can at times involve a recognition of the malleability of conventions (Thompson, 1992).

Overall, we identified many convention resources, including *π implies trig*, *origin is relative,* and *graphs read left-to-right*. Again, we propose that the convention literature might be considered a subset of graphical resources, in that these conventions are often simple, intuitive, and even implicit, ideas students associate with a graphical system.

Quantitative Resources

Another category of graphical resources related to quantities' relationships with contextualized graphs, which we call *quantitative resources*. These resources may be specific to graphs that represent real-world situations. While there were fewer resources in this category, they seemed quite impactful to students' thinking. To illustrate, students had particular ideas associated with what counted as "independent," influencing how they set up their graphical axes. When explaining why time was the independent variable in the pizza context, Anna explained,

> *Anna*: Like, time is going to march on no matter what happens.

We call this *independent as marching on*. The students' work often suggested this resource's use. For example, the bottle task stated height as the independent variable, leading both Eric and Caleb to inaccurately claim that height increase was consistent (or "constant" in their words).

> *Eric*: The height is the constant increase.

> *Caleb*: The height will always increase at the same pace.

In this context, volume might actually be considered the more steadily increasing quantity. This resource actually led several students to want to put the volume on the horizontal axis, even though it conflicted with their resource of "function output" being on the vertical axis.

This resource was strong enough that some students wanted certain graphs to be with respect to time, even when they were not. We call this *time as natural independent*. For example, In the bottle context, Anna and Aria were trying to make sense of height as an independent variable.

> *Anna*: It's weird. 'Cause it's not over a function of time like we've had in the last two graphs … Time feels way easier to me, but that's just me.
> *Aria*: …Time's pretty good and constant, in a sense … time goes constant.

Even when students did use non-time independent variables, they often spoke of it as "marching on" in real time, such as Blaine saying in the bottle context, "We're pouring in a constant volume at each interval of time."

Function Resources

Due to space constraints, we end our results by simply stating there was an additional category of graphical resources, *function resources*, though these figured into the students' reasoning less significantly than the others. Function resources were evidenced when students used explicitly function-based ideas to shape their graphical thinking. Some resources here were *input-output pair*, or *recall of graph shape*.

Discussion

Our contribution has been to expand the work on the fine-grained knowledge resources that students use when constructing or interpreting graphs. We identified six categories of resources students employed in their graphical thinking. This work is important, because these small-scale ideas tended to heavily influence how the students operated graphically, including where to start, how to put pieces of the graph together, how to put surrounding features together (e.g., axes), and what a graph is meant to convey. Collectively, an emergent combination of these graphical resources accounts for a lot of observed graphical activity. In fact, we claim these fine-grained graphical resources may underlie a much what has been discussed in the graphing literature.

For example, consider the work on misconceptions (e.g., Beichner, 1994; McDermott et al., 1987), in which the inferences students draw from graphs are often seen as larger, unitary mental objects. This perspective provides little explanatory and predictive power related to students' reasoning and how instruction can support students (Elby, 2000). Suppose a student sees a straight-line graph with axes that use a logarithmic scale. If a student thinks that the quantities vary linearly, a misconception perspective might posit the student does not understand logarithmic scales. However, it is possible this student is simply invoking the intuitive notion of *spacing means duration*, an assumption that has "worked fine" in the students' past experience (diSessa, 1988). There may be no stable misconception to replace; rather, the student may simply need to be redirected to the fact that *spacing* means something different in this context.

Next, consider the work on covariation (e.g., Carlson et al., 2002; Johnson, 2015; Moore et al., 2013; Thompson & Carlson, 2017). We believe our fine-grained approach can add clarity on how students go from covariational reasoning to a produced graph. That is, much of what is described in the covariational literature is fundamentally *quantitative*. The ideas of one variable increasing as another variable increases, or of tracking the changes in their values, are not inherently graphical. We posit that it takes these fine-grained graphical resources to translate the *quantitative* nature of covariational reasoning into a graphical inscription.

Finally, some important work has been done framing graphing as a situated social practice (Roth & Bowen, 2001, 2003) with community conventions (Moore & Silverman, 2015; Moore et al., 2019). We believe social practices are comprised of many small-scale beliefs that can be flexibly invoked, or not, given a certain context. For example, a student can hold ontological assumptions such as *graph preserves visual stimulus* and *graph as a story* simultaneously. Rather than one of these defining how a student operates for all graphs, they are both fine-grained beliefs that might be activated at different times, depending on the context. Furthermore, we note that some of the graphical resources related to features like the axes (e.g., *axes need labels*) reflect assumptions or beliefs about the nature of graphs or conventions related to graphical activity. This is important because of the way in which these simple ideas influence students' choices about how to proceed with a graphing task (e.g., convention resources such as *independent on horizontal* or *up means increase*).

Together with the previously described graphical forms, the various categories of graphical resources we have described in this paper can greatly enhance our ability to identify the knowledge and ideas students are using when creating or interpreting graphs. We assert this has the potential to serve as a foundation and a unifying perspective that incorporate the many different perspectives used in the graphing literature.

How Students Reason about Compound Unit Structures: m/s^2, ft-lbs, and (kg·m)/s

Intensive quantities result from quantitative operations on two or more extensive quantities. As such, their units of measure consist of "compound units." Students regularly encounter symbolically-written compound unit structures that are directly given to them, rather than constructed or developed, such as m/s^2, ft-lbs, or kg·m/s. It is consequently important to understand how students might try to reason about such symbolically-presented compound unit structures, which is the focus of this study. We examined "ways of reasoning" students used to make sense of such units, and describe in this paper five themes that emerged during analysis: (1) decomposing into separate units, (2) treating units as variables, (3) using covariational/ multivariation reasoning, (4) posing a quantification, and (5) bringing in pure math concepts.

Keywords: units, quantities, intensive quantities, compound units, ways of reasoning

Introduction and Brief Literature Review

In recent years, mathematics education has taken seriously the need to attend to students' quantitative reasoning (Johnson, 2016; Smith & Thompson, 2007; Thompson, 2011). While quantities might at first seem to be outside the realm of pure mathematics, such reasoning can be important for mathematical sense-making, deeper understandings, and being able to productively use mathematics outside of the mathematics classroom (Ellis, 2011; Jones, 2015, 2022; Moore, 2014; Moore et al., 2020; Thompson, 1994, 2011). Some quantities, called *extensive* quantities, have been defined as being directly measurable using a simple unit, such as length or volume. Other quantities, called *intensive* quantities, have been defined as not being directly measurable, such as speed or work (Kertil et al., 2019; Schwartz, 1988). In this definition, intensive quantities' units of measure consist of *relationships* between other quantities (Lesh et al., 1988). The way we symbolically write unit structures for intensive quantities, called *compound units*, usually suggests the quantitative operations done to achieve the measure, such as *m/s* suggesting a proportion (and hence division) between distance and time quantities (Thompson, 1994).

Much of the work on intensive quantities has focused on the construction of fairly simple intensive quantities and their units of measure (Bowers & Doerr, 2001; Johnson, 2012; Kertil et al., 2019; Thompson, 1994, 2011), or on how reasoning about rates and ratios is beneficial for mathematical learning (Ärlebäck et al., 2013; Boyce et al., 2020; Byerley, 2019). Yet, students regularly encounter more sophisticated intensive quantities and their symbolic compound unit structures, such as m/s^2, *ft-lbs*, or (*kg·m*)/*s*. Further, because context is often in the service of other mathematical learning goals, these compound units are typically given directly, rather than constructed. To use context and quantities effectively, it becomes critical to understand how students might think about these symbolically-presented compound unit structures. This paper contributes by explicitly examining how students might approach reasoning about these compound units. That is, we did not focus on the process of quantity construction, but rather on how students reason about given compound unit structures. Our research question was: What *ways of reasoning* do students use when presented with symbolic compound unit structures?

Theoretical Perspectives: Quantities, Reasoning, and Quantitative Reasoning

Our examination of students' *ways of reasoning about compound unit structures* is based on our theoretical perspectives on (a) quantities, (b) reasoning, and (c) quantitative reasoning. For quantities, we used Thompson's (1990, 1994, 2011) definition: a quantity is a cognitive entity that consists of an object or system, some attribute of that object or system, and a conceivable way to measure that attribute. The last of these defines the "unit" of measure, and it is common practice, for intensive quantities, to symbolically represent that unit in a way that suggests the relationships and measurement process (e.g., *m/s*). In this way, the symbolic unit structure is not necessarily an intrinsic part of a quantity, but is a widespread way to refer to it. However, more complicated compound units might obscure those relationships, such as using a "square" in m/s^2.

We define a way of reasoning as the "activities that students engage in while solving, explaining, justifying, identifying, and so on" (Hohensee, 2014, p. 136; see also Gravemeijer, 2004; McClain et al., 2000). Thompson (1990, 1994, 2011) defines *quantitative reasoning* as a special type of reasoning, specifically "the analysis of a situation into a quantitative structure" (1990, p. 12). Yet, this definition requires that the person start with some situation and then proceed toward a structure, and perhaps a symbolic representation of that structure (e.g., a formula, a unit, or an equation). We believe that students often might be in positions of needing to reason in the opposite direction, from a more complicated symbolic unit to an idea of what that compound unit means. It is this reverse act of quantitative reasoning we focused on in our study. Thus, we define a *way of reasoning about a compound unit structure* as the mental activities one employs when attempting to make sense of a given symbolic unit expression.

Methods

The data used for this paper comes from a 30-minute task-based interview (Goldin, 1997), in which students were shown symbolic compound unit structures and were asked to describe what they meant. This interview protocol thus mimics how we believe students often encounter unit structures in normal educational settings – without specific direction. Of course, the interview contained the artificial directive to make sense of that unit, meaning students' responses were very likely *in-the-moment* rather than *stable* (Thompson et al., 2014). The tasks were chosen to include compound units for different types of intensive quantities: (a) a rate within a rate, (b) a double-proportion (Thompson & Saldanha, 2003), and (c) a double-proportion within a rate:

- You have probably learned about acceleration, which can have this unit in the metric system [m/s^2 written on paper]. What does this unit mean?
- In science, "work" is defined as a product of force and distance, $W = F{\cdot}d$. If F is measured in pounds and d is measured in feet, what does this unit for work [*ft-lbs*] mean?
- In metric, "momentum" has this unit [$\frac{kg{\cdot}m}{s}$ written on paper]. What does that unit mean?

10 students (5 female, 5 male) participated in the interview, recruited from four different first-semester calculus classes at a single large university. The recruitment cite was purposeful (Patton, 2002), so that the students would have had exposure to different types of units in math or non-math classes (confirmed by most students' own statements). Our data analysis focused on identifying students' *ways of reasoning*. Analysis began simply by having each of us independently summarize the students' work on each task. We used these summaries to partition the interviews into bounded "reasoning" episodes, beginning when a student started to reason about the unit in a particular way and ending once that train of thought concluded. The students often had several "reasoning episodes" on a single task. Within each reasoning episode, we qualitatively described the actions the students seemed to be taking, based on what they said,

wrote, and gestured. We then grouped related ways of reasoning into distinct themes (Braun & Clarke, 2006), but also tracked variations within each theme. We were less concerned about normative correctness or robustness, and were mainly focused on identifying themes of *how* students approached reasoning about these symbolic unit structures, when asked to.

Results

We organize our results around the five different *way of reasoning* themes we identified.

Way of Reasoning Theme #1: Decomposing into Separate Units

The first theme involved ways of reasoning based on mental actions that split the compound unit structure into separate units, and imagining quantities associated with each part.

Decomposing m/s². For m/s^2, the students employed this reasoning in several different ways:

> *Student 1*: I think of it more as meters per second [writes *m/s*], speed. And an increase in meters per second, per second. This [points to *m/s*] is a rate, and then this [points to m/s^2] is a rate over time, so a change in rate.

> *Student 6*: Acceleration is a velocity over a given amount of time. And, I'm trying to think if that velocity, which is a distance over time, needs to be the same unit of time. [Later:] My natural thinking would put it [i.e., velocity] in meters over seconds… Then I would say it's [i.e., acceleration] over this amount of seconds as well [i.e., the same time value as velocity].

> *Student 10*: So the difference [i.e., between velocity and acceleration] would be the seconds being squared… Say your velocity is you're traveling 1 meter in 2 seconds [writes "$\frac{1\,m}{2\,seconds}$"]. Then, it [i.e., acceleration] would be 1 meter per every 2 seconds squared or 4 seconds [writes "$\frac{1\,m}{4\,seconds}$"].

Student 1 parsed the unit m/s^2 into a well-defined rate (velocity, *m/s*) and a separate well-defined extensive quantity (time, *s*). While Student 6 parsed it similarly, his issue was wondering if the two *s*'s in *m/s* and *s* represented the same time value. The quantities associated with *m, s,* and *s* seemed to retain extensive features for him (as opposed to combining distance and time into a well-defined rate quantity), such that both *s*'s were seen as the same extensive quantity. Student 10 broke up the unit quite differently, into two extensive quantities associated with *m* and s^2. The s^2 seemed to just signify "time," where its value was simply squared.

Decomposing ft-lbs. While *ft-lbs* can only be decomposed into *ft* and *lbs*, students still had different ways of reasoning about the decomposition, as seen in these two excerpts:

> *Student 2*: Maybe in units of, like, pounds-feet, like, you have this many pounds and you have to bring it 1 foot or 2 feet, or 1-foot or 2-foot or 3-foot increments.

> *Student 9*: It is quite literally the pounds of force times the amount of distance it is. So, if you're pushing on something with 20 pounds of force over 10 feet, that's 200 pound-feet.

The main difference was the relationship imagined between the quantities force and distance. Student 2 fixed one quantity (force) at a certain amount, and thought of it being iterated over the other quantity (distance). By contrast, Student 9 seemed to reason about pounds and feet as, essentially, separate quantities that did not interact other than through a multiplication procedure.

Decomposing $\frac{kg\cdot m}{s}$. There was even greater variety to how students decomposed $(kg\cdot m)/s$:

> *Student 1*: You could figure out, with an object's mass and its speed, you would have its momentum. And that would be, you can compare objects of different sizes and different speeds to each other.

> *Student 8*: So, a kilogram is the weight of something, I guess, right. And meters is how far it can travel, given an amount of time. So, like, if we have something that weighs 100 kilograms, and it goes 10 meters, and let's say 10 seconds, then that would mean momentum is 100.
>
> *Student 5*: So, weight over time times distance over time [writes "$\frac{kg}{s} \cdot \frac{m}{s}$"].
>
> *Student 10*: So, this top part [circles "*kg·m*"] is work. I know work equals, because that would be a weight times, or a force times a distance. So, we have work per second.

Student 1 broke the unit into an extensive mass (*kg*) and an intensive velocity (*m/s*). Student 8 broke up the unit into three separate extensive quantities (*kg, m, s*). Student 5 mistakenly broke it into two separate intensive quantities (*kg/s* and *m/s*). Student 10 grouped the unit by its numerator (*kg·m*) and its denominator (*s*), incorrectly associating (as other students did, too) "*kg*" with weight or force. This led him to associate this unit with the rate of change of work in time.

Way of Reasoning Theme #2: Treating Units as Variables

The second theme involved ways of reasoning that essentially interpreted the symbols in the unit structure as though they were algebraic variables instead.

Units as variables, m/s^2. Several students justified for themselves the appearance of m/s^2 using reasoning that cast "*m*" and "*s*" as if they were mathematical variables, such as *x* or *y*.

> *Student 8*: If it's the change in speed over time, then it's change in *m s* over *s* [writes "$\frac{m/s}{s}$"]. So then it's like *s* over 1 [writes "*s*/1" in denominator], and then if we flipped it up like that, then it would be, it'd just be meters divided by *s* times *s*. Or meters times 1 divided by *s* times *s* [writes "$\frac{m \cdot 1}{s \cdot s}$"], so it would be meters divided by seconds squared [adds "= m/s^2"]. That makes more sense.

Student 8's reasoning reflected algebra work. If we swapped the symbols *m* and *s* for *x* and *y*, the reasoning follows the operation of: $\frac{x/y}{y} = \frac{x/y}{y/1} = \frac{x}{y^2}$. The units' symbols, at this moment, were not being treated as units of measure for quantities, but rather as if they were variables. This result suggests that students may blur the line between symbolic units and quantities' values.

Units as variables, ft-lbs and $\frac{kg \cdot m}{s}$. The students also treated symbolic units as variables to justify to themselves why work had the unit of *ft-lbs* and momentum had the unit (*kg·m*)/*s*.

> *Student 10*: Force is measured in pounds. And distance is measured in feet. Pounds times feet.
>
> *Student 3*: If you take away kilograms, it's just meters per second [writes "*m/s*"]. And then you're multiplying by kilograms. You multiply by kilograms over 1 [writes "$\frac{m}{s} \cdot \frac{kg}{1}$"], because that's kilograms. And because of math, kilograms times meters over seconds [adds "= $\frac{kg \cdot m}{s}$"].

As before, these symbolic units are described as though being algebraically operated on. Student 10's use of pounds × feet is similar to the operation $x \times y = xy$, and Student 3's reasoning about mass × speed follows the algebraic steps of $(x/y) \cdot z = (x/y) \cdot (z/1) = xz/y$.

Way of Reasoning Theme #3: Using Covariational or Multivariational Reasoning

The third way of reasoning theme appeared to be based on a student having already *decomposed the units* and treated them *as variables*. After doing so, some students employed covariational or multivariational reasoning on the unit structures themselves (see Carlson et al., 2002; Jones, 2022; Thompson & Carlson, 2017). In short, covariational reasoning is the coordination of (usually) two variables changing in relation to each other, and multivariational reasoning is the coordination of more than two variables changing in relation to each other.

Covariational Reasoning, m/s^2. In conjunction with how the students decomposed the unit m/s^2, they used that decomposition to covary the quantities imagined as associated with the parts:

> *Student 7*: You have 1 second, 2 seconds, 3 seconds [draws a line and marks these on it]. And right here [points to interval prior to 1 second], the guy's bookin' it, he's going 10 meters per second. And then right here [points between 1 and 2 seconds] he's bookin', he's going 12 meters per second… Whenever you have meters per second squared, you're changing every time. Like every second, this number [points to 10 *m/s*] is changing.

> *Student 4*: If you were doing *s* is equal to 2, that's [i.e., s^2] going to be 4, because 2 squared is 4. And meters was 6. And then if we say seconds was 3, so 3 squared is 9. But then it [meters] was 20.

Student 7 had broken the unit up as *m/s* and *s* and described how the velocity value would change for different times. Student 4 had split up the unit as *m* and s^2, and thus covaried between time and distance. As s^2 changed from a value of 4 to 9, the value of *m* changed from 6 to 20.

Covariational/Multivariational Reasoning, ft-lbs. For the *ft-lbs* task, the students struggled to coordinate force (*lbs*), distance (*ft*), and work (*ft-lbs*) all together. Instead, they usually ignored the work value while only coordinating force (*lbs*) and distance (*ft*):

> *Student 1*: I think of it as, if you use a certain amount of force, then it's going to go a certain distance. And if you use less force, it going to go less distance. And if there's a greater force that's necessary to have it moved, then it's going to move less.

However, a couple students did attempt to coordinate all three quantities, as in this excerpt:

> *Student 2*: Because, like your work's going to obviously be less if you have to carry it, like, or move it a shorter distance versus a longer distance. But also it's going to increase with your pounds.

A final important part of the students using covariational reasoning with the *ft-lbs* unit structure is that some of them had a strong tendency to want the unit to reflect a *rate* rather than a double proportion. For example, Student 6 began this task by explaining:

> *Student 6*: I was just thinking that it'd be like, pounds over a given amount of distance [i.e., *lb/ft*]. But that's literally saying the opposite. Because this [$W = F \cdot d$] is multiply those two together, while putting it in that fashion of saying pounds over a certain amount of feet is in a sense a fraction.

Covariational/Multivariational Reasoning, $\frac{kg \cdot m}{s}$. The momentum context has several potential quantities: mass, distance, time, momentum itself, and possibly velocity or even (nonnormatively) "work", depending on the quantities the students envision. The students similarly used the mental action of fixing certain quantities in order to say how others varied.

> *Student 1*: If we're talking about something that goes, let's say 20 kilogram, going 1 meter per second. That's kind of a heavier object going very slowly. And that's going to have the same momentum as a 1 kilogram object going 20 meters per second.

> *Student 3*: Momentum is completely different for two different masses. Because of the difference in masses. The momentum of an entire planet is way different than the momentum of a marble.

Student 2: So, it's in like units of, to move 1 kilogram moving 1 meter per 1 second. And then that's your momentum. And your increments of momentum you'd be working with… So whatever your number means, that's how many times the momentum, that 1 kilogram over 1 meter over 1 second kind of a thing.

Student 1 had broken the unit into *kg* and *m/s*, and then held momentum constant to see the covariational relationship between mass and speed for a fixed momentum. By contrast, Student 3 held parts of the unit-quantities constant (distance and time) to imagine covariation between mass and momentum. Student 2 fixed each of the individual quantities (mass, distance, time) to "1", and then imagined them being iterated in order to create more units of "momentum."

Way of Reasoning Theme #4: Posing a Measurable Attribute

The fourth general way of reasoning involved imagining some attribute the unit might be associated with measuring. All of the students did so on their own, even though they had not been expressly asked to engage in a quantification process, indicating that imagining a quantity might be a common way for students to try to reason about a symbolic unit structure. Yet, they did not seem to think in terms of *unit → quantity → attribute*, but rather directly from *unit → attribute*, suggesting that students may blur the line between a quantity and its symbolic unit.

Posing an Attribute, m/s^2. The students knew that m/s^2 was a unit for acceleration, but when asked what the unit meant, they associated several "attributes" with slight nuances. These included: (a) speed change, (b) going faster or slower, (c) a distance-time relationship, (d) speed at a specific moment, and (e) speed duration over time. We note that (c), (d), and (e) are normatively incorrect, and (b) is ambiguous, as moving fast does not guarantee acceleration.

Posing an attribute, ft-lbs. When asked what "*ft-lbs*" meant, the students similarly associated several potential "attributes" with the unit. These included: (a) an acting force, (b) a sense of effort, (c) a torque (rotational), and (d) a change in kinetic energy. We note that (a) is normatively incorrect and that (b) is ambiguous, as effort and work are not necessarily equivalent. Also, while Student 9 was correct that *ft-lb* was a unit of measure for a change in kinetic energy, he was incorrect to also equate it to the change in velocity of the object.

Posing an attribute, $\frac{kg \cdot m}{s}$. The students created an even wider variety of attributes that they associated with *kg·m/s*. These included: (a) the strength of a collision, (b) the difficulty in stopping an object, (c) the damage or "hurt" done by an object, (d) the effort to move an object, (e) how far an object wants to move, (f) a mass in motion, and (g) an amount of time to cover a distance. Several of these attributes are well-connected to "momentum," though others are problematic, including an amount of time, a distance, and an effort to move an object.

Way of Reasoning Theme #5: Bringing in Related Mathematical Concepts

The final way of reasoning theme involved the activation and usage of related "pure" math knowledge, by which we mean knowledge pertaining to the abstract world of mathematics.

Using related mathematical knowledge, m/s^2. Several students invoked the derivative concept when reasoning about m/s^2. For example, Student 2 began this task by saying:

Student 2: Acceleration is the derivative of your velocity, which is how fast you're going. How many meters over a second. So, it's how much you're changing your velocity at any given point.

Bringing in the derivative helped Student 2 think about "speed over seconds," which then propelled her toward decomposing m/s^2 into *m/s* and *s* (see Theme #1).

Another pure math concept students invoked for m/s^2 was graphs. Student 9 used graphs to provide a reasonable justification for a velocity/time measure leading to the units $(m/s)/s = m/s^2$

> *Student 9*: [Draws a position-time graph:] So, as the slope is the change in position over time, which is exactly what velocity is… By the same vein, if we were to graph a velocity function [draws another graph labelled *v* and *t*]… Finding the slope at any given point of the velocity function gives the change in velocity over time at that moment, which is our acceleration.

Using related mathematical knowledge, ft-lbs and $\frac{kg \cdot m}{s}$. One pure math concept that the students used on occasion in reasoning about the *ft-lbs* and *kg·m/s* units was *factoring*:

> *Student 4*: Let's say there's 6 [*ft-lbs*]. There's some options like 2 and 3, or 6 and 1. So, then, if I travelled 3 feet and for each foot I traveled I applied 2 pounds, then overall the amount of work that was put in, is 6 foot-pounds.

Discussion

This study contributes by examining student reasoning in the "opposite" direction of how it is usually studied in the quantitative reasoning literature. That is, rather than examining the construction of a quantity and its unit (Bowers & Doerr, 2001; Johnson, 2012; Kertil et al., 2019; Thompson, 1994, 2011), we examined students' ways of reasoning when tasked with starting with the symbolically represented unit structure and reasoning from there. We posit that this is a common reasoning activity students need to do if we expect them to couple mathematical understanding with context and quantitative reasoning.

One important implication of our study is to problematize the frequent use of symbolic units for intensive quantities as though they are self-evident. A quantity like acceleration is frequently used in mathematics education to enrich understanding of mathematical concepts (Hitier & González-Martín, 2022; Roschelle et al., 2000; Schwalbach & Dosemagen, 2000; Taşar, 2010), but our study shows we cannot assume students have certain ways of reasoning about the unit structure, m/s^2. Our students exhibited many ways to reason, sometimes leading to normative interpretations and other times not. For example, while some students imagined m/s^2 to suggest a rate within a rate, $(m/s)/s$, others imagined it as suggesting a comparison between distance and time, m and s^2. Further, students struggled to make sense of *ft-lbs*, even though such double proportion units show up in algebra, trigonometry, and calculus (Stewart et al., 2021; Sullivan & Sullivan, 2009; Thompson & Saldanha, 2003), including "*person-hour*" tasks. Some students wanted *ft-lbs* to be a rate instead, *lbs/ft*, while others did not maintain a multivariational image between force, distance, *and* work simultaneously. Some students were also unsure of how to imagine $(kg \cdot m)/s$, either incorrectly associating *kg* with a force quantity, or treating all three as distinct extensive quantities (rather than a product of an extensive quantity and an intensive rate).

Our study sheds other useful light on how students think of symbolic units, as well. Students likely blur the line between a quantity, its value, and the symbolic unit used to represent a unit of its measure. The students regularly treated unit symbols, such as *m*, *s*, or *kg*, as though they were algebraic variables, even performing algebraic operations on them. Students also imagined potential attributes that were directly associated with the unit. Thus, rather than an image of a quantity as consisting of separate-but-related object, attribute, unit of measure, and value, the students seemed to freely blend these all together (and unproblematically, from their standpoint). Understanding these ways that students reason can help instructors be more attentive to what students might think when encountering contextualized quantities and units in learning math.

“The runner jumped back?”: Developing Productive Understandings of Symbolization Through Animations and Applets

Franklin Yu
Arizona State University

In this report, I discuss one potential role an applet plays in the context of a teaching experiment. Mathematics students are constantly tasked with understanding mathematical notation, which is often context-dependent or sometimes loosely defined. While the purpose of mathematical symbolization is to help mathematicians communicate concisely, researchers have indicated that students have difficulties understanding and utilizing mathematical notation to represent quantities. Therefore, examining the mechanisms by which students can refine their understandings into more conventional ones can be of value to the field of mathematics education. This study provides an example of using applets to help students engage in reflective discourse. The findings of this study indicate that giving students a medium to visualize their mathematics can support them in understanding what their mathematical symbolization actually represents.

Keywords: Symbolization, Applets, Desmos, Teaching Experiment, Average Rate of Change

Symbolization is an integral part in mathematics to represent quantities and operations. As mathematicians, we utilize numbers and symbols to encapsulate information (Pimm, 1991), such as $\frac{dy}{dx}$ to mean “the (instantaneous) rate at which the value of the variable, y, changes with respect to changes in the value of the variable x.” Comprehending and utilizing numbers and symbols is an essential skill in learning mathematics. However, researchers have indicated that students have difficulties interpreting and using mathematical notation to represent quantities (Tall & Vinner, 1981; Torigoe & Gladding, 2007; Chin & Pierce, 2019; Begg & Pierce, 2021). Therefore, investigating how students develop understandings of mathematical notation is an important area of research in mathematics education. Fonger et al.’s (2016) study is an example of the benefits of examining student learning with a focus on students’ representational fluency. Their study found that leveraging students’ ways of thinking supported their ability to reason quantitatively and utilize appropriate symbolization.

Theoretical Background

When a student engages in symbolizing or interpreting mathematical notation, they have an expectation of the calculations they envision and that the parts that compose an expression or formula represent a process of quantifying or representing quantities within a situation. This is what O’Bryan (2018) terms *emergent symbol meaning*. This perspective is important because symbols do not inherently carry meaning; instead, an individual interprets the notation based on their conception of the mathematical problem. For example, consider a situation involving an arithmetic sum of adding up the numbers 1 through 10 (inclusive). One student might utilize the expression $(1 + 10) * \frac{10}{2}$ [This would be of the form $\frac{n}{2}(a_1 + a_{10})$] to represent the process of adding up the first and last numbers and repeating this process $\frac{10}{2}$ times (i.e., 1 + 10, 2 + 9, 3 + 8, …). However, another student might write $\frac{1+10}{2} * 10$, to represent their conception that the average of this set of numbers is 5.5 (this holds true due to it being an arithmetic sequence), and they can imagine replacing all the numbers with 5.5 and adding those up 10 times ($5.5 * 10$). Despite using the same numbers and symbols, these students had different ways of conceiving the situation. Another student might incorrectly write $\frac{10}{2} * 10$ because 10 is the highest number of the sequence, and they want to find the middle number of the sequence (and thus write $\frac{10}{2}$) and then add that up 10 times. In this last case, the student can check that their result is incorrect but might not have the means to determine why their symbolization of the situation was incorrect (and how they might make refinements). This last case highlights the importance of determining how we can support students in reflecting on their symbolization and how we might assist students in making adjustments when they have an incorrect response.

One method of helping students reflect on their mathematics is the usage of animations and applets. According to researchers, animations can have an *enabling function* to help reduce the cognitive load (Mayer, 2001) and support reflective discourse by focusing the conversation on students' understanding (Cobb et al., 1997). One way to enable reflective discourse involves having students anticipate what they will see before the animation plays and then explain what they see in the animation (Schnotz & Rasch, 2005; Thompson, 2019).

In this study, I report on a teaching experiment that leveraged Desmos animations and applets. This report's research question is "What role does an animation or applet play in the context of reflective discourse?"

Methodology

This study was conducted by engaging 2 students in individual teaching experiments on the idea of rate of change. The teaching experiment involved six sessions that focused on characterizing and advancing students' ways of thinking about rate of change. In this paper, I discuss one of the sessions and how the students interacted with a Desmos applet.

Teaching experiment methodology (Steffe & Thompson, 2000) involves a sequence of teaching sessions that include a student, a teacher, a witness, and a camera to record each episode. A teaching experiment's purpose is to identify a start and ending point of student progress and how students construct knowledge as they progress through each teaching episode. The goal of a teaching experiment then is to hypothesize and test models of student thinking.

The Desmos Activity (a summary of the activity can be seen here: Desmos Activity)

In the teaching session, students were presented with a situation where a runner traveled 100 meters in 32 seconds at a varying speed (a non-constant speed). Students were tasked with

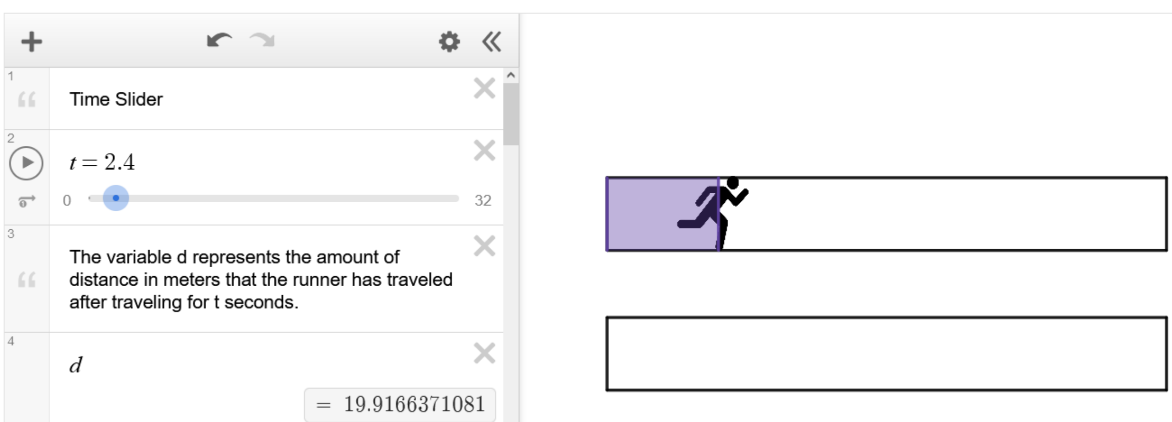

Figure 1: The Desmos Applet for the Runner Task

programming a function on Desmos to model the distance of a hypothetical runner that would run at the average speeds of the first runner in prespecified time intervals. On the Desmos applet (Figure 1) is a slider to vary the amount of time elapsed since the first runner started running (denoted by the variable, t). As students vary the value of t, the applet shows the value of d, the distance in meters that the first runner has traveled after traveling for t seconds.

Students are asked to program a second runner that runs at the average speed of the first runner over pre-defined time intervals. Initially, students are guided to split the 32-second interval (the total time the first runner took to travel 100 meters) into two equally sized time intervals and then utilize the first runner's average speed in each time interval as their programmed runners' constant speed. It is important to note that in the teaching session preceding this one, students developed a meaning for average rate of change as the constant rate of change that would achieve the same net change in the dependent quantity over the same change in the independent quantity. In this session, one goal was to support students in utilizing the value of a rate of change to determine how the related quantities of distance and time would covary. In this task, students were asked to define a function, b, where $b(x)$ represented the distance traveled by the programmed runner after traveling for x seconds. Some of the syntax needed to define a piece-wise function in Desmos was pre-made for the students to allow them to focus on defining a distance function by reducing the cognitive load (Mayer, 2001). As students progress through the activity, they are asked to program the runner using smaller and smaller time intervals with the eventual goal of making their programmed runner run at the same speed as the original runner (the goal is to form a basis for the idea instantaneous rate of change).

Results

This section discusses how the 2 students in the teaching experiment interacted with building the two-interval portion of the task and the role the Desmos applet played in supporting their ability to represent quantities with appropriate mathematical notation.

Scott

Scott was a first-year computer science major and had no trouble determining the appropriate average speeds for each interval. He used the time slider to determine the distance the first runner traveled by 16 seconds (67.098) and used this in his average rate of change expression, $\frac{67.098}{16}x$. However, for the next time interval, he wrote $\frac{100-67.098}{32-16}(x-16)$ (Figure 2). The interviewer then asked Scott what he attempted to represent with his expression. Scott replied that $\frac{100-67.098}{32-16}$ was the first runner's average speed in the second half of the race, and the expression $(x-16)$ represented an amount of time and together that would give you distance. He clarified that he wrote $(x-16)$ because "we have to worry about this interval and so total

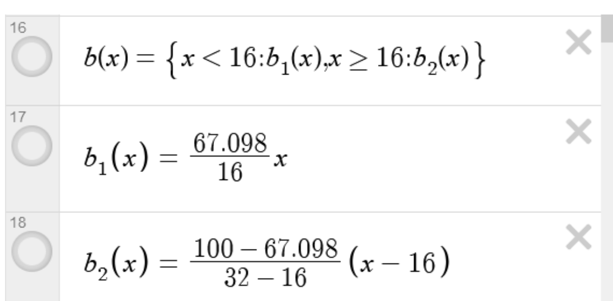

Figure 2: Scott's Initial Attempt at the Runner Task

time, x, that means we are taking away the first interval of time." His explanation suggested that he was using x to represent a number of seconds and that he conceptualized $(x - 16)$ to represent a new quantity, the number of seconds elapsed after the first 16 seconds of the race.

However, what was absent from Scott's second expression was the amount of distance traveled by the runner during the first 16 seconds of the race. The interviewer decided to press play on the animation to demonstrate what Scott's expression represented in this situation. When the time elapsed hit the 16-second mark, his runner jumped back to the starting position. Scott was surprised and stated "the runner jumped back?", and he paused to look at his expression, $\frac{100-67.098}{32-16}(x - 16)$. The interviewer then asked him what he attempted to represent and let the animation rerun. After watching the animation a second time, Scott remarked that he was missing the distance the runner had already traveled and proceeded to add 67.098 to his expression. He stated that he realized that his current expression only represented how his runner's distance would change, instead of his total distance traveled as time elapsed.

Throughout the rest of the teaching session, the Desmos applet played a pivotal role in supporting Scott in connecting his mathematical expressions with how he imagined distance accruing. The Desmos animation provided a visual representation of his mathematical expressions, and when the runner jumped back to the start of the race, Scott was perturbed by what he saw. Since Scott's expectation of what would happen did not align with what he observed, this prompted Scott to reconsider what quantities his symbols represented and then refined his function definition to accurately represent the quantitative relationships he intended. Having the Desmos animation display the runner's movement and distance from the starting line provided Scott with immediate feedback by displaying the quantities being represented by his expression. Seeing his programmed runner make an instantaneous jump back to the starting point prompted Scott to reconsider how to represent the distance he wanted to model (the distance of the programmed runner from the starting line as a function of time elapsed since the start of the race); in particular, he recognized that he needed both an expression to represent how that runner's distance would vary as time varied, $\frac{100-67.098}{32-16}(x - 16)$, and the initial distance already accrued (67.098 meters) after 16 seconds since the start of the race.

Hans

Hans was a first-year aerospace engineering major and in the previous teaching sessions, he struggled with associating quantities with a mathematical representation. Initially, during the 2-interval portion of the task, Hans only wrote the average speed, $\frac{67.098-0}{16-0}$, and then verbalized that he did not know what he needed to write to represent time passing. The interviewer used the time slider to show the first runner moving as time passed and asked Hans about how long the first runner had traveled for. Hans noted that it was whatever the value of the independent variable and then proceeded to "add time" to his previous expression by multiplying x to his $\frac{67.098-0}{16-0}$. He repeated this for the second interval by typing in $\frac{100-67.098}{32-16}x$, but he did not attend to x as representing the total amount of time elapsed; he also failed to include the distance the runner had traveled during the first 16 seconds (Figure 3a).

For the first issue, the interviewer hypothesized that Hans was thinking "rate multiplied with time equals distance" and was not yet distinguishing between total distance and distance varying within an interval (similar with total time and the amount of time elapsed in the interval). Before playing the animation, the interviewer asked Hans to explain what each portion of his expression represented. Hans identified the average speed for each interval and the amount of time elapsed and then noted that all together, it "represented a change in distance" (Figure 3b). Afterwards, the interviewer asked what the value would represent for specific values of time. Hans then noticed that he needed to change his second expression because "we need $(x-16)$ to account for the first 16 seconds of our race" and that"$(x-16)$ is our change in time from 16 seconds." Even though talking through what he was trying to represent helped Hans in making adjustments, he had not yet noticed his other error.

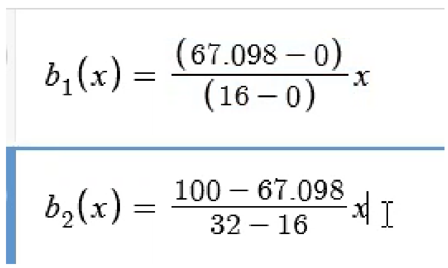

Figure 3a: Hans' mathematical expressions for the average speed runner

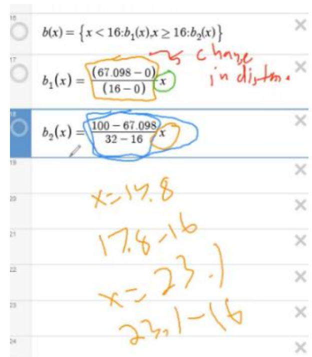

Figure 3b: Hans explaining his symbolization for specific time

To aid Hans in conceptualizing the distance traveled in the first 16 seconds, the interviewer played the animation, and the runner jumped back to the starting line after the runner had traveled for 16 seconds. Unlike Scott, Hans initial reaction was to add the expression $\frac{67.098-0}{16-0}x$ to $\frac{100-67.098}{32-16}x$. He appeared to conceptualize the expression $\frac{67.098-0}{16-0}x$ as a completed distance traveled that could be determined by multiplying a rate times a time (Table 1). The interviewer then prompted Hans to talk about the quantities he conceptualized and attempted to represent [Lines 4-6] while probing the conception of the starting point for a quantity's measurement [Lines 7-9]. Eventually, he noted that we still needed "the first distance" and proceeded to add 67.098 to his expression [Line 11]. Hans' statement that he needed "the first distance" suggested that he shifted to making a distinction between different distances in the situation since he chose to label the distance accrued in the first 16 seconds as the "first distance."

Table 1: Hans working through the Runner Task

1	Hans:	So would I… add the top?
2	Int:	So you want to add this? *Highlights $\frac{67.098-0}{16-0}x$*
3	Hans:	Yeah
4	Int:	Remember x is going to vary (Hans: oh yeah) so what quantity do you want to add?
5		So think about what you're trying to represent. This over here *highlights
6		$\frac{100-67.098}{32-16}(x-16)$*, what is this again?
7	Hans:	Um that's my change in distance.
8	Int:	From what?
9	Hans:	From $x-16$… like change in distance from… from 16 seconds
10	Int:	Okay so what part are we missing?
11	Hans:	The beginning part of the race… the first distance

The Desmos animation supported Hans in developing fluency in applying an average rate of change in a context and connecting his mathematical expressions with the quantities he attempted to represent. Similar to Scott, Hans was perturbed when the runner instantly jumped back to the starting line, which prompted him to reflect on what quantities his symbols represented. Upon seeing the runner jump back to the starting point, Hans realized that he needed the distance traveled by the runner during the first 16 seconds of the race, and this led to a conversation (Table 1) that supported Hans in making adjustments to accurately represent the quantitative relationships he conceptualized. Additionally, the Desmos applet's slider functionality aided Hans in understanding the role of a variable as representing the value of a varying quantity (Figure 3).

Discussion

Both students made similar errors in failing to distinguish between a change in distance versus total distance traveled. Additionally, before playing the animation, neither student indicated any uncertainty about what their mathematical expression would represent in the situation. In their mind, these students thought that what they symbolized would match what they expected (Figure 4a). However, when what they saw in the animation did not align with what they imagined, they experienced a perturbation that allowed the interviewer to facilitate a conversation to aid the students in reasoning about quantities and how they would represent them. This discussion led students to reconsider what they had symbolized and how to make refinements to represent the quantities they had in mind (Figure 4b).

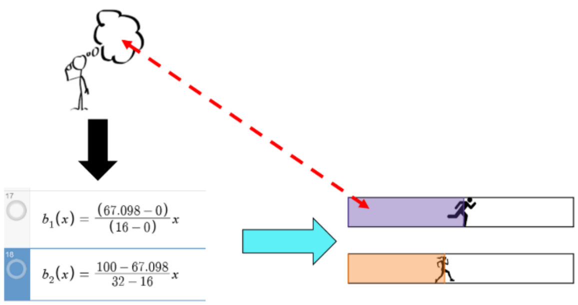

Figure 4a:A student anticipates what they might see

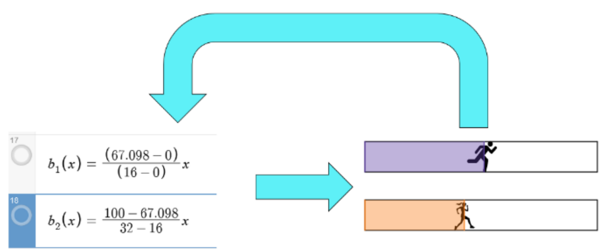

Figure 4b:Students reflect on what they initially symbolized

While the interviewer could have intervened and pointed out the errors in each student's notation, the Desmos animation provided a visualization of what their mathematics would represent and created opportunities for the students to experience perturbations in order to engage in self-reflection. This result suggests that students should have opportunities to explore and engage with what their mathematical symbolization might represent in a particular context.

Limitations and Future Directions

While the results of this study can only be known to be true for these 2 students, the findings of this study provide insight into how we may address the issue of students' difficulties with mathematical notation. Additionally, the tasks in this study utilized kinematic situations, but researchers have indicated that students often struggle to apply their understanding of mathematical ideas outside of kinematic situations (Rasmussen & King, 2000; Marrongelle, 2004).

Future research can further examine the role of applets and animations in a quantitative capacity through classroom studies. Further, more research on the usage of applets and animations should be conducted in non-kinematic situations.

University of Tennessee

Emily K. Campbell
University of Tennessee

Jessica L. Kingsley
University of Tennessee

Anne M. Ho
University of Tennessee

Past research typically assumes that an instructor is a high school or college instructor, but not both. The mechanisms to obtain teaching credentials for each are also traditionally separate, but some instructors teach at both levels simultaneously or transition between them during their careers. To better understand them, we surveyed instructors with experience in both high school and college math teaching. For our qualitative study, we asked questions centered around the Pedagogical Content Knowledge domains within Mathematical Knowledge for Teaching (Ball et al., 2008; Shulman, 1986). In this paper, we discuss the survey, data collection, coding, and findings on teacher perceptions of their jobs that fall across institutional boundaries.

Keywords: Pedagogical Content Knowledge, high school, college, teacher education, professional development

The University of Tennessee's Master of Mathematics program targets current U.S. high school math teachers interested in transitioning to postsecondary teaching. Some are interested in full-time employment as a lecturer/instructor. Others are interested in continuing their full-time high school careers with additional part-time teaching at a postsecondary institution, including dual-enrollment teaching. In both cases, we consider them as part of a pool of prospective VITAL faculty, which is the MAA's acronym for Visitors, Instructors, Teaching assistants, Adjuncts, and Lecturers, a growing teaching force in the US (Blair et al., 2018; Levy, 2019).

These prospective VITAL faculty are taking a nontraditional route to becoming postsecondary educators. Rather than enrolling in courses that form foundational knowledge for research, they enroll in courses emphasizing applications to teaching. Due to their current high school employment, these educators cannot also work as Graduate Teaching Assistants (GTAs) to gain college teaching experience. Even if they had the time, a traditional GTA role often caters to novice instructors (Speer, et al., 2005) and is arguably inappropriate for these educators who have more experience and knowledge of pedagogy. As a group, they are understudied in research. One reason is that many are associated with two-year colleges, and the literature on two-year math instruction is already sparse in comparison to K-12 or university education (Mesa et al., 2014; Mesa, 2017). A second reason is that dual-enrollment literature tends to focus on policy and students rather than on the instructors' practices (An and Taylor, 2019; Barnett and Stamm, 2010; Gonzalez, 2018; Johnson, 2018; Karp et al., 2004; Mokher and McLendon, 2009).

To better understand and eventually support these educators, our research team started by considering the views of similar faculty. In our qualitative study, we surveyed educators with experience in both high school and college math teaching. Because these educators work between institutional boundaries, they have a unique perspective and can directly compare high school versus college teaching in a way that other math educators cannot. For this first phase, we focus on the research question: What are the perceptions of math teaching for educators with experience in both high school and college?

Framework: Pedagogical Content Knowledge

As identified by Shulman (1986), an instructor should be proficient both in the material they teach and in pedagogy. Although he identified these two types of knowledge for teaching in separation, Shulman claimed that instructors employ both types of knowledge in conjunction and that research should reflect this. Furthermore, he proposed the existence of PCK, the idea that instructors must possess knowledge of the subject they are teaching which other experts of that subject do not require. Stemming from interest sparked by Shulman's work, Ball et al. (2008) formalized an empirically supported and practice-based framework of MKT. Two overarching domains compose the framework: Subject Matter Knowledge and PCK, the latter of which we focus on in our work because some subdomains of Subject Matter Knowledge aren't as clearly defined for secondary and post-secondary teaching (Speer et al., 2015). In addition to Shulman's Knowledge of Content and Curriculum (KCC), Ball et al. identified two empirically differentiable subdomains of PCK: Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT).

In more detail, KCC refers to instructors being familiar with the materials and resources available to them to teach their topic, as well as the contexts when they should be used, such as horizontal/lateral and vertical curriculum knowledge (Shulman, 1986). KCS refers to teachers anticipating students' thoughts and misconceptions (Ball et al., 2008). Lastly, KCT refers to instructors knowing how best to teach their subject with illuminating examples and appropriate scaffolding. We used PCK as our framework to study teachers with experience in both high school and college math teaching; we describe implementation details in the next section.

Methods

Survey and Cognitive Interviews

We developed open-ended survey questions relevant to each subdomain to explore various facets of teaching. We asked two versions of each question: the first being a version about high school math teaching, and the second being about college. We asked participants to describe their teaching practices, a strategy that aligns with Ball et al.'s (2008) practice-based approach.

We first conducted semi-structured cognitive interviews (Karabenick et al., 2007) with five participants using video meetings (Zoom), and we made slight adjustments to our questions for clarity before we collected data from our target population.

As an example of our questions aligning to KCT, we asked instructors how they choose class activities to help their **high school** students learn, and then we followed with a question about how they choose class activities to help their **college** students learn. We developed each question with one specific subdomain of PCK in mind (see Table 1), but during the cognitive interviews, we encountered a type of "boundary problem" like what was originally described by Ball et al. (2008) as some of our interviewees blurred the line between subdomains of PCK. As Ball et al. had originally admitted, "It is not always easy to discern where one of our categories divides from the next, and this affects the precision (or lack thereof) of our definitions" (p. 403). Thus, rather than attempting a perfect one-to-one mapping of our survey questions with subdomains of PCK, we take the stance that this boundary problem is inherent to the subject.

We further recognize that we, ourselves, are components to our instruments in our research (Maxwell, 2012). We acknowledge that our research team consists of individuals who have been in or are currently in a traditional research-focused math graduate program and have thereby not taken the same career path as the individuals in our study. One of our research team members has completed a teacher education program and has taught in a secondary classroom in the UK (instead of in the US). Four of us were GTAs for most of the first phase of this project. Currently, two of us are full-time lecturers at a large, public, and research-focused university.

Table 1. A classification of survey questions according to the subdomains of pedagogical content knowledge.

Question Pairs	Intended PCK Subdomain
Q4/5: Describe how you choose class activities to help your high school/college students learn.	KCT
Q6/7: Describe how you make decisions about which topics to teach in a high school/college class session.	KCC
Q8/9: Do you use technology to support high school/college student understanding of particular topics? If so, how?	KCT
Q10/11: Describe how you scaffold content for a class of high school/college students with a range of backgrounds.	KCS
Q12/13: Describe how you support high school/college students in communicating and justifying their mathematical thinking.	KCS
Q14/15: What do you think is the relationship between high school/college math courses and the rest of a student's education?	KCC

Data Collection

We sent the online qualitative survey instrument via relevant email and professional society message boards. The first question asked participants if they had taught both high school and college math courses in the U.S. Participants in the target population self-reported their experience in further detail with information about the types of institutions they worked at, courses they taught, and years of experience. In this first dataset, we have 26 responses. If we think of the "traditional" pathway to teaching college math as starting from graduate math coursework and ending in a tenured professor role, then our participants presented a range of nontraditional pathways to college teaching. For instance, Participant 5 started as a tutor and adjunct at a community college, moved to a full-time two-year college role, went back to math graduate school, and then ended up teaching at a private high school while continuing to adjunct at a college. Most of the participants started in high school and added on college teaching later, but we also have people like Participant 11 who started college teaching as a GTA in a math graduate program, taught full-time at a college, and then switched to full-time high school teaching. Most of our participants did not disclose their tenure-track or non-tenure-track status, but many discussed experiences in temporary (n = 11) or adjunct (n = 7) college teaching roles, and the average number of years of teaching is 17 (including part-time and full-time teaching).

Coding and Analysis

We analyzed our data with thematic analysis (Braun and Clarke, 2006). Our initial phase was familiarizing ourselves with the data by reviewing it in totality, which included typed responses and transcriptions from audio recordings—our survey was developed on the Phonic platform, which allowed participants to choose between typing written responses and recording audio responses (Phonic). We employed an inductive approach to search for potential patterns and to compile our initial codebook. Next, we organized an updated, condensed codebook with clearer definitions for a total of sixteen codes. We re-coded each question independently with two researchers per question. Finally, we computed percent agreement for interrater reliability, discussed discrepancies, and re-coded one last time.

Our codes emerged from our reading of the data, but we also find clear relationships between our codes and facets of PCK. For instance, we have three codes on the reasons behind an instructor's usage of technology, which relates to both KCS and KCT. Participant answers were typically coded as using Technology for Scaffolding, using Technology for Understanding (including visualization of content), or thinking that Technology is Distracting. We primarily used these codes on our pair of questions about instructor use of technology. Interestingly, we also found that these codes emerged in other pairs of questions. For instance, when we asked participants about choosing class activities, Participant 19 reported that they "try to choose activities that have a strong visual representation and, when possible, a dynamic piece of technology that they can engage with to explore mathematical relationships" (coded as Technology for Understanding). On the other hand, some participants merely listed technologies that they use when we explicitly asked about technology usage. For example, Participant 12 simply said, "Yes. Graphing calculators and Geogebra." Their answer involves technology but does not present any information past that, so we left this response uncoded.

As with the technology codes, we had other codes that we expected to see in certain pairs of questions. In one pair of questions, we asked participants to "describe how you support high school/college students in communicating and justifying their mathematical thinking." Rather than focusing on the frequencies of our Justification code here, we considered the times that it showed up in other questions unprompted. We focus on the details of the unprompted codes in the next section.

Findings

Instructors Have Student-Centered Intentions

Student Interests. One of our most common codes involves descriptions of practices that cater to Student Interests (including career goals, motivating examples, applications, other courses, and explicit mention of student engagement), and we saw this code across all questions in the survey. The Student Interests code emerged most frequently in Q14/15 when we asked, "What do you think is the relationship between high school/college math courses and the rest of a student's education?" Participant 1 indicated that they adapt their college teaching practices based on student career goals. For non-STEM students, they said, "in the end what I want the student to remember 5 years down the road is not the properties of logarithms but rather how I might engage with critical thinking and reasoning to work my way through solving a problem that arises." For STEM students, this instructor said, "I need my STEM students to understand how they are going to be using the math we are currently doing later in their studies and in their possible future careers. They still need those critical thinking and problem-solving skills, BUT they also need to [be] able to think more mathematically and quantitatively." When asked about topics in specific college class sessions, Participant 1 consistently centered on Student Interests as they stated, "I generally pick topics that I know students will need for subsequent courses or that I feel apply the mathematics in creative ways." Many other instructors were also attentive to student interests across questions, and we applied this code seventy-six times across all twelve content questions in our survey, which was one of the most frequent of the codes we used.

Interestingly, when comparing pairs of questions, we saw more mention of Student Interests for high school students than for college students in Q4/5 and Q6/7. Participant 15 is one of the instructors who mentioned student interests in their response about high school but not in their response about college. For high school teaching, they said that they must consider topics on the standardized exam "but that also help students connect math to the real world." This differs from their practice when teaching college-level math, for which they said, "I look for activities that students can start in class but finish at home, since many students work at different speeds and college class time is quite limited. I favor online activities that can be automatically graded." In college, the time pressure to cover content is so great that this instructor changed their teaching practice, and they opted for the ease of automatically graded problem sets.

Social and Emotional Needs. Another relevant code is that of the instructor attention to students' Social and Emotional Needs (including connections to peers, collaborative skills, attitudes, confidence, and comfort). We also saw this code emerge in every pair of questions that we asked, though it showed up more frequently in our questions about student justification and communication (Q12/13). When asked to "describe how you support high school students in communicating and justifying their mathematical thinking," Participant 14 simply described what the peer-to-peer interaction is in their class: "Students explain to each other how they got their answers. Students think about other approaches to a problem and try to explain other's methods." Several other participants also utilized group work and discussion in "think-pair-share activities" (Participant 17) or by having students "explain their work to each other" (Participant 18). For college teaching, multiple instructors said that their classroom choices were the "same" (Participant 17) or "identical to high school" (Participant 24). Furthermore, it was also important to some instructors to "build enough trust and rapport between [the teacher] and among the students to allow students to contribute imprecise or tentative ideas" (Participant 8). Participant 11 also emphasized the creation of a "comfortable" classroom environment. Overall, we found that our survey respondents believed that students' communication and justification skills were inextricably linked to their social and emotional needs.

Instructors are Influenced by Test and Time Pressures

Test Pressures. As expected, we saw our Test Pressures code appear in all questions, although it did not explicitly show up as frequently as other codes. In Q14, many teachers discussed foundational knowledge, but Participant 25 talked about the practical side of college applications by saying, "As long as math ability is tested on [the] SAT and a basis for college acceptances, it is probably the most critical course selection in a high school student's transcript. It can affect science classes and the ability to schedule any other honors level courses." Participant 22 also reported test pressures but in reference to Advanced Placement (AP) tests. In Q6, they reported, "For all but one year teaching high school, the school I taught at followed the AP curriculum (for better or worse). So the topics for the course were fairly well set in advance."

For college teaching, local expectations for exams also influence instructor choices. In the case of Participant 17, test pressure came up in the question about utilizing technology in the classroom, and they said, "I don't use technology as much in my college classes because they won't be allowed to use the technology during the exams, which make up most of their grade." For their high school teaching, this instructor used graphing calculators and Desmos, but they change their teaching practice in college when it didn't align with the expectations for the high-stakes exams. Participant 8 had a similar sentiment and said their department also had a "no-calculator policy"—since they couldn't "assume or guarantee access to graphing technologies," they would "rarely engage students in using technology to explore or understand ideas."

Time Pressure. For college teaching, our participants also felt that the lack of class time (when compared to high school) affected their classroom decisions. Notably, our code of Time came up more frequently in the question about choosing class activities for college classes when compared to the parallel high school question. As we saw earlier, Participant 15 was attuned to Student Interests but was pressured by the lack of time and so they chose online activities with automated grading. Participant 20 also thought college class sessions were too short, and although they reported a mix of lecture and group activities in their high school classes, they said, “Due to the limit of a 55-minute [college] class, it is mostly a lecture style class,” a choice echoed by Participant 18. Additionally, Participant 22 described how they heavily utilized Inquiry-Based Learning (IBL) in their high school teaching and tried to incorporate it in college, but “this did not work out—the students were not used to this type of learning, and because I had to get students ready for the next calculus course, I felt I didn’t have the time to use IBL methods.” Even for instructors who used more active learning methods in their high school teaching, some felt so much time pressure in college teaching that they used lectures more or active learning methods less.

Instructors Provide Commentary on Their Working Environment

Predetermined Content. One of our codes is about Predetermined Content, meaning the content was determined by someone other than the instructor themselves. We expected to see this when asking teachers about high school course content decisions as we assumed that state standards would frequently be discussed. Unexpectedly, we saw that this code came up more in the college teaching answers than for the high school ones—in fact, 64% of the responses for Q7 were coded as Predetermined compared to 30% of the responses for Q6. Perhaps Participant 7 explained this by saying, “My understanding is there is a lot more leeway with the topics that are taught at the college level. However, I believe there should be a bit of a consensus if you are teaching a class that is a prerequisite for another class.” We also expected there to be more flexibility in college courses overall, but our participants reported that they primarily taught introductory non-major courses, and so they were more likely to be working with a course coordinator or a preset list of topics. For Q7, Participant 9 had a representative answer: “The topics to teach are again completely set by the [department] syllabus—I don’t really have a choice on this.” When reflecting on their lack of autonomy, many instructors maintained a matter-of-fact tone without a positive or negative connotation; those like Participant 20 simply stated, “I am told which topics will be covered in the course.” However, in both descriptions of high school and college teaching, some instructors had negative associations with their lack of choice. For example, Participant 21 said, “Unfortunately, the district curriculum prescribes my topics and associated pacing.” When talking about their college teaching, the same instructor said, “Again, topics are already decided. In general, I will avoid teaching content that I know is not on the test. For example, even though I may find some underlying concepts in the complex numbers rather interesting, I avoid teaching them because students generally only need to know the procedure.” Due to predetermined content that was procedurally focused and test-driven, this instructor actively avoided teaching concepts and topics that they find interesting.

Commentary on the System. Another notable code is the one regarding Commentary on the System. This is a code that cuts across and outside multiple dimensions of PCK, but we saw it appear in every question of our survey. In most cases, teachers were providing commentary on barriers. Some of these barriers related to prerequisite student knowledge, such as when Participant 9 talked about how they must “spend a long time ‘undoing’ the unintended consequences of prior instruction. Students have typically automated all kinds of procedures without fully understanding when or why they should be used.” Other instructors, like Participant 4, commented on the lack of technological resources to support student learning: “It was a poor school district. The extent of technology in my classroom was a very old computer, an overhead projector, and 5 TI-85 calculators," a complaint that other instructors, such as Participants 25 and 26, mentioned as well.

Finally, multiple instructors commented on math classes themselves being barriers to students. On Q14, Participant 4 said, "Unfortunately, I think high school math serves as a sort of gatekeeper for college. Students who come to the university with poor math understanding get stuck taking remedial courses - often more than once, which can lead to setting back graduation or even dropping out." Participant 8 described the ideal role of math versus the perceived reality:

> Ideally, high school courses would help students construct foundational knowledge and develop skills in reasoning and problem solving that would support further study. In practice, high school math courses often lead to well-practiced but poorly understood procedures (and sometimes poorly recalled procedures) for technical tasks, and lead students not to trust their own reasoning and not to trust instructors to treat that reasoning as valuable or respected.

For Q15, Participant 26 added that math courses were "just a hoop for [students] to get through." Lastly, Participant 17 warned, "For students who struggle in these gateway courses, it changes the trajectory of their lives."

Conclusion

As far as the research team knows, this dataset and analysis provide the first direct comparison between the teaching practices for high school and college math classes in the US by instructors with personal classroom experience in both. We primarily examined these with a lens focused on subdomains of PCK, and we began to answer the question: What are the perceptions of math teaching for educators with experience in both high school and college?

Currently, we are implementing initial findings into our capstone course for the master's program to provide relevant perspectives from teachers in a more similar career trajectory to those of our prospective VITAL faculty. Additionally, we will next consider the specific views of dual-enrollment instructors, such as full-time high school teachers with an adjunct appointment at a college, full-time college instructors who teach high school students, or other arrangements that complicate the traditional secondary and post-secondary divisions.

Although readers of this article are more likely to be engaged in research and less likely to have taken the same career path as those in our study, we suggest that their responses provide a means of reflection for our own practices and policies as college educators, course coordinators, administrators, and leaders of professional development sessions. These educators who work between institutional boundaries have a unique means of direct comparison for high school and college math teaching. Thus, we end with a series of questions prompted by our engagement with our dataset: When faced with pressures and local policies, why do some instructors change their instructional practices from active learning to lecture while others maintain their course? How can we alleviate those pressures or modify policies to better leverage these instructors' existing PCK? What are the reasons that instructors think their own math courses are merely gatekeepers, and how can we make changes to better align the reality that these instructors describe to the ideals of their student-centered practices?

Values, Methods, and Facts: How Do Math and Science Align and Differ from the Perspectives of Mathematicians and Biologists?

Rachel Rupnow
Northern Illinois University

Margaret Remus
Northern Illinois University

Nicole Scheuermann
Northern Illinois University

Heather Bergan-Roller
Northern Illinois University

Despite the interrelated nature of math and science, limited work has characterized mathematicians' and scientists' beliefs about each other's disciplines or courses. In this study, we use nine interviews with mathematicians and biologists to characterize the interrelationship of community values, methods, and accepted facts in math and science and their relationship to introductory courses. Results include similar descriptions of biology and of what scientists do by all participants, but differing characterizations of what math is and what mathematicians do and claims that math courses do not teach students what they need. Implications include a need for the mathematical community to better align introductory course material with their values so that people outside the community better understand what mathematicians value and do.

Keywords: Interdisciplinary Education Research, Nature of Math/Science, Disciplinary Norms

Cross-disciplinary research connecting math and science education is a relatively new but burgeoning area of work. Much of this work has emphasized content connections, including how specific math-based content is learned and used in biology (e.g., Robeva et al., 2010; Williams et al., 2021), chemistry (e.g., Bergman & French, 2019; Jones, 2019), and physics (e.g., Jones, 2015; Schermerhorn et al., 2022; Serbin et al., 2020; Serbin & Wawro, 2022). Nevertheless, much work remains to be done at the interface of math and science education, especially as it relates to beliefs about teaching and the nature of math and science. In particular, we address the following research questions: (1) How do mathematicians and biologists characterize the nature of math, science, and biology? (2) What, if any, connection is there between how mathematicians and biologists view and want students to take away from their own and each other's disciplines?

Literature Review and Theoretical Perspective

Extensive work has characterized beliefs in math and science separately. Math educators have studied teachers' beliefs about math, teaching, and learning in K-12 and university contexts (e.g., Melhuish et al., 2022; Philipp, 2007). Much of the university-level work has focused on beliefs underpinning pedagogical approaches, such as influences on pedagogy (e.g., Johnson et al., 2018) and pedagogy in active-learning and lecture-based classrooms (e.g., Fukawa-Connelly, 2012; Woods & Weber, 2020). Moreover, work has examined perceptions of the nature of math (e.g., Ernest, 1989; Rupnow, 2021), including views of math as a disconnected set of tools, something discovered, or something created by mathematicians. Characterizations of science beliefs have focused on teaching influences (e.g., Al-Amoush et al., 2014; Rupnow et al., 2020); certainty of knowledge in science (Urhahne et al., 2011; whether views of science disciplines differ (Topcu, 2013); and descriptions of the nature of science (Southerland et al., 2003).

Studies attending to university math and science education simultaneously have been more limited. Apkarian and colleagues (2021) characterized instructional practices in math, chemistry, and physics, with special attention to active learning uptake. Reinholz and colleagues (2019) examined disciplinary cultures in biology, math, chemistry, and physics based on data from discipline-based education researchers at a cross-disciplinary education conference. From their work, they concluded that while STEM is often treated as one entity, meaningful differences exist between disciplinary cultures. Moreover, to our knowledge, research has not examined mathematicians' and scientists' beliefs about each other's courses and views of their disciplines, despite the impact understanding each other's perspectives might have on determining programs of study, who is best positioned to teach courses, and appropriate content in service courses.

Based on this background, we adopted Laudan's (1984) Triadic Network of Justification to frame our examination of faculty beliefs and their relation to introductory courses. The Triadic Network of Justification is grounded in philosophy of science and examines the interrelationship of axiology, methodology, and factual claims within a field's decision-making. In particular, a field's axiology (espoused values and principles) influences what counts as an acceptable methodology just as the feasibility of methods constrain what can be valued by the community. Similarly, use of acceptable methods impacts whether an assertion can be stated as fact while accepted facts within a community impact the methods that will be employed for exploring new areas. Finally, what is accepted as fact impacts the values of the community just as the values of the community impact what is acceptable as a fact. Laudan's work has been employed in math education research to examine the values (axiology) upheld through proof norms (methodology) (Dawkins & Weber, 2017). Here we will examine the values, methods, and accepted facts as taught in introductory courses in math and science and contrast their alignment in the two fields.

Methods

This research effort represents an interdisciplinary collaboration of math, statistics, and biology education researchers, and we believe our respective positionalities inform and enrich the research. Two members of the team are Assistant professors and two are graduate students. One member has extensive experience doing qualitative coding of interviews, and the other three have an intermediate level of experience. Our varied statuses and prior experiences impacted how we interpreted the data, and we worked to value and incorporate everyone's insights.

We audio-recorded interviews with five mathematicians and four biologists (nine total) at two R2 universities in the same state. One researcher, with a math education background, interviewed all participants for 60-90 minutes over Zoom or in-person. Interview questions focused on the nature of math, science, and biology; how these disciplines are learned; and how introductory courses in these disciplines are taught. Gender-neutral pseudonyms were assigned such that math faculty were given names starting with M and biology faculty with B.

The interviews were iteratively analyzed in accordance with thematic analysis (Braun & Clarke, 2006). First, two transcripts were open-coded by two authors who attended to prior work characterizing math and science but did not enter analysis with particular codes in mind. Those authors condensed and organized the open-codes into focused codes and applied them to the same transcripts. After refining, all authors independently coded the remaining transcripts, with at least two authors coding, discussing, and reaching consensus on each. This led to minor coding additions and refinements, and revisions were applied to earlier transcripts. Finally, all authors discussed clarity and themes, which led to adoption of the theoretical perspective. Final codes were aligned with the theoretical perspective and applied throughout the transcripts.

Results

Axiology: Cultural Values in Math and Science

Math knowledge, once gained, is definite and science is continually evolving. Participants noted many distinctions and similarities between math and science as fields. One distinction agreed on by mathematicians and biologists was that math knowledge, once gained, is definite and science is continually evolving. For example, Max said, regarding math and biology:

> It's my impression that biology as a discipline evolves at a so much faster pace than mathematics does. Mathematics absolutely expects that the calculus that you learn in calculus...is valid, will be valid, is state of the art....In biology...what was thought to be state of the art when you came in as a freshman might not be...by the time you leave.

Further, the idea that math is more certain than science, which thrives on constant evolution, was presented by many participants. Blake claimed, "If you put 10 mathematicians looking at the same data, all 10 should come up with the same answer, whereas in physics, chemistry, and biology I suspect that you'd get a lot more variation." Not only does this biologist see math results as more definite than results in science, but math results are also more widely accepted.

Math and Science are siloed/are separated by jargon. Several participants suggested silos or disconnections between disciplines might exist due to the need to specialize within one's own discipline. Brooks noted divisions even within disciplines: "even within biology, the medical biologists and the environmental biologists are completely different, and they don't communicate with each other." Further, several participants suggested differing cultures can create divisions between disciplines. Max noted the impact of being part of a culture on how one sees the world:

> It instills in one a discipline, whether it's history or math, or physics, or accounting, or whatever. Everybody who has been through a discipline has acquired a certain lens with which they see the world, and that lens is not unique to that individual...you share with others this way of thinking and seeing things that you, you can recognize as part of a community of thought...Each individual may bring their own little nuance to it. But...we recognize mathematics as a community of thought, and people in...a shared language.

Knowing the in-group approaches and language are part of becoming a member of a discipline, whereas not knowing them could make it difficult to communicate across disciplines.

Math is what mathematicians do/anyone can do science. Participants suggested that math is characterized by mathematicians' actions, but anyone can do science. Max, Morgan, and Marley claimed "math is what mathematicians do" when initially defining math. In contrast to math's community-membership focus, many participants reversed this in science, where anyone who acts like a scientist is part of the scientific community. Brooks stated:

> I think science is any investigation of something unknown. It could be anything we typically think of as physical sciences...but I also think it can just be trying to figure out something that you don't know in any sense. I know Adam Savage from Mythbusters says that everybody is a scientist, and I kind of agree with that mentality.

Similarly, Bailey noted "the scientist for me is someone that at least follow[s] scientific reasoning." These comments suggest that someone who engages in scientific processes is a scientist, whereas who does the activity determines whether something is math.

Science is a cross-disciplinary search for knowledge. Both math and biology participants emphasized the value and necessity of cross-disciplinary knowledge and interaction. Biologists discussed how different disciplines within science can work together to make each stronger, such as Blake's comment on students seeing methods in one area of science applied elsewhere:

> I think because of teaching and reiterating that scientific method and showing, for example, a physics student that the same scientific method you use over in physics can be applied in biology is really important for some of that connectivity....Anytime a biology student can broaden their knowledge base in other STEM fields, the more well equipped they are to ask less biased questions within biology.

Math is a tool. Relatedly, there was consensus that math acts as a necessary tool within science. All biology participants said math was an important tool within their discipline, many specifically using the word "tool". For instance, Blair said, "[Math is] providing some tools of how you describe biological processes quantitatively, in terms of models." Others, such as Blake, went further and did not see any applications for math beyond use in other fields:

> That sounds harsh, but I think that is how I think of [math]. So, it doesn't really have applicability on its own other than it's a tool. But it's like *the* tool all, all right to be used in all of these other fields....[italics are participant's emphasis]

Note this biologist sees applications of math in concert with other areas, just not on its own. Mathematicians, such as Mo, also referred to math's utility in problem-solving: "You use the mathematics to understand different parts of the world, different sciences, and also a lot of things that are not typically considered science, but you use it to analyze things."

Biology is the study of life. All participants characterized biology as the study of life. Max expanded that definition to include "the processes that make up life". Marley further included what biologists do, incorporating topics adjacent to life: "I mean, a biologist is not going to study something that's inanimate. It's going to be studying life or things that are very close to life, like viruses. They're not really alive, but they have an impact on life." Biologists described biology as the study of living things or organisms. Three of the four biologists provided an expanded definition of biology that incorporated biological systems, such as Bailey:

> So biology is a study of living things. And it can be as an organismal... for example, where the organism lives, their habitat. Then you zoom in animals by themselves, the behavior, then up to how a cell work[s]. And there's connection between all these.

While biologists were more precise and provided more nuance in their responses, mathematicians and biologists largely agreed on what biology is about.

Math is about patterns or numbers. Biologists largely described math as the study of numbers, such as Blake: "So thinking about how numbers may…relate to one another in new ways...coming up with new sorts of theories or laws or rules as to how numerical relationships correspond to one another or relate to one another." In contrast, mathematicians mostly focused on patterns and relationships with some references to numbers, such as Miller:

> If we have to add restaurant bill or divide restaurant bill, [my friends] say, "Oh, you're the mathematician, you do it," the joke is. And I say, "Guys, that's not mathematics. That's arithmetic." So, the definition of mathematics is not addition, subtraction. The definition of mathematics is to study how mathematical objects relate to each other, the rate of change, the tools and methods that are required.

While math includes numbers, Miller suggests math is about relationships among objects.

Methodology: Ways of Doing and Learning Math and Science

Science is done by the scientific method. All mathematicians and biologists described science as being done and/or connected by a systematic approach, especially the scientific method. For instance, Blake referred to the scientific method numerous times, including: "I guess [science] is a way of studying, a way of understanding…. when I think of science, I think of the scientific method." Mathematicians also focused on the systematic approach to data collection and analysis when defining science, such as Marley:

> Sort of the study of nature, but it's a little bit more than that. So if you allow me to give a definition that's as broad as my definition of mathematics, I think it's just...It's observation and analysis....There has to be observation. There has to be analysis to search for patterns.

While particulars varied, references to the scientific method or aspects of it, including hypotheses, data collection, analysis, and repetition consistently appeared across participants.

Math is done via proof or unknown. Mathematicians often characterized doing mathematics in terms of proof and logical deduction. For instance, Morgan observed:

> What do mathematicians look at? Well, they look at things that interest them. And it's usually not just, "Hey, where can I get—starting with these assumptions, where can I get just using rules of inference?" It's not so interesting work. You can take Peano arithmetic and say, "Okay. Well, what follows from that?" Well, no, look at things that interest us.

While mathematicians are expected to demonstrate results through a sequence of logical deductions, interests are also expected to play a role in mathematicians' approaches to research. In contrast, biologists expressed uncertainty about what mathematicians do. For instance, Bailey tentatively suggested mathematicians use the scientific method to focus on calculations:

> Maybe, I'm wrong, but I think you have a question. You want to demonstrate something. You have a hypothesis, so you will write down on top of your page what you—or, I don't know how you do it. And then you start to make equation and see if you can solve it.

Blake professed even broader uncertainty:

> Any time I've talked to someone who does theoretical mathematics it is, it is at its intro level of being explained to me so far over my head and so jargon filled that I can't pull from it the applicable aspects to my field. So I can't really explain to you what theoretical mathematics is other than it's, you know, developing theory in math.

Of note, while everyone seemed reasonably confident in characterizing what scientists do, biologists expressed uncertainty and/or differing characterizations of math than mathematicians.

How Learning is Approached. In addition to characterizations of how researchers do math and science, we also note approaches to learning math and science, as they could be considered ways to show appropriate methods for engagement in those fields. The most common description of how people learn math was through exposure and repetition. For example, Mo said, "A little bit like you acquire speaking skills. You see it used and mimic it and learn some things on your own." In contrast, the participants described how biology is learned through hands-on activity, including experiencing the natural world and research experiences. Brooks claimed:

> I think a lot of people learn biology growing up through experience...learning what animals are…these sorts of things people often learn before they've ever taken a biology course. And getting out into nature is often a way that many people get into environmental fields because they always loved going out to nature, going on hikes, watching birds...And then all of the human health pathways are a little bit more obvious because if you experience your own healthcare, you see how that works.

Further, the participants described how learning biology is done through research experiences. For example, Max noted students can do research even as undergraduates: "Biology, I think it's really possible for a undergraduate, you know, Junior, to be doing a real research project."

Factual Claims: Key Facts within Math and Science Taught in Introductory Courses

While accepted facts in math would include proven theorems or formulas and in biology might include widely accepted theories like cell theory (all organisms are made of cells), here we emphasize instead content students are likely to take away from their introductory courses.

Content in biology introductory courses. All the biologists made a distinction between what biology is taught at the introductory level for students majoring in biology (i.e., "majors") and those not (i.e., "non-majors" such as humanities majors, business majors). For example, Blake described how both versions of the introductory courses cover similar topics but emphasized forming a solid foundation of concepts and skills for majors to build on:

> I think the goal for non-majors is to provide them with background content on what biology is, so that it is the study of living organisms to provide some background content on the breadth of organisms that exist…and then do some introductory lessons on the scientific method, and some of those patterns and processes that we get into in later biology..... For our majors...teaching the same stuff that we're doing with non-majors but doing it at, with the expectation that they are going to build on that knowledge. So really driving home the scientific process, which they're going to use throughout the rest of their, their major, really driving home some of the core concepts in biology.

Of note, biologists claimed biology majors' first courses in college are meant to provide opportunities to engage with biology in the same manner as they would in subsequent courses, and non-majors' courses provide a similar experience, just with less detail.

Content in math introductory courses. In contrast, multiple math and biology participants noted math introductory courses tend to teach separated procedures and content that mismatches what is needed. For example, Brooks described the non-applicability of differential equations:

> Differential Equations, the only thing I took out of that class was learning how to do the math if I was filling up a bathtub that was emptying at the same time, right? That was all I saw in Differential Equations, so I think I do inherently just think of things in that sense and where is this coming from? Where's it useful for?

They later noted they appreciate math is "something behind the scenes… it's just a part of the whole system" but math is not taught in such an integrated way, instead "taught as a separate thing". The mathematicians agreed math is taught in a way that does not highlight utility, stating "for most people mathematics means algebra and algebra means meaningless symbol manipulation" (Max) and "they just sort of memorize algorithms and that's useless" (Morgan).

To remedy these issues with how math is taught, the participants suggested that introductory math should teach particular content that aligns with other disciplines and mathematical thinking. For example, when asked what biology majors should take away from introductory math courses, Marley proposed a calculus/ordinary differential equations (ODE) series with biology applications and gave an example about the rate of metabolizing tea:

> Students should take sort of a Calculus I and a Calculus II in preparation for biology, but it should be a biology-based Calculus I, Calculus II.…it's about related rates, rates of change.…I've got my cup of tea here, and I've learned how the body eliminates drugs from the bloodstream.…It's a very simple ODE. And now I kind of now understand why is it I drink my tea, I drink tea in the morning, and then I need more tea later, next day, why? Well, because it's natural that there should be some sort of an exponential.

In addition to applications, the participants also said that introductory math courses should teach connected mathematical thinking. For instance, Mo claimed:

> We want to give them an idea of where those formulas come from because I think that gives a better understanding of how everything fits together. So it's not just covering the topics that they need, but it is also making sure that it's not just 'formula is given', but increase their understanding of the mathematics behind the things.

Together, participants claimed math courses should be specific to the student audience and focus on why content works.

Discussion

This study aimed to examine views of math, science, and biology by mathematicians and biologists as well as consider how well aligned (or not) the values, approaches to research, and material taught in introductory courses are in math and biology. To the first point, there was general agreement that biology is focused on the study of life, science uses the scientific method, and math is a tool for solving problems. However, mathematicians characterized math in terms of who does it (mathematicians) and in terms of studying patterns among (varied) objects as well as treating proof as central to activity, whereas biologists largely focused on numbers or expressed uncertainty. All participants also largely agreed that introductory math courses often teach disconnected procedures and not what is needed for other disciplines. They also largely agreed that the scientific method and content about living things were taught in introductory biology courses, though biologists elaborated on depth differences for majors and non-majors.

To the second aim and returning to our theoretical perspective (Laudan, 1984), we see relatively close alignment when we consider the axiology, methodology, and factual claims (as represented in courses) in biology as portrayed by mathematicians and biologists. While some values are in tension (i.e., science as a cross-disciplinary search for knowledge, science separated by jargon/in silos), we can see that both values are attended to and incorporated in the scientific method. In particular, hypotheses are free to change as science evolves and the questions asked are free to be informed by broad research teams, though individuals may have expertise in only portions of the question being asked. The emphasis on teaching the scientific method as well as all participants' certainty of what biology is seems to suggest relatively clear alignment between methods taught and accepted facts in biology. Finally, the emphasis on methodology rather than particular facts reveals connections between accepted facts and the value that science changes.

In contrast, math's axiology, methodology, and factual claims represented through course choices are harder to connect. If we attend only to mathematicians' views, the values of math being definite and of math being about relationships among objects harmonize with the methodology of deductive reasoning in an axiomatic system. However, teaching disconnected procedures does not create a foundation for proof-production. Instead, they at best relate to math's role as a (potentially not understood) tool for doing science. Biologists seemed to view math as a tool focused on numbers but had limited ideas of what mathematicians do beyond vague references to "math theory" and computation. Because math methodology is unknown to them, they cannot connect it to values or facts. However, the focus on math as a tool related to numbers potentially connects to the individual procedures or particular content taught in courses. Thus, while some aspects are connected in each viewpoint on math, there are also reasons for biologists to wonder what mathematicians do and for mathematicians to wonder why introductory courses are taught as they are.

These disconnections in math's values and introductory courses highlight problems for the math and math education communities to address. It seems that math courses are trying to serve populations that do not fully agree on what math is, thus serving no one well. If other members of the STEM community do not incorporate mathematicians' definition of math into their own definition or know "what mathematicians do", it is not reasonable to expect those in less contact with math to know what math is about or what mathematicians do either. One way to address this is to encourage mathematicians to clearly articulate what math is about to people outside the mathematical community so that their definition becomes more accepted. Another route might be for math departments to co-teach distinct courses with and for different STEM disciplines so that "applications" are relevant to all STEM majors and align with their needs, while math majors separately have opportunities to learn more about the mathematical community and know what their final courses will be about before it is too late to change majors.

Understanding Instructors' Beliefs and Obligations within Cultures of Exclusion

Nina White
University of Michigan

Brian A. Smith
University of Michigan

We present a study of how five early-career college math instructors using active learning describe their role as instructors and situate these descriptions in two existing theoretical frameworks: Herbst and Chazan's theory of practical rationality and Louie's culture of exclusion. This overlayed theoretical perspective, grounded in our case studies, points to levers for faculty professional development and instructional change.

Keywords: Beliefs, Equity, Active Learning, Instructor Development, Professional Obligations

While the general pedagogical category of "active learning" in college mathematics classrooms is widely regarded to be better for student learning than traditional lecture (Conference Board of the Mathematical Sciences, 2016; Freeman et al., 2014; Theobald et al., 2020), many questions remain in how to best support college math instructors to adopt such practices, and carry them out to most successfully and equitably support student learning. We take it as given that instructor practices and beliefs have important and nuanced interactions in their effects on student learning. Thus, learning environments are improved by attending to both instructor beliefs and practices. The goal of this particular study is to better understand some of the beliefs held by instructors using active learning (in this case, beliefs related to how they view their role as an instructor), while recognizing that these beliefs are pieces of a more complex instructor ecosystem. Our research questions are the following:

RQ1: How do early-career math instructors using active learning describe their role as instructors?

RQ2: What professional obligations and aspects of the culture of exclusion are present in these descriptions?

Literature Review

Numerous studies across STEM fields have investigated instructor beliefs (Czajka & McConnell, 2019; Luft & Roehrig, 2007; Moore et al., 2015). Scholars working with post-secondary mathematics instructors have attempted to categorize instructor beliefs while establishing connections to their teaching practice, particularly those related to active learning (Päuler-Kuppinger & Jucks, 2017; Raychaudhuri & Hsu, 2012; Vishnubhotla et al., 2022). Päuler-Kuppinger and Jucks (2017) found that scholars in "hard disciplines," like mathematics, are more likely to have a static understanding of knowledge that corresponds with content- or teacher-centered teaching methods. The findings of Raychaudhuri and Hsu (2012) complicate those of Päuler-Kuppinger and Jucks (2017) in that instructors held ontological views of mathematics as a connected and deep discipline that conflicted with their teacher-centered, behaviorist pedagogical views. Vishnubhotla and colleagues (2022) found that in investigating instructors' practices when utilizing inquiry-based learning (IBL) approaches, instructors who believed that lecture positively contributed to learning were more likely to emphasize lecture in their IBL instruction. These findings reflect earlier claims regarding the relationship between beliefs and practice in mathematics teaching more broadly.

Previous findings, such as Leatham (2006), pushed for researchers to study beliefs in ways that aim to build connections between beliefs and view them as sensible systems. Ernest's earlier work (1989) enhances this notion as he asserts that connections or inconsistencies between beliefs and practice can be explained not only by how the instructor relates their beliefs to one another, but also the amount of awareness an instructor has of their beliefs and the institutional systems that surround the instructor. These claims are consistent with Thompson (1992), who argued that the relationship between beliefs and practice is complex and influenced by factors including instructors' views regarding the nature of mathematics as well as instructors' interaction with social and political contexts. These claims complement those of Speer (2005) who summarizes these conceptualizations of beliefs well: "Beliefs appear to be, in essence, factors shaping teachers' decisions about what knowledge is relevant, what teaching routines are appropriate, what goals should be accomplished, and what the important features are of the social context of the classroom" (p. 365).

While the previously referenced findings (Päuler-Kuppinger & Jucks, 2017; Raychaudhuri & Hsu, 2012; Vishnubhotla et al., 2022) focus on individual factors that shape teachers' decisions without taking into account much of the surrounding context, several scholars have emphasized the importance of *context* in understanding the relationship between beliefs and practice (Ernest, 1989; Speer, 2005; Thompson, 1992). Johnson and colleagues (2019) examined how individual and situational factors influenced the instructional practices of mathematics instructors. They found that individual factors, such as personal beliefs, were more likely to explain instructional differences across instructors than situational factors. Interestingly, Johnson and collaborators chose not to investigate how situational factors influenced the individual factors (beliefs, knowledge, and goals) for instructors. Several other studies investigate this problem through what Herbst and Chazan (2012) refer to as practical rationality, who argue that the justifications teachers use for their beliefs and practices can be understood by investigating their professional obligations to their content discipline, individual students, interpersonal interactions in the classroom, and institutions such as departments, schools, and districts. Scholars in post-secondary mathematics education have taken up this work, particularly as it pertains to active learning (Mesa et al., 2020; Shultz, 2022).

In the context of mathematics education, Louie (2017) argues that the dominant culture of exclusion is likely to influence the beliefs, knowledge, and skills of individual teachers. Across several studies, Louie (2017, 2018) and colleagues (2021) have shown that the culture of exclusion in mathematics, characterized by narrow definitions of mathematical activity and ability, prevents teachers and instructors from enacting instructional practices in ways that disrupt existing inequities. This applies to current efforts to understand instructor beliefs about active learning in two ways. First, it further supports the notion that focusing on individual beliefs without considering broader context is insufficient. Second, when examining contextual factors such as professional obligations, it is crucial to view these obligations as being embedded within the culture of exclusion. In doing so, professional obligations become potential reproducers or disrupters of the culture of exclusion. We will argue later that understanding the beliefs of instructors via their professional obligations within the culture of exclusion allows us to identify potential levers through which we can influence instructors' active learning practices in a direction that is inclusive and equitable.

Theoretical Framework

Our investigation assumes a complex interaction of instructor practices and beliefs, and also situates these interactions in an ecosystem that includes contexts with obligations, as well as the

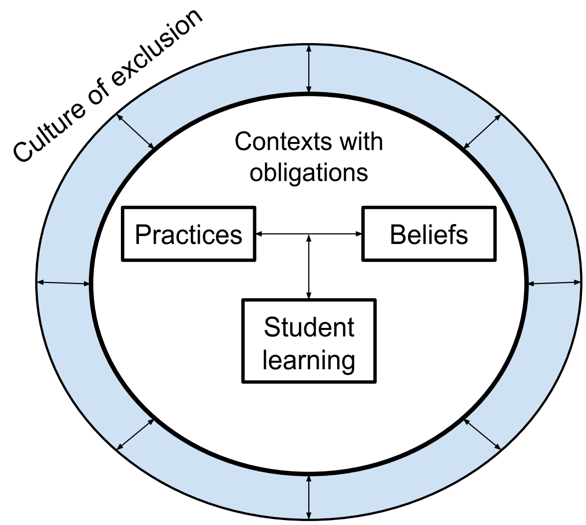

Figure 1. Illustration of theoretical framework

pervasive culture of exclusion (see Figure 1). From the extant literature, we conceptualize beliefs as factors influencing teachers' decisions regarding teaching and learning, consistent with Speer (2005). This conception of beliefs is in line with Leatham's (2006) in which the emphasis is not on the strength of the beliefs but rather their connections to the individuals' other beliefs and practices.

We also contend that an instructor's beliefs are informed by the professional obligations (Herbst & Chazan, 2012) with which they contend. Herbst and Chazan (2012) name four obligations: disciplinary, individual, interpersonal, and institutional. We see these four obligations as being situated within the culture of exclusion (Louie, 2017), which is characterized by narrow views of mathematical activity and ability. Each of the professional obligations has the opportunity to resist or reinforce the culture of exclusion. Figure 2 adapted from Louie (2017, p. 496) with obligation descriptions from Herbst and Chazan (2012), illustrates our proposal for how this might occur.

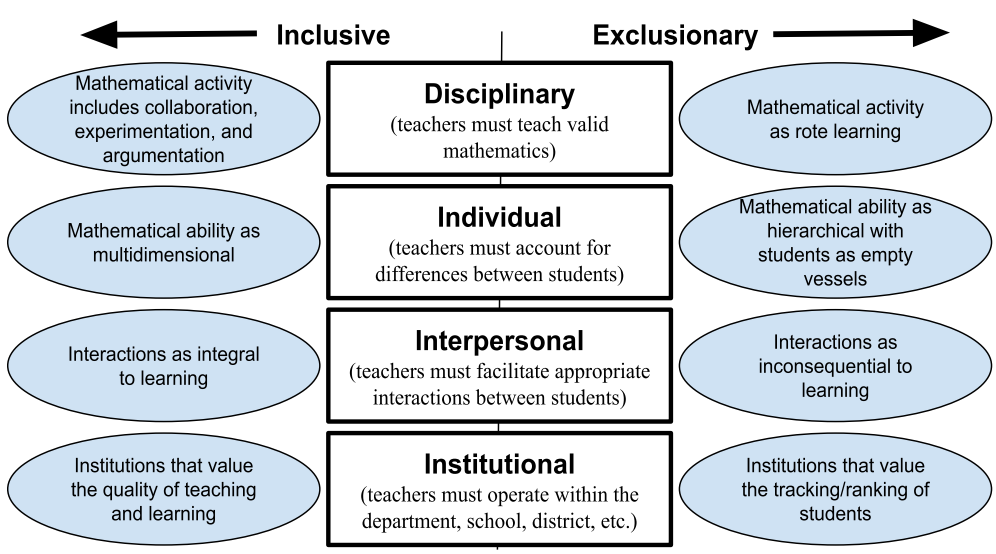

Figure 2. Relationships between professional obligations and the culture of exclusion

Data and Methods

Researcher Positionality

The first author is a white woman with a PhD in mathematics, who grew up in an income-secure household. These identities affect her worldview, often implicitly. Her personal goals as a college math instructor, faculty developer, and math education researcher are to create rich, supportive, and affirming learning experiences in college mathematics classrooms, especially for students who have been historically marginalized in mathematics; these goals explicitly affect her research questions and analyses. The second author is a white man who is a former secondary mathematics teacher and current PhD candidate in mathematics education. His commitments to equity and justice in education ground his approach to research, albeit from the limited perspective of a person with multiple privileged identities.

Participants

This study focuses on early career faculty (graduate students and postdoctoral fellows). The reasons for this are (1) this is a population with more malleable beliefs (Ellis, 2014); (2) this population is responsible for a meaningful percentage of college math courses taught (Ellis, 2014); (3) understanding beliefs of more novice instructors, in particular, yields insights into an important stage of belief development; (4) at the institution of this study, these instructors were overwhelmingly the population teaching with active learning. We invited eight postdocs, representing a wide range of pilot survey responses, to be interviewed; seven agreed to be interviewed. In contrast, the eight graduate student participants were selected on a volunteer basis via a departmental graduate student listserv. Out of those fifteen, we focus on the responses of five in this paper. Those five include four graduate students (two white women and two white men) and one post-doc (a white man), all of whom teach small sections (< 24 students) in multi-section coordinated courses (18 - 100 sections).

Interviews and Analysis

The interviews (15-30 minutes) included three questions adapted from the TBI instrument (Luft & Roehrig, 2007) designed to elicit important instructor beliefs: (Q1) How do you maximize student learning? (Q2) How do you describe your role as an instructor? (Q3) How do you know students are learning? Interview audio was transcribed using rev.ai, and cleaned for accuracy and anonymity. Among responses to Q2 was a surprisingly common response of "coach" (n=5) to describe their roles as an instructor. For the scope of this short paper, we restrict our attention to that recurring metaphor. The first author identified various sub-meanings of "coach" using open coding (Corbin & Strauss, 1990), then refined those meanings through discussions with the second author. The theoretical frameworks described above were not used to create these categories of meanings, but to understand their implications (see next section).

Results

In this section we characterize four different meanings underlying participants' use of the metaphor of coach to describe their role as instructors. We illustrate how each meaning alludes to particular obligations (Herbst & Chazan, 2012), while exploring whether those obligations are leveraged in a way that perpetuates or resists the culture of exclusion (Louie, 2017).

Responsive Supporter (n=4). *...providing responsive support to students; for example, by giving hints when needed or meeting with students one-on-one.* Our examples of this role draw primarily on the obligation to the individual because the interviewees described back and forth interactions with individual students, giving hints and asking questions; however, there is an implicit obligation to the discipline because the descriptions are focused on getting students to a mathematically correct answer. For example, one participant said: “When they are struggling on something, I try to, you know, give tips in some sense….But…sometimes it's more of leading questions, things like that.” Another said: “[I] really try to, you know, fill in gaps in knowledge, that kind of thing.” That is, instructors describe responsively interacting with individual students to correct misconceptions and fill in “gaps in knowledge”—disciplinary obligations. Although these are certainly caring instructors, we view both obligations implicit in this role—individual and disciplinary—as being leveraged in ways that perpetuate an exclusive (or dominant) framing of mathematics teaching. The *lack* of attention to the classroom community implies that interactions between students are relatively inconsequential to the instructor. Further, the goals of these interactions presuppose that the student is (mostly) an empty vessel, and the instructor is the knowledge-giver. While Responsive Supporters do acknowledge students as having some knowledge to be built upon, they do not describe their role as instructors as drawing out what students know, or making connections to students’ prior knowledge; rather, these instructors describe their role as to correct and redirect, highlighting students deficits rather than assets.

Skill Builder (n=3). *...helping students to build skills beyond the content, such as studying for exams, or approaching non-routine problems.* Our examples of this role draw primarily on two sources of obligations: individual and institutional. Descriptions refer to characteristics of students and their needs, not fostering a community or supporting interpersonal interactions, as seen in the following quotation: “I mean a lot of these students are freshmen … this is the first math class they're taking. So a lot of what they encourage us to do…is really trying to instill good, not just math study habits…but…taking exams in general.” We also see in the previous quotation two distinct references to institutional obligations: (1) the instructor is enacting what “they encourage us to do” and (2) what’s being encouraged is to help students succeed on the institutional measure of exams. Some respondents mention “problem-solving” or “learning from your mistakes”, which sound like a disciplinary obligation—how you *do* mathematics. However, when they expand more on what this means in their setting, we saw responses such as the following: “Cause you know, a lot of times, particularly in… that course when you're…solving problems that are about, like, justifying your answer, a student could have a correct numerical answer, but lose points because they didn't provide adequate justification for it. And so it's really important to look at where you've lost points on the other stuff...” That is, the “learning from mistakes” this instructor describes is less about actual mathematical learning, and more about learning to meet institutional expectations.

Preparer (n=3). *...helping students face a challenge on their own, that the instructor has no control over, such as a common exam.* This is distinct from the above role in that it is exam-preparation specific, and less about general skills. However, like Skill Builder above, this role leans heavily on both individual and institutional obligations. The institutional obligation is the more overt obligation in this case, since this role is explicitly about conforming to institutional expectations around exams. However, we also clearly see instructors’ obligations to the individual, wanting their students to succeed, in quotations like this one, “You are kind of like trying to get them to the point where they are prepared for this as much as possible...Like they are…being prepared by you in order to [perform] in some situation and you have some amount of, like, personal stakes in it and you really do want to see them succeed.” In the previous quotation as well as the following, we also see that the instructor and students are working as a team to overcome this hurdle: “There's going to be, there's going to be this exam...some adversary that we're all gonna work hard and practice together to get through together," though the consequence of low scores for the instructor are certainly less grave than for the students. Like the Skill Builder examples, it is caring and invested instructors who describe their role in this way. Nevertheless, in the Preparer meaning of the "coach" metaphor we see the iron grip of the institutional obligation to the common exam as supporting a narrow definition of mathematical activity and performance; this exclusionary frame is then also transferred to the individual obligation, by attending to the training and performance of individual students.

Cheerleader (n=2). *... a role of encouragement and emotional support.* Finally, our examples of Cheerleader most explicitly draw on obligations to individuals. However, when this instructor describes her role as "helping build people back up cause it's pretty common for people to have the first exam tear them down and then to, you know, help them get back on their feet and do well on the rest of the semester, which is totally possible," we also see an important underlying institutional obligation. This moral support is in the service of helping students navigate institutional structures and expectations. Rather than affectively supporting student joy around mathematics, we see her affective support as helping students recover from exam-induced trauma. That is, both obligations here are serving the culture of exclusion, rather than resisting it.

Discussion

Our first observation from the roles and obligations above is the absence of the interpersonal obligation. This is surprising given an obvious role of a "coach": helping a team learn to play together. While the role of helping students work together showed up in the larger dataset, it is not part of what instructors meant when they referred to themselves as a kind of "coach". Also notable is that only the role of Responsive Supporter seems particularly specific to an active learning environment, indicating that many components of how an instructor views their role in a college mathematics classroom transcend specific modalities.

Grounded in our observations from our case study of "coach" meanings above, we hypothesize that obligations to the individual, institution, and discipline may have a tendency to perpetuate the culture of exclusion. And, though missing from our sample, we hypothesize that beliefs derived from an interpersonal obligation may more naturally resist the culture of exclusion, since a defining characteristic of an *inclusive* frame towards mathematics learning is seeing "interactions and interpersonal relationships as integral to learning" (Louie et al., 2021, p. 101). These hypothesized tendencies are depicted in Figure 3. It's important to note that the obligations leveraged in our sample straddle this inclusive/exclusionary divide. However, despite some aspects of resisting the culture of exclusion—using groupwork at all, primarily using conceptual tasks, acknowledging that students come with some mathematical resources—the stronger forces (as described above) are in the exclusionary direction.

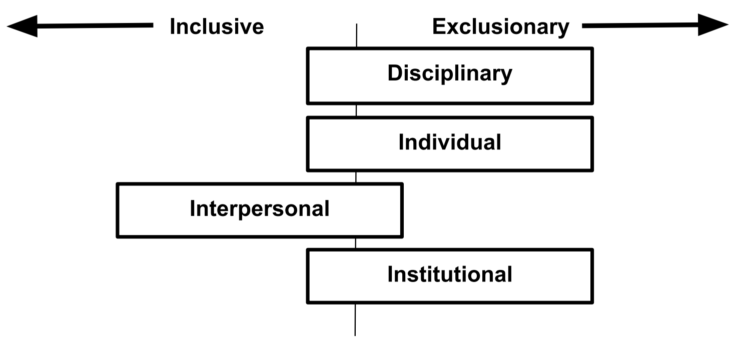

Figure 3. The tendencies of obligations to be inclusive or exclusionary based on case data

Suggestion 1: Reform the Obligation

Our suggestions refuse to view instructors as purely individual actors; rather they are embedded in cultures and institutions that must be considered as central to any change efforts. Our first suggestion follows from Webel's and Platt's (2015) strategy of leveraging existing instructor obligations (Herbst & Chazan, 2012) to effect positive change in practice. We layer onto their suggestion a need to reflect on how such obligations may readily sustain (or resist) the culture of exclusion (Louie, 2017, 2018). Take, for instance, Mesa and colleague's finding (2020) finding that coordinated courses may be an especially salient source of instructor obligations. Layering upon this finding a focus on framing surfaces a new question: how can features and structures of a coordinated course create obligations that *resist* the culture of exclusion, rather than perpetuate it? A requirement or expectation to use groupwork is one example of an institutional obligation that may help point instructors' beliefs and frames in an inclusive direction; but as we discuss in Suggestion 2, that expectation alone is not sufficient. Using coordinated course structures to resist the culture of exclusion may include both breaking down structures that perpetuate exclusive frames (e.g. curved grading schemes designed to rank students, timed exams that valorize correctness and speed) and simultaneously building more inclusive structures (e.g., course grade components that give credit for revising mistakes on exams and homework) and inclusive messaging (e.g., "exit tickets" at instructor meetings that ask instructors to reflect on the many different ways students were "good at math" in the last week).

Suggestion 2: Magnify the Interpersonal obligation

Another implication of our hypotheses is that a source of resisting the culture of exclusion may lie in magnifying instructors' obligations to interpersonal sources. For example, in coordinated courses using groupwork, instructors may settle on the sole purpose of groupwork as being "students do" rather than "students do together," unless course coordinators facilitate explicit, reflective conversations to illuminate the intended benefits of groupwork. A belief that groupwork is valuable simply for its hands-on nature (without respect to its collaborative nature) values student-instructor interactions, but fails to value student-student interactions.

Study Scope and Limitations

The sample size of the overall study (n=15) and the sub-sample presented here (n=5) can in no way characterize college math instructor beliefs across the United States; this is not our goal or claim. A second important limitation of this study is that we have no connection between these professed instructor beliefs and their classroom practices. Relatedly, we are applying an interpretive lens to this instructor discourse, that is colored by our experience as researchers and instructors.

Conclusion

By examining instructor beliefs through the frameworks of obligations and the culture of exclusion, we have pointed to two foci for instructional change: (1) examining the frames surrounding professional obligations with the ultimate goal of reforming obligations themselves to better resist the culture of exclusion; (2) magnifying professional obligations, such as the interpersonal obligation, that may more naturally and readily resist the culture of exclusion. We do not take it for granted that active learning modalities support equity simply by being hands-on; rather, in any pedagogical modality we must interrogate practices, beliefs, and obligations to best support a culture of inclusion.

Exploring Fitness Trackers as a Research Method for
Developing Personas of Stress during Classroom Problem Solving

Melinda Lanius
Auburn University

In this report, I examine the capacity of fitness trackers to assist in differentiating students' experiences of stress during classroom problem solving. I cluster $N = 26$ *students' heart rate variability plots based on categories of description created using a phenomenographic analysis of their reported emotional experiences during a scripted lesson on roots of polynomial functions. My results reveal that fitness tracker data can be a valuable indicator of when a student will report classroom distress. However, the tracker data can give both "false-positive" and "false-negative" indications a student will report distress, reinforcing that biometric data cannot be treated as a proxy for students reported experiences of stress. Nonetheless, my results do support the use of fitness tracker data to guide deeper inquiry into student experiences. For example, fitness tracker data can assist in identifying classroom moments to discuss in a video stimulated recall interview.*

Keywords: math anxiety, academic distress, problem solving, fitness trackers, heart rate

Although active learning may generally have a positive impact on students' performances in science and mathematics courses (Freeman et al., 2014), not all groups have equal access to these benefits; for example, because student participation is essential to most styles of active learning, there is a higher frequency of peer-peer interaction, creating more opportunities for students with minoritized social identities to experience a marginalizing event (Reinholz et al., 2022). Classroom stressors can foster academic distress, or anxiety caused by university course environments. Academic distress has other known correlates: coursework demands, assessment pressures, instructor teaching style, and a student's sense of belonging (Larcombe et al., 2022). Additionally considering the high prevalence of math anxiety among undergraduate students in the United States (Lanius et al., 2022; Lanius, 2022; Hopko et al., 2003; Hopko, Crittendon, Grant, & Wilson, 2005; Hopko, Hunt, & Armento, 2005; Isiksal et al., 2009; Rancer et al., 2013), studies concerning psychological stress during classroom problem solving are particularly timely and important. Wearable technologies capable of collecting heart rate data, more succinctly called fitness trackers, provide an alluring prospective tool for *in situ* indication of student anxiety or distress during classroom problem solving (Singh et al., 2018; Kim et al., 2018). To explore the research potential and pitfalls of fitness trackers, this report compares clusters of student's fitness-tracker data plots to categories of description created using a phenomenographic analysis of their reported emotional experiences during a lesson on roots of polynomial functions.

Heart Rate Fitness Trackers & Distress Indication

A meta-analysis of 37 studies concluded that current evidence supports the use of Heart rate variability (HRV) for the indication of psychological stress in a particular situation (Kim et al., 2018)—for example, job-strain (De Bacquer et al., 2011) or computer-work stress (Hjortskov et al., 2004). Additionally, HRV has been shown to be a statistically significant indicator of junior high students reporting math anxiety while performing an arithmetic task such as $7 + 2$ (Tang et al., 2021). Heart rate variability (HRV) is a summative measurement of the variation in length of time between heart beats during a window of time. Slight variations in length of time between heart beats is normal in healthy individuals and is caused by the autonomic nervous system receiving conflicting feedback from the parasympathetic nervous system (informally, the rest-and-digest-system) and the sympathetic nervous system (or the fight-or-flight-system) (Singh et al., 2018). When the sympathetic and parasympathetic nervous systems are in balance, there is greater variation in the length of time between heart beats. On the other hand, when the body needs to react to an external stimulus, such as stress, messages from the sympathetic nervous system overpower messages from the parasympathetic nervous system, and there is less variation in the length of time between heart beats. Ultra short term HRV, which uses heart rate data from a couple of minutes, can be reliably computed for monitoring mental stress (Salahuddin et al., 2007), thus allowing us to synchronize changes in a student's HRV to tasks and stimuli they experience in their undergraduate math course.

Research Questions

What are the stress-related emotional experiences of undergraduate students during classroom problem solving? How does an undergraduate student's heart rate variability change if they report experiencing math anxiety or academic distress during classroom problem solving?

Theoretical Perspectives

Concerning Methodology. I utilized phenomenography (Marton, 1986). To clarify how phenomenography differs from the more familiar phenomenology, in a phenomenological study the phenomenon itself is investigated; in a phenomenographic study the variation in how people experience the phenomenon is investigated (Larsson & Holmström, 2007). Phenomenographic research is an iterative process where the researcher familiarizes themselves with the descriptions of experience, identifies distinctive or structurally significant characteristics, groups and classifies similar answers, and builds named categories; see Table 1 of Han & Ellis (2019). The final product of my analysis is categories of description that explain the variations of experience present in the data. Phenomenography can then be used to build personas, lifelike characters to assist in student-centered design in educational contexts (Huynh et al., 2021).

Concerning Fitness Tracker Data. I must avoid data-essentialism, or the position that students can be reduced to their biometric data or that the data collected by fitness trackers is "objective" reality (Svensson & Poveda Guillen, 2020). Research data are produced through a laborious and time-intensive process involving the decisions of a variety of people. Further, fitness tracker data is limited by the capacity of our locations and technologies (Ribes & Jackson, 2013). Consequently, I view biometric data as a human artifact that must be situated in its context.

Methods

Fitness Trackers & Heart Rate Variability

Photoplethysmography (PPG) uses light-emitting diodes (LED) and photodiodes to detect blood volume changes directly under the surface of the skin, with each peak in blood volume corresponding to a beat of the heart (Singh et al., 2018); see Figure 1. The PPG sensor records the length of time between successive peaks of blood volume, providing an accurate approximation of the length of time between heart beats. To process the collected heart rate data, I partitioned each students PP interval data into 3 time windows and utilized the HRV variable root mean square of successive differences (RMSSD) to compute an HRV value for each student in each time window of the lesson; see Figure 1 for the RMSSD formula. The most common cause of inaccuracy with PPG measurement is motion artifacts (Fine et al., 2021), for example rapid arm movement, which occurs during certain types of intense physical exercise, where the optical sensor loses contact with the skin. Although I used a procedure for detecting and cleaning optical-coupling-based errors within the heart rate data, I sought to avoid the issue entirely and encouraged research participants to secure the watch snugly to the forearm of their non-dominant hand. Further, participants remained sitting during the experiment, which minimized the amount of arm movement.

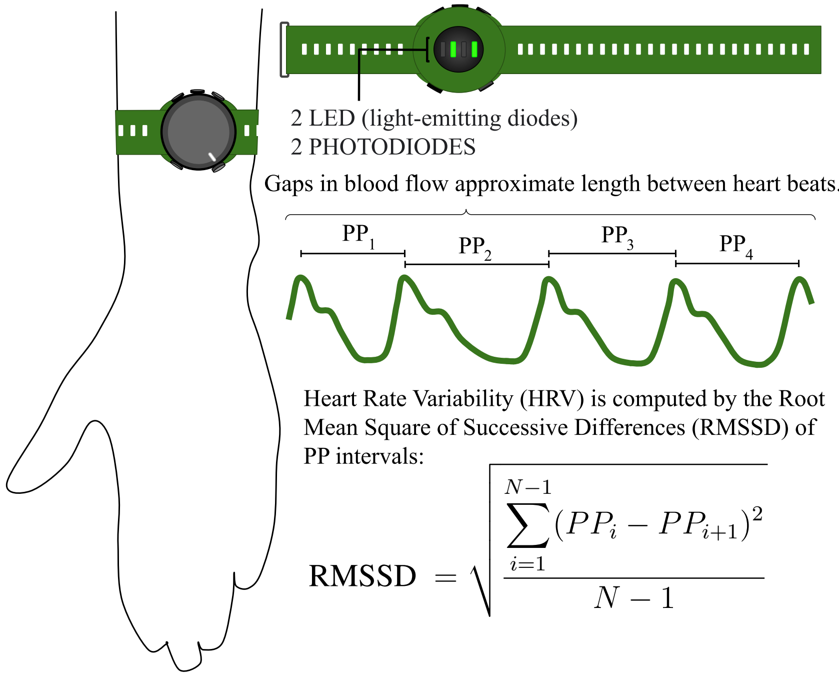

Figure 1. Photoplethysmography (PPG) sensor data to compute heart rate variability (HRV)

Scripted Math Lesson & Reflection Survey

After securing institutional review board approval from Auburn University's Office of Research Compliance, I invited undergraduate students enrolled in a lower-level math course to participate in my study. Students wore a fitness tracker during a 15 minute scripted math lesson. The lesson has a purposefully placed stressor called Cardano's formula (Harris & Stocker, 1998): Any cubic polynomial of the form $s(x) = x^3 + ax + b$ such that $4a^3 + 27b^2 > 0$ has real root

$$x = \sqrt[3]{-\frac{b}{2} + \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}} + \sqrt[3]{-\frac{b}{2} - \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}}.$$

Lesson Window 0. The lesson began with an instructor introducing the topic *Section 3.1 Roots of Polynomials* on a chalkboard. After seeing a notation-heavy definition of polynomial function, the instructor presented an example of a linear and a quadratic polynomial. The students were then assigned *Problem 1. True or False: The function* $s(x) = 4$ *is a polynomial* to complete on a provided handout. Window 0 will be treated as an acclimation period for the study and will not be included within participant's heart rate variability plots below.

Lesson Window 1. After waiting for visual cues that all students had completed problem 1, the instructor provided the correct answer and reviewed the definition of root and provided an example. Students were then instructed to complete *Problem 2. Find the root of* $p(x) = 3x + 1$.

Lesson Window 2. Again, after the instructor received visual cues that it was time to continue the lesson, they provided the answer to problem 2 and presented the quadratic formula, using it to find the roots of an example.

Lesson Window 3. Following a presentation of Cardano's formula, the instructor assigned *Problem 3. Use Cardano's formula to find a root of* $p(x) = x^3 - 1$ stating "Don't forget to check that Cardano's formula applies by verifying $4a^3 + 27b^2 > 0$." After waiting 2 - 3 minutes, the instructor revealed that the correct answer was $x = 1$ and concluded the lesson.

Note that the partition of events into windows 0 - 4 is done to guarantee each window has sufficient time for an accurate and reliable HRV computation and is not based on the composition of events. Immediately following the lesson, students completed a reflection survey to report when they had experienced anxiety and to describe their experience in their own words. Many students also chose to contemporaneously report their emotional experience by writing on the provided lesson handout.

Results

The 29 participants included 18 women and 11 men. Five students were enrolled in College Algebra, Finite Math, or Pre-Calculus. Twelve students were enrolled in Calculus I or Calculus II. Eight were enrolled in Calculus III, Differential Equations, or Linear Algebra. One student was enrolled in an elementary math content course for pre-service teachers and three participants did not specify a current math course.

Clusters of Fitness-Tracker Data Plots

I clustered participants HRV plots together based on the categories of description created from my phenomenographic analysis of students' reflection data and lesson handouts. Note that there is great individual variation in the typical ranges one might see for HRV-RMSSD values, which can be as low as 21 ms and as great as 103 ms (Umetani et al., 1998). To make the HRV plots comparable between individuals, I normalized every plot by dividing a student's three RMSSD values by their maximum RMSSD value. Within each normalized HRV plot, a dashed line is given as a visual indicator of values that suggest the student will report feeling distressed while attempting an assigned problem. The placement of this dashed line was determined using a logistic regression model that estimates the probability a student will report distress given their HRV value is below this line is greater than 50%, with the odds increasing the further the value moves below the line. This statistical analysis is not the focus of this report and thus is omitted here, but will appear in other work. I provide the line here as a visual aid to assist readers in interpreting the plots. For each cluster of plots, I constructed an average normalized HRV plot by averaging the normalized HRV values of students in that cluster. Of the $N = 29$ profiles to analyze, there were 5 categories of description that were common to at least 3 students. Categories with fewer than 3 participants will be excluded from this discussion because there were too few data points to meaningfully cluster the normalized HRV plots and take an average.

Categories of Description

Labels. I utilize the word distressed in labeling the categories to signify disruptive unpleasant feelings or emotions that interrupted or inhibited the student's ability to adapt or cope with a lesson stressor. The other key label is abstaining, which indicates that these students chose not to attempt an assigned problem.

Category 1: Distressed. These 5 students first reported distress in Lesson Window 3 where Cardano's formula was introduced and they were instructed to use the formula to find the root of a cubic polynomial. One participant wrote that they felt overwhelmed *"by the sudden barrage of variables and unfamiliar terms"* with another explaining, *"Not having enough examples before having to try by myself gave anxiety."* One participant experienced academic distress because they were not able to finish the problem before the instructor moved on; they wanted to be sure that they could get the right answer on their own. The normalized HRV plots of the five students in this cluster can be found in Figure 2. All but one students normalized HRV values remained above the distress indicator line until the third window, where all HRV values lie below.

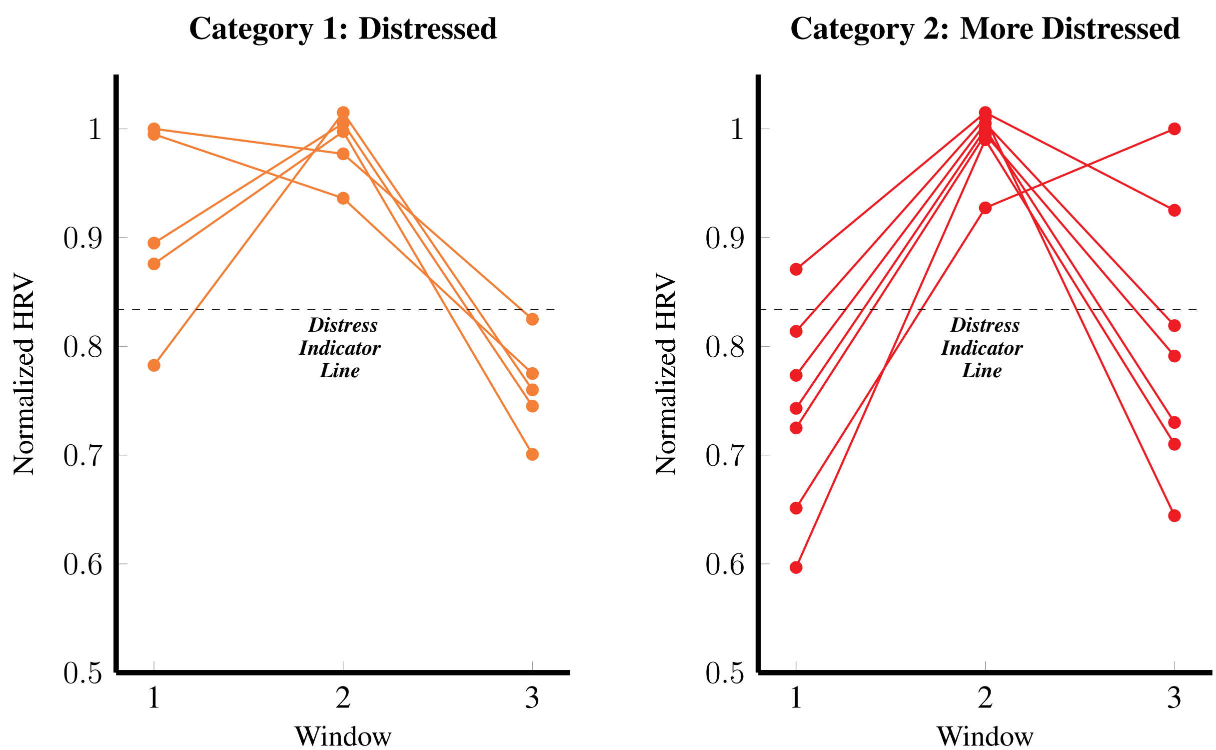

Figure 2. Clustered normalized HRV plots for Category 1 and Category 2

Category 2: More Distressed. For the 7 students in this cluster, the source of distress in Lesson Window 1 was the instructor announcing that problem 1 was true. Six students expressed that they felt bad or disappointed that they had gotten the answer wrong, with one student writing *"I felt like it was a trick question and felt badly that I didn't know it"*. Several students indicated that they did not understand why their answer was wrong, with one student explaining that their source of distress was that they thought the instructor lied or misspoke and that problem 1 was in fact false. Note that the lesson script does provide a brief explanation as to why problem 1 is true, but students were not given the opportunity to ask any questions of clarification during the lesson. None of these students reported distress during Lesson Window 2, which started with them receiving feedback that they answered problem 2 correctly. This group reported distress in Lesson Window 3, conveying feelings similar to those reported by the Category 1 group: anxiety, panic, overload, and "blanking out". The normalized HRV plots of the 7 students can be found in Figure 2. Note although one students plot makes the same inverted V shape as the majority of the other plots, their window 1 and window 2 values do not lie below the distress indicator line. Also note one participant's HRV lies well above the distress indicator line in window 3.

Category 3: Distressed & Abstaining. These 3 students first reported distress in Lesson Window 3, however - unlike the participants in the previous two categories - they chose not to attempt problem 3. One participant, rather than copying the problem from the board onto their handout, wrote *"I genuinely don't know how to do this one at all"* and another reflected after the lesson *"I simply did not know how to solve it."* Their 3 plots can be found in Figure 3.

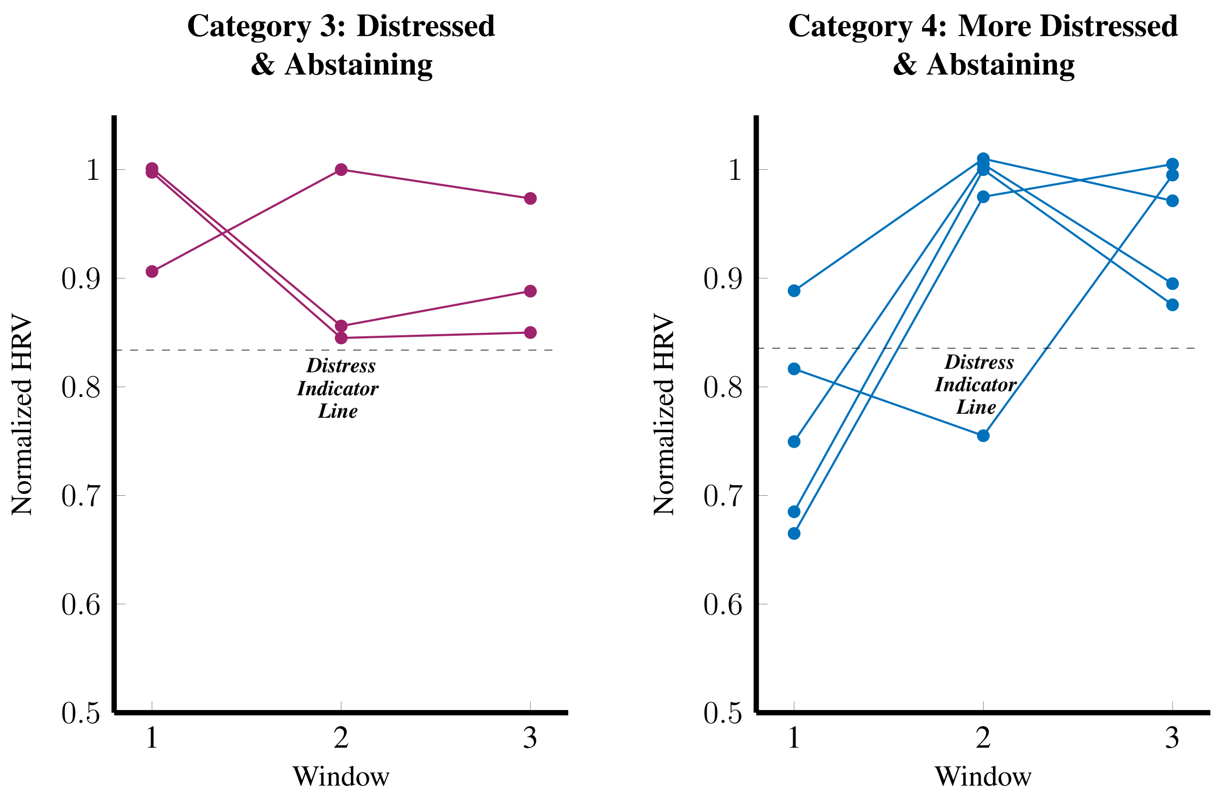

Figure 3. Clustered normalized HRV plots for Category 3 and Category 4

Category 4: More Distressed & Abstaining. For the 5 students in this cluster, Lesson Window 1 caused distress when the instructor provided the solution to Problem 1. One student wrote, *"I got it wrong, wasn't sure about my answer in the first place."* This group felt less stressed during Lesson Window 2, with one student explaining *"during the second problem I regained my confidence because I knew what to do"*. In Lesson Window 3, these students reported distress and chose not to attempt problem 3. One student wrote *"I literally would not know where to start"* in the space provided to copy the problem and do scratch work. Their normalized HRV plots are in Figure 3.

Category 5: Undistressed. The final category contains the 6 students who did not report feeling distressed during the lesson. Their normalized HRV plots appear in Figure 4. Note that at various times, participants normalized HRV values dropped below the distress indicator line.

Category Averages. The cluster average for each category of description appears in Figure 4. Note that, on average, student's normalized HRV values dropped below the distress indicator line if and only if they reported feeling distressed while actively attempting an assigned problem.

Discussion & Implications

Within the normalized HRV plots, there are 4 instances of a "false-negative", where the HRV plot suggests the student will not report feeling distressed while attempting to solve a problem and the student did report distress. There are 6 instances of a "false positive", or instance where the HRV plot suggests the student will report feeling distressed while attempting to solve a problem and the student did not report distress. Thus, the *overall alignment rate* across these 26 profiles was 87%. These results suggest that fitness tracker data can be valuable to guide deeper inquiry into the student experience; however, low HRV does not guarantee a student is distressed and high HRV does not guarantee a student is undistressed. Further, HRV cannot provide a direct measure of the *amount* of distress or give an instantaneous indication a person is experiencing distress.

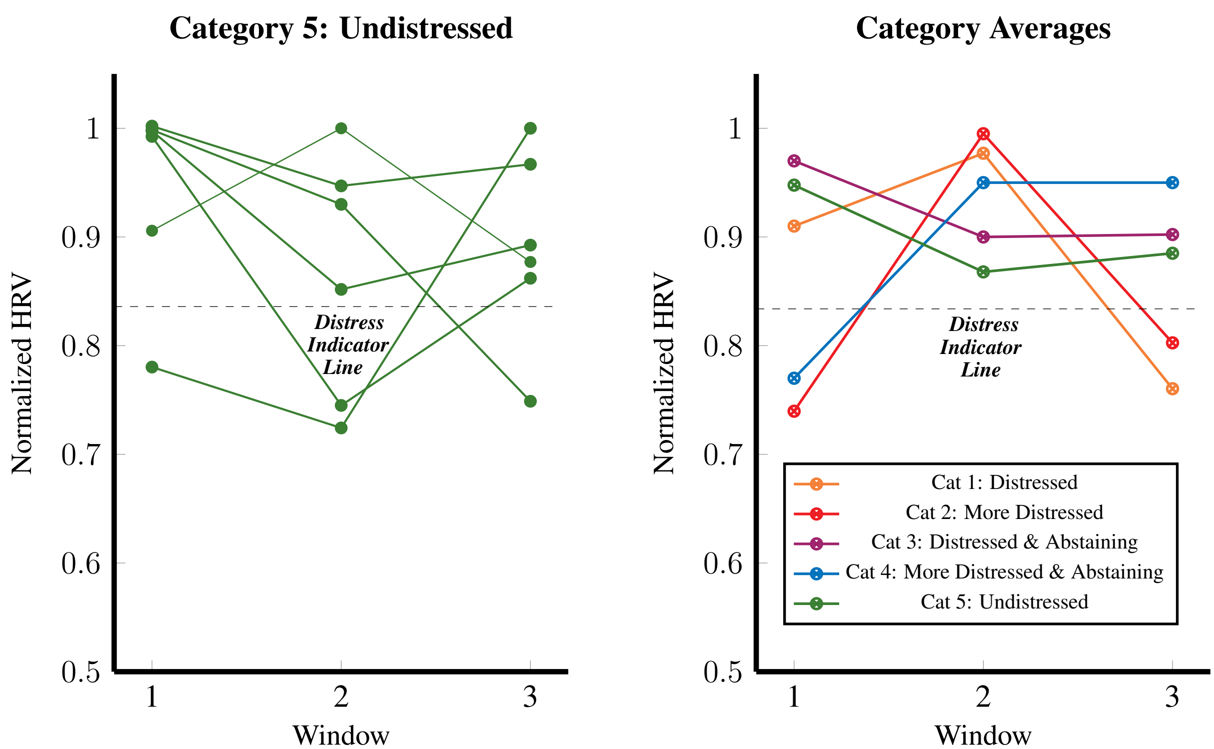

Figure 4. Clustered normalized HRV plots for Category 5 and Category Average plots

The role of HRV in Education Research

In Figure 4, we see that the plot average for Category 3: Distressed & Abstaining has the same overall shape and structure as the plot average for Category 5: Undistressed. This suggests that HRV can only discern when a student may report feeling distressed if the student is actively problem solving. I recommend that fitness tracker data primarily be used for triangulation, as a way to identify moments during classroom problem solving for video stimulated recall interview with research participants. With deliberate and careful use, fitness trackers provide an innovative research design tool that can integrate qualitative and quantitative measures in the study of psychological stress during classroom problem solving.

Star Polygons: Symbolizing as Advancing Mathematical Activity in a Scripting Task

Andrew Kercher
Simon Fraser University

Anna Marie Bergman
Fort Lewis College

Rina Zazkis
Simon Fraser University

Research indicates that investigating phenomena, rather than reproducing facts, should be a core experience in mathematics education. But despite its centrality to quality teacher education, it is still unclear how the effects of investigation tasks on teachers' mathematical development can be analyzed. In this study, we demonstrate the potential of scripting tasks as an avenue for capturing mathematical activity during an investigation. Participants, comprised of prospective and practicing teachers, explored the concept of a "star polygon" and recorded their deliberations, ideas, and conclusions as a scripted dialogue. We analyzed their submissions using the construct of advancing mathematical activity (Rasmussen et al., 2005; Rasmussen et al., 2015), focusing on how participants' interpretation and creation of symbols intersects other types of activity.

Keywords: Star Polygons, Scripting Tasks, Teacher Education, Advancing Mathematical Activity, Symbolizing

Introduction

Mathematics education research strongly advocates for learning environments centered on investigation, as opposed to techniques and procedures (e.g., Da Ponte, 2007, Yerushalmy, 2009; Leikin, 2014). Investigation tasks—also described as open problems or problem fields (Pehkomen, 2019)—require students to consider a particular object or a set of objects, collect data about them, identify their properties, and justify the discovered properties or relations. As such, conjecturing and then refining, proving, or refuting conjectures are the heart of investigation tasks.

There are multiple advantages for students engaged in mathematical investigations (e.g., Quinnell, 2010). For example, they develop a strong conceptual understanding, an awareness of the nature of mathematics as a discipline, and the ability to think creatively about mathematical ideas. Investigation-based learning environments also foster a supportive classroom atmosphere while simultaneously recreating the actual practice of mathematicians.

Numerous professional development efforts intend to prepare teachers for including problem solving and investigation tasks in their classroom and support them in this endeavor. However, for teachers to guide students' investigations, it is essential that teachers have experience in engaging in such activities themselves (e.g., Perdomo-Díaz et al, 2019). While mathematics educators agree on the importance of engaging teachers in mathematical investigations, there is no explicit guidance on how teachers' engagement in investigations can be studied.

Existing reports on teachers engaged in mathematical investigations employ close observations of teachers' work in class, video-recording of their work on a particular mathematical problem (e.g., Rott et al, 2021), and problem solving journals (Liljedahl, 2007) or portfolios (Gourdeau, 2019) in which research participants recorded their progress. In this study we present an additional approach—script-writing—for recording and analyzing teachers' engagement in a mathematical investigation. In doing so, we address the following research questions: *What aspects of participants' symbolizing activity are captured by scripted dialogues recreating their progress on an investigation task?*

Advancing Mathematical Activity

To answer this question, we turn to Rasmussen et al.'s (2005) alternative formulation of Tall's (1992) concept of advanced mathematical thinking that they call *advancing mathematical activity*. By focusing on mathematics that is "advancing," this construct allows researchers to study student activity that improves their understanding of mathematics, even if their work would not be considered "advanced" by some standard; by considering "activity" rather than "thinking," this construct attempts to capture a more holistic and diverse type of engagement with mathematics. Throughout their work, Rasmussen and colleagues identify four types of advancing mathematical activity that are socially or culturally situated practices: symbolizing, algorithmatizing, defining, and theoremizing (2005; 2015). In this report we focus on symbolizing.

Symbolizing "arises in part as a means to record reasoning" (Rasmussen et al., 2005; p. 57); that is, a symbol is a "notational device that [is] consistent with [a student's] mathematical reasoning," and symbolizing is the creation thereof (p. 58). The authors stress that they do not interpret symbolizing as necessarily an act of dissociation from context; designating a symbol as the representation of a quantity is not only a means of abstraction but also allows students to create, take ownership of, and share mathematical objects that characterize their thinking. Symbols, once refined, can act themselves as the input for future symbolizing activity. That is, symbols can manifest as a synthesis of multiple previous symbols.

Although we focus primarily on the presentation of symbolizing activity throughout this report, it is impossible to completely disentangle the types of advancing mathematical activity; with this in mind, we introduce the other types of activity as well. *Algorithmatizing* is the creation and discovery of (either local or global) algorithms. When engaged in *defining*, a student might construct a definition in light of examples and counterexamples; alternatively, they might leverage an existing definition in order to explore a related set of objects. Finally, theoremizing encompasses "both conjecturing and steps toward justifying the assertions" (Rasmussen et al., 2015; p. 264).

Methods

Participants and Setting

A total of 27 respondents participated in the study and, working in groups, produced 14 unique submissions; we refer to these as S-1 through S-14. The first seven submissions were generated by prospective teachers during a course on mathematical problem solving. This course, taken during the last term of the teacher certification program, leveraged problem solving activities to connect a variety of secondary and advanced topics in mathematics. The latter seven submissions were generated by practicing teachers who held at least a bachelor's degree in mathematics or science. The practicing teachers were enrolled in a professional development course that provided an overview of important topics and ideas in mathematics through the lens of pedagogy.

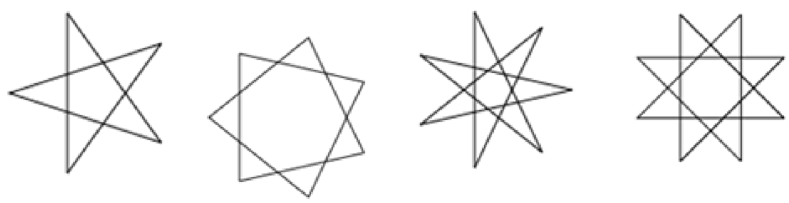
Participants' scripts often featured themselves as characters. To preserve their anonymity, throughout this report, named characters that appear in excerpts from submitted scripts have been given pseudonyms.

The Star Polygons Task

As part of their respective courses, both prospective and practicing teachers regularly engaged with *scripting tasks*; in such a task, participants are asked to write a script of a dialogue within a mathematical context. A scripting task might be used for lesson planning (where it is referred to as a *lesson play*, for example in Zazkis et al., 2009; Zazkis, et al., 2013). At other times, a scripting task is an activity that can be used to study how teachers respond to a student error (e.g., Zazkis et al., 2013), a student question (e.g., Bergman et al., in press; Marmur & Zazkis, 2018; Kontorovich & Zazkis, 2016), or an argument among the student characters (e.g., Marmur et al., 2020; Zazkis & Zazkis, 2014).

The *star polygons task* used in this study is a novel type of scripting task in that it prompted participants to record, as a script, their journey in a mathematical investigation. Preliminary pilot testing of a more open-ended version of the star polygons task showed that a certain amount of guidance was needed to support participants' initial engagement with the task. The revised task deployed in this study (Figure 1) provided a symbol system for naming and describing star polygons before asking participants to make sense of it. As we exhibit in the findings, this allowance facilitated communication and conjecturing without supplanting meaningful symbolizing activity.

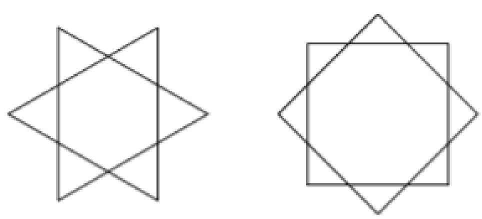
The figures below exemplify regular star polygons on 5, 7 and 8 vertices.



These are denoted – from left to right – as (5, 2), (7, 2), (7, 3) and (8,3). Explain the notation.

In (5,2) we refer to "2" as the number of "skips" or "steps" (skip to the second).

But these are NOT star polygons. Explain why.



Is there a star polygon on 10 vertices? On 12? On 30? On 31?

Explore different numbers. Describe your explorations and conclusions as a play, that is, in a form of a dialogue among problem solvers. Record your (your characters') conjectures and the ways of testing them.

Figure 1. The first part of the star polygons task.

The first part of the task introduced in Figure 1 engaged participants with investigating why select examples are not considered star polygons. Having justified this distinction, participants were instructed to explore whether a star polygon can be constructed on a given number of vertices.

A second part of the task, not pictured in Figure 1, prompted participants to describe a method for deciding if there exists a star polygon on N vertices and, if so, how many different star polygons on N vertices there are. Finally, participants exemplified their described strategy on a large number of vertices. Each part of the task was recorded as part of the scripted dialogues that comprised the collected submissions.

Data analysis

We initially analyzed participants' submissions using reflexive thematic analysis (Clarke & Braun, 2006, 2019; Nowell et al., 2017). That is, we hoped to allow the submissions themselves to guide our understanding of participants' mathematical activity as captured in their investigations. We began this process of immersion and interpretation by first reading and rereading the submitted scripts in order to thoroughly familiarize ourselves with the data. While doing so, we recognized that the most compelling aspect of the scripted dialogues was the description of the interaction between characters as they discussed and constructed a collective, social understanding and monitored each other's claims.

To emphasize the fundamentally communal nature of the activity reported by participants in their submissions, we leveraged Rasmussen and colleagues' (2005, 2015) four types of advancing mathematical activity. This decision was given credibility by the authors' emphasis that these are "acts of participation in a variety of different socially or culturally situated mathematical practices" (Rasmussen et al., 2005, p. 52). Furthermore, advancing mathematical activity has already been used to describe collective mathematical progress as part of an emergent framework (Rasmussen et al., 2015). We thus coded the data explicitly for instances of symbolizing, algorithmatizing, defining, and theoremizing. This process was guided by the definitions and examples of each practice presented in the advancing mathematical activity framework (Rasmussen et al., 2005; Rasmussen et al., 2015).

In the following section, we present instances of symbolizing activity that emerged during explorations of the star polygons task. Where appropriate, we point out where the symbolizing activity overlaps with other types of advancing mathematical activity. Finally, we pay particular attention to the ways in which participants' symbolizing activity was affected by their adoption of the prescribed (n, k) (n, k) notation within the task description.

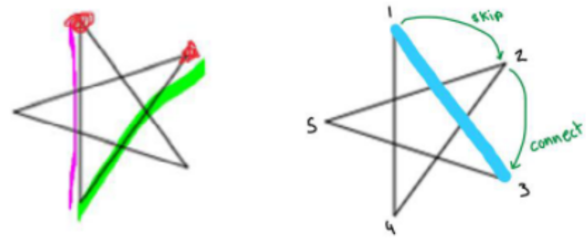
Findings

Evidence from student submissions suggests that the (n, k) (n, k) notation provided in the task description, despite providing a preconstructed symbol system to the participants, did not supplant participants' symbolizing activity. In fact, many submissions exhibited more robust symbolizing activity in direct response to the provided notation. For example, this occurred when participants used symbols to explain their intuitions about the notation to their groupmates. S-5 included the following exchange:

Martina: For the $(5,2)$ $(5,2)$ and $(7,2)$ $(7,2)$ stars, if you follow along and "draw" the lines, you are skipping 1 vertex to draw the next one. Maybe the 2 2 notates the number of steps you take as you draw the star polygon?

Bridget: Hmm let me know if I interpreted this the wrong way but here is what I got. To go from vertex Circle to vertex Triangle, I took the pink route then the green, so I counted those as two steps.

Joyce: Hmm, I was thinking about it differently. Here is a diagram of what I thought.



(a) Bridget's diagram (b) Joyce's diagram

Figure 2. Symbolizing activity in S-3.

Martina, Bridget, and Joyce demonstrate that there are multiple possible explanations for what constitutes a "skip" and use symbolizing activity to capture the underlying reasoning of each interpretation. Their discussion illustrates that participants still engaged in symbolizing activity in order to encapsulate and then compare their understanding of the (n, k) (n, k) notation within the context of the provided star polygon diagrams.

Other groups used symbolizing to hypothesize or reject alternative explanations for the provided notation. In S-13, a character proposes another interpretation of the k k in the (n, k) (n, k) symbol:

Abeni: I thought the 5 5 represented the number of vertices and the 2 2 represented how many times there are 5 5 vertices. So this one being $(5{,}2)$ $(5{,}2)$ means that it has 2 2 sets of 5 5 vertices. See in the picture below using the different colours. There are 5 5 blue vertices and 5 5 red vertices. Two different sets of vertices all together.

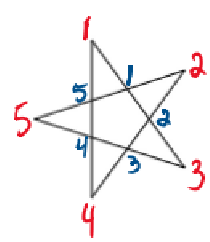


Figure 3. Abeni's suggestion for interpreting the (n, k) (n, k) notation in S-13.

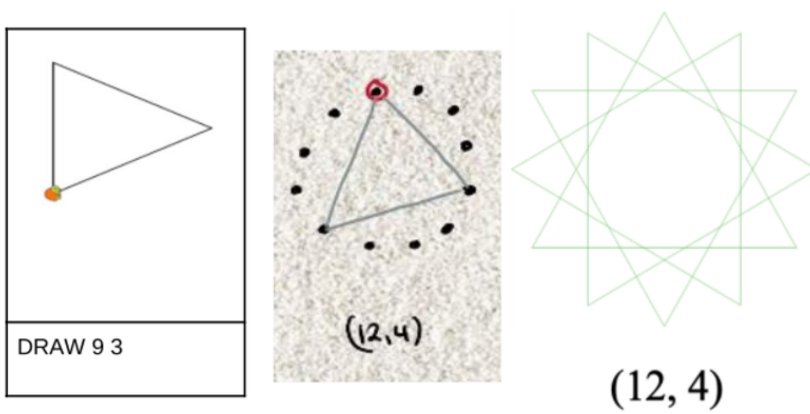
Abeni and her partner go on to draw and label multiple examples of star polygons, eventually concluding that both interpretations of the (n, k) (n, k) notation are valid. It is not until considering the provided non-examples that the characters recognize that Abeni's suggested interpretation cannot be used to differentiate these objects from the earlier examples. As Abeni observes, "My observation of 2 sets of 6 vertices holds true for this [the first non-example in Fig. 1]. So, I am not sure why it would not be a star polygon." In exploring this perceived contradiction, the characters of S-13 demonstrate how symbolizing can contribute to the act of defining.

Providing a symbolic notation had another unexpected benefit with respect to defining and theoremizing: many groups used the (n, k) (n, k) symbol as input for further symbolizing activity that facilitated the other types of advancing mathematical activity. For example, consider the following excerpt from S-5:

> *Matt*: I think that we can have two overlapping star polygons that generate irregular star polygons if we can find a number (x, y) (x, y) which satisfies the equation $(x, y) = 2 \cdot (a, b)$ $(x, y) = 2 \cdot (a, b)$ where (a, b) is a star polygon. So, for example $(14{,}6) = 2 \cdot (7{,}3)$ $(14{,}6) = 2 \cdot (7{,}3)$, and (7,3) is a star polygon. So, (14,6) should look like 2 2 star polygons layered on top of each other.

Here, Matt manipulates and generalizes the (n, k) (n, k) symbol through further symbolizing activity in order to apply that notation to a newly defined category of non-examples ("irregular star polygons"). After defining this object, Matt generates a conjecture about particular combinations of n n and k k and applies their symbol system to specific examples. In this way, Matt's symbolizing allowed him to better engage with defining and theoremizing activity.

Perhaps the most interesting symbolizing activity occurred when participants interpreted the (n, k) (n, k) symbol as instructions for executing an algorithm for constructing additional star polygons. The symbols that they generated as a result of this algorithm were simultaneously products of their algorithmatizing activity and symbols used to explain the rationale for their algorithms. Consider the following three symbols produced by S-14, S-9, and S-2 provided in Figure 4.



(a) S-14's diagram (b) S-9's diagram (c) S-2's diagram

Figure 4. Various applications of the (n, k) (n, k) *symbol as an algorithm.*

The characters in S-14 and S-2 used two different computer software systems to generate their symbols (Figure 4(a) and 4(c), respectively), whereas characters in S-9 produced their symbol (Figure 4(b)) by hand. Each final symbol is a composition of an essential symbolic component (the equilateral triangle) and various secondary symbolic elements (e.g., "unused" vertices, additional overlapping triangles, indications of a "starting vertex"). In total, each symbol in Figure 4 encapsulates its respective group's understanding of how the notational symbol (n, k) (n, k) can be interpreted and applied as an algorithm. The differences in their interpretations, manifested as the secondary symbolic elements, affected how each group would go on to define when two star polygons should be fundamentally "different."

Discussion

Overall, our findings illustrate a variety of ways in which symbolizing activity manifested while participants investigated the star polygons task. Participants' efforts to interpret the provided (n, k) (n, k) notation facilitated their future exploration of non-examples of star polygons; in this way, symbolizing led to more robust defining. Participants also created new definitions when they manipulated the (n, k) (n, k) notation and used these observations to conjecture relationships between different star polygons. These conjectures and their justification link symbolizing to theoremizing. Finally, most participants treated the (n, k) (n, k) notation as an algorithm that described the construction of a star polygon. Clearly, when this was the case, symbolizing and algorithmatizing were intimately connected.

These observations, in sum, contribute towards answering our research question: *What aspects of participants' symbolizing activity are captured by scripted dialogues recreating their progress on an investigation task?* That is, scripting tasks effectively capture symbolizing activity in a variety of modalities. Furthermore, these different manifestations of symbolizing connected to and supported the other types of advancing mathematical activity. Existing research often acknowledges this interconnection between advancing mathematical activities; this study contributes to mathematics education by highlighting specific instances of these relationships.

The Effect of Technology

In our findings, we observed that the provision of a symbolic notation for naming and describing star polygons did not detract from participants' advancing mathematical activity in general, or their symbolizing in particular; in fact, it often contributed to it. Interpreting, manipulating, and extending this notation was a productive focus of the submissions.

Just as the introduction of this notation had a positive effect on participants' engagement with the task, some kind of technology for generating star polygons was equally invaluable—it allowed participants to generate examples on a large number of vertices without constructing them tediously (and sometimes incorrectly) by hand. However, we also draw attention to the ways that technology removed opportunities to engage in advancing mathematical activity.

For example, Figure 4(c) is a star polygon that was generated by an online applet. We note that the default functionality of this applet is to draw "compound" star polygons when the number of vertices shares a common factor with the number of skips, rather than to leave some vertices "empty" (cf. Figure 4(b)). By supplanting participants' symbolizing with this particular representation of the notation, technology had a perceptible effect on participants' later mathematical activities. For instance, the symbol $(10,4)$ $(10,4)$ was interpreted by every group to be another non-example of overlapping polygons (in the vein of the provided non-examples in Figure 1) rather than a $(5,2)$ $(5,2)$ star polygon with more "empty" vertices. When this was the case, technology acted as a *reorganizer* (in the sense of Sherman, 2014) by shifting the focus of participants' thinking. Unfortunately, this reorganization appeared to remove an opportunity for theoremizing and defining.

Looking Forward

Another avenue for future research could be to investigate the didactic potential of the star polygons task itself for student guided reinvention of topics in either abstract algebra or number theory using the instructional design theory of realistic mathematics education (Gravemeijer & Doorman, 1999). Evidence in the star polygon submissions indicates that star polygons may act as an experientially real setting for recreating Euler's totient function, finite cyclic groups, their generators, and isomorphisms between finite cyclic groups of the same order.

Finally, we wonder what other ways this type of scripting task could be leveraged to observe mathematical activity in investigation group work. Future research may not be directly related to star polygons, but instead seek to apply scripting as a means of data collection for other mathematical investigations.

Kwadwo Oppong-Wadie	Michael Ion	Julia St. Goar
Elmhurst University	University of Michigan	Merrimack College

Authors of this proposal are members of an inter-institutional working group focused on the teaching and learning of transformations in college geometry courses taken by prospective secondary teachers. After exploring axioms and definitions for transformational geometry in our courses, we decided to shift to identifying not just what, but how students were learning about transformations in our courses. To explore this, we began a lesson study (Boyce et al., 2021). In this report, we discuss our engagement in the lesson study, its outcomes, and new directions.

Keywords: Geometry, Lesson Study, Professional Development, Transformations

The authors of this proposal are members of an inter-institutional working group focused on the teaching and learning of transformations in college geometry courses taken by prospective secondary teachers. As a newly formed group of educators with members representing a diversity of professional backgrounds in various higher education institutions from across the United States, it is not surprising that our preliminary work often focused on how different our courses and needs were. It was when we decided to move forward by focusing on our commonalities that the idea of conducting a lesson study took hold. We chose the goal of creating a lesson that could be used in all of our classrooms with a content focus on transformational geometry. As we refined that goal, we decided to craft a lesson that focused on definitions and axiomatic systems. We also wanted the lesson to engage students in learning from each other while comparing definitions in a way that was connected to secondary geometry objectives. Thus, we began our journey into a lesson study with a focus on transformational geometry.

Theoretical Framework

Lesson study, a teaching improvement and knowledge-building method with roots in Japanese elementary education, enables instructors to collaborate in small groups to prepare, teach, observe, and refine individual class lessons. It has been used extensively for professional development in K-12 mathematics settings; its use in tertiary settings is more limited but growing (Applegate et al., 2020; Kamen et al., 2011). The benefits of lesson study include building community and deepening mathematical and pedagogical knowledge (Fernandez, 2020). A guiding framework for the lesson study project can be found in the work of Cerbin (2011, p. 11).

The major phases of a lesson study cycle are:
1. finding a focus for the lesson study;
2. planning the research lesson;
3. planning the study;
4. teaching the lesson, observing, and gathering evidence;
5. debriefing, analyzing, and revising the lesson;
6. repeating the research cycle; and
7. documenting and disseminating lesson study findings.

In our case, the specific content focus for the lesson was the concept of isometry. In our planning, we chose to adapt a lesson successfully used by one of our group members, finding that it allowed us to embed all of our targeted goals for the lesson. As we focused on planning the study, we determined which of our group members would teach the lesson, whose classroom would be used, and how we would observe and record data related to student learning and their engagement with the lesson. Once the lesson was taught and the data and evidence were collected, we were able to debrief and organize the findings so that we could use what we learned to revise the lesson and begin again. It is important to point out that the data presented in this dissemination is from the debriefing sessions and represents the perceptions of the faculty involved. We used thematic coding (Gibbs, 2007) to categorize discussions in our debriefing sessions according to (1) our thoughts on the previous lesson and (2) what we planned to accomplish in future implementations of the lessons; and within each of these codes, we identified course content topics. In this report, we describe how engaging in lesson study has led us in new directions for attending to learning goals for our geometry students. We begin by providing some background on the lesson we created and implemented.

Lesson Background

At the onset we set some goals for the design of a lesson we could implement at our different institutions. We wanted students to learn from each other and talk about geometric concepts, definitions, and axiomatic systems in productive ways. We also wanted a lesson that would allow students to compare definitions and do so in a way that could be connected to secondary geometry from a transformation perspective. We explored several ideas for topics, such as symmetries and frieze patterns, and decided to design a lesson focused on Adinkra symbols. There are hundreds of Adinkra symbols, exhibiting a rich variety of symmetries and meanings (Adapo, 2010). Adinkra symbols originate in Ghana, and they have cultural significance, especially in Black urban communities within the United States (Oppong-Wadie, 2020). Introducing them to the prospective teachers in our geometry courses also had the potential to help them connect to this culture, which they could then build upon in their teaching.

The lesson we created consists of seven components. In the first component, students individually sort twelve Adinkra symbols and label their groupings. The second component involved students comparing and contrasting the ways their classmates created and labeled their groupings of the symbols (cf. Larsen, 2009). Did they identify symmetries or do something else? What mathematical language did they use in their labels of groupings? Here, the goals were to (a) establish a common vocabulary about symmetries and (b) provide opportunities for diverse mathematical thinking about the Adinkra symbols. During the planning stage of the lesson study, each member of the working group sorted the symbols themselves. They then compared and contrasted their groupings with the goal of anticipating the variety of student responses.

The third and fourth components of the lesson focused on a particular Adinkra symbol, Boa Me Na Me Mmoa Wo. Its name in English is, “Help me, and let me help you.” Boa Me Na

Me Mmoa Wo has reflectional symmetry (a vertical line of symmetry) and "nearly" has horizontal reflectional symmetry. For the third component, we asked students to identify the aesthetics of Boa Me Na Me Mmoa Wo and create another figure exhibiting those qualities. The fourth component involved them sharing and attempting to reach a consensus on a description of the aesthetic exhibited by Boa Me Na Me Mmoa Wo.

In the fifth component, the instructor provides additional foci for *mutuality*, which Eglash (2021) identified as the "near" symmetry aesthetic that Boa Me Na Me Mmoa Wo exhibits. Students read a one-page excerpt from Eglash's website that explains the concept of mutuality and calls for its definition as a mathematical property. The sixth lesson component involves students attempting to create such a definition. Working group members created and shared their own definitions in the lesson planning stage to help anticipate student responses. The final lesson component involves students reflecting on their learning experiences throughout the lesson.

The initial lesson was created with the intention of being repeated in a variety of settings. So far, it has been taught four times at three different universities. Due to differences in class time, some implementations moved initial or final lesson components to pre/post-class assignments. Each teaching session was delivered remotely, via Microsoft Teams or Zoom. Several (free-to-use) technologies were used to allow students to share their work (Flipgrid, Google Jamboard, Google Slides, and Padlet).

Research Questions

When considering the goals and results of a lesson study, there are two types of learning outcomes to investigate: the students' and the instructors'. Our purpose in this report is the latter; thus our analytical focus is on debriefing sessions of observers (including instructors) reflecting on lesson implementations. Our research questions are 1) to what did working group members attend in their debriefing sessions and 2) how did working group members' attentions shift over the course of the lesson study.

Methods

Data Sources

We primarily used Google Docs to create, document, and share our ideas, beginning with the group's initial lesson brainstorming and lesson planning. After the lesson was first taught, we incorporated (anonymized) versions of students' work as references for the observations that were written in the same shared document. In addition to screenshots of "final" student creations, we included screenshots of intermediate products (such as when students were working in breakout rooms). We incorporated transcriptions for all Flipgrid-completed video responses. Following the teaching of a lesson, we met over Zoom (recorded and transcribed) for an hour of debriefing, with at least one working group member taking notes. In addition to inputting their own observations, working group members added comments to the Google Doc to highlight others' ideas or to propose connections or questions for discussion. The initial lesson plan was modified between teaching sessions to accommodate differences in the class meeting duration as well as suggestions for modification from the working group participants. This updated copy of the lesson plan was used to enter copies of student work, observations and reflections, comments, and questions for the following teaching session.

Members of the working group were present as observers in two of the four teaching instances, the first and fourth. We focus on data from these two teaching sessions in the current study. The first observed setting was a 210 minute class taught in April 2021. The second observed setting was a 75-minute class taught in April 2022. We focus on the analysis of the post-teaching debriefing sessions for these two teaching sessions. The comparison of the two debriefing sessions aims to clarify how the teaching of the lesson has evolved from the observers' perspectives, how these outcomes inform lesson revisions, and how these changes reflect instructor learning.

Methodology

For the analysis of post-teaching debriefing sessions, the focus was on observers' (including the instructors') reflections on how the teaching went and what aspects could be continued or improved. The session transcriptions were open coded using qualitative data analysis software (NVivo 12). The second author (who was not involved in either debrief sessions or classroom observations) manually coded the data and compared it with the results of NVivo's automated insights to capture elements within the data that may have been overlooked. Multiple iterations of inductive/deductive thematic analysis (Braun & Clarke, 2006; Gibbs, 2007) were conducted to identify and refine the themes emerging from the data. The fifth author (who was involved in both debrief sessions and one of the observations) reviewed these themes and re-coded the data from each of the two debriefing sessions into two categories (thoughts on the implementation of the session and thoughts on next steps). The analysis shown in the results section represents the themes from the debrief sessions in a Sankey diagram (Figure 1), where the numbers in the diagram represent the occurrences of the themes in the conversations (Riehmann et al., 2005).

Results

The Session 1 [S1] debriefing was attended by six observers and the Session 4 [S4] debriefing was attended by five observers (including the instructors). Figure 1 depicts the eight coding themes that emerged from analysis across the debriefing sessions and their relationships with the two categories of reflection thoughts. We elaborate on these results by first identifying themes that were exhibited in one debrief but not the other, and then identifying themes that were present across the two debriefing sessions. In this way, we identify shifts in instructors' attentions over the course of the lesson study.

Divergent Themes Across Debrief Sessions

In the first debriefing session, *technology use and its issues*, *student self-evaluating, and student-instructor dialogue,* were three main points of discussion when talking about the effectiveness of the lesson. In one of these conversations about technology use, an observer mentioned, "....but they seem to get into precision and locked in on precision very quickly—they had to use GeoGebra. Because it wouldn't be precise, if they just sketched something." Another noted, "I also think sometimes the technology might have limited their own drawings." A co-instructor spoke about a norm of students self-evaluating their work in her class (the ones in this observation):

> And I mean, when it's really off that I would rather me say you're off task, I would give them the framework and tell me evaluate yourself: where do you see there's issues with what's happening and what's in relation to how effective this should be? And they're like, okay, yeah, this is off. And they kind of would make a note, but they would self-assess…because I hold them accountable.

Finally, when discussing the dialogue between students and teachers, the discussions focused on the necessity for these whole-class discussions to be more effective toward the goals of the lesson, as well as brainstorming ways to keep the class engaged. For example, a participant noted, “Because I think too often, we're always mesmerized by, you know, word choice. But is it mathematically sound? Is it accurate? What are they emphasizing? And if you're not careful, it’ll become non-productive.”

The fourth debriefing session highlights a shift away from identifying local issues with the lesson and towards more global issues, such as ideas for how the lesson fits more broadly with *meeting the goals of the course.* When it came to meeting the goals of the course, the debriefing participants discussed where to place the lesson in the course’s topic sequence: “I feel like this for me, would be a an initial lesson, as I don't see it as a heavy content-oriented lesson and I was thinking like where would I go after this if I took the class time?” and “[G]ood idea, because at the moment we don't have that follow up lesson and, yes, students might be left to think, what is it that I gained from this?”

Convergent Themes Across Debrief Sessions

A number of themes emerged across both debrief sessions. One example was how instructors could work towards aligning with other important mathematics education topics, such as *defining and precision*. When speaking about the role of the lesson and its relationship to defining and precision, an observer in S1 offered,

> I was thinking for the part where we would be offering a definition of mutuality and then looking at everyone else's sorting or their creation of their new symbol to see if that those fit the definitions, we could ask, ‘[W]hat makes a good mathematical definition—what is a mathematical definition?’

Another S1 observer commented that

> [I] thought that it was interesting that they were talking about precision, and in terms of like, being able to produce a very exact diagram. But, you know, you can be precise and have a very sketchy, inaccurate diagram. It's about like, how you're actually defining what's part of the diagram.

The other themes that were present across debriefing sessions, *student collaboration*, *technology and its issues*, *time management*, and *scaffolding*, were often intertwined with the *defining and precision* theme. For instance, an observer in S1 suggested,

> At [component three of the lesson], they are just trying to make something that has the same aesthetic as that figure. So [right now] it's still very open. So yeah, the idea that … it has to have ovals and triangles, and it has to have squares is valid. I mean, there's nothing to say that shouldn't be…. How soon do we want to tell them that that's wrong? Or guide them? … I think that if we did early, we might have been more apt to get more discussion about the transformations or the actual definitions.

Another S1 observer suggested,

> I’m wondering if we had gone into the groups, if we had been able to prompt them with a question. Like not, necessarily given it away, but had been able to ask them a question that could have, you know, prompted for their diagrams to get a little bit closer.

In S4, a different observer commented that,

> We provide only one example given to them and say this shape exhibits something we call mutuality. I’m wondering if we found a second shape that could be used, and after a certain point within the lesson said, ‘Okay, here’s another shape that exhibits mutuality,

how would you change your definition?’ If it’s a well-chosen second shape, it might start pushing them in the direction of using more of a transformational definition.

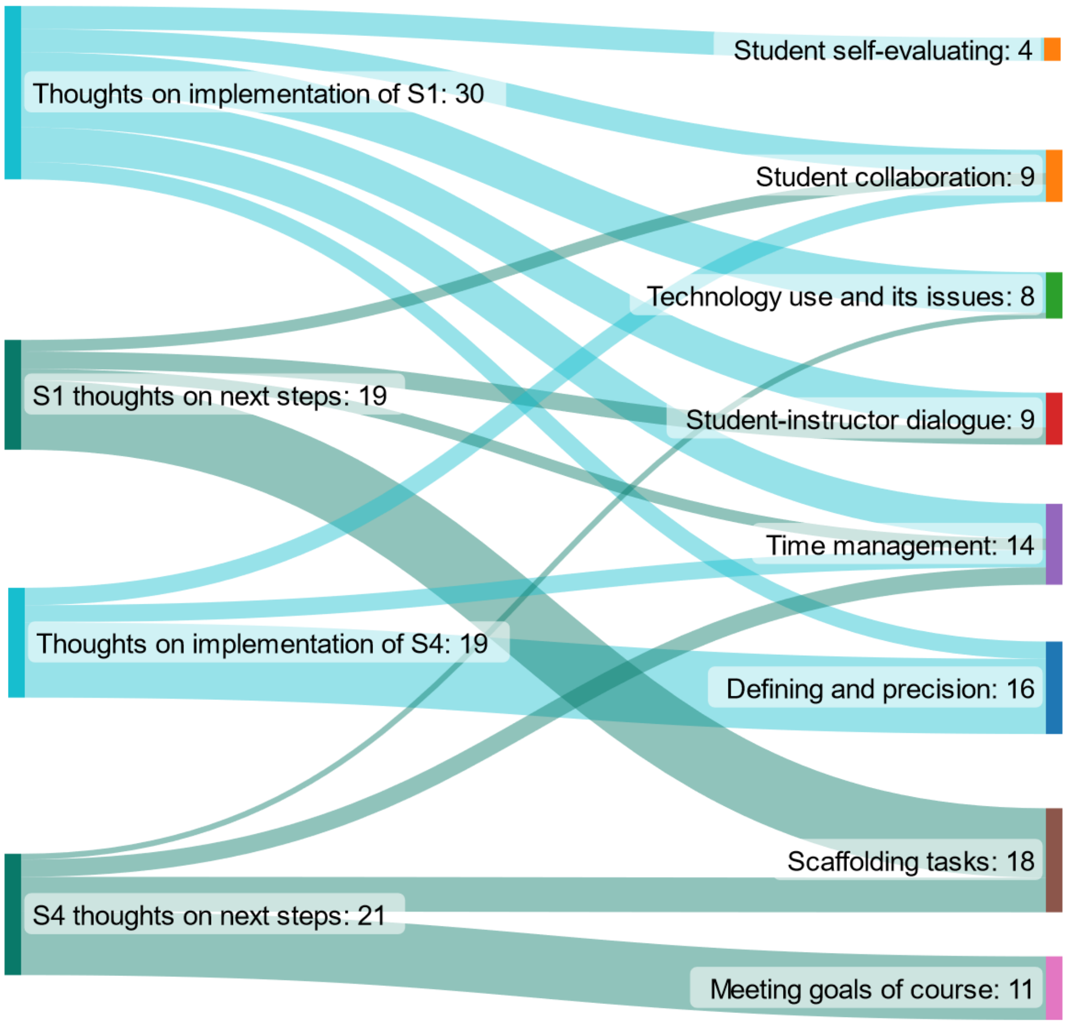

Figure 1: Sankey diagram of themes across debriefing sessions

Discussion

In this report, we have described how the foci of debriefing sessions changed over a one-year span within a lesson study. We have illustrated how observers’ attention regarding implementations and ideas for modifications evolved during debriefing sessions. These shifts accompany new ideas for lesson modifications. Our next steps in our lesson study include enhancing opportunities for instructors to make connections between the mathematical content found in the lesson we created to topics included in individual courses. An important outcome of these discussions is consideration of the placement of the lesson within a particular course. One instructor is planning for a next version of the lesson to be used as a springboard into a lesson about definitions in mathematics. The instructor wants to embed this topic into the course to better align the course offering with student learning outcomes developed by a group of mathematicians and mathematics educators. Those outcomes include that students will understand the role of definitions in mathematical discourse (GeT: A Pencil, 2022a). As a result, the next time the lesson is taught in this particular course, it will be followed by a lesson that will lead students to determine the need for precision in definitions by engaging them in an activity in which they will compare and contrast their constructed definitions during the lesson. In particular, they will examine if all constructed definitions of mutuality lead to the same symbols satisfying the definitions.

Furthermore, the next version of the lesson is planned to be modified to include more or alternative Adinkra symbols in order to give students sufficient opportunities to notice features that relate to transformational geometry topics of translations, reflections, rotations, and dilations. This is also a topic aligned to a targeted learning outcome whereby students will use transformations to explore definitions and theorems about congruence, similarity, and symmetry (GeT: A Pencil 2022b). In previous versions of the lesson, none of the symbols presented to students exhibited connections specifically to translations and dilations. Also, given that the change in Adinkra symbols will include more than one example that exhibits the concept of mutuality, the instructor will include time for students to reflect upon and discuss how the meaning of an Adinkra symbol might influence the existence of, or make more apparent, mutuality in the symbol itself.

As we continue to seek ways to make geometric concepts meaningful and engaging for our prospective teachers and their students, it behooves us to go beyond what has been done traditionally and venture into uncharted terrain. On the basis of his familiarity with Adinkra symbols, having conducted research on its uses in instruction and education by extension, the fourth author joined this project after the S4 debriefing to not only make meaningful contributions, but also emphasize that by designing and implementing a lesson study, students can be engaged in studying mathematics concepts from a non-western perspective. The task at hand includes working to provide a format for identification of geometric ideas and the development of working definitions in anticipation of student engagement with Adinkra symbols from the standpoint of its aesthetic qualities. The importance of the sorting activity to this lesson study will inform suggestions for the inclusion or deletion of specific Adinkra symbols when being revised. He will serve as a resource person for meanings, translations, and context of Adinkra symbols selected for use in this lesson study. By doing the aforementioned, we hope that prospective teachers will be exposed to different ways of teaching mathematics concepts and connecting to cultural knowledge for the benefit of learners.

Cerbin claims that "[a] lesson is a place where our instructional goals come to life" (2011, p. 3). Living that "life" with others serves to make the teaching experience deeper and more meaningful. A lesson study challenges us to not only individually decide what is important, but necessitates the communication of our beliefs to others. Through the process, we learn about ourselves and about others. We grow. Clearly, participating in this type of undertaking requires trust and respect. Without a doubt, the time spent on becoming a community and developing common goals and solutions has been time well spent for us. In the end, the work impacts our students. Focusing on a lesson as a shared experience allows us to nibble our way into broader changes with respect to what we teach and how we teach it. The experience also provides us a community where we can discuss student difficulties (in general) with others who care as much about the outcome as we do.

Centering Connections and Collaboration in the Evaluation of STEM Education Transformation

Carrie Diaz Eaton, Bates College, RIOS Institute
Yuhao Zhao, Bates College, RIOS Institute
Robin Taylor, RTRES Consulting

In this paper, we seek to understand the formation of a national network constructed for change in STEM education. To center the role of making connections in community and collaborations between network members, we use social network analysis (SNA) methods. We examine the impact of an in-person conference with the goals to bring together disparate groups around a common issue on network collaboration structure. We also examine the effect of post-conference virtual community building activities on network collaboration structure. A major limitation of SNA is response rate which, due to the pandemic, artificially drove a loss of collaboration. However, this loss was mitigated by new collaborations, particularly by influencers and boundary spanners. In addition, a sustained, year-long suite of virtual activities designed for community building and collaboration increased the collaboration activity in the network by 12.5%.

Keywords: evaluation, professional development, STEM education, networks, collaboration

A common form of professional development in STEM is the development of a learning community or community of practice. Originally designed to minimize professional development time while maximizing impact (Vescio et al. 2008), involvement in learning communities has been shown to impact postsecondary STEM classroom instructional practice (e.g. Manduca et al. 2017) and can also positively impacts persistence in STEM professional development activities (e.g. McCourt et al. 2017). The kinds of collegial interactions and support fostered in communities of practice have become recognized as a key factor in instructor adoption of cutting edge STEM classroom practices and can outweigh other barriers to reform (McConnell et al. 2020). McCourt et al. noted that participation in networks of individuals outside of one's department or institution provided participants with much needed space for pedagogical discussions and can transmit novel ideas across institutional boundaries (2017).

Educational innovation in postsecondary STEM education is both about infusing emerging technologies into classroom content, such as data science and course-based undergraduate research experiences, and about the broader human context, considering the social justice implications and the need to broaden participation (Rodenbusch et al. 2016, Holm and Saxe, 2016, Ballen et al. 2017, Alexander et al. 2022). This reflects a broader national dialogue on STEM education reform. In this context, an alternate target of intervention is the intentional building of networks and connections to support reform in undergraduate STEM education (e.g. Diaz Eaton et al. 2017). While the studies above focus on the efficacy of educator communities of practice in affecting classroom practice, a different set of literature driven by Kezar and colleagues strives to understand how these communities of practice can become communities of transformation (Gehrke and Kezar 2015, Kezar et al. 2018, Akman et al. 2020). However, researching programs that aim to act on a national reform level is challenging given the time scale of such change. In this paper we use network analysis as a tool to explore the structure of an emergent community of transformation. We ask:

- How does an in-person meeting affect collaboration network structure?
- Does participation in an in-person meeting affect engagement/persistence in the network?
- How does the availability of virtual professional development impact network collaboration structure and growth?

- Is network structure influenced by *boundary spanners* and/or *influencers*?

For the purposes of this paper, we define *boundary spanners* as individuals which broker knowledge between clusters of individuals and *influencers* as individuals who recruit a disproportionately large number of professional collaborations during the time of the study.

Theoretical Background

The co-authors come from a variety of educational training backgrounds in STEM and education including mathematics, education, biology, economics, and evaluation and include a variety of racial and ethnic points of view as Latinx, White, and Asian. Author 1, who is Latinx, draws their understanding of networks both from personal experience with support networks and from research in mathematical ecology and sustainability. However, both perspectives intersect in the writings of Rochelle Gutiérrez in "Living Mathematx: Towards a Vision for the Future" (2017). Gutiérrez outlines three Indigenous epistemologies, In Lak'ech, reciprocity, and Nepantla, which inform her framework for the teaching of mathematics, but which also deeply resonate with our theoretical perspectives on developing communities of practice and transformation. In Lak'ech describes a mutualistic community in which individuals can see the commonalities between each other. Reciprocity describes how communities of practice help one another achieve each other's goals through the sharing of experience and knowledge. Nepantla is the work of knowledge brokers and *boundary spanners*. *Boundary spanners* weave the community of transformation, moving across learning communities, negotiating tensions across contexts and goals, and moving the network towards transformation (Gutiérrez 2017, Masuda et al. 2018). We also draw from other frameworks which focus on the theory of change, or functional aspects of designing such learning communities and broader networks, and how they connect to change theory (Wenger 1998, LeMahieu et al. 2017, Gehrke and Kezar 2015). For example, an often first step of bringing together a community around a common goal, may be considered a way to foster In Lak'ech.

Social Network Analysis (SNA) is a mixed-methods approach that considers people (nodes) and the connections between them (edges) as important to the research question at hand and is often used in education research to examine learning effects due to peer interaction (Carolan 2013). In postsecondary STEM education, SNA research has focused on understanding classroom interactions and scientific mentoring (Aikens et al. 2016, Grunspan et al. 2017) and more recently has been used to examine adoption of evidence-based instructional practices in communities of practice (Ma et al 2019). However, SNA research in organizational theory examines community networks in the context of organizational change and the transformation of a field. We draw from mathematical work rethinking the influencer as someone who is well connected to someone which embodies reciprocity, making new active collaborations (Jun-Lan et al 2019). Work by Masuda et al. (2018) highlights the importance of Nepantla, examining the role of boundary spanning in innovation. Research by Frank et al. (2022) intervened in a network to promote boundary spanning. Still, many STEM education projects are designing networks as interventions, but lack techniques for evaluation of the network building aspects (Diaz Eaton et al. 2017). SNA promises an avenue that helps us understand both community formation and centers the connections and reciprocity important in a decolonized view of STEM education transformation. In this paper, we use data from a National Science Foundation (NSF)-funded research coordination network (RCN) in STEM education and use SNA techniques to explore the emergent community structure and collaboration.

Methods

Data Collection

The NSF RCN UBE program funds networks of individuals to advance undergraduate biology education and "activities across disciplinary, organizational, geographic, and international boundaries are encouraged" (NSF 2022, Diaz Eaton et al. 2016). The Sustainability Strategies for Open Resources to promote and Equitable Undergraduate Biology Education (SCORE-UBE) Summit was hosted by Bates College on October 17th through 19th, 2019. The goal of SCORE was to create a network for participants with various open education (OE) and STEM education affiliations to network, learn and address issues related to sustainability of open education and centering values of social justice, equity, diversity, and inclusion within open education. A total of 35 individuals representing more than 17 OE organizations participated in the SCORE Summit. The growth of the SCORE Network continued to grow through additional participation across new initiatives sponsored by additional funding grants and OE collaborations and via virtual activities hosted on QUBES Hub (an online community of math and biology educators who share education resources and methods to support instruction of undergraduate students to use quantitative approaches to tackle real, complex, biological problems). Over the 22 months of the study, activities included two virtual peer mentoring networks on equity and inclusion in open and STEM education and open educational practices, a virtual leadership program in open STEM education, a collaborative grant program which resulted in a virtual showcase of projects, and a working group on metadata justice for OER.

By June 2021, 72 individuals were current members of the SCORE group on QUBES Hub. SCORE members represented at least 67 different organizations/institutions – including 65 academic/higher ed institutions, nonprofits focused on open education, funding agencies/foundations, consulting firms, community of practice networks, professional societies, museums, and research labs. Members were geographically located across 28 US states and India. Disciplinary degrees of the steering committee included mathematics (2), biological sciences (2), STEM education (1), and library science (1).

All participants for the SCORE-UBE Summit and members who joined the SCORE group on QUBES Hub were asked to complete surveys using a multiple-criterion recognition question approach (Singleton and Asher, 1977). Members indicated the nature of their relationship with each participant in the network by selecting one of the following response options: (1) This is me; (2) I am not familiar with this person; (3) I am familiar with this person's work; (4) I have met this person; or (4) I have professionally collaborated with this person. For the survey, "professionally collaborated" was defined as actively engaging in cooperative work with another person, and this level is the focus of the social network analysis to follow. Response rates across survey administrations were 72.2% (26 of 36) of participants surveyed at pre, 30.5% (11 of 36) at mid, and 29.5% (18 of 61) at post. Over the course of the survey administration names were removed from the survey for those who did not participate in SCORE activities (i.e., registered but no attendance) and names were added to include new members who joined the SCORE QUBES Hub platform.

Network Analysis

Survey responses were de-identified by the evaluator in preparation for network analysis. For the purposes of the analysis below, we defined an edge between participant 1 to participant 2 if participant 1 reported that they had professionally collaborated with participant 2 (*i.e.* reported a level 5 connection in the survey). Therefore, the graphs constructed are directed graphs. For each pairwise comparison, we limited the adjacency matrix describing this network graph to those individuals who appeared in the both survey datasets, either as a respondent or as someone who was named as a collaborator. Comparisons of networks are visualized in a way that shows the transformation in collaboration during specific time intervals.

Connectance is calculated as the number of edges realized in the total network out of the possible connections. An individual is considered as an *influencer* if they gained a meaningful share of new edges during a particular time interval. An individual is considered a *boundary spanner* if multiple new collaborations are with individuals who are not already collaborating with each other.

Communities are detected using algorithm 'cluster_edge_betweenness' which calculates the *edge betweenness* (number of shortest path through the edge), removes the edge with highest value, and recalculates it, etc. Each color indicates a specific community in visualizations below.

All analyses and visualizations were conducted using the 'igraph' package in R (2022) and all code can be found on GitHub (https://github.com/yzha0/RUME_SNA).

Results

Summit's Effect on Collaborations

To gain a better understanding of how the Summit affected the network, we look at the general transformation of the network in Figure 1 over a time internal in which the SCORE Summit was held. Recall that connections in these graphs are those reported as "active collaborations." Connectance among individuals is somewhat low in pre-Summit survey (0.160), which is to be expected as the goal of this program is to bring together individuals across multiple contexts who may not have encountered each other before. From Figure 1, green links represent the new edge growth after the Summit and dotted links represent the loss of active collaboration in the network.

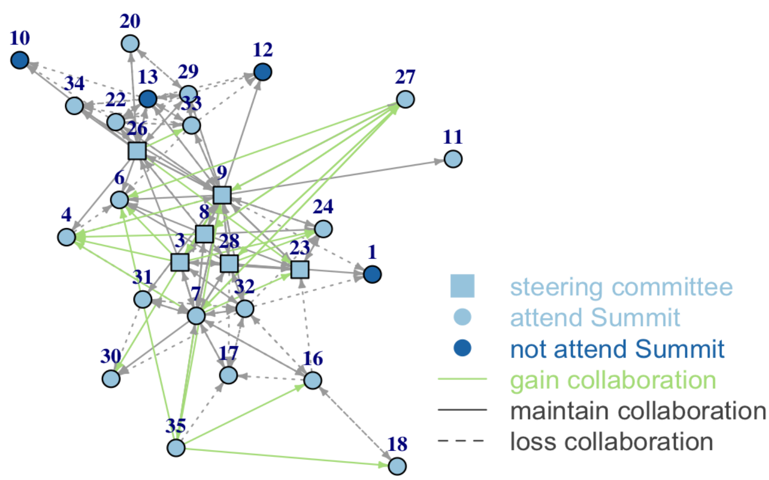

Figure 1. Change in collaboration network from prior to the SCORE Summit in October 2019 to after the SCORE Summit in February 2020. No activities other than the Summit were planned during this time interval.

Connectance decreases over this Summit time period (to 0.112). *A priori,* given the "have collaborated" language in the survey, we would not have expected any loss because historical collaboration would have continued to be reported. Indeed, very little of this loss (4 edges) were due to an individual reporting a lower collaborative status with another network member.

Instead, the majority of collaborative loss seemed to be driven by the response rate differentials. Individuals not attending the Summit (Figure 1, dark blue) suffered more collaborative loss than those who attended (Figure 1, blue), though most of these individuals did not respond to the February survey, which likely amplified this signal.

A few individuals were responsible for adding the majority of new connections, mitigating collaborative loss. Individual 3 seemed to report many new active collaborations, though the collaborators did not in all cases report them. It could be that Individual 3 was initiating collaborative discussions, whereas others saw them as more exploratory in nature. A clear influencer was Individual 27, who prior to the Summit, had weak connections to other SCORE Network participants - no active collaborations, but in some cases a familiarity with the person's work, but had never met. As a PI of a math education project, this person was an "outsider" to the "in-network" of a biology-heavy STEM education group, which brought new expertise and experience from outside the usual connections.

Promoting Collaboration via Virtual Activities

Between February 2020 and June 2021, the SCORE Network received additional funding from the Hewlett Foundation and launched multiple virtual activities. This included learning communities, a collaborative webinar series on Inclusive STEM Education, a newsletter, and a mini-grants program to foster collaborative projects within the network. While the network itself increased in size, in Figure 2 we limit ourselves to examining the change among those who were in the network in February 2020.

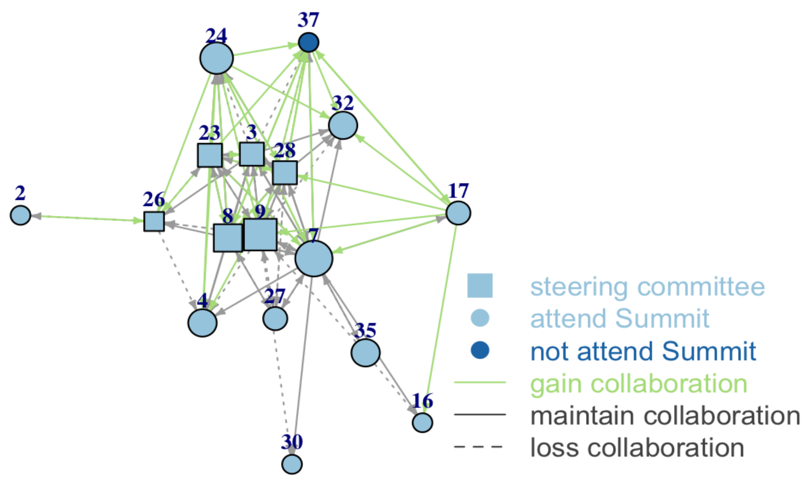

Figure 2. Change in collaboration network from just after the SCORE Summit in February 2020 to June 2021 at the end of the NSF SCORE-UBE grant period. A number of virtual and community building activities were planned during this time interval. Node size is scaled to the number of learning communities and mini-grants activities in which the individual actively participated during this time.

Despite another significant response rate drop among initially surveyed members, which should artificially drive connectance down, professional collaboration connectance in the network among survey respondents increased from 0.235 to 0.265, an effect size increase of 12.5%. By cross referencing the collaborations list to activity participation list, we can attribute a portion of this increase to a SCORE Network mini-grants program and joint authorship on an article about the Summit themes. The mini-grants program supported intentional collaborations across members to pursue and implement additional funding to support centering equity within

STEM Open Education as well as collaborations of members across multiple open education organizations to combine resources to support sustainability of their own initiatives.

At this point, SCORE Network members who were included in the initial survey, but ultimately did not attend the Summit are now no longer connected - ultimately they did not actively persist in this professional development network. However, we do see influencers and boundary spanners acting in this network. Individual 37 is a new member introduced to the network through virtual activities. They become an influencer in this network, gaining a significant number of active collaborations. Individual 17, who attended the Summit, becomes an influencer in the network and also a boundary spanner in the network, as their collaborations span across individuals that do not already have connections between each other.

In Figure 2, individuals that took part in multiple SCORE activities are represented with a larger node size. One can visually see that SCORE-sponsored activity participation does not necessarily correlate with increased collaborations.

Building an Interdisciplinary Community

Prior to the Summit, among the invitees, there were distinct two clusters of active collaboration in the network (see Figure 3, left), which together included approximately 43% of all nodes. The green cluster was primarily related to life and environmental science education and strongly tied to the QUBES community. The yellow cluster was related to the hosting location, Bates College. All other individuals did not have a strong clustering to each other and affiliation areas included Open Education, math, libraries, and non-profit foundations. By June 2021, the clustering has changed, so that approximately 82% of all nodes are now part of one cluster (see Figure 3, right) with open education, mathematics, and biology clustered together.

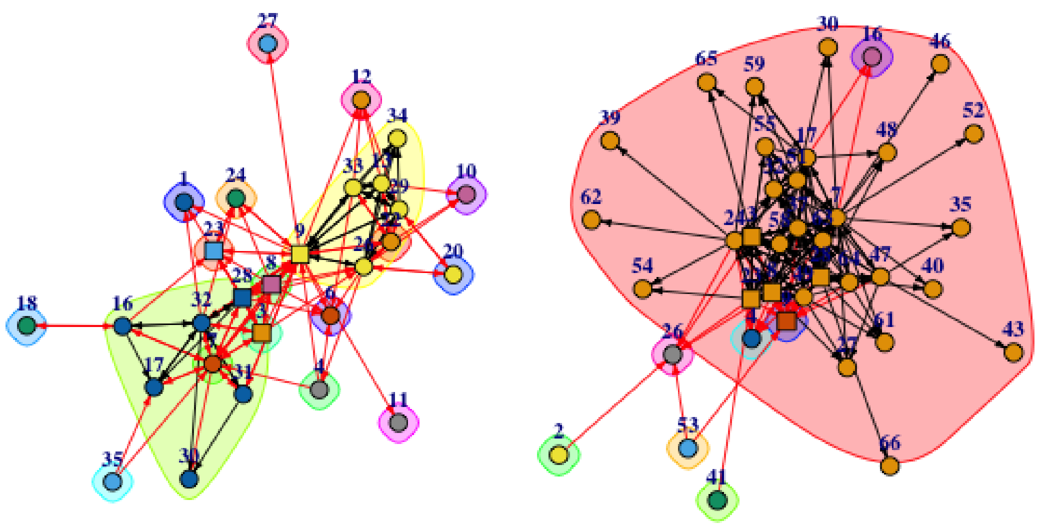

Figure 3. (Left) Clustering of the collaboration network in 2019 before SCORE activities. Navy nodes are included in the green-shaded cluster and yellow nodes are included in the yellow-shaded cluster. (Right) Clustering of the collaboration network after Summit and Virtual activities in June 2021. Orange nodes are included in the red-shaded cluster.

Discussion

The goals of the SCORE Summit were to help the community see commonalities, form relationships, and spark conversations about new directions and collaboration. The Summit itself did not provide a vehicle for active collaboration, yet individuals with new and boundary spanning interests provided an opportunity for new collaborations to launch. Attending the in-person summit seemed to affect persistence in the network for those that were present in the network early into the formation of SCORE. However, many more members joined during the virtual activities period, indicating that virtual activities are important to continued network growth. In addition, the vast majority of new collaborations were gained during virtual activities, and many virtual activities were led or co-led by SUMMIT participants. These virtual programs were designed to foster new and continued discussions on equity and inclusion and collaborations and spur new collaborations among Network members. This supports prior work pointing to the effectiveness of hybrid approaches (Brooks 2010, Hayward and Laursen, 2018). A network participant reflects on influence of this network in mathematics education reform:

> *"The [redacted mathematics society committee] has expressed an interest making considerations of diversity, equity, and inclusion more intentional and systematic in the way we think about the mathematics curriculum…Thanks in good part to the SCORE network and our summer study group, I feel more equipped to contribute to these discussions than I did a year or two ago."*

SNA allows us to quantify the increased collaboration and visualize the way that the structure of collaborations in the network has changed after a combination of in-person and virtual programming. We see a more unified community, possible indications of In Lak'ech - seeing commonalities. We can also see how particular *boundary spanners* and *influencers* aid in Nepantla, modifying the weave of the network to achieve this change.

Joining this structural data with qualitative surveys of learning due to the activities would help us better evaluate reciprocity - whether and how these structural bridges might reflect collaborative learning across the network. This would build on and connect to other work in STEM education studying communities of practice, such as Hayward and Laursen's paper (2018) which used SNA alongside qualitative techniques to understand the importance of receiving peer support and encouragement in implementing new ideas.

The determination of actors and relationships included in the pre-survey study were bounded by those who registered to attend the SCORE Summit, and while subsequent survey administrations sought to capture the relational data of new members to the network at these different time periods, this multiple-criterion recognition question approach (Singleton and Asher, 1977) did not capture changes in relationships for these additional members over time since new members were not included in previous survey administrations. Another limitation to examining network growth was the low response rates at mid- and final-survey administration resulting in an underrepresentation of network growth. While many factors are found to contribute to low response rates, it is uncertain how the increased use of survey-based research activities during the COVID-19 pandemic might have resulted in survey fatigue and decreased response rates (de Koning et al. 2021, Grandstaff and Webber 2021). Future network analysis which examines growth for communities of practice which evolve across time may consider different wording for multiple recognition questions or utilize an alternative approach such as the multiple name generator approach (Kogovsek et al., 2002). Despite these limitations with data collection, SNA provided valuable insights into structural changes in the network which may help support SCORE in a move towards a community of transformation.

APOS Levels, Stages, and Coordinated Topics as Transitional Points Case of Range of a Linear Transformation

Hamide Dogan	Candelario Castaneda

Gabriela A. Acuna	Zachary R. Rosalez
UTEP	UTEP

This paper discusses findings from an ongoing study investigating mental mechanisms involved in the conceptualization of linear transformations from the perspective of APOS theory. Data reported in this paper came from 44-first year linear algebra students' responses on a task regarding the range of a linear transformation. Our analysis revealed differences in APOS Levels, Stages, and Coordinated topics. Moreover, our findings pointed to connections between Levels/Stages of the range concept and mental mechanisms of representations of matrix multiplications. That is, our findings revealed that the absence of these representations from ones conceptualization process may result in irreversible misconceptions. More importantly, we identified more transitions occurring among Levels/Stages when linear combination expressions were considered as representations of matrix multiplications.

Keywords: Linear Transformations, APOS theory, Mental Mechanisms, and Transitional Points.

In linear algebra education, many topics, such as vector space and eigen-theory, have been studied extensively. To this point, linear transformations received very little attention. In the Literature, we found three studies that investigated connections between transformations and function ideas (Andrews-Larson, et al. 2017; Zandieh et al. 2017; Turgut, 2019), and only one by Oktac, et al. (2021) that investigated mental mechanisms of the null space of a linear transformation from the perspective of APOS theory. Our ongoing work is too investigating various features of linear transformations from the perspective of APOS theory. In this paper, we discuss APOS Stages, Levels and Coordinated topics our participants displayed in their responses to a question regarding the range concept. Our main goal was to examine potential transitional points in the learning of the range concept.

Literature and Theoretical Perspective

The Literature on Linear Algebra Education

Two recent publications, the ICME-13 Monographs and Journal of ZDM 2019 special issue on linear algebra, compiled most up-to-date research on linear algebra education. Between the two, some studies investigated general topics such as instructional approaches (Trigueros, 2018) and visualization (Harel, 2019) and others looked at specific topics such as vector spaces (Caglayan, 2019), eigen-theory (Karakok, 2019), and linear independence (Dogan, et al., 2022; Dogan, 2019). Many of them included, in their analysis, theoretical perspectives; for example APOS (Oktac, 2021), Tall's three worlds of mathematical thinking (Stewart et al, 2019), and Harel's DNR concepts (Harel, 2018).

Up to this point, we found only four studies concerning linear transformations. Three of which are by Andrews-Larson, et. al. (2017), Zandieh, et. al. (2017), and Turgut (2019). The forth is by Oktac, et. al. (2021). The first three studied the conceptualization of matrices as linear transformations. These authors discussed how the knowledge of the function concept had implications for one's identification of linear transformations. The fourth study by Oktac et. al. (2021), borrowing from APOS theory, discussed APOS Levels as displayed in their student responses to a question regarding the null space of a linear transformation, specifically, focusing on the pre-image notion. Their findings pointed to the role of reversal of linear transformations in the conceptualization of pre-image and null space ideas. Our work reported here, also borrowing from APOS, studied our participant responses to a question concerning the range of a linear transformation.

Theoretical Perspective-APOS

APOS theory describes features of mental mechanisms applied in the formation of the knowledge of advanced mathematical topics. The theory describes the mental mechanisms through Stages, namely, Action (A), Process (P), Object (O), and Schema (S). In our analysis, we considered APOS Stages as mental mechanisms our participants were working with at the time of the data collection. The theory considers the Stages (A, P, O, S), interchangeably, to stand for conceptions, structures, mechanisms, and stages (Arnon et. al., 2014).

According to the theory, learners are functioning at an Action Stage if they are acting on entities via external stimuli. For example, one may observe a learner functioning at an Action Stage if the learner feels the need to solve the system Ax=0 before determining the linear independence of a set of vectors. Here, solving the system Ax=0 provides an external stimulus for the learner.

APOS considers a learner to be working at a Process Stage if the learner determines the linear independence through a mental recognition (an internal stimulus) of certain features of vectors such as the ones with the same or different component values. Here, the mental recognition of the features provides an internal stimulus for the learner.

According to Oktac, et. al. (2021), "When Processes are encapsulated they become Objects to which Actions or Processes related to other concepts can be applied." (p. 3). Thus, a learner identifying linear independence via the comparison of number of vectors and the dimension of a space is considered to have encapsulated Processes. That is, the learner is considered to be acting at an Object Stage, having already objectified vectors as objects of a space (set).

According to APOS, there are additional conceptual entities that can facilitate the development of and transitions between Stages. The ones that are relevant to our work are named as Coordination, Reversal and Levels. Coordination is described as involving mental mechanisms where two or more mechanisms united to give rise to a new Stage. Reversal is described as mental processes being reverted. Levels are defined as partial mental mechanisms whose features fall in-between Stages. An example of a Level, between Process and Object Stages, is when a learner considers the linear independence concept in the context of a set of three vectors with only one having a zero component value. Here, the learner is clearly functioning with an internal stimulus, mentally recognizing a pattern among component values of vectors. That is, the learner is applying a mental mechanism acting at a Level between Process and Object Stages.

APOS, furthermore, considers Stages as invariant constructs and asserts the necessity of each Stage for the development of successive Stages (Arnon et. al. 2014).That is, Stages are considered to be sequential. Levels, on the other hand, are considered non-invariant and may vary. The theory further elaborates that "a subject may be able to move to the next Level or Stage rapidly so that a Level is skipped, done very quickly, or is not observable in the already acquired higher Level or Stage" (Arnon et. al. 2014, p. 139).

Methodology

Our data came from 44 first-year matrix algebra students' responses to a question on the nullspace and range of a linear transformation (see fig.1) at a US institution from spring 2020 semester. Student came from a matrix algebra course met twice a week at noon via Blackboard, an online course delivery platform, for an hour and 20 minutes. The question was administered before the end of a class meeting through a problem solving session lasting about 20 minutes. Groups of three to four were formed and sent to designated online rooms for groups to discuss the question among themselves. Instructor was absent from the rooms and discussions. Before leaving the main class meeting room to their designated rooms, students were instructed to, individually, submit online, by 11:59 pm the same day, their own responses with explanations in detail. The particular class meeting ended by groups finishing their discussions in the designated rooms. The student population comprised of engineering, science, and mathematics majors. Linear algebra was the first theory-oriented course with high abstract level that the students took. The students came with very little or no maturity for the high abstraction required by this course.

We analyzed student responses to the question from the perspective of APOS theory. Specifically, we, first, categorized the responses based on student descriptions of the range concept (or its vectors) of the transformation given in Figure 1. Next, we identified APOS Stages and Levels displayed in responses of each category. In this paper, we discuss only the findings that came from part ii of the question seen in Figure 1.

Consider T:R^2->R^2 with $T([a\ b\ ]) = [1\ 1\ 1\ 1\ ][a\ b\ ]$. State at least three vectors that are:
i) In Null space (T) ii) In Range (T). Explain your reasoning in detail.

Figure 1. Mathematical task considered during group discussions and individual responses submitted online.

Results

We identified five distinct categories. Table 1 summarizes categories, Levels, Stages, and Coordinated topics. Overall, categories 1 and 2 had the highest tally of responses (12). The highest variability among Levels/Stages came in category 3 with three different mental mechanisms and the least variability came in category 5 with one Stage. Each of the categories 1-3 considered a representation of the matrix multiplication given in Figure 1. By means of these representations, some responses in these categories applied external stimuli in determining range vectors. One external stimulus was the evaluation of the matrix multiplication, A$[a\ b\ ]$, mainly in category 1; the general form, $[a + b\ a + b\ ]$, in category 2; and the linear combination form, $a[1\ 1\ ] + b[1\ 1\ ]$, in category 3. Each of these evaluations were done for specific values of *a* and *b*. The values of *a* and *b* took varying roles (for the participants) from *(a, b)* pairs being vectors of the domain of the transformation to *a*, *b* values being scalars for the linear combination form, $a[1\ 1\ ] + b[1\ 1\ ]$.

Mental mechanisms applying internal stimuli were also present, in these three categories, in an increasing trend from category 1 to 3. That is, category 1 (discussed in detail below) included about 8% of responses (1 out of 12 responses in the category) with the application of internal stimuli. This presented itself when students considered a general structure, out of the matrix multiplication given in Figure 1, for range vectors making statements similar to: "the multiplication of the matrix and *a, b* values gives top and bottom the same." Category 2 included about 58% of responses (7 out of 12 responses in the category) where the expression $[a + b\ a + b\ ]$ was interpreted as range vectors having the same component values without any external calculations. Category 3 included about 70% of responses (7 of 10 responses in the category) mentally connecting the linear combination form, $a[1\ 1\,] + b[1\ 1\,]$, to a spanning set or a basis set of the range, and considering range vectors as the object of these sets.

In comparison to those in categories 1-3, category 4 (total 6) displayed drastically different mental mechanisms. Responses in this category determined range vectors based upon the structure of vectors of the null space. They did this, for the most part, acting on internal stimuli. This category is discussed in detail later in the paper.

Responses (total 4) in category 5 were either incomplete or irrelevant to the task on hand. One response, for instance, gave 2x2 matrices as range vectors. Three of them calculated externally the reduce row echelon form (Johnson et. al. 2002) of amalgam of the matrix in Figure 1 with specific values of *a* and *b*. They, however, fell short in, correctly, identifying range vectors by using the rref form. Two of these left their work at the rref form without any further explanations. The third one made a statement along the lines of: “no range since the rref implies no solution.” In class, the rref process was introduced to identify vectors of a basis/a spanning set for the range of linear transformations. The three students appeared to have recognized the rref process having something to do with linear transformations but fell short in displaying any knowledge of connections between the rref forms and bases/spanning sets.

Let’s us now look at categories 1 and 4 with little more details in order to give readers further insights into the nature of responses and mental mechanisms.

Table 1. Category, Level, Stage, Coordinated Topic, and Tally.

Range	Tally	#/Level/Stage	Coordinated Topics
1.MM*	12	2/A-P*	MM/Pi*/NS*
2. CV*	12	2/A-P	MM/Pi.
3. LC*	10	3/A-O*	LC/B*/S*
4. NS*	6	2/P-O	NS
5. IR*	4	1/A*	RREF/SS*

**A-Action Stage; P-Process Stage; O-Object Stage; *on prior-knowledge (not on Range); MM-Matrix Multiplication; Pi-Pre-image; NS-Null Space; LC-Linear Combination; S-Spanning set; B-Basis; SS-Solution set; CV-Component values; IR-irrelevant.*

Category 1: Range as the Result of Matrix Multiplications

There are 12 responses in this category. In order to determine range vectors, majority of participants evaluated matrix multiplications for specific values of *(a, b)* pairs, which represented (for the participants) domain vectors of the transformation. Moreover, some considered any values for *a* and *b* while others considered values with the condition, *a=b*. The response in Figure 2 exemplifies the latter behavior. This response is carrying out the multiplication of the matrix in fig 1 with *a, b* values where *a=b* i.e $[2\ 2\,]$. Figure 3 gives a case for the former behavior. This response is using different values for the pair *(a, b)*. For example, the participant is multiplying the pair $[10\ 7\,]$. with the matrix in fig 1 and obtaining a range vector $[17\ 17\,]$. Mental mechanisms displayed in both responses in Figures 2 and 3 needed external stimuli in determining range vectors. Thus, the mental mechanisms were acting at Action Stages.

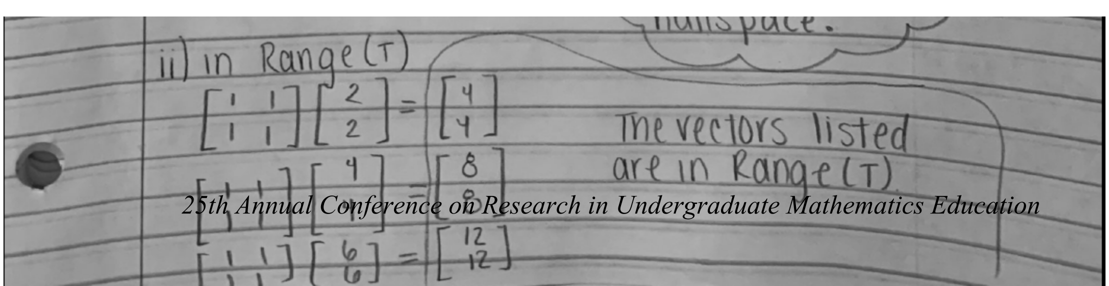

Figure 2. Domain vectors with a=b -externally calculating matrix multiplication.

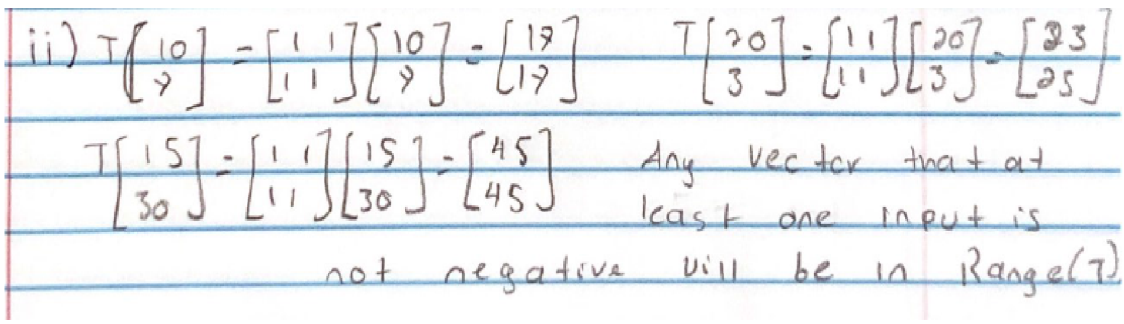

Figure 3. Domain vectors with any a, b values -externally calculating matrix multiplication.

In addition to the two behaviors described above, there were also a few responses revealing mental mechanisms acting at Process Stages. That is, they revealed participants considering matrix multiplication processes internally describing what would be obtained if a multiplication was carried out without any external computations. Figure 4 portrays one such tendency. This participant is considering generic pairs *(a, b)* and asserting that "all these vectors are the answer of $T([a\ b\ ]) = [1\ 1\ 1\ 1\ ][a\ b\ ]$" with no external calculations. The mental mechanism revealed in this response is clearly the one acting at a Level closer to a Process Stage.

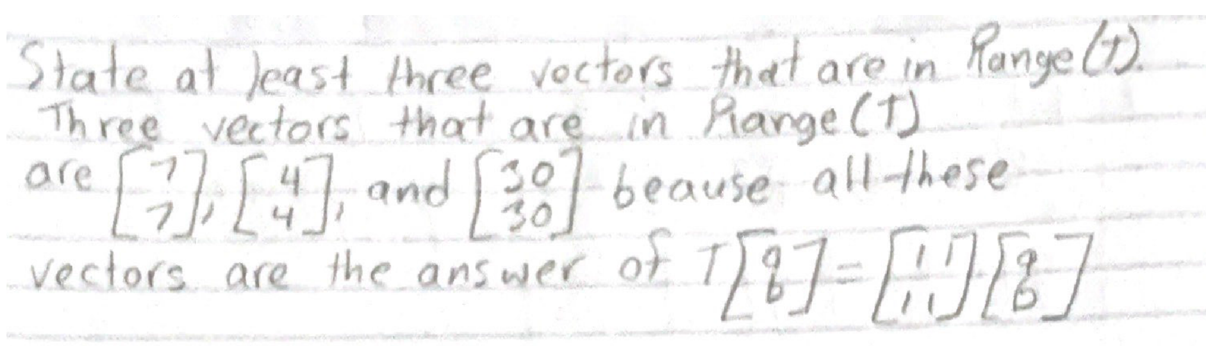

Figure 4. Consideration of matrix multiplication processes internally (mentally).

Category 4: Range Compared to Null Space

Responses in category 4 differed noticeably from those of categories 1-3. As far as we know, this category reveals mental mechanisms that have not yet been reported in the Literature. There are 6 responses in the category. This category determined range vectors based upon the structure of vectors of the null space of the transformation in Figure 1. We identified two distinct mental mechanisms in this category. One considered range vectors as those (from the domain of the transformation) with characteristics dissimilar to the ones in the null space of the transformation. Response in Figure 5 is displaying this tendency. This participant is considering vectors with same component values as vectors of the range. The participant's comparison of range vectors to vectors of the null space is clear in the explanation, “product with $[1\ 1\ 1\ 1\ ]$ will not give a $[0\ 0\ ]$ matrix.” Mental mechanisms displayed in similar responses are classified as acting at Levels closer to Process stages.

There were also responses considering the range and null spaces as complementary sets making up the domain of the transformation. Figure 6 is revealing this behaviour clearly. This participant is declaring that any vector that is not in the form $[x\ \ -x\ ]$ (identified as the structure of vectors of the null space) as the vectors of the range. In light of the following statement “any vector of the form [x;-x] <u>exists</u> within the null space of T,” (Emphasis is on the term “exists”) given for part i of the question, one can identify mental mechanisms, displayed in this response, as the ones acting at Levels closer to Object Stages. That is, in this response, vectors are considered as objects of the null space, subsequently objects of the range set.

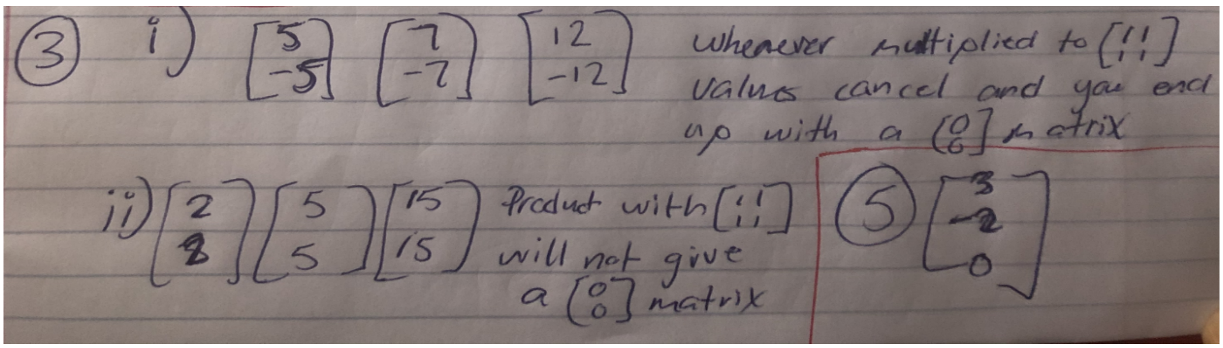

Figure 5. Range vectors in comparison to the structure of vectors of the nullspace.

3i.) Three vectors in the Nullspace of T are [1;-1], [2;-2], and [-3;3]. In fact, any vector of the form [x;-x] exists within the nullspace of T.
3ii.) Three vectors in the range of T are any vectors NOT of the form [x;-x], which creates an infinite list. Some examples are [1;-4], [5;2], and [x; y] such that y is not equal to x.

Figure 6. Vectors other than those in the nulspace (Response was typed by the student).

Unfortunately, even though mental mechanisms applied in the responses of this category were acting at higher Levels/Stages, inaccurate knowledge structures were displayed. This seemed to have been the result of, somehow, participants’ attention being directed to the null space concept, escaping any ideas from categories 1-3 (matrix multiplication representations).

Discussion and Conclusion

In this paper, we discussed findings from an ongoing study investigating mental mechanisms involved in the conceptualization of linear transformations from the perspective of APOS theory, specifically, findings from responses of 44-first year linear algebra students on a task concerning the range of the linear transformation given Figure 1. Our main goal was to identify transitional points in the learning of range ideas.

Overall, our findings show that responses employing various representations of the matrix multiplication, A$[a\ b\ ]$, in Figure 1, presented evolving Levels of mental mechanisms. That is, from category 1 to category 3, we documented mental mechanisms acting at evolving Levels from Action Stages to Object stages.

The highest variability among Levels occurred in category 3 when participants considered linear combination forms, $a[1\ 1\ ] +\ b[1\ 1\ ]$, in place of matrix multiplications. In this category, we documented mental mechanisms acting at all three APOS Stages, Action, Process and Object. Object Stage mental constructs were absent from categories 1 and 2. Indeed, category 3 and category 4 were the only categories whose responses revealed mental mechanisms considering range vectors as objects of sets (thus, acting at Object Stages). This notion was conducted accurately in category 3, but not so in category 4. Even though, in category 4, mental mechanisms were considering vectors as objects of a range set, acting at Levels closer to Object Stages, they were faulty mechanisms incorrectly recognizing range vectors as those of the domain vectors not in the null space (or not similar to the structure of vectors of the null space). In fact, participants, in this category, appeared to have skipped entirely the ideas included in categories 1-3, specifically, the consideration of representations of matrix multiplications.

We also found that approaches employing the rref process (a very common approach in many matrix algebra textbooks in the US) may not be very efficient in helping learners form an accurate understanding of the range concept. In fact, responses (total 6) in category 5 are testimonials to the inefficiency of these approaches.

In summary, our findings point to mental mechanisms reflected in categories 1-3 as being the more effective ones toward the accurate formation and advancement of the knowledge of range ideas. Our findings, furthermore, point to desired (in the context of accurate knowledge structures displayed in participant responses) transitions between APOS Stages to be occurring with the consideration of representations of matrix multiplications, especially, in the case of linear combination representations of matrix multiplications. Even though the notion of evolving representations is not specifically addressed in this paper (a topic of future studies), we conjecture that changing characteristics of the representation of matrix multiplications may be a sign of evolving mental mechanisms acting on the representations.

Professional development (PD) is often recommended to equip faculty to serve racially minoritized students through instruction. However, limited work has examined equity-oriented PD for mathematics faculty, who often hold views of instruction as race-neutral. This contributed report explores the influence of a two-year PD for faculty in a mathematics department engaged in equity-oriented reform at a Hispanic-Serving Institution. We present two cases of white faculty members who demonstrated a limited ability to interrogate their white racial identities in relation to their instructional impact, despite their engagement in a sustained PD designed to promote racial equity. Implications are provided for equity-oriented PD for mathematics faculty.

Keywords: whiteness, faculty, pedagogical reasoning, Hispanic-Serving Institutions

Study Purpose & Background

Faculty sensemaking about race directly influences instructional practices in postsecondary environments. For example, white faculty with high levels of racial consciousness often disrupt inequitable educational structures to expand educational opportunities for racially minoritized students, while white faculty with low levels of racial consciousness may incorporate instructional practices that uphold white supremacy (Haynes, 2021). Faculty’s critical reflection about their own identity is a component of this sensemaking that is vital to enact anti-racist pedagogy (Haynes & Bazner, 2019; Kishimoto, 2018). For example, white faculty who have interrogated their own racial identity demonstrated less concern for protecting white interests and assumed more risks to teach in racially equitable ways (Haynes, 2017). Similarly, faculty of color often draw on their experiences of race and racism to inform inclusive and humanizing teaching practices (e.g., Williams, 2016) despite the risks to their legitimacy that they assume when adopting unconventional teaching practices as minoritized faculty (e.g., Sulé, 2011).

Within STEM fields, ideologies related to social neutrality impede recognition of inequities (Gutiérrez, 2013; Leyva et al., 2022; McNeill, Leyva, White, & Mitchell, 2022). Colorblindness is a dominant ideology among STEM faculty as a group (Russo-Tait, 2021), with some documented race-consciousness especially among STEM faculty of color (Bensimon et al., 2019; Ching, 2022). For example, Haynes and Patton (2017) report on a white computer science instructor whose course content had racial relevance (e.g., a computer game using a migrant farm worker avatar) but who did not address race due to his perception of computer science as race-neutral. Mathematics reflects these trends with many instructors holding colorblind views of mathematics instruction, with exceptions found largely among faculty of color (McNeill & Jefferson, 2022; McNeill, Leyva, & Marshall, 2022).

Studies call for faculty professional development (PD) to improve instructional capacity to serve racially minoritized students and alleviate pressures on faculty of color to carry out institutional equity aims (e.g., Leyva et al., 2021; Casado Pérez, 2019). PD for mathematics instructors is often integrated through collaboration, apprenticeship, and guidance from course coordinators (Ellis, 2015; Rämö et al., 2019). However, such PD designs have not focused on equity. In a study of community college mathematics faculty in an isolated equity-oriented PD workshop, Ching (2018) found that faculty demonstrated conceptual change initially, but failed to sustain equitable instructional viewpoints over time. Such findings indicate a need for research that explores the efficacy of integrated and long-term mathematics faculty PD in promoting critical self-reflection about faculty identity and instructional practices.

To address this need, our report presents an analysis of racial sensemaking and identity development among two white mathematics faculty at a Hispanic-Serving Institution (HSI). We draw from a larger study of the department's reform of instruction and organizational practices to better serve Latin*[1] students, which involved faculty participation in a two-year, integrated PD. Our research questions explore how the PD influenced faculty's critical self-reflection: (1) How do faculty understand their white identities in relation to serving Latin* students through mathematics instruction?; and (2) In what ways does this change over the course of the PD? We raise implications for equity-oriented PD for mathematics faculty based on our findings.

Theoretical Perspectives

We engage two theories to guide our analysis of faculty sensemaking. To examine the ways that participants understand their identity in relation to serving Latin* students, we adopt emerging mathematical and racial identity constructions (EMRICs; Oppland-Cordell, 2014). Originally used to explore Latin* mathematics students' identity development, EMRICs characterize the multifaceted ways in which participants make meaning of their own racialized identities in mathematics spaces, individually, socially, and politically. For example, a Latin* student changing peer groups to enable math collaboration in Spanish can signify a shift in their EMRIC (Oppland-Cordell, 2014). Addressing inequity in mathematics requires white faculty to reckon with the tensions inherent in fostering Latin* student success within a historically white discipline (Hottinger, 2016) as white authority figures. Our uptake of EMRICs thus, facilitates exploration of faculty's reconciliation of their mathematics and racial identities.

Previous work has depicted mathematics faculty shifting between colorblind and race-conscious views of instruction (McNeill, Leyva, & Marshall, 2022). This reflects broader societal patterns in which whiteness demonstrates elasticity to maintain dominance in a continuously changing U.S. racial context (e.g. Bonilla-Silva, 2006). Whiteness flexibly adapts to embody contradictions and paradoxes that maintain racial inequity while seeming race-neutral or progressive at face value. To examine these contradictions in mathematics faculty sensemaking, we engage Yoon's (2012) construct of whiteness-at-work that explores how paradoxes are enacted to reinscribe whiteness as neutral and invisible while reinforcing the marginalization of people of color. For example, white teachers expressing a desire to call out colleagues on racially problematic viewpoints while also avoiding workplace conflict exemplifies whiteness-at-work (Yoon, 2012).

Methods

Study Context and Participants

Our present analysis comes from a larger study exploring the effectiveness of an ongoing, equity-oriented PD in the mathematics department at Sonoma State University (SSU), conducted by two SSU faculty involved in the PD, three SSU students, and educational researchers at

---

[1] The asterisk in Latin* creates space for fluidity in gender identities among Latin American people. Latin* responds to (mis)use of Latinx, a term reserved for Latin* gender-nonconforming peoples (Salinas & Lozano, 2019).

Vanderbilt University. SSU is a medium-sized, public HSI in the western United States. In 2021, undergraduate students at SSU were approximately 45% white, 35% Latin*, 7% two or more races, 5% Asian, 2% Black or African American, and 6% some other race. The two-year PD aims to develop culturally responsive instruction and student support practices to better serve Latin* students. PD began in summer 2021 and data collection started in fall 2021. This report presents an analysis of data collected over the first year of PD.

The SSU mathematics department holds a widespread commitment to advance equity, as evidenced by nearly complete mathematics faculty participation in the PD, and by approximately 75% of the PD faculty participating in the study. Active and inquiry-based learning is the norm in SSU mathematics instruction, and faculty regularly voice teaching philosophies related to normalizing mistakes, encouraging multiple approaches, building students' confidence with mathematics, and fostering positive instructional and peer relationships.

Data Collection

Educational researchers at Vanderbilt (1 faculty, 2 Ph.D. students, 1 master's student, and 1 undergraduate) assumed all data collection responsibilities to maintain participant privacy. Data from faculty participants consisted of journaling and interviews. Faculty journaled about events specific to instruction and support that they perceived as marginalizing or supportive for Latin* students, including a description of the event and a reflection on their interpretation. Faculty journaled throughout the 2021-2022 academic year without a required number of entries.

Near the end of each semester, participants completed a 90-minute, semi-structured individual interview on Zoom. Interviews were audiotaped and transcribed. The first interview explored how participants characterized serving Latin* students and solicited participants' interpretations of two instructional events that reflected emergent themes from journaling. The second interview explored participants' experiences of the PD, and asked participants how thinking about Latin* students as a group or as individuals supported their aims related to serving Latin* students. Both interviews prompted faculty to reflect on how their own identities shaped their perspectives, practices, and instructional efficacy in serving Latin* students.

Data Analysis & Positionality

Vanderbilt research team members de-identified data prior to sharing with SSU research team members for analysis. Information that explicitly or implicitly revealed participants' identities (e.g., names, professional histories) was redacted. For the present research report, we completed an analysis of data specific to two white participants, Tina and David, who regularly invoked ideologies tied to whiteness (e.g. universalism[2]). Our focus on white faculty responds to the reality that even at HSIs, most Latin* mathematics students will be taught by white faculty. Thus, understanding how white faculty develop capacity to serve Latin* students is essential. Our findings begin with profiles of the focal participants to provide context for interpreting their narratives. We omit details about their professional roles to maintain confidentiality.

A research team member from each university coded David's data. Two Vanderbilt team members coded Tina's data since de-identification was still in progress. Team members independently and inductively coded data to flag instances when participants grappled with their own identity in relation to professional practices. One coder from each pair synthesized codes for each participant's data to identify whiteness-at-work in their perspectives and described instructional practices. Themes were exchanged and discussed during weekly team meetings.

[2] In relation to whiteness, universalism describes the framing of white experiences as universal (Bonilla-Silva, 2006)

Our research team approached the present analysis with critical reflexivity. The team consists of a nonbinary Latinx person, a Latina cisgender woman, two Latino cisgender men, a Black cisgender woman, a Black and white mixed cisgender woman, a white transmasculine person, two white cisgender women, and a white cisgender man. We brought awareness of how our varying forms of privilege and oppression influence our inquiry on whiteness in mathematics. The team resisted deficit engagement with participants' reflections and constantly recognized how mathematics instruction is situated in broader systems of social power. Interviewers and coders bracketed their lived experiences when engaging with participants' reflections to avoid analytically distorting their perspectives, all while approaching the study with a lens of criticality to interrogate whiteness in mathematical contexts across HSIs.

Findings

David and Tina hold a combined 40 years of experience as mathematics faculty. They each entered interviews with questions prepared and took notes throughout, showing a desire to learn from the interviews. Of all faculty, David submitted the most journaled events and reported that he "spent a couple hours on every one of those" each week in addition to his PD participation. Tina discussed PD topics at home when struggling to integrate her learning about racism into her professional practices. Both shared a deep concern for students' comfort and wellbeing. As examples, David shared a time in which his offer of instructional support to a Latina student resulted in the student leaving the class crying for reasons he didn't understand. David sent multiple emails to the student afterwards in an effort to re-establish rapport and after the semester passed was "still losing sleep over that student." Tina shared an experience in which a Latino student sought her support after experiencing sexual violence, which she characterized as "one of the successes of [her] career… that a student in crisis felt comfortable coming to [her]." This context importantly illustrates that their ideological engagement in whiteness cannot be attributed to lack of effort or care.

In what follows we illustrate how David's and Tina's EMRICs depict whiteness-at-work, maintaining the invisibility of whiteness to impeding their focus on Latin* students, addressing our first research question about faculty's perception of their racial identities. Tina cited gender as an analog to support her (in)attention to race, using experiences of gender marginalization to claim insider insight into Latin* marginalization and alternately appealing to math as gender-neutral to justify her inattention to students' race. David demonstrates awareness of systemic racism, including inequity in education, but uses race-neutral frames to reason about teaching and learning in mathematics. In both cases, the construction of mathematics as socially neutral supports colorblindness in instruction. In each case, we discuss how their perspective changed over the first year of the PD, addressing our second research question.

Tina

Tina described "foster[ing] females who are going through the program" (Interview 1) as central to her professional role. This shaped her orientation to the PD, viewing her developing support of Latin* students as analogous to her support of women: "I like this idea of broadening my horizons of how to not just help females, but all students of all ethnicities" (Interview 1). Her characterization of helping "students of all ethnicities," however, illustrates incongruities in her analogy of gender to race; when discussing women, she explicitly names this group, while her reference to students of all ethnicities illustrates a discursive avoidance of Latin* identity. This incongruity signals whiteness-at-work; although Tina sees the PD as an opportunity to develop advocacy for Latin* students as she had for women, she does not center Latin* students when discussing issues of race as she does for females when discussing gender, as we further elaborate.

When asked how she saw herself serving Latin* students, Tina shared an experience of coordinating sections of calculus with all-male colleagues as an example of how she leveraged her own experiences of marginalization in mathematics to relate to Latin* underrepresentation.

> I was… the only woman in the room… I remember one of the males looking at me and saying – We're putting together a calculus final, you got to understand that – He looks at me and goes, "As a woman, what questions do you think should be on the calculus final?" And I thought, "As a woman?"... It wasn't an issue that should depend on gender at all… I think I may be able to understand a little better than maybe some people about how odd it is to be sitting in a room and to be, say, the only woman, or the only Hispanic student, or the only African American student, or the only…Muslim student… I taught a class once, I had a nun… She's obviously going to feel singled out. (Interview 1)

Although Tina cites her gendered experience as a way to relate to Latin* students, she doesn't discuss how Latin* students could experience marginalization in unique ways. Instead, Tina de-centers Latin* servingness by universalizing the experience of being singled out. Her framing of final exam questions as gender-neutral demonstrates how the construction of mathematics as socially neutral supports her generalizations about underrepresentation in mathematics.

Tina saw her gender influencing the effect of her professional practices on students, but did not identify her racial identity as playing a role. For example, when asked if there were any racial trends among students who seek her support, Tina described establishing mentoring roles specifically with female students, but characterized her student support as race-neutral.

> Math… you picture the male professor. And I think…females really associate with me just because they're seeing a female doing math… I really don't really have a perspective on ethnicity. I'm not sitting in my office keeping track of ethnicity of students, and anybody who comes to my office is always welcome in my office. (Interview 1)

Despite Tina's previous assertions that her experiences of marginalization sensitized her to Latin* underrepresentation in mathematics, she does not voice an understanding that Latin* students, like female students, may experience mentorship differently from faculty of different racial identities. Tina's statement that anyone is welcome in her office suggests that her white racial identity would play a role in student support only if she were to discriminate against Latin* students. She further elaborated this view when asked if she perceived her white racial identity as playing a role in Latin* students' comfort with class participation.

> The area we lived in [growing up] there was a lot of Hispanic students when I went to high school… maybe I'm a little different because I grew up constantly around them, constantly seeing them doing as well in their classes as I did, so I never had any stereotypes, any ideas of, they can't do this or they can't do that… My identity, maybe I just was more colorblind because that was just who I was with all the time. (Interview 2)

Tina discusses colorblindness as a desirable personality trait that negates the role of her racial identity in her teaching practices, rather than as one that reinforces systemic racism. Explaining her racial identity as formed from adolescent experiences suggests a stagnant EMRIC.

Tina's portrayal of her identity remained largely unchanged after a year of PD. However, at the end of the second interview she reoriented to focus on Latin* students. She shared, "I've spent a lot of time understanding what issues women deal with, I think it's important that I try to understand better what Latin students…specifically face that may or may not be the same challenges that other students face" (Interview 2). This pivot allowed her to mine her teaching experiences for insights on serving Latin* students. She shared, “From what I've seen with the Latin culture, I think it's harder for them to ask for help” (Interview 2). Such remarks still evade recognition of how her white identity influences serving Latin* students; she didn’t consider how Latin* students’ may seek help differently from white faculty or Latin* faculty, for example. However, this shift represents a disruption of her colorblindness that centers Latin* students.

David

David described himself as newly exploring issues of equity through the PD: “I've recently learned the difference between equality and equity… over summer during my reading on anti-racism, preparing for my workshop... My struggle is looking outside of my bubble to make sure that I can embrace those ideas” (Interview 1). As part of this struggle, David had trouble characterizing how race played into students’ experiences of mathematics instruction.

Interviewer: How do you see race or ethnicity playing a role in… students' concern about [speaking in class]?

David: Just that, if a student's not comfortable. And so how would race or ethnicity play a part of that? It's just, it would be common that they're not as comfortable as other students possibly. And yeah, probably just a comfort level and maybe they're shy for a number of reasons, but that's what I would think it is.

David’s response suggests race enters math instruction only to mediate students’ comfort. His understanding of how inequity arises in everyday mathematics instruction lacked specificity. For example, when asked what his goals were with respect to understanding and relating to Latin* students, David responded, “Let's zoom out, big picture, there's inequities in education. And now, understanding that's important, but when it comes down to in the classroom, helping students, I can't think of doing something specific directed towards Latinx” (Interview 2). Such responses demonstrate that David’s understanding of racial inequality was decontextualized from his professional practice, reflecting ideologies of mathematics as a race-neutral discipline.

David held an oversimplified understanding of whiteness as structural advantage that left him unclear about how to acknowledge his identity in classroom teaching, “I've yet to stand up… in front of the class and tell them that I'm a white male and that I apologize… I haven't figured out how to do that” (Interview 1). Similarly to his difficulty grasping the role of race in instructional contexts, David struggled to articulate specifics related to his white identity. When asked how his identity influenced his teaching practice, he initially characterized his identity as tasking him with the responsibility to help those with less privilege “I have to recognize that I'm white and that I do have white privilege, and I, just to be able to help other people and recognize that it's a real thing” (Interview 1). He further characterized his goals related to serving Latin* students as “trying to be educated on the subject and sympathetic” (Interview 2). Frequently, David referenced students’ “disadvantaged backgrounds” (Interview 1) as motivating his desire to help. These motivators suggest that David may be subject to the common pitfall of using pity to guide his attempts to serve Latin* students (Dowd & Bensimon, 2015). This orientation allowed for an EMRIC as a helper, fostering Latin* students’ assimilation for success in white disciplinary structures. Such orientations, combined with his limited ability to recognize inequity occurring in his classroom, leave the influence of his white identity, as well as the hegemonic role of whiteness in postsecondary mathematics, uninterrogated. Whiteness-at-work can be seen in David’s helping attempts that reinforce whiteness in mathematics.

While David articulated the role of his white identity in reductive ways during the first interview, he later characterized himself as not knowing the influence of his identity on his professional practices.

Interviewer: How you see your own identity… as a white person… as a man… shaping your perspective on how effective your teaching practices are in serving Latinx students?

David: How is my identity? I don't know. I don't know. How is my own identity? It's a really hard question. I'm not sure. One of the first things I was supposed to do in this [PD] workshop before the semester started was to come up with my own racial identity… It was the hardest thing. And how my identity relates to how I'm supporting Latinx students? I don't know. I'm not sure that being a… white male, what that does…Am I not as good because of my identity? I don't know. It's really challenging for me. (Interview 2)

Such recognition could be seen as progress in his developing white identity, as David shifted from a position of "helper" that reflects paternalism (Jones & Okun, 2001), to a position that reflects more openness to learn about his whiteness. His receptivity to learning was further underscored by his verbalized commitments to growth, despite the emotional strain he felt when discussing topics of race, "Just to be 100% honest, our last interview, it was really hard for me, but I just believe that I can't walk away from the conversation. I have to try" (Interview 2).

Despite David's expressed commitment, he reported reducing actions intended to develop capacity to serve Latin* students. In the fall, David described being "focus[ed]... [on] really paying attention to Latinx students" (Interview 1) despite feeling "uncomfortable" (Interview 1) in doing so. However, by the second interview, David had lessened his practice of paying particular attention to Latin* students, "This semester, when I tried to put myself in the headspace of like, 'Am I helping a Latinx student?' That just felt awkward" (Interview 2). David's shift in attention demonstrates whiteness-at-work. Although David's stated intention is to engage in equity-related learning despite the discomfort that may cause, he relinquished his practice of specifically attending to the needs of Latin* students because it "felt awkward." In this way, David's commitments had limited efficacy in advancing his EMRIC.

Discussion & Implications

Although David's and Tina's cases differed in many respects, they shared a struggle to recognize how their white identities influenced their capacity for serving Latin* students through instruction. Relatedly, both faculty demonstrated limited awareness of how race influenced the mathematics discipline or institutional structures. Tina's claim that test questions are gender-neutral, and her framing of race and gender as analogous, indicates that the construction of mathematics as socially neutral shaped her inattention to racialized features of mathematics practice. Although David made no explicit statements about mathematics as neutral, his appeal solely to decontextualized social phenomena, like student comfort, when explaining classroom inequities illustrates that he does not perceive mathematics itself as a racialized feature that should be attended to when serving Latin* students. The invisibility of their own white identities and of whiteness in mathematics served as mutually reinforcing to impede critical EMRICs.

Our findings indicate further need for PDs to integrate activities that scaffold examination of the hegemonic role of whiteness. Although, as David's reflection indicated, understanding one's own racial identity was an activity in the PD, this was not central to PD activities. We argue, contrary to David's articulation of his obstacle as "struggling to look outside of [his] bubble," that struggling to look *inside* their bubble was the primary obstacle in advancing equity. Equity-oriented PDs can address this by extending reflections on racial identity to explore characteristics of white culture (e.g., valuing white segregated environments; DiAngelo, 2016), white ideologies (e.g., meritocracy; Bonilla-Silva, 2006), and whiteness embedded in disciplinary epistemologies and values (e.g., proof; Hottinger, 2016; McNeill & Jefferson, accepted). Future research can explore the efficacy of PDs that integrate such methods.

Research-Informed Practice to Improve Inquiry-Based Calculus with Learning Assistants

Kelly Bubp
Frostburg State University

Kayla Heacock
Ohio University

Allyson Hallman-Thrasher
Ohio University

Despite the promise of inquiry approaches, student resistance can occur because active learning opposes their expectations of classroom norms and responsibilities. This study reports on students' experiences in inquiry-based learning (IBL) Calculus supported by learning assistants (LAs). We used an iterative process adapted from Hine (2013) to make changes to our study across three semesters to improve student experiences in IBL Calculus. Survey data of 285 students across 7 sections of IBL Calculus was supported by our observations of IBL Calculus and weekly LA seminars with 12 LAs to determine changes needed each semester. Quantitative data were analyzed using descriptive statistics and z-tests, and qualitative data were open-coded to evaluate the effectiveness of changes. We report changes made to LA preparation and course structure to support LAs' instructional practices and increase student buy-in to IBL Calculus. Over the three semesters, the overall student experience in IBL Calculus improved.

Keywords: research informed practice, inquiry-based learning, learning assistants

As practitioners, we strive to improve the experience, learning, and understanding of students in our own courses. As researchers, we strive to push the bounds of our knowledge of student experience, student learning, and student understanding in *all* mathematics classrooms. Our research should inform our practice so that we systematically use our new knowledge to directly and positively impact our students. While researching the implementation of inquiry-based learning (IBL) in Calculus supported by learning assistants (LAs), we determined aspects of LAs' work preparation and Calculus students' classroom experiences that were ineffective. We sough to answer the question, "How can an action research cycle be used to improve students' experiences in Calculus IBL classrooms with LAs?" Based on our data analysis, we made changes each semester to develop practices that support positive experiences for both students and LAs. In this paper, we describe the data-supported, iterative revision process we used over three semesters to redesign the Calculus course structure and LA preparation and report the results of these changes on student perceptions of the course.

Literature Review

One of the goals of research is to inform practice, but it can be challenging to translate research into practical strategies (Carlson & Rasmussen, 2008). Through action research, educators conduct research in their own classrooms with the practice-based goals of improving their instruction and the experiences of their students (Gibbs et al., 2017; Hine, 2013). Action research is commonly used in higher education to obtain "evidence of how practice can be improved and its impact on the learning of students" (Gibbs et al., 2017, p. 17). The cyclic nature of action research allows for refinement of current issues, a systematic approach to inquiry, and continuous learning for the educator (Hine, 2013). We used an iterative process adapted from Hine (2013) (Figure 1) to study our implementation of IBL in Calculus over three semesters. Whereas Hine's model moves directly from reporting outcomes to taking action, we added a critical intermediate step, “determining future changes” to capture the work of interpreting the results to hypothesize what changes to our IBL structure might improve student outcomes.

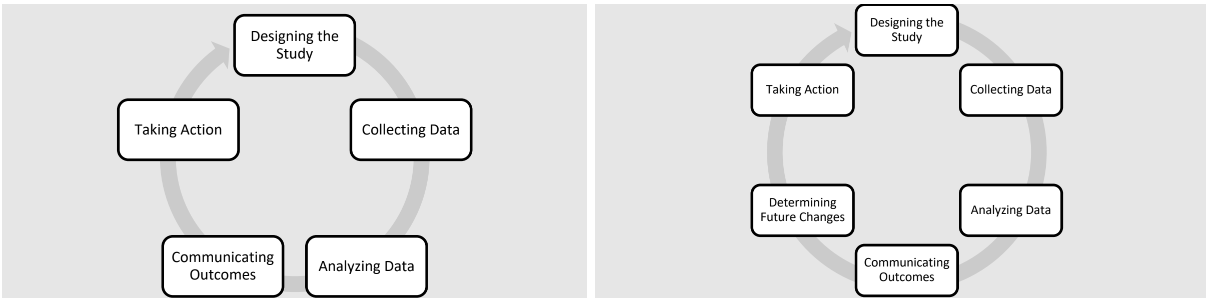

Figure 1: Action Research Cycle (Hine, 2013) and Modified Action Research Cycle (adapted from Hine, 2013)

Inquiry approaches to learning continue to grow in mathematics education (Laursen & Rasmussen, 2019). In IBL, students work through a “carefully scaffolded sequence of mathematical tasks” (Ernst et al., 2017, p. 570) under the guidance of an instructor to construct their own understanding of a given concept. Research has found that students in inquiry classes have reported improvements in learning specific content, developing affective skills, and communicating and collaborating with peers (Laursen et al., 2011). Despite the promise of IBL, students can be resistant because its structure contradicts their expectations of classroom norms and student/teacher responsibilities (Deslauriers et al., 2019). Students must develop autonomy in problem solving to be successful in an IBL setting, where instructors support student work instead of providing direct instruction on how to solve problems.

Student resistance to the change in student/teacher responsibilities has been associated with poorer student course performance (Cavanagh et al., 2016), and successful implementation of any inquiry approach to teaching and learning must account for student resistance to changed norms. Some ways instructors might combat student resistance to IBL include discussing reasons for the course structure (Deslauriers et al., 2019; Yoshinobu, 2019), presenting students with videos outlining the importance of working in groups (Clinton & Kelly, 2020), and explaining the importance of having a growth mindset (Cavanagh et al., 2018). In our implementation of IBL Calculus, we used LAs to help alleviate student resistance, by providing students more available access to help. LAs act as apprentice instructors, facilitate group work alongside the instructor, and have been shown to improve student outcomes in STEM courses. Barrasso and Spilios’ (2021) meta-analysis indicates that students in LA-supported STEM courses have better attitudes, course satisfaction, and learning gains than students in STEM courses without LAs.

Method of Inquiry

Context

This study was conducted within IBL sections of Calculus I courses in a large, public, midwestern university across three semesters. The IBL sections used the textbook *Active Calculus: Single Variable* (Boelkins et al., 2018) which was designed for use with an inquiry-based approach to instruction. Students spend the majority of class time working in small groups facilitated by the instructor and LAs to solve problems that emphasize key concepts and relationships of calculus. While groups worked on tasks, the instructor and LAs circulated to troubleshoot student difficulties, pose questions, check student understanding, encourage group discussions, and generally encourage student thinking and autonomy in problem solving. Of 303 students enrolled in IBL Calculus across three semesters of this study, 285 agreed to participate.

LAs attended IBL Calculus class three times per week and met with the course instructor once a week to discuss both their experiences as an LA in IBL Calculus and readings on active learning. This study incorporated 12 LAs in 7 sections of IBL Calculus. LAs were a mix of undergraduate and graduate students, males and females, international and domestic students, and all had an interest in active learning in mathematics.

Data Collection and Analysis

We collected LA weekly written reflections, field notes of LA seminar meetings, and observations of IBL Calculus. Two weeks prior to the end of the semester, we used a survey to gather student perceptions of the course. The surveys consisted of Likert scale questions and open-ended questions, all of which explored various aspects of students' IBL Calculus experiences. To analyze qualitative data, we open-coded free response questions, which were answered by all respondents. To analyze quantitative survey data, we calculated descriptive statistics and performed independent samples z-tests to determine the significance of changes in student responses from semester to semester. Employing our modified action research cycle (adapted from Hine, 2013) we interpreted the results to determine future changes needed to our enactment of IBL Calculus, which we implemented in subsequent semesters to continue our cyclical process. Here, we report the changes we identified from our analysis each semester and the impact of those changes on students' experiences in IBL Calculus (for additional details of the study see Bubp et al., 2020).

Results

Semester 1 Key Findings

After our first semester, we used student survey responses to determine students' assessment of their interactions with LAs. In particular, students reported the LAs were less helpful in class than the instructor and their peers, with 36% of students responding that LAs were 'little to no help'. Further, they identified the following LA actions to be 'little to no help': ask questions about your work (33%), ask you to explain your work (38%), give feedback on your work (24%), and help you but do not directly answer your question (50%). In the open-ended response questions, 20% of students indicated negative interactions with LAs. One student described their interactions as: "TA's coming over and staring over your shoulder, correcting your work only to give you a more confusing explanation." Similarly, from observations we noticed LAs struggled to employ effective questioning strategies and facilitate discussions in small groups.

Using student surveys, LA reflections, and LA seminar field notes we identified two problems with our LA preparation that contributed to their struggles interacting with students. First, by choosing LAs with strong content knowledge and some prior experience with active learning, we assumed that minimal preparation for facilitating student group work in advance of the semester start would be needed. However, LAs' content backgrounds had some gaps, and since IBL Calculus relied on objects-in-motion and graphing approaches with which some LAs were unfamiliar, many had difficulty helping students understand these approaches. Second, our weekly LA seminar did not sufficiently support the LAs in developing practical aspects of implementing and supporting IBL in the classroom. Instead, we read and discussed research literature on IBL to support our graduate students in developing their understanding of the current state of IBL research and consider how they might analyze data of IBL classrooms.

Semester 2 Revisions

To address these issues, we made strategic changes for the second semester. First, to better prepare LAs for their role in the classroom, we provided pre-semester preparation and communicated clear expectations for their role. A first-semester LA drafted an *LA Manual*, which we reviewed and required LAs to read prior to the start of the semester. We set the expectation that LAs had to complete for themselves all IBL Calculus classwork in advance of each class meeting where they would be assisting students on that work. The *LA Manual* also emphasized the importance of asking questions to move students forward in their work without giving them direct answers to problems. We shared ways to connect with students such as by learning names and ways to build trust by admitting mistakes and listening carefully to students.

Second, we improved during-the-semester preparation by making LA weekly seminars less focused on theory and research and more focused on classroom activity and problems of practice: what concepts students struggled with or excelled at, how groups worked together, instances of inequitable participation, and instances of LAs not knowing how to respond to a student. We specifically discussed strategies to help LAs develop an awareness of student understanding and an ability to improve their interactions with students and students' interactions with each other.

Third, in addition to improving LA questioning techniques, we changed some structural elements of how LAs functioned in the class to improve students' perceptions of their interactions with them. In the first semester we had three LAs to a section for a total of four teachers. This led to students being asked the same question repeatedly by different LAs and hearing too many different explanations from LAs. In the second semester we only used two LAs per section, assigned each LA to specific groups, and established a norm of LAs asking groups if they had already been questioned by someone about their work.

Semester 2 Key Findings

Second semester students found LAs to be more helpful than their instructor and peers, with 67% of students saying LAs 'helped a lot or the most' and only 13% saying LAs 'helped little or not at all' as compared to 46% and 35%, respectively, from the previous semester. Students who reported specific types of interactions with LAs (Table 1) as 'usually or very helpful' statistically significantly increased from the first semester and those reporting the interactions as 'little or not helpful' statistically significantly decreased.

Table 1. Percent of students reporting these interactions with LAs were or were not helpful.

Interactions	Semester 1		Semester 2	
	% little or not helpful	**% usually or very helpful**	**% little or not helpful**	**% usually or very helpful**
Question students' work	32.50	38.75	13.10*	61.90*
Ask students to explain work	37.50	36.25	8.33*	61.90*
Give feedback on students' work	23.75	51.25	6.02*	81.93*
Help but no direct answers	50.00	29.48	24.39*	52.44*

*Indicates statistically significant ($\alpha = .05$)

Although we saw important improvements in student-LA interactions in the second semester, we yet identified areas in need of improvement for the following semesters. Students indicated these interactions with the LAs occurred 'every day or nearly every day': waiting too long for help from LA (11%), LAs solving problems directly for students (32%), LAs providing an incorrect answer (6%), and LAs contradicting one another (6%). Students waiting too long for help indicated we needed to attend more carefully to how LAs monitored students. Though few students stated that LAs provided an incorrect answer or contradicted one another, that this was happening at all was cause for concern. While students might have considered LAs directly solving problems for them as beneficial, this was a practice we wanted to discourage.

Second semester findings showed that only 39% of students reported that the class structure 'helped a lot or most'. Additionally, we noted issues in the effective functioning of groups as 87% of students reported negative experiences working with groups. Specifically, 30% felt their group members were not knowledgeable, 11% believed their group members were on a different level, 14% indicated their group members did not regularly attend class, and 13% did not want to rely on group members over their instructor. We observed that student attendance issues impacted the groups through time lost to groups catching up absent students, inequitable contributions, and groups feeling responsible for carrying weak or non-contributing members. We hypothesized that students' struggles with group work influenced their appreciation of the IBL structure. The 67% of students who made negative comments about IBL referenced a need for more direct help from the instructor and less reliance on their groups: 26% wanted more lecture, 21% did not want to figure things out on their own, 21% wanted lecture for new material, 13% wanted more examples, and 13% did not want to depend on their peers.

Semester 3 Revisions

We made additional changes to the weekly LA seminar, shifting the focus from how to research IBL to understanding student thinking and facilitating group interactions. We hypothesized that students' continued poor reviews of classroom interactions were due to LAs responding to student questions and difficulties on-the-fly. Therefore, we oriented the seminar to prepare for what was coming up in class each week and not only what had previously happened. In addition to completing course materials in advance, we asked LAs to consider possible student misconceptions and questions they could pose to students in the upcoming classes. To further improve their pedagogical skills, LAs also read articles about pedagogical techniques such as questioning techniques, ways of providing feedback, and cognitive demand. LAs reflected on their readings and identified ways to apply them to their classroom practice.

Based on open-ended survey results, we hypothesized that student reaction to their and the instructors' changed responsibilities contributed to their dissatisfaction with the course structure. To address this student resistance, we developed four "Learning about Learning" (LaL) assignments that students completed early in the semester and were intended to help them understand the value of IBL and feel more comfortable as independent problem solvers who collaborated with their peers and communicated their mathematical ideas. The LaL assignments included readings (Anderton, 2019; Dunlosky et al., 2013) and the online course 'How to Learn Math for Students' (Boaler, n.d.) which addressed ideas such as: common misconceptions about math, good study habits, growth mindset, productive struggle and mistakes, communicating mathematical ideas, and collaboration. Each LaL assignment required a written reflection in which students discussed what they learned and how that related to their success in Calculus.

To address students' dislike of group work we used more purposeful groupings with similar majors grouped together and balanced by gender. To minimize group difficulties due to attendance, we deducted points for missing more than 4 classes per semester.

Semester 3 Key Findings

In the third semester, we observed further improvements in student interactions with LAs, a more positive response to the IBL structure, and more effective group work. Students had to wait for help statistically significantly less often, and additionally, although not statistically significant, LAs were solving problems for students, giving incorrect answers, and contradicting other LAs less often (see Table 2). In the open-survey questions, a student described, "They [LAs] were able to guide you in the right direction without giving you the answer outright... [and] we never had to wait long if we had a question." Another responded, "They provided help quickly when it was needed and helped us to understand concepts to solve a problem rather than telling us exactly how to solve the problem." This supports the quantitative analysis that student wait time was shorter and that LAs were no longer directly solving problems for students.

Table 2. Percent of students reporting the following frequencies of these actions occurring with LAs.

Interactions	Semester 2 **% occur every or nearly every day**	Semester 3 **% occur every or nearly every day**
Wait too long for help	10.71	1.33*
Solve problem for students	32.14	21.33
Give an incorrect answer	5.95	1.33
Contradict each other	5.95	1.33

*Indicates statistically significant ($\alpha = .05$)

The response to the IBL structure statistically significantly improved by the third semester, with the proportion of students reporting the course structure 'helped a lot' or 'helped most' increasing from 39% to 58%. In addition, statistically significantly fewer students responded that they needed lecture for new material and that they did not want to figure things out on their own. Although not statistically significant, fewer students responded that they needed more lecture in general and that they wanted more examples (Table 3). We note here that the percentage of students who reported needing more lecture remains high and we attribute this to the difficulty of overcoming students' expectations of what teaching and learning mathematics should be. We expect this issue to be an on-going focus of future revisions.

Table 3. Percent of students' open-ended responses coded with the following codes.

Code	% Semester 2	% Semester 3
Lecture needed for new material	20.24	5.93*
Want more examples	13.10	7.63
Need more lecture	26.19	22.88
Had to figure out on own	21.43	10.17*
Didn't want to depend on peers instead of professor	13.10	5.08*
Group members not knowledgeable	29.76	27.97
Group members move on without me/at a different level	10.71	14.41
Group members not attending	14.29	5.93*

*Indicates statistically significant ($\alpha = .05$)

With the changes to group structures, statistically significant more students valued their peers both in- and out-of-class (Table 4). Furthermore, statistically significantly fewer students responded that they did not want to depend on their peers instead of their instructor and that their group members were not attending class (Table 3). Qualitative data supported this finding; one student described, "My group is really amazing and we do a good job of collaborating and helping each other when one of us is stuck in or out of the classroom. They are all pretty good at explaining why they got a certain answer." We also note that some students still report group members are not knowledgeable, and hence not considered a good classroom resource, and that too much variability in groups made students feel left behind. This points to our need to continue addressing supporting students in working in groups.

Changes Across All Semesters

Across all three semesters of this iterative process, when we focused on understanding reasons behind our results, we were better positioned to determine changes for the future and take action. In determining changes from the first semester, we recognized the need to improve the LAs' interactions with students by better preparing LAs for their role in an inquiry-based classroom. And, in the second semester, we observed statistically significant improvements in students' responses to the LAs; the percent of students who found them unhelpful decreased and the percent of students who found them helpful increased (Table 4). Results also pointed to a need to focus on IBL structure, students' perceptions of that structure, and group interactions. And in the third semester we saw statistically significant improvements in students finding their peers more helpful (Table 4). On the other hand, there was no significant change in the student responses to the LAs being helpful and available in class. We interpret this reduced perception of LA helpfulness as the result of students becoming more comfortable with productive struggle with their peers. One interpretation of this finding is that as students' value for their peers increased, they became more autonomous in solving problems and less dependent on the LAs. Reduced need for assistance from LAs could in turn explain the decrease in the proportion of students who responded that the LAs 'helped a lot' or 'helped the most' with their learning.

Table 4. Percent of students reporting the following class features as helpful or not helpful.

Class Feature	Semester 1		Semester 2		Semester 3	
	% little/ no help	**% helped lot/most**	**% little/ no help**	**% helped lot/most**	**% little/ no help**	**% helped lot/most**
IBL Structure	38.55	31.32	39.29	39.29	21.56**	57.76**
LAs in Class	34.94	45.78	13.41*	67.07*	12.28	59.65
Peers in Class	25.30	56.62	21.69	46.99	9.57**	66.96**
Peers out of Class	30.16	39.10	46.99	27.12	25.00**	45.00**

*Indicates statistically significant from Semester 1 to Semester 2 ($\alpha = .05$)
**Indicates statistically significant from Semester 2 to Semester 3 ($\alpha = .05$)

Implications for Practice

In our work, we have again confirmed the power of using research to improve practice. We sought to use an iterative systematic process to improve the implementation of an innovative pedagogical structure and over three semesters were able to make that happen. Drilling down to identify specific difficulties students were having with our courses was essential for making appropriate revisions. The changes we made in our enactment of IBL Calculus were small, yet they often had a statistically significant positive impact on students' experience in the classroom. Through two sets of revisions, we improved LA preparation, in-class group interactions, and student appreciation for IBL. From this study we have learned some critical aspects of introducing novel pedagogical approaches: the importance of instructor preparation, of fostering student buy-in and understanding of the rationale for the pedagogical approach, and a systematic approach to understanding and reacting to students' experiences.

One Multilingual International Student's Experience in Collegiate Mathematics Classrooms

Jihye Hwang
Michigan State University

Although the number of multilingual international students is increasing in undergraduate mathematics classrooms, there is little research about this population at the collegiate level. To better serve this growing population, it is important to understand their experiences using multiple languages in their mathematics learning. In this study, I constructed a narrative of one multilingual international student, Jia. I used narrative inquiry as a research method and collected data from synchronous- and email interviews and observations. The narrative demonstrates how Jia used her Chinese and English and how she dealt with her challenges. The study found that engaging in groupwork was particularly challenging for her as a multilingual student. I focus on not presenting her multilingualness as a deficit feature and discuss how to mitigate challenges multilingual students can face in their mathematics learning.

Keywords: Multilingual, Active Learning, Groupwork, Linguistic Diversity, Narrative Inquiry

In the increasing globalizing world, the number of international students in collegiate classrooms worldwide has likewise been increasing, especially in undergraduate mathematics classrooms in the United States. When international students move from their home countries to the U.S, they bring much diversity into the classroom: racial, cultural, and linguistic, to name a few. I mainly focus on linguistic diversity in a mathematics classroom because having a different first language than the language of instruction (LOI) is directly related to communication, which can impact one's access to learning opportunities and mathematics identity. Despite a substantial portion of international students in undergraduate mathematics classrooms, such students' experiences have not received enough attention in the field. Researchers have focused on multilingual students' experiences in K-12 mathematics education (e.g., Huitzilopochtli et al., 2021; Moschkovich, 1999; Takeuchi, 2016; Turner et al., 2013), but there has not been much research at the undergraduate level, especially in multilingual international students in the U.S. Collegiate mathematics classrooms are likely to be more diverse in terms of students' home countries and languages that they bring compared to K-12 mathematics, where *bilingual* classrooms–classrooms that have two main languages such as Spanish and English–are more common for K-12 mathematics education study (e.g., de Araujo et al., 2018; Domínguez, 2011; Moschkovich, 2007).

In this study, I present a narrative of Jia's (pseudonym) experience answering the following research questions: *What is Jia's experience as a multilingual international student in college mathematics classrooms? How does she use her languages in college mathematics classrooms?* Jia's narrative reveals what challenges some multilingual international students experience, how they might feel or be positioned in mathematics classrooms, and how multilinguals use multiple languages in their mathematics learning. From this study, I call for more attention to multilingual international students in undergraduate mathematics classrooms from the mathematics education field so that the field can better understand the population and serve them more equitably.

Relevant Literature and Theoretical Perspectives

In this study, by multilingual, I mean people who use one language in some situations and another in other situations (Planas & Setati, 2009). This definition does not imply that multilinguals need to speak both languages fluently as if both are their native language, which is a common understanding of the term multilingual (Planas & Setati, 2009). According to this, international students who are traditionally described by terms such as "English as a Second Language," "English as Another Language," or "non-native English speakers" are "multilingual" as they use English during the official instruction of the course as well as some other contexts and often use their first language in other settings.

When multilingual international students move to the U.S. from their home country, their pattern of language use changes: the language that they use in their home country loses its position as the LOI and English–which is usually not a significant portion of their language use–takes the position as the LOI. The switch of the LOI is one of the challenges international students report (Brenner, 1998; Macintyre et al., 1998). Although their language usage changes regardless of various disciplines, mathematics becomes one of the contexts that require a specific discourse (Sfard, 2008). One of the common myths about mathematics is that "mathematics is language-free" because it uses its own symbols and equations (e.g., Schleppegrell, 2007; Takeuchi, 2016). However, even though students share the same mathematical symbols, they need to translate when they want to verbalize their interpretations because mathematical sentences with symbols are dense. Sfard (2008) construed mathematics objects as discursive constructs and hence argued that doing mathematics is having a discourse of (mathematical) discourse, which requires intense language use. Therefore, mathematics needs significant language use to perform, which means multilingual international students whose first language is not the LOI can struggle with mathematical languages. Language is a primary and unavoidable medium when people in classrooms communicate; hence, it can influence students' learning opportunities (Meyer et al., 2016).

Moschkovich (2002) reported that in the past, people had focused on multilingual students' experiences from the perspectives of monolinguals who use the LOI, such as focusing on acquiring vocabulary in LOI or building different meanings of words and grammar in the mathematics. It was not difficult to find when researchers focused on what multilingual international students do not do well, such as concentrating on not speaking English as fluently as native English speaker students do. Some researchers have framed or assumed that multilingual students have linguistic deficiency implicitly or explicitly and then studied how that deficiency influences their learning and experiences (Campbell et al., 2007; Hwang et al., 2022; Neville-Barton & Barton, 2005). I encourage mathematics educators to avoid using such deficit perspectives to understand multilingual students' experiences. Rather than focusing on what they cannot do, researchers need to focus on how students use their multiple languages in their learning and what their current experiences are in their mathematics education (Barwell, 2018; Moschkovich, 2002). Therefore, in this study, I focus on the mathematics identity of one multilingual international student, Jia, specifically focusing on how she used her repertoires of Chinese and English in proof-based undergraduate mathematics classrooms.

Language as Sources of Meaning

In this study, I adapt the view of Barwell (2018), who viewed language as sources of meaning. This perspective implies that language is fluid, agentive, and stratified. Barwell claimed that meaning-making is situated locally through utterance, which can evolve depending on the new utterance. Also, language is agentive as spoken language has the speaker's intentions connecting the past- and current speaker's intentions. Lastly, language is stratified because there were cases when people valued specific languages more than other languages, such as mathematical language and daily language in mathematics classrooms or English and other languages in U.S. classrooms. According to this perspective, language is social and political

(Barwell et al., 2007). It provides a lens to study the role of languages in students' interactions and experiences and their learning of contents.

Method

Part of the data used in this paper was collected as a part of a larger project that investigates students' agency and autonomy in the Introduction-to-Proof (ITP) course and some subsequent proof-based mathematics courses at a large public university in the Midwestern U.S. Jia volunteered to participate in the study in Fall 2019 while she was taking the ITP course. During the ITP course, two in-person interviews and seven activity logs about students' experiences related to the course were collected each week. I observed the course roughly once a week. The two in-person interviews were transcribed from the audio recording, and then I open-coded the data to find an initial list of the codes from her interviews and observations. After that, I found the themes in the initial list and then wrote a profile for her experience. In Fall 2021, follow-up questions specific about her experiences as a multilingual were asked via email interviews, given her preference. I received 12 email responses to the interview questions from Jia in the semester and the following semester. Each email response was analyzed to find initial codes of events (e.g., her group work experience in one ITP class or her use of Chinese in mathematics learning) and themes (e.g., her challenges related to languages) and to create the next set of questions. It was a repetitive and cyclic process. Once the data collection with her was finished, I found the themes (e.g., her challenges related to languages, or her experiences related to gendered bias) across the first and second rounds of data collection and built a narrative of her experiences. To deliver her story more vivid, I decided to use the first-person perspective for her narrative. After I wrote a narrative, I did member checking with Jia twice to have her agree on our narrative of her. Even with member checking, I acknowledge that there is no only "right" or "valid" way of her narratives, and it can evolve over time.

In the following section, I provide only a part of Jia's narrative that I wrote as our finding because of the constraints of the space. The whole narrative consisted of four parts 1) introducing herself, 2) challenges that she experienced in the ITP course and subsequent courses as a multilingual, 3) her ways to utilize her languages in mathematics learning, and 4) her motivations to pursue mathematics even with these challenges. For the sake of this paper, I wanted to highlight and call for attention to the challenges one multilingual student was experiencing, and hence first two parts were included.

Narrative of Jia

My name is Jia. I am a female Chinese, was born in China, and lived there until I came to the U.S for my undergraduate education. So, Chinese, or Mandarin, is my first language and English is my second language. As I am studying in the United States, the language "officially" used in the classroom is English, which I had some concerns with. As my major is statistics and minors are Computational Mathematics Science and Engineering (CMSE), data science, and mathematics, I have taken a lot of mathematics courses. Of course, languages matter in other disciplines as well, but today I am telling you about my experiences in mathematics courses.

Challenges in the Introduction-to-Proof Course

One of the mathematics courses that I remember is the Introductions-to-Proof course. I took the course in the fall semester of my sophomore year, and, as its name indicates, it was a transition course between Calculus courses and more proof-based mathematics courses. Actually, before the course started, I did not have a lot of ideas about the course. I asked some of my

Chinese friends and they said that the course is not difficult, but hard to do perfectly. They said that sometimes it asks you to explain your thoughts, but it can be quite difficult for international students, like us, to express thoughts clearly. And, I started to agree with them as the course was going on. There were several points that I was worried about my English while taking the course although I did well in this course. Sometimes I could not understand what the problem was asking to me or had difficulties understanding the definition, and other times were difficult because of the interactions with other people, like with the instructor or groupmates. I think these challenges were both from my language and my education, which are different here content-wise and teaching method-wise.

One of my biggest challenges was that the ITP course was based on groupwork. We had a lot of groupwork in the course, about two-thirds of the class each week was set aside for us to solve problems in groups, which I enjoyed and found helpful in general because groupwork helps me come up with some ideas or understand the material that I could not understand from my instructor's explanation... as the ITP course changed groups somewhat regularly, my experiences were diverse. The first week, we formed a group based on where we were sitting…. I wanted to have some familiar people in the class, so when I stepped into the classroom, I went to a Chinese female student. And then, there was another Chinese female student, so we became a group. We added each other on WeChat (a SNS that mainly Chinese use) and became good friends, and we sometimes asked questions about the class. (Actually, I became a good friend with one of them and we still hang out sometimes.) As we sat close to each other, they became my groupmates for the first two weeks in the class, which was a good experience for me. I liked it because I could use Chinese with them, which I think is efficient.

After that, my instructor and TA switched groups roughly every two weeks during the first half of the semester. The TA somehow generated the groups and wrote them on the board. And then, I started realizing that who I am assigned to work with in a group influences my groupwork experience. None of my second groupmates were Chinese and all of them looked like their first language was English. I think communication between groupmates is important. But, in this group, I felt isolated. No, let me rephrase that: I was not very engaged. The other people in the group were discussing enthusiastically, but I was like in an, "Ahh, yeah- (indifferent)" kind of mode. I felt my language was the biggest reason. I felt like I did not speak that good.

I always had ideas about how to solve the problems, but I could not explain my thinking succinctly and effectively, or I was not sure whether the words that I wrote were expressing my thinking in English. It happened several times in that semester. For example, something like this: Once, we were asked to compare a variable, x, with a number. In those processes, our group missed that x is a negative number and that led us to make a mistake by not changing the direction of less than or greater than sign (e.g., $>$ or $<$). I said, "x is negative, so we need to change the signal" and they did not understand what I was telling them. I was expecting some positive reactions from them, like "Oh, yes, that's the point," but they did not get it and so could not give me such a reaction. Because I was not sure how to say it any other way, I just wrote it down on my note and showed it to them. Then, one of the groupmates understood and he explained that to the other people. It was a little bit frustrating, but this kind of experience was common at that time. After some of those experiences, I started staying quiet because I knew other people would usually say the same idea that I would have if I waited. Of course, if it took too long, I spoke about my idea, but sometimes I felt I was wasting others' time because other people just could explain the idea in one sentence.

I did not think my experience was challenging only because I did not know how to explain mathematics in English. One other reason that I remember was that, sometimes, I could not be sure which ways or methods they learned to approach the same type of questions in their mathematics in their K-12 education. I thought we all would have learned similar mathematics, but it seemed not. I think it made the situation harder because I think that it would have been easier if we all had similar background knowledge about mathematics. Another part of my experience that I think added more difficulty was that I could not easily jump in on their small talk. This could also be related to my personality; I don't think I am a very social person. But sometimes they speak fast or say things about things from outside the classroom that I did not understand, and then I felt excluded. But I still thought that it was better than doing all of the work alone.

After another round of group rotations, I again was in a group with my friends from the first week as well as another Chinese female student. About middle of the way through the semester, our instructor sent us a survey asking if we had a preference on whom to work with and if so, who we wanted to work with. I put the three Chinese female students on my list, and so did the other three. So, we became a permanent group for the rest of the semester. I was very happy with the group because I felt our communication was so efficient; being able to speak Chinese reduced the time we needed to explain what we were not understanding in English. Compared to when I was in groups where there was the pressure that I needed to explain things precisely, which made me stutter and feel even more nervous, it was so easy to communicate. I became a lot more talkative. We could do small talk as well, and I enjoyed talking with them about my life outside the classroom.

Thinking back, I should have encouraged myself to step out of my comfort zone more. Now, I just try to express my thoughts as clearly as I can. And I will encourage others, as well, if they are in a similar situation. I thought about what I would have done if I were in China and some of my classmates were international students who were not speaking Chinese perfectly. Actually, I had an experience similar to this situation although it is not in school. I once went to a shopping mall in China, and one international traveler came to me and asked a question. But, his Chinese was not very good and so he expressed with some Chinese words with body languages. I answered both in Chinese and English, but he did not understand. I was not mad but patiently explained one more time with gestures. I did not think he bothered me, I knew he needed help, and it was not a waste of my time. Then, I realized that I would have been patient and willing to listen to those international students who do not speak perfect Chinese. I think that it should be the same in the U.S. What do you think?

Jia's Ways to Leverage Multiple Languages

When I was stuck, as I said just before, I search online or ask my Chinese friends. For instance, I struggled a lot in my Abstract Algebra I course. As the course was so challenging, I needed to re-learn the material from resources I found online. When I searched for the course materials online, I could find some parts of some textbooks as well as lecture notes about the course in Chinese. I read those and tried to learn the course material by myself. Although there was no perfect substitute for the course textbook in Chinese, it was still helpful. Sometimes I used videos on YouTube or Bilibili (video sharing platform like YouTube but in Chinese usually) as additional resources. When I search online, I use both of my languages. I usually start with English, but when it seems it will take a lot of time for me to understand, then I switch to Chinese.

In addition to searching the course material to help my understanding of the material, I sometimes search for the terms that appear on the question. If I was stuck on some problem, then the main problem was usually that I misunderstood what the question was asking. Although I struggle sometimes because I need to communicate mainly with my second language in the classroom, I see some benefits of being able to use both languages and have figured out how to deal with the challenge. In addition to what I already told you, I know I can ask some friends who speak English and other friends who speak Chinese when I have questions. Also, I use Chinese in my note-taking as well. I use it as an index so that I can quickly check where I need to look because I can notice Chinese easily and read Chinese a lot faster. Another time I use Chinese is for the definitions. I write some definitions or some keywords in Chinese so that I can remember them better. I switch between the two languages… I also write some memos or how I feel in Chinese, such as "don't fall asleep, you can do it!" "why is it so hard?" or "Confused, review after the class," so that I can focus more on the class and encourage myself.

Although I have been figuring out how to survive in mathematics classes, COVID-19 added another challenge. Because of COVID, all of my mathematics courses were changed to online, which led professors to explain mathematics lectures on zoom and write them on a sheet of paper. Compared to when they are writing on the board and explaining in front of physical students, they wrote a lot faster as they did not need to write it as big as they did on the board. Also, for some reason, they spoke faster and somehow it felt to me that they were reading the book rather than explaining things to us. I sometimes could not write everything in my notes and could not completely understand what they were explaining. Also, the courses did not have a lot of groupwork during the class time, so I could not even ask questions to peers during the groupwork. So, I tended to review the videos instead of going to the synchronous class because I could rewind and stop whenever I wanted to. …

So far, I told you a lot of the challenges that I experienced. But, all of these challenges neither discouraged me from studying mathematics nor led me to lose my confidence. I think my challenges in mathematics courses related to language mean that I just need more time than native English speakers, but they do not mean that I am not good at mathematics. … I think I just need to take more steps moving between the three languages, Mathematics, English, and Chinese. I think mathematics would have been hard even if I studied it in Chinese, but mathematics is charming so I would work hard anyway to understand the material. I am confident that I will definitely learn well if I have enough time (although time just becomes an issue).

Discussion

Jia's experience is one possible shape of many different experiences that multilingual international students have. This study documented how one multilingual student uses her multiple languages in various mathematical contexts, such as doing homework, taking class, or participating in groupwork. The narrative shows that it can be challenging for multilingual international students to participate in groupwork because the situation is not easy to use multiple languages to take advantage of multiple languages. Jia could use Chinese in various ways in other contexts, such as listening to lectures, taking notes, or doing homework. However, it was hard to use Chinese when working in groups, especially when she was with all native English speakers who could not speak Chinese (Hwang et al., 2022).

Jia's challenge in groupwork as a multilingual has significance, considering the emphasis on active learning in collegiate mathematics education, which is often connected to equitable learning for all (Freeman et al., 2014; Johnson et al., 2020; Prince, 2004). I am not suggesting that groupwork harms students but arguing that mathematics educators should be aware of possible challenges students can face. Although Jia attributed her challenging experiences during groupwork to herself, I claim we should focus on external reasons for her actions. Jia said that when she was in a group with at least one other familiar student, usually Chinese, she felt more comfortable sharing her thoughts, which has been found in existing research (Takeuchi, 2016). While she felt connected to having a peer from the same culture, she mentioned that she felt excluded when other groupmates were having conversations about their lives outside the classroom. Given that sometimes conversations that are not relevant to course material create changes in power dynamics between students (Esmonde & Langer-Osuna, 2013), not being able to join small talk because of cultural and linguistic differences can influence the power dynamics in the classroom, which connects to language as stratified and stratifying in mathematics classrooms (Barwell, 2018).

Further, I suggest reflecting on whether people are indirectly implying the notion that students should use English in the classroom and whether multilingual students are discouraged from using their other languages. In her interview, Jia noted that she asked a question to a Chinese teaching assistant, but he responded in English, which Jia thought might be his job. However, I question why the teaching assistant felt he needed to answer in Chinese even though both he and Jia probably knew that their conversation would be clearer and more efficient when they spoke in Chinese. This decision again might have come from the notion that because English is the LOI, it should be more valued than other languages (Barwell, 2018). English is the most reliable common language in U.S. classrooms, making it a good resource to use, but it does not mean other languages should be devalued. Instructors should be aware of and value different ways of communication among students and between instructors and students. This is not to develop "otherness" but for students to use all the assets that they have for their learning.

The current study calls for attention from mathematics educators on how instructors can help multilingual international students utilize the multiple languages that they have. For example, this finding implies that mathematics instructors need to think about how to form a group when they compose a group. In addition, from Jia's narrative, I also found that she used written discourse as an important source of learning, either when she communicated with her groupmates or when she was learning materials. Jia implied that writing on the board could serve as a visual recording and also slow the pace of the instructor's lecture, which provides room for all students to think about the materials.

In this paper, I introduced Jia's perspective as one of the numerous experiences of multilingual international students in mathematics classrooms. However, mathematics educators need to consider how multilingual international students are positioned or viewed in the classroom. In the larger study for which this data was originally collected, our research team has seen some participants describe "linguistic barriers" with international students, which might indirectly imply how general students consider international students. As classrooms in the U.S. are becoming more diverse, I believe how to deal with the perpetuated notion that multilingual international students have "linguistic barriers" in society is an important aspect to consider when mathematics educators teach students.

Quantitative Reasoning Augments Scaffolding for Mathematical Model Construction

Jennifer A. Czocher
Texas State University

Elizabeth Roan

Sindura Subanemy Kularajan
Texas State University

In this report, we begin to explore the value of leveraging constructs from quantitative reasoning for informing scaffolding moves that would assist modelers in overcoming blockages to their mathematization of canonical real-world problems from a first course on differential equations. Our claims are based in qualitative retrospective analysis of a set of 7 design cycles used to develop a task trajectory and resulting learning environment responsive to STEM students' mathematical reasoning during mathematical modeling. We present a set of four scaffolding moves contingent upon and responsive to participants' in-the-moment quantitative reasoning that guided them towards a meaningful model for a predator-prey scenario.

Keywords: mathematical modeling, differential equations, quantitative reasoning, scaffolding

Mathematical modeling and quantitative reasoning are both key skills for successful interdisciplinary collaboration (National Research Council, 2012). In many undergraduate STEM programs, a course on differential equations serves the need for developing these skills. Doing so requires a consistent emphasis on how mathematical relationships are tied to conditions in and assumptions about the real world (Czocher, 2017). Thus, one of the most-studied research problems in the mathematical modeling (hereafter: modeling) genre regards mathematizing – the process of expressing important aspects of a real-world scenario in conventional mathematical notation. Mathematizing is critical, but it is difficult for learners to do and difficult for researchers to operationalize (Cevikbas et al., 2021; Stillman & Brown, 2014). These dual difficulties have challenged educators' capacity to effectively scaffold students' reasoning during modeling. Stender and Kaiser (2015) have called for educators to enact scaffolding based on a "student's current thinking in terms of the problem and the student's possible cognitive operations" (p. 1256). Meeting this challenge requires a cognitive account of mathematizing.

Recently, scholars have characterized mathematization during modeling in terms of constructs from quantitative reasoning. Several scholars have taken the position that constructs from quantitative reasoning afford an explanation of how modelers imbue real-world meanings into their mathematical inscriptions, thereby ensuring their inscriptions are representations of the modeler's conception of the real-world scenario (Czocher et al., 2022; Larson, 2013; Thompson, 2011). The open question regards uncovering how familiarity with students' quantitative operations during modeling may underpin effective scaffolding for extending students' capacity to mathematize. In this paper, we begin to address the question of how constructs from quantitative reasoning could be leveraged for designing effective, contingent scaffolding.

Theoretical Lenses

We adopt a Vygotskian view of scaffolding as an interactive process between educator and learner that supports the learner in performing a task she might not otherwise be able to accomplish (van de Pol et al., 2010, p. 274). One of the key characteristics of effective scaffolding is contingency, or adapting to the learner's current level of performance (van de Pol et al., 2010). Specifically relevant to mathematical modeling, Stender and Kaiser (2015) concluded that the moves constituting effective scaffolding may depend on which phase of the modeling process the learner is engaged in.

From a cognitive perspective, modeling is conceptualized as an iterative process transforming a phenomenon in the real world into a mathematical problem to solve. Within this perspective, it is common to accentuate the duality of a model as a person's conceptual system and as a representation using graphs, tables, or equations (Lesh et al., 2003). A mathematical model as a conceptual system refers to the constellation of knowledge the modeler has about how the world works (e.g., cats breed very quickly) and ideas about mathematical concepts (e.g., a derivative is the slope of a line tangent to a curve at a given point). In the case of equations, an expression of a mathematical model refers to a written representation that uses conventional notation like symbols for variables and arithmetic operations.

For an equation to carry meaning as a model of a scenario, it needs to hold mathematical meanings for the modeler and those mathematical meanings need to have counterparts in the real-world situation at hand. Theories of quantitative and covariational reasoning – how individuals conceive of quantities and relationships among them (Thompson & Carlson, 2017) – explain how meaning is given to the variables and arithmetic operations that constitute an equation (Czocher & Hardison, 2019). Quantities are created in the mind of the modeler when she conceptualizes a specified object in the real world as having a specified attribute that can be measured. Quantities can vary independently or interdependently with other quantities. For example, a modeler could imagine that the number (measure of an attribute) of a population of birds (object) in a backyard habitat waxes and wanes. She could also imagine that the number of birds increases as the number of feral cats in the habitat declines. Quantitative operations produce new quantities from already-conceived ones, usually through combination or composition (Ellis, 2007; Thompson, 2011). For example, a modeler could conceive change in bird population between two points in time by subtracting the latter population from the former.

Methods

Our data are drawn from the Cats & Birds task, which appeared as part of a larger study of effective scaffolding for promoting modeling competencies.

Cats, our most popular pet, are becoming our most embattled. A national debate has simmered since a 2013 study by the Smithsonian's Migratory Bird Center and the U.S. Fish and Wildlife Service concluded that cats kill up to 3.7 billion birds and 20.7 billion small mammals annually in the United States. The study blamed feral "unowned" cats but noted that their domestic peers "still cause substantial wildlife mortality." In this problem, we will build a model (step-by-step) that predicts the species' population dynamics, considering the interaction of the two species.

We intended for participants to arrive at the following model (using their own symbol choices), which are a version of the Lotka-Volterra equations:

$$\frac{dB}{dt} = \gamma B(t) - [\lambda B(t) + \alpha\beta B(t)C(t)]$$

$$\frac{dC}{dt} = \kappa[\alpha\beta B(t)C(t)] - \rho C(t)$$

We worked with 19 undergraduate STEM majors who were enrolled in or had completed a course on differential equations. They participated in a series of 10 hour-long clinical task-based interviews. Cats & Birds featured structural scaffolding in the form of Subtasks to help participants learn to justify the quantities and relationships chosen for inclusion in a model. Seven iterative rounds of design research (beyond the scope of this report) aided in determining which conceptual steps needed to be addressed as subtasks and how big those steps needed to be. Relevant to this report, participants regularly exhibited difficulty handling the complexity surrounding the facts that the number of cats and birds can vary, not all birds meet all cats, and cats are imperfect hunters. Thus, the first three Subtasks were developed to support participants' thinking about how to mathematize the number of cat-bird interactions at time t $(B(t) \times C(t))$ and accounting for encounter rates (α) and successful hunting rates (β). We then followed with Subtask #4:

4. Consider the decrease in magnitude of bird population due only to cat predation during a short interval of time Δt. Write an expression modeling this decrease, in terms of the size of cat and bird populations present at time t.

Goal: Produce $\left[\alpha \times \beta \times \left(B(t) \times C(t)\right)\right] \times \Delta t$ and interpret it as the change in bird population due only to cat predation during a small, fixed, but arbitrary duration of time

The contingent interview protocol targeting mathematizing was designed to explicitly focus on aspects of quantities and quantitative reasoning. For example, follow-ups requested justification for choices of arithmetic operations (e.g., Can you say why you used × here?) or to explain how they were thinking of specific quantities (e.g., do you see ΔB as a change in bird population or as the number of surviving birds after some are killed? What units does B(t)×C(t) have?) in order to inform our interviewer-proffered scaffolding. We used cross fertilization (Brown, 1992) to adapt what we learned about student reasoning from one participant for use in another participant's sessions. Our retrospective analysis of the design cycles focused on participants' quantifications and quantitative reasoning that aided in mathematization.

Results

Among those who did not autonomously produce the target expression for Subtask #4, we found four scaffolding moves that effectively moved the participant towards the Lotka-Volterra equations as a meaningful model for the interaction of species in the backyard habitat.

Contingent scaffolding 1: attend to the object and/or attribute represented by the symbol for a variable. For example, some participants conceived *decrease in population as time passes* to mean a record of the population size at different points in time. Sensibly, they produced a model representing the remaining population, $B\left(t_f\right) = B(t_i) -$ Birds Killed. We asked the participant to reason through what quantity each symbol represented and then followed up with clarifying questions like: *Great! Do you see the computation on the right-hand side as yielding the number of birds remaining or the number of birds that died?* We then asked the participant to identify (and then focus on) the "change-by" amount and used small numerical values such as $B(t_i) = 10$ and Birds Killed $= 3$ to solidify the distinction. When answering the former, we asked the participant to identify (and then focus on) the "change-by" amount.

Guiding the participant to attend to object/attribute/symbol alignment also meant suggesting changes to their notation to better align their intended meanings with conventionally correct meanings. For example, some participants represented decrease in population as time passes using the symbols $B(\Delta t) = B\left(t_f\right) - B(t_i)$. We found that participants conceived the value of the change in population as dependent upon the length of time interval and strongly desired their model to reflect that. Introducing the notation $\Delta B(t, \Delta t)$ to signify the fact that population change depends on duration of time as well as when the duration began resolved the conflict between student meaning and conventional meaning for the symbols.

This scaffolding move was also supportive for participants who used t to represent an arbitrary duration of time (rather than Δt). For these participants, we found that explicitly appealing to convention as a rationale for swapping the symbol t for Δt endorsed the participant's reasoning while making a correction in a way that did not disrupt their thinking.

Contingent scaffolding 2: Use precise and detailed language to refer to referents. Returning to the example of participants conceiving *decrease in population as time passes* to mean a record of the population size at different points in time, we found that keeping careful distinction in language between *change* (for them, the result of a change) and *change-by* (the amount by which a quantity changes) was effective. Introducing the additional vocabulary was fruitful for these students who already associated a quantitative meaning with *change as result*. Another important area for precision of language was when discussing time, in particular, carefully and consistently using phrases like *at time* t and *during a fixed but arbitrary duration of time* Δt. This precision aided participants who inconsistently used $B(t)$ to refer to *population since time 0*. We purposefully avoided the phrase *over time* and instead used *as time passes*, to avoid signaling division in cases where it would be inappropriate. In all cases, we avoided referring to quantities by symbols, instead speaking what quantity the symbol represented.

Contingent scaffolding 3: Support participant in quantification. Some participants conceived *decrease in population as time passes* to mean *accumulation of dead birds since the beginning of time*. These participants intentionally used t to measure time lapsed from 0. We took care to acknowledge their model was correct *under the assumption* that intervals of time were always measured from time 0. Building on their own understanding, we asked: "Now what if we wanted to consider a duration of time that did not begin at 0?" We built on participants' demonstrated knowledge that $\Delta t = t_f - t_i$ to develop a brief intervention using a numberline and concrete values for an initial time t_i and a final time t_f. We emphasized that given Δt as an unknown, but fixed value, it could correspond to infinitely many specific time intervals with different starting (t_i) or ending (t_f) points, illustrated in the exchange below:

Int: Now what is the delta t between t equals 2 and t equals 5?

Peet: It would be 3.

Int: How did you get that?

Peet: Because I just subtracted 5 minus 2.

Int: So you found the distance between, in terms of time anyways. But you found the length of time, which is represented by a distance on the page, between 2 and 5. And you got delta t equals to 3. Can you find another pair of points corresponding to delta t equals 3?

Peet: Ok, yeah. I would do something along the lines of 0 and 3. Or 1 and 4. 2 and 5. 3 and 6.

In this excerpt, the interviewer aided Peet in *quantification*, the mental act of conceiving a measurement process for a specified attribute associated with a specific object (Thompson, 2011). The exchange continued:

Int: I'm going to say initial is 1.

Peet: OK.

Int: Delta t is 2.

Peet: OK.

Int: Where is t initial plus delta t?

Peet: It would be t final, which is 3.

Int: 3. Very good. And if t initial is 1 and delta t is 1.5, where is t initial plus delta t?

Peet: It's going to be 2.5.

Int: It would be at 2.5. So of independently we can set how long the duration of time is that we're looking at. And independently from that, we can set where does the duration of time begin.

Peet: OK.

Int: So going back up to your equation, we can think about tau as being the place where delta tau begins-- the moment that delta tau begins.

Peet: Right. OK. So in other words, you're saying the tau-- these two taus are the exact same.

Int: They don't have the same value. They have the same role.

Peet: Yes, yes. I understand.

Int: So tau 0 minus tau-- so just subtracting those two times-- should give us the delta tau.

Peet: OK.

Int: Did that help?

Peet: Right. Yes, it did. I'm trying to cement it into my mind

As a result of the above exchanges, Peet conceived Δt as a quantity that could vary independently of its composition from two values for the quantity *time*.

Some participants needed help conceiving a quantity as agnostic to usual units. For example, some participants arrived at Subtask #4 with the idea that $[\alpha \times \beta \times (B(t) \times C(t))]$ represented a count for bird deaths. For these participants, because the output units did not include a "per time" element, it did not make sense to them to multiply the expression by Δt. We found two approaches to support these students into developing a quantification of time that was agnostic to usual units like hours, months, years, etc.

1. All these participants agreed that "for something to have happened, time must have passed." We then noted that the birds must have been killed by cats during *some* finite block of time where the exact duration was unimportant. We asked them to consider $[\alpha \times \beta \times (B(t) \times C(t))]$ as the number of successful hunts (or birds killed) during one Block of time.
2. We leveraged participants' natural inclination to justify multiplication through repeated addition. To do this, we asked participants to successively iterate the expression: if $[\alpha \times \beta \times (B(t) \times C(t))]$ is the number of birds killed by cats during one Block of time, how many birds would be killed during two Blocks? During three Blocks? During five Blocks? During half a Block? During 2.7 Blocks? During a fixed, but arbitrary length of time Δt?

This approach had two advantages. First, it allowed participants to generalize to $\times \Delta t$ by building on a simple, observable pattern with concrete numbers. The exchange followed a pattern similar to development of units coordination among children learning proportional reasoning (e.g., Hackenberg, 2007). Second, it built for participants a conceptual object called a *multiplicative object* (Thompson & Carlson, 2017). A multiplicative object is the result of a mental act that couples quantities and their attributes, much like an ordered tuple, where each component of the tuple can vary independently and the resulting tuple is recognized as a quantity as well. Here, the participants formed a conception of "birds killed during an arbitrary time interval" by coupling $[\alpha \times \beta \times (B(t) \times C(t))]$ with Δt. For these participants, the units of the coupling were more similar to "light-years" than to "kills per unit time times time".

Contingent scaffolding 4: Guiding participant to re-quantify a quantity. Some participants realized that the cat and bird populations would vary as time progresses. These participants interpreted $\alpha \times \beta \times (\mathrm{B(t)} \times \mathrm{C(t)}$ as a per-unit-time rate that also varied as time progresses. They formulated an integral expression for the number of birds killed during $\Delta t = t_f - t_i$, $\int_{t_i}^{t_f} [\alpha \times \beta \times (\mathrm{B(t)} \times \mathrm{C(t)})] \cdot dt$. While this is a correct model for the question asked, it is not useful for moving toward a *differential equation* to model the interaction of the species.

We found two ways to help participants conceive $\alpha \times \beta \times (B(t) \times C(t)$ as (nearly) constant during a small Δt, a critical conceptual step for passing from $\Delta B/\Delta t$ to dB/dt. The first way was to suggest that $B(t)$ was large enough such that the fluctuation of a few birds would not matter so much. Many participants were surprised that "it was okay" to make this kind of simplifying assumption, since students often have strong impulses to preserve precision in their models (Czocher, 2019). We then directed the participants to consider a small duration of time, on the order of a day or an hour, rather than a month or a season. With these conditions in place, the participants were able to write $[\alpha \times \beta \times \left(B(t) \times C(t)\right) \times \Delta t]$. The second way was to encourage participants to consider an average value for $B(t)$ and $C(t)$ during Δt. Some students naturally thought of an arithmetic mean using the time interval's end points $B(t)$ and $B(t+\Delta t)$, some took the value $B\left(t+\frac{\Delta t}{2}\right)$, and others introduced concrete numbers to communicate the idea of a weighted daily average. For example, Niali used the notation $B_{\bar{x}}(\Delta t)$ to signify the average valule of the bird population during the interval of time Δt and obtained the following formula to represent the quantity "bird decline during Δt": $P_k \times \left[P_e \times [B_{\bar{x}}(\Delta t) \times C_{\bar{x}}(\Delta t)]\right] \times \Delta t$, where P_k and P_e notated the percent of encounters that end in a bird's death and the percent of encounters that happened per unit time, respectively. Through replication with other participants, we found that Niali's method was viable for those who had completed a course in probability or statistics, and the first method was sensible to a broader range of participants.

In Subtask #4, the same set of symbols can represent multiple aspects of the scenario. The expression $[\alpha \times \beta \times \left(B(t) \times C(t)\right) \times \Delta t]$ represented "successful hunts," "birds killed," and "change in bird population." Shifting interpretations for this expression is instrumental to making progress in the model's development, because eventually the expression needs to be associated with ΔB as its output. These equivalences are interchangeable for instructors, and also to many students, but for some undergraduate STEM majors, shifting interpretations of this expression is nontrivial. For these participants, these three interpretations correspond to three distinct quantities (mental constructs) because their referents in the scenario (objects and attributes) are distinct, as shown in Table 1. To scaffold these participants, we appealed to the tripartite nature of quantities to guide participants' attention towards the object attribute pairings forming the referent for each interpretation of the expression.

Table 1 Three interpretations for the expression$[\alpha \times \beta \times \left(B(t) \times C(t)\right) \times \Delta t]$ *with explicit reference to objects and their attributers in the scenario.*

Object	Attribute	Unit
Set of encounters	Successful hunts	Count
Bird population	Dead birds	Count
Bird population	Change during Δt	Count

Discussion & Conclusions

In this paper we reported four contingent scaffolding moves with quantities and quantitative reasoning at their foundation that supported undergraduate STEM majors to mathematize aspects of a canonical modeling problem from differential equations The interviewer questioning, which contemporaneously focused on students' quantitative meanings for their equations simultaneously revealed participants' conceptual difficulties and provided avenues for overcoming them. Contingent scaffolding move 1 targeted participants meanings for their notation. Guiding participants to attend to the object and/or attribute their notation represented helped them communicate their intended meaning with conventional notation, and in some cases, helped them modify their notation to correspond with their intended meaning. For example, asking the participant what quantity each symbol in $B(t_f) = B(t_i) - \text{Birds Killed}$ represented typically led to participants realizing $B(t_i) - \text{Birds Killed}$ represented "number of birds remaining" instead of the intended "decrease in the bird population." An appreciable subset of these participants then modified their model to $B(t_f) - B(t_i) = -\text{Birds Killed}$. It was then a natural next step for participants to associate $B(t_f) - B(t_i)$ with "change in bird population" via the expression $\Delta B = -\text{Birds Killed}$. Contingent scaffolding move 2 targeted clear and concise communication between participant and interviewer. This aided in mathematization by clarifying which aspect of the real-world situation the modeler intended to model. For example, the language "change in birds over time" is imprecise. It is reasonably interpreted as either "absolute change in the bird population during an arbitrary duration of time" or "change in the bird population per change in time." Contingent scaffolding move 3 aided in mathematization by helping participants quantify an important aspect of the real-world scenario that could reasonably (from their perspective) further operated upon. For example, Peet conceived Δt as a quantity that could vary independently of two specific values of time. Only then could he combine it with the already-constructed quantity *frequency of encounters that result in death* to mathematize *decrease in the bird population*. Similarly, scaffolding move 4 aided in mathematization by helping a participant quantify an important aspect of the real-world scenario so that they could combine that quantity with other quantities. However, the goal of move 4 is not to help them construct a new quantity, but to guide them into re-quantifying an already constructed quantity. In both examples, we helped participants conceive $\alpha \times \beta \times (\mathrm{B(t)} \times \mathrm{C}(t))$ in such a way that the modeler found it reasonable to combine $\alpha \times \beta \times (\mathrm{B(t)} \times \mathrm{C(t)})$ and Δt.

Some of the moves we implemented may seem counterintuitive. For example, typically curricular materials across grade bands assume that learners need to comprehensively study one variable functions before encountering multi-variable functions. The evidence we considered here suggests that some cognitive conflicts encountered during modeling could be resolved if learners had access to notational conventions and increased capacity for analyzing multivariable relationships. Participants clearly recognized complex multivariable interdependences, an observation echoed in the covariational reasoning literature (Jones, 2020). One troublesome implication is that the standard curriculum may be depriving learners of important mathematical tools for use in modeling that would allow them to identify and represent mathematical aspects of real-world considerations.

We wish to emphasize that at any moment during the interview sessions, we could have directly remediated errors or misconceptions, shown the correct equation, and explained why it was correct. However, our purpose was to understand how the participants were thinking and how educators could respond in student-centered ways that would build on or change their thinking. Hence, the nature of our claims take the form: "When a participant exhibited X under Y conditions, doing Z was supportive." While the numbers in our sample were small and the number of participants ripe for each contingency even smaller, the examples we shared are emblematic of the ways that quantitative reasoning, quantification, and quantitative operations can be both a source of cognitive dissonance for students as well as the basis for effective scaffolding in modeling that still respects learners' intuitive ways of reasoning.

Interactive Tutorials in Undergraduate Mathematics: What Are They Good For?

Sang Hyun Kim
University of Auckland

Tanya Evans
University of Auckland

In-person tutorials present a prime opportunity for students to work with others to engage their problem-solving and critical-thinking skills. We investigate the use of interactive tutorials in a large, second-year service mathematics course as part of a quasi-experiment whereby students could either attend in-person tutorials (for a participation mark) or complete the tutorials individually without attending the live sessions and submit solutions for credit. Our analyses of student data and self-efficacy measures suggest that consistent attendance at in-person tutorials may maintain and improve students' self-efficacy. Median changes to self-efficacy measures for students who attended in-person tutorials were higher than those who completed tutorials individually without attending the live sessions. The difference between the changes to the Emotional Regulation aspect of tutorial self-efficacy was statistically significant ($p = .031$)*, highlighting the role in-person tutorials play in supporting students' mathematical learning beyond academic outcomes.*

Keywords: self-efficacy, tutorials, in-person learning, online learning

The integration of online learning and technology into higher education continues to induce a paradigm shift in the way we view teaching and learning in mathematics. Recently, the Covid-19 pandemic has perturbed the norms of teaching and learning. Despite setbacks, it has been a chance for institutions to realize the potential and necessity for online delivery methods, not only as means to continue activities during a crisis but also to stay relevant in an increasingly competitive tertiary market. It is difficult to compete with the low-cost and flexible nature of online education. As a result, we can expect to see the number of online components within traditional courses continue to grow. The use of lecture capture technology and learning management systems have made it possible for lectures and resources to be readily accessible. However, finding an online substitute that can deliver the same level of engagement and retain the interactive components is an issue yet to be resolved. One component of undergraduate mathematics that cannot be easily replaced is the opportunity for collaborative face-to-face learning – in New Zealand, this usually happens during tutorials, which are weekly 1-hour classes scheduled in addition to lectures.

Tutorials, like those conducted within our course of interest, have not received as much attention from researchers, especially in comparison to lectures. Hence, we must gain a deeper understanding of the contribution of in-person tutorials to one's experience of learning mathematics. This study aims to quantify the effects of in-person undergraduate mathematics tutorials on self-efficacy and address the benefits that tutorials can provide that simply cannot be matched through online means.

Theoretical framework

Self-efficacy

Theoretical framework Self-efficacy is a psychological construct that allows researchers to understand how an individual's action can shape an outcome. Used extensively within educational psychology, Bandura (1997) defines perceived self-efficacy as "beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (p.3). Self-efficacy may have a potentially greater initial impact on performance than other related constructs, such as outcome expectations (Sexton & Tuckman, 1991).

Self-efficacy, first proposed by Bandura (1977), is influenced by four main sources: mastery experience, vicarious experience, social persuasion, and psychological states (1997). Mastery experience is considered the most significant source (Bandura, 1997; Usher & Pajares, 2008) as it provides the most realistic indication that students can succeed in a given task. All four sources have a significant contribution to self-efficacy beliefs.

Self-efficacy, the measure of one's belief in their ability to successfully perform a given task, has been well-established as a strong predictor of performance and intrinsic factors in mathematics. Early research into mathematics self-efficacy showed it had a much stronger direct effect on performance than variables such as prior experience, gender, or self-concept (Pajares & Miller, 1994). Similar positive relationships between self-efficacy and performance have been reported in schools (Pajares & Kranzler, 1995; Pantziara & Philippou, 2015) and at the undergraduate level (Pajares & Miller, 1994; Peters, 2013). As a significant predictor of achievement, analyzing measures of self-efficacy can help us to better understand their impact on students and inform the way they are implemented into higher education courses.

Motivation

Using a quasi-experimental design, we sought to examine the potential impacts of tutorials in two ways. First, we were interested to see if there was a significant difference in student performance (final exam grades and overall grades) between students that primarily attended the in-person tutorial sessions compared to those that submitted their work online. Previous studies in similar settings report the use of live components to be associated with higher achievement (Howard et al., 2018; Inglis et al., 2011). However, these studies focused on the difference between attending live lectures versus watching lecture recordings. Students often justify their use of asynchronous video resources by praising the control of pace it provides and the flexibility it affords (Howard et al., 2018). However, the negative association between achievement and higher use of lecture recordings has primarily been consistent across the undergraduate mathematics education literature reported in a recent systematic review (Lindsay & Evans, 2021). It is thought that lecture recordings promote surface-level approaches, thus degrading the quality of learning. However, considering the interactive nature of tutorials, we expect to see a similar relationship between in-person tutorial attendance and performance.

Second, we set out to investigate tutorials' impact on a significant intrinsic construct: self-efficacy. As a significant predictor of success, among other variables, understanding this impact would allow researchers and course designers to utilize this understudied aspect of undergraduate courses best, whether it be to justify policies in favor of more fully online mathematics education at undergraduate levels or as evidence to consolidate the use of in-person tutorials for the near future in a delicate time of change in education.

Study setting

This study investigated the tutorials within a large, second-year service mathematics course at the University of Auckland. The course, General Mathematics 2, is split into three main topics that cover the content required across many disciplines: calculus, linear algebra, and differential equations. Assessments in the course are divided into four sections: coursework (including engagement with tutorials) – 15%, mid-semester test – 20%, quizzes – 15%, and a final exam – 50%.

While the Covid-19 pandemic disrupted many on-campus activities throughout 2020 and led to a shift to remote delivery methods, the first semester of 2021 presented itself as a relatively unperturbed semester, with most university activities returning to campus. However, with the risk of Covid-19 still looming over the community and international students being located outside of the country, remote options to complete coursework were made available for students.

Tutorials

This format of interactive tutorials is standard at the undergraduate level at the University of Auckland and is often met with positive feedback from students that note the usefulness of learning from others in a supportive space (Oates et al., 2016). In the tutorials, students are given opportunities to collaborate with their peers while problem-solving. Each tutorial session is one hour long and occurs weekly. A tutor is available during the session to help address questions and monitor each group's progress. While attendance or completion of the tutorials in our course was not mandatory, it was highly encouraged for all students and had a small contribution to overall grades. Students could receive marks contributing to their coursework grade by attending an in-person session or completing the questions and uploading their work to a learning management system (Canvas).

The term 'tutorial' is often used in two contrasting ways in the literature. One refers to learning opportunities where attendance is optional and is directed at supporting students, often serving a remedial purpose. In many institutions, mathematics support centers subsume this role (Cronin & Meehan, 2021; Mullen et al., 2022). The other, which we utilize in this work, refers to a core component of undergraduate courses that, like lectures, aim to provide another medium to engage learners with the content. This shares many aspects of a lab session in chemistry courses, where students apply knowledge from lectures to engage their problem-solving and critical-thinking skills.

Data

Student Data

Student data was collected during the first semester of 2021 via Canvas. In total, there were 354 students enrolled in the course. Student data included tutorial attendance/completion and performance in the course, including final exams. Of the 354 students enrolled,186 students attended or completed all 9 tutorials. Due to Covid-19 health restrictions, the first scheduled tutorial session (in the second week of the semester) occurred online rather than in-person. To best capture the potential impact of consistent engagement of tutorials, we have not included the data of students that did not complete all the tutorials or were limited to one option in our analyses (e.g., offshore students that could not attend the on-campus sessions). Data from these 129 students (36% of the course) will be analyzed further to capture the impact of consistent tutorial engagement over the semester.

Self-efficacy Measures

Student self-efficacy was measured using the Measure of Assessment Self-Efficacy for Mathematics Tutorials (MASE-T) (Evans & Jeong, 2023; Riegel et al., 2022). The instrument measures assessment-related self-efficacy across two factors: *Comprehension and Execution* (CE), and *Emotional Regulation* (ER). The instrument has been validated and shown to be reliable at measuring student assessment self-efficacy across different contexts, including tutorials. Of the students enrolled in the course, 219 students provided measures of their self-efficacy at the start and the end of the semester. In total, data from 100 students who completed all tutorials and provided self-efficacy measures will be used for the analysis.

Attendance Groups

Students were classified into two groups by the number of tutorials they attended over the course. Table 1 shows the distributions of the 129 students by the number of in-person tutorials they attended. Students were grouped into two groups: those that attended less than half of the total in-person tutorials (i.e., 0-4 in-person tutorials attended, $n = 23$) and those that attended more than half of the total in-person tutorials (i.e., 5-9 in-person tutorials attended, $n = 106$). Herein, the two groups will be referred to as *online* and *in-person*, respectively.

Table 1. Number of in-person tutorials attended across the semester.

In-person tutorials attended	*n*	%
0	11	8.5
1	3	2.3
2	5	3.9
3	2	1.6
4	2	1.6
5	1	0.8
6	6	4.7
7	15	11.6
8	25	19.4
9	59	45.7

The attendance behavior of students throughout the semester suggests that students showed a strong preference for one of the learning environments over the other, as seen by the large proportion of students that attended either 0-2 or 7-9 in-person tutorials. The number of students opting for each method of tutorial completion (in-person/online) remained relatively consistent across the semester (Table 2). One possible explanation for the slight decrease in the number of in-person attendees for tutorials 4 and 5 could be that some students may have prioritized their time to prepare for the mid-semester test and completed the tutorials individually for those weeks.

Table 2. Tutorial attendance across the semester by attendance groups.

Tutorial	2	3	4	5	6	7	8	9	10
In-person	107	106	92	90	101	102	102	104	100
Online	22	23	37	39	28	27	27	25	29

Results

Performance

An independent-sample *t*-test was run to determine if there were differences in the mean final exam score and overall grade of online and in-person students. An initial assessment for outliers, normality (as assessed by Shapiro-Wilk's test ($p > .05$), and homogeneity of variances (Levene's test ($p = .405$, $p = .325$)) was conducted for both the final exam grade and overall grade data with no violations being detected in either set of data.

The mean final exam score was higher for online students (*M* = 73.8, *SD* = 13.3) than in-person students (*M* = 61.3, *SD* = 16.8), a statistically significant difference with medium effect size, *M* = 12.5, 95% CI [5.1, 19.9], $t(127) = 3.349$, $p = .001$, $d = .77$. The online group also had a higher mean overall grade (*M* = 78.2, *SD* = 9.9) than the in-person group (*M* = 70.8, *SD* = 12.6). This difference was also statistically significant with medium effect size , *M* = 7.4, 95% CI [1.8, 12.9], $t(127) = 2.637$, $p = .009$, $d = .61$.

Self-efficacy

Due to violations in the normality of the self-efficacy data, Mann-Whitney *U* tests were undertaken to determine whether there were any significant differences between groups. First, the median and mean ranks for all measures of initial self-efficacy were higher in the online group than in the in-person group. By the end of the semester, this was not the case. In particular, the median and mean rank for all tutorial self-efficacy measures were higher in the in-person group than in the online group. The online group still had a higher median and mean rank for all exam self-efficacy measures by the end of the semester. However, these results were not statistically significant ($p > .05$).

Second, the analysis of the changes in participant self-efficacy between the start and the end of the semester revealed the following. A significant difference was observed in the *Emotional Regulation* factor of tutorial self-efficacy, which was statistically significantly higher at the end of the semester for the in-person group (mean rank = 53.12) than for the online group (mean rank = 35.63), $U = 860.5$, $z = 2.153$, $p = .031$ (Figure 1).

Similarly, change in the *Comprehension and Execution* factor of tutorial self-efficacy (U = 792, $z = 1.491$, $p = .136$) and overall change in tutorial self-efficacy ($U = 835$, $z = 1.907$, p = .057) was higher for the in-person group with these differences almost reaching a level of statistical significance.

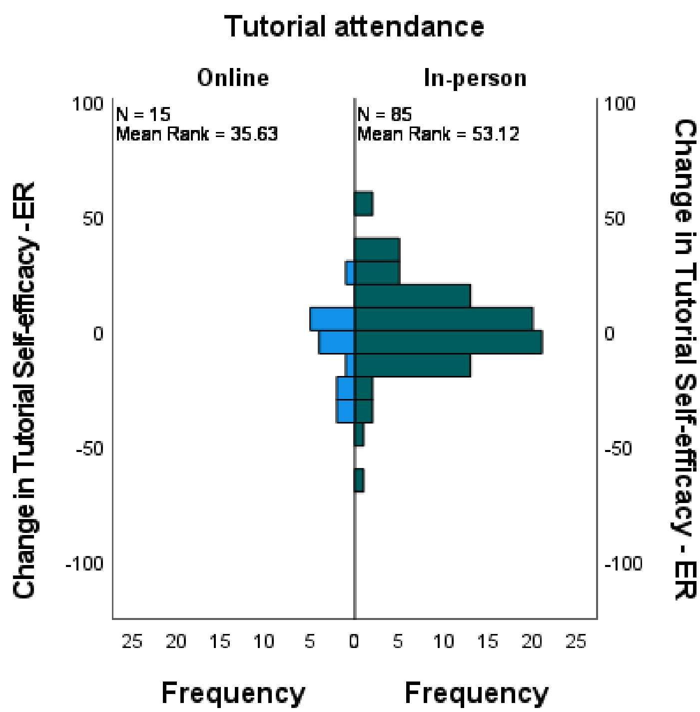

Figure 1: Histograms of the change in the Emotional Regulation (ER) factor of tutorial self-efficacy. The in-person group saw a greater increase than the online group, p = .031.

Discussion

Performance

Our findings showed a statistically significant between-group difference in performance in the final exam and overall grades in the course. A significant difference in performance between groups of students that utilize different study methods is not a unique finding. Inglis et al. (2011) reported that students that relied more on online recordings (lecture capture) were associated with lower grades in the course, while live lecture attendance was met with improved grades. Similar findings were reported by Howard et al. (2018).

While we report a correlation within our data pertaining to learning activities within a large undergraduate course, our study differs from the existing literature in two ways. The first is that our study investigated the use of tutorials, which, as an integral part of tertiary mathematics, has not been fully explored using quantitative analyses. This study analyses the value of undergraduate mathematics tutorials through the lens of self-efficacy. Secondly, our correlation found that using a live study component, that is, in-person tutorials, was associated with lower performance grades, unlike the studies mentioned previously. While we cannot say whether students with a higher aptitude for mathematics chose to study a particular way or that the use of tutorials may not foster mathematical learning, we speculate that there is more to this phenomenon that warrants further investigation. With both forms of tutorial engagement involving the same problem sets, it seems unlikely that this difference is due to differences in content coverage.

One possible cause for this difference could lie in prior knowledge. In a recent study, Zakariya et al. (2021) consider prior knowledge when examining students' approaches to learning and their performance. Their analysis suggests that low prior knowledge may be conducive to surface-level approaches to learning which can have a significant, negative effect on performance (Zakariya et al., 2021). Within our learning context, we can expect students enrolling into a service mathematics course to have a wide range of mathematical abilities that may have influenced how they choose to learn. Possibly, students with low prior knowledge perceived in-person tutorials as an easier option to score 100% by simply showing up, whereas the online option required a written submission for marking.

The presence of high- and low-achieving students in both groups could indicate that students are making more conscious decisions about how they choose to study. This may be driven by a heightened appreciation of the benefits of each study option. Research from the pandemic shows that many students desired opportunities for social interaction, immediate feedback, and wanted to return to campus, noting difficulties in staying focused and motivated at home (Mullen et al., 2022; Radmehr & Goodchild, 2022). However, the oft-praised flexibility provided by remote study options could very well be a priority for many individuals that prefer to study online (Thompson & McDowell, 2019). Thus, we cannot make any concrete claims about students' motivation behind their preferred study method without using qualitative data.

Self-efficacy

First, the median initial self-efficacy measures were higher for online students than the in-person students. While this difference was not significant, it is worth noting as a potential factor in student decision-making about how to study. This hypothesis is in line with the literature reporting that students find enrolling in online courses for subjects that are perceived to be easier for them to be more favorable (Jaggars, 2014).

When comparing the changes to self-efficacy, the in-person students saw no negative changes to the median exam and tutorial self-efficacy measures. For the online group, the change to median self-efficacy measures remained unchanged for the *Comprehension and Execution* factor of their exam self-efficacy, while it dropped for all others. The greatest median changes for online students were seen in their tutorial self-efficacy, with significant changes in the *Emotional Regulation* factor of tutorial self-efficacy. The localization of this significant change is consistent with the domain-specific nature of self-efficacy (Pajares & Miller, 1995). Additionally, it strongly suggests that the benefits of interactive tutorials at the undergraduate level can branch into affective factors. It may help to maintain positive beliefs within individuals and foster a greater sense of community between learners.

The in-person tutorials with a group-work component promote a high degree of social engagement between peers and experienced tutors, seen in the form of immediate feedback and words of encouragement and motivation. At the undergraduate level, these are conducive to active learning and position tutorials as positively contributing to achievement (Freeman et al., 2014). The negative correlation between achievement and in-person tutorial attendance, while significant, cannot be used to make a claim for or against one form of tutorial engagement. In order to do so, we need to control for factors that influence performance, such as prior knowledge. We can also reflect on the differences offered by each delivery mode.

One key difference between the two groups in our study is the learning environment where student active (cognitive) engagement occurs. In-person tutorials provide an opportunity for collaborative learning through the presence of peers and tutors. From the perspective of cognitive psychology, this could be beneficial, as evidenced by the *collective working memory effect* (Kirschner et al., 2011; Kirschner et al., 2018). This effect suggests that learning as a group is more effective than individual learning if the material is sufficiently complex, exceeding the limits of each individual student's working memory. "In this situation, the cognitive load of processing this complex material is shared among the members of a collaborative learning team enabling more effective processing and easier comprehension of the material." (Kirschner et al., 2018, p. 222). However, the researchers caution that bringing together a group of learners is no guarantee that the learning would happen efficiently as many other factors are involved.

Our findings show that, on average, the trajectory of students' *Emotional Regulation* component of tutorial self-efficacy is improved through their participation in in-person tutorials. Thus, shifting our perspective to what is uniquely offered by in-person tutorials could be worthwhile to better understand their importance in undergraduate mathematics learning.

Limitations

It would be ill-considered to generalize the finding to different courses or contexts or to completely refute the effects tutorials may have on other aspects of self-efficacy. Considering many of the differences were borderline statistically significant, it would be worth investigating different courses, including those specific to mathematics majors.

We recognize the importance of collecting more measures of learning, including qualitative data, such as students' perspectives on tutorials as a learning resource. This could improve our understanding of students' preferences, provide us with a different lens to analyze our findings, and allow us to explore the more nuanced differences between the delivery modes.

How Do We Disentangle Equality from Equivalence? Well, It Depends

Zackery Reed

John Paul Cook
Oklahoma State University

Elise Lockwood
Oregon State University

April Richardson
Oklahoma State University

In this paper, we report on interviews with mathematicians exploring the ways in which they think about the relationship between equality and equivalence. Given sometimes unclear and conflicting presentations of equality and equivalence in the literature, we are motivated to understand subtleties about how these constructs interact; doing so can have pedagogical implications, which we explore in this paper. We present three major themes that emerged from our analysis of the mathematicians' discussions of equality: 1) that equality represents a well-specified equivalence relation, 2) that audience matters when specifying equivalence and equality, and 3) that context is imperative when discussing equivalence and equality.

Keywords: equivalence, equality, equivalence relations, mathematicians

In this paper, we unpack the nuances of multiple mathematicians' understandings and uses of equivalence and equality, and the potential implications of these nuances for K-16 pedagogy. Rather than bringing new mathematical insights to light (see Mazur (2008)), we seek to consider pedagogical implications pertaining to relationships among and distinctions between equivalence and equality as expressed by mathematicians. We suggest that such insights are valuable for researchers who want to better understand the nature of equivalence, and for instructors who seek general principles and guidelines for supporting students in productive ways of reasoning about both equivalence and equality. We address the following research question: *How do mathematicians view the relationship between equivalence and equality?*

Relevant Literature and Theoretical Perspectives

In this section, we introduce relevant literature and situate our work within theoretical perspectives. This includes framing our working definitions of equivalence and some mathematical discussion about equivalence and equivalence relations.

Equivalence and Equality

There has been a considerable amount of research exploring equivalence and equality; much of this work has been conducted in K-12 settings (e.g., Knuth et al., 2006; McNeil & Alibali, 2005; Solares & Kieran, 2013), although some has explored these ideas with older students as well (e.g., Chin & Tall, 2001; Godfrey & Thomas, 2008; Stephens, 2006). We focus here on work that has explored the relationship between these two foundational mathematical notions, which are broadly synonymous but subtly different: while the equivalence concept is well-specified (via the definition of an equivalence relation), we observe that explicating its relationship to and distinction from equality is important but not yet well articulated or understood. Despite its ubiquity, for instance, equality has been referred to as "slippery" (Mazur, 2008, p. 222) and "precarious" (Saldanha & Kieran, 2005, p. 5). Hersch (1997) encapsulated this idea well when he noted that equality "is used freely, from kindergarten to postgraduate. It's never defined or explained" (p. 50).

The K-16 curriculum provides a multitude of examples that highlight the potential benefits of being able to disentangle equality from equivalence. For example, Saldanha & Kieran (2005) found that "many students' emerging thinking about equivalence was rightly bound up – indeed, arguably confounded – with notions of numerical equality" (p. 5). We infer that, here, *equality* refers to the equivalence of numerical expressions, whereas *equivalence* refers to the equivalence of algebraic expressions. Note that, in this situation, it would not be inappropriate to use equality to refer to *both* the equivalence of numerical expressions and the equivalence of algebraic expressions, as is in fact normative.

Also consider the notion of equation solving, which not only involves "a grasp of the notion that [the] right and left sides of the equation are equivalent expressions, but also that each equation can be replaced by an equivalent equation (i.e., one having the same solution set)" (Kieran, 1981, p. 323). That is, two forms of equivalence are at play. We observe that, in such instances, the algebraic expressions in question could be reasonably said to be equal (and thus also equivalent). Though while the equations are equivalent because they share the same solution set, they are *not* considered to be equal (we consider it normative to say, for example, that $2x + 1 = 5$ is *equivalent* to $2x = 4$, rather than to say that $2x + 1 = 5$ is *equal* to $2x = 4$). Thus, in contrast to the first example we discussed, equality applies to one instance (expressions) but not the other (equations).

The topics featured in these examples – the equivalence of expressions and equations – are foundational in the mathematics curriculum, yet equality does not uniformly apply in each situation. Indeed, these peculiarities illustrate that "[m]ath lingo sometimes says 'equal,' sometimes 'equivalent'" (Hersch, 1997, p. 50). We observe that the rules governing *when* one might use one or the other are implicit and underspecified. This spurs us to ask: in what situations might we use equality, and why?

The literature does contain some attempts to answer this question. Mazur (2008) conducted a deep and mathematically rigorous exploration, using category theory to explicate the relationship between equivalence and equality. However, we note that his argument – while undoubtedly useful to a research mathematician and generalizable across many context – is far beyond the scope of mathematics with which K-16 students (and most K-16 teachers) are familiar. What is needed, we propose, is an explanation of the relationship between these ideas that, in addition to being plausible and generalizable, is also accessible to K-16 students and instructors. In this vein, McNeil and colleagues (2012), for example, explained that numerical equivalence is "formally represented by the equal sign" (p. 1109). Similarly, Fyfe and Brown (2018) framed numerical equivalence as "the relation indicating that two quantities are equal and interchangeable" (p. 158). The example of equivalent equations, for instance, illustrates that equivalence is not always "formally represented by the equal sign" and certainly can – but need not always – indicate that "two quantities are equal." While these descriptions of the equivalence-equality relationship are certainly appropriate for the contexts from which they were drawn, we note that they do not frame the relationship in a way that generalizes to other contexts, and thus are of limited use for our purposes here.

Others have highlighted equivalence as a more general and sophisticated version of equality, but have pointed out that equality is nevertheless used differently (e.g., Rupnow & Sassman, 2022). Kieran's (1981) seminal paper on equivalence begins with Gattegno's (1974) observation that, with respect to equality, "equivalence is concerned with a wider relationship" (p. 83). Additionally, Fischbein (1999) argued that "the concept of equivalence is more general and much more subtle than the concept of equality. What seems to be trivial for equality, is not necessarily trivial for equivalence" (p. 23). Our initial impression is that framing the well-specified notion of equivalence as more general than the "slippery" and "precarious" notion of equality is both useful as a starting point for our analysis and consistent across mathematical contexts. A contribution of our work, therefore, is to further explore and elaborate these conceptual statements regarding the specificity of equality and the generality of equivalence as a result of analyzing the perspectives of multiple mathematicians.

Framing Equivalence

Here we define and characterize equivalence, which connects to our interview design and our analysis. We broadly draw on Cook, Reed, and Lockwood's (2022) framework, which employed conceptual analysis to identify three interpretations of equivalence taken on by students across mathematical domains and scholastic settings (these included *common characteristic*, *descriptive*, and *transformational* interpretations). We note that each of these focus on the features of students' possible interpretations of the equivalence of specific objects; that is, these interpretations involve what Hamdan (2006) calls a *local*, element-wise view of equivalence.

While we inferred the presence of these *local* interpretations when analyzing our interviews with mathematicians, we determined that the mathematicians' perspectives on the relationship between equivalence and equality can be better characterized in terms of a *global* view of equivalence, which "requires going beyond the element-wise conception of a relation" (Hamdan, 2006, pp. 130-131) in order to focus on the structure of a set in terms of the equivalence classes based on the relation that partitions the set. One key global interpretation of equivalence taken on by the mathematicians, which theoretically grounds our discussion of equivalence and equality here, is that objects "are identified as 'the same' if they lie in the same equivalence class" (Rupnow & Sassman, 2022, p. 119). A key aspect of this interpretation is that it is by nature a stipulated attribution of equivalence. Indeed, given any set, an extreme use of this interpretation might entail an arbitrary partitioning of the set and then attribution of equivalence to the members of each individual partition. While employing this interpretation is usually much more purposeful (and less arbitrary), we find that the key subtleties of attributing equality or equivalence to mathematical objects are grounded in one's ability to assign equivalence based on membership in an equivalence class. In fact, our exploration of when to use equality largely centers on the conditions by which the mathematicians might not just attribute equivalence to members of each class, but instead might determine it appropriate to ignore differences amongst elements in the same class altogether.

Methods

Data Collection

The data on which we report is taken from a larger study examining the ways that both mathematicians and students view equivalence across undergraduate mathematical domains. Early data collection targeted research mathematicians to, among other goals, generate hypotheses about how students might productively understand equivalence at high levels of mathematics. One outcome of these interviews was an early awareness that the relationship between equality and equivalence was relevant to these mathematicians' understandings and uses of equivalence, and that there were many subtleties to the mathematicians' views on equality that have key implications for mathematics instruction in general.

As part of the larger study, we interviewed research mathematicians specializing either in abstract algebra or in combinatorics. Our primary objective was to build an initial theory that accounted for the key ways in which algebraists and combinatorists might think about equivalence. This report is based upon individual semi-structured interviews (Fylan, 2005) we conducted with eight mathematicians, all of whom were tenured mathematics faculty at large universities across the United States. The primary data for this report were the video records of the 90-minute interviews conducted with the mathematicians (referred to here by the pseudonyms Dr. A, Dr. B, etc.). Though we asked a variety of questions about equivalence and how it manifests in their research and instruction, here we focus primarily on their responses to the following question: "Do you think that there is a difference between equivalence and equality? If so, please explain in what kinds of situations you would use equality and in what kinds of situations you would use equivalence. If not, please explain why."

Data Analysis

The video records were transcribed in full, and the transcripts were initially analyzed according to Cook et al.'s (2022) framework for interpreting local, element-to-element instances of equivalence. After inferring the various ways in which the mathematicians were interpreting equivalence, and determining that a global, equivalence-class based perspective on equivalence (Hamdan, 2006) would be more productive for analyzing the mathematicians' conceptions of equality, we isolated the segments of the interviews in which the mathematicians specifically discussed the relationship between equivalence and equality. We then employed thematic analysis (Braun & Clarke, 2012) on this subset of the data. Thematic analysis was useful for our purposes because it provided a mechanism by which we could identify themes related to the mathematicians' views of the relationship between equivalence and equality and also make sense of these themes with respect to our research question. Our analysis was primarily data-driven and exploratory, though we did use Hamdan's (2006) global perspective on equivalence and equivalence classes to guide our identification and description of themes. We followed Braun and Clarke's (2012) stages of thematic analysis (familiarizing oneself with the data, developing initial codes, searching for themes, reviewing themes, and characterizing and naming themes), then met to compare and negotiate our interpretations. From this process we identified the three themes that we discuss below.

Results

We now detail the overarching themes we identified regarding the nature of the relationship between equality and equivalence. Generally, the mathematicians we interviewed framed equality as a relationship between objects that results from declaring and imposing a well-specified equivalence relation. Their criteria for when they would comfortably use equality (instead of the more general notion of equivalence) to describe the relationship depended on our two major themes of *context* and *audience*. Though we observed instances of each of these themes across a multitude of excerpts and interviews in our data set, due to space constraints we present each theme only with prototypical, illustrative responses from our data.

Equality Indicates a Well-Specified Equivalence Relation

Our first theme is that equality indicates a well-specified equivalence relation. That is, equality is used to relate elements in the same equivalence class to each other once an equivalence relation has been clearly defined and enacted on a given set. To illustrate this point, we focus on responses from Dr. A, a combinatorist who explained the nuances of the equality-equivalence relationship by pointing out the differences in the role of equality before and after a well-specified equivalence relation is imposed. For Dr. A, before an equivalence relation is imposed, equality is “kind of the trivial case where every block of the partition is a single element.” In such cases, he said, “there’s one element that’s equal, you know, the equivalence classes have size one. There’s no variation.” In other words, prior to the implementation of a well-specified equivalence relation, equality means *identity*. That is, equality only applies to elements that are represented in exactly the same way with no variation in representation (e.g., prior to establishing what it means for two numerical expressions to be equivalent, 3 is only equal to 3 and is not, for example, equal to 1+2). Dr. A then explained equality in the context of using modular congruence as an equivalence relation:

> *Dr. A*: But if I’m willing to just say, “No, I’m not interested in all the integers anymore, I now just want one element from these classes,” I feel, like, okay committing to that. Then it’s okay. That's sort of my, that's what it means to me to now say, “Okay, when I say equals … I'm not thinking of three as three, I’m thinking of three as a … representative of this set [of integers congruent to 3 modulo 7],” or whatever. But it’s kind of like you’re changing the idea of what [the equal sign] even means. And now the definition of equality, I guess, is okay in my mind now […]. It’s just that that equality has to be defined.

We highlight two key features of this theme that we infer from this comment. First, Dr. A emphasizes that “equality has to be defined.” He made a similar comment at another point in the interview, noting that “I’m okay with [equality] once you declare it and clean it up.” We therefore infer that, for Dr. A, an essential element of declaring objects to be equal is that equality is well-specified. First, notice that Dr. A’s language distinguishes the meaning of equality *before* and *after* the introduction of modular congruence as an equivalence relation. Before, equality meant only identity (e.g., 3 is only equal to 3). After, the introduction of the equivalence relation and collapsing of the integers into equivalence class representatives establishes a new form of equality (e.g., 3 can now be considered equal to 10, 17, etc.). Bringing these two features together, we infer that equality indicates a relationship between elements that results after one declares and imposes a well-specified equivalence relation.

Audience Matters When Specifying Equivalence and Equality

Our second theme is that one’s use of equality is also conditioned by one’s image of the audience. For example, Dr. A noted that equality “has to be either explicitly there or at least understood by all the people in the conversation as an okay use of equality.” Also consider the following comment from Dr. B, who had previously indicated the importance of specifying what equality means:

> *Dr. B*: So, what’s probably going on in my head, the rule of thumb is if I, as the speaker, I’m confident that everybody in the conversation really understands what’s going on, then we can get careless. In [an introductory abstract algebra class], I don’t think it’s ever appropriate to have that confidence. […] So yeah, if I’m doing modular arithmetic in [class] $\overline{1} = \overline{8}$ instead of $1 = 8$. And I'm gonna be very clear that I'm always using bars […] because with that collection of students, I don’t know, there’s probably a significant fraction where the notational abuse is fine and honestly helpful, but there's another bunch

who are just gonna be so completely lost if you start to do it that I wouldn't try it. On the other hand, if I'm teaching […] the master's level class, yeah, I'm not putting those bars on after the first day that I introduced the quotient definition.

Dr. C offered a very similar explanation:

Dr. C: The students may not be comfortable with equivalence and equality being the same, like, and this probably comes up […] in modular. You know, if I'm in Z_5 and I'm saying, "Oh, six is the same as one," […] I think for mathematicians that's, we're very casual with our language, you know? So, […] that could be okay. But maybe for an undergrad that would be not so much okay to say 6=1.

Overall, the mathematicians we interviewed indicated that, with respect to a particular topic, equality might be allowable when in discourse with some populations (e.g., graduate students and mathematicians) but not advisable when in discourse about the same topic in other populations (e.g., undergraduates in their first abstract algebra course).

The Mathematical Context Is Imperative When Discussing Equivalence And Equality

Our final theme is that nuances related to the mathematical contexts under discussion also influence whether or not equality is used. For example, above we discussed a comment from Dr. B in which he discussed how he would feel free to write statements like $1 = 8$ to connote the equivalence of elements in the quotient Z_7 while amongst mathematicians or in a graduate course. He went on to add, however, that this might not be the case if he has "got multiple quotients interacting or something." We infer here that, in such situations, the mathematical context at hand might shape one's use of equality. Also consider the following comment from Dr. D:

Dr. D: So, equality is an equivalence relation, […] so if I'm looking at a quotient ring – so I'm defining, you know, ring mod ideal – then $Q = R$ mod i. Then I can really say that $a + i$ really *equals* [his emphasis] $b + i$ in Q because we have defined equality to be that way. […] So, in terms of discrete math, I will *define* $\{a, b, c, d\}$ to *equal* $\{c, b, a, d\}$. I will define those to be equal if I put the curly brackets on and I understand that these things are sets. But I will say (a, b, c, d) is not equal to (c, b, a, d). […] equality depends on the context that we've agreed upon.

Similarly, Dr. C explained that, to him, consideration of mathematical context also influences when equality might be most appropriately used:

Dr. C: It's very situational to the problem being asked. […] I might be going off on a tangent now, but I'm just thinking when I say equals it depends on where I'm working, you know? An integer, if I'm saying six and one are integers, then no, they can't be equal. They're different. But if I'm working in Z_5, then yeah, they're totally equal.

We view these considerations of the mathematical context as complementary (and not disjoint from) considerations of the audience.

Discussion

In response to our research question (*How do mathematicians view the relationship between equivalence and equality?*), our analysis indicates that – in alignment with the literature – equivalence is indeed the more general, comprehensive notion, and that mathematicians' use of equality is conditioned by (1) whether or not the form of equivalence in question has been well-specified, (2) the mathematical context, and (3) their images of the intended audience for the mathematical discourse in question.

A major goal of this report is to make a case that more care is needed when conceptualizing equality in educational contexts, and that there are subtle aspects of how we use equality in both research and teaching contexts that can have important implications for research and instruction. Returning to the literature, when it is said that equivalence is "formally represented by the equal sign" (McNeil et al., 2012, p. 1109), our findings suggest that there is more specificity needed to situate *when* we use equality to formally represent equivalence relations. This functionally brings clarity to the theme in the literature about how equivalence is more general than equality: for the mathematicians, equality represented a well-specified equivalence relation that was appropriate for the intended audience and mathematical context.

We believe our analysis builds upon other pieces of the discussion of equivalence and equality in the literature as well. Particularly, we propose that a reason that equality has been called "slippery" and "precarious" is perhaps because its use depends not solely on mathematical rigor and precision, but on the user's image of the audience and mathematical context. That is, to a certain extent, this is an *epistemological* – and not solely a *mathematical* – distinction. These themes support the idea that there is not just one definition of equality, underscoring the importance of our first theme (as well as many calls by researchers and curriculum designers): it is critical to specify exactly the scope of situations in a given context to which we apply notions of equality. As a practical takeaway, then, our findings highlight that we should be much more explicit about equivalence in our teaching of mathematics across the spectrum. Currently, there is a danger that equivalence is being brushed under the rug, under the guise of equality, and there are not opportunities for broader conversation about how and why we attribute equivalence. Further, it may be useful to emphasize that our use of the equal sign expands in complexity and layering as we progress throughout the K-12 curriculum (and then into the undergraduate curriculum). Our findings may raise additional suggestions for certain populations; for example, for pre-service secondary teachers this is an opportunity to draw potentially meaningful connections between advanced mathematics (e.g., equivalence relations and equivalence classes) and the secondary mathematics they will soon be teaching (e.g., equivalence in the context of rational numbers, expressions, and equations).

Exploring How Status Influences Relational and Participatory Equity in Inquiry-Oriented Small Group Interactions

Brittney Ellis
Texas State University

Tenchita Alzaga Elizondo
Portland State University

While inquiry approaches have the potential to open up more equitable spaces in the classroom, research has shown this is not guaranteed. In this study we focus on the role that status can play in creating (in)equities during small group work. In particular, we compare one low-status student's interaction with two high-status students in two small group episodes. We found that the two episodes differed in terms of participatory and relational equity and our results describe how status and certain patterns of interaction may account for this difference.

Keywords: Status, equity, small group interactions, inquiry-oriented instruction

There is some consensus that research on inquiry approaches in undergraduate mathematics classrooms needs to consider equity issues (Adiredja & Andrews-Larson, 2017; Laursen & Rasmussen, 2019; Melhuish et al., 2022). Scholars have suggested that group work – a common feature of inquiry instruction – may be a potential factor contributing to inequities in learning mathematics at the undergraduate level, particularly along gender lines (Brown, 2018; Ernest et al., 2019; Hicks et al., 2020; Johnson et al., 2020). Johnson et al. (2020) established that men achieved higher scores than women on a conceptual assessment after taking inquiry-oriented abstract algebra. The authors speculated that group work may open up opportunities for microaggressions and implicit bias to occur, which could negatively impact women's confidence in their own mathematical ability, resulting in lower performance. Ernest et al. (2019) characterized several student interactions during group work in an inquiry setting as overtly sexist and implicitly exclusionary towards women. This small body of research points to a need to better understand social processes during group work in inquiry classrooms that may be able to explain such inequitable findings.

Scholars at the K-12 level have argued that status and positioning during group work may amplify inequities in inquiry learning environments (Battey & McMichael, 2021; Shah & Lewis, 2019). Yet, how status influences (in)equitable interactions during group work has been underexplored in research at the undergraduate level. Therefore, this study set out to explore the role of status during group work in an inquiry setting from participatory equity and relational equity perspectives.

Theoretical Framework

In this study, equity is defined as situations in which all students can access resources they need for learning, and *in*equity as situations that *limit* access to resources needed for learning (Shah & Lewis, 2019). Resources needed for learning mathematics in small groups can include physical materials (e.g., notes, definitions, technology), skills to complete the task (e.g., problem-solving strategies, intuition behind a proof), and a safe learning environment (e.g., learn from mistakes, space to make sense). Two interrelated concepts further indicate how situations are more or less inequitable in small groups. First, participatory equity describes situations in which "opportunities to participate—and participation itself—are fairly distributed among all students involved in a learning interaction" (Shah & Lewis, 2019, p. 428). Second, relational equity (Boaler, 2008) describes situations in which the *quality* of interactions provides each student "access to opportunities to develop identities as capable learners" (p. 428). As human interactions naturally fluctuate, a situation will never be completely equitable or inequitable. For instance, in one situation a student may have more opportunities to participate and influence decision making at one moment, then limited access to such opportunities at another moment.

Unbalanced power dynamics due to differences in status characteristics may amplify inequities in small group work (Esmonde, 2009a; Shah & Lewis, 2019). A status characteristic is known as an "agreed-upon social ranking where everyone feels that it is better to have a high rank than a low rank" (Cohen et al., 1999, p. 84). In the classroom, academic status characteristics such as perceived ability are extremely powerful status markers (Cohen & Lotan, 2014), which can be impacted by diffuse status characteristics (Ridgeway, 2018) such as gender, race, ethnicity, socioeconomic class, etc. (Cohen et al., 1999). For example, it is a widely held belief that "Asian men are good at math" (Shah, 2017) which raises their perceived ability in math, thus increasing their status. Students with higher perceived status typically contribute more in class and small groups, gaining more opportunities to access resources needed for learning. Status hierarchies form quickly when people regularly interact with one another (Berger & Webster, 2018; Ridgeway, 2018) – a key characteristic of inquiry classrooms (Laursen & Rasmussen, 2019). While status hierarchies may become stable over time, it is possible to disrupt this process to promote more equal status positions between students (Cohen et al., 1999). We argue that exploring status positions while students work in small groups can help us understand the role status might play in shaping situations that are more or less (in)equitable.

To explore how status shapes group work interactions with respect to participatory and relational equity, we leveraged research using status and positioning theories to analyze small group interactions (e.g., Adams-Wiggins et al., 2020; Alexander et al., 2009; Chizhik, 2001; Esmonde, 2009b; Shah & Lewis, 2019). Table 1 provides the analytic constructs used in our analysis with low- and high-status indicators and examples from our data. The observable group activities in interaction come from status construction theory (Berger & Webster, 2018; Wagner & Berger, 1993), and the low- and high-status indicators were identified from several sources drawing on status theory (e.g., Chizhik, 1999, 2001; Cohen et al., 1999; O'Donnell, 1999).

Table 1. Status Constructs Used to Analyze Small Group Interactions

Observable Activities in Interaction	Low-Status Indicator	High-Status Indicator	Example from Small Group Data
<u>Opportunities to Contribute</u>	Grants opportunities to act (seeks help from others)	Receives opportunities to act (answers questions)	Justin: So now that we have this, how does this relate? (granting opportunities to act)
<u>Communicated Evaluations of Contributions</u>	Negative evaluations ("That is wrong")	Positive evaluations ("That is a good idea")	Alison: So, we have to define Q and W. They're just symmetries. Abigail: Yeah that's smart.
<u>Influence Over Group Decision Making</u>	Ideas rejected or ignored by the group (less ability	Ideas accepted by the group (influences the	Abigail asks if they should start on part two. This idea is not taken up as Justin

	to influence disagreement outcomes)	outcome of disagreements)	suggests they are not done with part one yet.

Methods

Data Collection and Episode Selection

Data comes from a project developing inquiry-oriented introduction to proof curricular materials designed to introduce students to various proof-related activities (e.g., proof construction and comprehension, defining, conjecturing, etc.) using real analysis and group theory concepts. We focused on a curriculum implementation in an Introduction to Proofs course that was taught remotely over Zoom (due to COVID-19) at a large public university. Table 2 contains the 14 participating students' ethnoracial background by gender (some students self-identified as more than one race/ethnicity). Students engaged in group work at least once per day with groups changing every day. The second author attended class each day, entering breakout rooms during group work as a silent observer to capture the students' activity. Screen recordings captured activity over Zoom as well as activity on Google Docs which became a virtual space for students to work together on tasks.

Table 2. Self-Reported Student Ethnoracial Backgrounds and Gender

Gender	White	East Asian	Southeast Asian	Hispanic/Latinx
Woman (*n*=6)	5	0	0	2
Non-Binary (*n*=1)	1	0	0	0
Man (*n*=7)	5	3	2	1
Total (*n*=14)	11	3	2	3

Two group work episodes were selected as the main data source for this study. A group work episode was defined as the time period in which students worked in groups on a specified task. The two episodes were selected based on the second author's extensive work studying the students' collective mathematical activity (see Alzaga Elizondo, 2022). First, in episode 1, Lee (Southeast Asian male) and Alison (white female) were working to prove that group isomorphisms preserve inverses. Lee took a clear lead in proposing and developing the mathematical ideas while Alison followed along, regularly providing evaluations. From the second author's classroom and group observations, Lee had higher perceived status among the classroom community. Contrastingly, in episode 2, Alison, Abigail (white female) and Justin (white male) worked to prove that a group element can appear at most once in a row of the group's Cayley Table. Alison contributed several key ideas to her group's proof such as the overall structure of a contradiction argument and several line-by-line justifications. While Alison was an active participant in both episodes, she appeared to contribute to the co-construction of mathematics in qualitatively different ways. Given the more collaborative activity in episode 2, we conjectured that empirically analyzing status in relation to participatory and relational equity while focusing on Alison would show episode 2 as being more equitable compared to episode 1.

Analysis

Students in remote environments communicate using different modalities when working together to solve a problem (Hoffman 2019). The first step in our analysis was to create multimodal transcripts that captured both verbal communication and any activity across different modes (i.e., on Google Doc and Zoom). To map any nonlinear forms of communication, we used descriptive text (i.e., "as she talks, she writes:" or "while everyone else works they edit the text") and/or time stamps. Together, the transcripts provided a complete image of the students' multimodal discourse, which we used with the video data for subsequent analysis.

We leveraged equity analytics (Reinholz & Shah, 2018) to quantify the number of talk turns, the duration of talk, and proportion of talk in each episode. Specifically, we used the multimodal transcripts to count the number of both verbal talk turns and non-verbal participation. Students often used the Google Doc to communicate and illustrate ideas (Alzaga Elizondo, 2022), thus we defined a non-verbal participation turn as any time a student added something to the shared document. Then, we used the constructs in Table 1 to analyze status relations. Specifically, at each talk turn in the multimodal transcripts, the first author attributed who granted/accepted opportunities to contribute, evaluated specific contributions, and whose ideas were taken up, ignored or rejected and how this impacted influence over group decision making. Additional analytic notes were recorded to describe how the students treated and interacted with one another as well as how status differences emerged. The second author went through all analytic notes and transcripts to add anything new or challenge the first author's interpretations. The two authors then met to discuss and compare analytic notes and reconcile any differences.

As we moved into an interpretive phase of analysis, we wrote analytic memos (Creswell & Poth, 2016) that centered on interactions between low-status and high-status pairings: Alison and Lee (Episode 1) and Alison and Justin (Episode 2). The purpose of creating the memos was to systematically find evidence and any counter-evidence for emerging interpretations of the interactions and compare across the two episodes. For example, in episode 2, we began to see an interaction pattern emerge between Alison and Justin that was different from interactions between Alison and Lee and seemed connected to Justin maintaining his high status position (which he implicitly established throughout the episode). The first author wrote memos from re-watching the video data with the transcripts and status analysis, and the second author served to challenge interpretations in the memos. Any disagreements were resolved through discussion.

Results

In the following, we first demonstrate how participation was distributed differently among the students in each episode, with Alison participating less overall in episode 2 compared to episode 1. Then, from a relational equity perspective, we found that the quality of interactions also differed between the episodes. We argue that the students' status relations provides insight into *how* the quality of interactions differed. Specifically, in episode 1, Alison was invited to co-construct a proof with Lee (a high status student) by evaluating lines in the proof, while in episode 2, Alison had to defend her mathematical contributions repeatedly to Justin, a higher status student who established himself as an expert on what formal proofs should look like throughout the episode.

Participatory Equity

Table 3 describes the verbal and non-verbal participation distributions across participants in each episode, which provides insight into how fairly distributed their participation was (Reinholz & Shah, 2018). Meaning, if participation is distributed equally across three people working in a group, each person should have about one-third of the whole amount of talk-time allotted to them. We caution that equitable or fair participation is not synonymous with equal participation (see Reinholz & Shah, 2018). With that in mind, in episode 1, Alison and Lee each participated about a proportionate 50% of the time, with Alison talking for slightly longer durations and Lee participating more non-verbally. In comparison, Alison participated less than her allotted one-third and for shorter lengths of time in episode 2, and Alison and Justin contributed about the same non-verbally (i.e., adding to the shared google doc). While Alison did not participate a fair share amount in episode 2, we would not claim that this alone implies inequity occurred. Therefore, to further compare the two episodes, we turn to our status analysis and interpretations from a relational equity perspective.

Table 3. Verbal and Nonverbal Participation Distributions.

Episode 1					
Participation	Talk Turns	Duration	Percentage	Proportion	Nonverbal
Alison	50	8.1 min	49.49%	0.99	9
Lee	49	6.6 min	50.51%	1.01	24
Total	**99**	**24 min**	**100%**		

Episode 2					
Participation	Talk Turns	Duration	Percentage	Proportion	Nonverbal
Alison	51	5.6 min	28.65%	0.86	7
Abigail	51	7.0 min	28.65%	0.86	11
Justin	76	9.7 min	42.70%	1.28	7
Total	**178**	**24.5 min**	**100%**		

Status and Relational Equity: Episode 1

The mathematical proof activity between Alison and Lee was characterized as less collaborative compared to the group's activity in episode 2 because Lee contributed most of the mathematical ideas used to complete the task and how Alison responded to those ideas had little impact on the mathematical direction of their work (Alzaga Elizondo, 2022). Our analysis suggests that Lee's higher status (relative to Alison) may have provided him with more opportunities to contribute a substantial amount of the mathematical work. However, throughout the episode, Lee regularly made moves to grant Alison opportunities to contribute to the task by inviting her to evaluate the work. We argue that the ways Lee invited Alison to check and evaluate lines of the proof and incorporated her suggestions provided evidence that Alison was trusted and viewed as a peer with expertise, which may have equalized their status differences to some degree. The following exchange exemplifies Alison and Lee's interactions:

Lee: From here can I just jump to like, therefore e_2- therefore phi(e_1) is the identity by definition or is that skipping some steps? (pause)

Alison: Hold on I'm thinking (pause) yeah I think that's good. (reads) "By definition of identity." So phi(e_1) must be the identity in-

Lee: Oh wait, but we're not saying for all H, we have to prove that that's all H.

Alison: the identity- What do you mean all h? Oh for the identity for all h? But we've already proved that there is only one identity. Isn't that in the definition of identity?

Lee: Yeah, but like this is showing the identity for all these, some elements of H until we show- I guess we can use onto right?

Alison: Yeah. (nods affirmatively) Yeah, we probably have to use onto.

Lee granted Alison an opportunity to contribute an evaluation by asking her if he could “just jump” to the conclusion “therefore phi(e_1) is the identity by definition” or if there were missing steps (which there were). Inviting Alison to check and evaluate their work in this way was a typical interaction pattern between the pair. Alison responded by asking for time to think, then accepted Lee’s invitation by saying she thinks the proof is “good” (positive evaluation). She continued reading the proof until Lee realized they did not prove that phi(e_1) is the identity “for all” elements in H. Alison offered the idea that the class had “already proved that there is only one identity” and asked if that’s in the definition of identity (granting Lee an opportunity to contribute). Lee accepted by first positively evaluating Alison’s contribution that there is only one identity (“yeah”), then suggesting that their proof is showing the identity property for “all these, some elements of H” (meaning all the elements in the image of phi, which may only be a subset of H). Lee granted Alison another opportunity to contribute by asking “I guess we can use onto right?” which she accepted and positively evaluated (“yeah”), further agreeing by reiterating they “probably have to use onto.”

While Lee (a high status student) contributed more substantial mathematical ideas than Alison (a lower status student), the way he granted her opportunities to evaluate their work before moving forward may have balanced out the potential status differences between them. From a relational equity standpoint, their interactions showed mutual respect for each other’s expertise and potentially provided opportunities to access a positive mathematical identity (Esmonde, 2009b).

Status and Relational Equity: Episode 2

In a prior study, this group’s mathematical proof activity was characterized as highly collaborative because all students contributed to the mathematical direction of their work (Alzaga Elizondo, 2022). However, their interactions viewed through a status and relational equity lens paints a slightly different picture. Specifically, one interaction pattern between Alison and Justin that emerged was Alison contributing a (valid) direction to make progress on their proof which Justin would positively evaluate only to then immediately question whether her idea was formal enough. The following exchange exemplifies this interaction pattern. Prior to the exchange, Abigail was defending her claim: by the nature of the (Cayley) tables, each entry in the first row and first column are unique (referring to the row and column headers). Justin and Abigail had a back and forth about whether she thought the identity symmetry was different than three rotation symmetries (for an equilateral triangle). Alison entered the conversation by contributing “it’s different actions” and suggesting an idea for their proof.

Alison: Yeah it's different actions but I think for the sake of our proof we need to somehow say we're limited to you know (pause) just four, well in this case we don't have- however many symmetries there are. (pause) I might be articulating that wrong. (pause)

Justin: I think the original route we’re going down is right, where we have this, I think this is definitely the right way. I’m just trying to make sure that we have the proper way saying that proper, like-

Alison: Yeah, I agree, we have to find the way to set it up before we can just say. (pause)

Justin: Well, (cross talk with Abigail) I just want to make sure there’s no holes, I guess-

Abigail: (cross talking) Q is identical to W then

Alison: (responding to Justin) I understand that.

Alison stated they need to argue there are a limited number of symmetries to choose from “for the sake of our proof.” She then made a self-doubting comment (“I might be articulating that wrong”), which we interpreted as a low-status indicator (see Adams-Wiggins et al., 2020). Justin positively evaluated Alison's contribution and her original idea to prove by contradiction ("I think the route we're going down is right") and countered by stating that he wanted to make sure it was formal enough (the "proper way"). Alison agreed with him that they "have to find the way to set it up." After a brief pause, Justin reiterated that he had to "make sure there's no holes" implicitly suggesting that Alison's logic may be faulty. Alison reasserted that she understood his concern ("I understand that").

We interpreted this repeated interaction pattern as potentially increasing rather than balancing status differences between Alison and Justin. Alison (a lower status student) contributed more substantial mathematical ideas than Justin (a high status student), which could have equalized their status. While her contributions were regularly met with initial positive evaluations, they were often immediately followed by repeated questioning from Justin who viewed himself as the expert on the "proper way" of proving (meaning, what is acceptable as a formal proof by the mathematical community). From a relational equity perspective, while their interactions were mostly friendly, Alison was treated as a peer with less expertise in formal proof compared to Justin, which could have potentially limited the opportunity to access a positive mathematical identity.

Discussion

Our results show how small group interactions that were deemed highly collaborative in terms of mathematical proving activity (episode 2) were potentially more *in*equitable compared to small group interactions that were characterized as less collaborative (episode 1). First, participation was distributed differently among the students in each episode, with the focal student, Alison, participating less overall in episode 2 compared to episode 1. Then, from a status and relational equity viewpoint, the quality of interactions also differed between the episodes. In episode 1, while Alison (a lower status student) contributed less substantial mathematical ideas than Lee (higher status), an interaction pattern between them may have balanced their status differences, promoting mutual respect for each other's expertise (attenuating inequity; Shah & Lewis, 2019). Contrastingly, in episode 2, Alison contributed more substantial mathematical ideas than Justin (higher status), yet an interaction pattern between them potentially increased their status differences by maintaining Justin's high status as an expert in formal proofs while implicitly lowering Alison's status (amplifying inequity).

We see two primary implications from this study. First, our work shows that studying small group collaboration in inquiry classrooms solely from a mathematical perspective does not paint a complete picture in terms of how (in)equities might occur. Second, if differences in status are not intentionally disrupted (particularly regarding gender and perceived mathematical ability), women's opportunities to access positive mathematical identities may be limited, which could lead to negative outcomes (e.g., Ernest et al., 2019; Johnson et al., 2020). Therefore, inquiry instructors may need specific training on how to enact group work in ways that mitigate such status differences (Melhuish et al., 2022). A direction for future work could be to adapt research at the K-12 level that has developed and implemented group work principles to reduce status hierarchies (i.e., Complex Instruction, Cohen et al., 1999) for undergraduate inquiry settings.

The Mathematical Inquiry Project engages mathematics faculty from all Oklahoma's public institutions of higher education in collaborative learning and resource development guided by three components of learning mathematics through inquiry: active learning, meaningful applications, and academic success skills. We report our analysis of participants' interpretations of these components and the social and cognitive mechanisms they entail. Our results (1) provide a descriptive analysis of beliefs and priorities about learning mathematics through inquiry held by post-secondary mathematics faculty and (2) contribute to research and outreach on faculty change using a model incorporating implicit and explicit learning theories, within which the professional activity and collaboration develop a community that supports productive aspects of learning mathematics.

Keywords: inquiry-based learning, entry-level math, professional development

The Mathematical Inquiry Project (MIP) and its Definition of Inquiry-Based Learning

The MIP is a collaboration among mathematics faculty from all 27 of Oklahoma's public higher education institutions. The project aims to improve learning in entry-level mathematics courses by engaging faculty in collaboration regarding inquiry-based learning, conceptualized to entail three components: *active learning*, *meaningful applications*, and *academic success skills*. The MIP defines these components through the lens of constructivist epistemology. The definitions were developed to guide project implementation and encourage participants to adopt a critical stance toward the nature of students' conceptions in their design of curricular materials that seek to engage students in the precise mental actions required to construct targeted mathematical meanings. The MIP defines the three components as follows:

> *Students engage in active learning* when they work to solve a problem whose resolution requires them to select, perform, and evaluate actions whose structures are equivalent to the structures of the concepts to be learned.
>
> *Applications are meaningfully incorporated* in a mathematics class to the extent that they support students in identifying mathematical relationships, making and justifying claims, and generalizing across contexts to extract common mathematical structure.
>
> *Academic success skills* foster students' construction of their identity as learners in ways that enable productive engagement in their education and the associated academic community.

In the summers of 2019-2021, the MIP leadership team (the authors) led five different week-long workshops during which faculty discussed key conceptual threads of entry-level mathematics courses and academic success skills in those courses. The leadership team aimed to support the participants' thinking about the social and cognitive mechanisms involved in developing productive ways of understanding foundational concepts in entry-level undergraduate mathematics, and how to design curricular materials that promote students' construction of those ways of understanding. For example, participants discussed the ideas of *conceptual analysis*

(Thompson, 2008) and *hypothetical learning trajectories* (Simon & Tzur, 2012), and critically examined curricular materials developed with these in mind. Participants also unpacked the MIP's definition of inquiry and its operationalizion in the design of sample curriculum materials. In later stages of the MIP, currently ongoing, participants are creating their own course materials and will share them via workshops and peer mentoring. The goal of engaging participants in curriculum development and dissemination is to build capacity through broad professional participation and leadership in an emerging community that values and supports reflective practice in learning mathematics through inquiry.

Active learning, meaningful applications, and academic success skills are of interest to the research in undergraduate mathematics education (RUME) community. In a review of the RUME 2022 proceedings (Karunakaran & Higgins, 2022), 12 of 82 contributed reports[1] contained the phrase 'active learning' in the abstract, keywords, or body. These reports tended to define or discuss active learning terms of pedagogical strategies (e.g., "think-pair-share," Cervello Rogers et al., 2022), its characteristics (e.g., student engagement and collaboration, Johnson et al., 2022), or affordances (e.g., equity; Rios, 2022). Two papers framed active learning with reference to cognitive theories (e.g., Kerrigan et al., 2022; Rogers et al., 2022). Some definitions of active learning in the proceedings mention engaging students in meaningful mathematical tasks or projects (e.g., Broley et al., 2022; Chowdhury et al., 2022; Fukawa-Connelly et al., 2022; Johnson et al., 2022). Moreover, the proceedings also indicate interest in academic success skills such as students' mathematical identity (e.g., Guglielmo et al., 2022; Voigt et al., 2022) and problem-solving (e.g., Corey, Weinberg, & Tallman, 2022). We generally observe, however, that much extant literature focuses on students' activity when engaged in such tasks and less on instructors' views of what meaningful mathematics might entail and how it might be productively realized in the classroom. We seek to address this gap.

Research on faculty change highlights that supporting strategies should seek to alter individual's beliefs as opposed to mandating "effective" curricular resources or enacting top-down policy initiatives to impact teaching quality (Henderson et al., 2011). The literature establishes a need to characterize faculty's conceptions of mathematical learning through inquiry and describe how particular professional development experiences contributed to their evolution (Williams et al., 2022). The MIP is one such professional development project. This paper contributes to research on faculty change by constructing models of participants' explicit and implicit learning theories in relation to their conceptions of the three components of learning through mathematical inquiry. We focus on the following research question: Following engagement in a professional development initiative centered on the components of mathematical inquiry detailed above, what are participants' images of (a) active learning, (b) meaningful applications, and (c) academic success skills?

Theoretical Perspective

The MIP definitions of active learning and meaningful applications are based on Piaget's genetic epistemology. We find this a useful way to characterize mathematical inquiry because (1) it focuses on an individual's cognition, which provides a means for MIP participants to conceptualize and think carefully about students' thinking and learning, and (2) the field, as noted in the section above, has typically not dealt with issues of active learning and inquiry from an explicit epistemological perspective. In Piaget's view, conceptual development is a process of constructing and modifying cognitive structures to enable individuals to establish a fit, or

[1] These numbers exclude our 2022 conference proceedings regarding the MIP.

equilibrium, between their conceptual model of reality and the reality they experience (von Glasersfeld, 1995). Piaget regarded cognitive development as a process that inclines toward a balance, or equilibrium, via *assimilation* and *accommodation*. Assimilation is the process whereby a subject incorporates experiences into existing cognitive structures, and accommodation entails the modification of an individual's cognitive structures to enable their assimilation of novel experiences. Assimilation and accommodation, and thus equilibration, rely heavily on the notion of *abstraction*, of which Piaget distinguished four varieties (*empirical*, *pseudo-empirical*, *reflecting*, and *reflected*). Piaget (2001) explained that higher forms of knowledge (such as logico-mathematical structures) derive from abstractions of the subject's actions and the results of applying them in specific contexts. The nature of mathematics knowledge structures, or *operative schemes*, are organizations of internalized (mental) actions constructed through the process of pseudo-empirical or reflecting abstraction. The *action of the subject* is thus the basis from which mathematical knowledge structures are constructed.

Commensurate with this epistemological framing, the MIP definitions of active learning and meaningful applications are established on the premise that supporting students' construction of mathematical knowledge is a process of engaging them in the specific *actions*—and engendering abstraction of either the products of these actions (*pseudo-empirical abstraction*) or the actions themselves (*reflecting abstraction*)—that reflect the structure of the internalized actions organized within the schemes that an instructor expects students to construct. Notice that the MIP definitions of active learning and meaningful applications specify the conceptual mechanisms engendered. The relation of our definitions to an explicit learning *process* differs from characterizations of learning mathematics through inquiry that specify the environmental, pedagogical, or social conditions that must be established for students to be actively learning or for a teacher to incorporate meaningful applications in their instruction.

The MIP definition of academic success skills is similarly informed by constructivist epistemology, while being supplemented by theories of emotion (Ortony, Clore, and Collins, 1988), identity (Blumer, 1986), and goal structures (Middleton, Jansen, & Goldin, 2017). See Tallman and Uscanga (2020) for a synthesis of these theories and their relation to students' affective experiences.

The MIP afforded opportunities for faculty members to engage with the definitions of the three components. Hence faculty experienced opportunities to engage in reflecting and reflected abstractions (Piaget, 2001) regarding the characteristics and mechanisms entailed in active learning, meaningful applications, and academic success skills. Our study was designed to investigate their images of these three components following this professional development.

Methods

We conducted semi-structured interviews on Zoom with 15 MIP participants in spring 2020. Interviewees had participated in at least one workshop. Interview questions included:

1. Please describe your image of active learning in entry-level college math courses.
   a. Why is this important for entry-level math courses?
   b. Can you describe a specific example of active learning in an entry-level math course, yours, or someone else's? What made this example effective? What could have been better?
   c. Has your participation in the MIP activities changed your thinking about active learning? How?
2. Here is the MIP's definition of active learning. [Participants were shown the definition].
   a. Are there parts of this that you think are important but haven't discussed yet?

b. Do you particularly agree or disagree with emphasizing any aspect of the MIP definition for improving instruction in entry-level college mathematics?

The questions were repeated twice more with ‘active learning’ replaced by ‘meaningful applications’ and ‘academic success skills.’ The interviews were audio recorded and transcribed for analysis.

We employed the constant comparative method (Strauss & Corbin, 1994) to identify themes in the data. For each of the three components of inquiry, one author read all the transcripts, highlighting phrases that characterized participants’ images of that component. When a new phrase was added to the list, the author reread previous transcripts seeking instances of it. The author then grouped similar items into themes and described each theme using the list of phrases. That author applied the themes to re-code all the data, adjusting the themes’ descriptions until they adequately described the span of participants’ images. To ensure consistency amongst coders, a different author independently coded the data, employing the first coder’s themes and seeking excerpts that were not described by the themes. The two authors discussed differences until they agreed on a final set of themes. The final themes for each component are described in the results. The themes for active learning refine those presented in Ireland et al. (2022). Themes for a component are not mutually exclusive; for instance, ‘motivating students with real-world examples’ was coded as both ‘real world examples’ and ‘affective affordance.’

Results

We present the answers to our research question in terms of themes we identified in participants’ interpretations of (a) active learning (b) meaningful applications and (c) academic success skills. Participants focused primarily on characteristics, affordances, and requirements of the three components with some attention to learning mechanisms. While each of the themes we explore below emerged in our analysis from a multitude of supporting transcript excerpts, here we illustrate a proper subset of the themes we identified and support them with one or two illustrative, prototypical excerpts.

Active Learning

Student engagement. All participants described student engagement as part of active learning. Jude, for example, defined active learning as “involvement of [students’] brains” in contrast to instruction in which only the “instructor’s brain that is running.” Generally, participants’ comments associating active learning to student engagement suggested that they viewed engagement (and related ideas of interest and involvement) as the mechanism by which mathematics learning occurs.

Format in which students engage with the content. All participants discussed active learning in terms of the format in which students would engage with the content, such as small-group work, projects, class discussions, guided or scaffolded problem sets, or using manipulatives or calculators. For example, Jack said, “I incorporate a lot of collaborative project learning so that they can see the math in action… the less I talk… the better.”

Participants’ descriptions within this theme focus on characteristics of active learning, that is, what active learning might “look like” to a classroom observer. This contrasts with our view of the MIP’s three components of inquiry, which all involve descriptions of cognitive activity that is not observable in the same way. From our theoretical perspective, active learning might occur when students work in small groups, but working in small groups is not a sufficient condition for students’ construction of a desired mathematical meaning.

Nature of the mathematical tasks. Some participants described characteristics of the mathematical tasks they present to students, such as novel problems (not exercises) that would support understanding over simple memorization. Participants believed active learning occurred when problems required students to struggle productively and problem-solve. Some participants believed real-world examples were useful for engaging students in active learning. The attention to these characteristics is notable because it indicates attention to a key consideration for curriculum design: what students are engaged in and how they are engaged in it is consequential for the mathematical meanings they construct.

Participants expressed their belief that productive struggle is a mechanism of learning. For example, Quinn described,

> I have come to see [active learning] as asking students to truly problem-solve in a way that, that they may or may not have seen before…. Instead of having me say "here are the tools that we're going to use, here is exactly how we're going to use them and exactly the order that I want you to use them… it's set up more like "okay here are the tools, now here's a problem and maybe here are some guiding questions."

Quinn was unique among participants in that she not only described productive struggle, but hinted at the idea of students needing to engage in particular mental activity (selecting "tools").

Reveals student thinking. Two participants valued active learning for revealing student thinking, allowing the instructor to modify instruction and address individual or critical issues. Reagan[2] said:

> active learning [makes it] easier for the instructor to know… where the students struggle… the instructor can… feed additional example or deep explain certain concept to help them better retain the information… my hope is through repetition they get the structure.

We infer that Reagan thought repetition was a learning mechanism that helped students "retain" information and "get" general structure.

Affective requirements and benefits of active learning. Participants' images of active learning included what they saw as affective requirements for it and affective benefits of it. Per the former, participants described that active learning would only be successful if students were interested in the problems, motivated to work on them, possessed perseverance, and if the classroom community felt safe. Participants felt students' having growth mindsets was important, and that a positive classroom community could help minimize students' math anxiety. For example, Finn said, "you have to have an environment where everyone's safe to throw out answers and get responses back." Participants also believed active learning could help students develop all these characteristics, noting that active learning sometimes served to increase students' interest, motivation, and perseverance. Eden, for instance, described active learning as "making them do the work, it's [building] self-efficacy."

Meaningful Applications

Format in which students engage with the content. Like their definition of academic success skills, participants described their images of meaningful applications as problems embedded in formats like small-group work or class discussions. One difference is that participants felt presenting a real-world example in a lecture constituted a meaningful application.

---

[2] English is not Reagan's first language.

Nature of the mathematical tasks. While the MIP characterization of meaningful applications hinges on applications that are mathematically meaningful, participants seemed to think of a meaningful application as one that was relevant to students' daily lives. Some participants mentioned that an application would be meaningful if it were relevant to other mathematics. For instance, Quinn said

> I also think of meaningful applications as in what can, what can they do with a definition within mathematics…And if it, and if it helps them with their problem-solving skill then it is extremely meaningful.

In addition to real-world examples, participants described that meaningful tasks were usually formed when students were given open-ended questions or novel problems. One participant noted that a task that supported students in generalizing would be a meaningful task, and several participants said tasks that connected to other mathematics were meaningful applications.

Affective requirements and benefits of meaningful applications. Participants' images of meaningful applications included the affective requirement of managing students' fear and dislike of applications. Affective benefits included piquing students' interest (which in turn supported student engagement and motivation) and increasing their mathematics self-efficacy.

Academic Success Skills

Instructor agency. Several participants described academic success skills in terms of their own agency as instructors in supporting students' development of academic success skills. This theme is notable because it indicates that some participants saw the intended connection between the three definitions: that active engagement with meaningful applications will build students' academic success skills. Participants mentioned that it was part of their duty as instructors to help students develop academic success skills (e.g., Quinn gave an example of developing time-management multiple times in the semester; Reagan described training students to include detail in their solutions). Others described how they used content to support students in developing affective academic success skills. For example, Ellison said,

> we want to be presenting students with problems that are at the right level… an interesting problem to the student but they still feel like they've got what it takes to be able to solve it, then it's going to keep them engaged.

Part of what participants saw as their agency as instructors was the necessity of their developing classroom community. Anna saw this as important because it enabled students to engage and participate productively:

> I can provide them opportunities to fail until they feel safe… [know] that they're not going to be laughed at… it's developing trust.

Characteristics of students. Participants' images of academic success skills included many skills they felt students needed to possess or develop. Participants' images of academic success skills included perseverance, knowing how to learn, knowing how to manage math anxiety, having an identity as a learner, having basic math knowledge, and having behavioral skills. For example, Ellison's response discusses many of these characteristics:

> If you have [academic success skills] it means that you have some knowledge about how to tackle different problems that you're given. You also have some positive motivation happening that's contributing to your desire and ability to be able to complete problems… Has an inherent sense that they can do it. And, and they also need to have the, the content knowledge skills to be able to, to solve a problem as well.

Most participants also mentioned that academic success skills also entailed behavioral skills such as time management, doing homework, taking notes, attending class, and doing homework.

Discussion

Participants' characterizations of the components of inquiry primarily emphasized environmental conditions or pedagogical strategies that would need to be in place for students to be engaged in active learning. Others have noted these sorts of emphases as common in faculty members' conceptions of active learning (e.g., Williams et al., 2022). The MIP participants attended somewhat to mechanisms of learning, seeming to believe that student engagement, repetition, generalizing, and productive struggle were learning mechanisms. These appeared to be rational, stable beliefs that the participants had developed over the course of their teaching careers. That faculty members hold these beliefs is not inherently problematic, but what students are engaged in (or repeating, or struggling with) is consequential for the mathematical meanings they develop. The participants' images of meaningful applications centered primarily around real-life relevance over mathematical meaning. Taking the images of active learning and meaningful applications together, we see a need for perturbing participants' images of these components in ways which go beyond students engaging with problems with relevant contexts. How to perturb participants such that they engage in the reflective abstraction that their current images of the components may be inadequate for supporting the development of mathematical meaning is an area for future research. We note work with provided definitions may perturb participants somewhat, and our evidence for this is Gemma's inclusion of generalizing as a learning mechanism because generalizing was specifically mentioned in the definitions. More broadly, we see participants' mention of engagement, repetition productive struggle as learning mechanisms as evidence of some attention to the idea of what a learning mechanism is, and both offer inroads to discussing how what students engage or struggle with as consequential. Thinking of the three pillars in terms of characteristics, rather than mechanisms, can be problematic because focusing on characteristics makes it harder to design and implement resources to support effective active learning. Without an understanding of why those characteristics may produce the conditions for learning and what concepts may be supported, an instructor cannot make instructional decisions to optimize the potential for students to construct desired concepts and reasoning patterns.

Our results broadly reinforce the literature on instructional change, which emphasizes that instructors' initial conceptions and beliefs about teaching are resistant to change and require continual, ongoing professional development. We propose that the themes we have identified nevertheless paint a clear image of how undergraduate mathematics instructors conceive of active learning, how they attempt to realize it in their classrooms, and what they value about it. These findings therefore provide important information for other researchers and change agents. More specifically, our results build on this prior research by describing the conceptions of undergraduate instructors across several institutions and after professional development has taken place.

How a Graduate Mathematics for Teachers Course
"Helped Me See Things from a Different Perspective"

Kaitlyn Serbin
The University of Texas Rio Grande Valley

Younggon Bae
The University of Texas Rio Grande Valley

Secondary teachers and college instructors are required to take several graduate-level mathematics courses to advance in their careers. However, there is a common disconnect between graduate mathematics courses and the teaching of secondary mathematics. We developed a graduate-level mathematics for teachers course that was designed to help teachers connect abstract algebra, real analysis, and statistics to the content and teaching of secondary/ early college mathematics. In this study, we examined changes in graduate students' confidence and perceptions of the relevance of advanced mathematics to teaching secondary and college mathematics. Students attributed changes in their perceptions of the connections between advanced and secondary mathematics to the course's implementation of pedagogical scenario tasks. We provide implications for the mathematical preparation of teachers.

Keywords: Graduate Courses, Mathematic Knowledge for Teaching, Perceptions of Relevance of Advanced Mathematics, Confidence

Mathematics teachers enroll in graduate-level mathematics courses for professional growth, graduate degrees, teaching certifications, and mobilities in a future career (e.g., academic specialist, college instructor). They are required to complete a significant number of credit hours, e.g., 18-credit hours to teach dual-enrollment courses. However, teachers are disconnected from the studies of advanced mathematics in graduate courses not only because they took their advanced mathematics courses several years ago, but also because the content and pedagogy of such graduate-level mathematics are not connected to their profession in teaching (Zazkis & Leikin, 2010). These graduate mathematics courses have acted as gatekeepers to professionals in teaching careers, inhibiting them from pursuing graduate studies in mathematics or dual-enrollment teaching certificates. The discontinuity between content courses and classroom teaching has been a long-lasting challenge in teacher preparation. Researchers have been addressing this challenge in their innovative approaches to improve curriculum and instruction for undergraduate-level mathematics courses and in their collaborative efforts to connect content and methods courses (e.g., Wasserman & McGuffey, 2021; Weber et. al., 2020). Graduate-level courses, however, have not been highlighted in the literature as much as undergraduate courses.

One way to address those discontinuities in graduate mathematics courses for teachers is to implement innovative course design and instructional practices that employ and empower teachers' mathematical and pedagogical practices in their learning. This will also provide a positive standpoint of *mathematics for teaching* within the discipline of mathematics by tackling the existing deficit view—inferior to and less rigorous or formal than real mathematics—and by embracing an alternative view—advanced mathematics for the teaching of mathematics.

In Spring 2022, we developed a course for students in the Master's program in mathematics with a teaching concentration at a large public university. The course design emphasized fundamental knowledge and skills in advanced mathematics and their applications to the teaching of secondary school mathematics and lower-level college mathematics including college algebra, calculus, and introductory statistics. The courses adopted student-centered activities in class to facilitate the mathematical development of secondary teachers and their reflection on the pedagogical implications for their teaching practices. In this paper, we present how the participating preservice and in-service teachers in this course perceived (a) changes in their views on connections between advanced mathematics and secondary/college mathematics, (b) changes in their confidence in advanced mathematics and teaching secondary/college mathematics, and (c) effects of the course design on those changes in their views and confidence.

Literature Review and Theoretical Background

Knowledge of advanced mathematics is perceived as an essential component of teachers' content knowledge (e.g., Conference Board of the Mathematical Sciences, 2012), especially when it connects to teachers' understanding of school mathematics. Constructs related to teachers' knowledge of advanced mathematics and its connections to school mathematics can ubiquitously be found in frameworks of mathematical knowledge for teaching (e.g., Ball et al., 2008; Ball & Bass, 2009; McCrory et al., 2012; Wasserman, 2018; Zazkis & Mamolo, 2011). Developing knowledge of advanced mathematics can lead teachers to understand relations among mathematical content and structures, hone mathematical practices, and hold core mathematical values, which have been shown to support teachers in various teaching practices (e.g., Baldinger, 2018; Serbin, 2021; Zazkis & Kontorovich, 2016; Zazkis & Marmur, 2018; Zbiek & Heid, 2018). Taking undergraduate and graduate-level mathematics courses thus has the potential for fostering the development of prospective and in-service teachers' mathematical knowledge, practices, and values. However, these potential outcomes might not come to fruition if the prospective or in-service teachers are not explicitly given opportunities to make connections among the content and practices used in both advanced and secondary mathematics.

To address the commonly documented disconnect between teachers' studies of advanced mathematics and teachers' teaching practices, teacher educators have implemented mathematics for teachers courses with innovative course designs and instructional practices that leverage teachers' mathematical and pedagogical practices in their learning (Goar & Lai, 2021; Wasserman et al., 2019). Researchers have argued for alternative curricula and instruction to explicitly address the mathematical pedagogical knowledge and practices for teachers. The design of innovative mathematics for teachers courses should include an emphasis on content connections and pedagogical mathematical practice connections. Teachers must be given opportunities to make connections among advanced and secondary mathematical content that help them better understand the content they teach. This is the premise of Wasserman's (2018) theory of Knowledge of Nonlocal Mathematics for Teaching. Wasserman (2018) claimed, "knowledge of nonlocal [advanced] mathematics becomes potentially productive for teaching at the moment that such knowledge alters teachers' perceptions of or ontological understandings about the local content they teach" (p. 121). Thus, advanced mathematics courses for teachers should be designed to guide teachers to make connections that change their understanding of the content they teach and thus have the potential to be useful in their teaching. These courses should also be designed to provide opportunities for teachers to develop *Pedagogical Mathematical Practices* (PMPs), which Wasserman and McGuffey (2021) defined by drawing on the extant literature on mathematical practices (e.g., Rasmussen et. al., 2005) and pedagogical practices (NCTM, 2014). PMPs lie in an intersection of two domains of mathematical practices and pedagogical practices and are the kinds of practices that are common across both mathematicians and mathematics teachers in terms of their actions, habits, and lines of reasoning. Examples of PMPs include attending to assumptions and mathematical constraints or limitations, using special cases to test and illustrate mathematical ideas, exposing logic as underpinning mathematical interpretation, using simpler objects to study more complex objects, and not giving rules without accompanying mathematical explanation. The conceptual framework informing the design of the course under investigation in the current study draws on Wasserman's (2018) theory of Knowledge of Nonlocal Mathematics for Teaching and Wasserman and McGuffey's (2021) framework of PMPs. These theories provide the rationale for the graduate-level Mathematics for Teachers course design, which is described further below.

Course Design

This graduate-level Mathematics for Teachers course aimed to provide mathematics teachers and college instructors with an opportunity to study key topics in advanced mathematics and to apply the topics to their mathematical knowledge and practice for teaching secondary school mathematics and lower-level college mathematics, such as college algebra, pre-calculus, calculus, and introductory statistics. This course consisted of three modules based on subject areas in mathematics at the graduate level: Abstract Algebra, Analysis, and Probability/ Statistics. Each module included a survey of definitions and basic properties of fundamental mathematical concepts in the corresponding area. The classroom instruction emphasized the role of in-class activities and projects to build students' conceptual understanding and develop their advanced mathematical reasoning and practices.

The Abstract Algebra module was designed using Wasserman's (2018) theory of Knowledge of Nonlocal Mathematics for Teaching, along with the design heuristics of guided reinvention from Realistic Mathematics Education (Gravemeijer, 1998) and pedagogical mathematical practices (Wasserman & McGuffey, 2021). The module was designed to guide students to develop an intuitive understanding of the structure of groups, rings, integral domains, fields, unique factorization domains, and isomorphisms. It implemented Larsen's (2013) task sequence for the reinvention of groups and group isomorphism, as well as an adaptation of Cook's (2012; 2015) task sequence for reinventing rings. The curriculum then guided students to connect their understanding of the Abstract Algebra content to content covered in secondary and early college mathematics. The course curriculum led students to apply their understanding of the connections between the advanced and secondary content through the implementation of pedagogical scenario tasks. These tasks typically gave samples of hypothetical student work and asked the graduate students to interpret the hypothetical student's understanding and decide how to respond if they were that student's teacher. The pedagogical scenario tasks also were presented in the form of Lesson Play scripting tasks (Zazkis et al., 2013), in which the graduate students were given a script of classroom dialogue between a teacher and students and were prompted to finish a script of the conversation. These tasks were designed to elicit evidence of students' use of mathematical knowledge and PMPs (Wasserman & McGuffey, 2021).

The Analysis module of this course adopted an instructional model, ULTRA, for teaching in real analysis courses (Wasserman et al., 2017) that emphasizes explicit connections between secondary and advanced mathematics by introducing pedagogical situations in secondary classrooms, stepping up to studies on relevant topics in real analysis, and stepping down to the same situation. This module used selected chapters of *Understanding Analysis and its Connections to Secondary Mathematics Teaching* (Wasserman et al., 2022) written for implementing the ULTRA model. Students participated in group discussions on classroom scenarios given in the textbook and collectively worked on mathematical tasks to review relevant real analysis concepts including epsilon arguments, limits, continuity, and differentiability.

Methods

In this study, we conducted a pre-survey, post-surveys, and semi-structured interviews designed to examine changes in their confidence in high school and advanced mathematics and their perceived content connections and relevance of advanced mathematics for teaching secondary or early college mathematics. Six graduate students enrolled in the course participated in this study and completed a pre-survey at the beginning of the semester and two post-surveys, one in the middle of the semester about the Abstract Algebra and Analysis modules, and the other after the semester about the Probability & Statistics module and the overall course experience. The surveys include 7-point Likert scale items about their confidence and views on connections between secondary and advanced level mathematics. We compared the average scores of students' responses to each of the items to determine changes in their confidence and perceptions about advanced mathematics for teaching. The participants also participated in the interview about their course experiences and changes in their confidence and perceptions after completing the second post-survey. The interviews were audio recorded in Zoom and transcribed for analysis. We used an open coding process (Miles et al., 2013) to examine the participants' perceived changes in their confidence and perceptions of connections between learning advanced mathematics and teaching secondary and early college mathematics. One author independently generated codes in the first round, and the other author confirmed the codes. Then both authors discussed codes, created axial codes, and identified themes explaining how the course experiences affected the ways in which students' confidence and perceptions changed.

Results

Table 1. Mean scores on pre-survey and post-survey items.

Survey Item	Pre-survey Mean Score (N=5)	Post-survey Mean Score (N=6)
1. I am confident with explaining concepts in high school mathematics.	5.80	6.00
2. I am confident with explaining concepts in undergraduate level mathematics.	4.40	5.67
3. I am confident with explaining concepts in graduate level mathematics.	2.20	4.50
4. Understanding advanced mathematics will help me better understand secondary-school level mathematics.	6.60	6.83
5. Understanding advanced mathematics will help me better perform secondary-school level mathematics teaching.	6.60	6.67

Changes in Confidence with Explaining Mathematical Concepts at Different Levels

The comparison between students' responses to the pre and post-surveys indicated that their confidence in explaining mathematical concepts at the high school, undergraduate, and graduate levels increased overall after taking this course. The average scores on the survey items related to their confidence increased from 5.80 to 6.00 at the high school level, 4.40 to 5.67 at the undergraduate level, and 2.20 to 4.50 at the graduate level (See Table 1). Their confidence increased more at the higher levels. The students reported lower confidence in more advanced levels in the beginning but made greater increases at the end (e.g., +0.20 at the graduate level, +1.27 at the undergraduate level, +2.30 at the high school level). Their interview responses indicated that their course experience helped increase their confidence in advanced mathematics and prepared them to take further advanced mathematics courses in their graduate program. Student E said, "I definitely feel more competent in doing certain types of mathematics". Student L said, "I think this class will be perfect for that, for future courses, and I do feel more prepared to go into those [further graduate] classes." However, a student reported that their confidence in advanced mathematics had not changed a lot because the course emphasized less on writing mathematical proofs and a deep investigation of advanced topics in this course than what they had expected from a traditional graduate-level mathematics course. Student R said the course helped increase his confidence not as much as he expected because of less emphasis on proof. He said, "I want to say [my confidence increased] a little bit, not that much since it wasn't really a class where I was taught how to do proofs again because I forgot it, it's been a while. And then I was just expected to do the proofs, not like that. So just a little bit, but not as much as I wanted to." Overall, this course helped students increase their confidence in all levels of mathematics, especially for higher levels in all three subjects in analysis, algebra, and probability & Statistics.

Changes in Perceived Content Connections and Relevance of Advanced Mathematics for Teaching Secondary or Early College Mathematics

This graduate-level Mathematics for Teachers course helped graduate students recognize content connections among advanced and secondary mathematics, and it helped change their perceptions regarding the relevance of advanced mathematics for the teaching of secondary mathematics. *Some students reported that they did not have an opportunity to reflect on connections in other graduate mathematics courses.* For example, Student S explained, "I don't think I've thought before about how they related… now I think it would be very helpful in teaching secondary math." This course gave students an opportunity to connect advanced and secondary mathematics, which they said they did not have in other graduate math courses.

Some students reported that after taking this course, they could *better understand advanced mathematical content and secondary mathematical content.* In the survey data, we identified a slight increase in the mean score of the survey item 4 (see Table 1) from 6.60 to 6.83 (on a 7-point scale). The students' responses to open-ended survey items and their interviews gave further insight into how they perceived a change in their understanding of mathematics. For example, one student wrote on a post-survey, "I had always had a bit of trouble understanding groups, rings, and fields, but seeing the connection of this topic with high school content and relating it to higher level thinking made me understand it more." Thus, they acknowledged that relating the advanced mathematics with secondary mathematics during the course helped them better understand the advanced mathematical content. Several students reported a change in their understanding of secondary or early college mathematics. For example, Student L explained,

> "Before, I used to see advanced mathematics as something different from high school…advanced mathematics is really connected rather than just a continuation of one and another. So really seeing the theory behind it helps, like I think I can teach this in a better way, and explain to the students a better way, rather than just saying 'that's just the way it is,' and giving them a little bit of theory behind it."

Student L previously perceived advanced and secondary mathematics as disparate. After the course, she perceived more connections among the content. She explained how understanding the theory from advanced mathematics helped her better understand the content and explain the content to students. Student A similarly acknowledged how studying advanced mathematics helped her make sense of often rote secondary mathematics procedures. She explained,

> "You can do, for example, exponents or logarithms very rotely just by following the procedure, but it doesn't make sense, I think, until you've studied it from a more advanced math point of view, and you can see why it's being done that way."

This illustrates how after taking this course, the students reported perceiving more connections among previously disparate content and better understanding both advanced and secondary math.

The students also acknowledged *a change in their perceptions of the relevance of advanced mathematics for teaching secondary mathematics*. In the survey data, we identified a slight increase in the mean score of the survey item 5 (see table 1) from 6.60 to 6.67 (on a 7-point scale). The students' responses to interview questions provided additional insight into how they perceived advanced mathematics as relevant to and helpful for their teaching. For example, Student E claimed, "It helped me see things from a different perspective. I didn't really ever think that some of the things that we did in the module were relevant to high school teaching or students' thinking at those levels." Students expressed a *wide variety of ways in which they thought advanced mathematics was relevant to and useful for their teaching*. Some of these included using their knowledge of advanced mathematics in their teaching practices of facilitating class discourse, providing visualizations of concepts, attending to precision in the mathematical terms used in definitions, and making sense of students' mathematical thinking. Furthermore, several students acknowledged that advanced mathematics would be helpful in their teaching practices of designing lessons, making content understandable to students, and giving explanations in response to questions. Particularly, Student R explained:

> "There are some kind of students, I call them to be scary… who ask you why…I never really asked myself why. So after having a student like that and taking this class where I see where things come, I can talk like, 'this is a group, this is what is happening.' Yes, this theory helped me out in the way I'm going to be now introducing lectures."

Student R recalled experiences in which he did not know how to respond to students who ask "why." He explained that understanding the theory from advanced mathematics (abstract algebra in this context) helped him understand and explain why certain procedures work in equation solving. Student R illustrated a change in his perception of how advanced mathematics could be useful for him in his teaching practices of responding to students and explaining content.

The *students attributed these changes in their perceptions of the relevance of advanced mathematics for teaching to both the mathematical content covered in the course and the pedagogical scenario tasks used in the course*. First, when asked if anything from the course might have affected a change in their views on the relevance of advanced mathematics for teaching, some acknowledged the mathematical content in the course. Furthermore, several students attributed this change to the course's use of pedagogical scenarios. Student A explained:

> "The scenarios were helpful in that regard, like where we actually were asked to think about that very question of, in a classroom… how to explain something to a student who had some kind of misconception. So how to explain it in a way that would make sense to them… I think that that's what helped, was to actually confront that in a scenario."

These students reported that the pedagogical tasks helped them relate secondary and early college mathematics to advanced mathematics, understand students' mathematical thinking, and learn "how to handle those classroom discussions" (Student L). Student S explained how these tasks helped her become aware of different ways that students can think about mathematics:

> "The scenarios…opened up the panorama about how our students could think outside the box. A lot of kids would think differently about just one topic…. Seeing how that relates to so much more than just basic math…helped me change my point of view."

Overall, these students self-reported changes in their perceptions about the connections between advanced and secondary mathematics and its utility in their teaching of secondary or early college mathematics. The students attributed these changes in perceptions to the mathematical content covered in the course and the pedagogical scenarios used in the course.

Discussion and Conclusion

In this study, we examined how a graduate-level Mathematics for Teachers course supported improving students' confidence in secondary and advanced level mathematics and their perceptions of content connections and relevance of advanced mathematics for teaching secondary and early college mathematics. This course helped students increase their confidence in explaining mathematical concepts at high school, college, and graduate levels, and it was more helpful at the higher levels. More importantly, this course helped them recognize content connections between advanced and secondary mathematics which they had not experienced in the past. Students reported the pedagogical tasks using classroom scenarios helped them to connect the content in advanced mathematics to the teaching of secondary and college mathematics. Students perceived the relevance of learning advanced mathematics for the teaching of secondary mathematics in ways that are meaningful for them, e.g., understanding problematized secondary mathematics content in the given situations from advanced standpoints, and using advanced knowledge of mathematics for reflecting on their teaching practices.

Our course design leveraged Wasserman's (2018) theory of Knowledge of Nonlocal Mathematics for Teaching, which broadly suggests that for a teacher's knowledge of advanced mathematics to impact their teaching, the advanced mathematics must first change the teacher's ontological understanding of the content they teach. This theory informed our course design heuristics of both (a) guiding students to connect advanced and secondary mathematics to better understand the secondary content they might teach and (b) incorporating pedagogical scenario tasks to connect the advanced mathematics to the *teaching* of secondary mathematics via pedagogical mathematical practices (Wasserman & McGuffey, 2021). Several of the graduate students enrolled in the course attributed the changes in their perceptions of the relevance of advanced mathematics to their teaching to the course's implementation of these pedagogical scenario tasks. Thus, these tasks helped the students recognize how their knowledge of advanced mathematics could be useful in their teaching of secondary or early college mathematics.

The utility of these pedagogical scenario tasks presents fruitful avenues for future research and implications for the preparation of mathematics teachers. We plan to continue our course design efforts by designing curricula that can support prospective and in-service teachers in connecting advanced mathematics to the teaching of secondary mathematics through these pedagogical scenario tasks. We will also further investigate how graduate students use their knowledge of advanced mathematics and their pedagogical mathematical practices (Wasserman & McGuffey, 2021) as they perform these pedagogical scenario tasks. We suggest that both undergraduate and graduate mathematics courses for prospective or in-service teachers should be designed to implement pedagogical scenario tasks, because they provide opportunities for students to identify points of connection between advanced and secondary mathematics.

Prioritizing Mathematical Topics for General Education Requirements

Jim Gleason
The University of Alabama

W. Gary Martin
Auburn University

Mariya Rosenhammer
Columbus State University

With increased availability of technology and data, the mathematical and statistical needs for many academic disciplines have likely changed over the past twenty years. In order to create appropriate general education courses in the mathematical sciences to meet these needs, a survey was conducted of individuals representing various academic programs in Alabama to determine the mathematical needs of students in their programs. The survey results indicate that traditional college algebra courses are not needed outside of the disciplines that require calculus. The needs of the non-calculus-based programs include linear and exponential functions; mathematical practices; statistical literacy; and the use of spreadsheets for data analysis.

Keywords: general education, data analysis, mathematical practices

Nearly all colleges and universities in the United States include at least one course in the mathematical sciences as part of the general education requirements for their bachelor's degree. Nearly half of the students enrolled in a post-secondary mathematics course in the United States are in courses focusing on polynomial, rational, exponential, logarithmic, and/or trigonometric functions (Blair et al., 2018, p. 213). While such topics are essential for students needing to understand calculus for their academic program, they may not be the best choices of topics for courses in the mathematical sciences for students who do not need an understanding of calculus.

A common alternative to the traditional algebra and function based undergraduate course is a course focusing on quantitative literacy. Beginning in the 1980's, the Consortium for Mathematics and Its Applications (COMAP) created curriculum for such courses (Campbell, 2007) and in the 1990's, the Committee on the Undergraduate Program in Mathematics of the Mathematical Association of America (MAA) created a sub-committee to explore how quantitative literacy could be included as part of undergraduate general studies programs (Sons, 1995).

To improve all lower-division mathematics courses the MAA Committee on Curriculum Renewal Across the First Two Years (CRAFTY) started the Curriculum Foundations Project to better understand the mathematics needed by students in partner disciplines. This involved a series of workshops with faculty members from mathematics-intensive disciplines (1999-2001) and less mathematics-intensive disciplines (2005-2007) (Ganter & Haver, 2020) resulting in two documents (Ganter & Barker, 2004; Ganter & Haver, 2011) describing the mathematical needs of students in partner disciplines. This interdisciplinary work continues with projects like the Synergistic Undergraduate Mathematics via Multi-institutional Interdisciplinary Teaching Partnerships (SUMMIT-P) consortium (Ellington, 2020; Ganter et al., 2019a, 2019b).

In order to more holistically determine the mathematical needs of students from various non-STEM disciplines, the Arkansas Department of Higher Education partnered with the Dana Center to form the Arkansas Math Pathways Task Force (AMPT) to create a survey for departments to provide feedback about which topics in the mathematical sciences would be beneficial for their students (Korth et al., 2018) in order to provide guidance on what general education mathematics courses would be most useful for students in different majors. In considering these results, a similar working group in Alabama felt less confident that the current mathematics courses included in the general education program were appropriate. Thus, the current study expands upon the work of AMPT by creating a survey of academic programs at public post-secondary institutions in Alabama at a finer grain size and for a larger number of mathematical and statistical topics and practices than the AMPT survey in order to guide the redesign of mathematics courses included in the general education requirements for different majors.

Methods

A working group of faculty members from the mathematical sciences and institutional assessment from multiple higher education institutions commissioned by the Alabama Commission on Higher Education created a survey of mathematical and statistical topics and practices based upon syllabi from introductory post-secondary mathematics and statistics courses, standard secondary mathematics curriculum (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), and post-secondary professional organization standards (American Association of Two-Year Colleges, 1995, 2006; GAISE College Report ASA Revision Committee, 2016; Mathematical Association of America, 2004, 2015). After the creation of the survey items, they were reviewed for content accuracy by 10 mathematics faculty and readability by four non-mathematics faculty that work in assessment divisions of their institutions.

Based on information provided by the chief academic officers from each of the public higher education institutions in the state, the survey was sent to individuals who oversee each academic program in the state. Calculus courses satisfy the general education courses for a range of academic programs, including Mathematics, Engineering, Physics, Chemistry, and Computer Science; these programs were not included in the study as they were outside its scope. Of the 548 eligible programs, 174 submitted complete responses for a 32% response rate.

Due to the sample size from our survey responses we are not able to draw conclusions at the level of a single major. However, by combining majors into meta-majors based upon assumed mathematical needs, we can attain more generalizable conclusions. Academic programs that include a significant focus on using large data sets and/or computer programming as a key component of their field are likely to have a significant need for mathematical and statistical knowledge outside of calculus. For this reason, we group together majors such as geographic information systems, computer forensics, econometrics, and computer and information sciences into a meta-major that we will call **Data Sciences**. We group academic programs such as biology, geography, environmental science, and nursing together into a meta-major that we will call **Natural Sciences**, although this grouping does not include physics or chemistry since they require calculus. Majors related to education, psychology, human development, political science, and social work all incorporate the use of data and interpretation of statistical studies in their fields, so we incorporate these disciplines into a meta-major that we will call **Social Sciences**. Academic programs with a focus on business and/or management are grouped into a **Business** meta-major. Although such programs often include "business calculus" for the general education requirement, calculus is not inherent to the work of those fields and so we included this in this study. Finally, the **Humanities** meta-major includes majors that focus on studying and/or contributing to human cultures, including languages, arts, communication, philosophy, religion, and anthropology. Number of academic programs and response rates in each of these meta-majors is included in Table 1.

Table 1. Response rates by meta-major.

Meta-major	Eligible Programs	Responses	Response Rate
Data Sciences	34	13	38%
Natural Sciences	115	38	33%
Social Sciences	164	48	29%
Business	106	29	27%
Humanities	129	46	36%
Totals	548	174	32%

Mathematical topics were arranged into five major categories commonly included in general education mathematics courses, while statistical topics were organized into eight general categories. In order to facilitate the completion of the survey while still getting the desired level of detail, the survey included items addressing broader topics of mathematics within each of these categories, for which respondents denoted that their students "definitely needed", "somewhat needed", or "not needed". The "definitely needed" and "somewhat needed" responses were compressed into a "needed" category and these respondents were asked one or two follow-up questions to determine the need of students at a finer grain analysis. For example, respondents were asked "What best describes the importance of the following statement about students in your degree (or program)?" with the statement regarding functions being, "Students will understand properties of functions (domain, range, compositions, inverses) and use algebraic, symbolic, graphical, and numerical techniques to model related contexts and solve related equations." The respondents who denoted this statement as needed for their students received follow-up questions about the types of functions needed and the properties of those functions that their students would need to understand.

For each of the items in the survey, the need for that topic or practice for each meta-major was determined by the proportion of programs denoting a need for the topic. If the proportion was above half to a statistically significant level ($p<0.05$), we considered that topic as needed for the meta-major. If the proportion was below 50% at a statistically significant level ($p<0.05$), we considered the topic as not needed for the meta-major. If there was no significant difference from 50%, we did not draw a conclusion about that topic for that meta-major.

Results

The primary result of the study is that most of the meta-majors did not need most of the mathematical content traditionally included in introductory college mathematics courses. However, all the meta-majors, other than Humanities, reported a need for all the general statistical topics and practices from introductory college statistics courses, although not all the subtopics.

Mathematical Topics and Practices

Of the students enrolled in introductory mathematics courses in the fall of 2015, 20% were enrolled in precollege level (courses not receiving college credit), 40% were enrolled in a course focusing on functions and equations that involve polynomial, exponential, logarithmic, and/or trigonometric functions, and 20% were enrolled in liberal arts or finite math courses focusing on some logic, set theory, financial mathematics, and probability (Blaire et al., 2018, p. 213). The respondents to our survey reported that these topics are not the ones that are most needed for students in their majors (Table 2). None of the meta-majors denoted a need for polynomial and trigonometric functions, core components of the most common introductory courses, and instead denoted a need for linear functions, a topic usually included in the precollege level course. Furthermore, the topics related to functions denoted as needed by the largest number of programs was the ability of students to find numerical approximations of solutions using technology, a topic often not a major focus of college courses.

Table 2. Mathematical needs by meta-major.

Mathematical Topics	Data Sciences	Natural Sciences	Social Sciences	Business	Humanities
Function	Linear and Exponential	Linear and Exponential	Linear		Not Needed
Equations and Inequalities	Linear	Linear			Not Needed
Geometry and Trigonometry			Not Needed	Not Needed	Not Needed
Logic and Set Theory		Not Needed	Not Needed	Not Needed	Not Needed
Financial Mathematics		Not Needed	Not Needed		Not Needed

The respondents did denote that their students need experience with the mathematical practices that come from general education mathematics courses:

1. Interpreting quantitative information (needed by all but Humanities),
2. Strategically evaluating, inferring and reasoning (needed by all),
3. Manipulating mathematical expressions and computing quantities (needed by Data Science; not needed by Social Sciences or Humanities),
4. Communicating mathematical ideas in various forms (needed by Business, not needed by Humanities),
5. Make sense of quantitative problems and persevere in solving them (needed by Data Science and Business; not needed by Humanities),
6. Apply the mathematics they know to solve problems arising in everyday life, society, and the workplace (needed by all), and
7. Look for patterns and relationships and make generalizations (needed by all).

Combining the information of topics and practices, the survey communicates a need for introductory mathematics in the general education curriculum with a course focusing on the mathematical practices within the context of linear and exponential functions and equations. Such content could easily be incorporated into a data analysis course that includes linear and exponential regression.

Statistical Topics and Practices

Using the goals for introductory statistics courses established by the American Statistical Association (GAISE College Report ASA Revision Committee, 2016), the survey asked the respondents about the following statistical topics and practices:

1. Students should become critical consumers of statistically-based results reported (needed by all),
2. Students should be able to recognize statistical questions and design appropriate statistical studies (needed by all but Humanities),
3. Students should be able to produce and interpret data visualizations, numerical summaries, and statistical models (needed by all but Humanities),
4. Students should recognize and be able to explain the central role of variability and randomness in the field of statistics (needed by all but Humanities),
5. Students should demonstrate an understanding of, and ability to use, basic ideas of statistical inference, both hypothesis tests and interval estimation, in a variety of settings (needed by all but Humanities),
6. Students should be able to interpret and draw conclusions from standard output from mathematical and statistical software packages (needed by all but Humanities, not needed by Humanities),
7. Students should demonstrate an awareness of ethical issues associated with sound statistical practice (needed by all), and
8. Students can use tools and techniques involving the theory of probability to understand the nature of chance and to quantify variation (needed by all but Humanities, not needed by Humanities).

We note that outside of the Humanities meta-major, all these topics and practices were denoted as necessary for students as part of their academic program. For the Natural Sciences, Social Sciences, and Business meta-majors, the only topics denoted as not needed by there students are creating and computing statistical representations by hand; using any technology other than spreadsheets, SPSS, or R; and details of the theory of probability involving probability distribution functions and the Central Limit Theorem. All the other sub-topics were either denoted as needed or it was inconclusive about the need.

Conclusions and Implications

The primary conclusion from the survey results is that there is a much greater need among undergraduate students for courses in statistics and data analysis than the traditional courses of college algebra and precalculus. The results also corroborate the goals for students in introductory statistics courses of the ASA GAISE Report (GAISE College Report ASA Revision Committee, 2016, p. 8), and its recommendations of what to teach in such a course: “Teach statistical thinking” and “Focus on conceptual understanding” (p. 6).

One implication is for colleges and universities to consider the role of the mathematical sciences in the general studies curriculum at their institution. Mathematical ways of thinking have always been a core component of a liberal arts education, and the current study confirms that academic disciplines across the spectrum still value students having those ways of thinking. What they do not seem to value is the current menu of topics that have been standard for introductory mathematics courses. This should cause departments in the mathematical sciences to reflect on the goals of their current course offerings and to perhaps create new courses for this broad constituency of students. As a result of the survey, the Alabama Commission on Higher Education that initiated the study changed the corresponding category from a Mathematics requirement to a Mathematical Sciences requirement and changed from not allowing statistics courses to satisfy the requirement to encouraging such courses to be used to satisfy the new requirement.

Many of the academic programs surveyed in this study have program requirements that include mathematics courses based on topics that they denoted as not needed by their students, either explicitly or implicitly as a prerequisite. The results of this study should motivate such departments to collaborate with the mathematical sciences departments to determine the most appropriate courses for their students: if such courses do not exist, they should work together to develop new courses.

Acknowledgments

We would like to thank the members of the Alabama Commission on Higher Education working group on options for gateway mathematics for their feedback and assistance throughout this project.

Student Quantitative Understanding of Single Variable Calculus

Jason Samuels
City University of New York

Student understanding of key concepts from Single Variable Calculus and the role of infinitesimals was investigated. Analysis was done using a framework which highlights quantitative reasoning. Data showed robust understanding of instantaneous rate and change across multiple representations. I examined the rich student connections between those concepts expressed discretely in Algebra and expressed instantaneously in Calculus, and how conceptions of infinitesimal quantities were formed in order to support those connections. Implications for instruction are considered.

Keywords: Calculus, quantitative reasoning, infinitesimals, derivative

Introduction & Literature Review

First semester Calculus is a critical course for all STEM majors, a required course containing foundational ideas for future study. Student success has been below desired levels for a long time, and efforts toward improving student success are extensive and ongoing (Bressoud, Mesa & Rasmussen, 2015). There has been much investigation into student understanding of Single Variable Calculus (SVC), exploring conceptions of limit (Oehrtman, 2009; Tall, 1992), derivative (Zandieh, 2000; Park, 2013), integral (Jones, 2015; Sealey, 2014), and the Fundamental Theorem of Calculus (Carlson, Smith & Persson, 2003; Radmehr & Drake, 2017). Some work has been done to connect those conceptions to a student's related prior conceptions (Thompson, 1994; Pustejovsky, 1999; Samuels, 2011). However, none of these studies investigated these questions for students learning Calculus using infinitesimals.

Recently there has been a growing call to revise Calculus instruction away from the Analysis-based approach using limits and toward a more quantitative approach (Augusto-Milner, Jimenez-Rodriguez, 2021). There have been a handful of documented attempts to do so with infinitesimals (Ely, 2021). Some research has theorized the underlying student thinking in such an approach (Ely & Ellis, 2018). None of these studies of infinitesimal-based Calculus instruction has examined how students conceive of important Calculus ideas. These intersecting gaps in the literature suggest the following research questions. (1) What is a characterization of student understanding of key Calculus concepts after one semester of Calculus taught with infinitesimals? (2) How are understandings of Algebra concepts in discrete form used to generate understandings of related Calculus concepts in instantaneous form?

Framework

To analyze student understanding of Calculus, an approach oriented towards quantitative reasoning (Thompson & Carlson, 2017) was used. This mode of reasoning entails "conceptualizing a situation in terms of quantities and relationships among quantities" (Thompson & Carlson, 2017, p425), where a quantity is a measurable attribute combined with a way to measure that attribute. The quantities of SVC and the relationships between them can be described using the ACRA Framework (Samuels, 2022). The framework is summarized here briefly with a delineation of the quantities and some of their relationships. An *amount* is a real value, a *change* is a difference between two amounts, a *rate* is a ratio of two changes, and an *accumulation* is a sum of consecutive changes. One important relationship is that the product of two rates is another rate. (The infinitesimal version is the chain rule, see Table 1.) Changes and rates over real intervals are encountered in a typical Algebra course; henceforth this scenario is referred to as *standard* (Keisler, 1976). Changes and rates over arbitrarily small intervals first arise in SVC. A positive infinitesimal is a positive number which is smaller than all positive real numbers; the usual rules of arithmetic apply. Instead of using limits, one can interpret differentials as infinitesimals to describe the arbitrarily small quantities in Calculus. (For further details, see (Samuels, 2022).) This study was targeted specifically at student conceptions after taking Calculus I. Because

Table 1. Part of the ACRA Framework for Quantities in Calculus

	Real	**Infinitesimal**
Change	$\Delta y = y_2 - y_1 = f(x_2) - f(x_1)$	$dx,\ dy$
Rate	$m = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$	$\frac{dy}{dx}$
Rate Equation	$\frac{\Delta y}{\Delta x} = \frac{\Delta y}{\Delta u} \cdot \frac{\Delta u}{\Delta x}$	$\frac{dy}{dx} = \frac{dy}{du} \cdot \frac{du}{dx}$

amount has no separate Calculus version, and because accumulation/integration is covered only briefly in the course, those topics were not explored in this study. Thus the part of the framework used, and the key Calculus concepts on which data was collected, included change and rate, and their relationships.

Methodology

In 2022 Spring the author taught a Calculus I course at a northeastern urban college designed to use infinitesimals instead of limits. Two months after the end of the course, a clinical semi-structured interview (Hunting, 1997) was conducted with one of the students, who had volunteered. A script was prepared beforehand with questions on rate and change, and the relationship between them, in both precalculus and calculus contexts, and in multiple representations (verbal, numerical, graphical, symbolic). Flexibility was allowed for follow-up questions which might be suggested in-the-moment by student responses. The interview was video recorded, transcribed, and coded using the framework.

Results

Ari [a pseudonym] was first asked to “talk about rate in a way that does not involve calculus”. He explained that rate is “rise over run… [it] could be expressed as ratio” and that a linear graph has a constant rate. Using numbers in an example he created, “the rate, the amount of inches after every 30 seconds is 0.5, it goes up by 0.5”. He then illustrated this with the graph in Figure 1, explaining that “it shows the change for x, which is 30 seconds, and the change in y, which is 0.5”.

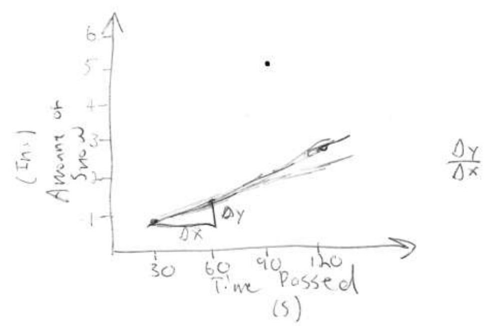

Figure 1. Ari’s inscriptions describing rate for a linear graph

In another example, Ari correctly explained how to calculate rate from two points. He used the standard formula, referring to it both as “delta y over delta x” and as “rise over run”, and referred to the result as both “rate” and “slope”. When asked for contextual examples of rates, Ari gave two: inches per second for snow falling, and miles per hour for a runner. Thus, Ari demonstrated a flexible knowledge of standard change and rate, including how to calculate them and to connect them, in multiple notations and representations.

Next, Ari was asked “can you give me an example where you would need Calculus if you want to talk about a rate?” From the example $y=x^2$, Ari observed that “the rate is always changing...it's not a constant rate. You would have to zoom in infinitely at a certain point on the graph to get, like, a slope. And then it gets straighter... that would represent the instantaneous rate.”

The interviewer gave Ari the graph of $y=x^2$ on Desmos with a touch screen, so the graph could be manipulated with fingers. He used a reverse pinch to zoom in at a particular point. He then observed that "when you get really far, it looks like the rise is like – you see how the line is much straighter, so it literally looks like a line – you would get like, the rate on y equals four." Subsequently he explained that this could also be depicted on the original (non-zoomed) graph as the tangent line at the point (2,4) with a slope of 4.

During a discussion of the slope of the magnified section of the graph, Ari wrestled with the magnitudes of the changes. He initially said that delta y was 4 and delta x was 1. After considering the graph at several levels of zoom, he corrected himself and identified the measuring unit of the grid lines of the graph (automatically drawn by the software) as the side of one square. He noted that the length, "when you zoom in, it always changes… it gets smaller". In the following excerpt, Ari starts by saying that infinitely small values do not exist, and by the end, says they do exist and exhibits a multifaceted conception of them. (His inscriptions during this exchange appear in Figure 2.)

Interviewer: We're going to imagine that we did what you said, which is imagine that we zoomed in infinitely far. We're not going to compare it to anything.

Ari: Okay, so if you zoom in it infinitely far, then it's going to keep getting smaller. Okay, so it's like to zero.

I: So once you zoom in infinitely and you say, I've done it, I've zoomed in infinitely, let's imagine that we accomplished that, then what would be the size of that?

Ari: You can't conceive of it. Yeah. Because it's infinite. It's not defined by any value.

…

I: Is there a positive number which is smaller than all positive real numbers?

Ari: No. Well, I mean, zero point 0 0 0 infinite zeros 1…

I: ... So if the length of this [horizontal] bit was point infinite zeroes 1, then what would be the length of this bit, the vertical bit?

Ari: It would be four times that, but it would be infinite still, the zeros would be infinite still, but it's like that same amount times 4. Which creates a change. Which causes a change because it's like 4…

I: Do we have any kind of name for these things? So, like, this horizontal bit of infinite zeros one, or this horizontal bit, which is also infinite zeros, but four times bigger.

Ari: So this [horizontal] bit would be like *dx*… and then the vertical bit is *dy*…

I: And then if you wanted to talk about the rate, how could you write that out? The rate for this specific example.

Ari: So *dy* is like the amount that it goes up an instantaneous rate. So at that point, when you do that a bit, that's how much it's changing at that point in the graph. So that's what *dy* represents. And then *dx* represents, *dx* represents when it changes by one to the right when you zoom out of the original function. So it's like you're relating the linear rate, like, how it would look linearly. This is like just one line, and that was like the rate then. Yeah, that's how it is. Right. But then at a different point, it would be different.

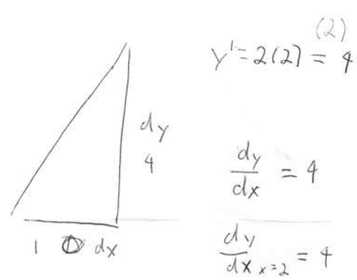

Figure 2. Ari's inscriptions when explaining that the instantaneous rate at a point is 4

In the next excerpt, Ari compared "very small" and "infinitely small" quantities from finite and infinite zooming, and their roles.

Interviewer: You started this by saying you have to zoom in infinitely in order to talk about the [instantaneous] rate. So if you were to zoom in a lot, so you get just keep on going until you get two point 100 zeros and then one, because you zoomed in a lot but not infinitely, is that enough to talk about rate?

Ari: Well, not if it's not infinite.

I: Okay. Why is that not good enough? If I zoom in a lot, why is that not good?

Ari: Because it is an exponential function and at every different point, the rate is always changing because 1.5 to the second power is, say like, okay, two squared is like four, and then three squared is nine, and then four squared is 16. So the difference between those is different. It would be the same the smaller the numbers are. So that's why you can't do that. So that's why it has to be infinite, because then you'll be able to figure out the instantaneous rate.

Ari also described a differential as an instantaneous change, and a derivative as a ratio of two instantaneous changes.

Interviewer: On this graph [in Figure 3], can you indicate for me, can you indicate *dy* and can you indicate *dt* on the graph?

Ari: So when you zoom in infinitely, vertically it would be *dy* [marking *dy*], this would be *dt* [marking *dt*], and then together [drawing the tangent line], that line right there is *dy*/*dt*.

[In response to a question, Ari used an equation he created to calculate *dy/dt* and *dy*.]

I: [What is the difference between] writing *dy* as opposed to writing *dy/dt*.

Ari: Oh, okay, yeah… *dy*/*dt* is like the ratio for the instantaneous change for both variables, for *t* and *y* in relation to each other, like this one [pointing to his earlier calculation for *dy/dt*]. And then when it's just *dy*, it's just the instantaneous change for *y*, which is how much vertically or how much the *y*-value is changing instantaneously at a point.

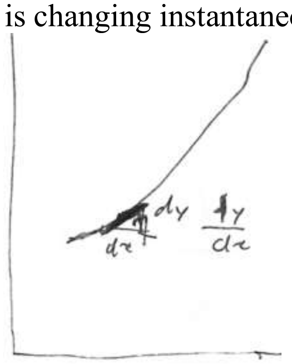

Figure 3. Ari's graph, used to indicate dy, dt, dy/dt, and the tangent line

Ari discussed derivative in context. When asked for other scenarios in which it would arise, he suggested the context of maximizing profit. He proposed a scenario relating profit in dollars, and quantity in bicycles. When asked for the units of the derivative he noted that it is "dollars per bicycle… Because the output, the value is represented by dollars."

Ari calculated a derivative using the chain rule (with substitution). For $y = \ln\left(\cos\left(e^{x^2+1}\right)\right)$, he used substitutions $g=x^2+1$, $j=e^g$, $h=\cos(j)$, $y=\ln(h)$, then used $\frac{dy}{dx} = \frac{dy}{dh}\cdot\frac{dh}{dj}\cdot\frac{dj}{dg}\cdot\frac{dg}{dx}$ before expressing the final answer correctly in terms of x. He then described his reasoning about it.

Interviewer: I noticed you made some cancel marks here. Can you talk about that?

Ari: Okay, so pretty much because when you take the derivative of g with respect to x and then j with respect to g, for instance, like, cross out dg because (pause). Well, I just see it as when there's a denominator and numerator, you cross it out because they, like, cancel each other…

I: Are you stating with confidence that's what you did or you stating with uncertainty that's what you did?

Ari: Well, I'm stating with confidence, but I think the problem is that because it's in derivative form. Because I remember when I took Calculus before somewhere, they said that you shouldn't see it as fractions. Like, you shouldn't see it as numbers. Like, it involves infinite number. And it's just kind of like, conceptually, it's not something you should do or see it that way. But it's just kind of like, in your class, I kind of just, like, memorized it this way because I've always hated the chain rule. And I was like, this is a good way to just do it.

When discussing the chain rule, Ari commented on proving derivative properties with limits and how unhelpful that was. "They showed the proof for the chain rule and for the product rule and all the rules, and it was very complicated. It was unlike anything like the calculus class I took, AP Calculus, it was just, like, very different, it was so much more complicated. I was like, what is this?"

Ari talked about which of his understandings improved from studying Calculus with infinitesimals.

Interviewer: Are there things feel that you understand better now after taking this class?

Ari: I guess the concept of the instantaneous rate of change, I think you showed me, like, there was some Greek letter [epsilon for infinitesimals], and then you multiply it with the number, and that would represent, like, the infinite value, the infinitesimal value, when you showed it to me that way. And that kind of like it helped me… Other classes introduce calculus with limits and that's very complicated, but that's the first thing that they do. Whereas [in this class there was] the delta x delta y thing first with the linear functions and then the rate function or change equation, rate equation. So, yeah, I kind of was able to grasp the concept of instantaneous change better. … When I don't understand something quick enough, sometimes it makes me learn it, because I want to understand it deeply. And then when I don't feel like I can, I just resort to, like with this [chain rule], memorizing and just putting it on the back burner. And other things were much easier. So I was just, like, that's what happened [with limits]. And then that's what kind of just held me back when it came to feeling confident in doing calculus. … I just think [previous Calculus instruction] was really focused on limits… it was your class when I first heard the term infinitesimals.

Discussion

Ari exhibited a rich and connected understanding of key concepts of Calculus. He was able to describe change and rate and the connection between them, both at a standard and infinitesimal level. He exhibited these conceptions in multiple problems across the four mathematical representations: numerical, graphical, symbolic, and verbal. Within the graphical representation, he was able to explain, for both change and rate, the connection between the standard presentation and the infinitesimal presentation. He did this using a verbal explanation, by drawing graphs and by manipulating a graph rendered by a computer grapher. He was very clear about the distinction between "very small" and "infinitesimal" magnitudes, and how the latter was necessary to describe an instantaneous rate, i.e. the derivative.

A significant part of Ari's concept image (Tall & Vinner, 1981) for instantaneous rate relied on the graphical representation, using infinite zooming to generate a straight graph. This conception of local linearity has been shown to be a productive cognitive root (Tall, 1991) in Calculus; several studies have shown that first introducing the derivative in this way leads to robust understanding and performance in Calculus (Tall, 1992; Samuels, 2012), and this study aligns with those results.

Ari described both the connection and the distinction between standard rate and infinitesimal rate. He utilized, first, a conception with finite real quantities, and second, a conscious introduction of the concept of infinity (in this case, infinitely small) to form a new scenario – in this case, quantities on the infinitesimal scale which are the context for infinitesimal change and rate. To characterize these two notions acting in concert, I introduce the term *transfinite thinking*. Thus, it can be said that Ari exhibited transfinite thinking in his conception of the derivative. Learner connections between finite and infinite scenarios have been investigated previously, both in Calculus and non-Calculus contexts (Ely & Samuels, 2019; Oehrtman, 2009; Mamolo & Zazkis, 2008). Here for the first time I provide a rigorous definition of transfinite thinking.

His conception of infinitesimals was given, not immediately, but after a progressions of statements. First, he conceived only of very small real values. Next, he said it would "keep getting smaller", indicating he was considering the *process* rather than the *result*. Then he said that an infinitely small quantity was something "you can't conceive of...because its infinite, its not defined by any value". Next he gave a numerical representation of an infinitesimal as "point zero zero zero infinitely many zeroes, one". Finally, he was able to perform arithmetic operations and make quantitative statements with infinitesimals, as when he referred to one (dy) being four times as large as another (dx). For Ari, the transfinite reasoning to extend his conception of rate between two points to rate at a single point was very much a multistage process which arose organically during the interview. This could form the basis for a hypothetical learning trajectory (Simon, 1995) for instantaneous rate with infinitesimals.

It is important to note that the idea of representing an infinitesimal as 0.00...1, a decimal with infinitely many zeroes, was never discussed in the Calculus class. This was a construction created by Ari in the moment. (Since he stated that he had never heard of infinitesimals before the Calculus course, I assume he did not hear of this somewhere else.) Research has previously shown that students have both spontaneous and intuitive notions of infinitesimals (Ely, 2010) which sometimes conflict with their classroom instruction. For Ari, it conflicted with his previous Calculus instruction but agreed with his experience in the current course. It is argued, both here and in the literature, that these intuitive notions should be encouraged, since they can form the basis of correct intuitions about Calculus which can be formalized into rigorous mathematics.

In constructing the infinite decimal, Ari gave quantitative meaning to the infinitesimal in the numerical representation. He was able to extend his quantitative reasoning further, making a *quantitative relationship between two infinitesimals*. He stated this relationship both multiplicatively and as a quotient. He described dy saying "it would be 4 times that [dx], but it would be infinite[simal] still…that same [infinitesimal] amount times 4". Initially he thought that $|dy|=4$, but he realized that $dy = 4$ units, where $dx = 1$ unit. He elaborated on the nature of that unit, describing it as infinitesimal and only apparent on the graph after an infinite zoom. Through unitizing and coordinating infinitesimals, he constructed a coherent quantitative conception of instantaneous rate.

Ari noted that his previous Calculus class began with limits and was "really focused on limits". He tried to understand them, but could not, calling them "complicated" and feeling limits "held me back". He resorted to simply memorizing procedures. Calculus students being forced to abandon understanding for memorization is unfortunate, and also consistent with previous results (Carlson, 1998). Particular difficulty with limits in SVC is also a common finding (Liang, 2016; Cornu, 1991).

An interesting aspect of Ari's situation was that he had previously taken a Calculus course. Students taking Calculus more than once is not only common, it is the majority experience among college Calculus students (Bressoud, Mesa & Rasmussen, 2015). How students negotiate this path is thus highly relevant. He was able to talk about the difference in his understandings in the two courses. Regarding calculating with differentials as in the chain rule, in his first course differentials were not thought of as canceling (i.e. arithmetic operations were not valid) even though those operations resembled the solving procedure, and he "hated the chain rule". In his last course, arithmetic with differentials was allowed, and in the interview he demonstrated the ability to calculate the derivative of a multiply nested function, calling the chain rule "a good way to just do it". Previously, proofs and explanations with limits created confusion, leaving him wondering "what is this?", and not understanding instantaneous rate. The presentation with infinitesimals allowed him to create personal understanding. After first discussing rate with the "delta x delta y … rate equation" in the standard case and then extending it using infinitesimals to instantaneous rate, he developed the rich understanding as previously described. This is evidence in favor of the calls to redesign Calculus to focus on the quantitative reasoning of infinitesimals and eliminate the Analysis of limits (Augusto-Milner & Jimenez-Rodriguez, 2021). The debate about relying on infinitesimals or limits for the foundation of Calculus has raged for centuries (Ely, 2021), and is likely to continue.

Ari exhibited two types of weakness in his understanding. One, some understandings were temporarily forgotten before being recalled. A likely factor was the researcher's intentional choice to conduct the interview two months after the course ended. Conceptions are likely only to be robust with either recency or reinforcement; without support in subsequent Calculus courses, meaningful and productive Calculus conceptions involving differentials can go away quite quickly and be replaced by unproductive and incorrect ones (Simmons et al., 2022). In the interview, Ari had space to (re)develop his conceptions, and in multiple cases did so with success.

Two, some topics were simply not understood at all. For example, while Ari was able to successfully calculate a derivative using the chain rule, he felt as though he only knew *how* to complete the procedure and he didn't understand *why* it worked. One possible explanation for his conceptual difficulty with this rate relationship was indirectly suggested by Ari. The conflicting instruction in previous Calculus classes may have made him wonder whether or not the cancellation of differentials in the fractions was actually legitimate. If students are taught explicitly that quantitative reasoning and arithmetic manipulation with differentials are incorrect and not allowed (a common practice), it may be challenging to get students subsequently to accept them. That is unfortunate, since those conceptions are mathematically valid and pedagogically productive.

It is important to point out that data in this study was drawn from a single student. I cannot claim that any observations generalize to the entire population. Rather, the analysis sheds light on how a student might possibly form conceptions about Calculus using infinitesimals. Due to the relative novelty of the context, this signifies a contribution to the literature.

Conclusion

In this report, I investigated an understudied area of student understanding of Single Variable Calculus, conceptions of rate and change after a one semester course on Calculus with infinitesimals. The data showed robust student conceptions of instantaneous rate and change across multiple representations. Graphically, change was conceived as a displacement, and a rate was the slope of a straight line, which could be presented as the ratio of two changes. There was an array of calculations with formulas and descriptions of applications. This conception was applied in both the standard and instantaneous contexts, demonstrating a strong link between prior and Calculus knowledge, connected using transfinite thinking. The student was able to articulate the role of infinitesimals in generating a locally constant rate to make meaning out of instantaneous rate. Graphically, this was described with an infinite zoom.

Calculus instruction using infinitesimals is not typical practice. There is a growing body of evidence that it is a propitious approach for students to make quantitative meaning in Calculus, and this study is a contribution in that direction. It also demonstrated how student knowledge of the quantities and relationships within Calculus, and their growth from prior knowledge by transfinite thinking, can be exhibited by students, and productively analyzed using the ACRA Framework.

In Proving Attempts that Generate Stuck Points, What Characterizes Undergraduate Students' Overall Proving Process?

Yaomingxin Lu
California State University, Fresno

Learning to prove mathematical propositions is a cornerstone of mathematics as a discipline (de Villiers, 1990). While the field has generated research that has analyzed the final products of proof (Selden & Selden, 2009) and there are frameworks for analyzing problem-solving processes (e.g., Carlson & Bloom, 2005; Schoenfeld, 1992), much remains to be known about analyzing undergraduate students' proving processes. With a focus on impasses in the proving processes, this study provides a more fine-grained account by characterizing students' overall proving process and navigating actions. The analysis lays the foundation for discussing the relative productivity processes students may take as they are engaging in proving.

Keywords: Proving Processes, Stuck Points, Navigating Actions, Productive Struggles

Since proving is a different mathematical activity as compared to students' prior experience, research has also shown that many undergraduate students struggle to learn to prove, including those who major in mathematics (Moore, 1994; Selden, 2012). Within the proof literature that focuses on undergraduate students, much work has concerned students' final proof products (such as written work or exams). However, such products cannot reveal the sequence of mental and/or physical actions that resulted in the final proof that students present in their written work (Selden & Selden, 2009). In particular, the proving process might entail several places where students get stuck, only some of which ultimately contribute to the final proof.

While the idea of struggle has been examined in problem solving in the middle grades (e.g., Warshauer, 2011), there has been sparse research on this idea in proving at the collegiate level. With a focus on impasses in the proving processes and the research questions "In proving attempts that generate stuck points, what characterizes undergraduate students' overall proving process?", this study provides a more fine-grained account by characterizing both undergraduate students' overall proving process and their navigating actions. Given the difficulty undergraduate students face in higher-level math courses, understanding the ways in which they struggle is important for building more inclusive classroom environments.

Literature Review and Theoretical Framework

View Proving as Problem Solving

A number of authors have remarked on the close relationship between problem solving and proving (e.g., Furinghetti & Morselli, 2009; Moore, 1994). In fact, Weber (2005) suggested focusing on problem-solving aspects of proof because this "allows insight into some important themes that other perspectives on proving do not address, including the heuristics that mathematicians use to construct proofs" (p. 352). Thus, in this study, I regard proving as problem solving and used Carlson and Bloom's (2005) Multidimensional Problem-Solving Framework to inform my research design. Expanding from Schoenfeld's (1985) framework, Carlson and Bloom (2005) developed four phases for problem-solving processes (Orienting, Planning, Executing, and Checking), each phase with the same four associated problem-solving attributes from Schoenfeld (resources, heuristics, affect, and monitoring). However, the original context of the work of Carlson and Bloom (2005) considered only how experts (like mathematicians) behave to successfully solve problems. Thus, their Multidimensional Problem-

Solving Framework does not characterize where a novice prover may seem to get stuck and how they may behave if they get stuck.

Immersion, Stuck Point and Productive Struggles

Wallas (1926) argued that creative problem-solving begins by first, immersing oneself in the problem to better understand it and exhaust conventional ideas. After a period of *immersion*, one likely reaches an impasse, or a mental block. The immersion phase of creativity shares some commonalities with *productive struggle* (Hiebert & Grouws, 2007), *productive failure* (Kapur, 2014) and other constructivist approaches to teaching in math education in which a student expends great effort during an initial period to explore and try to solve a math problem before receiving direct instruction. Involving in productive struggle in problem-solving is an invaluable mathematical practice which can help learners overcome uncertain obstacles to make sense of mathematics (Middleton et al., 2015). This is essential as students make meaning through productive struggle, or as they grapple with mathematical ideas that are within reach, but not yet well formed (Hiebert & Grouws, 2007; Kapur, 2008; Warshauer, 2014). From the student point of view, these *stuck points* have been described as perceived impasses, or moments when a student feels substantially stuck and unsure how to continue (VanLehn et al., 2003).

To date, research on stuck point in proving in the mathematics education literature has been sparse. Identifying a "stuck point" can be hard since it requires finding observable behaviors to serve as indicators of a person's internal mental state. Savic (2012) conducted a study of how mathematicians recover from proving impasses. In his study, all of the mathematicians were able to recover from the impasses, thus his focus was on their *Incubation Period*: where they temporarily shift their attention away from the problem and do something else. Methodologically, Savic used Livescribe pens that were given to the mathematicians for days to gather real-time data. Although a mathematician may have had a key insight while walking around (for example) that allowed them to get unstuck, from this study, we still know little about the actual cognitive process of getting unstuck. Thus, Savic (2016) had called for future study of proving processes involved several impasses (stuck points) with participants that are less skilled in math (different from mathematicians), since their incubation period might not help them to move forward. In this study, I thus began by characterizing the major actions that were evident in students' proof construction through "stuck points" in their proving processes.

Method

My study of undergraduate students drew participants from the Introduction to Proof course at a large research university in the Midwest. The Introduction to Proof (ITP) course is required for undergraduates majoring in STEM and mathematics education. The course focuses on developing mathematical argumentation techniques and proof strategies. The data for this study consisted of semi-structured task-based interviews with 10 undergraduates enrolled in a transition-to-proof course. Each participant was asked to prove or disprove two mathematical statements. The majority of the interviews took around 70 minutes, which provided enough time for the participants to have at least 30 minutes to engage with each task. In order to capture students' proving processes with their specific strategies and steps, a think-aloud protocol was used (Schoenfeld, 1985). Interviews were video-recorded, and students' real-time proof work was captured using a Livescribe™ pen.

As I have discussed in the literature review, in order to account for the proving processes of undergraduate students, the existing problem-solving frameworks need to be expanded. In particular, the role of students' stuck points in their process is important, as is understanding more about what students do when they get stuck. To do that, I utilize a combination of my own partition of students' process around "stuck point" and a modification of Boero (1999)'s proving phases and Carlson and Bloom (2015)'s Problem Solving framework. My partition was developed from the flowing three steps:

Step 1: Operationalizing and Identifying "Stuck Points". Like I have pointed out, identifying a "stuck point" can be hard since it requires finding observable behaviors to serve as indicators of a person's internal mental state. In this sense, body and facial language become more important in telling whether a person has gotten stuck. For my purposes, stuck meant a period of time during the proving process when a prover felt or recognized that their argument had not been progressing fruitfully and that they had no new ideas. Whether the participant discovered an error was not important; the prover's awareness that the argument had not been progressing, but they were *hesitant about what to do next* was the key focus for me. For the purposes of my study, an impasse (an episode of "stuckness") consisted of interruption in the proving processes that was initiated by a student struggle that was in some way visible, whether voiced, gestured, or written. An impasse ended when the student overcame a stuck point and continued attempting or finishing the task, or the student gave a sign of no resolution and indicated wanting to switch to a different task or end the interview. In total, there were 41 episodes of such "stuck points" and majority of them are in the last four phases according to Boero (1999): Exploring of the Content (identify appropriate argumentations and envisage possible links), Selecting of arguments into deductive chain, Organizing the chain of argument into proof, and finally Write a Formal Proof.

Step 2: Categorizing Major Actions Around Stuck Points. I used the existing Warshauer (2011)'s framework for the four categories of students' stuck point (getting started, carrying out a process, uncertainty in explaining and sense-making, and expressing misconceptions and errors) to enhance my initial coding scheme by developing sub-categories to capture students' actions. Different from Warshauer (2011)'s study that mainly aim to examine the categories of students' struggles in K-12 problem-solving environment with teachers' interaction, my study focuses more on undergraduate students' proving processes and their own navigating actions.

Through this process, several major categories were identified. Each student's proving processes were captured in three major categories initially: their arguments, their stuck point, and their actions. After identifying those bigger categories, smaller categories were then identified inside of each major category. Since I was primarily interested in students' arguments and actions around their stuck points, I refined categories related to proving activity to the following four: initial argument, stuck points, navigating actions, and related outcomes. Once the initial coding scheme with those themes was developed, I completed the first round of data analysis to test and refine those themes. Particularly, I reorganized my coding scheme to highlight students' responses to "stuck points" or impasses. Besides different types of stuck points that were identified by the students, their actions for attempting to resolve those stuck points, monitoring, and persistent actions were also classified and captured.

Step 3: Capturing Each Students' Proving Process with Map. To capture each student's stuck points for each individual task, I used a flow chart to map out each student's proving processes with their major navigating actions. I split the proving process map into two dimensions. Vertically, the process map captured the four categories as described in Step 2. Horizontally, the map captured the order of each individual argument and action. The arrows in between indicate the directions of the movements and the relationship between the arguments and the actions. Instead of capturing only arguments, I also added a category that captures students' actions to help bridge the gap of the relationship between the argument and the actions, as described above. In *Figure 1* below, I provide an example of one student's proving process map for Task 2. From this process map, one can clearly see the student's arguments, stuck points, navigating actions, and outcomes related to those actions, as well as how one moved from one to the other. This proving process map provides a bird's-eye view of the proving process for each task for each individual student.

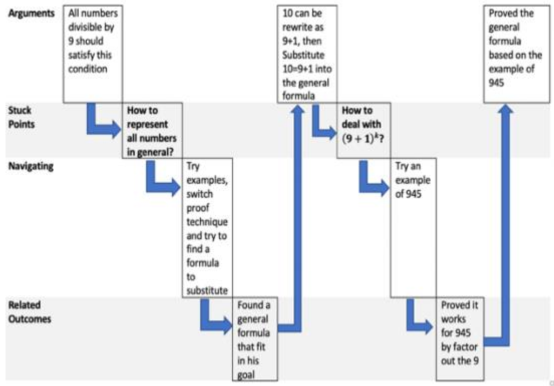

Figure 1. Example of Student's Proving Process Map for Task 2

Result and Discussion

In my subsequent work, the detail analysis of each student's proving process will be provided with map. In this proposal, I turn to focusing on the qualities of navigating actions students used, situated in the context of their entire proving attempts. My analysis resulted in three major types of navigating actions that were generated based on each participant's proving process map and the major categories of my analytical framework. For each task, each participant's proving process was characterized by their process map based on shifts between (1) initial argumentation (Argument), (2) major stuck points (Stuck Points), (3) actions they took to try to navigate out of being stuck (Navigating Actions), and (4) related results (Related Outcome). If they are able to use the related outcomes (i.e., new insight, useful calculation, or new connection) that they generated in a given cycle, then the proving process progresses, either to completion or until they reach a new impasse. In the next sections, I will describe the three major types of proving process around stuck points based on these shifts in the order of increasing complexity. Because of the limited space for this proposal, I will only discuss one student for each type for Task 2 (Prove or disprove: An integer is divisible by 9 if the sum of its digits is divisible by 9).

Type 1: No Related Outcome Produced

Trajectory: Arguments⟶ Stuck Points⟷Navigating Actions

For this process type (as in all the types I consider), the student started with some sort of argument and got stuck when trying to construct a proof. The student then took several actions or attempts to try to navigate out of the stuck point but did not produce any related results, thus going back to their navigating actions. In summary, this type can be characterized as going back and forth between stuck points and navigating actions without any related outcome to help one move forward (see *Figure 2*). I will use Nikki's process to explain this type.

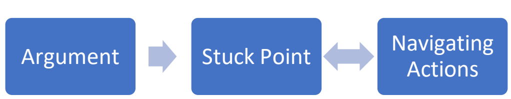

Figure 2. Process Flow for Type 1 Process Around Stuck Point

As soon as Nikki saw the task, she remembered that she had done a similar problem before. She quickly wrote down the problem and figured out what were the "P" and "Q" in this statement to set up for a proof by contrapositive. She then rewrote the statement as "If the sum $x_1 + x_2 + \cdots + x_k$ equals 9, then the number *n* is divisible by 9" (Nikki, Task 2). But Nikki got stuck after she had decided that was the argument that she wanted to prove. "How are they related?" she questioned. At this point she went back to the beginning of the problem and double-checked which statement should be thought of as "P" and which statement as "Q," then told me that she didn't know where to go next. She then started trying some examples such as 27, then thought about what happened if the sum was 9 or the sum of a multiple of 9 (like 18). But these navigating actions didn't help her to go forward. She asked aloud, "How can I represent this example in a more general form?" and she got stuck again with her attempts to try examples. Nikki then tried to look for the general equation for expressing the sum of the digits. She found the expression on the formula sheet and tried to understand the expression again by computing some examples and by rewriting 27 as $2 * 10^1 + 7$. But she was soon stuck again with the k^{th} term: "What does *k* here mean in the expression of 10^k? Is *k* the number of digits or something else?" (Nikki, Task 2). She told me this general form she found (on the provided formula sheet) didn't really help her, because she didn't even understand the expression itself. After several attempts, Nikki didn't produce any related outcome from her navigating actions, and she remained stuck in the end of the episode.

As I have noticed from Nikki's example, this type of process doesn't involve the production of related outcomes from navigating actions. Students with this process tend to go back and forth between stuck points and navigating actions since no significant related outcome is produced to help them move forward. Thus, in the end of the process, students don't overcome the stuck point and they are unable to make progress on their argument.

Type 2: Related Outcome Produced but Not Link to the Argument

Trajectory: Arguments⟶Stuck Point 1⟶Navigating Actions⟶Related Outcomes ⟶Stuck Point 2 (⟷Navigating Actions)

The majority of the participants' proving processes can be characterized as this type. For this process type, like before, a student starts with some sort of argument and gets stuck when trying to prove the argument. The student then takes several actions or attempts to try to navigate out of the stuck point (so far, as in Type 1). However, the student successfully overcomes one stuck point by producing a new idea or connection (a "related outcome"). But they soon run into another stuck point when they try to expand the related outcome into an argument. This process may also include some navigating actions to try to overcome the second stuck point, but the student is unsuccessful in doing so (see *Figure 3*).

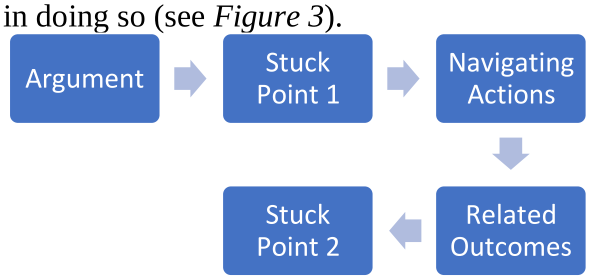

Figure 3. Process Flow for Type 2 Process Around Stuck Point

In Task 2, Devin conjectured the statement works for all multiples of 9 after trying examples like 9, 18, 27. But he then got stuck with how to show the statement in general. He tried to represent a given number in terms of the sum of its digits in a general form and assumed $9/N$ where N is a number such that $ones + tens + \cdots =$ multiple of 9 and $m1, m2, m3$ are the place values of each of the digits. Thus, any number can be represented as $N = 1 * m1 + 10 * m2 + 100 * m3 + \cdots$ But with this generalized formula in hand, how to use this to prove the statement became her new problem. He then thought about whether a number that is a multiple of 9 could be factored differently. Devin took the examples of 36 and 135 to try to factor them out and see whether he can have some insights. He rewrote them as $36 = 4 * 9, 135 = 1 * 100 + 3 * 10 + 5 * 1 = 100 + 30 + 5 = 2 * 5 * 5 + 6 * 5 + 5 = 5 * 27 = 5 * 3 * 9$. But "What do these factorizations tell me?" became his new question, a question he still had in the end.

The examples of Devin illustrate what Type 2 processes look like and how they differ from Type 1 processes in terms of the role of related outcomes. Devin had several related outcomes produced by overcoming some of their stuck points. This helped them to move forward, and, in fact, they were just a few steps away from fully overcoming all the stuck points and successfully proving the statement. Thus, at this point, it will be insightful to compare their processes with at least one related outcome linked with argument.

Type 3: At Least One Related Outcome Linked with Argument

Trajectory: Arguments⟶Stuck Points⟶Navigating Actions⟶Related Outcomes ⟶Arguments

Similar to the previous two types, for this type of process, a student also starts out with an initial argument, but they also get stuck. The student then takes several actions or attempts to try to navigate out of the stuck point (as in Types 1 and 2 process flows). However, the Type 3 process advances to proving the statement using the related outcomes generated in the process and ultimately results in having at least one related outcome linked with the argument. Since there could be multiple stuck points resulting in multiple processes, the student will be categorized in this type as long as at least one productive cycle is complete. The cycle can repeat if a second or third stuck point is encountered. To summarize, this type of process always involves a related outcome each time and the participant is able to leverage these related outcomes to move forward with developing their argument (see *Figure 4*). Note here that students are considered as making productive progress (Type 3) as long as at least one productive cycle is complete, which means they don't need to successfully prove the task in order to be considered as making productive progress.

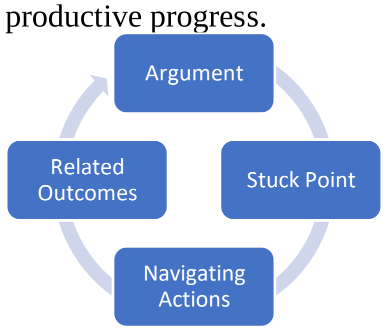

Figure 4. Process Flow for Type 3 Process Around a Stuck Point

Soni successfully overcame several stuck points in both Task 1 and Task 2. For Task 2, Soni started with outlining some of his ideas for finding the differences between counting by 9s and counting by 10s and rewrote 10 as $9 + 1$. Having this general goal in mind about what he would do, he felt the need for a generalized formula to represent any integer with its sum of the digits. Soni looked into the formula sheet and found the formula that any integer can be represented as $a_k(10)^k + a_{k-1}(10)^{k-1} + \cdots + a_0(10)^0$. But then how to use the general formula to prove the statement became his problem. Soni then thought about induction to help him achieve his goal. However, he soon realized that it didn't work here. He decided to go back to his initial thinking about representing 10 as $9 + 1$ and substituting all 10s in the formula as $9 + 1$. However, he got stuck again on how to expand $a_k(9 + 1)^k + a_{k-1}(9 + 1)^{k-1} + \cdots + a_0(9 + 1)^0$. Soni then decided to try a specific example (*Figure 5*) to show it could be factor out by 9, then follow the same way to show the generalized cases. Following this way of thinking, he successfully navigated out of his stuck points and proved the statement in the end.

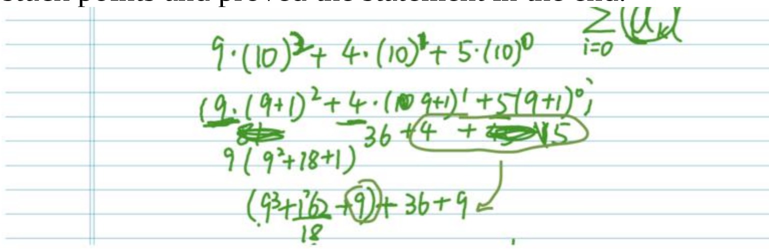

Figure 5. Soni's work of representing 945 using counting by 9s

From Soni, we see what could be described as a more productive struggle engaged in their proving processes since they completed at least one cycle of link back to the argument. Looking at Soni's case, we would see that he was clear about the goals for each of his navigating actions and had a clear understanding about where he got stuck. He also successfully produced several related outcomes from his navigating actions to help him move forward.

Conclusions and Implication

As I discussed in the literature review, although students' and mathematicians' proof practices have been examined in several ways, there are still important aspects that have not been examined in the existing literature. Previous proof construction research, building largely upon the work of Toulmin (1958), focused only on the structure of the argument but not the actual action and the actor (e.g., Pedemonte, 2007). To address those issues and characterize undergraduate students' proving processes, through our analytical process (conceptualizing stuck point, characterizing actions, and capturing general processes using map), I classified three different types of overall processes when undergraduate students face several stuck points and try to navigate out. In general, we can see that even though some of the students' navigating actions might look similar (e.g., look for a generalized formula to represent digits), students in Type 3 seems to make more productive progress compared to the other types. The reason could vary between students, but in general, students in Type 3 are able to clearly identify their stuck points, have a goal for each of their attempts, and able to produce related outcome from their attempt and then link that back to their initial goal/argument.

To conclude, students need to engage in a way that they can make some progress in order to be productive. In general, most of the students interviewed in this study had their process maps and actions categorized as Type 2. If we know where students get stuck in their overall proving process when trying to navigate out stuck points, we will be able to better support their productive struggles and help them to move to Type 3. In the subsequent study, I will describe individual cases in detail to discuss the relative productivity of different possible navigating actions students may take as they are engaging in proving. The different proving processes and navigation actions characterized in this study can help instructors to have a better understanding of students' proving processes when navigating out stuck points and to be more explicit in their own modeling of their own actions for their students.

Contextuality in Reasoning about the Exponential Function: A Microgenetic Learning Analysis

Elahe Allahyari
Western Michigan University

This paper explores how two undergraduate students come to perceive exponential structure in a series of word problems. This study investigates whether features of task situations can create opportunities for supporting students in recognizing situations as appropriate for using exponential models. The analysis is guided by coordination classes theory (diSessa & Sherin, 1998) and Transfer-in-Pieces perspective (Wagner, 2006; 2010), which emphasizes the role of multiple instantiations of a concept across multiple contexts as learners construct their understanding. The results suggest that contexts that embody the notion of recursive dependency may help students activate and use appropriate knowledge resources related to exponential models.

Keywords: Exponential models, Context-dependence, Knowledge in Pieces

Introduction and Purpose of the Study

There is an essential need to explore students' understanding of different topics at the college level, especially those topics that students find difficult. Exponential functions are a difficult, yet essential, mathematical concept that plays an important role in the study of advanced mathematics (Ellis et al. 2016; Weber 2002). Several researchers illuminated the importance of deep understanding of exponential function as an important topic in the mathematics education field (Brendefur, Bunning, Secada, 2014). Weber (2002) focused on students' initial understandings of the exponential function. The main result from Weber's (2002) work was that although all students could compute exponents in simple questions, only few students could reason about the process of exponentiation. The result stimulates some essential questions regarding understanding the exponential function: What features of contextual tasks do students notice and how does this impact their reasoning patterns? In particular, what features of tasks meant to cue the use of exponential models are salient to students? How do students' reasoning patterns shift as they engage with a sequence of tasks designed to help them link their prior experience with linear modeling to exponential modeling?

Theoretical Framework

This work requires a perspective that brings into focus on the role of contextuality of a task in students' thinking and reasoning. To this end, I turned to Wagner (2006; 2010) who addressed the role of knowledge in transfer processes. Wagner (2006) demonstrated in "transfer-in-pieces" that prioritizing context sensitivity of knowledge supports transfer. Wagner (2006) framed his analysis using the construct of *coordination classes* which is rooted in diSessa's (1993) Knowledge-in-Pieces (*KiP*) heuristic epistemological framework. Coordination classes give a model for conceptual understanding that involves how individuals extract concept relevant information from a context. These constructs can help to explain how learners initially interact with mathematics content in a wide range of contextual tasks. In describing the knowledge that emerged in this study, the coordination class theory construct of *concept projection* proved to be useful. A *concept projection* is, "the particular set of strategies and cognitive operations that are used by an individual in applying his or her concept (coordination class) in a particular situation…" (diSessa & Wagner, 2005, p. 128).

Wagner (2010) provided an extension of transfer- in-pieces in which the alignment with the Piagetian frame is explicitly pointed out to create a framework for transfer either in similar situations or accommodation of a new concept. "Concept projections are thus collections of assimilatory and interpretive knowledge elements associated with some concept, and the construction of new concept projections reflects a process of conceptual accommodation to new contextual situations" (Wagner, 2010, p.451). Building on Wagner's (2006, 2010) perspective, I explored how learners can build new knowledge elements —exponential understanding—which is the result of passing through multiple disequilibrium and accommodating particular context. In this work, another goal is to investigate the affordance of context for such accommodations. In other words, I seek to explore from the novice's perspective what is the feature of contexts that exponential understanding can be accommodated to? The affordances of a context are a fundamental aspect of investigation of coordination classes and transfer. "Transfer requires that the structure perceived in a new situation be matched or closely matched to the structure perceived in a previously encountered situation" (Wagner, 2006, p. 5). A major difficulty is the explanation of contextual situation which can be matched to the ultimate, desired abstraction (Wagner, 2006).

In this work, I investigate the affordances of *recursive dependency* implicit in very common exponential contexts for instigating productive conceptual conflict. I define recursive dependency as a feature of a context task in which reasoning about each step depends on the previous step. As an example, the molding process of the population of a city, increasing by a particular rate every year, needs learners to realize that the number of people of the city in each year *depend on the previous* year, rather than the initial year. I argue that the *recursive dependency* is the heart of, specifically, identification of exponential function as it is shown in two undergraduate students' reasoning in this study.

Data Collection

Data for this study were taken from semi-structured task-based interviews of four undergraduate students who enrolled in a developmental math course—Algebra II—at a large, public, Midwestern university. The interviews were conducted in an online format consisting of 60-100 minutes of problem solving. The interview involved screen sharing a specially designed set of slides I created through Desmos Activity Builder (DAB). Participants agreed to meet with me for 60-90 minutes one-on-one in an online private session. They worked in DAB and their thoughts as he described as they worked on a contextual problem involving exponential function was audio and video recorded. Screenshots of all written work in DAB were saved and some are represented in appendix A. All 60-100 minutes of the interviews were transcribed for detailed analysis.

The main interest to this research was moments in which participants' patterns of reasoning appeared to be in transition or if it appeared that they came to notice a conceptual conflict. Among four participants there was one student, Leia, who understood the context qualitatively in City A problem and calculated the population after 10 days and 20 days, however, introduced a linear model and stuck with a linear model. Another student, Nick, who already knew exponentiation in different contexts and models exponentially. Two students, Tom, and Andrew, who underwent conceptual change and came to discern exponential function in different contexts. This study focuses on how Tom and Andrew underwent some conceptual change to understand exponential function.

Among the problems presented to students were sets of common contexts for exponential situations, like population growth and the amount of a drug remaining in a patient's body. However, there is a special effort for raising the possibility of more engagement from each student. For example, city A and City B problems, presented in Table 1, is an explanation of the population of people who are infected by Covid 19. This study happened during the peak of the pandemic, when checking the number of Covid 19 outbreaks was a concern. the set of problems that students attempted to solve in the 60-100 minutes interview. I sometimes asked probing questions, however, I avoided taking an evaluative role and emphasized my appreciation for valuable sharing of their thinking with me. An analysis of explanatory language that Tom and Andrew used during the interviews enabled me to recognize the importance of well-matched recursive dependency in the exponential context to generate productive disequilibrium and support transfer.

Table 1. Exponential problems that participants worked on in the 60-100 minutes interviews.

Exponential problems
<u>Baseline problem</u> What does the function $f(x) = b^x$ mean to you? What do you think of when you see this function?
<u>People Diagnosed with Covid-19 in City A</u> In City A the number of people who have Covid-19 increases by 11% every 10 days. The initial population of people who are diagnosed with Covid-19 in City A is 1500. Create an equation that models this situation.
<u>People Diagnosed with Covid-19 in City B</u> In City B the number of people who have Covid-19 decreases by 11% every 10 days. The initial population of people who are diagnosed with Covid-19 in City B is 1500. Create an equation that models this situation.
<u>Drug Remaining in the Body</u> Imagine that a patient is taking 100 milligrams of a drug. Suppose only 27% of the drug remains in the patient's body after an hour. How long does it take before only 10% remains?

Analysis

Microgenetic Learning Analysis (*MLA*) is an analytic methodology for progressing from observations in video data of moment-by-moment reasoning processes to systematically describing the nature and form of knowledge growth and change. (Parnafes & diSessa, 2013). My study also can be summarized as MLA of two undergraduate students' (Tom and Andrew) reasoning, coming to understand and discern the appropriateness of contexts for modeling exponentially. In this work, the MLA process includes transcribing the episodes, enriching them with details about what was written and pointed to in Desmos by participants, and then summarizing the work on each task and the discussion around it. Describing learners' first reaction for a modeling system and how they both modeled linearly; then playing genuinely just with context helped them to go through an assimilatory activation and, ultimately, accommodate a new reality which was concept projection of exponential function. I defined this process of, first, reacting proportionally to, eventually, accommodating exponentiation as the process of "changing". As I observed, both learners could experience this "changing" process either in City A problem (Tom's experience) or in City B problem (Andrew's experience) with assistance of productive conceptual conflicts in which a well-imbedded recursive dependency appeared as a highly influential factor for change.

Analysis of Tom's reasoning

City A problem: Facing conceptual conflicts (disequilibrium). Coming to solve the problem of city A is the heart of this study, in which we can see the prominent pattern of logical readout of the situation, coordinating the context and his pattern of reasoning, experiencing a productive disequilibrium, accommodating new understanding of the situation, and finally, generalizing the problem to make an abstract model. To me, the key observation across the session was the moment that Tom in the middle of making sense of the structure leaves all his findings (including the population of Covid 19 after 20 days: getting 11% of 1665 and adding to 1665, not 1500, which had the result of 1848) and faces a huge *disequilibrium* with satisfying a systematic and already established proportional perspective.

Interviewer: How did you find that number?
Tom: I divided 1848 by 1500 and found 1.321 which does not make any sense
Interviewer: what about first 10 days
Tom: That works really well. 1665/1500 is 1.11 which makes a lot of sense. I thought 1848.15/1500 should be 1.22 because it increases 11% every 10 days

The *recursive dependency*, well-imbedded in the context task, appeared to help Tom to prefer working with his understanding of context rather than sticking with his proportional expectation. He eventually could coordinate his perception of the situation with his strategy for calculating an increasing Covid19 population in each step and to resolve an apparent contradiction in his thinking.

Tom: Ok! So, oh! Wow! That's a lot! Hah! Ok! So, in the first step we are taking 11% of 1500 and then plus 1500 which is 1.11×1500 and then in the second step we do $1.11^2 \times 1500$ and in the third step it should be $1.11^2 \times 1500$ right? Is that it?
Tom: SO! f (x) = $1.11^x \times 1500$ would be: Right? Cool.
Interviewer: Do you want to calculate what you find in the second step? I guess it would be interesting for you
Tom: Sure! It is 1.321! What? What is that? ***Is it magic?***

City B Problem: Testing Near Transfer. In Tom's work on the City B problem, he showed transfer more explicitly in a similar context. I asked him to calculate the population of people who have covid 19 after 10 days. While he was calculating it seemed that he already had the exponential model in his mind.

Tom: Ok! I found it! If I take this (1.11 from the previous model), because it is one point eleven! If I want to decrease (Looking ups and down)! hundred mines 11… like 89 percent? If

I do 0.89 (More confidently and surely say the last words) that gives me the model here, the 11 percent decrease (laughing happily!)

Interviewer: Do you want to write the model?

Tom: Yes, sure! I think it should be f (x) $= 0.89^{x} \times 1500$, right?

Remaining Drug Problem: Fidelity to Proportional Modeling when Context Lacking Recursive Dependency. After 73 minutes of productive challenge to understand exponential function, Tom confidently initiates reasoning proportionally. In the end, he modeled this problem with a linear and solved a linear equation to figure out how long it would take for 10% of the drug to remain. Figure 3 in appendix is a screenshot of Tom's work when he was sharing his problem solving on the WebEx. I tried to have a conversation to see why the first reaction to this question involves linear thinking. I asked him why he thinks that a linear model can work in this problem, and he answered that "I am not an expert, but our body must work linearly. It cannot work first slowly and then [become] hardworking!" At this moment in Tom's interview, I could have asked "why?" (Why can the body not work with different rates of the drug?) However, it did come to my mind as I was experiencing the first observation of how learning is highly contextual. In the interviews with Andrew which were conducted after Tom's, I was able to get more insight.

Analysis of Andrew's reasoning

City A Problem: Appropriate Use of Exponential Model. Andrew found a strategy to calculate the population of Covid19 immediately, however, just like Tom, after seeing some steps in the exponential model, he checked himself with a proportional model. Facing a contradiction between understanding of the problem and the linear model, I asked him what his decision is.

Interviewer: If I want you to calculate after 30 days, how do you go, are you plugging 3 in your linear model or you are calculating from the first strategy and why?

Andrew: I would probably do the first one, because the way that I understand the increases, it is not that taking the old percentage and taking 330, it is taking the ***11% from the new*** **number.**

I observed that a well-matched recursive dependency emerged to help Andrew to decide his strategy and confidently leave proportional thinking. Like Tom, Andrew eventually modeled exponentially this problem.

City B Problem: Facing a Multi-dimensional Disequilibrium. Andrew recognized what decreased means as he could see 0.89×1500 for the first set of 10 days and $0.89 \times 0.89 \times 1500$ for the second set of 10 days. I thought he was ready to make the model, just easily in a similar context; however, he was still in disrepair with the linear model.

Andrew: I think I could! it would be 1500 times (X-0.11)? so for the second step it would be 1500 times 2-0.11, but no! that would be an increase! No?! It cannot be correct, because it is two thousand and something which is not even a decrease.

Interviewer: Ok let's talk about your strategy, not the model… so far you found 0.89 … how about after 20 days?

There was an implicit point here in Andrew's reaction, in this episode. Although the similarity of City A and City B problem should have resulted in the transfer for abstraction more immediately, there was a tacit avoidance in Andrew's reaction in which, I believe, he was hesitating to connect a decreasing process to an exponential model. I think there was an intuition that if a number comes to the power of something, it should be an increasing process. Andrew was facing multiple conflicts simultaneously; that is why I made up the "multi-dimensional disequilibrium" for his reasoning pattern in the City B problem. Eventually, he could see the model after working on the population after 30 days.

Remaining drug problem: Fidelity to Proportional Modeling when Context Lacking Recursive Dependency. Like Tom, after 63 minutes of productive struggle for understanding the exponential model, Andrew returned to proportional thinking very confidently. He made the proportion for finding the slope and then a linear model. This time I had that crucial "why" to ask, moreover, involving more of learner's voice in the study:

Andrew: I was assuming a consistent rate
Interviewer: *Why* do you think it has a consistent rate?
Andrew: Based on kind of information that I get
Interviewer: So, imagine in the question we have this assumption that the drug is working exponentially in the body, how would your answer change?
Andrew: Exponentially cannot work here, because it just says this much left, or this much remains after the one hour.
Interviewer: What do you expect from a problem for model exponentially
Andrew: I think, special kind of increase or decrease

It turns out that "special kind of increase and decrease" is related to dependency to the previous step that I defined as recursive dependency.

Discussion

The analysis of Tom and Andrew revealed prominent patterns of logical readouts in the situation, coordinating context to reasoning, experiencing productive disequilibrium, accommodating new understanding of the situation, and finally, generalizing problems to make abstract models. During their reasoning about the contextual problems, both learners attempted to create a coordination between the context he perceived and a strategic pattern of thinking to solve the problem.

In the city A problem, there was a moment, in the first interview, when Tom could have made a generalization, but instead he faced a huge **conceptual conflict (disequilibrium)** with a previous normative and settled way of thinking: proportional reasoning. Andrew, however, experienced this productive disequilibrium majorly in the city B problem. Eventually, playing genuinely just with context helped Andrew to face a multiple disequilibrium to go through an **assimilatory activation** and, ultimately, accommodate a new reality which was **concept projection of exponential function.** Here, the strength of the context can be illuminated as the most important key, which can shadow the importance of similarity.

I conjecture based on the results of both interviews that if the context could have provided enough support for exponential thinking, perhaps students also could have moved through a possible conceptual conflict and accommodate the desired model to the context.

However, when the context was weak in establishing a recursive dependency, learners strongly coordinated the proportional reasoning and modeled the situation linearly.

To elaborate, the learners' mathematical behavior demonstrated a natural product of amplified understanding in the analysis, which is the core of transfer. Understanding a concept is, indeed, inseparable from developing logical readout strategies and **coordination of knowledge resources**. The analysis of Tom's and Andrew's exponential understanding is thus consistent with Wagner's (2006; 2010) Transfer-in-Pieces, where readout strategies and coordination of knowledge resources were matched with affordances of the contexts. After analyzing the interviews, I argue that the Remaining-Drug problem failed to afford recursive thinking. That is, the focus of the situation on the quantity "remaining," "staying," or even "half-life" could not create understanding of the amount of the remaining drug in each hour depending on the amount of the remaining drug in the previous hour. However, in contrast, the growing population of City A demonstrated a well-imbedded recursive dependency and afforded a dependence of the increased population to the previous increased population.

Implications

Such revelations about the interplay between contexts and the knowledge resources participants activate and use, is an important line of work that has practical relevance with respect to teaching and learning. Such analyses underscore the need for more epistemological investigations across disciplinary topics that can lend insight into the organization of learners' perceptions and inferences.

Students' Enumerations of Tiles within a Rotation-Based Tiling of the Plane: Juxtaposing Units Coordination and Spatial Structuring Perspectives

Joseph Antonides
Virginia Tech

Michael T. Battista
The Ohio State University

This report contributes novel insights into how undergraduate students think and reason about the number of tiles within a given tiling of the plane. We juxtapose two theoretical perspectives—units coordination and spatial-temporal-enactive (or S-) structuring—to provide an analytic account of how two undergraduate students reasoned about the tiling. In particular, this work suggests potential qualitative differences in how undergraduate students might engage in multiplicative reasoning in an unfamiliar spatial context.*

A tiling (or tessellation) is a collection of spatial structures that have been arranged in such a way that (a) there are no gaps or overlaps between adjacent structures, and (b) if the collection were repeated indefinitely, it would cover the entire plane. This report focuses on the tiling shown in Figure 1c. Few empirical studies have examined how students make sense of and reason about numerical and spatial units within tilings of the plane. Prior research has examined elementary school students' constructions of spatial tiling units in relation to their constructions of numerical units (e.g., Reynolds & Wheatley, 1996; Wheatley & Reynolds, 1996). Other research has focused on tilings from the perspective of mathematical aesthetics (e.g., Eberle, 2014, 2015). However, to date, the research literature has not yet captured how students, particularly those operating at higher levels of units coordination, form spatial and numerical units to enumerate tiles within tilings of the plane. In this report, we contribute initial insights toward this direction. Specifically, using the perspectives of units coordination and S*-structuring, we aimed to understand what multiplicative reasoning undergraduate students might use to enumerate the tiling shown in Figure 1c.

Figure 1. (a) Six-tile structure (6TS), (b) 42-tile structure (42TS), and (c) 294-tile structure (294TS)

Conceptual Framework

Reasoning about Numerical Units

The theory of units coordination constitutes the first component of our conceptual framework. Grounded in Steffe's work (e.g., Steffe, 1992, 1994), and subsequently developed by

Hackenberg, Norton, and colleagues into a three-stage[1] theory of students' multiplicative concepts (Hackenberg, 2010; Hackenberg & Tillema, 2009; Norton et al., 2016) and related forms of additive reasoning (Ulrich, 2015, 2016), units coordination posits that students gradually develop increasingly sophisticated ways of approaching (i.e., assimilating) additive and multiplicative situations. Stage 1 students can assimilate problem situations using units of one, and they can use units of one to actively build a unit of units (i.e., a level 2 unit) out of perceptual or imagined material. Stage 2 students can assimilate problem situations using both units of one and level 2 units; they can use these unit structures to actively build a unit of units of units (i.e., a level 3 unit) out of perceptual or imagined material. One indicator of Stage 2 reasoning is a tenuous or fleeting awareness of a three-levels-of-units structure. Stage 3 students can assimilate problem situations using three levels of units. That is, they can anticipate, at assimilation, the multiplicative structure of a situation, and they can reliably and flexibly use three levels of units in reasoning.

To illustrate how students at each stage might reason within a multiplicative context, consider the Bars Task (adapted from Norton et al., 2015). This task was presented to the students discussed in this report. Each student was shown a large bar, a medium bar, and a small bar. Placed end-to-end, three medium bars were of the same length as one long bar, and four small bars were of the same length as one medium bar (all bars had equal width). Stage 1 students can characteristically iterate the small bar (using number word utterances or motor-kinesthetic pulses) to determine how many small bars make up one large bar (12). Stage 2 students can iterate the medium bar, with each iteration representing a unit of four units (small bars). Stage 3 students can immediately determine that 12 small bars make up one large bar, with the understanding that the large bar consists of four medium bars, and each medium bar is equivalent to three small bars.

Reasoning about Spatial and Combinatorial Units

To date, little research has examined students' units coordinating structures within spatial/geometric contexts, with some notable exceptions. Wheatley and Reynolds (1996), for instance, found strong parallels between elementary school students' constructions and coordinations of numerical and spatial units. While prior research identified the unitization action as fundamental to the construction of *numerical* concepts (Steffe, 1992; Steffe et al., 1983; von Glasersfeld, 1982), Wheatley and Reynolds also found this action, in addition to mental imagery, to be critical within *spatial* contexts.

Outside of but related to the literature on units coordination, substantial research has aimed at understanding the mental operations and strategies that students use when engaged in tasks for enumerating spatial structures in contexts of geometric measurement (e.g., Barrett et al., 2017; Battista, 2004, 2007; Battista & Clements, 1996; Battista et al., 1998; Clements, 2004; Cullen et al., 2018; Smith & Barrett, 2018). We define the term *spatial unit* to mean a perceived or conceived object in space that is conceptualized as a singular entity (through an act of unitization). How one reasons about spatial units depends on how the individual mentally organizes, or structures, those units. Battista and Clements (1996) defined *spatial structuring* as "the mental act of constructing an organization or form for an object or set of objects" (p. 282). Without a viable spatial structuring to guide their enumerations of spatial units, students may experience difficulty keeping track of spatial units, which can lead to double-counting, or missing, some spatial units. Battista et al. (2018) defined *spatial-numerical linked structuring*

[1] Hackenberg's usage of the term "stage" is consistent with von Glasersfeld and Kelley's (1982) definition.

(SNLS) as a form of numerical reasoning that is linked to one's spatial structuring. From the perspective of units coordination, Zwanch et al. (in press) found that students with the second multiplicative concept (comparable to Stage 2; see Ulrich, 2015) may experience difficulty maintaining an awareness of a three-levels-of-units structure in geometric contexts, such as conceptualizing a strip of paper as a unit, each containing 7 units (7 inches), which each contain 2.5 units (roughly 2.5 cm per inch). Thus, enumerating spatial units depends on one's spatial structuring of the relevant spatial information *and* on one's available units coordinating structures. We hypothesize that the former may depend on the latter—that is, how one spatially organizes units depends on their current additive and multiplicative concepts.

In our research on students' combinatorial reasoning (Antonides & Battista, 2022), we elaborated Battista and Clements' (1996) construct of spatial structuring, defining a new construct called *spatial-temporal-enactive structuring* (or *S*-structuring*). We also defined S*NLS as the analog to SNLS, using S*-structuring in place of spatial structuring. S*-structuring focuses on how students construct, organize, and operate on composite units (level 2 units) and composites of composite units (level 3 units). Antonides and Battista (2022) identified and illustrated two specific forms of S*-structuring. *Intra-composite structuring* entails organizing units into individual composite units (such as combinatorial outcomes)—that is, actively constructing level 2 units out of level 1 units. For instance, within our framework, students engage in intra-composite structuring when they apply a pairing operation (Tillema, 2013) to append objects together to form a combinatorial outcome (e.g., a shirt-pant "outfit," a two-card hand, or a three-cube tower). *Inter-composite structuring* entails organizing composite units into composites of composite units—that is, actively structuring level 3 units out of level 2 units. For instance, students might construct all six 3-object permutations without repetition, organized into three groups with two permutations (i.e., two level 2 composites) in each group.

Methodology

The data discussed in this report come from a larger study (Antonides, 2022) that examined five undergraduate students' reasoning about enumeration. Each student participated in one-on-one clinical interviews and teaching episodes. Pre- and post-assessments took the form of semi-structured interviews (Clement, 2000), and the remaining sessions with students took the form of teaching episodes. During teaching episodes, direct instruction was not the general pedagogical approach; rather, each student was posed with tasks, questions, and scenarios (e.g., digital environments) that we hypothesized, based on our current models of their mathematical understandings, would provoke an accommodation to their current ways of operating. Two tasks are relevant to the current report.

> *Rotational Tiling Task*: Write an expression for the number of tiles in the tiling shown here [students were shown the image in Figure 1c]. One tile is a shape like this [they were shown an example of one tile].
>
> *Extension Task*: If this tiling pattern were to continue, how many tiles would be in the next step of the tiling?

Data were collected remotely, via Zoom, in the Spring 2020 semester. Students used a laptop and an iPad in all video conference calls: the former to capture facial expressions and gestures, and the latter to capture students' inscriptions. Sessions were recorded to capture audio/video data.

This report focuses on the cases of Claire and Kira (pseudonyms). Both students were in their first year, were 18 years of age, and used she/her pronouns. Claire was an elementary education major enrolled in a first-semester content course for future teachers (focusing on number and operation), and Kira was a psychology major enrolled in an intermediate algebra course (a prerequisite for college algebra). All data pertaining to students' solutions to the Bars Task (see the Conceptual Framework) and to the Rotational Tiling Task were transcribed. Analytic memos and codes (Maxwell, 2013) were used to make inferences about the data. Particular attention was given to the types of numerical units that students seemed to construct, and on which they seemed to operate in order to build higher-level unit structures. We further identified moments in our data where students seemed to engage in S*-structuring, and we made inferences about the nature of students' S*-structuring.

Findings

Our analyses of the Bars Task suggested that all students were operating at units coordination Stage 3. Knowing that three medium bars make one large bar, and that four small bars make one medium bar, each student quickly reasoned that 12 small bars would make up one large bar, with the understanding that the large bar could be seen as three groups with four small bars in each group. It should be noted, however, that the Bars Tasks have been validated as a written instrument for assessing the units coordinating structures of middle school students (Norton et al., 2015), but not undergraduate students (including preservice teachers). To date, no such written instrument has been validated for the latter population.

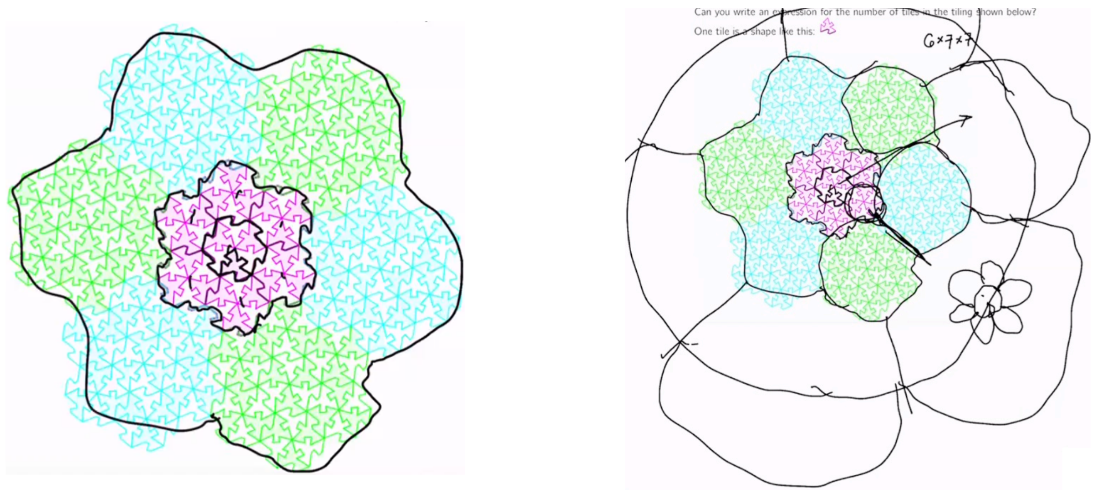
In describing our results and inferences, we use the terms 6TS to refer to a tiling structure consisting of six tiles (e.g., Figure 1a), 42TS to refer to a tiling structure consisting of 42 tiles (e.g., Figure 1b), and 294TS to refer to a tiling structure consisting of 294 tiles (e.g., Figure 1c), all with six-fold rotational symmetry.

The Case of Claire

Excerpt 1: Rotational Tiling Task. The interviewer read the Rotational Tiling Task to Claire, who immediately identified several embedded multiplicative group structures.

C: So, one of these. [She outlined a tile in the center 6TS; see Figure 2a.] The first time I would group those would be in this shape. [She outlined the entire 6TS.] And it looks like there's six of them. And then, the next grouping, I would say, is probably this shape. [She outlined the center 42TS.] And, in this one, it looks like there's one, two, three, four, five, six, seven [6TS structures]. So I'd probably say six times seven. … And then, I would do the same thing, but with this. [She outlined the entire 294TS.] And, um, I would define groups by the different colors. So this one [the center 42TS], in general, looks pretty pink. This one green, blue, and they all appear to be the same shape. And this also has seven [copies of 42TS in 294TS; see Figure 2a].

Claire's final answer to the Rotational Tiling Task was the written expression $6 \times 7 \times 7$.



(a) (b)

Figure 2. (a) Claire's illustration of four levels of units, and (b) her extension of the tiling pattern

Excerpt 2: Extension. The interviewer then read the Extension Task to Claire.

C: So, it would expand outward, I think. … I think there would be another ring, like this. So since this has, like, a *seam*, almost, with each, like, circle here [she drew a line segment separating two exterior 42TS in the original figure; see Figure 2b], I would probably say the same thing. It'd be like that… and another seam on each sort of thing.

Claire drew six large round figures along the exterior of the original tiling figure.

C: And then, I guess within each one, it would be all the levels before it. So, let's see. They would all start with an individual, and then a circle [6TS], and then this [42TS]. And then, like, this part [294TS]. … I guess I could probably copy it.

She then modified her multiplicative expression to $(6 \times 7 \times 7) \times 7$.

Analysis. In Excerpt 1, Claire established a multiplicative relationship between single tiles and one 6TS, constructing a level 2 unit (an instance of intra-composite structuring). She realized one 42TS could be made by iterating 6TS seven times, meaning she constructed 42TS as a level 3 unit. We interpret this as an instance of intra- and inter-composite structuring since she established a new unit as an organization of composite units. She expressed the number of tiles within one 42TS as 6×7. Finally, she established the entire image (one 294TS) as a level 4 unit structure (another instance of intra-/inter-composite structuring). To count the total number of tiles, she operated on her prior multiplicative expression, producing $(6 \times 7) \times 7$.

Claire's robust spatial/multiplicative reasoning becomes especially salient in the Extension Task. In this, she introduced the notion of a "seam" and used this concept to spatially structure units of 42TS within the 294TS. She then imagined, in mental activity, iterating units of 294TS along each seam, producing a new (level 5) unit structure—an instance of intra-/inter-composite structuring. Further, made clear in her verbal explanation and drawing in Figure 2b, she maintained the unit structures nested within each iteration of the 294TS.

The Case of Kira

Excerpt 3: Rotational Tiling Task. Kira approached the Rotational Tiling Task by first focusing on and counting the number of larger groups (42TS) in the figure.

K: So, I'm thinking I could count the number of tiles in each group. And then, um, multiply that by seven. And it would tell you the total number of tiles altogether.

To count the number of tiles in a larger grouping, she focused on the center 42TS. She counted six tiles in one smaller grouping (6TS), and she counted seven 6TS in the central 42TS.

K: So, six times seven, is 42. So, it looks like there's 42 tiles in one group. So… seven times 42, I feel like… would tell the number of tiles… tiles altogether? But just to be sure, I'm going to count the number of tiles in one of them, on the outside, because I don't want to just make that assumption about all of them.

To count the number of tiles in another 42TS, Kira shifted her focus to a 42TS on the right side of the tiling figure. She counted six tiles within one 6TS, and she counted seven 6TS within the grouping. She said $6 \times 7 = 42$, which she said was the same number of tiles that she found before. Feeling more confident that there are 42 tiles in each larger grouping, she concluded there are 42×7 tiles in the entire tiling. Using a calculator, she found the product to be 294.

Excerpt 4: Extension. Kira was then posed with the Extension Task.

K: So, like, would there be six more on the outside?

Int: Six more what?

K: Of the groups I've created, like the one, two—it looks like there's a group of 42. So, would there be six more of those groups on the outside, kind of?

Kira drew a picture, showing six 42TS structures added along the outside of the tiling figure, wedged between pairs of green and blue 42TS structures (see Figure 3).

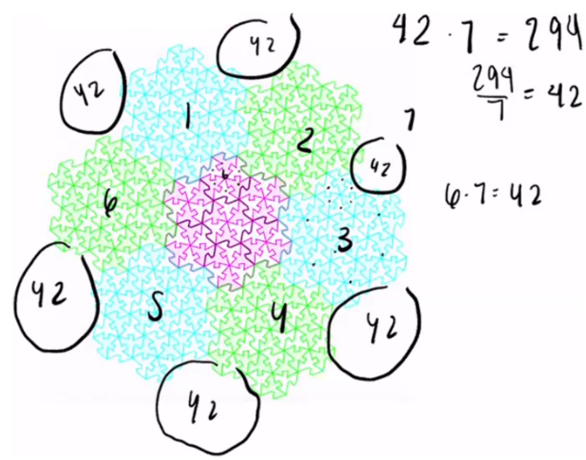


Figure 3. Kira's illustration of how the tiling pattern would continue

K: Now that I'm looking at the image again, I notice that it's like, odd, which is bothering me. So I don't know if there would be another circle somewhere else. But, I'm guessing since it's the same… number? Like the pattern of seven would continue.

Kira seemed to notice that there were seven 42TS in the original tiling, with seven 6TS in one 42TS, and from this she seemed to expect the "pattern of seven would continue." However, unlike Claire who conceptualized the original tiling image as a unit, and who iterated that unit so that seven copies were represented on the screen, Kira anticipated a seventh additional 42TS would need to be drawn, though she was unsure of where to draw it.

K: So I don't know where that one would go when it would continue after that. But, not looking at the image, I would just, um, take my original problem, 42 times 7, and make it 42 times 14? And I feel like that would give the number of tiles in total.

Int: Okay. Where's the 14?

K: Um. So the 14 came from seven plus seven, the number of tiles, if it would be—like this is me not looking at the image. Just, in my head. Since there were seven, I guess it would be, um, another seven. So 14. And there's 42 tiles in each group … 588.

Analysis. In Excerpt 3, Kira conceptualized the entire tiling as a level 3 unit structure. This was indicated by her strategy: count all tiles in one larger grouping (42TS), then multiply by the number of larger groupings (7). In counting the tiles in 42TS, Kira realized it consisted of seven smaller groupings (6TS), and so she multiplied 6×7, and thus she established 42TS as a level 3 unit. Unlike Claire who seemed to immediately anticipate a level 3 unit structure, Kira seemed to establish this unit structure in activity. She planned to operate on this level 3 unit by multiplying it by seven, but she expressed uncertainty. She became more confident only after performing 6×7 to count tiles in another 42TS. Even after she multiplied $42 \times 7 = 294$, finding the number of tiles in the original tiling image, she felt the need to check her answer by applying the inverse operation, $294 \div 7 = 42$, shown in Figure 3.

In Excerpt 4, Kira first extended the tiling pattern by constructing a spatial structuring with six additional 42TS. However—presumably noticing that there were seven 42TS in the original image—Kira anticipated that seven, rather than six, additional 42TS should be added in the extension, though she could not determine where to place the seventh structure. From this, she suggested there would be 42×14 tiles in the extended pattern. Kira, unlike Claire, did not seem to imagine a level 4 or level 5 unit structure. Rather, she created additional level 2 units (42TS) to create a larger level 3 unit.

Discussion and Conclusions

In this report, we set out to examine two undergraduate students' reasoning about the enumeration of tiles within a tiling of the plane using two analytical perspectives: units coordination and S*-structuring. While much work still needs to be done toward elaborating the relationship between these two perspectives (an avenue for future research), we believe this report offers initial steps toward this goal.

Claire established the tiling image in Figure 1c as a level 4 unit, clearly articulating and illustrating the multiple levels of units that she abstracted. She made several acts of intra-composite structuring and linked intra-/inter-composite structuring along the way, establishing 6TS as a level 2 unit, 42TS as a level 3 unit, and ultimately 294TS as a level 4 unit. Note that each level of unit is described as such because Claire could think about the four levels of multiplicative relationships that she built up to establish 294TS. She extended the tiling pattern by taking the 294TS as an object that she could iterate, guided by her spatial structuring of the original figure that was mediated by her notion of a "seam." Overall, Claire demonstrated S*NLS reasoning of a student who could establish, interrelate, and iterate four levels of units to construct a level 5 unit structure.

Kira enumerated tiles in the original tiling by establishing it as a level 3 unit—a unit of seven units, each containing 42 units. She separately counted each 42TS as a unit of six units, but she did not maintain this relationship, and it was not used in her enumeration of tiles in the tiling. In the Extension Task, Kira's S*NLS was distinguished from Claire's since her S*-structuring of the extended tiling was a level 3 unit—a unit of 13 (or 14) level 2 units—rather than an iterated level 4 unit.

“Just Get Rid of It:” Students’ Symbolic Forms for Cancellation

Kaitlyn Stephens Serbin
The University of Texas Rio Grande Valley

Rosaura Uscanga
Mercy College

Students use symbolic manipulations when performing cancellation as they solve equations. Rather than performing rote manipulation of symbols, we want students to understand the meanings that these symbols convey. In this paper, we examine three pre-service mathematics teachers’ symbolic forms for additive, multiplicative, and compositional cancellation. Students used symbol templates where they either wrote both the identity and inverses, one but not the other, or neither. We further explore students’ varied conceptual schemas associated with these templates, as well as the relationships that exist among these symbolic forms.

Keywords: Abstract Algebra, Cancellation, Symbolic Forms, Prospective Teachers

Symbols are ubiquitous throughout all mathematics. Instructors typically want their students to use symbols with an understanding of the meanings conveyed by the symbols (e.g., Sherin, 2001). Students’ reasoning about symbols can be analyzed using Sherin’s (2001) symbolic form construct, which is the association of the symbols one writes and their understanding of the meanings those symbols convey. Students’ symbolic forms are present in a variety of contexts, particularly when they reason with symbols while performing cancellation in secondary algebra and abstract algebra contexts. When students cancel terms, they might conceptualize this procedure as “getting rid of terms” or “moving terms to the other side.” This process of cancellation is much more complex than this, as it involves the use of the inverse group axiom, defined as for all elements $a \in G$ where $(G,*)$ is a group, there exists an inverse element $b \in G$, such that $a * b = b * a = e$, where e is the identity element in G. For example, when solving the equation $x + 3 = 1$, one adds the additive inverse of 3 to both sides of the equation to obtain $x + (3 + -3) = 1 + (-3)$, which implies that $x + 0 = -2$. This point of connection that prospective secondary mathematics teachers (PSMTs) can make between abstract algebra and secondary algebra has been the focus of several research studies (e.g., Murray & Baldinger, 2018; Serbin, 2021; Serbin, 2022; Wasserman, 2014). Wasserman (2014) suggested that teachers’ understanding of algebraic structures could support them in “unpacking the interconnected role of inverse and identity elements in the ‘cancellation’ or ‘simplification’ process” (p. 204). We refer to the process of adding an element’s additive inverse to that element to yield the additive identity 0 (e.g., $3 + -3 = 0$) as additive cancellation. We similarly refer to the process of multiplying an element by its multiplicative inverse to yield the multiplicative identity 1 (e.g., $3 \cdot 1/3 = 1$) as multiplicative cancellation. We also refer to the process of composing a function with its inverse to yield the identity function (e.g., $e^{\ln(x)} = i(x) = x$) as compositional cancellation. We hypothesized that students might have similar symbolic forms for these different types of cancellation, as they all involve the explicit or implicit use of inverse and identity elements. We explore the following research question: What symbolic forms do students have for cancellation involving additive cancellation, multiplicative cancellation, and compositional cancellation, and what relationships exist between these symbolic forms?

Literature Review and Theoretical Background

Symbols are used for a variety of purposes in mathematics, some of which include communicating meaning, notating concepts and processes, and illustrating relationships between mathematical objects (Zandieh et al., 2017). Researchers have focused on students' symbol sense (Arcavi, 1994) and their practice of symbolizing, which is broadly defined as reasoning with inscriptions (Zandieh & Andrews-Larson, 2019). Some of this work has addressed students' symbolization in calculus (e.g., Jones, 2013) and linear algebra contexts (e.g., Henderson et al., 2010; Smith et al., 2022; Zandieh & Andrews-Larson, 2019). Reasoning with symbols involves both creating symbols to convey meaning and interpreting the meaning in inscriptions. Sherin (2001) suggested, "The particular arrangement of symbols in an equation expresses a meaning that can be understood" (p. 480). Sherin claimed that students should understand the meanings that the symbols and manipulations convey: "We do not want meaningless symbol manipulation; if students use symbolic expressions, we want them to use the symbols with understanding" (Sherin, 2001, p. 479). However, this is a nontrivial task for students. Furthermore, students often have different interpretations of symbols' meanings (e.g., Jones, 2013). Reasoning with symbols is a central activity in mathematics, so students should have productive understandings of the meanings symbols convey and draw on them as they perform symbolic manipulations.

Students use symbolic manipulations while performing algebraic cancellation as they simplify expressions and solve equations. Instead of performing rote cancellation without attending to the meaning of the symbols or manipulations, students should understand the properties used to manipulate symbols in equations. The properties that allow one to cancel terms while solving equations are the inverse and identity axioms of groups and rings. Wasserman (2014) suggested that understanding these algebraic structures could support teachers in "unpacking the interconnected role of inverse and identity elements in the 'cancellation' or 'simplification' process" (p. 204). Serbin (2021; 2022) found that reasoning about group and ring axioms helped PSMTs understand the shared structure of additive, multiplicative, and compositional identities and inverses. Interpreting the symbols and symbolic manipulations used while canceling terms may involve making sense of how the inverse elements are operated together to yield the identity. In this study, we focus on students' understandings associated with their symbols used in additive, multiplicative, and compositional cancellation. To do so, we leverage Sherin's (2001) construct of symbolic forms.

Symbolic forms (Sherin, 2001) are cognitive resources (Hammer, 2000) that students can activate as they do mathematics. A *symbolic form* is an association of a conceptual schema with a symbol template. A *conceptual schema* is the meaning that symbols convey, and the *symbol template* is the structure or arrangement of written symbols that expresses that meaning. Sherin asserted students develop symbolic forms by associating meaning with the structures symbolized in equations. This association can occur as students write symbolic expressions or interpret them. One symbol template can be associated with several conceptual schemas, and one conceptual schema may be associated with multiple symbol templates (e.g., Jones, 2013). The template-schema pair that students choose to activate while solving a problem depends on the framing or context of the situation (Hammer et al., 2005). We investigate the relationships between the symbolic forms that students activate for the three different types of cancellation.

Methods

Three PSMTs, Amelia, Christina, and Derek, who majored in Mathematics, participated in this study. Each was enrolled in a senior-level Mathematics for Secondary Teachers course at a large university in the US. During the course, the students learned how the properties of groups and rings were used to justify the procedures used to solve equations. Two individual 60-minute task-based clinical interviews (Clement, 2000) were conducted with each of the PSMTs. These two interviews were designed to elicit evidence of the PSMTs' understanding of the content covered in the two course instructional units. The first interview was conducted after the unit on ring properties and equation solving. The second was conducted after the unit on functions and inverses. Some of the interview tasks prompted students to solve equations and describe the properties used and show that two functions are inverses. Given the semi-structured nature of these interviews, the PSMTs were all given the same tasks but were asked different unplanned follow-up questions based on their responses. Both interviews were conducted virtually and transcribed. Copies of the PSMTs' written work from their task responses were also collected.

We analyzed the transcripts and task responses to identify the symbolic forms the PSMTs used to perform cancellation while solving equations. We first classified the type of cancellation according to the operation involved: additive, multiplicative, or compositional. We then inductively coded (Miles et al., 2013) the transcripts by assigning each instance of cancellation present a code that captured the essence of the symbol template and a code that captured the essence of the conceptual schema evident in the data. Each task response contained multiple codes. Furthermore, there were cases in which multiple conceptual schemas were associated with one symbol template, so each of those symbol template-conceptual schema pairs was coded separately. We coded the symbol templates and conceptual schemas together to reach an agreement on the assignment of each code. After, we performed axial coding to group the symbolic forms into broader categories. We identified four axial codes that captured the essence of every symbol template used in these PSMTs' written work of canceling terms: the participant wrote (a) both the identity and inverses, (b) the inverses but not the identity, (c) the identity but not the inverses, and (d) neither the identity nor the inverses. We lastly examined which relationships exist between these symbolic forms. For each participant, we identified the different conceptual schemas that were associated with each of the four symbol template categories. We wrote analytic memos (Maxwell, 2013) to describe patterns and inconsistencies that were present in each participant's use of symbolic forms representing the different types of cancellation and used these to compare the symbolic forms used by each student.

Results

As follows, we describe the four types of symbol templates for cancellation. The symbolic forms for each type of template are presented in Figures 1-4. In the symbol templates, { } refers to an expression with multiple terms, [ ] refers to a monomial, c_i refers to constants, a, b, c refer to set elements, f, f^{-1}, g refer to functions, and $\Longrightarrow$ refers to an implication.

No Attention to Inverses or Identity

All students used symbol templates for multiplicative and additive cancellations that did not contain symbols for the inverses and identity (see Figure 1). Amelia's conceptual schemas were focused on algebraic operations rather than on the structure of operating inverses together to get an identity. She used her conceptual schemas to justify "getting rid of terms" but did not focus on the inverse-identity structure. Christina also seemed to have a computational focus. An exception was when she referred to using multiplicative inverses, however, she only used the terminology to justify removing or "getting rid of" a coefficient. She was the only student who did not write the inverse or identity elements when performing compositional cancellation. Her conceptual schema in this case was still focused on the procedure of doing something to both sides of the equation. Derek demonstrated an understanding of the structure of operating inverse elements together to obtain the identity, even when he did not write out inverse or identity elements. Overall, students tended to ignore inverses and identity when getting the answer or simplifying expressions, moving terms over, getting rid of terms, or operating on both sides of the equation.

Attention to Inverses but Not Identity

Symbol templates containing inverses but not the identity occurred in all cancellations. Students attended to inverses but ignored the identity when doing something to both sides of the equation or getting rid of terms (see Figure 2). Amelia's conceptual schemas focused primarily on the operations that needed to be performed, rather than on the structure of operating inverses together to get an identity. However, when performing compositional cancellation, she used the "operate inverse elements together to get identity" conceptual schema to explain why e and ln cancel. Christina's conceptual schemas were focused on doing something to both sides of the equation to get rid of terms. Derek's conceptual schemas focused on the inverse-identity structure even when his symbol template did not contain the identity. This was how he justified simplifying, getting rid of terms, or doing something to both sides of the equation.

Attention to Identity but Not Inverses

Students used symbol templates that contained the identity but not inverses while performing additive cancellation (see Figure 3) when the additive identity was the only term left on one side of the equation. Amelia used this template when doing something to both sides of the equation.

	Symbol Template	Conceptual Schema	Student who Used Form
Multiplicative Cancellation	1. $c_1\{\ \} = c_2\{\ \} \Rightarrow \{\ \} = c_3\{\ \}$	Move over	Amelia
	3. $c_1\{\ \} = c_2 \Rightarrow \{\ \} = c_3$	Do something to both sides	Derek
		Use inverses (no attention to identity)	Derek
	4. $\frac{[\ ]}{\{\ \}} = [\ ] \Rightarrow [\ ] = [\ ]\{\ \}$	Do something to both sides	Amelia
		Get rid of something	Amelia
		Get the answer/simplify	Amelia
	8. $\frac{[\ ]}{[\ ]\{\ \}} + \frac{c_1\{\ \}}{[\ ]\{\ \}} = \frac{c_2}{[\ ]\{\ \}} \Rightarrow [\ ] + c_1\{\ \} = c_2$	Do something to both sides	Amelia
		Get rid of something	Amelia
		Get the answer/simplify	Amelia
		Use inverses (no attention to identity)	Amelia
	11. $c_1\{\ \} = c_2 \Rightarrow \{\ \} = \frac{c_2}{c_1}$	Get rid of something	Christina
		Use inverses (no attention to identity)	Christina
	15. $c_1[\ ] = c_2 \Rightarrow [\ ] = c_3$	Do something to both sides	Derek
		Get the answer/simplify	Amelia, Christina
		Use inverses (no attention to identity)	Derek
		Operate inverses together to get identity	Derek
Additive Cancellation	2. $[\ ] + c_1 = [\ ] + c_2 \Rightarrow [\ ] + [\ ] = c_2 - c_1$	Move over	Christina
	4. $[\ ] + c_1 = c_2 \Rightarrow [\ ] = c_3$	Move over	Derek
		Do something to both sides	Derek
		Get the answer/simplify	Amelia, Christina, Derek
		Use inverses (no attention to identity)	Derek
	14. $\{\ \} + c_1 = c_2 \Rightarrow \{\ \} = c_3$	Move over	Christina, Derek
		Get the answer/simplify	Amelia
		Uses inverses (no attention to identity)	Derek
Compositional Cancellation	2. $\{\ \}^k = c_1 \Rightarrow \pm\{\ \} = c_1$	Do something to both sides	Christina

Figure 1. Symbol Templates Containing No Inverses and No Identity

	Symbol Template	Conceptual Schema	Student who Used Form
Multiplicative Cancellation	2. $c_1\{\ \} = c_2 \Rightarrow \frac{c_1\{\ \}}{c_1} = \frac{c_2}{c_1} \Rightarrow \{\ \} = c_3$	Move over	Amelia
	6. $\{\ \} \cdot \frac{[\ ]}{\{\ \}} = \{\ \} \cdot [\ ] \Rightarrow [\ ] = \{\ \} \cdot [\ ]$	Do something to both sides	Derek
		Get rid of something	Derek
		Operate inverses together to get identity	Derek
	7. $c_1[\ ] = c_2 \Rightarrow \frac{1}{c_1} \cdot c_1[\ ] = c_2 \cdot \frac{1}{c_1} \Rightarrow [\ ] = c_3$	Use inverses (no attention to identity)	Derek
	9. $\left(\frac{c_1}{\{\ \}} + \frac{c_2}{[\ ]} = \frac{c_3}{[\ ]\{\ \}}\right) \cdot ([\ ]\{\ \}) \Rightarrow [\ ] + c_2\{\ \} = c_3$	Do something to both sides	Christina
		Get rid of something	Christina
	10. $[\ ]\{\ \} \cdot \frac{\{\ \}}{[\ ]\{\ \}} = \frac{c_1}{[\ ]\{\ \}} \cdot [\ ]\{\ \} \Rightarrow \{\ \} = c_1$	Do something to both sides	Derek
		Get rid of something	Derek
	16. $c_1[\ ] = c_2 \Rightarrow \frac{c_1[\ ]}{c_1} = \frac{c_2}{c_1} \Rightarrow [\ ] = c_3$	Do something to both sides	Amelia
Additive Cancellation	1. $[\ ] + c_1 = [\ ] + c_2 \Rightarrow [\ ] + c_1 \pm [\ ] \pm c_1 = [\ ] + c_2 \pm [\ ] \pm c_1$	Move over	Amelia
		Do something to both sides	Amelia
		Get rid of something	Amelia
	3. $\{\ \} = [\ ] + c_1 \pm [\ ] \Rightarrow \{\ \} = c_1$	Move over	Derek
		Do something to both sides	Derek
		Use inverses (no attention to identity)	Derek
		Operate inverses together to get identity	Derek
	6. $[\ ] + c_1 = 0 \Rightarrow [\ ] + c_1 \pm c_1 = 0 \pm c_1$	Do something to both sides	Derek
		Use inverses (no attention to identity)	Derek
	9. $[\ ] + c_1 \pm c_1 = c_2 \pm c_1 \Rightarrow [\ ] = c_3$	Move over	Christina
	10. $[\ ] + c_1 \pm c_1 \Rightarrow [\ ]$	Get the answer/simplify	Amelia, Derek
	12. $\{\ \} + c_1 \pm c_1 = c_2 \pm c_1 \Rightarrow \{\ \} = c_3$	Use inverses (no attention to identity)	Christina
	15. $\{\ \} + c_1 \pm c_1 \Rightarrow \{\ \}$	Get the answer/simplify	Amelia
	16. $[\ ] + c_1 = c_2 \Rightarrow [\ ] + c_1 \pm c_1 = c_2 \pm c_1$	Move over	Amelia
		Do something to both sides	Amelia
	17. $\{\ \} + c_1 = c_2 \Rightarrow \{\ \} + c_1 \pm c_1 = c_2 \pm c_1$	Move over	Amelia
		Get rid of something	Christina
Compositional Cancellation	1. $\{\ \}^k = \left(\{\ \}^{\frac{1}{k}}\right)^k \Rightarrow \{\ \} = \{\ \}$	Do something to both sides	Christina
		Get rid of something	Christina
	3. $\{\ \}^k = \left(\sqrt[k]{\{\ \}}\right)^k \Rightarrow \{\ \} \cdots \{\ \}$ (k times) $= \{\ \}$	Do something to both sides	Derek
	4. $\left(\sqrt[k]{\{\ \}}\right)^k = (c_1)^k \Rightarrow \{\ \} = c_2$	Do something to both sides	Amelia, Derek
		Get rid of something	Derek
		Get the answer/simplify	Derek
		Use inverses (no attention to identity)	Amelia
	5. $\left(\{\ \}^{\frac{1}{k}}\right)^k = (c_1)^k \Rightarrow \{\ \} = c_2$	Get rid of something	Christina
		Get the answer/simplify	Christina
	6. $\ln\{\ \} = c_1 \Rightarrow e^{\ln\{\ \}} = e^{c_1}$	Do something to both sides	Amelia
		Operate inverses together to get identity	Amelia
	7. $\{\ \}^k = c_1 \Rightarrow \sqrt[k]{\{\ \}^k} = \sqrt[k]{c_1}$	Do something to both sides	Amelia
		Get rid of something	Amelia
	8. $e^{\ln(c_1)} = c_1$	Get rid of something	Derek
		Use inverses (no attention to identity)	Amelia
	11. $\left(\sqrt[k]{[\ ]}\right)^k = [\ ]$	Get the answer/simplify	Amelia, Derek
	12. $\sqrt[k]{\{\ \}^k} = \{\ \}$	Get the answer/simplify	Amelia, Derek

Figure 2. Symbol Templates Containing Inverses but Not Identity

However, her conceptual schema did not involve any attention to the identity. Christina and Derek did not attend to the identity when canceling except when they wrote 0 on one side of the equation to not leave it blank. However, even when Derek did not write out inverses, his conceptual schemas referenced the structure of operating inverses together to get the identity.

	10. $f(f^{-1}(x)) = x = f^{-1}(f(x))$	Operate inverses together to get identity	Amelia

Figure 4. Symbol Templates Containing Both Inverses and Identity

Attention to Both Inverses and Identity

When the students used cancellation symbol templates that included symbolizations of both inverses and the identity, their associated conceptual schemas focused on the structure of operating inverse elements together to yield the identity element (see Figure 4). Amelia exhibited the "operate inverse elements together to get identity" conceptual schema for multiplicative cancellation only when she was working on abstract algebra tasks. She did not attend to the inverses and identity while solving equations. Furthermore, her symbol template for compositional cancellation contained symbols for the inverses and identity only when verifying that two given functions are inverses of each other. On the other hand, when Christina's symbol templates for additive and multiplicative cancellation contained symbols for the inverses and identity, her conceptual schemas were focused on the inverse-identity structure, i.e., that operating inverse elements together yields the identity. In regard to Derek, when his symbol templates for multiplicative and compositional cancellation included both the inverses and identity, his conceptual schema also referred to the inverse-identity structure of operating inverses together to get the identity. When Derek's symbol template for additive cancellation contained symbols for the inverses and identity, his demonstrated conceptual schema only focused on using inverses, without explicit attention to the identity.

Discussion and Conclusion

We examined three students' symbolic forms for additive, multiplicative, and compositional cancellation. We found that the students used four general types of symbol templates, in which they wrote (a) both the identity and inverses, (b) the inverses but not the identity, (c) the identity but not the inverses, and (d) neither the identity nor the inverses. We then examined the varied conceptual schemas associated with these templates. Amelia only explicitly attended to both multiplicative inverse and identity in the context of abstract algebra tasks and functional inverse and identity only in tasks that required her to determine if two given functions are inverse pairs. However, she did not attend to the structure of both inverse and identity as she performed cancellation while equation-solving. Amelia's evoked conceptual schema seemed to depend on her framing of the task. Ticknor (2012) had a similar finding that teachers' understandings of commutativity, associativity, and inverses were only situated in abstract algebra settings. Christina's symbolic forms were mainly procedural in nature. She attended to the structure of both inverse and identity only for multiplicative and additive cancellation. Her conceptual schemas focused on the equation solving process, as evident in her explanations of moving terms over, doing something to both sides, or getting rid of a term. She did not use any symbol templates that contained symbols for both inverse functions and the identity function when she performed compositional cancellation. She thus did not focus on the structure of the composition of inverse functions yielding the identity function while performing that cancellation. Finally, Derek's symbolic forms always demonstrated an understanding of the structure of operating inverses together to get the identity. Even in cases where he did not write out the identity or inverses, it was clear that he was aware of the inverse-identity structure in the cancellation.

As Amelia's and Christina's conceptual schemas demonstrate, having an understanding of abstract algebra concepts does not necessarily imply students can automatically use it to make sense of secondary mathematics content like equation solving. In Amelia's case, she only attended to both multiplicative inverses and identity in the context of abstract algebra where she is more likely used to that terminology and reverted back to procedural equation-solving, without attention to the inverse or identity, in most other situations. Ideally, teacher educators want PSMTs to understand that operating an element with its inverse yields the identity and be able to use that in other situations. We hypothesize that solving equations while attending to the structure of the inverse, identity, and binary operation will allow students and PSMTs to develop meaningful understandings of the symbolic manipulations involved in equation solving.

Our findings have some implications for teaching and future research. Mathematics instructors who prepare PSMTs should prompt PSMTs to explicitly write out the symbols used to represent inverses and identities while solving equations. Instructors should also guide students to identify which group or ring properties are used while solving equations. This has been found to be a fruitful way for undergraduate students and PSMTs to connect abstract algebra and secondary algebra (e.g., Cook, 2012; Cook, 2015; Murray & Baldinger, 2018; Wasserman, 2014). We intend to extend this analysis of the relationships that exist among students' symbolic forms for different types of cancellation. Future research can explore how mathematics teacher educators can guide PSMTs to make connections across abstract and secondary algebra that are not only situated in abstract algebra contexts.

“The Shape Will Have No Volume”: Relationships Students Observed about Determinants in a Dynamic Geometric Applet

Megan Wawro	Matt Mauntel	David Plaxco
Virginia Tech	University of New Hampshire	Clayton State University

We discuss two Dynamic Geometry Software applets designed as part of an Inquiry-Oriented instructional unit on determinants and share students' generalizations based on using the applet. Using the instructional design theory of Realistic Mathematics Education, our team developed a task sequence supporting students' guided reinvention of determinants. This unit leverages students' understanding of matrix transformations as distortion of space to meaningfully connect determinants to the transformation as the signed multiplicative change in area that objects in the domain undergo from the linear transformation. The applets are intended to provide students with feedback to help connect changes in the matrix to changes in the visualization of the linear transformation and, so, to changes in the determinant. Critically, the materials ask students to make generalizations while reflecting on their experiences using the applets. We discuss patterns among these generalizations and implications they have on the applets' design.

Keywords: Determinants, dynamic geometry software, inquiry, student reasoning

Matrix determinants are often taught formulaically, obscuring geometric connections between determinants and linear transformations. The Inquiry-Oriented Linear Algebra (IOLA) curricular materials (Wawro et al., 2013) build from experientially real task settings that allow for active student engagement in the guided reinvention of mathematics through student and instructor inquiry (Gravemeijer, 1999). The IOLA determinants task sequence uses distortion of space as an experientially real starting point to support students’ development of determinant as a measure of (signed) multiplicative change in the area. The sequence uses GeoGebra applets that allow students to actively explore the geometric effects of changing 2x2 and 3x3 matrix transformations and note their effect on the determinant. Through exploration of the applet, students observe links between the determinant and concepts such as linear (in)dependence, span, and invertibility, as well as how changes in matrix entries impact the determinant. In this study, we investigate the research question: Based on interacting with our curriculum's dynamic geometry applets, what relationships do students observe between matrices, determinants, and geometric objects transformed by the associated linear transformation?

Theoretical Background and Literature Review

According to Axler (1995), “determinants are difficult, non-intuitive, and often defined without motivation” (p. 139). Aygor and Ozdag (2012) found that students have difficulty identifying what happens to the determinant when switching rows, multiplying a column by k, row-reducing a matrix, and performing column operations. This might be because of difficulties relating the numeric, algebraic, and geometric aspects of the determinant (Durkaya et al., 2011) or the reliance of the determinant on bilinearity (Donevska-Todorova, 2016). These difficulties would be mitigated by connecting to students’ existing reasoning and understanding, as is consistent with the curriculum design theory of Realistic Mathematics Education (RME; Freudenthal, 1991). Adopting this theoretical framing for our curriculum design, we identified students’ understanding of matrix transformations as distortions of space as an experientially real starting point for developing notions of determinant. We sought to design an activity that could support students in establishing an understanding of determinants as a measure of how matrix transformations distort space and then leverage these connections toward more general properties of determinants. We situate this work within our research group's design research (NSF DUE 1915156, 1914841, 1914793), referred to as a Design Research Spiral, in which the design team iteratively drafts, implements, reflects, and refines the task sequence as guided by multiple design research theories at each cycle of refinement (Wawro et al., 2022). This paper presents materials and results from the penultimate cycle of refinement for this unit.

In order to support students' generalizing from their situated activity, we turned to Dynamic Geometric Software (DGS), which synchronously display dynamic representations of numeric, geometric, and algebraic aspects of the determinant. This makes DGS a suitable tool for supporting students' exploration of determinants and connecting this to geometric and algebraic knowledge. research has shown that DGS applets allow students to investigate, visualize, make predictions, calculate, simulate, and generalize certain situations, all of which are critical practices for inquiry (Gol Tabaghi & Sinclair, 2013; Gol Tabaghi, 2014; Greefrath et al., 2018; Hollenbrands, 2007; Paoletti et al., 2020; Zandieh et al., 2018). In linear algebra, applets, games, and simulations have been used to explore key topics such as linear combinations (Mauntel et al., 2021), eigentheory (Gol Tabaghi & Sinclair, 2013; Gol Tabaghi, 2014), and determinants (Donevska-Todorova, 2012, 2016; Donevska-Todorova & Turgut, 2022).

Donevska-Todorova (2012) used DGS to support students' exploration of determinants in a teaching experiment setting and found that DGS can help build meaningful connections between the determinant and conceptions of area in 2D. The author attributes the DGS's ability to simultaneously display numeric and geometric feedback as important for connecting to students' prior geometric understanding. However, Donevska-Todorova's setting is more focused on direct instruction and approaches the determinant as a way to calculate the area of a parallelogram at the origin whose sides correspond to the column vectors of the matrix, rather than connecting the geometry to the linear transformation defined by the matrix. In our materials, and consistent with the above cited literature, we designed the materials so that students contextualize the DGS relative to their existing notions of linear transformations. The goal is that this additional context will provide students with a foundation for the connections they make while using our applet.

The Determinants Task Sequence

The main goal of this unit is to build from students' knowledge of matrices as representations of linear transformations towards a conceptualization of the determinant of a 2x2 or 3x3 matrix as a measure of (signed) multiplicative change in area or volume, respectively. Task 1 is designed to support students toward suggesting *change in area* as a way of quantifying distortion that objects undergo from specific matrix transformations. In Task 2, students reinvent the 2x2 determinant formula so that by the end of Task 2, when the term *determinant* is introduced, the class has developed the notion of the determinant of a 2x2 matrix A as: (1) the signed area scaling factor of the linear transformation defined by A [i.e., the multiplicative change in area]; (2) the signed area of the unit square's image under A; (3) the signed area of the parallelogram created by the columns of A; and (4) $det(A) = ad - bc$, for $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$. The main goal of Task 3 is for students to reinvent $det(A^{-1}) = 1/det(A)$ for invertible matrices by coordinating their knowledge of invertible linear transformations with their developing understanding of determinants as a measure of change in area. Tasks 1 and 3 provide space for students to use their understanding of composition of functions to reinvent $det(AB) = det(A)det(B)$ for matrices A and B and justify them via change in area lines of reasoning.

In Task 4, students further explore the geometric interpretation of matrix transformations and their determinants via GeoGebra applets for 2x2 and 3x3 matrices, which can be found at https://www.geogebra.org/u/iolalinearalgebra. Each applet consists of a matrix, sliders to control each entry in the matrix, a real-time calculation of the matrix determinant, and a real-time dynamic parallelogram or parallelepiped showing the image of the unit square or cube under the matrix transformation. As shown in Figure 1, both applets have sliders (a) & (h) that students use to change the matrix entries. The applets also calculate the determinant of the matrix in real-time as the user changes the entries of the matrix (b) & (i). In the 2x2 applet, users can see (and alter) a geometric representation of a preimage object (c) composed of a yellow vector, blue vector, the parallelogram they form, and the inscribed ellipse (defaulted to the standard basis vectors, unit square, and its inscribed circle). Users can change this shape by moving the terminal endpoints of the yellow and blue vectors (d). These color-coded vectors correspond with their images under the transformation (e). In the 3x3 applet, the preimage is fixed as the unit cube (defined by the standard basis vectors) and is not shown or alterable because of the complexity of programming such an object in GeoGebra. In both applets, the image of the respective image is shown on the right side of the screen (f) & (j) and changes color from green to red when the matrix determinant is negative. Users can reset the applet (g) & (k), which will revert the matrix back to the identity matrix and, in the 2x2 applet, will reset the preimage to the unit square.

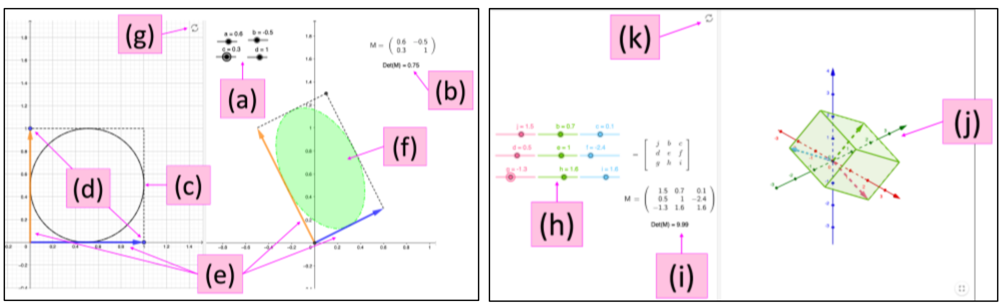

Figure 1. Screenshots of the two determinant applets, with markers (a) - (k) to help explain the applet components.

With the applet components, students are able to create any matrix within the constraints of the parameters (between -4 and 4, in increments of 0.1) and see how the changes affect the distortion of the image of the unit square or cube. Consistent with Rumack and Huinker (2019), Task 4 explicitly champions the role of mathematical curiosity as students explore, observe, conjecture, and justify; this allows students' mathematics to be what is leveraged and furthered. Adopting the RME design heuristic of guided reinvention, the instructor’s role includes facilitating students' open-ended activity toward more organized and focused statements or generalizations connecting changes in matrices to changes in the distortion of the space and how they relate to determinants.

Methods

The data for this study come from in an in-person introductory linear algebra class at a large, public, research university in the Mid-Atlantic region of the US. There were 27 students in the course, 13 of whom gave consent and completed the assignment analyzed here. In the university system, eight of these students chose he/him/his pronouns (pseudonyms begin with “M”), four chose she/her/hers pronouns (pseudonyms begin with “W”), and one did not choose pronouns (pseudonym P1). Most were second-year students by credit hours and were general engineering majors. The prerequisite was a B or higher in Calculus I or a passing grade in Calculus II.

The data analyzed and present herein are student responses to a written reflection. After most class sessions, students were asked to complete a reflection by the end of the day and submit their work via an online learning management system. Students were asked to spend 5-10 minutes on a reflection, for which full credit was awarded based on effort rather than correctness. The following is the reflection prompt analyzed in this paper: "We covered a lot of ground in class today! Let's focus on the applets and what they helped you understand. Give at least two observations you made from using either/both applet(s). State it in words / mathematical symbols and illustrate with a snapshot from the applet(s) to help convey it. If you have started to think about "why" for the observation, go ahead and include that, too." The prompt also included the URLs for the applets and a reminder that the class slides were on the course cloud-based folder.

To analyze the data in service of our research question, we aimed to understand what observations students made from their interactions with the determinant applets. Extending our previous preliminary analysis with a similar data set (Kerrigan et al., 2012), we first focused on three aspects of students' responses that align with features of the applets that users attend to: a user can notice (changes in) the entries of the matrix, (changes in) the value of the determinant of the matrix, or (changes in) the graphical appearance of the transformed object. For brevity, we label these as pertaining to the matrix [M], the determinant value [D], or the graphical imagery [G]. For each student response, we coded phrases as M, D, G, or "other." Distinctions between phrases were indicated by transition words such as "if," "then," "and," and "because," as well as by punctuation use. To establish viability of the coding scheme, two of the authors independently analyzed about half of the data according to these codes, and obtained a high level of agreement. These authors explained their codes and rationales to the third author and then all authors coded the remainder of the data set, again reaching near-total agreement. We expected and thought it natural that an observation from the applet would likely involve at least two phrases (e.g., "when I change this entry in the matrix" [M], "the determinant stays the same" [D]). Thus, we examined the data for relationships between phrases, looking for any causality or logical structure in the relationships (e.g., the aforementioned example has an implied if-then structure, so it would be coded as [M⇒D]). We referred to the phrases paired with their logical structure and additional supportive justifications (if they existed), as observations. Such an analysis is important to us as instructors and curriculum designers because the structure in these initial student observations is foundational in setting the stage for the co-development of key theorems (such as "Suppose A is a nxn matrix; A is not invertible $\Leftrightarrow det(A) = 0$"), and they grow out of students inquiring into the mathematics and the instructor inquiring into student reasoning (Rasmussen & Kwon, 2007).

Results

From the phrases within the 13 student responses, we found 43 phrases pertaining to the matrix [M], 41 phrases pertaining to the determinant [D], and 24 phrases pertaining to the graphical appearance of the transformed object [G]. Overall, we found there to be 42 observations. We organize the remainder of this section according to summaries of each of the three main phrase categories and then a summary of the various student applet observations.

Summary of results at the individual phrase level

First, 43 of the phrases pertained to aspects that students noticed regarding the matrix [M] in the 2x2 or 3x3 applet. 16 of these phrases related to the columns of the matrix forming a linearly dependent set. Although only 5 of the phrases say linear dependence explicitly, the other phrases give specific examples of linear dependence: the matrix entries being the same number (2), at least two columns being scalar multiples (2), and the matrix containing a column of zeros (7). As researchers, we grouped the latter three as types of linear dependence, but we cannot know if the students who wrote them were considering that concept as they wrote their phrases. The bulk of the remaining phrases coded with [M] had the common trait of focusing on changes in the matrix entry. Students wrote phrases about individual matrix entries or multiple entries (e.g., the values of the diagonal components), as well as about interchanging two columns, and multiplying row(s) or column(s) by a constant. As previously mentioned, the identity matrix is what first appears when opening or refreshing the applet, and the students are able to manipulate each individual matrix component. To reason about the ideas related to linear dependence and the ones related to multiplying a row, column, or the whole matrix by a constant, students had to set the entries to be the values they desired. On the other hand, for phrases that focus on "as an entry changes," the phrase has a more dynamic character. These are further detailed in the next section.

Second, 41 of the phrases pertained to observations the students made regarding the value of the determinant [D] that appeared in either the 2x2 or 3x3 applet or its computation. 15 of the phrases focused on a zero determinant value, 6 phrases focused on noticing a negative determinant value or a change in its sign, and 2 phrases highlighted an unchanging determinant value. Third, 24 phrases pertained to the graphical appearance of the transformed object [G] in either applet. Of these, 8 mention the resulting parallelepiped's volume (one also mentioned the resulting parallelogram's area in the 2x2 applet); more specifically, all but one mention a volume (or area) of zero. We group another 7 of the phrases together because they relate to the object losing dimension (e.g., the vectors are on the same line), and 5 phrases were other observations about the resulting image (such as flipping orientation). Finally, 2 students included snapshots of the 2x2 applet, 7 included snapshots of the 3x3 applet, and 4 did not include any snapshots. We did not code the images with [M], [D], or [G] unless a student explicitly referenced them in their written explanation. This occurred 4 times (twice for two students), all of which were coded [G].

Summary of results at the observation level

The prompt that students responded to stated "Give at least two observations you made from using either/both applet(s)." We referred to the phrases paired with their logical structure and any supportive justifications as observations. Consider student M1's response as an exemplar:

> "If a column has all zeros, the determinant is 0, and if the determinant is zero, the shape has no volume in the third dimension. Thinking about the determinant as (new volume)/(old volume), we can algebraically see that the numerator must be zero for the quotient to be zero. Also, if one of the column vectors is the zero vector, the shape does not span all three dimensions so it cannot possibly contain a volume"

We coded "If a column has all zeros" as [M], "the determinant is zero" as [D], and "the shape has no volume in the third dimension" as [G]. In the first part of M1's response, we coded two observations with these three phrases: [M⇒D] and [D⇒G]. The middle portion of his response, in which he brings in knowledge about the determinant as "(new volume)/(old volume)" and "the numerator must be zero for the quotient to be zero" was coded as "other" because it is something that the student could not directly observe in the applet itself. We coded "one of the column vectors is the zero vector" as [M], "the shape does not span all three dimensions" as [G], "it cannot possibly contain a volume" as [G], and paired those as observations [M⇒G] and [G⇒G].

Overall, our analysis shows that a vast majority of the observations that the students made began with a matrix statement [M]. In fact, only 5 of the 42 observations started with a statement about the graph [G] or the determinant [D] (see Figure 2). Relating back to the previous section, the [G] phrases mentioned were about the shape or the volume of the resulting parallelepiped.

Observation		
Phrase One	*implies*	*Phrase Two*
The shape does not span all three dimensions [G]		It cannot possibly contain a volume [G]
At least 1 dimension of the image would be 0 [G]		To the whole area/volume to be 0 [G]
When a matrix creates just a line or a plane [G]		The determinant would be zero [D]
The determinant is zero [D]		The shape has no volume in the third dimension. [G]
The determinant is zero [D]		Image was either flat or a straight line [G]

Figure 2. The 5 observations that started with a graphical statement [G] or determinant statement [D].

The most common type of observation was what we refer to as [MDG], by which we mean the student observation was of the form "[M] implies [D], which makes sense because of [G]." For example, M8 wrote, "If any of the columns in the 3x3 are LD with another, the det(M) will be zero due to there being no volume, only area or a line." He noticed when a certain matrix characteristic [M] occurred that a certain determinant value occurred [D], which he explained as sensible because of the corresponding graphical imagery [G]. We posit this likely corresponds to the nature of student activity while interacting with the applet: first manipulate the matrix, notice things about the determinant, and explain that in terms of what you see geometrically. Another example of an [MDG] is W4's observation (coding in the data): "One observation I made was that if the set is linearly dependent [M] or has two or more vectors that are scalar multiples [M], the determinant will be zero [D]. I found out after our discussion that this is because the vectors will be all on the same line [G] and therefore the shape will have no volume [G]."

As stated above, some observations conveyed a dynamic character, meaning that the student was most likely actively changing something in the applet while noticing the associated impact of that dynamic action. For example, M3 stated, "When observing the 3x3 applet in class today, I noticed that entries a_{11}, a_{22}, and a_{33}, as well as sometimes a_{13} and a_{31} were the only entries that changes the volume of the image," and M9 stated, "when moving the last column the 'footprint' didn't move, it just wobbled around like jelly." Both these observations are of the type [M⇒G]. We hypothesize that, for instance, M3 was dragging the slide for entry a_{11} and noticing the simultaneous change in the parallelepiped's volume. Or that M9 was, for instance, dragging the slider for entry a_{13} (called "*c*" in the applet) and noticing the simultaneous movement in the "top" of the parallelepiped. We note that the applet allows only one slider to be dragged at a time. As previously mentioned, 7 phrases were about a matrix with a column of zeros; each of these were part of an observation about the resulting determinant being zero. Because the default matrix in the applet is the identity matrix, it is likely that the observation was able to be made by only dragging one slider because each column of the identity matrix only has one nonzero entry.

In comparison to the dynamically oriented observations, some required multiple changes in the matrix entries and thus may have required many separate actions within the applet before an observation was made. For example, M6 wrote, "When I change two columns in the 3x3 applet, the determinant flips sign. It works the same on the 2x2 applet. I think it's because it flips the shape," which we coded as [MDG]. W6 wrote, "Another observation from the applet is that if you multiply one row by a constant the determine [sic] increases by that constant, and if you multiply the entire matrix by a constant, the determinant is multiplied by k to the power of n. For example, in a 2x2 matrix the determinant would be multiplied by k^2" which we coded as three instances of [M⇒D]. The actions needed to carry out both M6's and W6's second observation – switching one column with another and multiplying a matrix by a constant – require dragging multiple applet sliders *and* comparing an existing determinant with a resulting determinant. W6's first observation – multiplying a row by a constant increases the determinant by a factor of that constant – may have been made from only changing a row of the identity matrix or other diagonal matrix, in which only dragging one slider would have been needed for the observation.

Discussion

As design researchers, part of our work involves reflecting on student observations with respect to our curriculum design goals. Within the design research spiral (Wawro et al., 2022), considering student reasoning during tasks in light of the overall learning goals informs revisions that we make to the task sequence and supplementary materials, such as the applets. The first overarching learning goal include of this task sequence is (1) having students deepen their understanding of the geometric interpretation of linear transformations in $\mathbb{R}^2$ and in $\mathbb{R}^3$ through observing the impact that varying the matrix entries has on the determinant and on the transformed image. The second overarching learning goal is (2) for students to actively engage in the guided reinvention of key properties of nxn matrices A and B, such as: (2a) $det(A) = 0 \Leftrightarrow$ columns of A are linearly dependent, (2b) $det(A)$ is positive or negative according to whether the linear transformation defined by A preserves or reverses the orientation of the transformed objects ⇔If B is obtained by interchanging two rows (or two columns) of A, then $det(B) = -\,det(A)$, (2c) If B is obtained by multiplying a row (column) of A by scalar k, then $det(B) = kdet(A)$, and (2d) If $B = kA$ for a scalar k, then $det(B) = k^n det(A)$. Through reflection on data collected through various parts of the design research cycle, including the data analyzed in this paper, we feel confident that the applets have strong potential in helping an instructor achieve (1) and (2a) with their students. In particular, the results here show (2a) as a strong connection students make while working with the applet. These results also indicate that, when students are provided specific ideas to explore in the applet (namely, switching two columns or rows, multiplying a row by a constant k, or multiplying the whole matrix by a constant k), they can use the applet to make conjectures equivalent to (2b) - (2d). We would, however, like to consider ways that refining the applet might facilitate students' exploration of (2b) - (2d). For example, including features that can swap columns, swap rows, scale columns, or scale rows (rather than requiring individual entries to change one at a time), might help students develop (2b) - (2d) entirely on their own, rather than requiring targeted exploration prompts.

Our results showed that most student observations began with statements about the matrix [M] in either the 2x2 or 3x3 applet. We believe this is sensible, given the current design of the applets. The current aspect that is the most interactive is adjusting the matrix component values. For instance, students can rotate or zoom in on the transformed parallelepiped in the 3x3 applet but cannot manipulate, for instance, the image of the basis vectors that define the parallelepiped; if they could, we posit there may be more instances of students making [G⇒M] or [G⇒D] observations. One reason this is important to us as curriculum designers is the biconditionality of determinant-related properties and theorems. This informs applet revisions to better facilitate student understanding of and role in reinventing the biconditionality of the generalizations.

One limitation of the analysis presented here is that we analyzed post-hoc data of students' generalizations after interacting with the applet in class. We did not collect data of the students exploring the applet and conjecturing in real time. Analyzing real-time interactions would allow us to make stronger inferences about students' generalizations and the examples they explored to support them. We also had limited access to student thinking about why their observations were true because it was not required that they share justifications. Finally, students were informed all semester to spend 5-10 min on reflections and that they were graded on effort. Thus, we cannot know if students would have answered differently in a different setting. We look forward to our future work revising the applets, such as designing aspects to further facilitate specific learning goals. This work will also allow us to explore and theorize the alignment between specific aspects of RME, such as emergent models, and student exploration and engagement in DGS.

Structuring and Connecting 2D and 3D Space Using Linear Combinations

Matthew Mauntel
University of New Hampshire

Developing a rich understanding of linear combinations is key to understanding linear algebra. In this paper, I explore the rich connections students make between the geometric and numeric representations of linear combinations through playing and analyzing a video game. I look at population of students who have never taken linear algebra before and analyze how they structure space using the video game, Vector Unknown, as a realistic starting point. I detail and analyze this activity including the activities that transition them from 2D to 3D space.

Keywords: Linear Algebra, Linear Combinations, Game-based Learning

Linear combinations are the heart of linear algebra and involve understanding variety of different representations and connections between those representations (Hillel, 2000; Sierpinska, 2000; Larson & Zandieh, 2013). Video games that are well-designed can help students engage with a variety of representations (Ke & Clark, 2019) and build connections between these representations resulting learning complex systems. (Gee, 2003). The game *Vector Unknown* (Author, 2021; Author, 2019; Zandieh et al., 2018) is a well- designed game created to connect different representations of linear combinations by combining the ideas of Realistic Mathematics Education (RME), Inquiry-Oriented Instruction (IOI), and Game-Based Learning (GBL). In this paper, I will look at how the game can be used as a realistic basis for establishing a student structuring of space built upon taking linear combinations and explore how students connect 2D and 3D space.

Literature Review

The Magic Carpet Ride task (Wawro et al., 2013) was the basis for the game *Vector Unknown*. The task begins with a sequence that initially introduces linear combinations and then develops the ideas of span and linear independence. The task leverages the idea of the travel metaphor, which is one of the keyways students understand linear combinations (Plaxco & Wawro, 2015). Dogan-Dunlap (2010) explored linear combinations using Sierpinska's modes of reasoning (2000) to analyze student reasoning about linear independence and found that students' geometric reasoning could provide a gateway to analytic thinking about linear independence indicating the importance of developing geometric reasoning about linear combinations. Paraguez and Oktac (2010) found that a lack of geometric representation resulted in the students having difficulty forming a schema of vector spaces, a keyway of organizing space. Zandieh et al. (2019) analyzed student metaphors of basis and found that when students changed their metaphors when describing basis in 2D and 3D space indicating a shift in understanding. This indicates a need to explore both how students connect geometric representations of space with more analytic elements and how they transition from 2D to 3D.

The Game Vector Unknown and Prior Game Research

Vector Unknown (https://tinyurl.com/linearbunny) is a game developed by capstone students at Arizona State University (Author, 2022; Author, 2021, Author, 2019). Participants are presented with four vectors in 2D, which they can drag into a vector equation and scale. The goal of the game is to reach the goal location, which is represented by a basket on a geometric grid. The game has three levels that were used for this interview. During the first level, the game provides the player with a geometric representation of the linear combination of two selected scaled vectors. The second level removes the geometric representation to force them to reflect more deeply upon the vector equation. Finally, the third level requires the player to visit several keys before reaching the goal. This forces the player to look at the geometric aspects of the game as the coordinates of the lock are not provided to the students.

Author (2021) found four core strategies that players used to play the game. The first strategy, quadrant-based reasoning, focuses on matching the quadrant of the vectors in the linear combination with the quadrant of the goal. The second strategy focuses on one vector involved and the player selects a vector and scales it to be as close to the goal as possible and then uses another vector to reach the goal. Thus, the player focuses on one coordinate involved, chooses either the x- or y-coordinate of the goal vector, and adjusts the scalars to match that one coordinate. The final strategy, button-pushing, involves players choosing vectors and rapidly adjusting the scalars to find a path to the goal. Each of these four strategies had a more geometric version in which players focused on the graphical display and a more numeric version where the focus was more on the vector equation.

Theoretical Framing

In this study, mathematical learning has been theorized as student's mathematical activity (Freudenthal, 1971, as cited by Gravemeijer & Terwell, 2000) that relates to the topic of linear combinations. The goal of this study is to describe the emergent mathematical activity relevant to topics in linear algebra such as linear combinations, span, and linear dependence developed from playing *Vector Unknown,* analyzing the gameplay, and designing a new 3D game based on the core choices made in *Vector Unknown*. I call this emerging activity structuring space. The sequence was designed to have students engage in at least three levels of activity from Realistic Mathematics Education (RME) (Gravemeijer, 1999). First, students engage in the situation of the game, which involves taking linear combinations. Next, they have to consider how other players might play the game referring to their own experiences. Finally, they have to develop design ideas for the 3D game which is intended to move them towards making generalizations about the linear combinations that are relevant beyond the 2D game. This paper presents an overview of the student's structuring of space from as situated in the dissertation work (Author, 2022) while providing examples to the core research questions:

1. How did students who have never taken linear algebra structure two-dimensional space with respect to linear combinations in relation to the game *Vector Unknown*?
2. How did students adapt their structure of two-dimensional space to a three-dimensional setting when designing a three-dimensional game based upon *Vector Unknown*?

Structure of the Interview

The interview was conducted over the course of four days. During the first day, the participants played the game individually. For the second day, I paired the participants into three groups according to their gaming experience (Gamer/Gamer (GG), Gamer/Non-Gamer (GNG), Non-Gamer/Non-Gamer(NGNG)). This was done because, at the time, it was thought that gaming experience might impact their activity with the game. First, each pair was asked to describe all possible goal locations that could be obtained from a set of vectors. Second, they were asked to create a set of easy, medium, and hard vectors (since the game had an easy, medium, and hard level) to reach a fixed goal of <-3,5>. Each group was shown how to use

GeoGebra during the second day for geometric exploration of all possible goals. On the third day, each pair was asked to design a 3D game by either creating easy, medium, and hard vectors and illustrating all the available vectors or creating easy, medium, or hard vectors to reach the goal <3,-4,5>. During the third day, students were again provided access to GeoGebra 3D to explore the geometric aspects of the linear combinations in 3D. During the final day, each participant played the game individually. This was done to explore if the participants' strategies for playing the game changed from the initial playthrough. This paper focuses on days 2 and 3 of the interview to analyze how they structure space.

Participants, Data Sources, and Methods of Analysis

For this paper, I looked at six students recruited from Calculus 1 and Calculus 2 classes from a large Southern University. None of the students had taken linear algebra before participating in the interview. The groups consisted of Alex(G)/Angel(G), Marti(G)/Betty(NG), and Gabby(NG)/Dee(NG) (demographic information provided in Table 1). The gaming experience was determined by the number of hours students spent per week gaming, with gamers being those who played 5 or more hours per week.

Table 1. Participant Demographic Information

Pseudonym	Year	Major	Gaming Experience	Gender Identity	Hispanic or Latino	Race	English Primary Language
Marti	Soph	Environment al science	G	Gender Variant/Non-conforming	Yes	White	No
Betty	Soph	Biology and Education	NG	Woman	Yes	White	Yes
Alex	Fresh	Civil Engineering	G	Man	No	White	Yes
Angel	Fresh	Mechanical Engineering	G	Man	Yes	White	Yes
Gabby	Fresh	Mechanical Engineering	NG	Woman	No	White	Yes
Dee	Junior	Mathematics and Education	NG	Woman	No	Other	Yes

I conducted the interviews over Zoom. They were recorded on a secure server and auto-transcribed using the Zoom software. The videos and transcripts were reviewed for instances of structuring space for each group and open coded (Strauss & Corbin, 1990). These codes were then condensed across all three groups to produce categories of structuring space. Finally, a round of axial coding was conducted to find themes of structuring space across the categories: structuring by design, structuring by generating, and structuring across dimensions.

Findings

In this section, I present four different types of structuring that are meant to capture the student's activity with examples of each from the student's work. Emergent categories are bolded throughout this section, and the emerging themes are the types of structuring. Structuring by design contains different design choices that were made by participants as they created different elements of the game that were based upon the participant's assumptions about the game and/or its difficulty. Structuring by generating captures process by which students generated example vectors which they utilized to generalize. Structuring all possible goals presents how students describe their structuring of all possible goal locations (or linear combinations). Structuring across dimensions describes how students made transitions and connections between 2D and 3D space. Together these four themes are meant to capture how students structure space in the context of analyzing the 2D game and designing a 3D game about linear combinations of vectors.

Structuring by Generating

This section presents different methods the participants utilized to create new vectors either to reach a provided goal or to list all possible goals given a set of vectors. **Pairing** vectors refers to selecting two vectors from a set and adding them together to generate new vectors. **Scaling** refers to scaling one or more vectors in pairs to generate a new goal location. Pairing and scaling [Figure 1] were used systematically for all three groups to generate goal locations spanned by a set of vectors. Here Betty pairs <-3,2> with each of the vectors <-2,4>, <1,2>, <-6,4>. She then pairs <-2,-4> with the remaining vectors <1,2> and <-6,4>, and finally <1,2> and <-6,4>. She then begins to scale the first vector in the first pair she generated. This progression of scaling was also seen in GeoGebra when students scaled according to difficulty. Gabby describes the activity of generating vectors to reach the goal of <-3,5> by **adding up/subtracting down** as looking "for two numbers that would add up to –3, –2, and –1. Fairly simple numbers, because it's medium difficulty, and then two other numbers that would add up to 5." Here she focused on the *x*-coordinates first and found two numbers that *add up* to -3, and then looking at the *y*-coordinate and she found two numbers that add up to 5. Adding up/subtracting down is the process of finding pairs that add up or subtract to goal x- or y-coordinate.

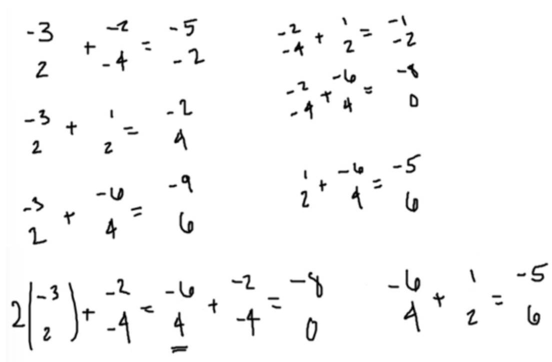

Figure 1. Example of pairing and scaling by Betty to generate possible goal locations

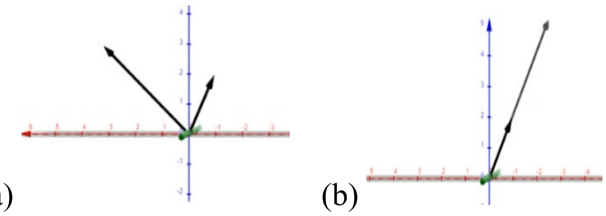
Structuring Across Dimensions

In this section, I investigate activities that students engaged in both 2D and 3D or activities that allowed them to connect the 2D and 3D worlds. Betty illustrates several of these strategies while looking at the linear combination of $v(-2, -4, -3) + o(3,0,0)$ and trying to determine all the possible goal locations [linear combinations] of these two vectors. Betty stated that she looked at where each of the combinations fell in the different planes. First of all, the 2D plane and then the 3D plane. This combination here [points to $v(-2, -4, -3) + o(3,0,0)$] has at least the capacity to go through all four 2D planes. Oh I mean quadrants [she manipulates the sliders to illustrate how it can go into all four planes from a top down view in Figure 2a]…and it can go into the upper level of the z-plane [she adjusts her view, Figure 2b, and adjusts the scalars to illustrate the point moving up and down along the blue axis].

First, Betty adjusted the camera to obtain a top-down viewpoint [Figure 2a]. From this viewpoint, she adjusted the scalars in the linear combinations to illustrate that the linear combination $v(-2, -4, -3) + o(3,0,0)$ visited all four quadrants in xy-plane, indicating that **reasoning about quadrants**, describing vectors using the signs or quadrants that they are located. After this, she rotated the camera and adjusted the scalars to illustrate that the point also went to the "upper level of the z-plane." I call this **traveling along an axis**, which is using checking to see if a point travels outside a particular. Essential to Betty's reasoning is here **adjusting the viewpoint,** which consists of rotating the camera to obtain an optimal view for checking a particular property or technique.

(a)  (b) 
Figure 2. Betty's analysis of the linear $v(-2, -4, -3) + o(3,0,0)$]

Marti, Betty's partner, also employed adjusting the viewpoint to see connections between the 2D and 3D worlds. In 2D, Marti was looking at the linear combination $f<-2,-4> + g<1,2>$ and noticed that it does "not matter how you multiply it seems to be moving along the same line. You can move it along both of the sliders, and it still moves in the same direction." This was in contrast to the linear combination $a<-3,2> + b<1,2>$ which "seems to cover the entire 360 [degrees] of the graph depending on what you multiply them by." Marti then began to classify other linear combinations according to whether or not they were in the **same line** or **rotated around 360 degrees**. This became an important design consideration when Marti started to design her 3D game. When creating vectors to reach a goal she wanted vectors that "had as much of a reach around the graph as possible." Marti tested linear combinations by rotating the camera to viewpoint that projected onto a plane and adjusted the scalars to ensure they traveled around 360 degrees [Figure 3a]. When two linear combinations aligned she changed the vectors in one of the linear combinations [Figure 3b]. This indicates that Marti was reflecting upon Marti's 2D work when creating vectors in the 3D game, in particular the delineation between linear combinations that traveled in the **same line** or rotated **360 degrees**.



(a) (b)

Figure 3. Marti looking for linear combinations that are in the same line or rotate 360 degrees

Structuring across dimensions is important because it captures activities that participants thought worked in both 2D and 3D dimensions, such as quadrants and same line/rotations. Also, adjusting the camera view was an important activity that allowed participants to build connections between 2D and 3D. Betty was able to see the connections using different viewpoints, and coordinate these viewpoints which occurred. She coordinated a planar projection viewpoint with an isometric viewpoint to deduce that the goal locations traveled off the projected plane. This category answers the research question 2, how students structure space across dimensions.

Structuring by Design

This section presents design choices students made while creating their own vectors for different difficulties in the 2D and 3D game. First, students would **attend to coordinate properties** which encompasses designing vectors by selecting coordinates with specific numerical properties such as being big numbers (such as 6 through 9), small numbers (such as 1 through 3), or zeroes for individual x-, y-, and z-coordinates. Since the game only allowed x- and y-coordinates that were between -20 and 20, several groups only considered possible goals locations that Marti described as "**within the grid**." This category was important because it provided an activity for students like Betty to generate goal locations and noting that $<-3,2> + 3<-6,4> = <-21, 14>$ and "found it would be going off the 20 and it would be going off the mark so it wouldn't count" as a possible goal location. While designing vectors to reach the goal of <-3,5>, Alex and Angel decided that they wanted to design a "**bluff vector**" which was intentionally designed to not help the player reach the goal. For example, they used the vector <5,-3> as a bluff vector. Finally, scaling **vectors according to difficulty** refers to the design decision to have more vectors to be scaled with the difficulty of the game. For example, Gabby and Dee present easy goal locations as (2,0,1) + (-1,2,3), medium difficulty as b(2,0,1) + (-1,2,3) or (2,0,1) + b(-1,2,3), and hard difficulty as b(2,0,1) + c(-1,2,3). Structuring by design was important because it presented goals created by students in the design of the game that generated activity allowing them to notice patterns.

Discussion and Limitations

I initially set out to categorize the different types of activities that students engage in after playing, reflecting, and designing a 3D version of the game *Vector Unknown* in regards to structuring space and linear combinations. Now that I have presented these results, I want to reflect on the ways in which my findings can inform a more general definition of structuring space. Examining my data, I found that students engaged in the following activities:

1. Worked with a variety of objects, including coordinate vector representations such as $\begin{bmatrix}1\\2\end{bmatrix}$; points and arrows on a 2D or 3D plane; symbolic representations of vectors; representations of paths in 3D space.

2. Took actions such as **pairing** and **scaling** vectors both on paper and in GeoGebra (through adjusting the sliders), **changing the viewpoint**, and creating vectors using **adding up/subtracting down**.
3. Set design goals that shaped their structuring activity such as structuring by design with **fitting the grid**, **having bluff vectors**, or wanting vectors with specific **coordinate properties**.
4. Made observations such as recognizing if **vectors span all quadrants** or lie along the same line in **structuring across dimensions** and observing **coordinate properties** about individual vectors.

Taking actions, setting goals, creating objects, and making observations form the skeleton of structuring as its key components. The act of structuring involves doing one or more of these activities and re-evaluating the connections between the remaining elements. In this way, introducing an action like changing the viewpoint might have the students set new goals such as finding the best viewpoint, work with different objects such as projections down to 2D space, and make new observations such as being able to classify 3D vectors as in the same line or a rotation. Now the foundation of a particular structuring is the starting activity that sets these parts in motion with example actions, goals, objects, and observations. Playing the game *Vector Unknown* provides the initial set of actions, goals, objects, and observations for structuring space under linear combinations for this study. Here the actions are the moves by the player (scaling and choosing vectors), the goal is to reach the basket, the initial objects are the vectors and their geometric representation, and the observations are highlighted by feedback provided to the player from the game. Playing the game and asking questions about the game introduce or modify each of these components resulting in a student structuring of space.

I observed that the idea of linear independence was observed through the idea of same line/visiting all quadrants/rotating 360 degrees. Quadrants appearing in both this analysis and the video game strategies (Author, 2020) indicate that they might be a fruitful starting point for understanding linear dependence. Additionally, I found that understanding viewpoint and, in particular, coordinating viewpoints was crucial to the participants transitioning between 2D and 3D space. This is important because looking at viewpoints is a paradigm that is often relegated to dynamic geometry software (such as GeoGebra) and video games and may not be covered in classes without these tools. Future work will investigate this data more thoroughly doing an in-depth analysis of the different viewpoints utilized and linking them to the mathematical activity for each viewpoint. I see view this as important to developing the geometric intuition that is considered valuable by Dogan-Dunlap (2010) and Paraguez and Oktac (2010). Finally, I want to stress the importance of the game in the student's structuring by contributing elements such as fitting the grid and designing bluff vectors. These design ideas from the game provided students with goals and a reason to generate vectors which they then used to make generalizations and explore advanced mathematical concepts creating a complex network of ideas (Gee, 2003).

The project was conducted with only three groups of students and thus does not capture the entirety of structuring space. Additionally, the students were introduced to GeoGebra at different times during the interview and in different versions. Some students utilized a GeoGebra applet in 3D, while others chose to use the default program. Because of this, their structuring when working in GeoGebra was likely impacted by the tool and when it was introduced.

San Francisco State University

Those who lead the preparation and assessment of novice college mathematics instructors for teaching (Providers) do their work in many ways (e.g., course coordination, seminars, workshops). Using data from a large national survey, this study examined reporting among 95 Providers about the structures of their departments, their goals for the professional development work they do, and their relative valuation among goals. Respondents completed a sorting and ranking activity about professional development goals and answered an open-ended question describing their sorting decisions. Qualitative coding identified six main themes for the respondents' 285 descriptions. Quantitative analysis used the rankings of goals within respondents' sorting categories to examine how Providers describe and value professional development goals related to professional community, classroom and department culture, and instructor response to students within their classrooms.

Keywords: Mathematics Graduate Student Instructors, Teaching Assistants, Professional Development, Pedagogy, Community, Q-Sort Methodology

Introduction

A significant and continuing challenge to undergraduate student success is the nature of instruction in college mathematics courses (Freeman et al., 2014; Laursen & Rasmussen, 2019). The last decade has seen several national efforts aimed at addressing this well-known problem, including online repositories of activities for use in the preparation of graduate students for teaching (i.e., CoMInDS), online professional learning opportunities for faculty to focus on student learning, and the release of student-centered policy documents like the Mathematical Association of America's (MAA) *Instructional Practices Guide* (IPG). Higher education leaders are now looking to departments to improve the preparation of college mathematics instructors (CMIs); particularly novice CMIs who are graduate students beginning their teaching journey as mathematics graduate teaching assistants (teaching in sessions adjacent to a primary course) and graduate teaching associates (teaching as instructor-of-record). Here, we use **GTA** to refer to both groups collectively and, as needed, distinguish between them with Lab-TA for teaching assistant and GSI-TA for teaching associate. These new CMIs are a critical subgroup because: (1) they teach thousands of undergraduates (Belnap & Allred, 2009), (2) many start as LabTAs, and (3) most have little or no preparation for teaching. In addition, there are many variations in type of institution (e.g., master's granting, doctoral granting) and structure within departments around professional development (PD). Depending on location, GTAs will be offered learning opportunities that may include short orientation workshops, teaching seminars, pedagogy courses, mentoring, or course coordination. Thus, mathematics departments have reached the point where they are asking which resources they should use, and how, to help their graduate students' learn to teach. They know the ingredients exist and are looking for the recipe for their local departmental use.

Context of the Study

This study is part of the CMI Preparation Project. The overarching goal for the project is to document and extend the use of effective professional learning about teaching for a variety of institutional and instructional contexts by generating a CMI Design Tool for use by departments. This study focuses on the findings from a national Needs and Uses Survey with the aim to understand how communities are described and discussed by providers. Analyses from the survey are informing the development of the tool.

Within this survey, respondents were *Providers*: those who work with novice CMIs to support learning about teaching undergraduate mathematics. In the survey, Providers answered questions about their department structure and the design of the professional development available locally to novice CMIs. The survey used a variant of the *Q-sort methodology* (Willig & Stanton-Rogers, 2017) where **Goals** for professional development were *sorted* and *ranked* into up to three **buckets** which were then *titled*. The Goals offered in each activity were developed in the project's earlier work by eight expert Providers from diverse backgrounds (e.g., from private and public, masters and doctoral granting institutions) who merged and distilled critical topics of CMI PD from their experience and research.

Each of the 15 Goals (Table 1) had an associated exemplar (when a respondent hovered over the Goal). Each respondent was asked to sort the 15 Goals into three buckets, rank each Goal within that bucket, and then provide a title and justification for that bucket's title.

Table 1. Goals Sorted by Providers

A: learn how to notice and manage challenges to equity, access, and success among undergraduates
B: learn how to initiate and sustain a productive classroom culture
C: learn about ways for students to build their math learner identities
D: learn strategies to promote and facilitate collaborative learning
E: get feedback on their teaching from peers
F: learn about students thinking and analyze how it reflects instructional decision-making
G: learn how to foster student in-class engagement
H: create a community of instructors and are supported in its creation
I: build knowledge on how students learn
J: learn methods for promoting whole-class discussion
K: learn how to recognize teaching practices that create a sense of belonging among students
L: learn how to implement self-assessment in teaching
M: plan and prepare lessons
N: learn how to develop teaching portfolios
O: learn about and promote student use of outside-of-class learning resources

This qualitative sorting methodology was chosen because prior research in ranking of such PD goals had illustrated that it was difficult to disassociate the judgment of value of teaching method from the logistical expectations of a department (Yee et al., 2018). To address this, for this survey, respondents had choice in how to assign goals to buckets, could freely rank within buckets, and were asked to give and explain bucket titles. There were three of these bucket activities (each having the participant sort Goals into three buckets) in the survey, each on its own page. This report is focused on the bucket activity that emphasized community and how PD

Providers view communities within teaching (Gobstein, 2016; CoMInDS, 2020; Yee et al., 2022). This sub-study addressed the questions

RQ1: How do Providers describe Goals that focus on community?

RQ2: How do Providers value Goals focusing on community?

Background and Theoretical Perspectives

Multiple calls for action to include inquiry-based mathematics education (Laursen & Rasmussen, 2019) and active-learning methods (Braun et al., 2017) have been on the forefront of suggestions for the professional development of CMIs. Recent research and development in collegiate mathematics education has attended to professional communities in several ways. The *Student Engagement in Mathematics through an Institutional Network for Active Learning* (SEMINAL) project (Gobstein, 2016) is expanding use of collaborative learning methods through active-learning. Additionally, the *Promoting Success in Undergraduate Mathematics through Graduate Teaching Assistant Training* (PSUM-GTT) project (Haddock et al., 2018) is diversifying multiple uses of peer-mentoring, training, and seminar courses for CMI professional development. With all of these resources and suggestions, it is easy for a mathematics department to be overwhelmed (Pengelley & Sinha, 2019).

In fact, although 70% of departments in a recent national study indicated they provide some kind of instructional development for novice CMIs, the nature of it varies widely (Ellis et al., 2016; Speer et al., 2017). Novice CMIs today are the very instructors who will play key roles in addressing the nation's need to improve student enrollment, retention and persistence in science, technology, engineering, and mathematics (STEM) courses and majors (Holdren & Lander, 2012; Laursen & Rasmussen, 2019). The opportunity and need coalesce in the first two years – where undergraduates first encounter college mathematics and novice CMIs are most likely to be teaching (Belnap & Allred, 2009). Clear from the proposers' and colleagues' work in developing, offering, researching, and disseminating ideas about professional learning in college mathematics instruction, central to success is strengthening novice CMIs' understanding of student thinking (Roach et al., 2013; Speer & Wagner, 2009; Wagner et al., 2007). Specifically, GTAs are a critical focus of novice CMI professional development.

Bragdon and colleagues (2017) categorized approaches in 120 different master's and doctoral-granting departments into nine models for PD focusing on GTAs. However, a challenge still remains: how to leverage and communicate about these characteristics with and in mathematics departments. To be able to do this we need to understand (1) how department members, including Providers, describe their Goals and (2) how they value their Goals. Research into CMI preparation has demonstrated how Providers' goals for novice CMIs significantly overlap with topics of secondary and primary mathematics methods courses (Yee et al., 2022). Yee et al., (2018) analyzed touchstones in methods courses from two perspectives: those of teacher educators and those of in-service teachers. The focus of this national study was phrased in terms of perceived importance: "Please tell us how important you feel it is for each of the following content items to be valued and addressed by secondary mathematics methods courses for preservice teachers." Although a very valuable study, what respondents valued was conflated with departmental expectations. To get around that, this project used a Q-sort methodology that more clearly isolated respondents' values from their departmental expectations by not only having respondents sort and rank the Goals, but also create and justify a *title* for each bucket, so that we can see the respondents' language and values directly.

Methods

This study used embedded mixed methods where qualitative thematic coding of bucket titles was embedded within the quantitative analysis of the ranking and frequency of Goals within bucket descriptive themes (Creswell, 2017). Respondents for the survey were recruited because they provided professional development about teaching to novices in their departments. The survey was sent to 242 people, 95 of whom completed the sorting activity. These 95 responses, with three descriptive bucket titles each, formed the data pool of 285 bucket titles used for the analysis shared here. Respondents came from a variety of academic positions (see Table 2).

Descriptive analysis along with central tendencies provided a context for interpreting the Community bucket activity data (Table 2). To answer RQ1, thematic coding was used on the descriptive titles created by respondents for their buckets. The goal for the thematic coding was to examine and characterize the language that was used by the respondents (see Table 3). For example, respondents' language suggested one theme be described as "learn how to foster student in-class engagement" – this *in vivo* title represents Provider language (alternatively, the researchers could have abbreviated this as "active learning"). However, we *purposefully* capture respondent language so that we can make sure the content is accessible by people who are not educational researchers, such as those in mathematics departments who will (one day) use the CMI Design Tool for which the survey is a first step.

Researchers went through four stages of thematic coding of the 285 bucket titles by (1) generating a modified word cloud of all titles to generate a preliminary set of themes, (2) collaboratively coding 30 bucket titles into themes and revising themes together, (3) choosing 30 new bucket titles of the 255 uncoded buckets and coding them individually then comparing the codes and revising themes and coding, (4) each researcher then coded each of the remaining 225 bucket titles, then met to discuss revisions until consensus was reached (100% agreement) amongst the bucket titles being coded and the wording used for the themes. It is important to note that for this study the Goals within each bucket were not considered when identifying the themes of the titles, only the titles.

To answer RQ2, we embedded the themes into the quantitative analysis of Goals' within-bucket and weighted rank (see Table 4). Thus, with each theme, we could see what value (weighted rank) was given to that Goal within that theme. Because few buckets had more than six ranked Goals, we wanted to weight the Goals accordingly. We chose to use harmonic progression (reciprocal progression) so that rank 1 of a Goal within a theme was weighted as 1, rank 2 was weighted as ½, rank 3 was weighted at 1/3, and so on. These weighted rankings were then added together for each Goal within each theme to generate a "heat map" (Table 4).

Findings

We first describe the contexts for Providers who did the survey, then how the bucket titles were themed, and finally how the Goals were valued within each theme. Providers identified, on average, 38 novice CMIs out of an average of 84 mathematics instructors for each of the departments. Those novice CMIs accounted for (on average) 45% of the teaching done within a department (median 49%). Additionally, Providers stated, on average, that graduate students were 30 of the 38 novice CMIs, suggesting 78% of novice CMIs within their departments were graduate students (median 74%). We also asked about a Provider's position and the target group for their PD. Among respondents, 40 were teaching faculty, 33 tenure-track research faculty, 3 tenure-track teaching faculty, and 16 "other" (described as former/current department chair, directors in Math department, non-tenure track teaching/research faculty, lecturer, and postdoc).

This suggests the largest group taking the survey were teaching faculty, followed by research faculty. Together these two groups constituted 80% of all respondents. The novice CMIs target groups were graduate students who were either LabTAs (e.g., recitation instructors, *N*=36) or GSI-TAs (i.e., instructors of record, *N*=35). Together graduate students made up 76% of the target groups for the respondents. Table 2 illustrates the respondents' departmental information relative to the teaching workforce.

Table 2. Structure of Departmental Teaching Workforce and CMI PD (out of 95 responses)

		Median	**Mean**	**SD**	
# of people teaching mathematics for the department		70	84	55	
# of above group who are novice CMIs		34	38	31	
# of novice CMIs who are graduate students		25	30	26	
Role within the CMI Professional Development	Teaching Faculty	Research Faculty		Adjunct Faculty	Other
	43	33		2	16
Target group for CMI Professional Development	LabTA	GSI-TA	NFI*	ULA**	Other
	36	35	7	1	14

**NFI=non-faculty instructor and **ULA=undergraduate learning assistant.*

Bucket Title Themes

To answer RQ1, themes were refined three more times as two researchers expanded, revised, and refined the initial themes to cover the most bucket titles and to best reflect respondents' choice of language. For example, the word "Knowledge" in Th3: (Teaching and Classroom Skills, Strategies, and Knowledge) had similar uses within the respondents' title justifications as use of the word "skills" when referencing teaching. This is important to note: "knowledge" and "skills" for teaching were not distinguished by Provider respondents. The six themes reported here covered 92% of all Goals that were sorted into buckets. Altogether, buckets with titles that fell under Th1, Teaching Community and Culture, contained 106 Goals, 9% of all Goals sorted by all Providers while Th2 bucket titles contained 240 (19%) of all sorted Goals (see Table 3).

Table 3. Bucket Title Themes, Frequencies, and Relative Frequencies

Theme Code	Theme Title	Goal Count	% Sorted Goals
Th1	Teaching Community and Culture	106	9%
Th2	Individual Teacher Development such as Assessment, Feedback, and Reflection on Teaching	240	19%
Th3	Teaching and Classroom Skills, Strategies, and Knowledge	263	21%
Th4	Student Learning, Support, Engagement, and Identity	256	21%
Th5	Classroom Identity, Community, Environment, and Culture	168	14%
Th6	Pedagogical Diversity, Equity, and Inclusion/Belonging Especially in the Classroom	100	8%

The survey asked respondents to briefly justify their bucket titles. Bucket justifications were only used when struggling to thematically code a bucket title. Overall, only 23 of the 285 bucket titles had more than one identified theme.

Goals Valued within Themes

With respect to RQ2, weighted rankings were assigned relative to the Provider's chosen rank for each Goal within each bucket. Table 4 provides a heat map coloring the Goals within each theme (row) – the highest weighted value in green and the lowest rated value in red. For example, for all respondents who had a bucket title that was coded under Th3, the most highly weighted value was 19 on Goal M: plan and prepare lessons. Goals (column headings) were ordered across the top to group greens and reds (see Yee, 2022 for more on the method).

Table 4. Heat Map of Goals within Each Theme According to Weighted Ranking

Goal: Theme	E	N	L	H	A	B	K	M	I	F	O	G	D	J	C	Total
Th1	11	8.6	7.6	18	0.3	1	1.2	2.4	0.5	0.6	1	0	0	0	0	52
Th2	25	16	20	20	2.1	1.3	3.1	7.8	8.3	7.6	2	1.3	0.5	0.5	1	117
Th3	4.4	3.4	2.9	5.5	11	8.6	3.1	19	7.7	4.7	5.1	15	8.8	7.5	3.9	110
Th4	1.3	0.4	0.8	0.8	7.8	7.5	5.9	9.9	17	11	8.5	13	12	7.7	9.9	113
Th5	0	0	0.1	1.1	13	13	7.9	3.5	1.7	2.2	2	6.7	5.9	7.7	4.1	69
Th6	0	0.2	0.2	0.4	12	9.4	6.3	1	1.6	1.4	1.4	1.5	1.6	1	6.4	44
Total	41	29	32	46	45	41	27	43	36	28	20	38	29	24	25	505

In the Total Row, adding up all weighted rankings of single columns, we see Goals H (46), A(45), M(43), B(41), and E(41) were the highest valued across all six themes. Goals A and B focused on classroom community among students while H and E focused on community around instructors. We also see that Goal O: learn about and promote student use of outside-of-class learning resources, had the lowest weighted ranking total (20). When looking across all rows, we see that every Goal but one, O, was in some themes' top five highest valued Goals. This suggests that Goal O was not highly valued for the participating Providers.

When looking at the Goals within each theme, we see some have higher values than others. Goal A "learn how to notice and manage challenges to equity, access, and success among undergraduates" was the highest weighted rank in Th5: Classroom Identity, Community, Environment, and Culture. This is interesting because Providers used the words that define Th5 and then associated this with Goal A. Specifically, equity, access, and success were encapsulated by Providers using the words Identity, Community, Environment, and Culture. These latter words may illustrate Providers seeing the outcomes of managing challenges around equity, access, and success as focusing on classroom environment and culture rather than the individual student. Goal H is a focus on the community of instructors and was the second highest valued in Th2 which focused on feedback and reflection. This may suggest Providers see a strong connection between teacher community, personal reflection, and assessment of teaching by others.

When comparing Th1 and Th2 in Table 4, we see Th2 had higher weighted ranks with Goal I and F, where the focus is on knowledge of how students learn, student thinking and how it affects instructional decisions. Th1 focused on community and culture while Th2 focused on individual development. Thus, Providers seemed to view Goals around student learning and thinking as less impactful to community development than to individual teacher growth.

When comparing and contrasting Th5 and Th6, we see these themes did not highly value Goals E, N, L, and H yet did value Goals A, B, and K highly. This aligns with the focus of Th5 and Th6 around the classroom. Goals D, G, and J had higher valued weighted ranking in Th5 over Th6. This suggests Providers who title buckets with Diversity, Equity, and Inclusion did not value engagement, collaboration, and whole-class conversation as much as those who titled their buckets with Identity, Community, Culture and Environment. More work is needed to understand this finding given that research in active learning has suggested that collaboration and engagement seem to encourage diversity, equity, and especially inclusion (Laursen et al., 2014).

Discussion

Overall, we found that Providers responding to the survey were primarily teaching faculty, followed closely by research faculty within mathematics departments. The Providers' departments had a workforce where on average 45% of all instructors were novice CMIs. These Providers focused primarily on the 75% of novice CMIs that were GTAs. In answering RQ1, we found that there were six dominant themes that captured the 285 bucket titles. Language chosen by the Providers was preserved within these themes illustrating important differences between how educational researchers use terms (such as knowledge and skills) and how Providers use these terms. These differences are important as we move forward in creating a Design Tool with language that is meaningful to its users. When looking across the themes, at how the Goals were sorted and ranked, certain distinctions about how themes and values varied illuminated additional challenges and opportunities for offering mathematics departments' guidance on Provider resources.

When comparing and contrasting weighted ranking of Goals within Th5 and Th6, Goals D, G, and J were all slightly higher with Th5 suggesting responding Providers associated student engagement, collaboration, and whole class discussion (Goals D, G, & J) within classroom identity, community, environment and culture (Th5), rather than within what Providers identified as "diversity, equity, and inclusion" (Th6). More investigation is needed on this. For example, it could be an artifact of assumptions about the nature of CMI influence on classroom culture, environment, and community as different or easier than that what Providers associate with diversity, equity, and inclusion (i.e., Providers were less inclined to connect engagement, collaboration, and whole-class discussion goals with Th6: Diversity, Equity, and Inclusion).

One of the largest implications is the need for clear distinction in the Design Tool between departmental values related to communities of undergraduates (e.g., a classroom community) and community among novice instructors (e.g., in a comparison of Th1 and Th2 versus Th5 and Th6 in Table 4). We see those Goals valued in Th1 and Th2 are not valued in Th5 and Th6. Moreover, the highest valued Goals overall (Table 4) were Goals H (46), A(45), M(43), B(41), and E (41). Goals H and E focus on the teacher community while Goals A and B focus on classroom culture and equity, access, and success with students (classroom community). Goal M, plan and prepare lessons, seemed to be the only Goal that was moderately valued across nearly all themes (Table 4) and had a high overall value. This may suggest that Providers can leverage planning and preparing lessons to bridge discussions among these communities. For example, when planning a lesson, the discussion can revolve around the student community, while discussion on how the lesson plan is used, by whom, and how, could connecte conversation back to instructors' community.

A Measurement Hat Trick: Evidence from a Survey and Two Observation Protocols about Instructional Change after Intensive Professional Development

Professional development about teaching is an important lever for change toward evidence-based instructional practices. Yet few studies in higher education offer robust evidence about whether and how instructors' teaching practices actually change as a result of professional development. We studied instructors who attended a four-day intensive workshop on inquiry-based learning (IBL) in college mathematics and who provided data about their teaching before and after. Of 293 instructors who attended, 136 provided complete survey data and 15 video-recorded their teaching, which we coded using two observation protocols. Comparing pre-workshop and follow-up teaching data, we find significant and well-corroborated changes toward IBL methods across all three methods, with effect sizes near 1, generally viewed as large in education research. The findings demonstrate that well-designed professional development can have a substantial impact on instruction even within the first year of implementation.

Keywords: IBL, professional development, TAMI, RTOP, measurement of teaching

Teaching-related professional development (TPD) is widely seen as important to encourage the uptake of evidence-based instructional practices (EBIPs) by college STEM instructors. TPD is attractive as a lever for change because research has demonstrated that EBIPs can make a big difference in students' experiences and success, and tested classroom resources are widely available to instructors in all STEM disciplines. Proponents argue that TPD is impactful because most college instructors have ample room to improve: while deeply grounded in their discipline, most have little formal knowledge of learning and teaching. Moreover, the effects of TPD will be amplified as each instructor teaches many courses and thousands of students across a career.

However, these arguments are not currently well backed by research showing that TPD does have the desired effect on instructor practice. At present, professional developers and funders can point to examples of impactful TPD as proof of concept (e.g., Khatri et al., 2013; Laursen et al., 2019), but the formal literature relies much on case studies of small programs: large, high-quality studies are scarce. Exceptions include recent work on TPD in mathematics (Archie et al., 2022) and studies in several science fields (Bathgate et al., 2019; Borda et al., 2020; Chasteen & Chattergoon, 2020; Ebert-May et al., 2011, 2015; Manduca et al., 2017) that measure instructors' implementation of active approaches after TPD, and the barriers and supports that shape this.

Building knowledge about TPD in higher education has been slow and challenging. Simply measuring teaching and change in teaching is difficult (AAAS, 2013); common tools such as surveys and observations both offer pitfalls. Moreover, studies of TPD outcomes cannot be done as experiments: researchers must find large, well-designed, and stable TPD programs to serve as study sites to provide adequate sample sizes and a consistent, high-quality intervention. TPD is neither required nor routinely offered by institutions of higher education, unlike K-12 settings. Finally, teachers need time to learn and enact new ideas and practices, then more time to become proficient enough to improve student learning, a reality that further extends the research timeline.

Thus, it is no surprise that rigorous studies examining the outcomes of TPD are needed. Our study of workshops on inquiry-based learning (IBL) in college mathematics addresses many of these challenges. The workshops reached nearly 300 instructors, yielding samples large enough for quantitative analyses. Built on a decade of prior work, the workshop model was informed by learning from K12 and college TPD experience, evaluation feedback, and education research on professional development. Workshops were led by teams of skillful IBL educators who worked from a common general structure and schedule, drew from and contributed to a shared set of workshop and course materials, and engaged in TPD leadership training. Together these features ensured sound program design and consistent, high-quality TPD delivery.

To address the measurement challenges, we used three instruments—a survey and two observation protocols—and compared the results. Funding constraints meant we had to measure implementation just one year after workshop participation, likely before teachers had mastered new approaches. We thus chose two descriptive, behavior-focused measures (one survey, one observation protocol), positing that new IBL users would first adjust how they use class time—e.g., using less lecture and more of the student-centered activities that are common in established IBL classrooms (Laursen et al., 2014; Hayward et al., 2016). Even if instructors were not yet skilled in facilitating these activities, we could detect initial changes in their choices about the use of class time. To address quality of instruction, we chose a second observation protocol that offers an evaluative perspective via holistic ratings of each lesson. With thorough video sampling we could reliably characterize instruction for the course as a whole, not just in selected episodes (Weston et al., 2021). In this analysis, we consider: *What do three independent measures of teaching tell us about whether and how instruction changed after professional development?*

Context for the Study

To situate the study, we provide brief descriptions of inquiry-based learning in mathematics, in the general form that was practiced by workshop leaders and taught in workshops, and of the IBL workshop design. For more detail, we refer readers to the references cited below.

Inquiry-based learning (IBL) is a form of instruction that has become increasingly common as an approach to active and collaborative learning in college mathematics. Laursen and Rasmussen (2019) identified four pillars, or core principles that IBL shares with other forms of inquiry-based mathematics education (IBME). In effective IBL classrooms, students engage deeply with meaningful mathematics and make sense of these ideas in collaborative work with their peers, which may take a variety of forms. Instructors support these student experiences by inquiring into student thinking—drawing out student ideas and helping them toward further sense-making—and by making design and facilitation choices that involve all in rigorous mathematical learning and identity-building. The “big tent” philosophy of IBL recognizes that instructors will implement these principles in different ways, depending on their setting, adjusting to suit their course material, class size, student audience, and personal preferences.

Consistent with other research on EBIPs (Freeman et al., 2014), IBL offers cognitive and affective benefits and supports student persistence and success in later courses (Kogan & Laursen, 2014; Laursen et al., 2014; Laursen & Rasmussen, 2019, & references cited therein). On average, IBL approaches were found to close equity gaps in student experience compared to lecture-heavy approaches (Laursen et al., 2014), again consistent with general findings in the literature (Theobald et al., 2020). Of course, IBME is no silver bullet (Ernest, Reinholz & Shah, 2019; Johnson et al., 2020; Reinholz et al., 2022): instructors must take proactive steps to develop self-awareness and empathy and to select pedagogical approaches that foster mathematical identity and enhance classroom climate (Dewsbury & Brame, 2019).

The design of the IBL workshops was purposeful, research-aligned, and iteratively refined (Yoshinobu et al., 2022). Briefly, four interwoven strands of workshop activity sought to foster IBL-supportive knowledge, skills, and beliefs and prepare instructors to implement IBL in their own teaching contexts. Video lesson study sessions helped instructors develop a mental model for an IBL classroom, while literature-to-practice sessions used provocative readings and discussion to help instructors internalize the four pillars and reflect on their own beliefs. "Nuts and bolts" sessions shared facilitation and task-design tactics to build instructor skills, and course planning sessions provided planning exercises and personal work time to help instructors consider how to prepare their own IBL course. Through an active e-mail mentoring program, peers and facilitators provided follow-up support—resources, ideas, trouble-shooting, encouragement—as instructors implemented their IBL course after the workshop (Hayward & Laursen, 2018). Deliberate attention to equitable instruction and assessment practices was increasingly incorporated into the workshops across the 2016-2019 period that we studied.

Study Methods

The study design was approved by the university's IRB and all instructors gave informed consent. Students in video-recorded classes were given information explaining that the focus of the study was their instructor, not them. They could move out of camera view if they wished.

Study Population and Survey Sample

The study examined participants in 11 IBL workshops conducted in 2016-2019 (Archie, Hayward & Laursen, 2021). Online workshops in 2020 were omitted from outcomes analysis. They were surveyed at two times: All 293 answered the pre-workshop survey, and 199 (68%) the follow-up survey about 17 months post-workshop. Of these, 136 (68%) identified a target course before the workshop and then described implementing IBL (or not) in their target course on the follow-up survey; they form our sample to study instructional change.

Overall, the implementing respondents were very similar to the workshop attendees. Half were women. Most (87%) were US citizens, nationals or residents; of these, 80% were white and 5% were Asian. About 3% described themselves as Hispanic or Latino/a/X. Participation was well balanced among people in tenured (30%), untenured (30%), and non-tenurable (30%) positions, from departments granting four-year (42%), masters (23%), and PhD (21%) degrees, and some from two-year (13%) colleges. About 23% taught at a minority-serving institution. Overall, they were modestly more diverse than the U.S. mathematics professoriate as a whole, and they came from institutions that broadly represent teaching settings in U.S. higher education.

Survey Methods

Survey instrument. The survey included closed- and open-ended items previously described (Hayward & Laursen, 2014; Archie, Hayward & Laursen, 2021; Archie et al., 2022; Hayward et al., 2016). Some items were used to provide formative feedback to workshop leaders, to characterize workshop features, and to measure participants' knowledge, skills and attitudes. Participants self-reported personal and professional demographic information. Responses across time points were matched via unique identifiers. Here we focus on items used to describe teaching strategies at both times, from the TAMI-IS (Toolkit for Assessing Mathematics Instruction-Instructor Survey; Hayward, Weston & Laursen, 2018). These descriptive, behavior-focused items ask "*what did you do*?" rather than "*how well did you do it?* Taking the course as a whole, instructors estimated the frequency of use for each of 11 teaching practices often seen in college math courses (e.g., group work, whole class discussion, formal lecture, short explanations, student presentations), coded using the scale: 0 = never, 1 = once or twice during the term, 2 = about once a month, 3 = about twice a month, 4 = weekly, 5 = more than once a week, or 6 = every class. Open-ended items probed patterns in practices and special events and elicited text descriptions of 'lecture,' 'presentations,' and 'group work' as practiced in courses.

Survey analysis. We created a composite variable to measure instructors' overall use of IBL methods. This variable, IBL frequency score, includes five of the 11 practices classified as 'core IBL' practices because they measure all variations of IBL that were emphasized or de-emphasized in workshops and was calculated as follows: *IBL frequency = student group work + student presentation + class discussion - lecture - instructor problem-solving*. IBL frequency scores were calculated for pre-workshop and follow-up time points; scores could range from -12 to +18. Lower scores indicate less frequent use of IBL teaching practices and more frequent use of lecture and instructor problem-solving, while higher scores indicate more frequent use of IBL methods and less frequent use of lecture and instructor problem-solving. We conducted paired samples t-tests to measure change in IBL frequency between pre-workshop and follow-up times for instructors who did (n=15) and did not (n=136) participate in classroom observation.

Observation Methods

Observation sample. The observation sample was a subset of the survey sample: 15 workshop participants who registered early and volunteered to collect video data in their target course in the term before their summer workshop, and for the same or similar course the next academic year. Their personal and institutional characteristics are broadly similar to the survey sample. Instructors placed a video camera in their classroom several times a term and completed the survey at the end of the same term. We asked them to record about 1/3 of class time. In all, we coded 278 class sessions, averaging 9 classes per course and totaling over 300 hr class time.

Observation instruments. We applied two observation protocols that emphasize different dimensions (Hora & Ferrare, 2013a). The TAMI-OP (TAMI Observation Protocol) is a segmented, descriptive (behavior-focused) protocol that aligns with the TAMI-IS (Hayward, Weston & Laursen, 2018). It is adapted from the TDOP (Hora & Ferrare, 2013b) and COPUS protocols (Smith, Jones, Gilbert, & Wieman, 2013) to reflect practices we saw in college mathematics. Twenty activity codes for instructor and student behaviors were coded within each 2-minute segment. Fourteen end-of-class holistic items, designed by our team, query features of classroom atmosphere and student-teacher interaction (Laursen et al., 2011; Appendix 2).

The RTOP (Reformed Teaching Observation Protocol) is a holistic, evaluative protocol developed for K12 science instruction and increasingly used in higher education (Sawada et al., 2002). Raters score the lesson on 25 items in 5 categories: lesson design, teaching of content and procedural knowledge, communication, and student-teacher relationship. For each lesson, items are scored 0-4 to describe how often each feature is seen: "never occurred" to "very descriptive" of the lesson. Summed RTOP scores of 0-100 indicate the degree to which a course is "reformed" toward student-centered, evidence-based instruction emphasizing inquiry.

Observation analysis. Using data from the TAMI-OP and RTOP instruments, two global measures were used to assess change in teaching:

1. the RTOP-Sum (RTOP), a composite of 25 observational survey questions. Here ratings are summed over all questions and averaged over observed classes in a course.
2. the Proportion of Non-Didactic lecture classes (PND) across a term of observation using the TAMI-OP. PND provides an estimate of the proportion of classes, for one instructor, that use non-lecture teaching methods.

The analytical method for TAMI-OP is based on Latent Profile Analysis (LPA), a statistical clustering method applied to a large observation data set (790 observations of 74 teachers) from this and other projects (Weston, Hayward & Laursen, 2023). The LPA yielded four reliable class types (Didactic Lecture, DL; Interactive Lecture and Review, IL; Student Presentation, SP; Group Work, GW) based on the proportions of various teaching activities present in an individual class session. From the LPA results, we created a simple dependent measure to characterize a teacher's course based on the proportion of all observed classes for each instructor (over an academic term) that were *not* classified as didactic lecture (PND, proportion non-didactic). A paired-sample t-test was used to assess pre-post change in the observational indicator. We used the Cohen's D effect size for the analyses, which is the difference in pre/post means divided by the standard deviation of the difference.

Results

We analyzed the data sets for pre- to post-workshop changes for all three measures and summarize the results in Table 1.

Table 1: Pre- to post-workshop changes in instruction using three measures from survey (S) & observation (O)

S/O	Measure	N	Mean, pre	Mean, follow-up	Effect size	t	df	p
S	IBL frequency from TAMI-IS	136	0.03	6.34	0.88	10.31	135	< 0.001
S	IBL frequency from TAMI-IS, observation subset only	15	2.27	8.80	0.96	3.71	14	0.002
O	PND from TAMI-OP	15	0.58	0.81	0.80	3.13	14	0.004
O	RTOP-Sum	15	37.89	55.06	1.17	4.58	14	<0.001

The range for each measure is IBL frequency -12 to +18; PND 0-1; RTOP-Sum 0-100.

Instructional Change Based on Surveys

Figure 1 shows the distribution of IBL frequency scores at pre-workshop and follow-up, for both the full survey sample and the observation subgroup. A paired samples t-test showed a statistically significant increase in IBL frequency from pre-workshop to follow-up (Table 1).

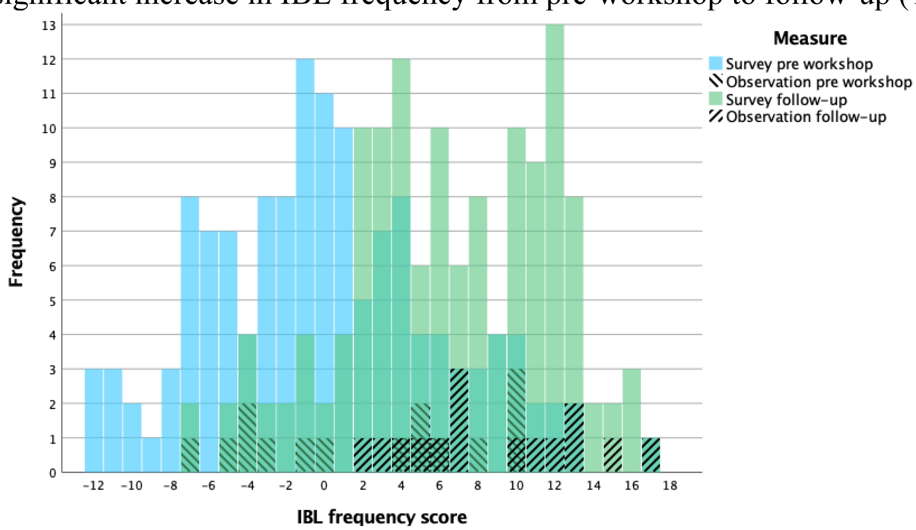

Figure 1. IBL frequency score from surveys, for full sample and observation subgroup at two times.

For video study participants, the change in IBL frequency score from pre-workshop to follow-up was also statistically significant, and comparable in magnitude to the average shift among all survey respondents (see Table 1). Video study participants used slightly more IBL core practices both before the workshop and subsequent to it, but these differences between the main group and video subgroup were not significant.

Half the main sample, and all 15 video participants, self-described as implementing at least “some IBL methods;” one third of the main sample and half of video participants described their implementation as a “full” IBL course. These are lower limits to the overall implementation rate, as 32% of all workshop attendees did not report on implementation. Their target courses served first-years to seniors; math majors (28%), mixed STEM majors (42%), non-STEM majors (13%) and pre-service teachers (4%). About 90% implemented IBL in a class of 35 students or fewer.

Instructional Change Based on Observations.

In general we saw gains in the average scores for both observation measures from pre to follow-up. Comparing these using paired samples t-tests, the changes in both the RTOP-Sum and the PND were statistically significant. For both measures, negative or no change was observed only for small numbers of instructors who had initial high scores. Figure 2 illustrates pre-post changes in PND for the 15 instructors. Each observed class session fits a latent profile (one colored cell) and PND for each course is based on the set of such profiles (one row of cells).

We also used LPA to examine changes in teaching approach. In post-TPD classes, instructors used less continuous lecture and more interactive lecture and group work, but also made less use of student presentations. Participants also adjusted the sequencing of activities. For example, changes in the timing of lecture and group work suggest a more structured and strategic approach to group work, with more consistent use of short lectures to summarize or signpost.

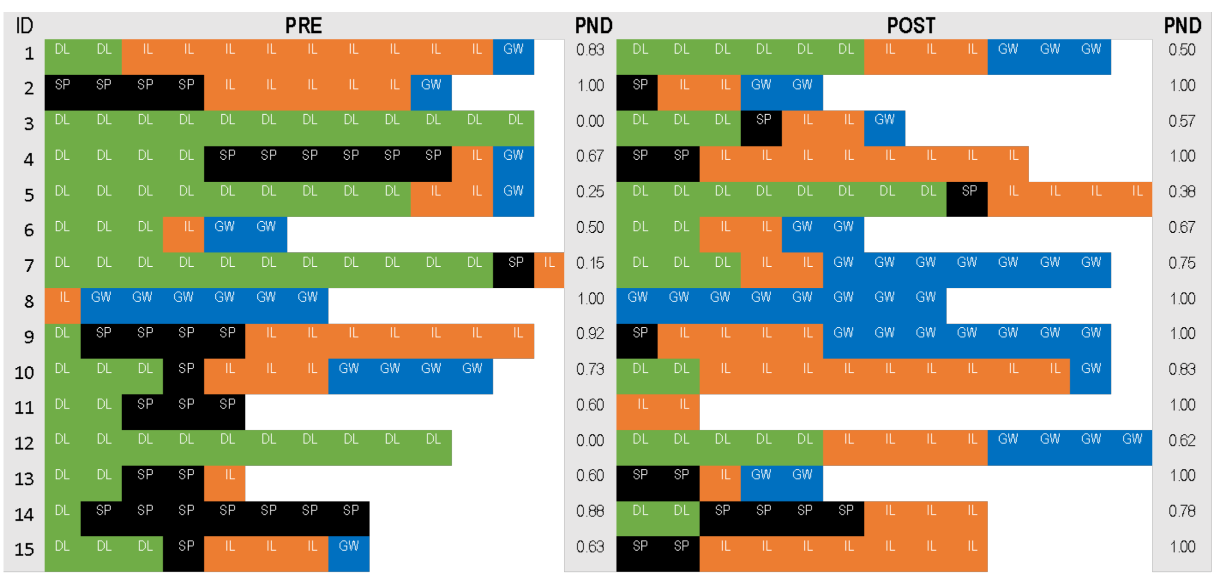

Figure 2. Latent profiles and PND for 15 observed courses for the same instructors (IDs 1-15) at pre-workshop and follow-up (“post”) times. Cells represent 1 observed class fitting a profile from LPA. DL (green) = didactic lecture; SP (black) = student presentation; IL (orange) = interactive lecture & review; GW (blue) = group work.

Discussion

This study identifies significant changes in the teaching practices of instructors after PD, using a rigorous approach to measurement. We found significant changes using three distinct measures. The effect sizes are impressively large (0.8 to 1.2) for an educational intervention. We used well characterized tools and large samples, and drew on different methods (survey vs. observation) with different foci (behavioral vs. evaluative). The TAMI-IS and TAMI-OP offer evidence that instructors' classroom practice shifted toward inquiry-based methods after TPD, and the RTOP-Sum offers evidence that post-TPD classes offered more student-centered, engaging and encouraging environments that were better aligned with evidence-based practice.

Survey responses from the subset of 15 instructors who were observed reflect a significant pre/post change similar to that seen in the larger survey sample. This indicates that such changes in teaching are not outliers, due to self-selection for video observation, but typical of the workshop's impact on instructors' teaching. Robust time sampling ensured that the coded observations were not "dog and pony shows" showing only the most active teaching days.

Other survey data enable us to attribute these changes to the workshop. Following the workshop, we observed robust and sustained growth in participants' knowledge and skills to use IBL; their motivation to use IBL and belief in its effectiveness remained strong and stable over time. In this sample and a larger group of IBL workshop participants, such growth in knowledge and skills, or "IBL capacity," was a good predictor of participants' later implementation of IBL (Archie et al., 2022). That is, changes in teaching behaviors are linked to the nature and strength of the gains that participants reported and sustained. Thus, the observed changes can be ascribed to participants learning and applying ideas they gained at the workshop.

Other studies of substantial TPD interventions for college instructors offer context for interpreting these results. Two studies, like ours, compared individuals to themselves before and after a TPD intervention. Chasteen and Chattergoon (2020) used the PIPS survey (Walter et al., 2016) to measure pre/post change in teaching practices of early-career physics faculty after a multi-day workshop, with an effect size of 0.8. In contrast, Ebert-May et al. (2011) reported no significant changes in RTOP scores after their TPD program for early-career biologists.

Two more studies compared teaching practices of TPD participants to samples of people who did not undergo TPD, and provided the data needed to compute effect sizes for mean differences between treated and untreated groups. After refining their biology TPD workshop, Ebert-May et al. (2015) measured differences in RTOP scores for participants vs. non-participants with an effect size of 0.68. Manduca et al. (2017) also used RTOP scores to compare treated (TPD) and untreated groups of Earth science instructors, with an effect size of 1.06. Both types of studies suggest that the changes seen here are impressive but not implausible—in line with what others have measured for STEM instructors who have taken part in thoughtfully designed, well supported, multi-day programs offered by skilled faculty developers in their discipline.

Conclusions

We report a "hat trick" of TPD measurement: three independent measurements of instructional change after a well-designed TPD intervention. The changes are large, statistically significant and well corroborated, and can be ascribed to the workshop. We propose that the workshop has this substantial impact due to its strategic approach (Kennedy, 2016), providing instructors with a set of principles and tools to achieve a desired teaching goal, thus empowering them to adapt their practices in ways sensitive to their own context and preferences (Yoshinobu et al., 2022).

Acknowledgments

The authors thank the enthusiastic facilitators who led the workshops and supported participants as they planned and implemented their IBL courses. This work was funded by the National Science Foundation under awards DUE-1525058 and DUE-1525077.

Modifying symbolic forms to study probability expressions in quantum mechanics

William Riihiluoma
University of Maine

Zeynep Topdemir
University of Maine

John R. Thompson
University of Maine

As part of an effort to examine student understanding of expressions for probability in an upper-division spins-first quantum mechanics (QM) context, clinical think-aloud interviews were conducted with students following relevant instruction. Students were given various tasks to showcase their conceptual understanding of the mathematics and physics underpinning these expressions. The symbolic forms framework was used as an analytical lens. Various symbol templates and conceptual schemata were identified, in Dirac and function notations, with multiple schemata paired with different templates. The overlapping linking suggests that defining strict template-schema pairs may not be feasible or productive for studying student interpretations of expressions for probability in upper-division QM courses.

Keywords: Quantum mechanics, probability, notation, representation

Introduction and Background

Mathematics is used in physics for far more than simple computation. Physicists make use of mathematical expressions and relationships to help them understand and reason about the world (Uhden et al., 2012). This is more true than ever in quantum mechanics (QM), where physical intuition developed in everyday life has little application and one must rely on mathematical reasoning to help intuit, understand, and predict systems on the quantum scale. The level of abstraction and mathematical sophistication required in upper-division QM courses has been extensively shown to be difficult for students in many ways (Singh, 2001; Singh, 2008; Singh & Marshman, 2015; Emigh et al., 2015; Passante et al., 2020). Some of the reasons for this difficulty are the number of different notations on offer, the vast differences in how they each appear, and the variety of mathematics they each require (Gire & Price 2015).

In QM, particles and systems of particles are described as existing in "quantum states." These states are defined as having some set associated, measurable quantity or quantities, such as specific energy values, positions, or momenta. Often, these quantities are incapable of being simultaneously determined together, and the most we can know about a particle with one definite quantity is the likelihood of measuring the various possible values of a separate quantity. Physicists primarily use linear algebra to express these probabilistic relationships, and use Dirac notation to express these states as vectors: $|\psi\rangle = \sum_{n} c_{n}|n\rangle$. Here, $|\psi\rangle$ is a vector representation (called a "ket") of the state our particle is in, and the various $|n\rangle$'s are representative of the various states the particle could be measured in – an eigenbasis – each corresponding to a different value of whichever quantity we are measuring. The probability of measuring each of those $|n\rangle$ states is given by $\left|c_{n}\right|^{2}$, or by taking the complex square of the inner product of the initial state (vector) with the particular possible state (vector) that we're interested in. In Dirac notation, this is written as: $P_{n} = |\langle\psi\rangle|^{2}$. This type of analysis is only applicable when the quantities in question are discretized, but is extended to include defining states with wave functions: $|\psi\rangle = \int_{-\infty}^{\infty} \psi(x)|x\rangle dx$. This can then be used to find probabilities for measuring that quantity within a range of values: $P_{a\rightarrow b} = \int_a^b |\psi(x)|^2 dx$. The discrete probability written before can also be written with these wave functions: $|\langle\psi\rangle|^2 = \int_{-\infty}^{\infty} \varphi_n^*(x)\psi(x)dx$, where $\psi(x) = \sum_n c_n \varphi_n(x)$. The difference in appearance and the type of mathematics required for these different probabilities is one of the reasons for the aforementioned difficulties for students learning and using the requisite mathematics in QM.

One framework that has been used to explain student reasoning with mathematical expressions is that of symbolic forms (Sherin, 2001), which was proposed by Sherin to explain how students could generate symbolic expressions for different physical scenarios. Largely based on the knowledge-in-pieces model (diSessa, 1993), symbolic forms is predicated on the notion that students learn to develop a sort of grammar and syntax for different mathematical operations in physics, and subsequently apply that logic to make sense of physical relationships. Sherin found that there were some universal forms that expressions take that students grow to recognize, which he called symbol templates, and that students learn to associate these templates with a conceptual understanding known as a conceptual schema. Symbol templates, when combined with their associated conceptual schemata, become symbolic forms, which Sherin argues form the building blocks for student interpretations of mathematical expressions used in physics. For example, the *parts-of-a-whole* symbolic form has "[□ + □ + □ + ...]" as its symbol template, and its conceptual schema contains the idea of multiple parts of a larger entity being summed together. This framework has since been extended to study the structure of expressions in more advanced topics in physics (Dreyfus et al., 2017; Schermerhorn & Thompson, 2019; Ryan & Schermerhorn, 2020) and has been looked at as a means to describe students' blending of conceptual and formal mathematical reasoning (Kuo et al., 2013).

Previous work has also looked at the affordances and limitations of the different notations used in QM (Gire & Price, 2015; Schermerhorn et al., 2019; Wawro et al., 2020). Dreyfus et al. (2017) posited a number of potential symbolic forms within Dirac notation that they suspect students likely develop through the course of an upper-division QM course, though little work has been done to address how students interpret and work with expressions across and within the different representations that are commonly used in upper-division QM.

As part of a study on how students reason about expressions in the various notations used in QM and the ways in which they translate between them, we conducted clinical think-aloud interviews with a number of students following a one-semester, spins-first, upper-division QM course. In a spins-first course, students begin working with Dirac notation immediately in the context of spin-1/2 systems, before eventually including wave function notation when position is introduced as a continuous observable. The mathematical connections between Dirac state vectors and wave functions are shown in an effort to help deepen students' understanding of Dirac notation, as well as to make the transition to wave functions as smooth as possible. We asked the students to both generate and relate different expressions in both Dirac notation and wave function notation. Due to our focus on student understanding and interpretation of symbolic expressions, Sherin's symbolic forms framework (Sherin, 2001) was used as a starting point for analysis. Our analysis suggests a modest expansion of the symbolic forms framework to address multiple overlapping sets of templates and schemata. This paper describes our analysis of student interpretations of expressions for probability in both Dirac and wave function notations, as well as the ways in which students translate between the two.

Study Design and Methodology

In order to elicit students' understanding of expressions commonly used to represent probability in QM, both in-person (paired, N=2) and virtual (individual, N=2) clinical think-aloud interviews were conducted following a one-semester upper-division QM course in two separate academic years. Students in both interview formats were asked to generate expressions for probabilities and to reason about both the expressions they generated as well as the processes by which they were generated. The virtual interviewees were provided with a number of symbolic building blocks with which to construct their expressions (see Figure 1), while the in-person interviewees were given a whiteboard and markers. In both cases, subjects were asked to generate expressions for probabilities based on scenarios similar to those studied in class. Some in-person interview questions gave the participants an expression describing a state and asked them to use it to find specific probabilities. The virtual interviewees were also given a card-sorting task where they were asked to sort a variety of expressions commonly seen in QM coursework, as well as generic vector expressions such as $\vec{v}$, $\hat{j}$, and $\vec{u} \bullet \vec{v}$.

The students' responses were transcribed and analyzed to determine which expressions they either grouped or generated, any intermediary expressions they used, and the language they used to explain their expressions. Excerpts of interest contained episodes of students interpreting specific expressions, explicitly connecting templates and schemata.

$$\boxed{\hat{S}_z} \ \boxed{|x\rangle} \ \boxed{\varphi_n(x)} \ \boxed{\langle E_n|} \ \boxed{|} \ \boxed{|^2} \ \boxed{\hat{x}} \ \boxed{|\psi\rangle} \ \boxed{\varphi_n^*(x)} \ \boxed{\hat{H}} \ \boxed{\int_a^b} \ \boxed{x} \ \boxed{\psi(x)} \ \boxed{\langle x|} \ \boxed{dx} \ \boxed{|E_n\rangle} \ \boxed{\int_{-\infty}^{\infty}} \ \boxed{\psi^*(x)} \ \boxed{\langle\psi|}$$

Figure 1. The symbolic building blocks of expressions that virtual participants had to work with when constructing their expressions.

Results and Discussion

Our analysis has revealed several different conceptual schemata, as well as a number of symbol templates with which students tended to associate them (Table 1). Despite differences in the tasks given between the two interview formats, our analysis did not suggest any modality-based distinctions. We propose that the focus on template-schema pairs common to symbolic form analysis is limiting when multiple symbol templates share the same conceptual schema.

Table 1. Identified conceptual schemata with their associated symbol templates. Some schemata are associated with multiple templates and vice versa.

Conceptual Schema	Symbol Templates
Vector in a space	$|\rangle$, $\langle|$, $c_1|1\rangle + c_2|2\rangle + \ldots$
Function in a space	$c_1 f_1(a) + c_2 f_2(a) + \ldots$
Quantum state	$|\rangle$, $\langle|$, $f(a)$, $f^*(a)$, $f_n(a)$, $f_n^*(a)$
Projection/dot product	$\langle\rangle$, $\int f(a)g(a)da$

Probability density	$\langle\rangle$, $\lvert f(a)\rvert^2$
Probability	$\lvert c_n\rvert^2$, $\langle\rangle$, $\lvert\langle\rangle\rvert^2$, $\int f(a)g(a)da$, $\int \lvert f(a)\rvert^2$

Dirac notation paired with vector ideas

Students across all three interviews in this study (Aliyah and Bilbo in the virtual interviews and Castor and Delilah in-person) explicitly referred to both kets and bras as representing vector-like quantities, and Dirac brackets as being akin to dot products between them:

Bilbo (discussing sorted category containing $\vec{v}$*,* $\hat{j}$*,* $|\psi\rangle$*, and* $|E_n\rangle$*)*: to me, all vectors. Unit vector [$\hat{j}$], generic vector [$\vec{v}$], state- ... wave vector [$|\psi\rangle$], eigenstate vector [$|E_n\rangle$]

Bilbo (discussing operating $\hat{S}_z$ *on* $|\psi\rangle$*)*: certainly changes the state ... if the state is purely in Z [meaning expressed as a superposition state in the $\hat{S}_z$ spin-1/2 basis], I believe it'll still change it, but I think by only lengthwise stretching ... rather than rotating.

Aliyah (discussing $\langle\psi\rangle$*)*: why would I do ψ of ψ? Because physically like I'm thinking in terms of vectors it represents ψ along ψ

Aliyah (explaining what they mean by "__ along __"): it's a traditional way to think about vectors like because our dot product represents- like $\vec{a} \bullet \vec{b}$ represents, basically, the projection of $\vec{a}$ along $\vec{b}$ or projection of $\vec{b}$ along $\vec{a}$

Castor (explaining why for $n{\neq}m,\ \langle E_m\rangle = 0$*)*: Because of like orthonormality, the eigenstates are perpendicular in a space

Castor (explaining why $\langle E_2\rangle = 1$*)*: Because, like 100% of E2 [gestures at the bra] is in the direction of E2 [gestures at the ket]

These responses largely match up with what one would expect, as a large focus of a spins-first QM course is to help students reason geometrically with Dirac notation.

Through the lens of symbolic forms, two conceptual schemata appear to be expressed here: a "vector in a space" and the "projection" idea that often arises with dot products. The former conceptual schema is linked to "$|\rangle$" and "$\langle|$", while the latter is linked to "$\langle\rangle$".

Dirac bras and kets paired with "quantum state"

While interesting in its own right, a vector-like understanding is not the only way that students worked with and thought about these Dirac expressions. All four students described bras and kets as stand-ins for quantum states as well:

Aliyah: This [$|E_n\rangle$] represents a ket energy eigenstate, and this [$\langle E_n|$] represents a bra energy eigenstate. So these [$|\psi\rangle$ and $\langle\psi|$] are general ones, these [$|E_n\rangle$ and $\langle E_n|$] are specific energy eigenstates

Bilbo (discussing $|x\rangle$*)*: You could make x an eigenstate, you could make it a spin state ... put anything in there ... I just need it to be a ket

Castor: So typically when I write [$|\psi\rangle$] in terms of the energy eigenstates [points to $|E_2\rangle$]...

Delilah (discussing a superposition state written $|\psi\rangle = \frac{1}{2\sqrt{2}}\left(\sqrt{3}|E_1\rangle + |E_2\rangle + 2|E_3\rangle\right)$): We just represent it as the probab- the square root of the probability times the first state [points to $|E_1\rangle$] plus the square root of probability times the second state [points to $|E_2\rangle$] plus the square root of the probability times the third state [points to $|E_3\rangle$]

These students appear to be using some of the same symbol templates as in the previous section ("$|\rangle$" and "$\langle|$"), but with a "quantum state" conceptual schema. This is unsurprising, as the first half of a spins-first course uses bras and kets as representations for a quantum state.

Other Dirac pairings

An additional common use of Dirac brackets was as a means of describing and calculating probabilities or probability amplitudes:

Aliyah: This [$\langle\psi\rangle$] will also represent the probability of finding x - sorry, the probability of finding the general state ψ in the eigenstate x

Bilbo: That [$\langle\psi\rangle$] is just an inner product, though, I had been saying the inner product squared is a probability and that this [$\langle\psi\rangle$] is... just a density

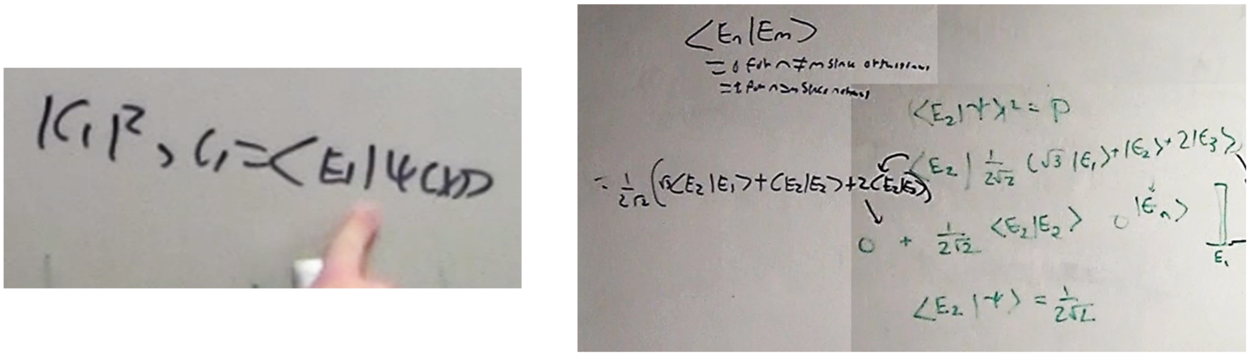
Again we see a symbol template from before ("$\langle\rangle$") being associated with a different conceptual schema: in this case, that of a probability-like concept. We note that "probability," "probability amplitude," and "probability density" are used somewhat interchangeably by the students throughout these interviews. Every student also eventually squares many of these Dirac brackets, which suggests yet another symbol template, "$|\langle\rangle|^2$" also with an associated "probability" conceptual schema.

While Castor and Delilah also related Dirac brackets to probability concepts, they almost exclusively did so by first claiming that the Dirac bracket gives "the coefficient," and that "the coefficient squared" then gives the probability:

Castor (explaining why a number they found was a probability): Because it's the coefficient for the first energy state. ... because we do, we do the same thing as... [writes $\langle\psi(x)\rangle$]

Delilah: Our probability for energy is the coefficient squared. And the coefficient is, E sub one times psi [writes $\left|c_1\right|^2,\ c_1 = \langle\psi(x)\rangle$] (see Figure 2a).

Castor and Delilah's focus on "the coefficient" as a sort of requisite step to allow a Dirac bracket to describe a probability was not seen in Aliyah or Bilbo's virtual interviews. This may be a case of Aliyah and Bilbo glossing over a step that they have since automated, or it could be evidence of Castor and Delilah using the Dirac bracket's "dot product" conceptual schema to reason about a larger process of "pulling out a coefficient" from an expression for a superposition state. This process was shown explicitly by Castor and Delilah, as can be seen in Figure 2b. This suggests that these students developed another symbol template during this course: "$c_1|1\rangle + c_2|2\rangle + ...$". The associated conceptual schema appears to be that of a vector being described with components along various basis vectors, in which case it is likely a compound form as discussed by Dreyfus et al. (2017), potentially of the "parts-of-a-whole" and "magnitude direction" symbolic forms, the former from Sherin (2001) and the latter from Schermerhorn and Thompson (2019). It also seems clear that Castor and Delilah make use of another symbol template, that of one of these coefficients squared, "$\left|c_n\right|^2$", and that they associate with it the conceptual schema for a "probability" as well.



(a) (b)

Figure 2. (a) Delilah expressing how the Dirac bracket gives the coefficient, which can then be squared to find a probability, and (b) Castor's (right) and Delilah's (left) work explaining how ⟨ψ⟩ yields the coefficient, which is then squared to find the probability. Delilah's work supplements Castor's by explicitly distributing the bra throughout the sum.

Functions paired with state ideas

Moving away from Dirac notation, students in all interviews also worked with functions, often describing them as representing quantum states:

Aliyah: Those [$\psi(x)$, $\psi^*(x)$, $\varphi_n(x)$, and $\varphi_n^*(x)$] represent states ... some of them represent general states [$\psi(x)$ and $\psi^*(x)$], some of them represent specific energy states [$\varphi_n(x)$, and $\varphi_n^*(x)$], but they represent states

Bilbo: This [$\psi(x)$] is just another function, so what I'm thinking of is like an eigenstate [$\varphi_n(x)$] and just a generic state [$\psi(x)$]

Castor: These [φ_1 and φ_2 in $|\psi(x)\rangle = c_1\varphi_1 + c_2\varphi_2 +$] are the position eigenstates

Delilah: $\psi(x)$ ... is, like c_1 times $\varphi(x)$ [writes $\psi(x) = c_1\varphi_1(x) +$] ... I think these [points to $\varphi_1(x)$] are the energy eigens- the energy eigenstates written in the position basis

Castor is being somewhat loose with their notation, mixing Dirac notation together with wave function notation in the same expression, but seems to have "translated" the kets they wrote previously into functions directly below them (see Figure 3). At this point the "quantum state" conceptual schema is being used to describe a very different-looking symbol template (that of a function, perhaps "$f(a)$" or "$f_n(a)$"). These excerpts potentially suggest a distinction between "$f(a)$" and "$f_n(a)$" as representing specifically "generic states" and "eigenstates," respectively. Figure 3 also suggests another symbol template analogous to that discussed in the previous section, but in this case in wave function notation: "$c_1f_1(a) + c_2f_2(a) + ...$". The paired schema is that of a "function in a space," described as a sum of component functions—analogous to the compound form discussed above.

This shared schema is a reasonable instructional outcome as, once students begin working with wave function notation, they are often told that kets can be translated to functions and use $\psi(x)$ and $\varphi_n(x)$ to describe generic states and energy eigenstates, respectively.

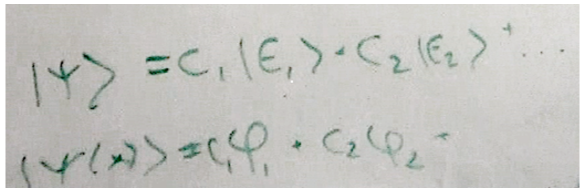


Figure 3. Castor's expressions for a superposition state. They wrote the top line first, then the bottom beneath it.

Other function pairings

Students would also often write integrals of these functions when asked to generate expressions for probabilities. Below is an example of Bilbo's response after being asked how they would find the probability of measuring a given energy:

Bilbo: in this case [$\int \varphi_n^*(x)\psi(x)dx$] here ... I'm thinking okay, you have this state [points to $\psi(x)$] ... and you want to ask the question of, you know, "what about that state [$\psi(x)$] being in this [$\varphi_n^*(x)$] eigenstate." And, or what is- to me I'm looking at this thing I'm thinking, "what is the projection of this eigenstate onto this wave function," or maybe vice versa, but I don't think it should matter- dot products are ... commutative

Bilbo generated an integral when asked for a probability, and discussed it with very similar language as was used for Dirac brackets above—that of a "projection" of one state onto another, both being represented as different functions within the integral. This supports a potential symbol template of "$\int f(a)g(a)da$" being paired with a conceptual schema encapsulating ideas of "projection" or "dot product," providing the functional analog to the Dirac inner product expression.

Castor and Delilah were asked to find the probability of measuring a particle to be in the left half of an infinite square well, and used very different language to discuss their work:

Delilah: [writes $\int_0^{\frac{L}{2}} \frac{1}{8}\left(\sqrt{3}\varphi_{E_1} + \varphi_{E_2} + 2\varphi_{E_3}\right)^2 dx$] So we're- at every position we're computing [points to integrand]- like every infinitesimally small position we're computing the probability [again points to integrand]-

Castor: You're taking the probability, kind of at like an instant, and taking that like, infinitely small sum to get your, like, probability distribution.

Delilah: [writes "$|\psi(x)|^2 = Probability\ Density$"] So yeah, so it just yeah, every- every infinitesimally- ... dx, yeah, essentially. We're finding the probability of it being there ... [it's] just the summation of all the values in the left half of the well.

It is worth pointing out that Castor and Delilah are, on the surface, doing a very different problem than Bilbo was above. Bilbo was finding a probability for an energy value, while Castor and Delilah were finding the probability of a range of position measurements. While a mathematical equivalence can be shown between these two problems, they appear to be different problems to the students, as they reasoned about the two integrals very differently. First, even though Castor and Delilah generated an integral, the symbol template is very different. Rather than two different functions (representing two separate quantum states) as the integrand, they instead used $|f(a)|^2$ (which may perhaps be thought of as $f^*(a)f(a)$, or the complex conjugation of the same function with itself). Second, Bilbo used very similar "projection" reasoning as was paired with the Dirac brackets in all three interviews, even explicitly bringing up dot products. Castor and Delilah instead reasoned with probability distributions and Riemann sums, invoking an "adding up pieces" model for integration (Hu & Rebello, 2013; Jones, 2015).

The difference in how these integrals are written and interpreted suggests Castor and Delilah are utilizing a different symbol template here: "$\int |f(a)|^2 da$" or perhaps "$\int f^*(a) f(a)$". It also seems evident that there may be a further symbol template here: "$|f(a)|^2$", which Castor and Delilah associate with a schema of "probability density."

Conclusions

The symbolic forms framework gives us a language with which to discuss student interpretations of symbolic mathematical expressions. In our study we have seen that, in a spins-first context, students develop a multitude of conceptual schemata and numerous symbol templates, each often associated with multiple of the other. While we could take each identified template/schema pair and declare them all as separate symbolic forms, the level of overlap between many of them suggests it may be more productive to instead treat them as laid out in Table 1: as conceptual schemata that can be expressed in various ways by using various symbol templates, depending on context. This could be seen as a complication of an otherwise simple framework, but we believe that it is a more accurate description of the reasoning needed in upper-division QM coursework. Students need to be able to start from either a Dirac state vector expressed as a ket or a wave function and work their way to an expression for a probability, sometimes expressed in Dirac notation and sometimes in wave function notation. We posit that it is these shared conceptual schemata among different symbol templates that allow for students to understand how and where to make mathematical decisions to arrive at an answer—and that they may even partially explain how students reason and translate across notations. Developing this interwoven mathematical vocabulary is one challenging aspect of learning quantum mechanics.

With an increased call to attend to diversity, more postsecondary mathematics instructors are interested in using equitable and inclusive teaching (EIT) practices. Yet, ambiguity persists on what EIT practices look like in mathematics classrooms. Our study investigates the characterizations of EIT from 13 participants, each involved in a year-long equity focused workshop, with the purpose of describing what topics arose in their characterizations. Our analysis shows characterizations of EIT included both the student and teacher role in EIT, and focused heavily on awareness of students' experiences and backgrounds, student engagement, and teacher self-reflection. We provide specific details from participants' characterizations for each category and connect them to established EIT literature. These findings can help researchers and department leaders engaged in change for EIT see what topics in EIT are being consumed and what topics might need emphasis or introduction.

Keywords: Equitable and inclusive teaching, instructor beliefs, postsecondary mathematics

The past two decades have seen enhanced calls to promote diversity, equity, and inclusion (DEI) in postsecondary education broadly and mathematics specifically (e.g., Inniss et al., 2021.; MAA, n.d.; U.S. Department of Education, 2016). Such efforts are often tied to the increasing gaps in Bachelor's degree attainment between white students and members of some racial minorities (National Academy of Science, 2010; Riegle-Crumb, 2019; U.S. Department of Education, 2016). In particular, Black and Latina/o students who enter college as a STEM major are more likely than white students to switch to a non-STEM major or leave college altogether (Riegle-Crumb, 2019). Participation in the "mathematics pipeline" plays a particularly significant role in shaping the opportunities for economic and social advancement afforded to students (Gutiérrez, 2012a, p.19), yet school mathematics traditionally excludes people of color, women, and individuals who have disabilities. Many educators agree students need opportunities to engage in mathematics that valorizes their own cultural experiences, and gives them a tool for challenging the status quo in mathematics and Western society broadly (Gutiérrez, 2012a). However, research has shown instructors may struggle to provide such opportunities for their students (Rubel, 2017), and more work is needed to better understand how instructors conceptualize equitable and inclusive practices.

Postsecondary mathematics instructors play a key role in both determining the mathematics students are exposed to, as well as in shaping cultural norms around teaching within mathematics departments (Reinholz & Apkarian, 2018; Smith et al., 2021). Their beliefs and attitudes toward equitable and inclusive teaching (EIT) determine their decisions in the classroom, and further their ability to advance change in their departments (Johnson et al., 2022). There has been a shift in the field toward the use of active learning teaching methods as a way to address inequities in mathematics participation, but these methods do not automatically create an equitable classroom

(Brown, 2018; Johnson et al., 2020, Reinholz et al., 2022). Williams et. al (2022) analyzed participants' conceptualizations of active learning and found that equity was rarely connected. Given the close tie between beliefs and practices (e.g., Speer, 2008), it is important to understand how mathematics instructors conceptualize equity. An analysis of how "inclusion" has been used in research articles from 2010 to 2016 shows this term is used as a single ideology and as a way of teaching (Roos, 2018). Thus, the phrase "equitable teaching and inclusion" has the potential to be used and understood in many different ways, possibly diluting its intention and power. Therefore, it is necessary to monitor how postsecondary instructors are interpreting and influenced by these concepts. To this end, we studied how postsecondary mathematics instructors committed to active learning and teaching more equitably conceptualize EIT. Our overarching research question is: *What characteristics arise when mathematics instructors are asked to define EIT?* We intentionally left our research question broad to capture the varied and rich responses shared by our participants; in our discussion we draw connections between our findings and the research literature.

Theoretical Background

Learning is a sociocultural experience involving a complex interaction among instructor, students, content, and the underlying social and cultural systems in which these components operate (Hawkins, 1974; Lampert, 2001). Mathematical knowledge is co-constructed in the classroom with students through a focus on establishing sociomathematical norms and the development of a mathematical identity (Brown, Collins, & Duguid, 1989; Cobb & Bowers, 1999; Cobb, Yackel, & Wood, 1992; Lave & Wenger, 1991). Yet, Gutiérrez (2012b) argues even those who acknowledge a sociocultural perspective on learning and see knowledge as constructed in negotiation with others in a community of practice (Wenger, 1998; Cobb & Yackel, 1998) often fail to take into consideration students' identities or issues of power in a class community's construction of mathematical knowledge (Gutiérrez, 2010).

Gutiérrez (2002) defines equity as "the inability to predict mathematics achievement and participation based solely on student characteristics such as race, class, ethnicity, sex, beliefs, and proficiency in the dominant language" (p. 153). In later work, she expands this definition to include four dimensions: access, achievement, identity, and power (Gutiérrez, 2012a). Briefly, access refers to the resources students have access to for learning, and achievement references educational student outcomes. Both dimensions make up the dominant axis of equity, as they focus on helping students succeed according to the dominant culture's values. Identity and power make up the critical axis. Gutiérrez uses a mirrors and windows metaphor to describe identity, which focuses on opportunities for students to see mathematics as meaningful in their everyday lives: there should be places in the mathematics curriculum both for students to see their identity reflected back at them (mirrors) as well as be given access to the broader world of mathematics (windows). Power refers to issues of social transformation, including which voices are highlighted in education, using mathematics for social justice, etc.

There are several pedagogical traditions which prioritize inclusivity (e.g., culturally relevant pedagogy, critical pedagogy, humanizing pedagogy, reality pedagogy). While each tradition has different foci, collectively, inclusive pedagogies highlight the importance of empowering students by using students' rich cultural backgrounds and identities to design curriculum, providing students the tools to enact social and political change, positioning students as experts in the learning process, fostering caring and trusting relationships between instructors and students, and embracing students' voice and lived experiences (including their social, political, psychological, and emotional selves) in the classroom (Carter, Andrews, & Castillo, 2016; Emdin, 2016; Howard, 2003; Macrine, 2009; Tuitt, Haines, & Stewert, 2018).

Methods and Participants

This qualitative study investigates how 13 undergraduate mathematics educators from eight institutions involved in SEMINAL's (see Smith et al., 2021 for more information) equity-focused professional learning community (PLC) conceptualize EIT. Each participant was paid a $1,000 stipend to participate, which met every two weeks from September 2020 to May 2021. Participants were interviewed for approximately 60 minutes at the beginning, middle, and end of this timespan. They shared their racial and gender identities in the interview and names were pseudonymized to support participants' confidentiality. Participants include three women of color (Aadaya, Camila, and Cassandra), one man of color (Robert), five white women (Crystal, Emma, Kathleen, Lacy, and Shea), and four white men (Bill, Collin, Mark, and Thomas).

For this study we focused on responses to the question "How would you define or characterize equitable and inclusive teaching (EIT)?" from their first and last interviews. We analyzed responses using rounds of first and second cycle coding (Miles et al., 2014). For the first cycle of analysis, we developed 13 participant summaries to identify key ideas within the participants' responses. These key ideas were highlighted within the transcript, summarized below, then agreed upon by at least three of us. In pairs we then engaged in a second cycle of coding to sort the summarized key ideas for one-third of the 13 participants into different categories. Each pair looked at a different third of the participants. We then met to compare categories. The commonalities across groups led to a condensed structure that focused on awareness of students, student engagement, teacher reflection, and specific actions for EIT. The first three authors drafted a codebook (see Table 1) of these overall categories with defined subcategories, independently coded three participant responses (by coding each of the highlighted key ideas within the response) and met to reconcile and subsequently refined the codebook. Afterwards, they independently coded and reconciled the remaining 10 participants.

Findings

We generated three major codes of how participants characterize EIT: *Awareness and Consideration of Students, Student Engagement,* and *Reflective Practice* with relevant subcodes (see Table 1). All participant's conceptualizations of EIT included each of these three codes. Table 1 includes counts for each subcode. Below we describe each of these codes in detail using examples from participants' responses.

Table 1. Characterization of EIT and Number of Responses

Code	Description	# of responses (n=13)
Awareness and Consideration of Students: Awareness and consideration of how students' environments and lived experiences impacts their identity and capacity; this one is about the more general classroom environment		

Background and Learning Experiences	Mention of the student's broader background or environment: prior academic/learning experiences, "meeting them where they are," etc. E.g., "They bring different experiences to the classroom"	11
Access to Material Resources	Mention of student access to materials, finances, resources E.g., "Some students can't attend office hours"	6
Emotions	Mention of students' feelings, emotional health, "social belonging" (which includes a nod to gender, identity, disabilities, bringing whole self to the classroom) E.g., "Students should feel safe"	11
Student Engagement: Emphasizes the student experiences and academic culture of the classroom; ensuring each student possesses a sense of academic belonging		
Participation	Focus on student participation in the classroom E.g., "Students should engage with peers and content"	13
Ownership/ Investment	Focus on student investment and ownership of participation (ownership of their learning), usually more specific than general participation E.g., "Students should feel like the material is for them"	3
Reflective Practice: Acknowledges influence of pedagogical or personal views on the classroom environment as well as specific actions for EIT		
Self-reflection	Acknowledging and/or reflecting on personal biases and teaching practices; may include broad statements of what an instructor should believe or do E.g., "I had all these preconceived notions"	12
Actions	Specific actions or teaching practices teachers ascribe to themselves as beneficial for the individual student experience as well as the classroom as a whole E.g., "Bring in examples that bring up topics of racism"	9

Awareness and Consideration of Students

All thirteen participants discussed being aware of students' experiences and considering how these experiences connect with issues of equity and inclusivity in the classroom. Three subcodes emerged: Background and Learning Experiences, Access to Material Resources, and Emotions.

The Background and Learning Experiences subcode refers to a broad consideration of students' individual backgrounds and characteristics (e.g., race, culture, socioeconomic status, first generation status, marginalization, prior academic experiences, etc.). For example, Cassandra asserted no one should have an "advantage or disadvantage based on something they have no control over" referring to students' background. Emma also discussed this idea, saying part of EIT is “accepting that your students are coming into class with different lived experiences and that affects how they interact in the classroom.” Mark’s definition of equity in the classroom included his recognition of “different levels of preparation, [...]comfort, or different prior experiences.” Some participants went further, suggesting consideration of students' backgrounds is necessary but not sufficient for EIT. Crystal explicitly noted it is not enough to “recognize” students – EIT involves being “proactive” although she did not elaborate on what this means.

Access to Material Resources captured explicit references to financial restraints or situations possibly impacting student access to the resources necessary to succeed in class. Responses ranged from minimizing financial strain on students (Thomas) to acknowledging the impact priorities outside the classroom (e.g., having to take care of siblings) have on student capacity to learn in and outside the classroom (Cassandra and Shea). There was significant overlap between the Access to Material Resources subcode and other subcodes under Awareness and Consideration of Students; five of the six participants whose excerpts were coded the former were double-coded with another subcode in this code. For example, Cassandra described how “you shouldn't be made to feel that your questions or answers or situation is somehow your fault or an indicator that you do not belong because of your financial background, because of what you look like, because of any physical or emotional issues that you may be dealing with," which involves both students’ backgrounds and their access to material resources. Participants in this category are making connections between a student’s background experiences and how they affect student access to materials.

Eleven out of 13 participants considered students’ emotional health and comfort level in class. The following excerpts describe the major ideas of this subcode: that students “shouldn’t be made to feel like [their] questions or answers or situation is somehow [their] fault or an indicator that [they] do not belong because … of any physical or emotional issues” (Cassandra) and that when in the classroom, students “feel like they can be their whole selves” (Shea). Seven participants explicitly used the keywords “safe”, “welcoming”, and “belonging” when describing their ideal classroom environment. In addition, several participants also made the distinction between “for all” and “for each” instruction, implicitly linking their responses to equity. Thomas observed that students with certain characteristics connect with teachers and peers “if they’re lucky”, while Crystal wanted “everyone in [her] classroom to feel valued and feel heard.”

Student Engagement

All participants mentioned providing student opportunities to engage and participate in the classroom as part of EIT, with a common theme of making sure certain groups of students were not “overlooked” in the classroom. The Participation subcode focuses on response excerpts focused on student participation and additions to the classroom; as Aadaya stated, “equitable and inclusive means that I'm not, you know, overlooking some students or kind of leaving them out of a discussion. So this is the participation aspect.” Thomas related student participation to his own experiences: “So I would want to involve students like me who, you know, who don't mind working on their own. I want to make sure that the quiet ones, which is, I guess, how I characterize myself, are not overlooked." In addition, Camila described inclusive teaching as “reaching out to the students in class, making sure that they participate in the class and again that it's not dominated by one group versus another." Crystal also discussed giving students who are “marginalized” opportunities to participate:

> One aspect is like recognizing everybody that's in the room, like the people who are marginalized. I want to be able to recognize and give them a chance to participate and have

them feel valued and seen as well as the more confident students who sit in the front of the room and participate all the time.

Some participants addressed wanting students to feel safe in the classroom, but Crystal's excerpt goes beyond this, illustrating she also wanted students to feel safe to "participate all the time".

The Engagement subcode shifts perspective to excerpts where participants described wanting to ensure student access to the mathematical content and students' sense of ownership in the classroom. Robert discussed creating a classroom where "each student has not only access to whatever we're talking about through whichever entry point, but then also them feeling empowered and safe to speak up in class." Similarly, Mark described wanting students to "feel like the mathematics is there meeting some need or meeting some interest, or like it's something that is presented for them … that they have some sense of ownership." Mark then elaborated: "I would say that they're not kind of feeling alienated from [the mathematical content], or that they're like trespassing somehow on a domain that the property belongs to someone else. That [the material], it's for them."

Reflective Practice

All 13 participants mentioned something about the role of the teacher, specifically a self-reflection and/or a specific teacher action for EIT. We use this section to discuss categories.

Twelve out of 13 of participants' responses were coded with Self-reflection. This subcode captured responses that indicated the importance of self-reflection to teach equitably and inclusively, as well as responses in which participants engaged in self-reflection about their own teaching practices. For example, Shea shared that as an instructor, she needs to "sit with the discomfort of knowing" that even if she thinks an activity is going well "that doesn't necessarily mean that it is inclusive or equitable," suggesting that EIT requires reflection on how students and teachers may experience the classroom differently. Other participants further discussed how reflections about student experiences should inform practice. Ryan shared the importance of "meeting students where they are and not having students meet you where you are" in EIT. In this example, Ryan acknowledged that his practice of teaching should change even if he did not include a specific way to enact that change. Of note is the specificity of some reflections. Aadaya discussed her realization that despite self-characterizing as "approachable", she possesses many "preconceived notions" regarding "this is how all students are." She concluded by linking a specific focus on being "vulnerable to understanding" students and their backgrounds as part of her definition of EIT.

We used the subcode Actions when participants described something specific that a teacher did or could do in connection with EIT. If the action was general, like "be more open," then it was not included. Nine out of the 13 participants' responses included a specific task or practice including pointing students (especially students with less access) to specific resources, purposefully including topics of racism or environmental change into the classroom, coordinating sections to be more comparable to one another, making sure that "everyday life problems" are inclusive, making an effort to pronounce names correctly, intentionally asking identity-related questions (e.g., "What pronouns do you use?"), making sure that the grading system aligns with letting students grow and be their whole selves, not reacting negatively to students who do not follow academic social norms because they might not have access to them (e.g., "not being insulted when students communicate with me in a way that is not academic"), and learning and changing teaching practices to help with student needs and disabilities (e.g., try to not talk while facing the board for students who read lips). Most of these specific actions were described as EIT practices instructors should do.

Discussion & Implications

Each of the participants' responses is categorized by at least one subcode from the overarching codes: Awareness and Consideration of Students, Student Engagement, and Reflective Practice. This suggests participants view EIT in terms of who students are, how that impacts their engagement in the classroom, and what the instructor can do to affect that engagement. Connecting to Gutiérrez's (2002) definition of equity, several participants expressed the belief that students should not be disadvantaged based on their backgrounds, including characteristics such as race, as well as students' academic experiences and access to material resources. This includes a belief that it is the instructor's responsibility to make sure students are not disadvantaged, or feeling alienated, by the dominant, sociomathematical norms of postsecondary mathematics classrooms. This reflects Gutiérrez's (2012a) notion of the importance of addressing students' access to resources for learning.

Many participants also reflected on their actions as teachers, specifically on their personal biases and practices. In particular, responses indicate that identifying areas of growth, maintaining flexibility, and leaning into the discomfort of change are necessary to create equitable classrooms. As Tuitt et al's (2018) state, instructors engaging in EIT practices must be resilient, as EIT involves a significant amount of discomfort and emotional labor. Additionally, this reflective practice (Schön, 1983) is central in all teaching, but in EIT this reflection involves thinking about how students experience the classroom differently than oneself and acting accordingly. Some participants mentioned efforts in their teaching to consider how students experienced their classrooms and recognize that experience differs from their own.

While some discussed the importance of including what Gutiérrez's (2012a) calls mirrors in the curriculum, or, as Tuitt et al. (2018) describe, opportunities for students to personalize content by seeing examples from their cultural or lived experiences, as well as the importance of including topics such as racism, most participants did not stress EIT as a tool for social and political change. This is unsurprising given how difficult instructors find it to create mirrors for their students in the classroom (e.g., Rubel, 2017). Yet, most participants view EIT as important in addressing students' emotional wellbeing, aligning with more humanizing pedagogies which encourage students to embrace their whole selves in the classroom, as well as desire to have students take ownership over their learning.

Our findings can help researchers and department leaders engaged in change for EIT see what topics in EIT are being consumed and what topics might need emphasis or introduction. The participants were connecting EIT with being aware of a variety of aspects about students, but we did not see many responses explicitly mentioning how these aspects relate to power. Yet power is an integral part of EIT and needs to be better understood. Who has the power in EIT? How do you distribute power in EIT? What role do departments have in distributing power within and outside classrooms? Additionally, participants often connected student participation with EIT, but there is an opportunity for emphasizing how students are feeling when they are participating. How are teachers supposed to learn how to attend to student learning, student feelings, and their own learning about EIT? How can departments help support their teachers learning this level of attention?

Acknowledgments

Data was collected through an NSF funded project (DUE 1624639, 1624643). We would like to thank the SEMINAL project for designing the larger project from which this data was collected.

Adapting the Argumentative Knowledge Construction Framework to Asynchronous Mathematical Discussions

Darryl Chamberlain	Zackery Reed	Karen Keene
Embry-Riddle Aeronautical University

Weinberger and Fischer (2006) designed a framework for analyzing learning the context of asynchronous discussion activities. Operationalizing this framework, we analyzed the social and cognitive aspects of a discussion activity in an asynchronous calculus course. From this analysis, we identified aspects of Weinberger and Fischer's (2006) framework lacking in explanatory power for mathematics-specific discourse and developed an amended framework. We propose that this amended framework may enable in-depth analysis of major dimensions of students' mathematics knowledge construction as they engage in activities in an online asynchronous modality. This framework may also support the curriculum development for online asynchronous mathematics coursework.

Keywords: Calculus, Knowledge Co-Construction, Asynchronous Instruction, Design Research

Introduction

Classroom discourse can provide a powerful opportunity for students to gain mathematical knowledge. Though many students learn mathematics in asynchronous formats, the kinds of learning taking place in asynchronous formats remains severely underexamined. We are motivated to explore in more detail the learning within asynchronous discussions; specifically, we study discussion activities as we contend they are a primary point of contact in asynchronous formats among students, their peers, and their instructor.

In prior work (Keene, et al., 2016), we proposed use of Weinberger and Fischer's (2006) *Argumentative Knowledge Construction* framework for design research. We now present the results of a study operationalizing and extending Weinberger and Fischer's framework to examine the knowledge construction taking place in asynchronous calculus discussions. Our analysis of multiple discussion boards revealed that aspects of Weinberger and Fischer's framework required alteration to increase the explanatory power of the framework and enable an accounting of students' contributions to the discussion from an anti-deficit perspective. In this report, we present key aspects of our updated framework, highlighting its ability to gain insights into the learning taking place in discussions across social and cognitive dimensions. Accordingly, we propose to answer the following research questions:

1. How do the social, epistemic, and argumentative dimensions of knowledge construction interact with each other in the context of a mathematics classroom?
2. How does the *Argumentative Knowledge Construction* (AKC) Framework change when contextualized in a mathematics class?
3. What alterations to the AKC Framework increase our understanding of student learning in online calculus courses with discussions?

Theoretical Framework – Argumentative Knowledge Construction

Weinberger and Fischer proposed that computer-supported collaborative learning could be analyzed according to four dimensions: *participation, epistemic, argument,* and *social modes of co-construction* (Weinberger and Fischer, 2006).

The *participation dimension* examines the quantity and heterogeneity of students' contributions to the discussion board for each discussion activity. The *epistemic dimension* focuses on the content of students' contributions, attending particularly to the degree to which students' contributions adequately relate the particulars of a problem with the intended concepts that the problem engages. The *argument dimension* derives from Toulmin's (1964) model of arguments to qualify the types of micro- (single line) and macro- (multi-line) argumentative moves put forth by students in pursuit of a solution. Finally, the *dimensions of social modes of co-construction* "describe to what extent learners refer to contributions of their learning partners" (Weinberger & Fischer, 2006, p. 77). In an asynchronous modality, participants' textual, imagistic, and video submissions can be retroactively analyzed to build group-by-group comprehensive accounts of the knowledge construction associated with a particularly designed prompt. We consider the dimensions to productively account for knowledge construction in the online setting and so our work attempts to refine these dimensions in the mathematics context.

Table 1: Summary of Argumentative Knowledge Construction framework (Weinberger and Fischer, 2006).

Social Modes ● Externalization ● Elicitation ● Quick Consensus Building ● Integration-oriented Consensus Building ● Conflict-oriented Consensus Building	**Epistemic** *Construction of…* ● Problem Space ● Conceptual Space ● Problem ↔ Conceptual Space ● Problem ↔ Prior Knowledge ● Non-Epistemic Activities
Argument ● Single Arguments (micro-) o Simple, Qualified, Grounded, Grounded & Qualified, Non-Argumentative ● Line of Argumentation (macro-) o Argument, Counterargument, Integration, Non-Argumentative	**Participation** ● Quantity ● Heterogeneity

Literature Review

Despite the prevalence of online mathematics courses, we still know very little about the ways that students make mathematical meaning in these formats (Trenholm et al., 2019). From what has been explored thus far, some have considered mathematics courses among the more difficult to teach in an online format (Engelbrecht & Harding, 2005).

While discussion activities are common in face-to-face mathematics courses, discussions are not widely used in asynchronous formats. For instance, in a survey targeting the format and content of asynchronous courses, 39% of instructors surveyed used at least 1 discussion (Trenholm et al., 2015). Thus far, research on discussion activities focusing on Weinberger and Fischer's (2016) AKC framework have studied face-to-face mathematics learning (Keene, et al., 2016) and asynchronous learning in nonmathematical courses (Schrire, 2006; Clark & Sampson, 2008; Dubovi & Tabak, 2020). We contribute to this literature by examining the learning taking place within an asynchronous mathematics discussion activity, exploring how the AKC framework can be operationalized specifically in a mathematics setting.

As noted in the framework above, one part of the AKC framework is supported by the work of Toulmin (1958). In Toulmin's model, he provides a structure and function for argumentation in learning. This work involves the identification and connections between data used in argumentation, claims that participants make, and warrants they provide. Toulmin's model has been used in the analysis of in person mathematical discussions in active learning classrooms (Giannakoulias et al., 2010; Groth & Follmer, 2021; Mariotti & Pedemonte, 2019) but not in asynchronous learning. Nevertheless, this work supports our modifications of the AKC framework to contribute to our understanding and support design of new asynchronous learning activities.

Methodology

The data analyzed for this study were comprised of the textual records of two small-group discussion activities assigned to a fully asynchronous calculus course. Participants for this study were Calculus 1 students at an online, primarily undergraduate university during a 9-week term in spring 2022. The student population at this university is non-traditional: the average age is 31, 13.7% of the population is female, 60.3% of students are active military, and 19.5% of students are veterans. The data consisted of five discussions activities given to four assigned groups and moderated by one of the authors.

One researcher (the instructor of the course) initially reviewed each group's work according to the *participation* dimension. For our initial theory-building purposes, we sought to analyze groups for which there was potential to inform the interactions of the argumentative, social, and epistemic dimensions. As such, for the first analysis, we selected one group that we determined to have high participation, both in quantity and in heterogeneity. This group contained 3 male students that we refer to as BK, LG, and DG.

We began by examining this group's work on two discussion activities. For the first discussion activity, we individually coded each line of the discussion according to a single dimension of the AKC framework. We then met to compare and negotiate the codes for the selected dimension. After the discussion was coded for each dimension in the AKC framework, we discussed whether any lines in the discussion were not captured by the AKC framework or would benefit from a modification to the AKC framework. From this analysis, we proposed changes to that framework so that the epistemic, argumentative, and social dimensions yielded more robust insights for math-specific knowledge construction. We then analyzed the same group's discussion on a second discussion task according to this new framework in a similar iterative manner: individual coding for a single dimension, meeting to compare and negotiate codes, repeating these two steps until all dimensions were analyzed, and ending with a discussion of what was not captured by the modified AKC framework.

Due to space limitations, we will present results of the analysis on the second discussion prompt:

> *Your overall goal is to draw a random curve representing a function f defined on the interval $[2,\ 12]$, and then construct the graph of a second function g such that the following requirement is satisfied: For the composite function $h(x) = g(f(x))$ (meaning g composed with f), $h'(x) = 2$ at each x-value on $[0,\ 10]$.*

Data Analysis

Posts and replies to the discussion prompt were collected and manually entered to an Excel sheet. Posts were split by sentence and any equations/graphs were linked to a separate page. The researchers then individually coded each sentence by dimension according to the altered AKC framework. After each dimension was individually coded, the researchers negotiated the final coding for that dimension and discussed how effective the coding captured knowledge construction. Once all posts/replies were coded by each dimension, the researchers met to analyze the codes to gain cross-dimensional insights into the knowledge construction occurring during the discussion. This cross-dimensional analysis originally included tallies of the various codes and attention to the density or sparsity of certain interactions considering the progress made by each student in the epistemic dimension. While this provided general insights into how the students' interactions contributed to their epistemic progression, we determined that a more refined account of the social interactions would yield more robust insights. We present the results of our analysis considering this refined account of the social dimension.

Results

Due to space limitations for this proposal, we present one noteworthy result to appear from our initial analysis: conceptualizing the social dimension as a network of argumentative interactions. This alteration of the social and argumentative dimensions allowed us to analyze the interaction between macro- and micro-argumentative codes and provided insights that allowed for more readily seen inter-dimensional insights. What follows are two examples from the three-person group discussion of BK, LG, and DG. These examples will highlight what we learned by using the revised AKC framework. We will then present our revised framework in the discussion.

Interactions within the Argumentative Dimension

Figure 1 presents the visualization of 4 different chains of posts for the chosen discussion and group. The codes are chronological as they move down the page. Each column represents the analysis of one post and its replies. The three student participants were assigned different shades of grey: black (BK), light grey (LG), and dark grey (DG). Arrows represent replies to either the original post or another reply in the post chain. Visualizing these chains of arguments allowed us to identify patterns that were not easily identifiable in our original coarse analysis. Macro-argumentative codes are visualized by the shape of the post/reply as described in the legend.

We found that including Toulmin's model allowed for a more robust depiction of the social contributions of the students throughout the discussion than the original depiction of the social dimension. In these discussions, and more generally in mathematics discussions, social interactions largely (or most productively) entail argumentation. As such, including Toulmin's scheme in conjunction with the macro-argumentative codes allowed our new Argumentative dimension to account both for the argumentation taking place and for the social interactions contributing to knowledge construction. Moreover, the inclusion of Toulmin's Scheme for Argumentation allowed us to identify the type of data being used to make mathematical claims.

The visualization of the argumentative dimension also allowed for identifying social moves students made. For example, consider chain 1. We coded the first reply as a macro-counterargument and yet as a non-argumentative move. This captured a social counterargument that was not grounded in mathematics and was coded as conflict-oriented consensus building in the social dimension in the original AKC framework. We see another example in chain 2 with a circle X pairing, which suggests an integration-oriented consensus building in the social dimension in the original AKC framework. These results suggest that interactions within the argumentative dimension can account for codes in the original AKC social dimension, as we hypothesized by our alteration of the original framework.

Interactions between the Argumentative and Epistemic Dimensions

Figure 2 presents the visualization of the same 4 chains of posts with the epistemic codes placed within the macro-argument codes. The major result from our using our modified framework for the analysis is greater insight into the interactions between the epistemic and argumentative dimensions. Specifically, our original analysis flagged the original discussion as largely argument-driven (rather than incorporating counterarguments and integrations heavily), and that much of the epistemic change was independent of the social interactions in the discussion. With this altered framework, we drew clearer links between epistemic progression and counterarguments or integrations. For example, in chain 1 we see LG integrate BK's argument including composition as both a product (as BK did) and as inputs/outputs. We then see BK integrate LG's integration and include composition as inputs/outputs. Another example occurs in chain 2 where the instructor introduces the idea that derivatives describe where a function is increasing/decreasing and then BK uses this idea to integrate three different arguments. These examples illustrate that the inclusion of a new epistemic code can cause students to either counter this new idea or integrate it into their own argument. Moreover, tracking epistemic codes allows us to see that interactions are not restricted to explicit replies. For example, the conceptualization of derivative as increasing/decreasing, as presented by the instructor in chain 2, was present by BK in chain 4. This is important to note given the asynchronous nature of the discussion and the ability of students to read over what others have said without directly interacting.

Discussion

After analyzing and discussing two sets of discussion posts, we arrived at three major revisions to Weinberger and Fischer's (2006) Argumentative Knowledge Construction framework:

- Inclusion of Toulmin's Scheme for micro-argumentative codes;
- Removal of the original social dimension; and
- Switch from deficit to asset-based view of epistemic dimension.

Toulmin's Scheme is included in the micro-argumentative codes as it provides a way to track the types of data students use in their arguments and the ways students justified their arguments. The original social dimension was removed as we found the macro- and micro-arguments sufficient for describing social moves students made when constructing knowledge. Moreover, the mathematical nature of the discussions tended toward non-social arguments. The switch from a deficit-based view of understanding as a connection between the problem and conceptual space to ways students understand concepts allows us to apply current mathematics education research to evaluate how students' understanding evolves over time. An overview of our current Argumentative Knowledge Construction framework specific to mathematics is presented in Table 2.

Table 2: Current Argumentative Knowledge Construction framework specific to mathematics.

Argumentation	
Macro-Arguments • Argument • Counterargument • Integration • Non-Argumentative Moves **Micro-Arguments** • Claim • Data (Graphical, Symbolic, Tabular) • Modal Qualifier • Warrant, Backing, Rebuttal • Non-Argumentative Statements	**Epistemic** • Prompt-Specific Understandings • Progress Towards Coordination of Relevant Understandings • Broader Ways of Thinking Mathematically (When Applicable) **Participation** • Quantity • Heterogeneity

Conclusion and Next Steps

As is seen by looking at research published in undergraduate mathematics education, as well as the huge addition of online asynchronous mathematics teaching in the last 20 years, we believe that understanding how asynchronous learning may happen is a significant contribution to RUME. Our goal was to adapt Weinberger and Fischer's Argumentative Knowledge Construction Framework to asynchronous mathematics discussions and identify ways to systematically analyze student posts between dimensions. While more work is needed to refine the AKC framework specifically to mathematics, we feel that the use of macro-argumentative codes as a basis for visualizing student posts as a web of interactions will play an important role in analyzing knowledge development as it progresses through a discussion post.

We will continue to analyze further asynchronous discussions in Calculus using the modified framework. One particular type of response we would like to incorporate into the framework is non-content, non-social knowledge construction. For example, the instructor explaining how to use Desmos would not constitute mathematical knowledge in the epistemic dimension, nor would it constitute a social or non-social argument that would be captured in the argumentation dimension. Additionally, we anticipate expanding our work to other mathematics courses, and possibly sciences courses as well, which would require either generalizing what is contained in the epistemic dimension or creating subdimensions that work in unison.

This work is part of a larger design project to engage students and faculty in online mathematical learning. We will use our results and altered framework to support revisions and development of STEM courses in asynchronous environment. We also believe the new framework will be applicable to face-to-face student discussions in mathematics. Understanding how student communication is mathematics learning can be seen as an important area that can change mathematics instruction both online and in-person.

Modeling South Korean Citizens' Quantification of COVID-19 Vaccination and Infection Risks Using Benchmark Values

Mina Gong
University of Georgia

Dru Horne
University of Georgia

Hyunkyoung Yoon
Arizona State University

Cameron Byerley
University of Georgia

During the COVID-19 pandemic, citizens have had to make new decisions about vaccination and social contact based on their personal risk estimates and the risk estimates of experts and governments. We analyzed survey data with 50 participants and interview data with three participants to model how South Korean citizens quantify risks associated with COVID-19 vaccination and infection and the severity and level of concern they associated with these percentages. We found participants' quantifications for COVID-19 risks and their meanings for their estimated risks are substantially different than experts. Participants used benchmarks such as 10% risk and 50% risk to estimate and reason about their COVID-19 risks.

Keywords: Probability, Understanding Percent Risk

Since the start of the COVID-19 pandemic, mathematics educators have been interested in contributing to the collective effort to reduce risk from COVID-19 using prior mathematics education research (Krause et al., 2021). Citizens' perceptions of risk play an important part in their choices, and their choices impact personal and societal risk (Raiffa, 1982). Doctors and epidemiologists often communicate risks with percentages, and mathematics educators are well positioned to study how citizens' make sense of this mathematical information. We know the concept of percentages (and the related concept of fractions) is difficult for many people, including those with undergraduate degrees and students taking advanced mathematics such as calculus (Byerley, 2019; Mullis et al., 1991; Wright, 2006). Specifically, the RUME community has an interest in preparing undergraduates to make sense of real-world mathematics as well as an interest in informal adult education about mathematics (SIGMAA on RUME, 2022). To contribute to this mission, we studied South Korean citizens' mathematical understanding of risks associated with COVID-19 vaccination and infection.

We focused on risk estimates related to both vaccination and infection because vaccine hesitancy is a top ten global health issue (World Health Organization, 2019; 2020). There is a statistically significant association between COVID-19 vaccination status and US citizens' perception of the relative risk of vaccination and infection (Yoon et al., 2022). The study found that US citizens who thought COVID-19 infection was less risky or equally risky than vaccination were less likely to be vaccinated than those who thought COVID-19 infection was more risky than vaccination. Even though the risks due to COVID-19 infection are orders of magnitude higher than the risks due to COVID-19 vaccination (CDC COVID-19 Response Team & Food and Drug Administration, 2021), only 48% of a random sample of US citizens thought COVID-19 infection was more risky than vaccination (Yoon et al., 2022).

In contrast to the previous study by Yoon and colleagues (2022), we used South Korean participants in this study. It is important to study real-world mathematical thinking in a variety of cultural contexts because much can be learned by investigating similar questions in contrasting cultures (Stigler & Hiebert, 2009). The pandemic response, vaccination campaign, and mathematics education in South Korea are notably different from that in the United States. By early August 2022, more than 87% of the population in South Korea had been fully vaccinated and more than 65% had received booster shots (Korea Disease Control and Prevention Agency, 2022). Many South Korean citizens complain about social pressures to get a COVID-19 vaccine and believe the vaccination mandate is not reasonable despite the high vaccination rates (Han, 2022).

In order to better understand the South Korean public's vaccine hesitancy through a mathematics education lens, it is necessary to understand how citizens perceive the risks associated with COVID-19 infection and vaccination which are often expressed in percentages. Thus, this study investigates two research question: (1) How do South Korean citizens quantify their risk associated with COVID-19 infection and vaccination? and (2) What meanings do participants hold for their percentage estimates?

Literature Review and Theoretical Framework

Risk Perception

Risk has been defined as "a probability of an event combined with the magnitude of the losses and gain that it will entail" (Douglas, 2013) or a "probability-based forecast of the future" (Bernstein, 1996). Experts define risk based on relative frequency of occurrence, and while laypeople can assess frequency if asked, they tend to include other factors in their risk judgements (Covello et al., 1986, 1987; Slovic, 1987). These differences in the way the public and experts perceive risk can lead to miscommunication in which laypeople understand risk differently than experts or government agencies (Botterill & Mazur, 2004; Covello et al., 1986). For example, in the August, 2021 Gallup Poll, US citizens' mean estimate of the risk of dying from COVID-19 if infected and unvaccinated was higher than 50% (Rothwell & Witters, 2021), which differs dramatically from estimates by epidemiologists. Because, on average, citizens are giving such different estimates of risk than epidemiologists, it follows that their meaning for these percentages is likely different than that of epidemiologists. For example, citizens who estimated the mean risk of dying from COVID-19 if infected is 50% might disagree with the mathematically similar statement "half of the people who had COVID-19 died."

Risks in Frequency Formats and Percentage Formats

Prior research has shown that risks described in frequency formats (e.g., 10 of 100) are perceived as more serious than those in percentage formats (e.g., 10%) (Gigerenzer, 2011; Hoffrage et al., 2000; Slovic et al., 2000). Slovic et al. (2000) found that when assessing whether a hospitalized patient with mental disorder would harm others, people perceived a risk described with the frequency format, "20 out of 100 patients", as more serious than the same risk described in the percentage format, "20% of patients". Another study suggests expressing a small risk using a frequency format can frighten people because it is psychologically different from the same risk expressed as a percentage format (Purchase & Slovic, 1999). Another important aspect of understanding COVID-19 risk is numeracy which is defined as an individual's number sense and ability to understand and use numbers with concept of proportion, fractions, percentages, and probability (Dieckmann et al., 2009; Peters, 2012; Peters et al., 2006). Highly numerate people are more likely to be able to interpret the same risk presented in either frequency or percentage as equivalent (Peters, 2012; Peters et al., 2006). Exploring citizens' use of frequency format and percentage format may provide insight into how citizens understand probabilities when estimating risks associated with COVID-19 infection and vaccination.

Using Benchmark Values to Estimate Probability

Benchmarks are initial values that function as a point of reference to compare, assess, and adjust estimates of probabilities. We use the term *benchmark value* in this work to describe percentages that citizens' use frequently and easily assign meaning to. Citizens often use benchmark values as a point of reference, and they adjust estimates up or down from these values. Tversky (1974) suggests that when estimating the probability of an uncertain event, people tend to use a starting value and adjust it to produce the final estimates. Then, different initial values result in different estimates; if the starting point is too high or too low, the subsequent adjusting process yields a final answer that is close to the starting information, which may lead to overestimation or underestimation (Epley & Gilovich, 2006).

For example, a prior study found that many US citizens used the benchmark values, 0%, 50%, and 100% for their estimates of risks associated with COVID-19 infection and vaccination (Yoon et al., 2022). Konold (1989) suggests that people who use the 'outcome approach' in their probabilistic reasoning focus on outcomes of single trials of events by interpreting 0% as meaning 'no', 50% as meaning 'I don't know', and 100% as meaning 'yes'. Yoon and colleagues (2022) used the outcome approach construct to hypothesize the citizens' meanings for those benchmark values. Our theoretical focus on citizens' meanings is inspired by Thompson's work on mathematical meaning (Thompson, 2015). We remained alert that two different people could have different meanings for the same percentage and used the outcome approach as a way to make sense of the different meanings participants might have.

Methods

We collected interview and survey data. Both asked South Korean citizens to quantify their risks associated with COVID-19 infection and vaccination and to discuss how they reason about the risks. First, we conducted a survey with a random sample of 50 South Korean adults on June 13, 2022 using a Korean survey company, Survey Top (https://www.surveytop.co.kr/)[1]. In our sample, there were 23 male and 27 female participants. The mean of participants' age was 41.34 years (*SD* = 14.77). As the level of highest education, 22 citizens reported a high school diploma and/or some college credits, and 28 citizens reported having a bachelor's degree or higher. Out of the 46 participants who received at least one dose of COVID-19 vaccines, 13 citizens were fully vaccinated for COVID-19 (two-doses of Pfizer of Moderna or a single dose of J&J vaccine), 31 citizens were fully vaccinated for COVID-19 with one booster shot, and two citizens had received two booster shots. Four citizens responded that they had never received a COVID-19 vaccine. Survey questions were developed in prior research (Yoon et al., 2022) and included: 1) If you were infected with COVID-19, what do you think your percent risk of hospitalization from COVID-19 if infected. Why? 2) If you were infected with COVID-19, how concerned would you be about getting hospitalized? 3) If you receive a COVID-19 vaccine in the future, what do you think your percent risks of a serious adverse reaction would be? Why? Other questions are also asked such as demographic information, their reasons for vaccination, and general probabilistic questions.

We also recruited three South Korean citizens for interviews. All participants were male, in their thirties, and held an undergraduate degree in non-mathematical fields. Both Chang-seob and Byung-soo (pseudonyms) were fully-vaccinated with a booster shot. Byung-soo was vaccine-hesitant; he received COVID-19 vaccines because of social pressure. Sun-kyu (pseudonym) had

---

1 The survey company provides information about the demographics of the panel and how to select a random sample from the panel (https://www.surveytop.co.kr/online-survey-panel).

not received any vaccines. Interviews were conducted through Zoom in Korean by the first author between June 19th, 2022 and July 4th, 2022. Each interview lasted approximately an hour and a half. During the interviews, the first author asked participants to quantify various risks associated with COVID-19 infection and vaccination, their opinions about COVID-19 vaccination, and to interpret meanings of particular percentages in various contexts. The first and third authors, who are South Korean, translated the US survey and interview protocol into Korean. We coded the data using a priori and emergent codes and conducted a thematic analysis (Braun & Clarke, 2006). While conducting our study and analyzing data, we were alert to the possibility that South Korean citizens would use benchmark values to reason about risk and that their meanings for a particular percentage might differ from experts' meanings.

Results

We found that participants' risk perceptions and reasonings were complex, but they commonly used benchmark values as a starting point for estimating their COVID-19 infection and vaccination risks. In both the survey and interviews, we observed that many participants used certain values, 0%, 1%, 10%, and 50%, as benchmark values. In order to answer the research question, we focus on how South Korean citizens quantify risks using benchmark percentages and make sense of the severity of those percentages.

Citizens' COVID-19 Infection and Vaccination Risk Estimates on Survey

In the survey data, we found noticeable clusters at 10% and 50% in citizens' estimates. In response to questions about risks related to both infection and vaccination, 10% was the most frequent estimate. When estimating their personal COVID-19 hospitalization risk if infected, 24% of citizens (12 of 50) estimated 10%. Further, 16% of citizens (8 of 50) estimated their risks of serious adverse reactions to COVID-19 vaccination as 10%. The question about adverse reactions clarified "An example of a serious adverse reaction is an allergic reaction requiring treatment in a hospital. Do not include your risk of common side effects such as fatigue." Another frequent estimate was 50%. For their COVID-19 hospitalization risk if infected and COVID-19 vaccination risk, 18% of citizens (9 of 50) and 12% of citizen (6 of 50) estimated 50%, respectively (Figure 1).

We also wanted to understand citizens' meanings for estimates of 0% because there is a small cluster at 0% (6 of 50) in the estimates of COVID-19 hospitalization risk if infected, and 0% is a value that appeared in our study of US citizens (Yoon et al., 2022).

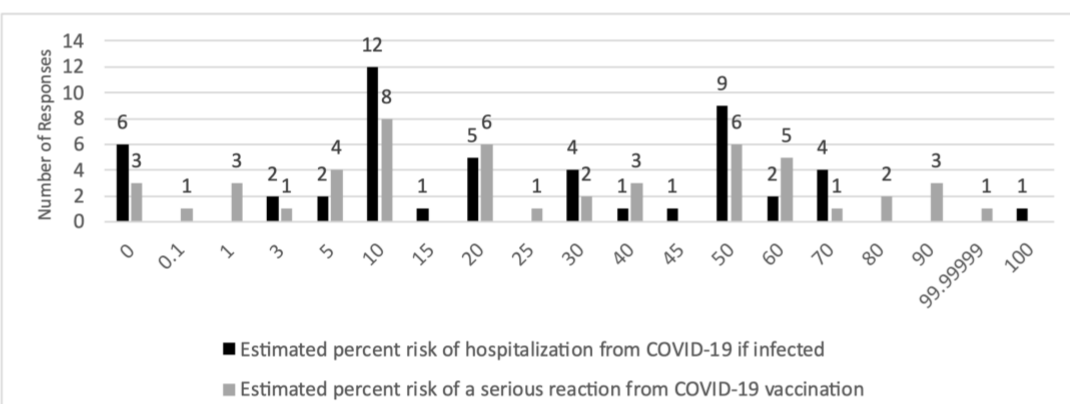

Figure 1. Citizens' estimated percent risk associated with COVID-19 infection and vaccination.

Use of Benchmarks in COVID-19 Infection and Vaccination Risk Estimates

Because 0%, 10%, and 50% were common estimates in the survey and interview data, we decided to focus on interview participants' meanings for these values and how they used them as benchmarks for estimation. Additionally, we discuss 1% as a benchmark value which emerged in our interview data, and we relate interview data with short fill in the blank responses on the survey.

50% as a Benchmark. During the interview, Byung-soo estimated his COVID-19 hospitalization risk if infected and unvaccinated as 50%. When asked how he quantified the 50%, Byung-soo said "I really don't know. I don't know how to estimate that risk as a probability. I have no reason for it". His response suggests his meaning of 50% is "I don't know" which may be explained by the outcome approach (Konold, 1989). Similarly, in the survey data, four of nine citizens who estimated their risk of COVID-19 hospitalization if infected as 50% and three of six citizens who estimated their risks of serious adverse reactions to COVID-19 vaccination as 50%, gave the reason for their estimate of 50% as "because I don't know". Thus, many citizens used 50% as a benchmark if they were unsure of their risk.

0% as a Benchmark. Chang-seob initially estimated his risk of dying from COVID-19 if infected and unvaccinated (in the case of the Omicron variant) as 0% since he thought that it would never happen to him. When asked to estimate his risk of dying from COVID-19 if infected and unvaccinated, he said: "I think my COVID-19 death risk from Omicron is 0% because I think I will not die if I were treated". Chang-seob used 0% as a benchmark to estimate his COVID-19 death risk if infected and unvaccinated given various treatments. Sun-kyu, who also thought that he would not die from COVID-19 if infected and unvaccinated, said "my risk would be convergent to 0%".

Similarly, in the survey, all six citizens who estimated their risk of hospitalization from COVID-19 if infected as 0% explained that they are unlikely to be hospitalized from COVID-19 if infected. An outcome approach explains that a benchmark of 0% means "No, it will not occur" (Konold, 1989). Therefore, 0% is associated with an event that is impossible or unlikely to occur.

10% as a Benchmark. Sun-kyu used a benchmark of 10% for estimating his risks associated with COVID-19 infection and vaccination. Sun-kyu estimated his risk of COVID-19 hospitalization if infected and unvaccinated and his risk of a serious adverse reaction from COVID-19 vaccination as more than 10%. On the other hand, he gave estimates less than 10% for his risk of COVID-19 hospitalization if infected and vaccinated (Table 1).

Table 1. Sun-kyu's estimates of risks associated with COVID-19 infection and vaccination.

Risk of		
COVID-19 Hospitalization, if infected and unvaccinated	COVID-19 Hospitalization, if infected and vaccinated	a serious adverse reaction to COVID-19 vaccine
10~20%	5~10%	30~40%

He transformed 10% into 1 out of 10. In this way, he interpreted 10% risk as "I don't think that 10% risk associated with COVID-19 infection is high. But, one or two out of 10 people is not too low to ignore. So, I would be concerned about it a little". In addition, he estimated his risk of serious adverse reactions from COVID-19 vaccination as 30~40%: "With a risk of 30%

related to vaccine side effects, I could be the one who had severe vaccine reactions, so I would much worry about it". Sun-kyu considered 30-40% as risky because it is more than one or two out of ten people, and so he used 10% as a benchmark and adjusted from a low risk of 10% to a higher risk of 30-40%.

In the survey, we found that all 12 citizens who estimated their COVID-19 hospitalization risk if infected as 10% tended to think that 10% is not very risky on a multiple choice follow up question. Of the 12 citizens, three responded that they were not concerned, five responded that they were slightly concerned, and four responded they were somewhat concerned about getting hospitalized if they were infected with COVID-19. Thus, participants from both the survey and interviews may use a benchmark as 10% to estimate a risk of an event that seem not very risky.

1% as a Benchmark. During the interviews, we observed 1% was used as a benchmark to estimate risk and participants adjusted the 1% upward or downward to reach their final estimates. We also found that participants thought 1% was a small risk and that risks with less than a 1% chance were unlikely to occur. Two interview participants thought COVID-19 risks less than or equal to 1% are not worth worrying about. For example, Chang-seob used 1% as a benchmark for all estimates of his risk associated with COVID-19 infection and vaccination (Table 2).

Table 2. Chang-seob's estimates of risks associated with COVID-19 infection and vaccination.

COVID-19 Risk of			
Hospitalization, if infected (unvaccinated)	Hospitalization, if infected (vaccinated)	Dying, if infected (vaccinated)	A serious adverse reaction to vaccine
1%	0.1%	0.001%	0.001~0.0001%

When the first author asked Change-seob to estimate his risk of hospitalization and dying from COVID-19 if infected and unvaccinated, he said:

> I estimate 1%, at most, that I would be hospitalized from COVID-19 if infected and unvaccinated. I think my risk of dying from COVID-19 if infected and unvaccinated would be from 0.01% to 0.1%. Assuming I am treated, I multiplied 0.01 to the 1% risk of hospitalization from COVID-19 and multiplied 0.1 to the 1% if not treated. Similarly, when vaccinated, I multiplied 0.1 to the 1% and got 0.1% risk of hospitalization from COVID-19 if infected. Also, I multiplied 0.1 to 0.01% risk of dying from COVID-19 if infected and unvaccinated and got 0.001% for my risk of dying from COVID-19 if infected and vaccinated.

Chang-seob started from 1% as his estimated risk of COVID-19 hospitalization risk if infected and unvaccinated. Then, he adjusted the 1% to 0.1% and 0.01% to estimate his risks associated with COVID-19 infection if infected and vaccinated. He thought every other risk in Table 2 was less likely than hospitalization if infected and unvaccinated. He adjusted his 1% estimate downward by multiplying 1% by 0.1, 0.01 and 0.001 to estimate other risks. Thus, Chang-seob used a benchmark of 1% for estimates of his risk associated with COVID-19 infection and vaccination. Additionally, he thought a 1% chance of hospitalization is not risky to him:

> I'm just splitting the risks less than 1%, so I feel like 0.1%, 0.01%, and 0.001% are all the same to me which are extremely low and 0.0001% is almost 0%. If a risk is less than 1%,

I think the probability is low no matter what the value is, because it means less than 1 out of 100 people.

Sun-kyu made a similar judgement about a 1% risk associated with COVID-19 infection and vaccination: “But if the chance has more zeros in the percentage such as 0.000…%, I would feel safe and comfortable with the risk”. He interpreted risks of the form 0.000…% as “1 out of 1,000, 1 out of 10,000, and so on”. Both Chang-seob and Sun-kyu used 1% or 1 out of 100 people and noted that if risks are less than 1%, it is meaningless to differentiate between them.

Discussion and Conclusion

From surveying and interviewing South Korean citizens about their COVID-19 risks, we found they used benchmark values of 0%, 1%, 10%, and 50%, and participants conveyed that 10% and 1% risk are not risky. Interview participants used and interpreted the benchmark values of 1% and 10% for their COVID-19 risk as 1 out of 100 people and 1 out of 10 people, respectively, for who would be at risk. This may have led participants to perceive risks less than 1% as small and negligible because they count the number of people out of 100 people, and 1 person is the smallest countable number from those 100 people. Compared to a sample size of 100, they perceived the occurrence of 1 out of 10 people as something that cannot be ignored but is slightly risky. Thus, reasoning with a frequency format using the number of people out of 10 or 100 may explain the use of benchmark 1% and 10% and why those risks were not perceived as risky.

In contrast, risks under 1% were more likely to be measured in a percentage format by a number of zeros in a decimal. When asked to transform 0.1% and 0.01% into a frequency format, the interview participants were able to correctly get 1 of 1,000 and 1 of 10,000. Nevertheless, they preferred to quantify risks less than 1% in a percentage format. Thus, the participants’ use of denominators (100 and 10) may explain why they thought 1% was not risky, and the smallest risk value they would pay attention to because 0.1% means less than 1 person dies out of 100.

However, if the infection fatality rate of COVID-19 was 1%, and all 50 million South Korean citizens were infected, 500,000 people would die. Although the South Korean citizens in both our interviews and survey viewed risks near 1% as not too serious, it is clear that these risks are serious on a population scale. South Korean citizens’ estimates of risk in our survey are problematic and worthy of attention in the international mathematics education community. Before vaccines were available, the infection fatality rate of COVID-19 was estimated to be about 0.68% (Meyerowitz-Katz & Merone, 2020). Although this is less than 1%, it was still significant enough to cause significant loss of life, overwhelm medical systems, and lower life expectancies. A 10% or even 1% infection hospitalization rate would be catastrophic from an epidemiological perspective.

Measuring small risks is hard. Small risks are represented in both frequencies and percentages. When thinking about the meaning of a percent in the COVID-19 context, it is important to think about that percent of a population of people. Moreover, it is important to understand the equivalent relationship in fractions and percents for risk perception, but many students as well as adults struggle with it (Sharp, 2002). These difficulties in understanding probabilistic information may cause problems in risk communication (Covello et al.,1986). Imagine if an epidemiologist tells us that a disease has a 5% infection fatality rate thinking that this will convey that the disease is extremely serious but what is actually conveyed to people is that they do not need to worry because it is less than their benchmark of 10%. As college instructors, it is important for us to ensure the graduates of our institutions are prepared to make sense of risks and develop more productive meanings for percent risks.

Students' Perceptions of Active Learning Classroom Community

Gary Wright
University of Nebraska Omaha

Karina Uhing
University of Nebraska Omaha

Classroom community plays a pivotal role in student success, especially when students have the opportunity to interact with their peers and instructors. This study explores how students perceive classroom community and its impact on their learning. We present findings from an essay reflection assignment where students were asked to share their experiences with learning mathematics. We found that students felt more comfortable to ask questions and were able to develop interpersonal skills in conjunction with mathematical skills because of the classroom community. Conclusions drawn from this research can provide insights for instructors who are interested in fostering strong classroom communities in engaging learning environments.

Keywords: community, active learning, group work, student-instructor relationships

Being part of a classroom community has been described as having feelings of belonging and obligation to one another so that each members' educational needs will be met through commitment to shared goals (Rovai, 2002). Research has shown that these two facets of a classroom community, sense of belonging and social interdependence, are crucial to students' well-being and academic success (Awang et al., 2014; Johnson & Johnson, 2008). Classroom community develops through interactions between students, instructors, and content (Cohen et al., 2003; Lampert, 2001). These interactions often depend on the pedagogical choices of instructors and how students are positioned (e.g. active learners vs. passive recipients). In recent years, research has shown that active learning instructional strategies increase student engagement and success in undergraduate mathematics (Freeman et al., 2014). While several studies have focused on academic student success (Freeman et al., 2014; Laursen et al., 2014; Theobald et al., 2019) and differences in student outcomes in active learning classrooms based on gender (Johnson et al., 2020; Reinholz et al., 2022), few studies have looked at students' perceptions of the classroom community in an active learning setting and how they perceive community to impact their learning.

The purpose of our study is to investigate students' perceptions of an active learning classroom community and how they interacted with their peers, their instructors, and the mathematical content. This proposal focuses on the following research question: How do students report that the community of an active learning class supports them in their mathematical learning? Our work provides insight for other institutions, departments, and instructors who are interested in incorporating more active learning into their undergraduate mathematics courses and highlights areas where more research is needed.

Context

Our study takes place in the context of a mathematics department that has recently undergone several major changes to its first-year mathematics program. Prior to Fall 2021, all first-year mathematics courses at this institution were taught using the emporium model (Twigg, 2011; Webel et al., 2017). Under this instructional model, students would attend a one hour lecture each week and then were required to spend a minimum of three hours in a computer lab working independently on online homework problems. Students were able to get individualized help from undergraduate tutors who worked in the computer lab, but there was little community developed amongst students and their peers. When COVID-19 emerged in Spring 2020, issues associated with the emporium model were exacerbated. Lectures and tutoring hours were held over Zoom making it easy (and normalized) for students to turn off their video cameras and avoid interactions with their peers and instructors altogether.

In Spring 2021, a team of faculty members were hired to improve first-year mathematics courses at this institution. Course redesign efforts began in Summer 2021, and major changes were implemented in Fall 2021. Instead of using the emporium model, courses were scheduled to meet for 75 minutes twice a week, and sections were capped at 40 students. Each section had a designated instructor of record along with two classroom learning assistants. Courses were tightly coordinated with a team of faculty members working together to develop curricular materials, assess student learning, and make revisions to courses throughout the semester. The instructional team's overall goal was to improve student learning in these first-year mathematics courses by creating an inclusive classroom environment where students felt safe to make mistakes and learn from them while working together with their peers. Thus, developing a strong sense of classroom community was central to the course redesign efforts.

Background Literature and Theoretical Framing

Classroom community is difficult to define, and many definitions exist in research literature (Summers & Svinicki, 2007). Baturay (2011) defines classroom community in terms of two components: "(a) social community or the feelings of connectedness among community members and (b) learning community or their common expectations of learning and goals" (p. 564). In our study, we viewed classroom community through the lens of the instructional triangle; i.e. considering how students' experiences in the classroom are influenced by interactions between students, instructors, and mathematical content, and the environment in which these interactions occur (Lampert, 2001; Cohen et al., 2003). Community is developed (or not) through these interactions, and classroom communities are formed when there is a "culture of learning, where students come to see themselves as contributors to their own learning and that of the community" (Bielaczyc & Collins, 2009, p. 10).

Our study is situated within the context of an active learning classroom environment. Several definitions of active learning exist in the literature (Williams et al., 2022). For this study, we define active learning broadly as "classroom practices that engage students in activities such as reading, writing, discussion, or problem solving, that promote higher-order thinking" (CBMS, 2016, p. 1). Another common definition of active learning draws on the four pillars of Inquiry-Based Mathematics Education: students engaging deeply with mathematics, students working collaboratively, instructors inquiring into student thinking, and instructors fostering equity in their teaching (Laursen & Rasmussen, 2019). In this study, we investigate how students perceive the classroom interactions described by these pillars (between students, instructors, and mathematical content) and how these interactions relate to the classroom community.

Finally, our work builds on the SEMINAL Project, which focuses on incorporating more active learning into first-year undergraduate mathematics programs. As part of this project, the second author and colleagues analyzed survey data from over 2500 students taking a range of first-year mathematics courses at several institutions across the United States. In their open-ended survey responses, students discussed five major topics: student-to-student interactions, relationships with instructors, course format, assessment, and students' affective experiences (Uhing et al., 2021). While this data was gathered in a different context, similar themes arose in our findings. In this proposal, we discuss and build on student-to-student interactions and relationships with instructors and relate these themes to classroom community.

Methods

Data for this study come from a Mathography assignment that was assigned to students enrolled in a College Algebra course at a large, Midwestern, metropolitan university during Fall 2021. The assignment was based on Drake (2006) and included prompts such as "Describe what you learned in College Algebra. These can be mathematical topics but also non-math things, like anything you learned about yourself or your ability to do math or what math is." Out of 459 students enrolled in the course at the beginning of the semester, 228 completed the assignment, which was collected at the end of the semester. Students were informed that class assignments would be gathered for research and course evaluation purposes.

Mathographies were analyzed using Dedoose (2022). To establish a preliminary set of codes, deductive coding was conducted with an initial set of codes from the SEMINAL Project (Uhing et al., 2021). In order to refine our analysis, a set of subcodes was created for most initial codes. At least two researchers tagged each response to prompts in the Mathographies with these initial and secondary codes. Researchers then met to discuss and reconcile disagreements until agreement was reached. Excerpts were then sorted by initial codes and the code "Community and Culture" was selected for a second round of coding. Inductive coding was used to create sets of themes for each subcode, which illustrate how students experienced the classroom community.

Findings

Secondary analysis of the "Community and Culture" code yielded four subcodes. We describe themes that emerged under two of them, Student/Student Interactions and Student/Instructor Interactions, in this proposal.

Student/Student Interactions

Group work was a large focus of the College Algebra active learning curriculum. Students spent the majority of class time working together to solve problems posed by the instructor or complete classroom activities. As a result, Student/Student Interactions was the most common secondary code from Community and Culture (n=234 excerpts out of a total of 538 excerpts). Table 1 provides an overview of the most common themes under the Student/Student Interactions code.

Table 1. Major Themes for Student/Student Interactions

Theme	Summary	Student Excerpt
Working in a team	Learning mathematics through positive experiences with peers	"I liked having people around me in my group that can help me understand concepts and I can do the same for others."
Meeting new people	Building social networks and friendships with classmates	"I got a lot out of this class lik em ynew [*sic*] friends that I happened to get partnered up with at the beginning of the class."
Building collaboration skills	Developing collaboration and other interpersonal skills	"I learned how to better manage my time, how to work in a group with efficiency, and how to learn alongside my peers."

Disliking group work	Preferring step-by-step instruction (i.e. lecture) or individual work over group activities	"Something that didn't work so well for me in this class was all the independent work time we had with our groups to work on worksheets/packets."

Working in a team. The notion of working with others was a common, positive response from students as almost 37% of the Student/Student Interactions excerpts referred to the concept of teamwork. In many cases, students felt that working with their peers allowed them to grasp mathematical concepts in a way that they had not been able to in prior math courses. There was a realization amongst students that the ability to collaborate with one another gave them additional resources, other than just the instructor, when they struggled with a mathematical concept. One student's response illustrates this idea: "the use of groups allows students to help each other so more people learn than if the teacher was answering every individual student's question. This also allows students to create some connection to the people in the course."

Several students also mentioned feeling comfortable working in groups and asking their classmates questions. One student remarked, "I think that discussing the problems in a judgement free environment helped me advance in this class a lot." Another student explained how this course felt different from past experiences in which they had felt rushed or judged:

> We were giving each other pointers, and just getting along well and we weren't rushing anyone, or judging one another if one was confused. It felt good on how well we were responding to each other. In the past there would always be someone trying to rush you, or make you feel less if you don't understand, or catch on right away. Even teachers would do that. It made me realize people are respectful and patient when it comes to trying new things.

As illustrated by these excerpts, students felt comfortable working in teams in a "judgement free environment", and as a result were able to more deeply engage with the content and "advance" their mathematical knowledge.

Meeting new people. Since College Algebra is a first-year mathematics course, many of the students who take this course are early in their academic careers. Moreover, during the Fall 2021 semester, when data were collected, many students had just experienced several months of remote or online classes due to COVID-19, emphasizing the significance of this theme. About 18% of the Student/Student Interactions excerpts described how students made new friends or developed close relationships with classmates while taking College Algebra. One student mentioned how they were new to the area and making friends and forming connections was critical in their success in College Algebra:

> I feel that I got friends out of the class and a more in-depth version of a high school math class, except it was college. Friends are important to me because I am new to [this city], and I felt welcomed by everyone in that class. It made me feel like I belonged to a big math family and community.

This excerpt highlights how a strong classroom community can help students build social networks. Even though this student was new to the area, they were able to make friends with other students in College Algebra because of the "welcoming" environment, thus helping them feel a sense of belonging to a "big math family and community".

Building collaboration skills. In addition to developing mathematical skills, some students felt that they were able to develop their collaboration skills as a result of the emphasis on group work in College Algebra. Approximately 10% of excerpts under Student/Student Interactions referenced building these collaboration and networking skills. One student described their experience:

> While I learned many new mathematical skills in this class, which I will no doubt be carrying into my future classes, I think that the most important lessons that I learned in this class did not pertain to math. While in [College Algebra], I learned a lot about myself and about networking. I learned that I could put aside my pride and independence when I need help. I can ask questions and not be judged – something that I had feared before. I also learned that I am capable of networking. By this, I mean that I was able to form relationships with my colleagues and professor that could help me in the future.

Although this student acknowledged that their new mathematical skills will be useful in future classes, they emphasized that the "most important" part of College Algebra was building their collaboration ("networking") skills.

Disliking group work. Although the interactions with their peers resulted in many positive experiences for students, some students felt that this style of learning did not work as well for them. Around 8% of the excerpts indicated some kind of negative experience in relation to Student/Student Interactions. One student conveyed: "the style of learning that I learn best with is lecture-type style where I have an instructor explaining the concept step-by-step and less of me and my table partners working together to figure it out ourselves." In this case, the student explicitly stated that they preferred learning in a passive, lecture-style learning environment compared to the active learning environment in which the class was designed, which is consistent with other research (e.g. Deslauriers et al., 2019).

Not all excerpts tagged under this theme, however, were critical of the active learning environment. Some students were able to provide specific interactions with other students which created a negative experience for them. One student recounted such an experience: "I really liked working in groups however some of them were hard to get along with [...] I didn't feel comfortable asking my group for help in certain cases because another member was very aggressive." Another interaction a student discussed related less to the fact that they did not like working with their peers, but more that they found it easier to compare themselves to other students which resulted in a feeling of inadequacy:

> I remember when we were to work with our small groups over a set of problems that involved identifying parts of a quadratic function via a graph. While all three of them could understand how to find [the] domain, how to locate the vertex, and so much more, I couldn't. I felt like if I asked for help, that I'd be labeled as something rather than intelligent. I was scared to even share my answers.

Although most students who submitted the Mathography assignment enjoyed learning in a more active setting, these excerpts show that some students had uncomfortable experiences in this classroom setting due to poor group dynamics or personal insecurities.

Student/Instructor Interactions

After Student/Student Interactions, Student/Instructor Interactions was the next most common subcode under the Community and Culture (n=186 out of 538 excerpts). Table 2 describes common themes associated with Student/Instructor Interactions and example student excerpts. Overall, comments under this subcode were positive in nature; only six out of 186 excerpts were somewhat negative. The majority of these negative comments referred to students wanting more direct guidance from instructors (e.g., "I also feel like the guessing games waiting for someone to magically conjure an answer out of thin air gets annoying, I would prefer to be guided and shown the way rather than having to find the way myself.").

Table 2. Major Themes for Student/Instructor Interactions

Theme	Summary	Student Excerpt
Creating a supportive, engaging classroom environment	Providing in-class general instructional support to students	"My professor was very engaging and always emphasized participation and asking questions."
Providing opportunities for support outside of the classroom	Interacting with students outside of class time (including tutoring, review sessions, and office hours)	"I also felt better about this when I went into tutoring the next week and my teacher told me I did really well."

Creating a supportive, engaging, classroom environment. Several students expressed how their interactions with instructors in class affected their learning. Some students appreciated how they were able to quickly get support from instructors as compared to other experiences where an instructor would lecture for the duration of the class. One student compared this course with others that they had taken saying, "this was my favorite I was able to talk to the professor or his Aids [*sic*] for help." This student went on to say that "having the constant support was better than just having a professor stand in the front and just do problems all lecture and instead walk around and engage students." Thus, because of the instructional methods and classroom community, students felt like they could get help immediately from instructors in class when they needed it.

As mentioned in the Student/Student Interactions section, students occasionally felt reluctant to ask instructors for help or to ask them a question. Some students wrote that they appreciated when an instructor would approach them and ask how they were doing. As one student commented:

> Both the teacher and the teacher assistants, [TA Name] in particular, were very helpful and were always going around asking if people needed help and were most often able to provide an answer. Communication between everyone was very good and helped me feel more comfortable in the class when asking questions to the teacher or TA.

Since the community of the classroom allowed for instructors to check on individual students and groups, students who were apprehensive about initiating a conversation with their instructors were still able to get the help they needed. Moreover, this type of classroom environment also allowed instructors to build trust with their students and eventually some students felt that they could ask their instructors questions when they did not understand a topic. Another student reflected on this growth:

> I also liked these assignments because I was able to ask my professor questions one-on-one and get the clearer answers that I needed. At the beginning of the semester, I was a very shy and independent student. I think that these peak experiences helped me to "come out of my shell" and become more participative in class. I think that these experiences helped me to realize that it's okay to ask questions.

Overall, students appreciated the in-class support provided by their instructors. These in-class student/instructor interactions allowed students to not only get the help that they needed when dealing with challenging mathematical concepts, but also learn how to ask questions and speak up when they needed help.

Providing opportunities for support outside of the classroom. In addition to their in-class experiences, students also wrote about getting help outside of the classroom. Although getting help with classwork outside of class can be a daunting task for students, one student recounted when they went to their first review session:

> A high point for me in [College Algebra] was when I went to the review session for the class. I felt a bit uneasy and nervous about going there at first because I thought it would be awkward. When I gained the courage to go there, I saw the professors and students from other class periods. The environment was friendly. The professor sat down with me to help go step by step through the [learning outcomes] I had problems with. They answered all my questions, made me feel relieved about the coming [exam], and lifted the stress of not completing this class.

The community aspect of the course and students' relationships with their instructors allowed them to have the courage to ask for help when they needed it and better advocate for themselves outside of class. One student commented:

> What did I get out of this class? Honestly, I feel like this class taught me to approach my professors regarding any questions or concerns I may have. Honestly, that's what they're there for, and really to take the initiative to attend office hours because they are beneficial in the success of this course.

These excerpts illustrate that students felt comfortable enough to approach instructors and ask them for help outside of class because of the open classroom community that was cultivated.

Discussion

The majority of excerpts about Student/Student Interactions were positive, showing that students were able to form a strong classroom community in an active learning setting. For the most part, students felt comfortable working together and asking each other questions even though there were some students who expressed disliking group work and feeling inadequate compared to their classmates. In addition, the excerpts relating to Student/Instructor Interactions show that students appreciated being able to develop close relationships with their instructors in an active learning setting. Due to the supportive classroom community that instructors helped to cultivate, students felt comfortable enough asking questions in class and seeking help from their instructors outside of class.

These findings provide insight for others who are interested in developing supportive classroom communities in active learning settings. To facilitate positive student interactions, instructors should be intentional about structuring group activities and helping students create group norms that promote the sharing of ideas in a "judgement free environment". In addition, instructors should strive to develop individual relationships with their students to help students feel more comfortable asking for help. Although this paper sheds light on interactions between students and instructors in active learning settings, further research is needed to better understand how these types of supportive classroom communities are cultivated.

Positive interactions between students and their classmates and instructors are crucial to creating a strong classroom community in which students are able to excel in their mathematical learning. First-year mathematics courses play a pivotal role in students' overall college success, so it is important that students feel like they belong in these classes. As demonstrated by our findings, a strong sense of community can help students feel both comfortable and confident in their interactions with other students and their instructors, thus supporting students in their learning and helping them to succeed in these courses.

How do STEM Undergraduates Structurally Conceive Change During Modeling?

Sindura Subanemy Kularajan
Texas State University

Jennifer A. Czocher
Texas State University

Using data from teaching experiments and theories from quantitative reasoning, we built second-order accounts of students' mathematics on how they conceived change via operating on existing quantities. We report three different ways STEM undergraduates structurally conceived change as they constructed mathematical models for real-world scenarios.

Keywords: Quantitative Reasoning, Mathematical Modeling, Change

A student's conceptualization of change plays a central role in their mathematical models they construct for real-world situations. Researchers have looked into how students' conceptualizations of change inform the mathematical decisions students make while modeling dynamic situations. For example, researchers have investigated students' conception of rate of change, limit, and accumulation through considering students' images of change in dynamic situations (e.g., Carlson et al., 2002; Thompson, 1994a). In addition, researchers have also studied how students' conceptions of change influence how students conceive variation and make sense of dynamic situations (Castillo-Garsow et al., 2013). However, these studies report on accounts of student thinking by focusing on students' variational and covariational reasoning as the student reasons about how values of a quantity are *changing*. We still need an account of how students conceive *change,* as a measurable attribute of a varying quantity, through establishing relations among existing quantities. Thus, we ask: how do STEM undergraduates conceive change while constructing mathematical models for real-world scenarios?

Theoretical Underpinnings

Our research lies within the cognitive perspective of mathematical modeling (Kaiser, 2017). In this perspective, mathematical modeling comprises the cognitive processes involved in constructing a mathematical model for real-world scenarios. We define a mathematical model to be a representation of the relations among conceived quantities.

Quantities are conceptual entities that exist in the mind of an individual. Thompson (1994b) defined *quantity* as a mental construct of a measurable attribute. It consists of three interdependent entities: an object, a measurable attribute, and a quantification. *Quantification* involves conceiving a measurable attribute of an object and a unit of measure and forming a proportional relationship between the attribute's measure and the unit of measure (Thompson, 2011). Quantification takes place in the mind of an individual and, as observers, we can only use an individual's externalized actions to infer whether and how she has quantified an attribute. Czocher & Hardison (2021) presented eight observational criteria that can be taken as indication that a student has conceived measurement process for a measurable attribute of an object.

A relation among measurable attributes is established through operating on quantities. Thompson (1994b) defines *quantitative operation* as the "mental operation by which one conceives a new quantity in relation to one or more already-conceived quantities" (p.10). As a result of a quantitative operation a *quantitative relationship* is created: the quantities operated upon along with the quantitative operation are in relation to the result of operating (Thompson, 1994b). In other words, a quantitative relationship is the "conception of three quantities, two of which determine the third by a quantitative operation (Thompson, 1990, p. 12)." Examples of quantitative operations include *combining two quantities additively*, *comparing two quantities* *additively, combining two quantities multiplicatively*, *comparing two quantities multiplicatively*, *instantiating a rate*, *generalize a ratio*, and *composing two rates or ratios* (Thompson, 1994b). Thompson defined (1990) defined *quantitative structure* as a network of quantitative relationships. For example, the total number of feral cats that visited a backyard during one weekend is a quantity that may be constructed by *additively combining* the number of cats that visited the backyard on Saturday and the number of feral cats that visited the backyard on Sunday. At the same time, the total number of feral cats that visited the backyard on Saturday during the time period 9am to 5pm is a quantity that maybe constructed by *instantiating a rate* of 10 cat-bird interactions per hour for 8 hours.

Borrowing ideas from the aforementioned constructs we define *structural conception of change* as conceiving change as a measurable attribute of an object through forming a relation among constituent quantities (i.e., operating on quantities). We operationalize change as a measurable attribute of a varying quantity, that can be quantified via a quantitative relationship. The research question addressed in this report is: In what ways do STEM undergraduates structurally conceive change while constructing mathematical models for real-world scenarios?

Methods

We present data from a pair of 10-hour individual teaching experiments (Steffe & Thompson, 2000) conducted with undergraduate STEM majors at a large university. The overall goal of the teaching experiment was to investigate how students conceive real-world situations through quantities and relations among quantities. Our participants, Szeth and Pai were both enrolled in differential equations at the time of the interviews. Throughout the teaching experiment, Szeth and Pai worked on 10 and 9 tasks, respectively, that were based on real-world scenarios. In this report we present data from *The Disease Transmission Task*, *The Pruning Task*, and *The Population Dynamics Task*. We focus on these tasks because they exemplify how Pai and Szeth operated on quantities that they had previously constructed, to structurally conceive change.

The Disease Transmission Task: Suppose a disease is spread by contact between sick and well members of the community. If members of the community move about freely among each other, develop a mathematical model that informs us about the dynamics of how the disease would spread through the population.

The Pruning Task: Imagine you have a hedge in your garden of some size, S, and you want it to increase its size even more. You hire a gardener for some advice on growing this particular plant. She advises you that the overall rate of growth will depend both on the extent of pruning and on the regrowth rate, which is particular to the plant species and environmental conditions. Both rates can be measured as a percentage of the size of the plant. The pruning rate can be adjusted to result in a target overall growth rate. Can you derive a model for the rate of change of the size of the plant?

The Population Dynamics Task: Suppose in a laboratory setting, we are looking at large populations of breeding stock in which individuals give birth to new offspring but also die after some time. Suppose that on average each member of the population gives birth to the same number of offspring, α, each season. The constant α is called per–capita birth rate. We also define β as the probability that an individual will die by natural causes before the next breeding season and call it the per-capita death rate. Construct a mathematical model that describes the dynamics of this population.

The interviews were retrospectively analyzed to construct second-order accounts (Steffe & Thompson, 2000) of students' reasonings via inferences made from students' observable activities such as verbal descriptions, language, written work, discourse, and gestures. The retrospective analysis consisted of multiple passes of through the data to arrive at examples that illustrate the different ways Szeth and Pai structurally conceived change. First, we watched the videos in MAXQDA in chronological order and paraphrased each interview by chunks. Next, we created accounts of students' mathematics and the reasons they attributed to their mathematics. Next, we went over the accounts we created and the videos at the same time and refined our accounts by adding details using theories from quantitative and covariational reasoning. We credited a student to have instantiated a quantity if we were able to infer from his reasonings that he had conceived an object, attribute, and a measurement process for the attribute. As evidence of student to have conceived a measurement process, we checked if at least one of the quantifications criteria was met (see Czocher & Hardison, 2021). We used segments of transcripts, where the students engaged in quantitative reasoning along with inscriptions and gestures as evidence for our claims. Next, from these accounts, we selected instances where the students engaged in structurally conceiving change. Next, while watching the videos and going over our accounts of students' structural conception of change, we further refined our accounts by adding details of how Pai and Szeth operated on constituent quantities to form a relation in order to conceive change. Next, we went through our accounts of Pai's and Szeth's structural conception of change and observed any patterns, in terms of operation on constituent quantities, that were consistent throughout the sessions. We made note of them by summarizing the pattern. We watched the videos in their entirety again and made sure all of the different ways of conceiving change were recorded. Finally, we refined our second-order accounts by seeking clarification on utterance and gestures to support our claims on Pai's and Szeth's structural conception of change. We present some of these second-order accounts below.

Findings

Pai structurally conceived change as accrual and as the additive comparison of quantities. In contrast, Szeth structurally conceived change as an instantiation of rate. I illustrate these structural conceptions using Pai's work from *The Disease Transmission Task* and *The Pruning Task* and Szeth's work from *The Population Dynamics Task*.

Change as the Accrual

Conceiving change as the accrual entails an image of accruing the amounts at different points in time, by additively combining the amount present before and the amount that was newly added. In *The Disease Transmission Task*, Pai constructed the expressions in Figure 1 to represent the change in healthy people and change in infected people.

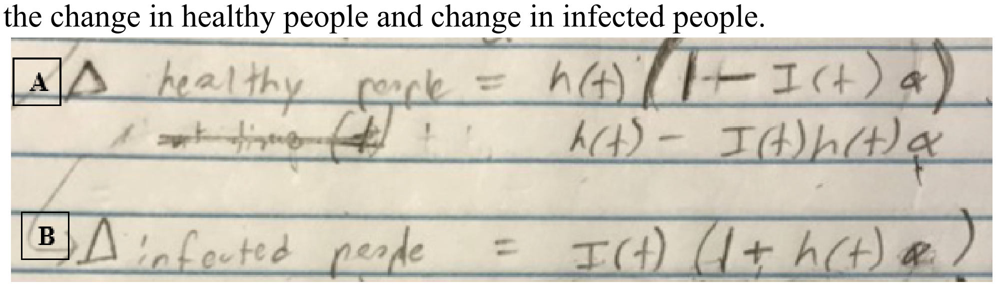

Figure 1. Pai's expression for the change in infected people and change in healthy people

After Pai constructed the above expressions, we asked him by how much the infected people would change. The goal of this question was to document how Pai was distinguishing between "$\Delta\, infected\; people$" and $I(t){\cdot}h(t){\cdot}\alpha$, because these two quantities carried the same meaning to us. Interestingly, Pai said that the "increase [in infected people]" was $I(t){\cdot}h(t){\cdot}\alpha$. Even though we used the term change when we asked him by how much the infected people changed, Pai replied with the "increase" in infected people. We interpret that Pai associated two different meanings to the attributes change and increase of the infected people, while he continued to associate change in infected people with expression B in Figure 1. This interpretation was further evidenced in the excerpt below.

Pai: Well, yeah. Change in the infected people is the base infected people at time t, plus those again, infected at time t. And this is just an increase. $h(t)\cdot I(t)\cdot\alpha$. Is going to be less than... You're going to be adding this to...to the base population.

Interviewer: Okay. I see. So yeah, you are seeing the delta infected people as the change in that sense, the total number of infected people that would be at the end of an infectious period?

Pai: Right.

Interviewer: Whereas the other one, how much... How many are getting infected that you have to add to the base.

Pai: Yeah, it's the increase, but just the increase of people infected in this time period.

Interviewer: Okay.

Pai: Maybe I could write that better saying this is the people infected in time period t [pointing at the expression $h(t)\cdot I(t)\cdot\alpha$]. That was a better statement of it. Like people infected... Well, people infected... In current period t. Whereas $I(t)$ is just how much we had already. Initially, before interactions with other healthy people. If that makes sense.

From the above excerpt, we interpret that Pai quantified change in infected people and increase in infected people differently. While Pai quantified the change in infected people as the "base population" plus how many more got infected, he quantified the increase in infected population as just the how many more people got infected, which to him was $h(t)\cdot I(t)\cdot\alpha$.

Pai continued to reason as to why expression B in Figure 1 represented the change in infected people as "cause that's a change in two - over two time periods because you're adding one. Cause you're adding another time period." From his reasoning, we interpret that Pai imagined to be representing the change in infected people as an accrual of the infected population at different points in time. For Pai, $I(t) + h(t)\cdot I(t)\cdot\alpha$ represented the change in infected population as an accrual of the amounts of infected people across a progression of time. On the other hand, for Pai, $h(t)\cdot I(t)\cdot\alpha$ represented increase in infected people during the moment of interest. Therefore, Pai structurally conceived change in infected people as the *additive combination* of the amount of infected people present at the beginning of the moment of interest and amount of people that got infected at the moment of interest.

Change as the Additive Comparison of Quantities

Structurally conceiving change as the additive comparison of quantities entails constructing change in the amount during a time period $[t_1, t_2]$ as the additive comparison of the amounts at t_1 and t_2, respectively. In *The Pruning Task*, Pai constructed the following expressions to represent the size of the plant at the end of the first and second pruning periods, respectively.

$$S_1 = S_0 - p(S_0) + r(S_0)$$
$$S_2 = S_1 - p(S_1) + r(S_1)$$

In the above expressions, Pai defined S_0 as the size of the plant at the beginning of the first pruning period, S_1 as the size of the plant at the end of the first pruning period, S_2 as the size of the plant at the end of the second pruning period, r as regrowth rate of the plant, and p as the extent of pruning. After constructing the above expressions, Pai constructed the expression below to be the change in size of the plant during the second pruning by *additively comparing* the quantities S_1 and S_2.

$$\Delta S = \ - p\left(S_1\right) + r\left(S_1\right)$$

Next, Pai constructed a general expression for the change in size of the plant during any pruning period of 1 unit, to be the following expression.

$$\Delta S = \ - p\left(S_t\right) + r\left(S_t\right) \quad (1)$$

In the above expressions, Pai structurally conceived the change in size of the plant during a particular period by *additively comparing* the sizes of the plant at the beginning and end of the particular pruning period. Pai's structural conception of change, in this manner was also prevalent in the remaining of his work in this task. We illustrate this episode below.

Pai started working on deriving an expression for the rate at which the size of the plant was changing with respect to time. As Pai was not sure how to proceed, the interviewer directed him to derive an expression for the change of plant's size during a pruning period of length Δt. The intent of this question was to guide Pai towards thinking of the average rate of change of the size of the plant and how it can be manipulated to derive the instantaneous rate of change. Pai constructed the expression below to represent the change in size of the plant during two successive pruning periods.

$$\Delta S =- p\cdot\left(S_{t+1}\right) + r\cdot\left(S_{t+1}\right) - \left(- p\cdot\left(S_t\right) + r\cdot\left(S_t\right)\right) \quad (2)$$

Although expression 2, for Pai, represented the change in size of the plant during two successive pruning periods, normatively it represents how much more the plant changed in size than the previous pruning period.

The interviewer emphasized to Pai that expression 1 is the change in size of the plant during any one pruning period and asked what the change in size of the plant would be during two such pruning periods, given that the change is the same for each pruning period. The intent of the question was to give Pai the opportunity to structurally conceive overall change during two successive pruning periods as the additive combination of the changes in size of the plant, during each pruning period. However, Pai was still referring expression 2 to as the change in size of the plant during two pruning periods. Pai gave the following reasoning:

Pai: Because it's a change of the size of the plant over two periods. This is the change of... It's the second pruning period, $t + 1$ [*pointing at* $- p\left(S_{t+1}\right) + r\left(S_{t+1}\right)$], minus the initial pruning period change [*pointing at* $- p\left(S_t\right) + r\left(S_t\right)$].

When the interviewer pointed out that expression 2, to her, represented a "change minus change," Pai recognized expression 2 did not achieve his goal.

In an attempt to reduce Pai's cognitive load and to aid in unpacking his conception of change, the interviewer modified the scenario to be such that the change in size of the plant during a pruning period would be a constant β instead of ΔS. The interviewer asked Pai what the change in size of the plant would be over two time periods, given that β is the change during each pruning period. Pai said that it would be "The beta of the second pruning period minus beta of the first pruning period". This again serves as evidence that Pai's structurally conceived of change as the *additive comparison* of quantities.

The interviewer pointed out to the fact the quantity he constructed – "the beta of the second pruning period minus beta of the first pruning period" – was change in change. She asked what the overall change would be from the beginning of the first pruning period to the end of the second pruning period. Pai's responded with "You take the end, the change... Well, take the size at the end of period two minus the size of initial before period one. That's overall change." Again, Pai was only measuring the attribute change in size of the plant through comparing the sizes of the plant at different times.

To circumvent Pai's thinking of change as "beta of the second period minus beta of the first period" the interviewer shifted his focus to the quantities S_1, S_2 . The interviewer asked Pai that given $\beta = S_2 - S_1 = S_3 - S_2$, and so on, what the total change in size of the plant be from the beginning of the first pruning period to the end of the third period. To that, Pai answered $S_3 - S_1$ (Figure 2, point A). The fact that Pai was still considering the difference between S_1 and S_2 (instead of $\beta + \beta$) to find the change in size of the plant confirms our conjecture that his structural conception of change predominantly entails the *additive comparison* of the amounts at different points in time. When the interviewer asked him what $S_3 - S_1$ was in terms of β, Pai solved for the system of linear equations to get 2β. He attained 2β through comparing the quantities S_3 and S_1 and not by adding the $\beta's$ during each compounding period (See Figure 2). Only after arriving at 2β, Pai realized that it is "two changes in size β".

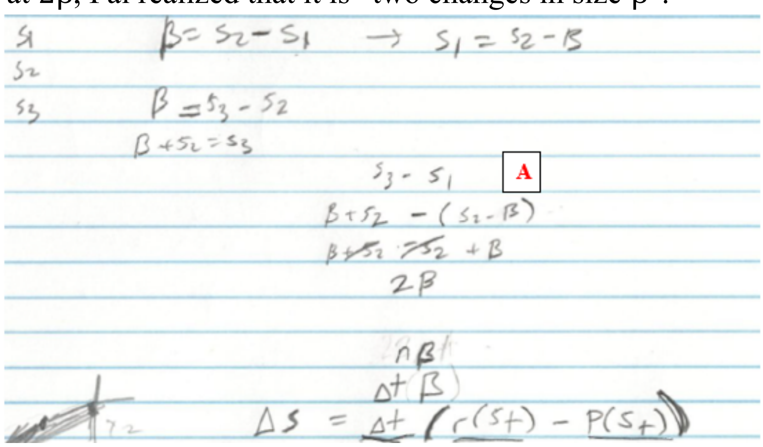

Figure 2. Pai additively compared the sizes of the plant at different times to evaluate the change in size of the plant

Change as the Instantiation of Rate

Structurally conceiving overall change as instantiation of change entails constructing overall change through *multiplicatively combining* the change during an interval of one unit of time and the length of the time period. In *The Population Dynamics Task*, Szeth constructed the expression in Figure 4 to represent the "size of the population at time t."

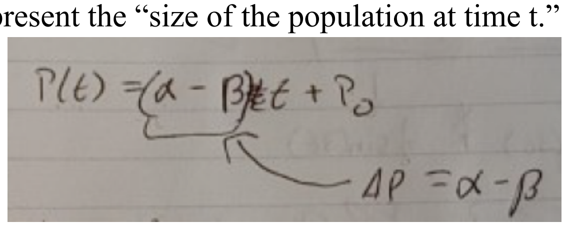

Figure 4. Szeth's expression for the size of the population at time t

In the expression in figure 4, Szeth defined $P(t)$ as the "size of the population at time t," P_0 as the population "that is already there" and α and β were given in the task as the per-capita birth rate of the population and the per-capita death rate of the population of the population, respectively. In the above expression in Figure 4, Szeth nominalized $(\alpha - \beta)\cdot t$ as "how much it [*the population*] is growing by," and $\Delta P = \alpha - \beta$ as the change in the population during one season. Szeth explained that he multiplied $\alpha - \beta$ by t because he wanted a "method within the equation for it to iterate over time [because $\alpha - \beta$] is based on the one season." When Szeth referred to $\alpha - \beta$ as "based on one season" and denoted $\Delta P = \alpha - \beta$, Szeth conceived the change in the size of the population during an interval of one unit of time as $\Delta P = \alpha - \beta$. Then to construct overall change in size of the population during a time period, Szeth *multiplicatively combined* the net change in the population during an interval of one unit of time and the length of the time duration. For Szeth, the length of the time duration was from $t_i = 0$ to $t_f = t$.

Discussion

We presented three examples of differing ways that Pai and Szeth structurally conceived change in terms of operating on constituent quantities. Structurally conceiving change as the accrual entails constructing an image of accruing the amounts at different points in time, by additively combining the amount present before and the amount that was newly generated. Structurally conceiving change as the additive comparison of quantities entails constructing change in the amount during a time period $[t_1, t_2]$ as the additive comparison of the amounts at t_1 and t_2. Finally, structurally conceiving overall change as instantiation of change entails constructing overall change through multiplicatively combining the change during an interval of one unit of time and the length of the time period.

In *The Disease Transmission Task*, Pai structurally conceived change in as an accrual through *additively combining* the amount of infected people at the beginning of the moment of interest and the amount of people who got infected at the moment of interest to construct the change in the amount of infected people. However, in *The Pruning Task*, despite the interviewer's efforts in having Pai to construct change in the size of the plant during two pruning period through additively combining the change in the size of plant during each pruning period, Pai consistently constructed change as an *additive comparison* of quantities. We conjecture that Pai had a strong preference for structurally conceiving change as the additive comparison of quantities, that he dropped the situational attributes of the quantities operated on and the resultant quantities were measuring. In contrast, Szeth structurally conceived change as an instantiation of rate where he unitized the change in size of the population and then multiplied the unit change by the length of the time period.

Knowing the different ways students structurally conceive change provides insights about the mathematical decisions students make during their mathematical modeling activities. This knowledge has implications for the teaching of mathematical modeling. For example, for a student who structurally conceives change as an instantiation of rate, like Szeth, the construction of instantaneous rate of change – typically the desired output while modeling dynamic situations – can be scaffolded by first constructing the change during a time period to the average rate of change during a time period, and finally to the instantaneous rate of change by considering infinitesimally small time periods. For someone who conceives change as an accrual, like Pai, focusing on the amount increased/decreased may yield favorable modeling outcomes. As quantities are building blocks of a mathematical model (Larson, 2013), understanding how students operate on existing quantities to construct a new quantity informs researchers and educators *where* and *how* to intervene in the students' mathematical modeling process.

A Case of a Computational Setting Facilitating Empirical Re-Conceptualization

Adaline De Chenne
Oregon State University

Elise Lockwood
Oregon State University

The use of computer programming is ubiquitous for research mathematicians, and two common practices are facilitation of experimentation and testing of conjectures. These practices align with empirical re-conceptualization, which is the process where empirical data is used to identify patterns, form related conjectures, and then re-interpret the conjectures from a structural perspective. However, literature on empirical re-conceptualization has only examined student work done by hand. We present case study data of one student, Allen, using the programming language Python to facilitate empirical re-conceptualization as he found the closed-form solution for binomial coefficient C(n,k)*. We discuss why the computational environment was productive for empirical re-conceptualization and provide avenues for future research.*

Keywords: Computation, Re-Conceptualization, Combinatorics, Generalization

Introduction, Motivation, and Relevant Literature

Mathematics as a discipline has adopted computation to progress research that has historically been performed by-hand, to provide additional insights into existing theory, and to pursue new solution methods for difficult problems. As computation—which, for our purposes, refers to the use of a computer to carry out, or otherwise assist in, a solution to a mathematical task—becomes increasingly ubiquitous in the discipline, there has been a push by mathematics education researchers for investigations into the interplay between computational environments, mathematics, and students. This has included investigating how computational environments can be used to facilitate conceptual development in novel and complementary ways (e.g., Sand et al., 2022), how to assess student use of computation (e.g., Buteau & Muller, 2017), how computer programming informs student affect towards mathematics (e.g., Purdy & Lockwood, 2020), and how further research might benefit from theoretical perspectives that accommodate the increasing relevancy and diffusion of computing into mathematics (e.g., diSessa, 2018). Computing is now an authentic mathematical practice (Lockwood et al., 2019), and as mathematics education research seeks ways to foster student development of authentic mathematical practices across subject areas, we feel there is an opportunity to do so for computing. Specifically, Lockwood et al. (2019) identified ways in which mathematicians use computing in their work. In this paper, we build on two possible ways students can use a computational environment that align with those identified in Lockwood et al., (2019): to facilitate experimentation, and to test conjectures.

Experimenting and conjecturing align with the concept of empirical re-conceptualization (ER) (Ellis et al., 2022), which is "the process of identifying a pattern or regularity, forming an associated generalization, and then re-interpreting those findings from a structural perspective" (p. 2). As yet, the literature on ER has only examined student work performed by hand. This work includes either the researchers providing a data set for students to study and conjecture about, or the students creating the data set themselves. We feel that a computational environment can facilitate ER by providing the means to quickly produce large data sets in ways that are intractable by hand, and to test the veracity of conjectures over these data sets. Moreover, this provides an opportunity to investigate how a computational environment can be used in problems students are capable of solving while still having them engage in practices that are authentic to the discipline.

In this paper, we seek to demonstrate an instance of a computational environment facilitating ER for a student, Allen (a pseudonym), as he finds a closed-form expression for the binomial coefficient, *C(n,k),* by writing computer code in Python. We will show that Allen used the computational environment to create data sets based on the parameters *n* and *k*, and he used the data sets to iterate between creation and validation of conjectures. In doing so, we hope to contribute to the literature on computation in mathematics education, and to the literature on conjecturing and generalization, by documenting one way that a computational setting can be used to open the door for students to engage in mathematical generalization. We also contribute to the literature on combinatorics education by discussing how Allen's counting process for *C(n,k)* involved enumerating and tallying the entire set of outcomes, and discussing how he had difficulty connecting his counting process to the closed-form expression. This paper addresses the research question "In what ways might a computational setting facilitate empirical re-conceptualization (ER) as students find closed-form expressions for binomial coefficients?"

Theoretical Perspective on Empirical Re-Conceptualization

Curricular development and mathematical reasoning hierarchies expect students to move from empirical toward deductive reasoning, and they broadly frame empirical reasoning as less sophisticated than deductive reasoning, or as a stumbling block to overcome. This is justifiable, as empirically-found patterns can be faulty, lack explanatory power (Bills & Rowland, 1999), and students may overly rely on a small number of cases to check the validity of mathematical statements (Knuth et al., 2009). Yet, students can be adept at empirical patterning (Küchemann, 2010), and they demonstrate dynamic interplay between patterning empirically and arguing deductively, just as mathematicians do (de Villiers, 2010). Because students have difficulty shifting from empirical to deductive reasoning (e.g., Stylianides & Stylianides, 2009), there is motivation to search for ways of leveraging the productive aspects of empirical reasoning in order to enhance, or otherwise inform, deductive reasoning. As an example, empirical reasoning can give insight into a problem's structure in a way that supports deductive reasoning. Further, students flexibly reason between multiple representations when reasoning empirically (Amit & Neria, 2008), which can be beneficial for deductive reasoning. Ellis et al. (2022) propose the concept of ER as one way that empirical reasoning can be leveraged to enhance deductive reasoning.

Empirical re-conceptualization is "the process of identifying a pattern or regularity, forming an associated generalization, and then re-interpreting those findings from a structural perspective" (Ellis et al., 2022, p. 2). A structural perspective refers to the last four categories of structural reasoning as described by Harel and Soto (2017), whose five major categories are (a) pattern generalization, (b) reduction of an unfamiliar structure into a familiar one, (c) recognizing and operating with structure in thought, (d) epistemological justification, and (e) reasoning in terms of general structures. The first category further elaborates the difference between result pattern generalization (RPG), which is a way of generalizing that attends only to results, and process pattern generalization (PPG), which is a way of generalizing that attends to a process (Harel, 2001). Generalizations formed through empirical reasoning are examples of RPG because only the results (i.e., the empirical data) are used to create the generalization. A structural perspective refers to the other four categories of structural reasoning. ER can thus be evidenced by a shift from RPG to PPG, which entails a shift from pattern generalization to any of the other four categories. In this study, we use this notion of ER to frame our student Allen's work, and we highlight the ways in which the computer supported Allen's ER.

Methods

Participants and Data Collection

The data presented here are from a teaching experiment (TE) (Steffe & Thompson, 2000) that consisted of 3-4.5 hours of contact time each with four students in 60- to 90-minute interview sessions over the course of several weeks during a single academic term. This TE is part of a broader study that aims to investigate how a computational environment can be leveraged to enrich student understanding of mathematics. We focus on a single student, Allen (pseudonym), who was an Electrical and Computer Engineering major recruited from an introductory computer science course at a large university in the western United States. We chose Allen based on his responses to a recruitment questionnaire, which indicated that he had never taken a discrete mathematics course, and he exhibited a strong computer science background. We interviewed Allen in person over three 90-minute sessions, and we focus on the last session in this paper. We chose these data because they exemplify using computational techniques to engage in ER through experimentation and conjecture validation in a sophisticated way. Indeed, Allen's mastery of fundamental computer science ideas indicates that most students would not produce similar results, but we nevertheless believe our findings have useful theoretical implications about using computer programming to engage in ER. For example, our findings might speak to how future studies could create tasks and scaffolding intended to elicit generalizing activity, such as ER, in a computational setting.

During the TEs, the students sat at a desk and worked individually on a desktop computer in the programming environment CoCalc. CoCalc is an online-supported application that allows users to write in Jupyter notebooks, which include cells where Python code can be written and executed. Jupyter notebooks allowed the students to write separate pieces of code for each task, or multiple pieces of code for a single task, and to quickly reference code they had previously written. We also gave them paper handouts of the problem statements and provided a brief introductory guide to Python syntax. To capture the interviews, we videotaped and audiotaped the interviews, took screen recordings of the desktop computer, and scanned the students' hand-written work.

Tasks

Allen worked on a number of counting problems that involved finding the solution by hand, and writing a computer program that enumerates and tallied all possible outcomes. Throughout the TE, he worked on problems involving Cartesian products, arrangement with repetition, arrangement without repetition, and one problem involving selection without repetition. Allen used the multiplication principle to solve these problems by hand (with the exception of the selection without repetition problem), and his computer programs used nested *for* loops to implement an odometer strategy, similar to those reported by De Chenne and Lockwood (2022).

We focus on his work on the Book Problem: "Suppose you have eight books and you want to take three of them with you on vacation. How many ways are there to do this?" The solution to this problem is $C(8,3) = 56$, the number of ways to *select* (without arrangement), three of eight books. We chose these data because Allen initially solved the problem incorrectly, and after finding the correct solution he decided to search for patterns between his initial incorrect answer and the correct answer. The pattern he found made him curious about how the pattern would change with different parameter values, and Allen engaged in ER ultimately to find a closed-form expression for the binomial coefficient, *C(n,k)*. We elaborate on Allen's solution, and his ER, in the Results section.

Data Analysis

We chose this episode because it demonstrates an instance of a computational setting facilitating ER. The first author identified key moments where Allen used his computer programs to reason empirically about the relationship between *C(n,k)* and *P(n,k)*. She then created an enhanced transcript of the episode by including pictures of Allen's work and screenshots of the computer programs he wrote. This analytic process allowed us to make a narrative of Allen's reasoning about *C(n,k)* as it relates to *P(n,k)*, and capture instances of conjecturing, validating conjectures, and re-conceptualizing the empirically-found patterns. Finally, both authors reviewed the enhanced transcript and identified ways in which Allen's work with the computer demonstrated instances of ER.

Results

We first provide a chronological narrative of Allen's work finding a closed-form expression for the binomial coefficient, *C(n,k)*. Then, we discuss three ways in which the computational environment facilitated the ER: (1) isolating generalizable relationships, (2) generating data, and (3) validating conjectures.

Allen began his work on the Book Problem (stated above). The correct solution to this problem is *C(8,3)*, the number of ways to *select* three of eight books, but Allen's initial solution was *P(8,3) = 8*7*6 = 336*, the number of ways to *arrange* three of eight books. The first author asked him how he would verify if his solution was correct, and Allen verbally described a computer program that would enumerate the outcomes. The computer program he described enumerated all *arrangements* of the books, which was consistent with the numerical solution he found, but was incorrect because it overcounted the outcomes. The first author asked him to write down the first ten outcomes his computer program would produce. When he wrote down these outcomes, Allen noticed that the computer program he described would produce both *1,2,3* and *1,3,2*, which represent the same outcome. Based on his realization that *1,2,3* and *1,3,2* represent the same outcome, we infer that Allen understood that different arrangements of the same three books do not constitute different outcomes in this problem.

After realizing his error, Allen was unable to find a closed-form expression that correctly counted the outcomes, but he was able to write a computer program that would correctly enumerate all the outcomes. To do so, he modified his enumeration strategy for arrangements so that a length three number sequence was enumerated only if the numbers in the sequence were in increasing order, as seen in Figure 1. This modification ensures a unique order for any length three number sequence, and so each combination is only counted once. Allen justified this modification by stating "Say I pick book number 5 as my second book. I don't need to pick book 1, 2, 3, 4, or 5 [as the third book] in that case, so I'd only have three books to choose from." After executing his code, Allen found that the correct answer was one sixth of his original, incorrect answer; that is, Allen found that *P(8,3) = 6*C(8,3)*.

After finding that his initial solution was six times greater than the correct solution, Allen stated

> *Allen*: That's interesting, *8*7* is *56* … Completely the third value [the value *6* in *8*7*6*] didn't even really matter it looks like … I just want to see if bringing the total number of books down by one, does that make it equal *7*6*? Is there a relationship there?

This is the first instance where Allen reasoned empirically about a generalizable pattern. He noticed that his initial solution was $8*7*6$ and the correct solution was $8*7$, and he conjectured that $C(7,3)=7*6$. We infer that Allen's conjectured pattern was that the correct answer could be found by first finding his original answer, and then removing the last term in the product. Hence, because $P(7,3) = 7*6*5$, Allen conjectured that $C(7,3) = 7*6$ because the term 5 would be removed. This is an instance of RPG because Allen found the numerical pattern based solely on the results, and he did not provide structural reasoning that justified the pattern, or connect the pattern to his computer program. Allen modified his computer program to find $C(7,3)$, seen in Figure 1, and he found that $C(7,3) = 7*5$. After observing that $P(7,3) = 6*C(7,3)$, and the ratio was not 5 as he anticipated, Allen conjectured that $P(n,3) = 6*C(n,3)$ for every value of n. This conjecture is another example of RPG because he justified the pattern based only on the observed results. To validate this conjecture, Allen wrote a function that would return the ratio for an input value of n (which is called 'book' in his code), and he used the function to check that the ratio was 6 for all n values up to 21. After validating this conjecture for those n values, Allen concluded that the ratio was 6 for all n values.

```

    for i in range(1,book+1):
        for j in range(i+1,book+1):
            for k in range(j+1,book+1):
                count = count + 1
                #print(str(i)+" "+str(j)+" "+str(k))
    return (book*(book-1)*(book-2))/count
```

Figure 1: Allen's computational solutions for C(8,3), C(7,3), C(6,3), *and* C(n,3).

Allen then conjectured how the ratio of $P(n,k)$ to $C(n,k)$ would change for other values of k. To generate a conjecture, Allen observed that $6=2*3$, and he connected the 3 in the product to the parameter value 3 in $C(n,3)$. He conjectured that $P(n,4) = 12*C(n,4)$ because $12 = 4*3$. This is another instance of empirical patterning, as Allen did not provide, or search for, structural justification for why the parameter value 3 was connected to the ratio. To validate his conjecture, Allen modified the function he previously wrote for $C(n,3)$ to calculate $C(n,4)$. This modification did not appear to be difficult for Allen, and he made the appropriate changes without prompting by the researchers. Using this function, Allen found that $P(n,4) = 24*C(n,4)$, which was not the ratio he anticipated. He then characterized the change in ratio from 6 to 24 as a multiplication by 2^2, not as multiplication by 4, which we take as further evidence that Allen was empirically patterning based on the 2 in the original product $6 = 2*3$. Allen then conjectured that $P(n,5) = 40*C(n,5)$, where the $40 = 2^3*5$. This is another example of RPG, where Allen generalized the results (factors of 2) without structural justification. However, after further modification of his code to calculate $C(n,5)$, Allen found that the correct ratio was 120.

At this point, Allen had found that $P(n,3) = 6*C(n,3)$, $P(n,4) = 24*C(n,4)$, and $P(n,5) = 120*C(n,5)$, and he observed that $24 = 6*4$, and $120 = 24*5$. Based on these results, he then conjectured that "my next guess would be 120 times six, which would be 720," which is to say that he conjectured $P(n,6) = 720*C(n,6)$. This is correct, and in describing the pattern he states "What I noticed is each time you go up, you multiply by the next number. So 6 times 4 equals 24, which multiplied by 5 equals 120, which multiplied by 6 equals 720." To formalize his conjecture regarding the ratio between $P(n,k)$ and $C(n,k)$ for any parameter values n and k, Allen wrote the expression in Figure 2, which he characterized as his original solution, $P(n,k)$, divided by $k!$. Although he had found the correct closed-form expression for the binomial coefficient, he had done so solely through empirical patterning. The first author asked Allen why dividing by $k!$ might yield the correct solution. Allen recognized that $k!$ represents the number of ways to arrange k objects, which he used as justification for why dividing by $k!$ yields the correct answer. We view this justification as a shift from RPG to PPG because Allen moved from using empirical results to create patterns, to justifying those patterns structurally by arguing how the mathematical expression connects to the outcomes he was counting. Hence, this episode demonstrates ER because it presents an instance of finding a pattern (a constant ratio between permutations and combinations), forming an associated generalization (the closed-form expression for the binomial coefficient), and re-interpreting the generalization from a structural perspective (justifying the ratio based on the outcomes being counted).

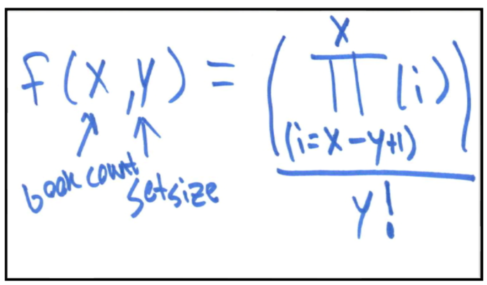

Figure 2: Allen's closed-form expression for the binomial coefficient

Having presented Allen's work, we now discuss three ways in which the computational environment facilitated the ER: (1) isolating generalizable relationships, (2) generating data, and (3) validating conjectures. Together these highlight specific ways in which the computational environment served to support this practice of ER.

Isolating Generalizable Relationships

Allen's generalizing activity in this TE centered on the relationship between $P(n,k)$ and $C(n,k)$, which is the relationship between a mathematical expression he found by hand, and a numerical solution he found computationally. Because $C(n,k)$ is a 2-variable function, isolating this relationship required understanding the relationship as both variables changed. In Allen's code, the variable k was hardcoded as the number of *for* loops, while the variable n was an assigned integer. Allen could easily change the value for n, which he used to his advantage by cycling through values of n in a *for* loop and observing the relationship between $P(n,k)$ and $C(n,k)$ for a fixed value k. However, changing the value for k required writing a new function, which can explain why Allen only examined the relationship for $k = 3, 4, 5, 6$. Having the two variable values manifested differently in the computer programs may have been beneficial, as it forced Allen to only change one variable value at a time. Creating conjectures that generalize the effect of changing one value while keeping the other constant may have been easier than if he had the ability to change both variable values simultaneously.

Generating Data Sets

Allen wrote computer programs to generate sets of outcomes that are intractable to write by hand. To do so, he was required to engage with the sets themselves, as generating them required creating an algorithm that enumerated every outcome. His conjectures evolved as he generated each data set, which may indicate that writing the computer programs is more beneficial to ER than if he were given the data sets by the researchers. In addition, Allen was unsure how to calculate $C(n,k)$ without writing a computer program. Hence, we posit that this episode would not have occurred if not for the computational environment.

Validating Conjectures

Much of Allen's work iteratively moved between conjecturing and validating conjectures. The computational environment seemed to positively impact how he formed conjectures by motivating him to form conjectures that he could validate computationally. Every time Allen formed a conjecture, he immediately wrote a computer program to validate that conjecture. What Allen decided to conjecture about may have been informed by the elements of his computer program that seemed immediately adaptable. For example, Allen could easily change the value of n, and his initial conjectures formed around how n impacted the numerical solution. We posit that Allen's mastery of basic computer programming allowed flexibility in how he could adapt his code to accommodate changes in variable values. This flexibility manifested in his conjecturing by allowing some flexibility in the conjectures he was able to validate.

Discussion

In this paper, we have attempted to demonstrate a case in which a student leveraged a computational environment (and his computational facility) to engage with a combinatorial task, particularly using the computer meaningfully to engage in ER. We see much potential for ER to be a useful construct in considering students' mathematical activity (particularly relating to the practices of generalizing and conjecturing). In light of this, we think it is important to explore different aspects of this construct. Further, given the growing importance and ubiquity of computing in mathematics, and mathematics education, we see value in particularly exploring ways in which ER may be reinforced via the computer (and, reflexively, how a computational environment can specifically support practices such as ER). In this way, our findings contribute to a growing body of literature that demonstrates ways in which computational activity supports students' mathematical thinking and activity. Moreover, our findings also contribute to literature that demonstrates students using a computational environment in sophisticated ways that reflect the practices of research mathematicians.

We were fortunate in this study to uncover a case of a student leveraging the computer in a powerful way to support ER. Further research could more explicitly target not only instances of students using the computer meaningfully, but could investigate ways to support and engender productive use of the computer to support students' engagement in practices such as ER.

Resources for Participation: Examining Multilingual Students' Perspectives on What it Means to Participate in Active Learning

Jocelyn Rios
Colorado State University

More college mathematics classrooms are adopting active learning practices like collaborative learning. Participation in these practices typically requires students to engage in verbal communication and interpersonal interactions, which are mediated by language. Despite this, the experiences of multilingual students have often been overlooked in the literature on active learning. Through analyzing interviews with 26 multilingual students, this study explores what participation in active learning meant to these students. It also explores the resource that students perceived to be necessary in order to participate in active learning, for example, being comfortable speaking English. Finally, this study demonstrates how classroom discourses and broader social discourses about language shaped students' perceptions about participation.

Keywords: Multilingual learners, active learning, groupwork, classroom norms and discourses

Introduction

Active learning has become a well-established teaching pedagogy for improving student learning and promoting equity in undergraduate mathematics courses. Although this approach to teaching includes a broad range of strategies, students in active learning classrooms are often expected to work on mathematics collaboratively with peers. For instance, groupwork is a common way that instructor choose to infuse active learning into their courses (e.g., Bennett, 2022). Collaboration is also a core pillar of inquiry-based learning (Laursen & Rasmussen, 2019). As such, groupwork and collaboration are often integral parts of how students experience active learning in undergraduate mathematics courses.

When students work in groups, they are typically expected to participate in talk-intensive activities, like discussing their thinking and arguing for why their solutions are correct (see also Laursen & Rasmussen, 2019; Voigt et al., 2022). These activities also require interpersonal communication, as students learn through social interactions with others. Therefore, in active learning classrooms, participation is often mediated by language and communication.

Active learning has traditionally been linked with promoting equity in the undergraduate mathematics classroom. Analyzing data from over 100 courses, Laursen et al., (2014) found that inquiry-based learning (IBL) helped remove the gender performance gap that was observed in lecture-based courses. However, a growing body of research, questions whether students from underrepresented groups experience active learning in the same way and equitably benefit from it (Ernest et al., 2019; Henning et al., 2019; Johnson et al., 2020; Reinholz et al., 2020). For instance, Ernest and colleagues (2019) demonstrated that women's verbal contributions during groupwork were less likely to be revoiced in whole class discussions.

Given the mediational role of language in active learning classrooms, students' linguistic identities may also shape how they experience active learning. At the post-secondary level, Hwang et al. (2022) documents two contrasting cases of students (Jia and Falon) who felt excluded during groupwork based on their home language identity. At the K-12 level, much has been learned about multilingual students' experiences with groupwork. Numerous studies have found that multilingual students tended to participate more in small group settings than in whole class discussions (Brenner, 1998; Civil, 2008; Gorgorió & Planas, 2001; Planas & Civil, 2013;

Planas & Setati, 2009). In addition, these findings demonstrated how normative discourse about language can shape power and participations structures in the classroom. Planas and Civil (2013) show how students in Barcelona felt the need to use the language of instruction, Catalan, in whole group discussions. This perception contributed to students feeling less comfortable sharing ideas during class.

As globalization increases, undergraduate mathematics classrooms are becoming more linguistically diverse. More research is needed to better understand how multilingual students' experience classroom pedagogies like active learning. To this end, the goal of this study is to explore multilingual students' perceptions about what it means to participate in active learning and how these perceptions are influenced by social and local discourses.

Theoretical Perspectives

A Sociopolitical Perspective on Participation

A situated perspective (Lave & Wenger, 1991) emphasizes the connection between learning and participation. That is, learning can be conceptualized as changes in students' classroom participation (Sfard 2007) where, by working together, individuals access resource for participation and become better able to engage in activities (Wood, 2013). Building on this perspective, a sociopolitical approach (Gutiérrez, 2013) recognizes that power and identity shape how participation structures unfold in active learning classrooms. A sociopolitical perspective argues that learners are not always inherently positioned in the same way in relation to the community that they are trying to participate in (Walkerdine, 1994). For example, students learning English may be positioned as less intelligent and have less access to participate in mathematical discussions (Flores et al., 2015). Thus, participation is subject to the norms and discourses[1] established by a social practices. These discourses constitute what is considered meaningful participation (Lerman, 2000). Discourses also shape what resources for participation are consider legitimate and lead to full participation (Barton & Tan, 2009). For instance, being able to formally articulate mathematical thinking is often framed as an important resource for participation in mathematics classrooms (Moschkovich, 2002).

A Sociopolitical Perspective on Language

Like mathematics, learning a language also requires participating in a new language community (Barwell, 2005). Similarly, dominant social discourses about language constitute what it means to be a legitimate language-user. For example, although English has become a lingua-franca and is spoken in many parts of the world, discourses about nativeness give preferential status to native speakers from western countries (Ferri & Magne, 2021). Subtirelu (2015) claims that these discourses operate to position groups of people as Others (i.e., different from the dominant group). "Nonnative" varieties of language can become socially stigmatized to discredit and exclude the speaker (Birney et al., 2020). Furthermore, native speakers may feel less obligated to "ensure successful communication" with nonnative speakers (Subtirelu, 2015, p. 36) and less willing to listen to and meaningful engage with their verbal contributions (Rios, 2022). A sociopolitical perspective on language recognizes that language and language status are inherently connected to who is afforded power in the classroom (Takeuchi, 2016) and whose linguistic resources are legitimized (Planas & Civil, 2013).

---

[1] Gee (2015) defines discourse as: "distinctive ways of being, doing, and saying. They are ways of using words, doing deeds, valuing, thinking, believing, and feeling, as well as ways of using objects, tools, and technologies that allow us to enact or recognize socially meaningful identities" (p. 245).

Research Questions

The research questions that this study addresses are: (1) How did multilingual students conceptualize participation in active learning and what resources did they feel were needed in order to participate? (2) What discourses (both at the classroom level and more broadly) were relevant in shaping students' perceptions about participation?

Methods

This paper draws on data from semi-structured interviews with 26 multilingual undergraduate students whose home languages were not English. The study took place at a large Hispanic Serving Institution. Eighteen of the students interviewed were international students (countries of origin included Bangladesh, China, India, Iran, Peru, Saudi Arabia, South Korea, Trinidad and Tobago, Uzbekistan, and Vietnam). The remaining students were either immigrants (from China or Mexico), refugees from Afghanistan, or transitional students who grew up near the border with Mexico and lived and attended school across both countries (Hamman et al., 2010). Participants were selected based on: (1) their language identities, and (2) their enrollment in a pre-calculus or calculus course that used active learning. Based on students' descriptions during interviews, their instructors typically implemented active learning by having students work on math problems in groups of three or four during class. Therefore, in this study, active learning is operationalized to be instances during class where students work on mathematics collaboratively via groupwork.

All interviews were recorded and fully transcribed. Pseudonyms were assigned to each participant. Data analysis focused on exploring students' perception about participation in active learning and the classroom and broader social discourses that shaped these perceptions. To do this, a data-drive approach to thematic analysis was used (Braun & Clark, 2006). In the first stage of analysis, transcripts were carefully read over numerous times. The data was then coded using an open coding system to identify instances where students talked about participation. Codes were categorized based on whether they reflected how participation was defined or a resource for participation. Descriptors of the codes were developed. The final step of the analysis focused on comparing, contrasting, and connections codes and identifying themes across the data. Although interviews were transcribed verbatim, the quotes presented in this paper have been modified slightly for clarity. No modification impacted the meaning or feel of any of the sentences in the quotes.

Results

Most students in this study described participating less frequently in active learning classrooms compared to their English dominant peers. Figure 1 illustrates how the students conceptualized participation in active learning: that participation meant speaking. Given this framing, students also shared a range of different resources that they perceived to be necessary in order to be active participants in the classroom. These resources were essentially personal attributes, like being comfortable speaking English, being extroverted, being brave, being good at mathematics, being aggressive, and being resilient (the font size in Figure 1 corresponds to how frequently each resource was mentioned during interviews). The second stage of analysis focused on unpacking how local classroom discourses and broader social discourses influenced these perceptions about participation.

In this section, I document what participation meant to students and how this was influenced by local classroom discourses. Next, I discuss two of the resources for participation mentioned by students, being comfortable speaking English and being aggressive, and demonstrate how these resources were influenced by broader social discourses about language. The first resource was chosen because it was the most frequently discussed and the second one was chosen because it represented an interesting case.

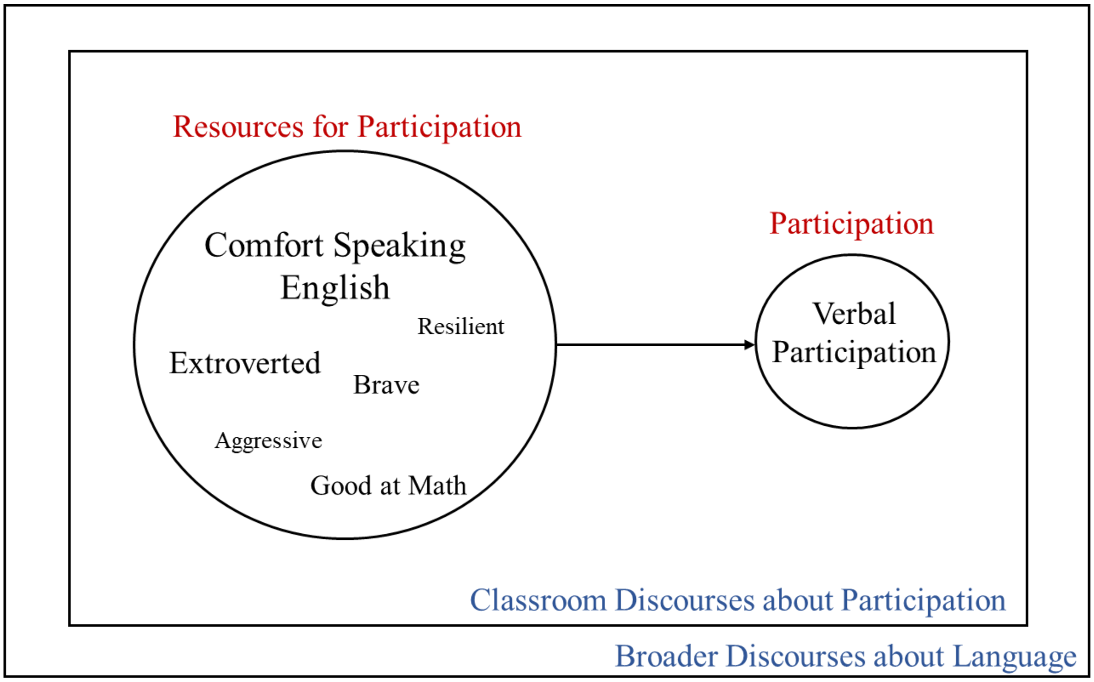

Figure 1. How multilingual students conceptualized participation and necessary resources for participation.

What Participation Meant: *Speaking*

During interviews, students frequently discussed classroom participation in terms of speaking. Whether it was in analyzing their own participation, or the participation of others, students generally associated participation with actions that centered verbal contributions (e.g., contributing ideas, responding to peer ideas, asking questions, etc.). Students shared that participation meant: “you basically speaking in front of everyone” (Dan, Trinidad and Tobago) and is “all about the group work and like I have to speak up in the class” (Sun-Hi, Vietnam).

Students also assessed their own participation in the course based on how often they spoke. For instance, although Dan was invested in the mathematics he was learning, he perceived himself as having poor participation in his calculus course because he rarely spoke during class: “When I'm not engaging much I feel like shoot. Especially when we have a question we don't understand and the other TA comes and help us with the question, my groupmate will be the one asking the question, not me”. Despite being involved in groupwork, Dan was disappointed by his level of participation because he was not the one verbalizing the group’s question. This exemplifies how participation was almost always associated with verbal communication.

Classroom Discourses about Participation. Findings also demonstrated how classroom norms and discourses about participation communicated to students that participation meant speaking. For example, students frequently discussed the teaching moves that their instructors used to elicit more verbal participation during class. Several instructors used cold-calling[2] as a way to ensure that all students were contributing (verbally) to class discussions. Similarly, one students’ instructor did not allow groups to leave until a group member, randomly chosen by the instructor, explained the group’s solutions to the class. These teaching strategies, geared toward

[2] Cold-calling refers to randomly choosing students to answer a question or discuss their solution.

enhancing participation, all aimed at fostering verbal participation. Therefore, these strategies also reinforce to students the norm that participation in the classroom is a verbal activity.

A Resource for Participation: *Being Comfortable Speaking English*

Students felt strongly that English was the only language that could be used in the mathematics classroom. Additionally, every student in the study described the importance of being comfortable speaking English in order to fully participate (verbally) in active learning. Makhmud (from Uzbekistan) shared that the “students who are more comfortable speaking English” are the ones that are “more engaged in the math classes” and are “more active”. Prisha (from India) shared how being comfortable speaking English allowed her to be an active participant in her group:

> If it's a monolingual classroom like we have here in [the US], it pretty much forces people to get out of their comfort zone if they're not comfortable talking in English. If, say I'm not very comfortable explaining my thought process in English, it would hinder my way of communicating and collaborating and it would hinder how I put myself out there, how I talk to my teachers, or how pretty much I express myself in the classroom /…/ I wouldn't be comfortable asking questions. I wouldn't be comfortable putting myself in uncomfortable situations, because just speaking in English alone is uncomfortable for me.

Groupwork in math can be a vulnerable, risk-taking activity where students are expected to produce the “right answer” and asses the correctness of their peer’s ideas. Tamir (from Afghanistan) described how these activities can feel “uncomfortable”. Engaging in them when you are already uncomfortable speaking the language “is pretty a lot to ask from somebody”. This demonstrates the importance students placed on needing to be comfortable speaking English in order to begin (verbally) participating in active learning.

In addition, students felt that if they were not comfortable speaking English in the classroom, and as a result participated less, the responsibility was on them to become more comfortable. For example, Leo felt more comfortable interacting in Spanish and shared that it was “intimidating to try to participate with others” in English. When asked what instructors could do to make speaking in groups feel more comfortable, he responded “It’s not something that they can do. It’s just something that we have to get over. It’s something we have to work on”.

Broader Discourses about Language. In contrast, study findings demonstrated how social discourses about language can impact students’ comfort speaking in the classroom. When Luis was asked if language mattered in his mathematics classroom, he responded “It’s mainly about how comfortable you feel speaking English in your class when you’re not like 100% good at the language”. Although language is a tool for communication, this quote evidences the expectation students can feel to be “100% good” at English. Numerous students described “staying silent” during class because they were afraid of making language mistakes or speaking with an accent. Many students also reported experiencing negative feelings (e.g., feeling nervous, anxious, ashamed, scared, or embarrassed) about their own language-use because they perceived it to be not “good enough”:

> - I don't feel so good when I talk. I don't know it's because of I'm an international student and my English is not perfect. – Nader, international student from Iran
> - Sometimes I really feel like too bad [because] sometimes in classes, I can't always speak as fluent English. – Abril, international student from Peru
> - A lot of times I was embarrassed to use my English because I didn't think it was good enough. – Habib, refugee student from Iraq

In addition, peers and instructors were often less willing to engage with the communicative contributions of multilingual students. For example, Anaís (from Mexico) described how others "avoid" talking to people with an "English accent" and Prisha shared how others are "not very willing to put in the same amount of effort as they would be if somebody was more fluent in English". Makhmud felt that "if you're not good at English, it's boring for others who are listening to you". This highlights that being comfortable speaking English also reflects the sociopolitical contexts of the classroom and the discourses about language that often stigmatize the linguistic resources of non-native speakers.

A Resource for Participation: *Being Aggressive*

As an international student from South Korea, Sun-Hi's prior math education experiences had been with traditional lecturing where students "hardly speak up in the class". For Sun-Hi, active learning required students to "speak", engage in "more participation in class and more interaction with instructor", things she was "not used to". To Sun-Hi, these practices felt "more aggressive" than traditional lectures. In fact, she used the word aggressive to describe active learning more than ten times throughout the interview.

Sun-Hi expressed that in order to participate in the active learning classroom, students also needed to be aggressive. This involved "being able to engage the instructor or disagree with opinions or discussing about the questions". Although Sun-Hi did not explicitly articulate why these forms of participation felt aggressive, she did share that aggressive students were more likely to be noticed by the instructor. It may be the case that when students participated, they seemed to be competing for the conversational floor and the instructor's attention, which felt aggressive to Sun-Hi. Sun-Hi expressed wanting to become more aggressive so that she could also "get noticed from the instructor". She shared: "talking with the instructor helps me a lot, so I think being aggressive has more benefits than not aggressive".

Broader Discourses about Language. Sun-Hi shared that being aggressive was hard for her. As a non-native speaker of English, she felt "not comfortable in English" and "not that confident to speak in class". She also explained that: "When I speak up in class, I'm afraid, what if I'm like, I look like a silly one". Sun-Hi worried that the way she communicated in English might be interpreted by others as "silly". This again demonstrates the sociopolitical nature of language and its impact on students' comfort and confidence speaking English in the classroom.

Discussion

By exploring the relationship between language and participation, the current study reveals another complexity in striving for equity using active learning. Study findings suggest that classroom discourses had an impact on how active participation in the classroom was characterized. By overemphasizing verbal participation (in English), instructors created a narrow window of what active participation could look like (i.e., someone who speaks regularly during class), which had the tendency to exclude language diverse students. Other forms of participation, like writing, listening, gesturing, participating in embodied activities that utilize materials (Nemirovsky & Ferrara, 2009), and communicating using home languages should also be recognized as valid ways that one can be an engaged member of the classroom (see Figure 2).

Furthermore, conceptualizing participation as speaking established a narrowly defined set of available resources for participation. This is particularly true in the context of multilingual students, given the stigma they often navigated in relation to their language identity. For example, discourses about language seemed to suggest to students that only English should be used for communication in the mathematics classroom. This became a missed opportunity for students to leverage their home language in their mathematical sensemaking.

Multilingual students also overwhelmingly perceived being comfortable speaking English in the classroom as a necessary resource for active participation and felt it was something they needed to continue developing. Fitri and Aeni (2021) state that the talk-intensive nature of active learning can help multilingual students practice speaking and feel more confident doing so in the classroom. While this may be true, the responsibility should not be exclusively placed on students for becoming more comfortable speaking. As the data in this study revealed, the sociopolitical realities of the classroom cannot be ignored. The ability to feel comfortable speaking English in the classroom encompasses more than just language skills, as students also often navigate accent bias, lack of access to peers who are willing to communicate with them, and so forth. Therefore, instructors must be aware of the complexities involved with developing comfort speaking in the classroom and work to establish norms that push back on these discriminatory discourses.

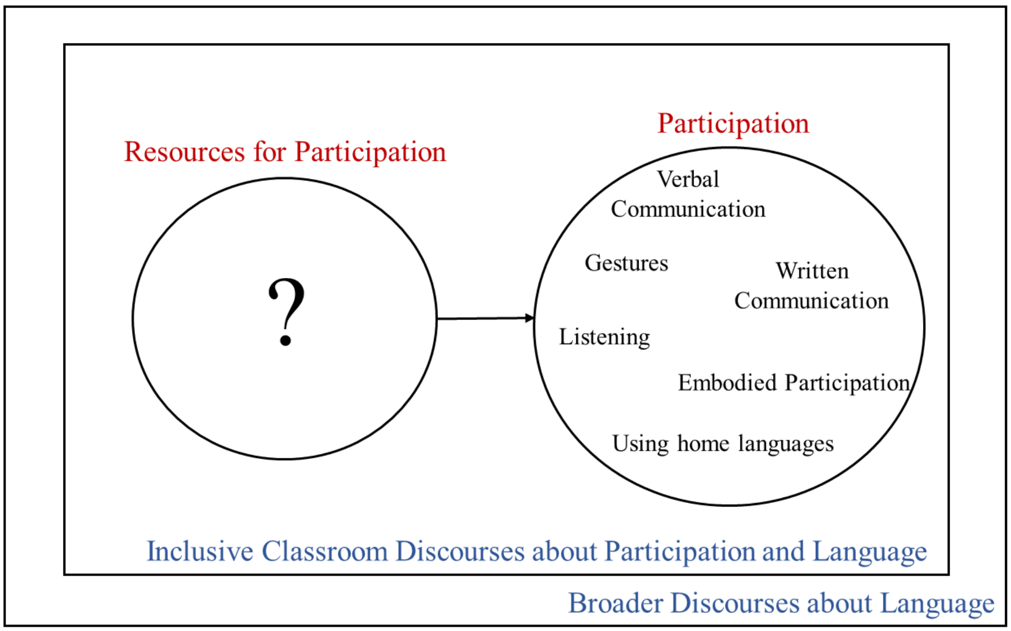

Figure 2. A reimagined and more inclusive model for conceptualizing classroom participation.

The set of resources for participation that students described were often personal attributes they did not possess, but felt they needed to develop (e.g., become more comfortable speaking English in the classroom, become more extroverted, etc.). If instructors work to create more inclusive classroom norms (i.e., norms that validate all students' linguistic resources and expand what counts as legitimate classroom participation), then the set of available resources for participation will likely become more inclusive. Ideally, these resources will embody things that students bring into the classroom (e.g., speaking in their home language, being able to visually express or gesture their understanding). Exploring this can be an area for future research efforts.

Finally, Sun-Hi and other international students described numerous cultural differences they experienced navigating active learning in their mathematics classrooms. Although all students might struggle to adjust to active learning pedagogies, international students might find certain norms and practices very different from previous classroom experiences. Making explicit some of the norms of participation and being mindful of other cultural practices can help students adapt to the new classroom environment.

The Orchestrating Discussion Around Project (ODAP) was conceived of as an investigation into how instructors might support a student-centered classroom with aims of engaging students in authentic mathematical proof activity. The design-based research focused on engineering tasks and specific high leverage teaching practices to promote student engagement with three focal proofs in Abstract Algebra. In this report, we share a series of project learnings related to supporting students in accessing formal proof activity and promoting more equal participation amongst students. We focus specifically on how complex task launch, structuring group work, and working with student ideas in whole class discussion may be shaped to support more students in authentic mathematical proof activity.

Keywords: design-based research, teaching practices, participatory equity, proof

In the United States, there has been a substantial push for undergraduate mathematics classes to become more student-centered. To this end, several researchers have developed curriculum materials that provide resources for instructors to promote active engagement in classes. In the context of upper division proof-based courses, these innovations often exist within the inquiry paradigm (inquiry-oriented to inquiry-based) where students engage actively in constructing and presenting proofs, or in reinventing abstract definitions and theorems. In general, the field is in consensus that more active classes support deeper learning (Freeman et al., 2014). Others have suggested that active classes or in some cases inquiry in particular can lead to more equitable learning environments (Laursen et al., 2014; Tang et al., 2017; Theobald et al., 2020). Yet, others have argued that instruction geared towards inquiry can also open space for more inequitable interactions as students become more actively involved (Brown, 2018; Ernest et al., 2019). Recent large-scale results reflecting a performance disparity between men and women on a group theory concept assessment (Johnson et al., 2019) in inquiry classes has raised questions about how such instruction may alleviate or exacerbate inequity in classroom environments. That is, when classrooms are opened to be more student-centered, we now have students and instructors engaging with each other in ways that would not be found in a traditional lecture class. Thus, the classroom space can become a place where societal inequities can be reproduced and only certain students fully participate. There are several cases (Haider & Andrews-Larson, 2021; Rasmussen & Kwon, 2007) that illustrate the potential for inquiry-oriented teaching to have a very positive impact on student learning. However, as noted in their recent literature review (Melhuish, Fukawa-Connelly, et al., 2022), we know little about the details of instructional practice that may account for when inquiry approaches are successful in supporting students. As noted by Adiredja and Andrews-Larson (2017), “more work is needed to document if, when, and how these instructional approaches are equitable for all students” (p. 459).

In this paper, we share some lessons we learned during our design-based research project that was designed around participatory learning goals in proof classes: engaging students in authentic activities related to comprehending, validating, and constructing proofs. That is, we explored the question, in what ways might HLTPs be incorporated in the proof setting to support our participatory goals? We made the decision to forefront instructional practices, a set we identify as high-leverage teaching practices, as objects of design. These practices stem from the K-12 literature and have been documented to play a key role in structuring student-centered classes and have the potential to increase access and inclusion. Through cycles of design and engineering we found that our practices supported students in engaging in the type of mathematical activity we valued, yet, if we focused on the who and how of engagement, participation was often unbalanced across students. As we transitioned from the lab setting with small groups of students to the classroom setting, we found a need to disentangle our authentic activity goals into two underlying participation heuristics:

- (Access) Providing access to opportunities to participate in authentic mathematical proof activity.
- (Engagement) Promoting participatory equity in authentic mathematical proof activity engagement.

We share a few key insights from our design cycles. We found that just having high-quality tasks and centering student reasoning was insufficient to support all students in engagement, and thus made several modifications to promote more equitable participation. For the scope of this work, we focus specifically on launching tasks, structuring group work, and selecting student ideas for discussion. We note that our focus on participation is a narrow view on equity, and caution that this exploration reflects just one dimension related to promoting equitable learning environments. While the question is beyond addressing fully in a single project like this, our report thus intends to help address the question, "What instructional practices support students' engagement in authentic proof activity and promote participatory equity in such activity?

Background and Perspective

For the scope of this project, we view learning as participating in activity that resembles a broader community of practice (e.g., Sfard, 1996). That is, the proof-based mathematics classroom is a setting where students can be apprenticed into the work of research mathematicians. To adhere to these goals, we focus on learning in terms of student engagement in what we deem *Authentic Mathematical Proof Activity*. These activities include not just constructing formal proofs, but comprehending and validating them. A full treatment of valued activities can be found in Melhuish, Vroom, et al. (2022).

We assume that that the classroom is a complex system and that instructional practices, those we consider high-leverage teaching practice, can serve to mitigate complexity in student-centered classrooms and promote space where students can engage in authentic activity. We integrate several scholars' (Ball et al., 2009; Woods & Wilhelm) definitions of high-leverage teaching practices to define these practices as those that:

1. can be implemented routinely,
2. use, shape, or otherwise integrate students' mathematical thinking,
3. have potential to increase equity, access, and/or engagement, and
4. are supported by research connecting the practices to students' learning.

Ultimately, we aim to support participatory equity, defined as "fair distribution of both participation opportunities and participation itself as students engage in the learning process" (Shah & Lewis, 2019, p. 423).

For the scope of this paper, we focus on three such practices: complex task launch, structuring group work, and selecting and working with records of student thinking. These three practices can serve to structure a lesson and have been well studied and developed in the K-12 setting. See Table 1 for descriptions and key citations.

Table 1. Definitions and key citations for focal high leverage teaching practices.

High Leverage Teaching Practice	**Descriptions (found in Melhuish, Dawkins, et al., 2022)**
Complex Task Launch (Jackson et al., 2012; Jackson et al., 2013; Khisty & Chval, 2002; Wood & Wilhelm, 2020)	*The teacher engages students in making sense of tasks via attending to relevant mathematical language, ideas, relationships, task contextual features, and development of a common understanding of the task goals and context. This practice occurs prior to or in parallel with problem-solving, but does not scaffold or directly instruct on solutions to the task*
Structuring Group Work (Cohen, 1994; Esmonde 2009; TeachingWorks, 2018; Webb, 2009)	*The teacher structures and manages partner and group work in order to engage all students meaningfully in mathematical activity. This can include scripts, clear mathematical activity expectations, and/or roles that provide guidance for how students are to interact with each other and the mathematics.*
Selecting and Working with Records of Student Thinking (Durkin et al., 2017; Stein et al., 2008; TeachingWorks, 2018; Wilburne et al., 2018).	*The teacher orchestrates mathematical discussion where (1) students publicly present ideas and (2) students are prompted to meaningfully engage with the ideas through analyzing, critiquing, and/or comparing across student ideas.*

Methods

This report summarizes findings from the ODAP design-based research project. This project consisted of six cycles of design and refinement (two in a lab setting, and four in classroom settings) all occurring at a Hispanic-serving, doctoral-granting research institution in the United States. The focus of instruction was engaging advanced undergraduate mathematics students in authentic proof activity related to three focal theorems in Abstract Algebra: Structural Property Theorem, Lagrange's Theorem, and First Isomorphism Theorem. At a prior RUME conference, we shared some initial work designing and implementing for HLTP from the lab setting where we provided data showing that the K-12 practices could be adapted robustly to this setting (Melhuish et al., 2020). In this paper, we focus primarily on later cycles of development and key aspects of design that emerged during the rather complex transition (see Lamberg & Middleton, 2009) from working with small groups of students in a lab to full classroom implementations.

We focused on key hypotheses about how HLTPs could support students in participation in authentic activity. This analysis occurred in several layers. All implementations were video recorded, transcribed, as well as observed by several members of the research team. Observers took field notes on ways that students did or did not engage in hypothesized activity with attention to issues of access and imbalances in participation. Between lessons, we engaged in debriefing and coming to a consensus related to lesson goals, HLTPs, and student activity. We attended specifically to ways our hypothesized relationships between HLTPs, and student participation were or were not realized. After the completion of each cycle, the team reflected more holistically on prior cycles, revisited important points in the data, and in some cases conducted extended analysis using specific frameworks to analyze elements of our study more systematically. For instance, we analyzed student activity (Melhuish, Vroom, et al., 2022), instructional moves (Melhuish et al., 2020) and distribution of authority in small groups (Hicks et al., 2021). After these debriefs and analyses, we made evidence-based modifications to improve the enactments of our HLTPs and developed new hypotheses of characteristics of HLTP and how they support student activity in proof settings. At the completion of the project, we have engaged in retrospective analyses to better describe elements of the HLTPs leveraging our data corpus. In this report, we share examples that span our project and evidence of what played out in proof contexts and particular instances that led to modifications.

Results

In this section, we focus on several adaptations and refinements we made to the three focal HLTPs for reasons related to either the proof context or participation inequities that emerged during the classroom implementations (see Table 2).

Table 2. Questions related to each focal HLTP and student participation.

High Leverage Teaching Practice	Considerations	Key Features
Complex Task Launch	What information do students need to make sense to engage productively in a given task?	• Attention to quantification and referent objects • Discussions of informal ideas that parallel formal tools
Structuring Group Work	What task features are needed to support students in shared engagement amongst group members?	• Eliciting expertise beyond proof construction • Distributing roles and expertise
Selecting and Working with Records of Student Thinking	How can public records represent a multitude of student reasoning? What tools are needed for students to work from each other's records productively?	• Expanding records beyond proof construction • Introducing partial linking ideas

Complex Task Launch

In the proof-based setting, complex task launch involved supporting students in sense making about a focal theorem in ways that may anticipate important conceptual insights or proof structures. Ultimately, complex task launch serves the purpose of supporting access to the major ideas and tools needed to engage in a focal task. Our implementations shared many features of the K-12 versions; however, we found two needs specific to the proof context. First, in addition to questions about meaning, examples, and relationships, we also found a need to ask specific questions about *quantifiers* and *referents.* For example, to engage with the Structural Property Theorem that a group isomorphism preserves commutativity, complex task launch involved unpacking the different definitions involved including isomorphism and abelian. During these conversations, students often provided imprecise explanations, such as articulating "G is abelian" as "*ab*=*ba*." Both quantification (recognizing that a statement applies for all elements in in a group) and referent objects (recognizing that the isomorphism function must be introduced) are essential to the formal proof. Without these tools, many students hit an impasse about how to prove the statement or provided a proof that did not cover all elements in the codomain.

We also found a need to explicitly consider *parallelism* between explorations of theorems and how these link to proofs. For example, in order to prove Lagrange's Theorem, students were positioned to recognize this is a theorem about multiplication, and they were easily able to retrieve a relevant definition of divisibility ($|G| = k|H|$ for some k). However, this formal definition did not evoke the parallel multiplicative structure (G being composed of k disjoint subsets the same size as H) they needed to leverage to create a proof. In our first cycle, the students attempted to create a proof by cases depending on the order of the group, suggesting, "What if we did a couple of cases, like where the order of the group was even, or it was odd?" They introduced ideas of using different remainders to make the argument, soon recognizing the number of cases became unwieldy. We suggest that the formal statement evoked prior knowledge related to number theoretic proofs, rather than drawing on the idea of repeated addition or totaling equal sized sets. We modified this element of task launch in later cycles to incorporate explicit conversation about the *conceptual meaning* of multiplication that better paralleled the proof structure of Lagrange's (e.g., "[L]et's think back to elementary school when we write these things, and we're gonna make a similar type of visual to go with this that's kind of connected to what we mean by multiplication."). In all cycles with these discussions, students built on notions of "repeated addition" or "totalling up" for their proof approaches.

Structuring Group Work

Structuring talk in group work became a major focus of design during the switch between lab setting and whole class setting. In our lab settings, we relied on mechanisms such as think-pair-share and peer review to structure group work. When we switched to whole-class implementations, we found these structures insufficient to disrupt status differentials between students. For example, students were asked to share proofs of the Structural Properties Task written at home and answer "What is one thing that makes sense? What is one thing you have a question about?" in regard to your partner's proof approach. The conversation often devolved into the student with a more complete proof teaching the student with a less complete proof. For example, in one exchange, we noted one of the partner stating they "don't know anything" and the other partner walking them through what was "missing" from their proof. In this case, the introduction of a "function from G to H that is one-to-one and onto."

This led us to modify our focal proof activity. Instead of students peer-reviewing proofs they had written, they were each tasked with making sense of one of two prototypical student proofs provided by the instructor and becoming experts on the proof they read. The student conversations about these proofs were much more balanced both in the quantity of participation and in students' mutual engagement (as opposed to exchanges resembling one-on-one tutoring). This change draws attention to a major theme in our work: *expanding the evoked expertise beyond proof construction.* If the only way to show competence is through constructing formal proofs, we are necessarily amplifying the status of certain students who have become more adept at engaging in this complex and challenging practice.

In other tasks that had less support for equitable small-group discussion, we identified even more foundational issues. For example, when students were tasked with making sense of parts of the First Isomorphism Theorem, some groups of students talked very little and did not appear to engage in meaningful comprehension. In later cycles, we changed the structuring of this task such that each member of the group was responsible for leading a discussion on a specific question, such as identifying the difference between the isomorphism and homomorphism involved in the proof the First Isomorphism Theorem. This structuring served to not only support students' access into the proof, but also *individual and shared accountability* across students.

Selecting and Working with Records of Student Thinking

Finally, when we consider whole class discussion and comparison of student ideas, we found it important to attend carefully to whose ideas made it into the public space. As we anticipated certain approaches to select and sequence, we found the instructor was limited in whose proofs make it to the focus of discussion. In first classroom implementation of the Structural Property Task, the only students with largely complete (though possibly not fully correct) proofs were the more vocal, white men. This informed two modifications: expansion of expertise so that a presenting student would not have to have proven a statement (as discussed in the prior section) and developing *interdependent ways of creating public records*. For example, when students created examples to illustrate the First Isomorphism Theorem, the records were subdivided such that each student had a different role: writing domain and codomain elements, creating the homomorphism map, identifying the kernel, creating the isomorphism map (see Figure 1). In this way, discussions around this student work focused on a truly shared product.

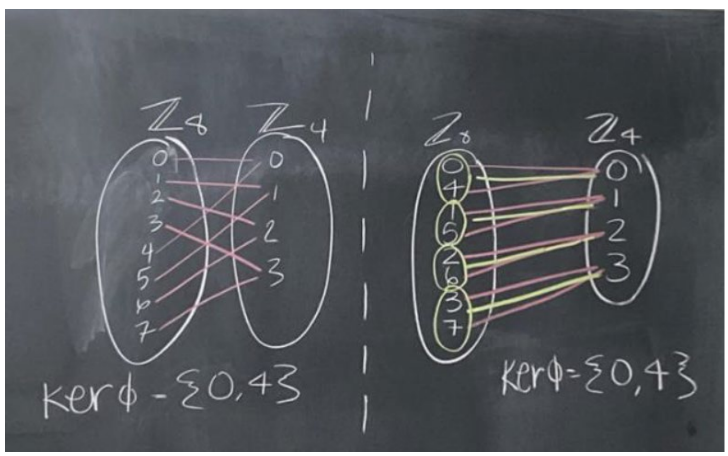

Figure 1. Cycle 5 small group student board work illustrating the FIT

The other major component of comparing and using records of student reasoning was to position students to generalize and see important features of their ideas that may connect to more formal representations. This modification to our task implementation required a large amount of attention and reflection, because, as we compared across implementations, we found that certain discussions could easily devolve into an initiate-respond-evaluate conversation where the instructor was doing majority of the reasoning (and students were left searching for the target insight). To support students in further reasoning and meaningful contribution, we found it useful to introduce *partial information* that linked student ideas and the formal proofs. For example, we provided a partially written isomorphism map for students to complete "β (____) = ____" (First Isomorphism Theorem), a partial function diagram (Structural Property Task), or a series of formal lemma statements that students were asked to pair with their own informal conjectures (Lagrange's Theorem). By providing partial information, the instructor navigated between students' ideas and formal mathematics while providing students explicit tools to increase access and engagement.

Discussion

Working in the formal proof setting, we encountered two substantial hurdles: (1) navigating between formal and informal ideas (Raman, 2003;Weber & Alcock, 2004; Zazkis & Mills, 2017; Zazkis et al, 2016); (2) student status differentials occurring based on students' speed and ease working within the formal proof setting (cf., Weber & Melhuish, 2022). Regarding the first hurdle, we found for complex task launch to provide students access to necessary tools, the conversations had to draw attention to structural ideas (both formal and informal) and help connect imprecise language to quantification or to identifying referent objects involved. Simply unpacking definitions or creating examples was not sufficient to support later proof aims. We also found that orchestrating student discussions to promote comparison and generalization from their proofs and examples required careful attention to ways to connect between formal and informal representations systems (our access heuristic of authentic mathematical proving activity). Often the instructor would introduce an object to focus discussion and promote students in engaging in translating between systems and noticing important ideas.

The second hurdle required us to return to the literature on promoting more equitable group work. As noted by many scholars, active engagement in proof contexts can favor students who are more comfortable with academic language or more quickly engage with the norms of proof (Brown, 2018; Weber & Melhuish, 2022). This can foster divisions of status between students and large inequities in who participates. To better navigate this issue, we incorporated more intentional features related to group-worthy tasks and Complex Instruction (Cohen & Lotan, 1996). By subdividing responsibilities – for example, leading an assigned portion of discussion or taking on a specific role in the construction of an example – and promoting distributed expertise – for example, placing each student in charge of a particular proof approach – we were able to engage more students in authentic activity during group work (our engagement heuristic of authentic mathematical proving activity). This also freed us from constraints we previously experienced in selecting student ideas, as we were no longer tethered to finding certain, anticipated proof approaches or using an example that primarily legitimized only one students' contribution.

We suggest other design researchers consider the dual participation heuristics and engineering of HLTP implementations as they move from small-group lab settings to whole-class instruction. Issues of access and participatory equity become amplified in the latter, where an instructor can no longer interact with each individual student throughout a lesson. HLTPs provide a means to manage some of this transition, but as we found in our project, also require intentional analysis and modification related to our heuristics and the specifics of theorems and proofs involved to meet our participation goals.

Shifting Students' Feelings and Mindsets about Learning Mathematics through Standards-Based Grading

Karina Uhing
University of Nebraska Omaha

Amy Been Bennett
University of Nebraska-Lincoln

Standards-based grading is an alternative assessment method that is gaining traction in undergraduate mathematics courses. Reported benefits for students include reduced math and test anxiety, increased achievement rates, and deeper understanding of concepts. However, evidence is mixed, and researchers have called for qualitative studies to explore students' feelings and experiences with standards-based grading. In this study, we examined 228 College Algebra students' responses to an end-of-semester reflection assignment. We discovered that some students expressed a shift in their feelings and mindset towards mathematics, and that these shifts were connected to the standards-based grading assessment structure. We present these findings, which describe how students viewed their learning and how shifts in their feelings and mindsets related to specific features of the course. We also discuss the internal and external motivations for these shifts and pose questions for future research related to students' experiences with non-traditional assessment structures.

Keywords: Standards-based grading, feelings, mindset, assessment

Traditional grading and assessment methods are the norm in undergraduate mathematics courses, particularly at the introductory level (Harsy et al., 2021). However, in recent years, there has been a growing interest in alternative approaches to assessment. These alternative approaches share several characteristics, a primary one being that grades should reflect students' final understanding of a learning objective after they have had multiple opportunities to demonstrate their learning. One such alternative assessment method is standards-based grading, where grades are intended to reflect students' proficiency in clearly defined learning objectives (Lewis, 2021). Points and letter grades are de-emphasized in favor of thorough feedback given to students after an assessment, with students having multiple attempts to demonstrate their understanding on learning objectives throughout the course.

The analysis presented in this proposal builds on a larger research study that examined how students perceived their mathematical experiences in a newly redesigned, introductory-level, mathematics course. Three themes emerged from preliminary data analysis: community, assessment, and mindset, with students discussing both positive and negative feelings throughout their reflections (Uhing et al., 2022). Through this analysis, we discovered that some students expressed a shift in their feelings and mindset towards mathematics, which prompted us to further examine this phenomenon. Students who discussed this shift primarily did so in the context of the assessment structure, which involved standards-based grading. Thus, the purpose of our work is to better understand shifts in students' expressed feelings and mindset with respect to an alternative grading structure.

Background Literature

Standards-Based Grading

While changing the undergraduate mathematics norm of summative exams to implement a new assessment method can be challenging (Elrod & Strayer, 2018), mathematics education researchers argue that it is a worthwhile endeavor for increased student learning (Prasad, 2020) and decreased test anxiety (Harsy et al., 2021). In a study with 132 undergraduate students in the U.K., students rated less traditional assessments, such as presentations and projects, as some of their least preferred methods of assessment (Iannone & Simpson, 2015). Instead, they preferred more traditional assessments, such as closed book exams and weekly homework assignments. In addition, students preferred assessments that were better discriminators of mathematical proficiency and that seemed the fairest. Notably, this study did not include a standards-based model, where closed-book exams are accompanied with feedback and can be taken repeatedly.

Students in Zimmerman's (2020) large-scale standards-based grading College Algebra course expressed that this assessment structure held them accountable for their learning, gave them more feedback, and led to a deeper understanding. Zimmerman concluded that a standards-based grading approach "removes the extrinsic motivation factor that often fosters unproductive learning behaviors" (p. 1052); however, their precise meaning of "extrinsic motivation factor" is unclear. In our study, we sought to explore different types of motivating factors and how they influence students' shifts in feelings and mindsets about learning mathematics.

Emotions and Expressed Feelings toward Assessment

Wass and colleagues (2020) documented 14 distinct negative emotions expressed by students who completed undergraduate course assessments, such as "satisfaction", "fear", and "worry". The two most common positive emotions were "happiness" (7%) and "pride" (5%) and the most common negative ones were "annoyance" (17%) and "frustration" (10%). They found that students' positive or negative emotions toward assessments corresponded to their performance and argued that understanding students' emotions better could help educators design more effective and supportive assessment structures.

In our study, we use the term "expressed feelings" rather than "emotions" as "emotions are thought of as very primitive, extremely fast, unconscious mechanisms" while feelings are the "conscious and cognitive perceptions" of those emotions (Hansen, 2005, pp.1426-1427). Indeed, much of psychology research is in agreement that there are 27 distinct human feelings, which can be divided into two disjoint groups: positive feelings and negative feelings (Cowen & Keltner, 2017). This dichotomy of feelings allows for examination of a change in feelings valence (e.g., Kleine et al., 2005).

Traditional forms of assessment have been linked to increased feelings of stress and anxiety for students (Lewis, 2020; Prasad, 2020; Wass et al., 2020). A reported benefit of standards-based grading formats is that they are lower-stakes, and thus can reduce anxiety for students (Harsy et al., 2021), although the evidence across disciplines is varied (Lewis, 2020). In mathematics, Lewis (2020) received contradicting responses from students on a survey related to their mathematics text anxiety in Linear Algebra and Differential Equations courses taught with a standards-based grading approach. Specifically, analysis of pre/post survey items showed that test anxiety significantly increased over the semester; however, students self-reported a decrease in text anxiety at the end of the semester and an appreciation for the standards-based grading format in their qualitative responses to open-ended questions. Lewis (2020) called for future research to examine this apparent contradiction using qualitative study methods.

Mindsets about Learning Mathematics

The notion of reflecting on, revising, and reattempting work builds on a growth mindset perspective of learning (Dweck, 2010). A student with a growth mindset believes that through their efforts they can nurture and develop a better understanding of a mathematical concept;

whereas, a student with a fixed mindset believes that mathematical ability is innate and unchangeable. As students enter mathematics classrooms with (sometimes deficit) views of their mathematical abilities, it is up to the practices of growth-mindset instructors to foster "academic growth by encouraging and recognizing students for their growth in learning" (Harsy et al., 2021, p. 1073). Standards-based grading emphasizes that learning mathematics is part of a process; deep understanding of concepts may not happen immediately. In this way, a growth mindset is a potential outcome of an experience with standards-based grading (Dweck, 2007).

In a study with 104 students in mastery-based teaching Calculus and Linear Algebra courses, Harsy and colleagues (2021) found that there was no statistically significant change throughout the semester based on their responses to growth mindset items on a Likert-type survey. Additionally, regarding a growth mindset toward mathematics, they found no difference between students who experienced mastery-based testing and those who did not. However, they did not qualitatively explore the 89 students (85.57%) who disagreed or strongly disagreed with the fixed-mindset statement "Your math intelligence is something about you that you can't change very much." This exploration is a place for further research.

Research Questions

Using the existing literature to frame our study, the research questions we sought to address were:

1. How did students' experiences with a standards-based grading structure in a College Algebra class lead to shifts in their expressed feelings and mindsets about learning mathematics?
2. Which aspects of students' experiences in this course were most prevalent in their expressed feelings and mindset shifts about learning mathematics?

Methods

The data for this study come from a Mathography assignment that was collected at the end of the Fall 2021 semester from students enrolled in College Algebra at a large, metropolitan university. Out of 459 students enrolled at the beginning of the semester in 14 sections of College Algebra, 228 students submitted the assignment. During this semester, instructors were involved in a large-scale course redesign effort that involved developing new curricular materials around active learning and using standards-based grading for the assessment structure. Assessments were called Learning Outcome Assessments (LOAs) and were created based on clearly articulated learning outcomes (i.e., objectives). Students were allowed multiple attempts over the semester to complete each learning outcome. Sections of the course were also coordinated, using the same instructional materials and assessments.

The Mathography data included student responses to prompts that were adapted from Drake's (2006) mathematics story interview, particularly the "peak experience" and "nadir experience" that students experienced during their time in College Algebra. We coded all 228 Mathography assignments in Dedoose individually and met pairwise to discuss and reconcile disagreements until we achieved 100% interrater agreement. Our predetermined codes in Dedoose (2022) included: emotions (subcodes of positive and negative), community and culture, assessment (subcode learning outcome assessments), and personal growth/mindset, which were determined after preliminary analysis of the data (Uhing et al., 2022).

For the analysis of shifts in expressed feelings, we considered excerpts tagged with "assessment" AND "positive emotion" AND "negative emotion" codes. This produced 61 excerpts. We analyzed these excerpts to determine if a negative to positive shift in feelings occurred, which reduced our sample to 48 excerpts. In our initial tagging of excerpts for positive and negative emotions, we were careful to only include excerpts where students voiced an explicit emotion or feeling. For example, we did not include excerpts where students used verbs such as "struggling", as this action could be connected to both positive or negative feelings (e.g., enjoying a challenge or feeling frustrated by a problem). To compare, we also looked at excerpts tagged with "positive emotion" AND "negative emotion" AND not with "assessment". This yielded a total of 16 excerpts, only 9 of which exhibited a shift. We chose not to include these excerpts in our analysis as we wanted to focus on the context of assessment.

For the analysis of shifts in growth mindset, we considered excerpts tagged with "assessment" AND "personal growth/mindset". This produced 150 excerpts, 27 of which we had already included from the expressed feelings set. We analyzed the remaining 123 excerpts to determine if a shift toward a growth mindset occurred, which reduced our sample to 56 excerpts. Most excerpts included explicit shifts from a fixed mindset (e.g., "I didn't think I could learn this.") to a growth mindset (e.g., "It made me realize that if I work hard enough for something then I can accomplish it."). However, some showed more implicit growth in mindset by discussing a "turning point" moment where they "kicked it into gear" or "started to turn things around". Overall, excerpts varied in length but were generally 2-5 sentences in response to a single prompt.

We emphasize that the final excerpts in our analyzed dataset are focused on a *shift* in feelings or mindset, not simply a single state. Several excerpts were tagged with positive feelings as students expressed their enjoyment, satisfaction, and confidence as a result of the assessment structure in this course. However, here we focus on excerpts where students first expressed a negative feeling or mindset, such as concern or nervousness, and subsequently expressed a positive feeling or mindset as a result of some shift during their experience in this course. Then, we used open, data-driven coding (Saldaña, 2016) to analyze the excerpts for the type of shift that occurred.

Findings

In our analysis, we found five primary causes that students attributed to a shift in their feelings or mindset (see Table 1). Three of the causes (the assessment structure, grading scale change, and LOA performance) related directly to the implementation of standards-based grading in the course, while the other two causes (external resources and overall course experience) were more general in nature.

Table 1. Causes of Shifts in Students' Feelings or Mindset

Cause of the Shift	Description
Assessment Structure	Overall structure of the assessment and grading system
Grading Scale Change	Instructors changed the grading scale nine weeks into the semester from needing to complete all 24 learning outcomes (LOs) twice, to having 5 "core" LOs and 19 "supplemental" LOs
LOA Performance	How students did on a particular learning outcome assessment (LOA) (i.e., a specific grade or outcome)

External Resources	Other people (e.g., instructors, TAs, classmates) or other external resources
Overall Course Experience	Reflecting back on their experience in the course as a whole (e.g., talking about the hard work that paid off or things they learned about themselves)

Table 2 shows the frequency across student excerpts for each cause with respect to shifts in feelings and mindset. Excerpts were only coded under one cause for a particular shift (e.g., a student excerpt that related to a shift in mindset was only attributed to a single primary cause, such as assessment structure). We expand on these findings below and provide illustrative student examples.

Table 2. Number of Student Excerpts Relating to Different Causes of Shifts in Feelings and Mindset

Shift	Assessment Structure	Grading Scale Change	LOA Performance	External Resources	Overall Course Experience	Total Number of Excerpts
Feelings	7 (14.6%)	7 (14.6%)	23 (47.9%)	9 (18.8%)	2 (4.1%)	48
Mindset	9 (16.1%)	0 (0%)	21 (37.5%)	10 (17.8%)	16 (28.6%)	56

As shown in Table 2, LOA Performance was the most common cause of a shift in feelings or mindset for students. Several students discussed how getting feedback on an LOA cause them to experience this shift. For example, one student remarked:

> A peak experience that happened to me in [College Algebra], was after the second to last LOA of the semester. I hadn't gotten any LO's the previous assessments and was very concerned about my grade, especially since I had a core LO that I still needed 2 points in. I put in about an hour and a half of studying leading up to the day of the assessment and, and came out of class feeling accomplished. Every question I answered, I ended up getting the points for, giving me confidence that I will end up succeeding in class.

This excerpt shows how performance on an LOA caused the student to feel "concerned" about their grade, which led to them studying more and doing better on the subsequent assessment, causing the student to then feel "accomplished" and confident.

In terms of mindset, several students mentioned how their performance on LOAs caused them to "push themselves" and "work hard" to achieve better results. One student commented:

> A peak experience in my math story took place this year. I looked at my LOA scores and realized that I needed to pick it up or I would have problems passing the class. So, when the next LOA came up, I studied more than I had for any other test, and it paid off and now I am on pace to pass the class if I keep up my study habits for the next couple of tests. This experience says that I as a student am someone who learns well from their mistakes and is a hard worker who wants to achieve his goals.

Instead of giving up after earning a low score on an LOA, this student viewed their mistakes as an opportunity to learn, thus providing motivation to study harder for the next assessment and demonstrating a growth mindset.

Several students mentioned a major change to the grading scale that occurred nine weeks into the semester in their reflections. About halfway through the semester, after reviewing assessment data and having multiple discussions about the assessment structure, instructors of the class decided to reduce the number of learning outcomes that students needed to demonstrate skill on twice. Several students discussed this key event and attributed it to feeling less stressed about the course overall. One student remarked,

> At the start of the year, we were having to complete quite a few LOs and we had to do them twice, which was stressful. Once the grading got changed to only having to do the supplemental LOs twice, it helped me gain confidence.

Another student expressed a similar sentiment:

> A low point in Math 1220 this semester would be right before the grading requirements were changed. I hadn't scored very well on the LOA's at that point and I wasn't sure if I'd be able to meet all the requirements. Overall, I was very discouraged and didn't think I would be able to pass. I have definitely grown since then in my math skills and math confidence.

Both of these students described shifts in their feelings from being stressed and discouraged to feeling more confident in their mathematical abilities. It is also interesting to note that while this grading scale change was expressed as a cause of shifts in feelings (7 out of 48 excerpts), it was not discussed with respect to shifts in students' mindsets (0 out of 56).

On the other hand, shifts in mindset seemed to occur over the duration of the semester, leading to the code Overall Course Experience. For instance, one student discussed their view on "being good at math" and how they had persevered throughout the semester:

> While many people would describe being good at math as simply receiving good grades, that is not necessarily the case. For me, being good at math means persevering when you are not completely sure how to complete something. Being able to make a mistake while learning and growing from it is extremely valuable, not just in math but in life as well. Initially, my goal was to receive a C in the course [...]. However, closer to the end of the semester, my goal is to receive an A in the course. [...] I will be much happier knowing I gave this class my full effort and was rewarded for it.

For this student, the overall experience of being in a course that used standards-based grading helped shift their mindset from wanting to earn a passing grade to wanting to give their "full effort" and feeling "rewarded" for doing their best.

Discussion

The most prevalent cause of a shift in both expressed feelings and mindset was students' LOA performance, meaning how well they did on a specific LOA. This finding surprised us as we were expecting that LOA performance might be more closely related to a shift in feelings (as feelings are more fleeting and transitory) as compared to mindset (which is sustained over time). However, our findings suggest that students' mindsets can also be shifted by their performance on assessments. Moreover, it is clear that even in a standards-based grading environment, students still cared about their grades on assessments as LOA performance was the most commonly referenced cause of both shifts in feelings and mindset.

Zimmerman claimed that a standards-based grading approach "removes the extrinsic motivation factor that often fosters unproductive learning behaviors" (p. 1052). In other words, when students demonstrated a shift in expressed feelings regarding assessment or evidence of a growth mindset, did it appear to be motivated by extrinsic factors? Although the assessment LOA structure was a standards-based grading approach that allowed for multiple attempts, students were still concerned about their immediate results on the individual assessments. This suggests that many students are still motivated by grades and, oftentimes, by their performance on the first attempt of an LOA.

In addition to seeing a shift in mindset, we saw strong evidence for the presence of a growth mindset in several students, although it was sometimes unclear whether or not they previously held more of a fixed mindset toward learning mathematics. This finding supports other research which claims that the structure of standards-based grading courses provides students with multiple chances to succeed and thus helps students foster growth mindsets about learning mathematics (e.g., Harsy et al., 2021). Our findings further suggest that a standards-based grading structure may encourage students to metacognitively consider their internal and external sources of motivation and to persist toward their learning goals, rather than becoming discouraged after a nadir event (e.g., failing the first exam).

Finally, one finding that we are still investigating is the difference between shifting to positive feelings/mindset versus shifting to non-negative feelings/mindset. For instance, we observed a marked difference between those excerpts that expressed a shift from negative to (explicitly) positive emotions (e.g., from worry to confidence) versus those that went from negative feelings to "decreased negative" or neutral feelings (e.g., from stress to a sense of relief/calmness, such as, "I felt relieved" or "I felt better"). In particular, "relief" appeared to be qualitatively different from the other feelings.

This emergent finding may be connected to Lewis's (2020) contradictory research with math test anxiety, which suggests that the feeling of relief plays a role in how students express their feelings towards mathematics assessments. Namely, does the timing of the survey (or Mathography assignment, in our case) matter? If students respond to questions at the end of the semester, are they more likely to express relief and positive feelings, or, is the stress of final grades weighing more heavily on their minds? Kleine and colleagues (2005) stated that future research should examine the direct relationship between achievement-related emotions and academic performance. We are continuing to explore this research finding.

Implications and Limitations

As other researchers and practitioners of standards-based grading have claimed, it is necessary to carefully consider how the course is designed (Collins et al., 2019), what the learning objectives are (Zimmerman, 2020), how the grading system is communicated with students (Kelly, 2020), and what strategies should be used for implementing these alternative grading approaches. In our study, we found that considering these components was not sufficient for *all* students to shift away from a grades/performance mindset to learning mathematics. We were, however, encouraged by the number of students (56 of 228 students, 25%) who demonstrated a shift toward a growth mindset for learning mathematics, especially those who clearly expressed that they initially held a fixed mindset about their math abilities. However, we emphasize that standards-based grading is not a cure-all for mathematics instruction. Implementing this assessment structure should be done thoughtfully and not prescriptively. Moreover, we should continue to explore how students' feelings are entangled with grading and assessment and how we can work (within the confines of our educational system) to encourage a growth-oriented mindset toward learning mathematics.

Acknowledgments

We would like to thank Gary Wright, Michael Matthews, Emily Stinson, and Greg Sand for their help with the preliminary analysis of the Mathography assignments.

Mathematicians' Conceptions of Active Learning and Equitable and Inclusive Teaching: A Set Theory Analysis

Amy Been Bennett
University of Nebraska-Lincoln

Karina Uhing
University of Nebraska Omaha

Molly Williams
Murray State University

Nancy Emerson Kress
University of Colorado Boulder

Although research on active learning suggests strong connections to equitable and inclusive teaching, few studies have explored the relationship between the two concepts. For this proposal, we examined how 13 participants in an equity workshop described the relationship between active learning and equitable and inclusive teaching. We used set theory as an analytic tool to categorize their descriptions. We found that all participants saw active learning and equitable teaching as related. The two most commonly held views were that active learning and equitable teaching are related yet independent sets, or that equitable teaching is a subset of active learning. We discuss implications of these findings and pose questions for further exploration.

Keywords: Active learning, equitable and inclusive teaching, set theory

Active learning, equity, and inclusion are often-referenced terms in undergraduate mathematics education. Despite their popularity, these terms are nuanced and often difficult to define (e.g., Roos, 2019). One well-known framework for conceptualizing active learning (AL) is Laursen and Rasmussen's (2019) Four Pillars of Inquiry-Based Mathematics Education, which includes ideas about both AL and equitable and inclusive teaching (EIT). In past work (Williams et al., 2022), we used this framework to explore how various stakeholders in mathematics departments across multiple institutions conceptualized AL. We found that we were unable to categorize definitions of AL based solely on stakeholder role, and overall, stakeholders mentioned aspects of teaching and learning that related to the four pillars of inquiry-based mathematics education (students, content, teachers, and equity) in their definitions of AL. While stakeholders most frequently mentioned the actions of students in their definitions, they rarely acknowledged how equity played a role in their conceptualization of AL. This led us to wonder how members of a mathematics department perceive the relationship between AL and EIT.

For this proposal, we examined how mathematics faculty members enrolled in a year-long workshop focused on equity described the relationship between AL and EIT. We used set theory as a tool for carrying out our analysis. Specifically, if AL and EIT are viewed as two sets, then how do they intersect (or not)? Thus, our guiding research question was: How do mathematics faculty members engaged in work on active learning and equitable and inclusive teaching view the relationship between the two concepts? We provide a brief theoretical framing and background before describing how we applied set theory to understand how participants described the relationship between AL and EIT.

Theoretical Framing

Equitable and Inclusive Teaching

One definition of equity in mathematics education includes three criteria: 1) "Being unable to predict students' mathematics achievement and participation based solely upon characteristics such as race, class, ethnicity, gender, beliefs, and proficiency in the dominant language" (Gutiérrez, 2007, p. 41); 2) "Being unable to predict students' ability to analyze, reason about, and especially critique knowledge and events in the world as a result of mathematical practice, based solely upon characteristics such as race, class, ethnicity, gender, beliefs, and proficiency in the dominant language" (p. 45); and 3) "An erasure of inequities between people, mathematics, and the globe" (p. 48).

Accomplishing these three criteria requires teachers to attend to the dimensions of equitable mathematics, which lie along dominant and critical axes (Gutiérrez, 2007). The dimensions of the dominant axis are access and achievement, while the critical axis consists of identity and power. Studies on learning mathematics have frequently focused on the dominant axis by suggesting that interactive classrooms provide opportunities for students to access rich learning experiences, and by showing that student learning increases in classrooms that use collaborative, student-centered practices (Gutiérrez, 2013; Smith et al., 2021). However, creating equitable and inclusive mathematics classrooms involves thinking about how identity and power influence classroom interactions. In other words, EIT involves paying attention to how personal relationships and societal norms impact students' interactions and experiences (Gutiérrez, 2007). Power dynamics and students' identities affect students' learning experiences, and thus should be considered in mathematics classrooms that are interactive (Adiredja & Andrews-Larson, 2017).

Active Learning

There are several definitions of active learning in research literature (e.g., Williams et al., 2022; Prince, 2004; Stains et al., 2018). In their well-known metastudy, Freeman et al. (2014) provided a definition of AL that explained the difference between AL and passive lecture:

> Active learning engages students in the process of learning through activities and/or discussion in class, as opposed to passively listening to an expert. It emphasizes higher-order thinking and often involves group work (pp. 8413-8414).

Another broad definition was provided by the Conference Board of Mathematical Sciences (2016), which referred to AL as "classroom practices that engage students in activities, such as reading, writing, discussion, or problem solving, that promote-higher-order thinking" (p. 1). While these definitions provide us with some notion of what AL is, there is not a single, commonly agreed upon definition in undergraduate mathematics education. Therefore, recent studies have begun to examine the nuances and complexities of the term AL, and how it is operationalized in undergraduate mathematics classrooms (Williams et al., 2022).

Research showing that AL can lead to improved student outcomes has contributed to a consensus in the field that AL is an equitable practice (Freeman et al., 2014; Laursen, 2019); however, student experiences with AL vary (Johnson et al., 2020; Reinholz et al., 2022). There is evidence from the context of upper-division mathematics courses that when directly compared to lecture-style instruction, AL may result in greater performance disparities between women and men (Johnson, et al., 2020). Moreover, Rios (2022) found that students in introductory-level courses whose preferred math language was not English felt a decreased sense of belonging in English-dominant math classrooms as AL practices increased. These findings, coupled with evidence that AL increases achievement outcomes for students from underrepresented groups in STEM (Theobald et al., 2020), suggest that the relationship between AL and equity is complex and not fully understood.

Although research on AL suggests strong connections to EIT, such as Laursen and Rasmussen's (2019) Four Pillars framework, few studies have explored the relationship between the two concepts. Moreover, these studies tend to focus on student outcomes, rather than how the instructor's view of these concepts may influence their role in the classroom. Thus, more work is needed to understand how members of mathematics departments view the relationship between AL and EIT.

Methods

Data Collection

Data were collected from a total of 13 participants. These participants were undergraduate mathematics faculty members at a variety of institutions across the US who were participating in a year-long equity workshop as part of a larger study, which focused on AL in first-year mathematics courses. Interviews were conducted over the span of the equity workshop in September 2020, January 2021, and May 2021. Data presented in this proposal come from the final interview after the conclusion of the workshop in May 2021. As part of this interview, participants were asked to provide their definition of EIT, and discuss whether and how this definition might have changed over the previous academic year. Participants were also asked to respond to the following prompt: "Some people equate active learning with equitable and inclusive teaching. How do you see these as related, and in what ways are they different?" Participants' responses to this prompt form the data set for this proposal.

Data Analysis

To analyze the data, we used set theory to list the possible relationships between AL and EIT. If we view AL and EIT as two distinct sets (see Figure 1), we can investigate the ways in which these two sets can interact. In this context, there are five possible relationships which correspond to five diagrammatic representations. Table 1 shows the five possible relationships between AL and EIT and provides descriptions from mathematical set theory along with interpretations of how we applied this logic structure to the data in our study.

An implicit assumption that we made in our analysis is that AL and EIT exist in the same domain and that it makes sense for these sets to be intersecting. We also assumed that AL and EIT are clearly defined terms and we can thus determine what is contained in each set. We discuss these assumptions further in our Findings and Discussion sections.

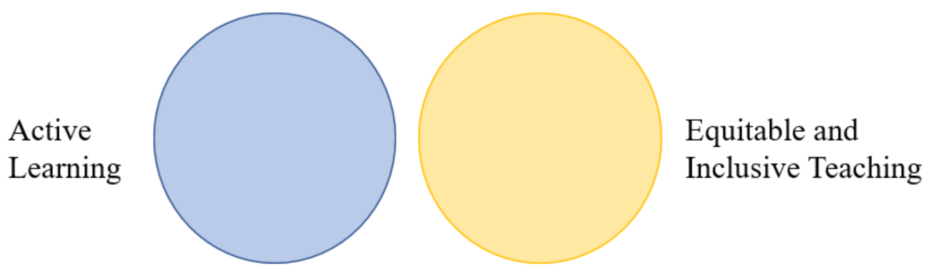

Figure 1: AL and EIT as Two Distinct Sets

After interviews were transcribed, the excerpts where participants were asked about the relationship between AL and EIT were identified and organized into a matrix for coding. Each row represented a participant and their specific response. The columns represented the different possible relationships between AL and EIT (as seen in Table 1). Our goal was to look for evidence of how the participant viewed the relationship between AL and EIT. We then decided on what relationship(s) from Table 1 the participant discussed (either saying that AL and EIT were related or were not related in the following ways) and copied text from their response to support our decision. The decision categories we used were:

- YES: if there was <u>strong</u> evidence in the participant's response that aligned with that relationship
- MAYBE: if there was <u>possible</u> evidence in the participant's response that aligned with that relationship
- NO: if there was <u>no</u> evidence in the participant's response that aligned with that relationship OR there was evidence <u>against</u> that particular relationship (directly or indirectly) in the participant's response

Every participant's response was coded independently by at least two of the authors, who then met to reconcile and discuss any differences (Creswell & Creswell, 2018).

Table 1: Set Theory Relationships between AL and EIT

Relationship between AL and EIT	Set Theory Description	Interpretation
Disjoint 	• The intersection of AL and EIT is empty ($AL \cap EIT = 0$)	Whenever AL occurs, EIT does not occur. Whenever EIT occurs, AL does not occur.
Equivalent 	• AL and EIT are equivalent sets ($AL = EIT$) • AL exists if and only if EIT exists.	Whenever AL occurs, EIT occurs. Whenever EIT occurs, AL occurs.
Some Overlap 	• The intersection of AL and EIT is not empty ($AL \cap EIT \neq 0$) AND • There exists EIT that is not AL, and there exists AL that is not EIT.	AL and EIT can occur together, and they can also occur independently.
AL Contained in EIT 	• AL implies EIT ($AL \rightarrow EIT$) • There exists EIT that is not AL. • EIT is a necessary condition for AL	Whenever AL occurs, EIT also occurs. However, EIT can occur without AL.
EIT Contained in AL 	• EIT implies AL ($EIT \rightarrow AL$) • There exists AL that is not EIT. • AL is a necessary condition for EIT	Whenever EIT occurs, AL also occurs. However, AL can occur without EIT.

Findings

Our overall findings are summarized in Table 2. We provide examples and descriptions of participants' responses in each of the set theory relationships in the following paragraphs.

Disjoint and Equivalent

All participants (13 of 13) provided strong evidence that AL and EIT were not equivalent. Similarly, almost all participants (12 of 13) provided clear evidence that they saw some relationship between AL and EIT (i.e., that these two concepts were not disjoint). For example, Lacy stated, “they’re related, but they’re not equal.” This provided evidence that Lacy saw that there was some relationship between AL and EIT, but that they were also not the same.

Emma was the only participant who potentially saw AL and EIT as disjoint concepts. In her response, she discussed the difference between AL and EIT, describing AL as a “paradigm for learning” and EIT as what the teacher is doing to create an equitable environment in the classroom:

> The definition of active learning is that students need to construct knowledge for themselves and that we can provide them with information and scaffolding and opportunities to construct it for themselves [...] this is different from equitable teaching, right? Equitable teaching is sort of making a classroom where students of any background can learn and that's different from sort of this philosophical understanding of how learning happens.

From this response, it was unclear whether Emma saw AL and EIT as disjoint (possibly in two separate universes without the same domain). One possible interpretation is that Emma saw AL from more of a student perspective (i.e., how students learn and construct knowledge in the classroom), whereas EIT is more focused on the teacher (i.e., what the teacher is doing to create an equitable environment). This led us to consider the possibility that perhaps AL and EIT could be viewed as existing in different universes (learning paradigms vs. teaching strategies) with no potential for overlap because they did not have the same domain. Therefore, we decided to code Emma’s response as a “MAYBE” under disjoint.

Table 2: Evidence of Relationship between AL and EIT

Participant	**Disjoint**	**Equivalent**	**Some Overlap**	**AL Contained in EIT**	**EIT Contained in AL**
Aadaya	NO	NO	NO	NO	YES
Bill	NO	NO	NO	NO	YES
Cassandra	NO	NO	NO	NO	YES
Crystal	NO	NO	YES	NO	NO
Collin	NO	NO	MAYBE	YES	NO
Camila	NO	NO	MAYBE	NO	MAYBE
Mark	NO	NO	YES	MAYBE	NO
Kathleen	NO	NO	YES	NO	NO
Lacy	NO	NO	MAYBE	NO	MAYBE
Emma	MAYBE	NO	MAYBE	NO	NO
Robert	NO	NO	MAYBE	NO	NO
Shea	NO	NO	NO	NO	YES
Thomas	NO	NO	MAYBE	NO	YES

Some Overlap

Most participants (9 of 13) viewed AL and EIT as related to some extent. For some, the evidence for this relationship was straightforward; Robert said, “I think they intersect, but yet they’re not equal.” For other participants (Crystal and Kathleen), their expressions supported this relationship because they claimed AL and EIT are related and provided evidence against both containment relationships. For example, Kathleen said, “I was kind of surprised by that prompt, because they definitely have an overlap, but I don't see them as being equal to each other” (evidence for some overlap); she added, “while I think that active learning benefits all students, and also helps with teaching equitably, I think that teaching equitably is also like, it includes other things as well" (evidence against EIT contained in AL), and "even though [group work] is an active learning strategy, it's not necessarily equitable unless we think about equitable practices" (evidence against AL contained in EIT). Thus, some overlap best fit Kathleen's view of the relationship between AL and EIT.

Six participants (coded as "MAYBE" for Some Overlap) gave responses indicating that they saw AL and EIT as related, but it was not clear which relationship aligned best with their explanation. One participant, Camila, explicitly used set theory in her response and said, "I haven't thought, 'which is a subset of the other,' but it could be that maybe equitable and inclusive learning is a subset of active learning. I'm not quite sure yet." Her acknowledgment of subsets shows she was considering the concepts to at least have some overlap, but then expressed doubt of a final relationship.

AL Contained in EIT

Overall, participants' responses were least aligned with the relationship that AL is contained in EIT. Only one participant, Collin, expressed strong evidence for AL existing within the set of EIT, describing AL as a "specific pedagogical strategy" within the "more ingrained [...] act of learning". He shared that

> "active learning is a specific pedagogical strategy, whereas equitable and inclusive learning is something less explicit and more ingrained in how you're doing the act of learning. [...] active learning sort of, in my mind, inherently has this idea that students are capable of learning independent of their background, so, in a sense, you are creating space for equity by allowing students to discover and have dialogue with the material."

Collin viewed AL as "inherently" equitable, implying that AL exists within the domain of EIT.

EIT Contained in AL

Seven participants' responses aligned with EIT as a subset of AL, with five providing strong evidence and two providing possible evidence for this relationship. Aadaya's response encapsulated this relationship as follows: "I think that they are related but yeah I think one would kind of be incorporated into the other." She elaborated further, stating, "So those are things you could do that maybe make students feel more included in the class when they're doing their active learning activities." In other words, in a classroom in which AL is being implemented, there are additional strategies that can be used to help students feel more included. This suggests a view that EIT is a special case of AL.

Bill described a similar viewpoint with the response, "equitable and inclusive learning … might be more purposeful." He went on to say, "there's things that you can do to be very purposeful as opposed to my current understanding of active learning as just good pedagogy, not necessarily, you know, driving in awareness of inequities." This points to a view that AL alone is not necessarily equitable or inclusive unless the instructor is "purposeful" about using equitable and inclusive teaching practices.

Discussion

Although our set theory framework allowed for the possibility of five clearly defined relationships, an overall glance at Table 2 shows that most of our participants' responses fell into two categories. The strongest evidence aligned with the relationships involving some overlap of the two concepts or containment of EIT in AL. We originally conjectured that EIT might be a larger, umbrella term that contained AL. In other words, AL as a set of teaching practices might be situated within equitable and inclusive teaching as a broader ideology (e.g., Roos, 2019). However, participants' responses primarily pointed toward the reverse containment relationship, where EIT exists within AL. This finding is consistent with studies that showed that not all AL classrooms and practices are equitable for all students (e.g., Johnson et al., 2020; Rios, 2022). We continue to explore how this finding aligns with the Four Pillars framework (Laursen & Rasmussen, 2019), where equity as a pillar could be interpreted as one element contained within the larger set of AL, or that equity is a necessary condition of AL and thus AL is contained in EIT. Furthermore, the equity workshop was situated within a larger study on AL (SEMINAL Project; see Smith et al., 2021), where instructors were first introduced to AL in mathematics instruction before connecting this concept to EIT. Thus, the primary focus on AL might have prompted participants to think about EIT within an AL context.

We also emphasize that participants shared their perceptions of the relationship between AL and EIT *at the end* of a year-long workshop on equity and equitable teaching practices. In other words, it seemed reasonable to presume that participants would have similar notions of EIT, AL, and the relationship between them. However, our data showed that participants expressed varied notions of the domains in which these terms exist (e.g., learning theories, pedagogies, specific teaching practices) and how they function in a mathematics classroom, much like Roos's (2019) findings about the role of inclusion. Our findings illustrated that even after participating in a workshop focused on equity, instructors and other mathematics faculty can still hold diverse views of the relationship between AL and EIT. This has major implications for instructors who implement these pedagogical concepts in their classes and for future professional development centered on AL and EIT. Understanding this relationship and being aware of the potential differences in stakeholders' views can inform how mathematics departments frame their collective efforts toward implementing AL and EIT, which is imperative to systemic and sustained change (Williams et al., 2022; Laursen, 2019).

In some ways, our work generated more questions than answers. For example, does having one containment view of the relationship (compared to the other) change how educators implement these practices in mathematics classrooms? Based on someone's view of the relationship, are some ideas privileged over others? Is there one "right" way of viewing the relationship between EIT and AL? Is it possible to hold multiple views of this relationship simultaneously (as responses from some of our participants suggest)? While we cannot definitively say which relationship between AL and EIT is "true" or even if one exists, our work raises questions about the implications of different views of this relationship, particularly for researchers and educators who are interested in instructional change efforts.

Finally, we acknowledge that our analysis brings to light a tension between straightforward mathematical logic and messy teaching constructs. Mathematics often involves creating well-defined categories in order to organize objects. For this analysis, we used set theory as an analytic tool to classify complex, fluid concepts within an exploratory qualitative study. As mathematicians, the structure of set theory is compelling and satisfying; however, as education researchers, we grappled with how to fit participants' responses into precisely one set relationship. Further exploration is needed to better understand the relationship between AL and EIT and the implications it has for improving undergraduate mathematics education.

Teaching Experience as a Frame for Contributions of Academic Mathematics Coursework to Teacher Learning

Yvonne Lai
University of Nebraska-Lincoln

Frances Anderson
University of Nebraska Omaha

We analyzed end of course reflections of graduate students in mathematics courses for practicing teachers. Participants were asked questions about mathematics content, habits of mind, and whether being a concurrent mathematics teacher while taking the graduate course impacted the value that they saw in either area. Participants were also asked to reflect on whether they believed the course would have been valuable when they were an undergraduate student. We first coded these reflections with Hoffman and Even's (2018, 2021) framework including essence, doing, and worth of mathematics. As a result of our analysis, we suggest extending their framework to mathematics and mathematics teaching, and to include content. Discussion includes suggestions for future research to understand how teaching mathematics reframes learning mathematics, and the importance of framing to understanding the uptake of mathematics courses for both prospective and practicing teachers.

Keywords: Content Courses for Teachers, Mathematical Knowledge for Teaching, Masters Degree Programs

Introduction & Background

We open by recalling a conversation that one of the authors often encounters when teaching a content course for secondary teachers, although this proposal will address content courses for practicing elementary, middle, and secondary teachers. The conversation begins when the topic of abstract algebra is brought up, a course where prospective teachers first learn modular arithmetic. A prospective teacher says, "I hated abstract algebra. I learned in that class that I don't like math." Yet, when practicing teachers in a graduate summer course, from the same district, learn modular arithmetic once more, they will say, "I really liked this class! I want to find a way to teach mods to my kids."

The two courses, the undergraduate abstract algebra course, and the graduate summer course, are taught by faculty in the same department. They address similar topics. Across different years, different faculty members, and different cohorts of teachers, these contrasting conversations repeat, as if in a time loop. Why does the conversation change, as teachers in this district cross the threshold from future teachers to current teachers?

While there is evidence that some teachers benefit greatly from taking graduate level coursework (University of Waterloo, n.d.), and there is evidence that content-focused professional development does impact teacher productivity across elementary and secondary (Harris & Sass, 2007), there is also evidence that it is pedagogical coursework and development that may ultimately make a larger impact on student outcomes (Baumert et al., 2010; Ottmar et al., 2015). Moreover, in some cases, the additional coursework may address content that overlaps with undergraduate coursework. There is a problem: the efficacy of undergraduate and graduate course taking, in terms of impact on teachers' teaching or in perceived usefulness of the course, is debatable and idiosyncratic.

The puzzle for us is this: mathematics teachers need more mathematics than they have learned in elementary, middle, and high school, in order to teach at that level. Yet taking mathematics as an undergrad--a natural place for candidate teachers to prepare mathematically to teach mathematics--seems to be met with adversity. There is a seeming paradox in how experience with teaching may mediate the uptake and relevance of mathematics courses.

Hence, we are interested in why teachers may find graduate and undergraduate courses useful or not. Our overarching research question is: How does teaching experience mediate teachers' uptake of mathematics? We address: *(RQ1) How do practicing teachers describe the contribution of graduate mathematics coursework on their learning? (RQ2) How would the same practicing teachers assess the relative value of this same mathematics coursework, had they taken the course as an undergraduate, prior to any teaching experience?*

In this study, we use *teachers* to refer to PK-12 classroom teachers, *students* to refer to PK-12 students, and we only use *instructor* to refer to tertiary level instructors.

Related Literature

In the existing empirical literature on the contribution of academic mathematics experiences to teacher learning, many practicing and prospective secondary teachers have been documented to find their mathematics experiences disconnected from teaching (e.g., Goulding, Hatch, & Rodd, 2003; Zazkis & Leikin, 2010) to be difficult in unexpected and sometimes unpleasant ways compared to secondary mathematics experiences (see Corriveau & Bednarz, 2017 for a review). At the elementary level, some prospective elementary teachers have found courses to be emotionally stressful and detrimental to their mathematical confidence, and to be disconnected from their teaching (e.g., Hart, Oesterle, & Swars, 2013). The literature also suggests that instructors of mathematics courses for elementary and secondary teachers design courses to combat disconnects and to support students' learning (e.g., Lai, 2019; Li & Superfine, 2018).

This literature has gaps. First, the literature does not distinguish between viewpoints of teachers before and after teaching. As our experience suggests, there may be a change of viewpoint that occurs after teachers enter the classroom. Second, the literature tends to report results from either multiple institutions, so it is hard to disentangle results from context, or from small case studies, meaning that it is hard to generalize. Our study addresses these gaps.

In designing our study, we observed that multiple guiding documents, in the US and beyond, emphasize the value of mathematical *content* and mathematical *habits of mind* (e.g., Ministry of Education, 2007; National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). We also used the results of Hoffman, Even, and Mytlis on the contribution of academic mathematics to teacher learning (Hoffman & Even, 2018, 2021; Mytlis & Even, 2021). Their findings suggest that teachers and mathematicians view contributions in three categories: (1) the *essence* of mathematics, that is the nature of mathematics, or "what is mathematics"; (2) *doing* mathematics, or "how is mathematics done"; and (3) the *worth* of mathematics, for its own sake or for its applications. We interpret the *doing* of mathematics to be synonymous with *habits of mind*. We used content and habits of mind as a proxy for what may be explicitly taught in a mathematics course, and we use the results of Hoffman, Even, and Myrtis as a hypothesis for the learning that teachers perceive from these courses.

Conceptual Framework

Our past experiences influence our current perception. From our expectation of success at a task, to how much we value doing a task, to reaction time, our past experience can mediate how we respond to a current moment (e.g., Eccles & Wigfield, 2020; Pearson & Brascamp, 2008). In the case of teachers, prospective and practicing mathematics teachers differ in one significant respect: only one of them has past experience of classroom mathematics teaching. We hypothesize that this difference in past experience mediates how they experience mathematics learning, so that prospective teachers and practicing teachers may view the same mathematics content differently. Our study is an initial step to test this hypothesis by posing to practicing teachers who were enrolled in mathematics courses a counterfactual: would they have found this course just as valuable had they taken the course as an undergraduate prior to teaching?

We investigate potential differences in terms of framing (Goffman, 1974): how a person defines a situation. For instance, if one teacher defines a situation of learning as a "hoop to jump through", and a second teacher defines the same situation as "a place to learn how to do mathematics better", they may end up having different experiences of the same situation.

Participant Context

At Indigo University, the STEM Education Center, in collaboration with the Department of Mathematics, offers graduate mathematics courses taken by K-12 mathematics and science teachers (all institutional names are pseudonyms). Although many teachers enrolling in these courses are local, there are also teachers who enroll from out of state, as well as from countries outside the US. These graduate courses have been offered for almost two decades, and typically feature high end-of-course evaluations from the enrolled teachers.

We anticipated this site would be a fruitful context for our research questions for several reasons. The variety of backgrounds of teachers made it more likely that these teachers would have come from different undergraduate institutions. In this way, their collective viewpoints about experiences with undergraduate mathematics would reflect more than one particular institution or pedagogy. Moreover, we were interested in the case of a success story with mathematics. Frankly, we thought it would be more interesting and productive to document ways that experiences with graduate mathematics coursework are useful, rather than the opposite.

Data & Method

Participants included 46 practicing teachers who were enrolled in 9 mathematics courses in the summer masters program at Indigo University. Participants consented to sharing an end-of-course reflection assignment, which formed the data source for analysis. In total, the 46 teachers submitted 61 separate responses, as some teachers were enrolled in more than one course. Among these were responses from courses intended for elementary teachers and for middle and secondary level teachers. Instructors who taught the participants agreed to include three common prompts for reflection. One prompt posed to teachers the counterfactual situation that they had taken the course prior to classroom teaching:

> Suppose you had taken this course as an undergraduate, before having any significant teaching experience. Would you have found the experiences with habits of mind less or more valuable than now? Would you have found the content less or more valuable than now? For what reasons?

This was Prompt 3 of the reflection assignment. We report only on analysis of responses to this prompt. Prompts 1 and 2 asked about how their experiences with habits of mind and course content might change the way they taught an activity or topic in the future, and defined habits of mind as "approaches to creating mathematical ideas or working on math problems". Example habits of mind and course content specific to the particular course were included in Prompts 1 and 2 (e.g., "looking at a problem from multiple perspectives" and "using precise definitions" were example habits of mind; and "Pascal's triangle" and "linear regressions" were example mathematical content).

Analysis for RQ1: Characterizing the contribution of masters coursework in mathematics to teacher learning

We used a combination of inductive and deductive coding (Miles, Huberman, & Saldana, 2018). We began with deductive coding of responses according to Hoffman and Even's (2018) categories of the contribution of academic mathematics to teacher learning: Essence, Doing, and Worth of Mathematics. However, we noticed statements describing contributions of the masters' course to teachers' learning that did not fit neatly into Hoffman and Even's descriptions, and wanted to differentiate between contributions for the purpose of mathematics from those for teaching. We inductively expanded the categories as shown in Figure 1 (next page). In tabulating the coding, we elected to use the unit of analysis of teachers rather than responses. We noticed that some teachers who had enrolled in different courses used the same phrasing across responses to different courses, and that this phrasing was essential to our coding.

Analysis for RQ2: Comparing relative value of coursework before and after teaching

We initially categorized responses as stating that the graduate course was *more valuable before teaching*, *more valuable after teaching*, *valuable either way*, or *none* (meaning, the response did not explicitly make a comparison of value before or after teaching). Then, as we noticed teachers stating that some aspects were more valuable before teaching and others more valuable after teaching, we inductively coded for the aspect of relative value (e.g., experience with habits of mind, content, technology).

Finally, we excerpted *frame* statements from responses, that is statements that explained something to the effect of, "Teaching experience made a difference in how I learned in the course because …". We surveyed these frame statements for themes in how teaching experiences framed the contributions of the mathematics courses to teacher learning. In tabulating this coding, we elected to use the unit of analysis of responses rather than teachers, because the comparison of contributions was course-dependent, and some teachers stated different comparisons for different courses.

Figure 1. Categories of contribution to teacher learning for RQ1

Contribution		Description: Statement that the course experiences …
Essence	Essence of Math	Changed a teacher's conception of "what is mathematics", or will help them convey to students a conception of "what is mathematics"
	Essence of Math Teaching	Changed a teacher's conception of the nature of teaching, including the possibilities of what teaching can look like
Doing	Doing of Math	Contributed to a teacher's mathematical habits of mind, or that the course will help teachers cultivate students' mathematical habits of mind, including struggling or persevering through mathematics
	Doing of Math Teaching	Statement that the course exposed teachers to teaching practices or activities they see as valuable or beneficial
Worth	Worth of Math	Statement that the course improved a teacher's sense of the value of mathematics, or helped a teacher convey to students the value of mathematics, either for its own sake, or because of its applications to science, technology, etc.. or that the course
	Worth for Math Teaching	Statement that the course improved a teacher's sense of the value of mathematical knowledge for the purpose of teaching
Content	Content Knowledge	Statement that a teacher developed specific content knowledge, or that the course will help teachers support students' acquisition of specific content knowledge, including connections among topics and better explanations (Shulman, 1986)
	Pedagogical Content Knowledge	Statement that a teacher developed specific pedagogical content knowledge, including detecting the potential of activities to facilitate learning; knowledge of student conceptions; or knowledge of or about multiple representations and explanations (Baumert et al., 2010)

Results

Characterizing the contribution of masters coursework in mathematics to teacher learning

Across our participants, the most frequently cited positive contribution of coursework was to the categories of doing mathematics (16 participants; 34.8%) and content knowledge (12 participants; 26.1%). Our prompt specifically mentioned content and habits of mind, and hence it is unsurprising that these categories are mentioned frequently. Table 1 summarizes the results.

Our main differences from Hoffman and Even are (1) introducing Content as a category and (2) extending contributions to both mathematics and mathematics teaching. This delineation allowed us to record that one possible benefit of these courses is the teaching itself: teachers mentioned the benefits of exposure to “great habits of teaching” (Doing of Math Teaching), or “realiz[ing] that how I am teaching now is not fulfilling what my expectations are for my students” (Essence of Math Teaching). Among our participants, 12 cited content knowledge as a contribution, for example, discussing the value of learning about concepts of calculus, or properties of number lines. Teachers explained the value in terms of being able to see more connections or providing better explanations in the future. All but 12 teachers cited a contribution of the graduate course in the responses analyzed.

Table 1. Contributions of coursework in mathematics, with unit of analysis being teachers (n = 46)

Contribution	Math/Teaching	# Participants mentioning contribution (%)
Essence	of Math | Math Teaching	0 (0%) | 2 (4.3%)
Doing	of Math | Math Teaching	16 (34.8%) | 7 (14.2%)
Worth	of Math | Math Teaching	0 (0%) | 2 (4.3%)
Content	CK | PCK	12 (26.1%) | 5 (10.9%)

Analysis for RQ2: Comparing relative value of coursework before and after teaching

We found that teachers parsed the relative value in terms of habits of mind, content, the course as a whole, and technology. We coded *valuable either way* when teachers wrote about benefits in both directions. We coded more *valuable AFTER teaching* only when teachers wrote about benefits in one direction (resp. *BEFORE)*. See Table 2. We only coded *course as a whole* when the teacher did cite a specific aspect, but unambiguously stated relative value.

Table 2. Aspects of contribution and their relative value, with unit of analysis being responses (n = 61)

	Course as a whole	Habits of Mind	Content	Technology
More valuable AFTER teaching	4 (6.6%)	24 (39.3%)	18 (29.5%)	1 (1.6%)
More valuable BEFORE teaching	3 (4.9%)	9 (14.8%)	11 (18%)	0 (0%)
Valuable either way	1 (1.6%)	6 (9.8%)	6 (9.8%)	0 (0%)

We found in total 27 framing statements. Analysis of framing statements suggests that overwhelmingly, teachers found an aspect more valuable after teaching because they could envision how the aspect could be applied to their teaching – and that they could not do so before. As one participant stated, “"Without teaching experience, I would not be thinking about those things as we go along." For brevity, we discuss only habits of mind here. Participants mentioned that habits of mind were useful now, and not previously, primarily because they now saw the value of habits of mind to students ("... now that I have had experiences working with students, I understand the importance of being able to solve using multiple strategies") or because they could better empathize with students ("When I actually had the experience of teaching in a classroom, I was surprised how many students struggled with the content. Having to struggle through habits of mind problems helped me to see what my students go through daily. I think if I would have taken this class earlier, it would not have resonated with me as much.").

Discussion & Conclusion

We undertook this study because of a local phenomenon that teachers seemed to have differing evaluations of the value of similar mathematics coursework, depending on whether they took the material after or before teaching experience. We posited that teaching experience mediated the uptake of course experiences in some way. Consequently, we examined how practicing teachers describe the contribution of graduate mathematics coursework to their learning, and how they would assess the relative value of this same coursework, had they taken the course as an undergraduate, prior to any teaching experience. We posed to teachers in an end-of-course reflection assignment the counterfactual situation of taking the same course as an undergraduate.

We found that most teachers cited some contribution of the graduate course to their learning, including the emphasis of the course on habits of mind, or the course's content. We also found that the plurality of responses indicated that teachers felt this course was more valuable after teaching than prior to teaching. To investigate why this may be the case, we examined framing statements. In these statements, a common theme was that without teaching experience, teachers did not realize the worth of habits of mind, or of content, for cultivating these aspects in students. Another common theme was that struggling in graduate coursework gave teachers empathy for their students, which would ultimately help the teachers be more understanding of students in the future.

We view our main contributions to be twofold. First, we extend Hoffman and Even's (2018, 2021) theoretical framework, and elaborate the possibilities for how academic mathematics coursework can contribute to teacher learning. Not only may they learn about mathematics, but they may also rethink their own teaching, or find teaching practices and activities modeled by the instructor they wish to bring into their classroom (cf. Wasserman & McGuffey, 2021). Second, we introduce the notion of framing as an explanation for why teachers may find courses useful or not, and how utility may shift over time. Prior work on teachers' conceptions of academic mathematics experiences have not differentiated between viewpoints before and after teaching experience. But as our results suggest, undergraduates and practicing teachers may frame their mathematics learning very differently. We suggest that further work investigating these frames can contribute to improving courses for both populations, as well as potential differences to work into course design with intention.

In the past two decades, there has been a trend in materials for mathematics courses for prospective secondary teachers: more opportunities for teachers to "apply mathematics to teaching". That is, materials increasingly highlight how mathematical knowledge learned in the course can be useful in secondary teaching, and provide opportunities for teachers to harness this knowledge in simulations of teaching. There is little known about the effects of this curricular reform on teachers' competence. In this report, we use data from the Mathematics of Doing, Understanding, Learning, and Educating for Secondary Schools MODULE(S^2) project to examine the potential impact of using such curricular materials. The data include over 300 prospective secondary teachers' responses to 3 sets of Likert pre-/post-term surveys addressing: mathematical knowledge for teaching; expectancy for enacting selected core teaching practices; and valuing of enacting these practices. We found mean increases across the survey results. We conclude with directions for future research on the impact of this curricular reform.

Keywords: Content Courses for Secondary Teachers, Mathematicians, Mathematical Knowledge for Teaching, Expectancy, Value

Introduction & Background

Many secondary teachers do not find their tertiary mathematics experiences usable in secondary mathematics teaching (e.g., Goulding, Hatch, & Rodd, 2003; Winsløw & Grønbæk, 2014; Zazkis & Leikin, 2010). In response to this problem, multiple scholars, including within the RUME community, have advocated for mathematics courses for prospective secondary mathematics teachers to provide explicit opportunities to connect university mathematics with secondary mathematics teaching (e.g., Álvarez et al., 2020; Lai, 2019; Wasserman et al., 2017).

In these scholars' view, the disconnection problem in the US may be a consequence of historical attempts to emphasize tertiary-secondary connections through *mathematics* (e.g., The Panel on Teacher Training, 1971) at the expense of attention to *mathematics teaching practice.* To rectify this situation, secondary mathematics teacher educators have in the past decade or so developed materials that articulate links to teaching practice (e.g., Álvarez et al., 2020a, 2020b; Bremigan et al., 2011; Buchbinder & McCrone, 2020; Hauk et al., 2017; Heid et al., 2015; Lischka et al., 2020; Sultan & Artzt, 2011; Wasserman et al., 2017). An instructional device common to each of these materials is *applications of mathematics to teaching* – where teachers respond to a description of a secondary teaching situation by leveraging material learned in a tertiary course (cf. Bass, 2005; Stylianides & Stylianides, 2010).

Since the advent of this curricular reform, there have been relatively few studies describing the potential impact of the use of materials featuring applications of mathematics to teaching. As far as we know, there are two exceptions (Buchbinder & McCrone, 2020; Wasserman and McGuffey, 2021) which though promising, also featured fifteen and six teachers only. Hence advancement of research and practice in secondary mathematics education faces a problematic gap: we do not know much about the impact of a growing curricular trend in materials for mathematics courses for secondary teachers.

The purpose of this report is to take a first step in addressing this gap, by examining changes in teachers' competence. As explained below, we view competence as including mathematical knowledge for teaching, expectation of success of enacting core teaching practices, and valuing of core teaching practices. The research questions guiding this report are:

Over the course of a semester-long experience featuring applications of mathematics to teaching that were coordinated with mathematical content learned,

1. *To what extent did teachers' mathematical knowledge for teaching change?*
2. *To what extent did teachers' expectation of success for carrying out selected core teaching practices change?*
3. *To what extent did teachers' valuing of these selected core teaching practices change?*

We note that while statistics and mathematics are distinct disciplines, in secondary education, "mathematics" is often seen as including statistics, a practice that we will follow in this paper. Unless otherwise indicated, we use "teacher" to mean a prospective secondary mathematics teacher, "student" to mean secondary student, and "instructor" to mean a university instructor.

Conceptual Perspective

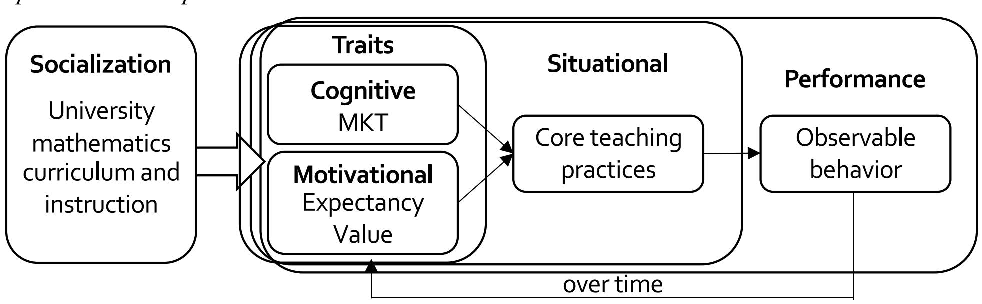
We follow Blömeke et al.'s (2015) notion of competence for teaching to include cognitive, motivational, and situational resources. Cognitive and motivational resources are also known as teacher traits; we see these as malleable. Cognitive resources include mathematical knowledge for teaching (MKT; Ball et al. 2008; Thompson & Thompson, 1996), the knowledge entailed in carrying out recurrent work of teaching. Within motivation, we focus on expectancy and value. Expectancy is the expectation of success at enacting a task in a particular situation (Wigfield & Eccles, 2000). Value is the subjective value of enacting the task, and it encompasses utility, enjoyment, and personal fulfillment (see Eccles & Wigfield, 2020, for a review).

Situational resources include teachers' understandings and conceptions of core teaching practices. These practices are those that benefit students in equitable ways; are learnable by teachers; and have the potential to promote teaching improvement over time (Grossman et al., 2009). Example core teaching practices include generating questions and discussion that promote students' reasoning, and learning about student understanding using their explanations.

We follow Eccles and Wigfield's (2020) framing that one's choices and performance feed iteratively into one's expectancy and value, and vice versa. If one experiences successful performance in mathematics and its applications to teaching, one is more likely to try again in the future. Conversely, if one perceives failure, one might desire to avoid core teaching practices.

From this perspective, an important role of teacher education is socialization: providing opportunities for teachers to learn and succeed, so as to encourage them to choose to engage in core practices in the future. Figure 1 summarizes our conceptual perspective.

Figure 1. Perspective on Competence



Data & Method

Study Context

Our report examines change in teachers' competence over the course of using MODULE(S^2) project materials in four different mathematical areas: algebra, geometry, mathematical modeling, and statistics. Materials for each area were intended to be used across one semester, and each featured 6 extended prompts. These extended opportunities specified a secondary student-level task, a goal for the scenario involving engaging students in a mathematical practice, and in most cases text or images of sample work drawn whenever possible from secondary student work obtained from secondary classroom teachers consulting for the project. Teachers were to respond to half of the prompts by writing a narrative describing how they would use the given responses to set up a whole class discussion, and the other half by videotaping themselves responding to sample student contributions as if they were personally responding to a student in their own class. For all responses, teachers were asked to make specific reference to the students' thinking, elicit student conceptions, and pose questions to advance mathematical understanding. All materials came in instructor-facing and teacher-facing versions, with the instructor-facing providing guidance for enacting core teaching practices in their own instruction.

Participants

Participants were 368 teachers enrolled in tertiary mathematics courses using MODULE(S^2) materials with 65 instructors at 54 different institutions across the United States and Canada. These participants consented to participation and completed various of the instrument forms detailed below. We defined "completion" as completing the majority of questions on that form.

Courses were taught at institutions ranging from large public research universities to small private colleges to regional public universities, and from those that served predominantly white populations to those that served predominantly minoritized populations.

Phases of Study and Instruments

Research occurred in two phases, before and after the first year of the covid-19 pandemic. Phase One spanned the project's Years 1 and 2, with data collected in two content areas per year. Phase Two spanned the project's Year 4, with data collected in all four content areas.

MKT measures. At the beginning and end of the term using MODULE(S^2) materials, we measured teachers' content knowledge for teaching. These include items from the Exponential, Quadratics, and Linear assessment (Howell et al., 2016); Geometry Assessments for Secondary Teaching (GAST; Mohr-Schroeder et al., 2017); Anhalt and Cortez's (2016) instrument on preparation for teaching modeling; and sample items based on the Levels of Conceptual Understanding of Statistics repository (LOCUS, n.d.), and an assessment item developed by Randall Groth (personal communication). To analyze change in teachers' content knowledge for teaching, we used Cohen's d to quantify effect size for knowledge change in each area. As of writing, we scored only assessments from Phase One data collection, so we only report those results.

Expectancy and value measures. At the beginning and end of the term, we measured each teacher's expectancy and value for enacting selected core teaching practices (SCTPs) in the area emphasized by their course. In Phase One, we used the same form in pre- and post-term administrations. After analyzing these results, and in view of conversations with piloting faculty, we posited that the large pre- ratings potentially obscured changes in expectancy and value for participants. In particular, faculty reported that teachers enrolled in their class remarked on how much they learned that they did not know could be learned. In Phase Two, to take this perception into account, we modified the post-term form to include a retrospective pre-rating for each item on the post-term measures. Moreover, in Phase Two, conversations with piloters and among the research team suggested adding an SCTP. See Table 1 for SCTPs included in each phase. See Figures 2 and 3 for a sample Expectancy item with a retrospective pre- rating; the post-term Value forms featured similar items. Underlined portions indicate parts specific to a content area.

We analyzed categorical shifts from pre- to post-test on the expectancy and value instruments across SCTPs and content areas using descriptive statistics of differences paired by teacher. We are interested in *the effect size* of any changes, rather than simply asking *whether* a difference exists. We use Cohen's d to quantify effect size for expectancy and value for enacting each SCTP; it measures the practical significance of the observed difference by accounting for variability in the difference. Common benchmarks for interpreting Cohen's d are 0.2 for a small but non-negligible effect, 0.5 for a medium effect, 0.8 for a large effect, and 1.3 for a very large effect (Sullivan & Feinn, 2012).

Table 1. Selected core teaching practices emphasized in materials used by study participants

Code	Definition	Phase One	Phase Two
SCTP1	Ask questions so that middle and/or high school students make conjectures.	✓	✓
SCTP2	Ask questions and lead discussions that help middle and/or high school students come up with mathematical explanations.	✓	✓
SCTP3	Ask questions that help middle and/or high school students make connections between different representations of the same idea		✓
SCTP4	Ask questions so that middle and/or high school students understand how to build on their thinking and what to revise.	✓	✓
SCTP5	Analyze middle and/or high school students' responses to understand their reasoning	✓	✓

Results

Changes in mathematical knowledge for teaching (MKT)

Table 2 indicates that all areas exhibited a mean increase in teachers' MKT. All effect sizes are above the threshold for large practical significance (Cohen's $d > 0.8$). All post scores are less than 50% of the maximum score, and pre- and post- means across all areas are roughly comparable. As context for interpreting this finding, we turn to validation studies of measures for content knowledge for teaching geometry, where there has been significant work at the secondary level with reported raw scores. Mohr-Schroeder et al. (2017) validated GAST forms to measure mathematical knowledge for teaching geometry with a sample of predominantly practicing teachers. In contrast, our participants were strictly prospective teachers. On full GAST forms, the mean score was 20 points out of 30 possible. Mohr-Schroeder et al. did not compare prospective and practicing teachers' performance in their sample. However, in reports of their results with a different instrument (MKT-G), Milewski et al. (2019) reported that most prospective teachers' scores were comparable to those in the lower half of practicing teachers' scores. In view of these results, it is not surprising that the teachers in our sample scored, overall, in a lower range than those in Mohr-Schroeder et al.'s sample, and apparently in a similar range over all areas. Finally, we note that the indicated sample sizes include only those teachers who completed both pre and post forms. Because not all piloters administered the post form, participant numbers are lower in some areas.

Table 2. Paired difference results for MKT, reported in terms of percentage of maximum score on each area assessment

Area	Pre-Mean	Post-Mean	Mean Δ	SD_Δ	Cohen's *d*
Algebra (*n*=9)	20.8%	39.2%	18.3%	13.5%	1.36
Geometry (*n*=63)	25.6%	35.9%	10.3%	10.1%	1.02
Mathematical Modeling (*n*=20)	31.3%	44.4%	13.1%	17.9%	0.73
Statistics (*n*=40)	26.6%	42.2%	15.6%	16.4%	0.95

Changes in expectancy and value for enacting selected core teaching practices (SCTPs)

Tables 3-8 summarize our findings. For brevity, the table does not include all 32 + 40 combinations of expectancy and value (Phase One: 4 SCTPs × 4 content areas ×{expectancy, value}; Phase Two: 5 SCTPs × 4 content areas ×{expectancy, value}), but we discuss their characteristics now. In Phase One, all *expectancy* effect sizes among SCTPs are non-negligible (Cohen's $d > 0.2$). Eight of the 16 indicate at least medium practical significance (Cohen's $d > 0.5$), and 1 indicates large practical significance (Cohen's $d > 0.8$). Among effect sizes for *value*, 9 indicate non-negligible practical significance, with most of them being for SCPT1 and SCTP2.

Retrospective pre-ratings were overall lower than actual pre-ratings, confirming our hypothesis that teachers, when looking back, now believe they perceived less expectancy and value at the beginning of term, as compared to their perceptions at the actual beginning of term. The lowest mean expectancy *retrospective* pre-rating for any SCTP in any content area was 2.58, compared to 3.20 for *actual* pre-ratings. The lowest mean value *retrospective* pre-rating for any SCTP in any content area was 3.46, compared to 4.28 for *actual* pre-ratings.

All effect sizes for *actual difference in pre/post expectancy* are non-negligible, 16 indicate medium practical significance, and 8 indicate large practical significance. Effect sizes for actual pre/post increases in expectancy in Phase Two are slightly larger than those in Phase One; this may be due to improvements to the materials, or simply to differences in students and instructors. All effect sizes for *retrospective difference in pre/post expectancy* are non-negligible and in fact are above the threshold for large practical significance and 15 indicate very large practical significance (Cohen's $d > 1.3$). Among effect sizes for *actual difference in pre/post value*, 14 indicate small practical significance, and 1 indicates medium practical significance. All effect sizes for *retrospective difference in pre/post value* are above the threshold for medium practical significance, and 11 indicate large practical significance.

Discussion & Conclusion

We sought to examine changes in teachers' competence before and after a semester-long experience featuring applications of mathematics to teaching. Our results address a gap in the literature concerning the impact of curricular reform on teachers' competence. We analyzed data about teachers' cognitive and motivational resources, specifically MKT, and expectation of success and value for enacting core teaching practices when teaching a particular content area. Overall, we found that teachers' MKT, expectation of success, and value increased after this semester-long experience.

A significant strength of our results is that they come from teachers across a variety of institutions, with different instructors, across four distinct content areas. Our results on motivation are limited in that, like most studies in this area, we rely on self report. Teachers may have felt pressure to respond more positively than the reality. Nonetheless, the overall increase in all variables, across all areas, indicates that it is plausible that expectation of success and value did improve, even if it is to a lesser extent than reported. Hence, we theorize that teachers benefit when using materials that coordinated mathematical learning opportunities with applications of mathematics to teaching, and these benefits come in the form of increased competence for teaching.

Any conclusions that can be drawn from these results are limited in two crucial ways, which also point to directions of future research. First, correlation is not causation. Although we designed the materials to enhance teachers' competence, the data here do not say what factors exactly supported the mean improvement over time we found across our data. We cannot say whether the benefits derive from the materials' design, the confluence of taking the content course alongside a pedagogically-focused methods course, a time effect that when teachers take similar pre/post forms they will generally improve, or another factor. Beyond technical studies of how teachers' knowledge appears to change or not simply by having been exposed to an assessment of MKT, we also suggest that examining potential mechanisms for change is also important. Future studies, for instance, could investigate whether certain instructional practices are associated with changes in teachers' competence; whether teachers' knowledge changes as a result of propositional knowledge or change in mathematical practice; or how opportunities to learn mathematical content and applications of mathematics to teaching interplay.

Second, we have not addressed directly the problem that many teachers themselves have been documented to find content courses not useful. We and other scholars believe that teachers would find applications of mathematics to teaching useful, but we cannot conclude this based on the analysis reported here. We are currently in the process of analyzing the data from MODULE(S^2) project to address this gap.

Finally, we observed that teachers' retrospective pre- ratings of their motivation were generally lower than their actual ratings from the beginning of term. This finding suggests practical and methodological questions. The practical question is: What changes their perspective? The methodological question is: in what areas of competence would self-reports change retrospectively, and what are the affordances and limitations of retrospective ratings?

Although it is well known that motivational and cognitive resources influence secondary teachers' instructional quality, less is known about the tertiary instructional factors that influence secondary teachers' development of these resources. To address this gap, we report on factors that prospective secondary teachers attribute to their learning. We draw on survey responses of 70 prospective secondary teachers enrolled in mathematics courses for teachers using Mathematics of Doing, Understanding, Learning, and Educating for Secondary Schools (MODULE(S^2)) materials in one of four content areas. We triangulate response themes with data from 300 prospective secondary teachers on their perceptions of instructional practices used in a mathematics course for teachers using the same suite of materials. Then, we compare these themes with literature documenting implementation of mathematics curricula in these courses. We argue that coordinating mathematics content, applications of mathematics to teaching practices, and tertiary instructional practices are key to success of these mathematics courses.

Keywords: Content Courses for Secondary Teachers, Mathematical Knowledge for Teaching, Instructional Practices

Although prospective teachers take many tertiary mathematics courses (e.g., Hill, 2011; Tatto & Bankov, 2018), many find their experiences in these courses irrelevant to secondary teaching (e.g., Goulding, Hatch, & Rodd, 2003; Zazkis & Leikin, 2010). One response to this problem is to incorporate applications of mathematics to teaching into content courses for secondary teachers (e.g., Álvarez et al., 2020a, 2020b; Bremigan et al., 2011; Buchbinder & McCrone, 2020; Hauk et al., 2017; Heid et al., 2015; Lischka et al., 2020; Sultan & Artzt, 2011; Wasserman et al., 2017). Emerging empirical scholarship on the impacts of such applications points to the promise of this solution (e.g., Buchbinder & McCrone, 2020; Wasserman & McGuffey, 2021). However, as with any curricular innovation, it is not just the curriculum materials that matter, but also how the curriculum materials are deployed (e.g., Cohen, 1990; Stein et al., 2007).

Our purpose in this report is to identify instructional factors in successful tertiary-level mathematics courses for prospective secondary teachers. By success, we mean that the prospective teachers develop their competence for teaching; and by competence, we include teachers' cognitive and motivational resources for teaching. We focus especially on the resources of mathematical knowledge for teaching, value commitments, and expectation of success in mathematics and teaching. We address the research questions: *(RQ1) What instructional factors do prospective secondary teachers attribute to their learning in a mathematics course for teachers? (RQ2) To what extent do tertiary instructors' instructional practices associate with prospective secondary teachers' increase in their expectation of future success?*

In the remainder of the report, unless otherwise noted, we use "teacher" to refer to prospective secondary mathematics teacher, "instructor" to refer to the instructor of a tertiary-level mathematics course, and "student" to refer to secondary students.

Background & Conceptual Perspective

Design and impact of mathematics courses for secondary teachers

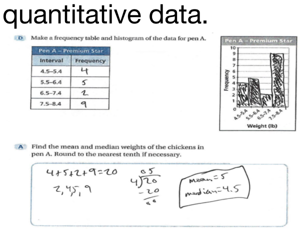
A teacher's instruction benefits from robust mathematical practice and knowledge of secondary content from an advanced perspective (Baumert et al., 2010; Sword et al., 2018), and course design has historically reflected this understanding (e.g., CUPM, 1961; CBMS, 2001; Murray & Star, 2013; Tucker et al., 2015).

However, results into the last decade also suggest that design principle for mathematics courses around *only* mathematics falls short: many teachers saw their mathematics courses as disconnected from their future teaching (e.g., Goulding et al., 2003; Zazkis & Leikin, 2010). Even when teachers enrich their understanding of the secondary mathematical concepts that they will teach, they may still exit tertiary mathematics believing that they may have become better mathematicians, but not better mathematics teachers (Wasserman & Ham, 2013).

In response to the inefficacy of mathematics courses for teachers, a number of scholars have advocated for the inclusion of *applications of mathematics to teaching* in these courses (Álvarez et al., 2020; Artzt et al., 2011; Bremigan et al., 2011; Heid et al., 2015; Lai, 2019; Lischka et al., 2020; Wasserman et al., 2017). By applications of mathematics to teaching, we mean opportunities for teachers to respond to secondary teaching scenarios using content addressed in the course. Two examples of such applications are shown in Figure 1. Bass (2005) and Stylianides and Stylianides (2010) argued that drawing on mathematical knowledge to address problems of teaching is enacting a form of applied mathematics. Their arguments are consistent with principles of a practice-based theory of professional education (e.g., Ball & Cohen, 1999).

Figure 1. Example snapshots of applications of mathematics to teaching

Two parts of a student's work on a task are shown below. Identify what the student has done well when analyzing the data, and areas to work towards understanding about analyzing univariate quantitative data.



As students are working independently on rotations of a flag around a point, you observe two students with the following work completed.

Record a video of yourself providing a response to both Student 1 and Student 2. Build on their thinking to help the student finish their thought, prompt the student to investigate an error, or help the student move forward in their thinking.

Pilot studies examining courses where such applications are used suggest that, in contrast to previous studies, teachers are able to articulate how course content connects to future teaching (e.g., Fukawa-Connelly et al., 2020; Wasserman & Galarza, 2018). Further, the 15 teachers in Buchbinder and McCrone's (2020) study went on to incorporate task designs from their tertiary mathematics course into a lesson for secondary students while student teaching. Teachers in Wasserman and McGuffey's (2021) study of 6 teachers attributed teaching moves to their experiences in a real analysis course featuring these applications. Attributions were predominantly of two kinds: experiences with applications, and instructional practices that were modeled by their real analysis instructor.

Instructional practices in middle and secondary grades and at the undergraduate level

Multiple studies with middle and secondary students suggest the beneficial impact of core teaching practices (e.g., Grossman et al., 2009) that maintain and elevate cognitive demand, and elicit and build on student thinking (e.g., Gates Foundation, 2012; Voss et al., 2011). Yet Banilower et al.'s (2013) national survey suggests that many secondary teachers may not teach in these ways. They found that only 55% of secondary teachers focus on developing students' mathematical practices, including mathematical justification. Banilower et al. do not suggest reasons for their findings. However, based on other literature, we do know that teachers' practices may depend on their self-efficacy (Zee & Koomen, 2016), values (e.g., Schoenfeld, 2010), and pedagogical content knowledge (Baumert et al., 2010).

Perhaps unsurprisingly, the principles of effective instruction for middle and secondary grades carry through to the undergraduate level. Undergraduate instructors are increasingly aware of benefits of eliciting undergraduates' reasoning and supporting undergraduates' collaboration (e.g., Laursen & Rasmussen, 2019). These teaching practices benefit student outcomes overall (e.g., Bressoud & Rasmussen, 2015).

Summary of perspective based on the above literature review

Altogether, we take the view that mathematics courses for teachers are a productive place to incorporate the kinds of teaching practices that have been shown to be effective at the middle and secondary level, where many candidates of secondary mathematics teacher education programs will end up teaching. These teaching practices are consistent with trends at the undergraduate level and benefit undergraduate students. Further, there is evidence that teachers may transfer instructional practices experienced at the tertiary to the settings of their future secondary teaching (Buchbinder & McCrone, 2020; Wasserman & McGuffey, 2021). Hence one way to move the needle on secondary teachers' practice may include tertiary instructors' modeling of effective teaching practices.

Data & Method

Study Context

Our report examines teachers' perceptions of their experiences in a mathematics course for teachers, during a term when the course used MODULE(S^2) project materials in one of four different mathematical areas: algebra, geometry, mathematical modeling, and statistics. Materials for each area were intended to be used across one semester, and each area featured 6 extended applications of mathematics to teaching, termed "Simulations of Practice". The examples from Figure 1 are excerpts of these Simulations of Practice. These activities asked teachers to build on sample student thinking, and to generate questions that elicited student reasoning. Simulations were designed to apply the mathematics learned through the materials. All materials came in instructor-facing and teacher-facing versions, with the instructor-facing providing guidance for building on teacher thinking, and generating questions that elicited teachers' reasoning. Elsewhere we have analyzed teachers' pre- and post-term expectation of success and value of carrying out core teaching practices, and found mean increases in these variables across all content areas (see Lai et al. in these proceedings). Instructors received support from the project team in the form of summer workshops and meetings with materials developers throughout the academic year.

Participants

Data were drawn from responses of 368 teachers enrolled in tertiary mathematics courses using MODULE(S^2) materials with 65 instructors at 54 different institutions across the United States and Canada. These participants consented to participation and completed various of the instrument forms detailed below. We defined "completion" as completing the majority of questions on that form. Courses were taught at institutions ranging from regional public universities to large public research universities to small private colleges, and from those that served predominantly white populations to those that served predominantly minoritized populations.

Instruments, Analysis, and Phases of Data Collection

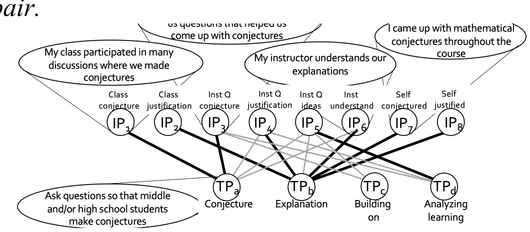
RQ1: Teacher Perceptions of Learning (RQ1). We distributed a survey at the end of the term where we asked teachers to identify factors that influenced their learning. These open-ended questions asked teachers, "What did you learn about doing [content area] as a result of this course? What was most helpful about this course for learning to do [content area]?" and "What did you learn about teaching [content area] as a result of this course? What was most helpful about this course for learning to teach [content area]?"

We examined factors influencing change in expectations of success or value in mathematics or mathematics teaching. We coded responses for *expectation of success:* confidence or facility in aspects of doing mathematics, learning mathematics, or teaching mathematics (Eccles & Wigfield, 2020); *value*: importance, benefit, worth, or enjoyment ascribed to aspects of doing mathematics, learning mathematics, or teaching mathematics (Eccles & Wigfield, 2020); and *course attribution*: attributing change in expectation of success or value to instruction, where instruction includes course activities, norms, or interactions (e.g., Cohen et al., 2003).

RQ2: Pre/Post Expectation of Success in Teaching Practices (TPs). We measured each teacher's expectation of success for enacting selected teaching practices (TPs) in the area emphasized by their course. Our items for this construct use phrasing from Eccles et al.'s (1993) study. All items used a Likert scale from 0 (not at all) to 5 (very much) and read: "Suppose you are teaching middle or high school [content area] students [about key concept]. How well does this statement describe how you feel? 'I would be comfortable [TP].'" Key concepts aligned to curriculum materials (e.g., covariational reasoning was an algebra key concept). We analyzed categorical shifts from pre- to post-test on the expectancy and value instruments across TPs and content areas using descriptive statistics of differences paired by teacher.

RQ2: Perception of Instructional Practices (IPs). We surveyed teachers' perception of the extent to which they experienced instructional practices (IPs) similar to TPs. Item phrasing mirrored that of TPs, phrased from the perspective of learning ("I did ...", "My class did ...") and teaching ("My instructor ..."). We identified clusters of TPs that corresponded to or supported each other: for instance, an instructor or teacher's capacity to build on learner thinking supports the capacity to ask questions that elicit conjectures. We used the Pearson correlation coefficient *r* to measure correlations between teachers' expectation of success in a TP and IPs whose modeling corresponded to or supported the TP. For brevity, we do not list all TPs and IPs in full, but only a selection of them. These are shown in Figure 2.

Figure 2. Correlations explored between TPs and IPs. Bold line indicates a corresponding TP-IP pair. Gray line indicates supporting TP-IP pair.



Phases of Data Collection. Research occurred in two phases, before and after the first two years of the covid-19 pandemic. Phase One spanned the first two years of the project, with data collected in two content areas per year. Phase Two spanned the fourth year of the project, with data collected in all four content areas. RQ1 analysis has only been completed with Phase Two data at time of writing. RQ2 analysis is reported with Phase One and Phase Two data.

Results

Instructional factors prospective secondary teachers attribute to their learning

Table 1 summarizes the percentage of teachers who made at least one statement regarding expectation of success, value, or course attribution to their learning, across their entire response to the Teacher Perception of Learning survey. This table also shows the number of total statements of expectancy, value, or course attribution.

Table 1. Coding results for responses to Teacher Perceptions of Learning.

	% participants mentioning expectation of success	% participants mentioning value	% participants mentioning attributions	# Expectation of success statement (Pos + Neg)*	# Value statements (Pos + Neg)*	# Attribution statements (Pos + Neg)*
Algebra (*n* = 28)	82.1%	60.7%	67.9%	37+0	25+2	27+2
Geometry (*n* = 6)	100.0%	83.3%	50.0%	12+0	7+0	5+0
Math Modeling (*n* = 23)	78.3%	95.7%	73.9%	30+0	48+2	25+5
Statistics (*n* = 13)	92.3%	76.9%	61.5%	21+1	14+2	9+3

*Pos = positive statement, neg = negative statement

Across all areas, teachers overall described increased facility in content knowledge and working with students. In algebra and geometry, multiple teachers cited increased knowledge of "why things work", describing "deeper" levels of understanding (e.g., "Being challenged to dig deeper into these ideas will be helpful in my future career"). In statistics and mathematical modeling, multiple teachers described little previous knowledge of these topics, and feeling more confident about teaching the topic as a result of the course.

When looking across instructional factors that teachers reported as influential, the most common elements across all areas are applications of mathematics to teaching, or simulations of practice (22 mentions; e.g., "The videos we had to create where we looked at a student's answer… get them to think where they might come up with the answer on their own without me giving them the answer I found very beneficial and helpful!") and discussion with other teachers (35 mentions; e.g., "Having conversations with peers and being given time to absorb and reflect on ideas was really helpful.") All the above factors were mentioned across all areas. Teachers also cited curricular structure and content (e.g., "Assignments that led us to figuring out an idea before giving the definition of that idea really helped make the definition impactful"), opportunities to develop conceptual understanding (e.g., "The thing that was most helpful was discussing why things work and seeing how it all connected"). For brevity, we only list themes with at least 5 mentions found in attribution statements. See Table 2.

Negative statements were comparatively rare, and differed by area. For instance, in Algebra, two teachers stated that the depth of content was inappropriate for secondary teaching. In Mathematical Modeling, all five negative attribution statements were from one instructor's course and all described repeated experience with modeling as redundant. In Statistics, two stated that they still felt uncomfortable with statistical concepts, and one stated they had insufficient opportunity to apply statistics to teaching. In statistics and modeling, three described "unnecessary" inclusion of social justice issues.

Correlating changes in teachers' expectancy and instructional perception

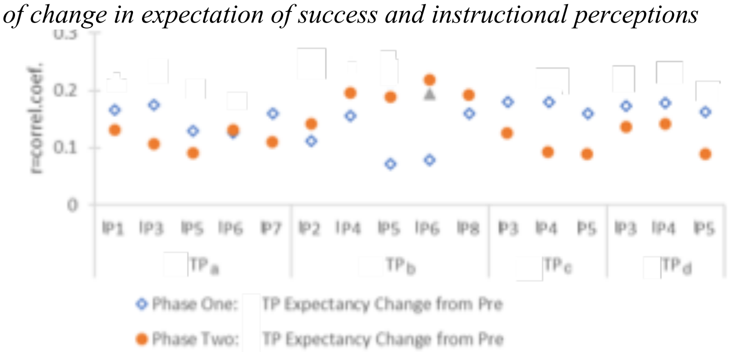
Figure 3 indicates positive correlations between pairs of variables examined. Although all correlations are relatively small ($0.07 < r < 0.24$), that they are all positive indicates an overall pattern that larger increases in expectation of success can be predicted by teachers' more positive experience of their instructional environment, in particular, their perception of how much they experienced core teaching practices during the content course.

Table 2. Attribution categories for instructional factors

Attribution category	# statements (Pos + Neg)*	Content areas of mentions◊	Example
Discussions with other teachers (including instructor role in facilitation)	35+0	A, G, M, S	"In this class, the teacher was probably the most helpful. She did a great job pushing us to talk and discuss each problem. Then looking back, you can see the results of those discussions. Being able to do that myself will be a massive help."
Simulations of practice	22+0	A, G, M, S	"The videos we had to create where we looked at a student's answer… get them to think where they might come up with the answer on their own without me giving them the answer I found very beneficial and helpful!"
Course structure and content	7+4	A, G, M	"When I heard the phrase "in the future your students will ask you.", I never really thought about it, but after witnessing it first hand and with the exact same topics from class... I was shook and thankful that I have this class to teach me fundamental techniques and strategies to help with my future class. Thank you!!!!!!!!!!! :)" "Although at some point it felt like I was doing the same assignment but with a different skin. What I mean by that is I felt like the assignment was the same for each new topic. The only difference was that we were given a new topic. I felt like there was nothing new to really learn after the first few weeks of the class."
Doing math modeling	11+0	M	"I think viewing and practicing modeling problems ourselves made it easier to see what modeling is and does."
Written materials	3+2	A, G, S	"The way that the book, and the class as a whole, took us step by step through each new content element was incredibly helpful." "The book was not helpful"

* Pos = positive, Neg = negative
◊ A = Algebra, G = Geometry, M = Mathematical Modeling, S = Statistics

Figure 3. Correlations of change in expectation of success and instructional perceptions



Discussion & Conclusion

We set out to examine the instructional factors that teachers attribute to their learning, and to what extent instructors' practices associate with teachers' increase in their expectation of future success. We found that discussions with other teachers and applications of mathematics to teaching were mentioned most as attributions to increased competence. In some ways, these results are not surprising. The findings bear out the working hypotheses of a practice-based theory of professional education: when teacher preparation is explicitly and intentionally linked to the practice of teaching, it is more likely to be effective.

Our findings are important because teachers attributed usefulness to specific features of curriculum and instruction. We strengthen results from existing smaller studies (e.g., Buchbinder & McCrone, 2020; Wasserman & McGuffey, 2021) by establishing the impact of instructional practices and applications of mathematics to teaching in four different content areas, with over 50 different instructors in over 50 different institutions.

Generalizations from this study are limited by the fact that piloting instructors volunteered to participate and had support, so they may have been more equipped to enact the curriculum as intended. The survey responses are based on teachers' self-report, and they may have felt compelled to respond more positively than they felt, or to not write as many negative comments. Nonetheless, given the sheer number of mentions of applications of mathematics to teaching, and discussion with other teachers, along with the overall small but positive associations between instructors' practices and teachers' expectation of future success in related practices, we conclude that applications of mathematics to teaching are a key innovation for secondary teachers to see the usefulness of the course content. We also conclude that instructors' practices do shape the impact of the course on teachers.

The practices identified by teachers in our study as well as in Wasserman and McGuffey's study, such as facilitating productive whole class discussions, are consistent with principles of inquiry-based mathematics education (e.g., Laursen & Rasmussen, 2019). Yet we emphasize that our conclusion is not that inquiry-based mathematics education is needed (though we believe this), but that practices of such instruction are part of a bigger picture. This picture includes both how the course taught and what is taught. Instructional practices are how a course is taught; what is taught includes the opportunities to learn from the curriculum, including activities such as the applications of mathematics to teaching. Our curriculum features intentional coordination of content with applications of mathematics to teaching. We propose that this coordination is an essential feature of curriculum for secondary teachers, if the course is to be perceived as useful, and to support the development of teachers' cognitive and motivational resources for teaching. Moreover, we posit that the instructional practices should be consistent with the images of teaching practice in applications of mathematics to teaching.

Looking forward, we see the need for further studies to document the impact of instructors' practices on teachers' development, for instance conducting case studies of courses with higher and lower mean gains in teachers' competence. With the hope that this curricular reform takes even greater hold, we also suggest studies into how instructors enact materials with applications of mathematics to teaching.

Previous studies have established teacher questions as a significant interaction component in proof-based courses whether lecture-based or student-centered. However, little research has been conducted to investigate behind the types of questions asked in class. In this report, we share an analysis of three instructors' lessons on the First Isomorphism Theorem. We characterized instructor question types and then conducted interviews with each instructor to investigate how their pedagogical beliefs relate to the types of questions they ask in class. We found that the instructors held similar pedagogical beliefs about student learning, but diverged in their views on the purpose of the course. Both beliefs on learning and their beliefs on purposes of the course linked to the nature of the questions asked in class.

Keywords: Instructor beliefs, instructor questioning, proof presentation

Instructor questioning is one of the primary ways students are invited to participate in mathematical proof courses (Artemeva & Fox, 2011, Melhuish et al., 2022; Paoletti et al., 2018). We conjecture that the types of questions instructors asked are shaped by their beliefs about teaching, learning, and proof-based courses. While we know broad information about instructors' pedagogical decisions, investigations into the how and why of instructional practices in proof-based courses are still needed.

In this paper, we set out to address the research question: how do abstract algebra instructors' pedagogical beliefs relate to the types of questions they ask in class? In proof-based courses, research on teaching practices can be sorted into two categories: lecture style teaching and student-centered teaching (Melhuish et al. 2020). Analysis of teaching actions, such as types of questions asked, is largely limited to lecture settings where instructors frequently engage in "chalk talk" (Artemeva & Fox, 2011) writing proofs on the board, adding verbal commentary, and asking questions. In contrast, in student-centered instruction studies, most focus has been on student activity and tasks with the role of the instructor backgrounded. There has also been some work has focused on the mathematical and noticing activity of instructors and how these shape in-the-moment instruction (e.g., Johnson and Larsen, 2012; Johnson 2013). With these different foci, several questions are open including the nature of questioning in more active classes, and rationales for how and when instructors ask questions across both settings. This study makes a comparison between instructors who teach a lecture style classroom versus those who teach a student-centered classroom. Specifically, we plan to investigate the way that instructor pedagogical beliefs shape the questions asked in class. For most classes, questions are one of the most common ways for students to be invited to participate in the class (c.f., Melhuish et al., 2022; Paoletti et al., 2018).

Relevant Literature

Researchers have investigated instructor actions in lecture and rationales for their teaching styles. Paoletti et al. (2018) found that instructors typically ask factual and next step type questions (see Table 1 for definitions question types) during lectures in proof-based classes. Fukawa-Connelly et al. (2016) surveyed mathematicians and found that lecturers chose the style because of concerns about time and covering material. Woods and Weber (2020) reported similar findings. They also discussed other goals and orientations of lecturing instructors and how these can affect the instructor's in-class behaviors such as lecture allowing for mathematical precision and formalism. That is, the literature largely suggests that lecturers are intentional and have robust rationales for the way they teach (Melhuish et al., 2022).

Instructors also diverge on views of advanced courses and what the overall emphasis should be (e.g., Alcock, 2010). For example, Johnson et al. (2013) conducted interviews with mathematicians implementing an inquiry-oriented (IO) abstract algebra curriculum and found that some instructors held different goals for the abstract algebra course (with or without the IO curriculum they were implementing). She found that one of her instructors emphasized mathematical practice and activities, while the other instructors had a heavier focus on the abstract algebra content. Each of these instructors had beliefs about what students should gain and learn from the course and then implemented and focused the course on these beliefs, even when using the IO curriculum.

A recent case study was conducted by Rupnow (2021) where instructors were interviewed on their beliefs about mathematics instruction and their abstract algebra classes were observed to determine how these beliefs were enacted. In terms of questioning, Rupnow observed that the IO instructor asked more questions than the lecturer. Rupnow reported on two instructors, one using an IO curriculum where students were more actively working on mathematics in class while the other instructor more traditionally lectured. The instructors' beliefs impacted the structures of the class and these structures changed over time due to additional beliefs such as those related to coverage.

Conceptual Framing

The framing underlying our study draws on Leatham's (2006) sensible system framework. In this framework, teachers are viewed as sensible actors who can and do hold many beliefs. These beliefs work together in a sensible system, with some holding more power than others and some beliefs leading to other beliefs. A teacher's belief may seem contradictory to an observer's point of view, but from the teacher's point of view all their beliefs are consistent and work together. Some relevant beliefs may reflect orientations towards teaching, learning, and course goals.

We then make the assumption that beliefs play a mediating role in the nature of questions asked in classrooms. To parse question types, we adopt Paoletti et al.'s (2018) analytic framework (Table 1) of types of questions that were asked by instructors in proof-based classrooms.

Table 1: Paoletti et al.'s (2018) Question Type Framework

Question Type	Definition
Fact	Questions that elicit a closed form mathematical response. These questions do not call for a course of action from the students.
Next Step	Questions that elicit recommendations from students on what to do next within a proof or example. The purpose of these questions is to create logical progressions.
Proof Framework	Questions that elicit higher-order levels of proof structure. Such questions targeted proof structure such as type of proof or how to generically prove a construct such as one-to-one.
Warrant	Questions that elicit justification responses to a statement or claim.
Evaluation	Questions that elicit the truth-value of a statement. Typically answered with a yes or a no.
Convention	Questions that elicit mathematical convention of proof writing or notation.
Other	Questions that do not fit into any of the other question types.

Methods

Data for this study was collected for a larger NSF-funded design-based research project[1]. Data were collected in three instructors' abstract algebra classes at a large research institution in the United States on days they covered three key theorems in the class. This paper focuses on the lessons addressing the First Isomorphism Theorem (FIT). Instructors A and B used an inquiry-oriented approach to help students in comprehending the FIT. Instructor A was involved in the creation of the materials, and both Instructors A and B used these materials in their classes. This lesson was implemented across two 80-minute (160 minutes total) class days, with each instructor taking a total of approximately 61 and 65 minutes, respectively, of whole class instruction. Instructor C covered the FIT via an interactive lecture in one 80-minute class day with their lesson taking 54 minutes. All instructors have had prior experience teaching abstract algebra and had strong student evaluations. Instructor A has a Mathematics Education Ph.D., and their primary area of research is teaching and learning in advanced proof classes. Instructor B holds a Mathematics Ph.D. with a focus in geometric group theory but has transitioned to mathematics education research. Instructor C holds a Mathematics Ph.D., and his primary area of research is graph theory and combinatorics. Focal lessons from each instructor were video recorded and transcribed. At the end of the academic year, semi-structured stimulated recall interviews (Schepens et al., 2007) were conducted with each instructor. For each participant, a member of the research team went through the transcript data of classroom observations and identified all questions that met the following two criteria: (a) the question had to have been posed to the whole class and (b) the question had to have adequate wait time of at least 3 seconds. The first criterion was implemented so we could analyze the ways in which instructors ask questions posed to the class and how these questions may reflect their beliefs. The second criterion was established to rule out questions where the instructor posed the question and immediately answered it. Questions that were asked towards individual students or groups of students during small group discussions or independent thinking were not considered for this analysis.

[1] DUE# 1836559

Once all questions asked by the instructor had been identified, the research team independently went through each of the participants' questions to identify a representative set of questions. That is questions of a similar type (such as the multiple instances where instructors would ask students for the definition of a concept). The research team then met to determine which questions would be part of the stimulated recall interviews. Instructor A was interviewed first by the whole research team and the data was initially used as a pilot for interview protocol question creation and interview practice. Two members of the research team interviewed Instructor B and two other members of the research team interviewed Instructor C.

In addition to having instructors provide rationales for their questions, they were also prompted to answer questions about how students learn, the purpose of the course, and the meaning of mathematics. The interviews were then analyzed by two research team members independently to open code for salient instructor beliefs. The questions asked during the lesson were coded using the above analytic framework by two members of the research team. Any discrepancies in coding were resolved through discussion. After completion of this initial analysis, the interview transcripts and question rationales were considered in light of the types of questions asked, instructor beliefs, and the rationales provided by the instructor to develop initial explanatory mechanisms for the types of questions asked.

Results

To contextualize our results, we provide the frequency of types of questions in Table 2. Note that Instructor C's question profile is reminiscent of most lecturers from Paoletti et al.'s (2018) study. Instructor C asked mainly fact questions (63%[2]) with next step as the second most frequent (19%). Instructor A asked "other" questions most frequently (43%) and fact questions (40%) as the second most frequently asked question type. While Instructor B asked fact and other types questions equally frequently with both having the highest frequency in comparison to the remaining question types (34%). We also note that unlike in Rupnow (2021), the number of questions asked in the lecture class and the active classes were not substantially different. Rather, we see that the type of questions asked in the inquiry proof comprehension lessons were qualitatively different than those asked in the lecture class on the same theorem.

Table 2: Frequency of question types

Instructor	Facts	Next Step	Proof Framework	Warrant	Evaluation	Convention	Other	Total
Instructor A	23	0	3	5	2	0	25	58
Instructor B	23	3	4	5	5	4	23	67
Instructor C	39	12	6	1	2	2	0	62
Total	87	15	13	11	9	6	45	186

[2] All displayed percentages are rounded percentages of total questions asked by that instructor

In order to make sense of these qualitative differences, we turn to the instructors' stated beliefs. All three instructors shared similar ideas about how students learn focusing on students being actively engaged in the learning process. Instructor A explained that students need to be "actively engaging in things by making connections to prior knowledge" elaborating that this is hands-on and not just mimicry. Instructor A elaborated that students "need to have opportunities to really think through ideas." Instructor B explained that experience and problem solving are the most important things for students to learn, stating "you learn through problem solving." Adding that to accomplish this, Instructor B tries "to set-up a learning experience so there are opportunities to be active where being active will lead to at least some degree of success; some degree of intuition building." Instructor C stated that, "You learn by doing." For Instructor C, they viewed this idea of doing by having students engage in proof production, whether in-class by answering questions or by reproducing proofs on their own that they may have already seen. Each of these instructors viewed similar notions about learning in having students be active in their courses and attended to providing opportunities for students to engage in the course.

While the instructors provided similar ideas about learning, they diverged on their primary foci in describing the aims of the course. All instructors had a shared focus on advanced mathematical content and thinking more broadly with Instructor A discussing apprenticeship into research mathematics, Instructor B stating that 90% of the course is "what it does for you as a mathematics learner" and Instructor C explaining the course as an "introduction to more advanced mathematics." The instructors also all valued abstract algebra content-specific aims, such as better understanding underlying mathematical systems and structures students have seen. However, the respective weights and interpretations of each component differed. Throughout the interview, Instructor A tended to focus on understanding the concepts specific to abstract algebra, Instructor B focused on the problem-solving involved in proving and sense-making, and Instructor C focused on developing knowledge to succeed in constructing formal proofs.

We believe the similarities and differences in beliefs, as expressed in the responses to how students learn and the aims of the course play a large role in the questions asked in class. All three instructors believe students should be active in their learning, and this manifests in different ways through the questions. Further, we hypothesize that the belief in the purpose of the course also interacts with the questions asked by further pushing their narratives in what the students should be focused on when discussing or contributing to the content.

Throughout the interview with Instructor A, we saw many references to the importance of having students wrestle with complex ideas within class and a focus on abstract algebra specific content. For example, when asked about the purpose of turn-and-talks (a frequent occurrence in Instructor A's class), Instructor A stated that they want to get "more students actively involved in the conversation. And give them a chance to tackle something that is kind of complicated." For example, Instructor A gave students question prompts such as, "What in the world is a quotient group?... And I don't care if it's a formal definition or an informal explanation, but what is a quotient group for us?" (Other type question). This question had students actively engaging in their learning but also focuses them on the abstract algebra content of the course. Instructor A provided further rationale that they choose to ask questions about content-related issues that might be "stumbling blocks" for students. For example, Instructor A prompted another turn-and-talk sequence with "What is the image of G? What do we mean by that? What is that thing representing?" (Other type question). This prompt focused students on attending to the difference between phi as a function and phi(G) being the image of a function. They chose the turn-and-talk mechanism to specifically give more students opportunity to talk and actively develop their conceptual understanding. This reflects the stated value of having all students draw on their knowledge and participate in making sense of complex ideas.

Unlike Instructor A, Instructor B was using curriculum materials that were developed externally. His value on problem-solving led him to note that without this task he may have "handed off actually more of it to the students" in terms of constructing the proof rather than just comprehending it. Instructor B's focus on process and problem-solving came through via questions even though his lesson contained many of the same features as Instructor A's. For example, Instructor B prompted his students to construct an isomorphism map that takes a coset to its image (first requesting what to call the input (convention question) then where it might map to (next step question)). He noted, "I kind of wanted students to experience coming up with that." Instructor B further added that this also gave students more agency, stating "I feel like if I can hand a little bit of that agency of coming up with the map off the students, then then they own a little bit more of that now." A student then suggested mapping to the representative element ($\beta(aK) = a$). Instructor B then asked, "So what might be problematic about saying this image is going to be just lowercase a here?", an *other* type of question. Instructor B is encouraging students to engage in analyzing their mistakes and rectifying, a key part of problem-solving. Another example is during the student presentations of each portion of the FIT proof. Instructor B gave students the prompts "focus on helping the class understand why this stuff is happening. Why did they do this?" Instructor B focused on problem-solving and processes, allowing students to be the owners of their learning and frequently putting them into situations in which they can productively struggle with the concepts and the proving process.

For Instructor C, many of his questions asked for next steps and facts during the proving process. These questions were asked to engage students in the production of the proof. He explained that "students will tune out if they don't feel ownership in what you're doing right, so that's certainly… if I am going to do something, I want them to be interacting with me." Instructor C further elaborated that in an instance of a complex theorem, such as the FIT, his role is to break the proof into "bite sized pieces" for students to develop understanding of the idea in each of the pieces. For example, Instructor C asked the proof framework question "What else do we have to do?" This question had students attend to the different pieces of the FIT proof, specifically the different pieces of showing a mapping is an isomorphism. Instructor C also modeled the types of actions students would want to take in their own proving endeavors by asking next steps questions ("How can I use that ψ is onto?") and for definitions ("So what does ψ from A to B being a homomorphism mean?") to contribute to the proof construction. Instructor C noted that one of the major goals of the course is for students to use definitions to structure proofs and that students struggle with this idea. Instructor C's way of creating active learning is to engage students by asking small, manageable questions for the students to handle while he supports them in using the formal proof system, definitions, and attending to appropriate precision.

Discussion

We selected a common lesson focus across three instructors to better understand the nature of questions asked in an advanced undergraduate class and ultimately the rationales for selection of questions. Two of the instructors implemented an inquiry-oriented lesson where students engaged in comprehending the proof of the First Isomorphism Theorem. The third instructor presented the theorem and constructed its proof through an interactive lecture. Our first contribution is illustrating that the three instructors had many commonalities in terms of how they believed students learn. All instructors discussed students being actively involved and doing mathematics. Furthermore, throughout the interviews, all three instructors talked about students taking ownership over the mathematics in the class. However, we can note that the type of activity asked of the student varied. Instructor B had much of the activity divided between group work and whole class instruction with a focus on what students could construct or problem-solve. Instructor A used a combination of group work, but also a turn-and-talk strategy where students engaged with partners briefly before responding to whole class discussion questions about points of difficulty related to the abstract algebra content. Instructor C used interactive discussion focusing on targeted questions that allowed students to contribute to the construction of the proof while also modeling ways to structure a proof based on using formal definition.

As noted in Melhuish et al.'s (2022) literature synthesis, the choices that instructors make in advanced classes are well grounded and rational in view of pedagogical goals. Instructor C provides additional insight into the results of Paoletti et al.'s (2018) paper on lecture instruction in proof-based courses. The questions Instructor C asked were in service of students being both actively engaged in the proof construction process, while also being constrained enough such that the instructor can model nuances in this new way of thinking: using definitions to construct proofs.

In contrast, Instructor A and B would have been considered anomalies in terms of their question profiles; however, quite similar to each other. However, where we saw substantial differences was in their questions in the "other" bin. Instructor A frequently used their knowledge of where students might struggle with abstract algebra ideas and notation to provide students time to recall prior knowledge and use their own words to make sense of ideas. Instructor B commonly focused on elements of problem-solving and letting students construct components where possible. These results contribute to the larger narrative about instruction in inquiry settings and surface somewhat distinct questioning profiles.

The overarching beliefs about course purpose provide some insight into these differences with Instructor A focusing heavily on abstract algebra content, Instructor B on the problem-solving process, and Instructor C on formal proofs and their connection to definitions. If we turn to Alcock's (2010) identification of four modes of thinking in proof classes, we could suggest that Instructor C tended towards syntactic thinking (generating proofs of statements by formal structure), Instructor A towards semantic thinking (developing understanding of a statement via attention to concepts), and Instructor B towards creative and critical thinking (examining objects to support proving and checking correctness.) Of course, any such classification would oversimplify the instruction and instructor rationales as elements of each thinking can be identified across instructors. Overall, we suggest that these orientations may play a more substantial role in questioning types in an advanced class than more general beliefs about learning and mathematics which tended to be rather uniform (at least from the surface) for our three instructors.

New Graduate Teaching Associates and Student-Centered Instructional Methods

Christopher Gibson
San Francisco State University

The importance of student-centered approaches took on new importance when the COVID-19 pandemic caused a tectonic shift in college instruction in 2020. In Fall of 2021, I reached out to all 13 of the new graduate teaching associates (GTAs: graduate students who were instructor-of-record for undergraduate courses) in the department. Eight of the 13 completed three rounds of survey and two rounds of interview. The goal was to find out what they knew about student-centered instruction and how that changed over time. GTAs spoke of the importance of supporting students in evaluating knowledge claims, learning how to learn, how to collaborate, and how to seek help. Their greatest opportunities for professional growth at the end of the year were with teaching that supported students to: become capable of self-assessment, to be resilient, and in building skills in what to do when they (students) do not know what to do.

Keywords: graduate teaching assistant, graduate teaching associate, GTA, novice instructor, student-centered

Many departments rely on graduate students to teach introductory courses and course-adjacent lab/discussion sessions. Such teaching experiences provide financial assistance to graduate students and reduce the workload of the faculty (Muzaka, 2009). There has been evidence that the work of graduate teaching assistants and associates (GTAs) leads to increased retention of undergraduates (Zehnder, 2016). Also, undergraduates learn more and have higher pass rates in classes that de-center instructors (e.g., where class time is spent on activities, collaborative group work; Freeman et al., 2014; Laursen, et al., 2014). Over the past 30 years more effective support for GTAs to learn about teaching has emerged (Deshler et al, 2015). An additional factor in the development of teaching skills since 2020 has been the COVID–19 pandemic and the formidable challenges of synchronous online instruction (Lopez, 2021).

Activities and discussions about teaching, course-specific instructor interaction, and, more generally, working with graduate student teaching-peers increase GTA confidence and the desire to teach in the future (Ellis, 2015; Stes et al., 2010). Graduate students have little prior experience with instruction that is student-interactive (Oleson & Hora, 2014). Yet, due to changes in K-12 education, today's graduate students are likely to be teaching undergraduates who do have experiences with student-interactive mathematics instruction (Yonezawa, 2015). In analysis and reporting results, I used Goodyear and Dudley's (2015) theoretical perspective that describes types of engagement entailed by student-centered approaches.

This study, at a large master's-granting institution, explored what knowledge about student-centered instruction GTAs built in their early experiences of teaching. The courses taught by GTAs as instructor-of-record were pre-calculus, business calculus, and a statistics co-requisite support course. Each of the courses had established curricula (e.g., materials for activities and assessment) and regular course coordination meetings. GTAs in this study were offered several forms of support for learning about teaching. There was a week of pre-semester workshop sessions, university-sponsored professional learning opportunities, and a 3-hour per week semester-long course in the mathematics department. This course, Mathematics Graduate Teaching Workshop, focused on developing and refining teaching skills for student-centered instruction. Half of the GTAs in this study also participated in one or more university-sponsored "Teaching Squares" – where four instructors agree on a topic (e.g., "making group work work") and commit to meeting for at least ten hours across the semester as they rely on each other to address the shared topic in their own teaching. The research question driving the study was: *How does GTA knowledge about student-centered instruction develop over time when GTAs are in online professional development for online teaching?*

Methods

Participants

Many GTAs at the study site had little to no experience with active student-centered instruction as either learners or teachers. The new GTAs in the study were also dealing with online struggles. The GTAs were new to synchronous technology for teaching, particularly for generating and maintaining online student interaction. To recruit participants for this research, I sent an email to all of the 13 new GTAs in the mathematics program in Fall 2021. Of these, 9 consented to participate and 8 of the GTAs completed all three surveys and both interviews. The pseudonyms of participants encode some basic information. One syllable indicates a person with no teaching or tutoring experience or professional learning about teaching. A two-syllable name indicates a person with some experience as a tutor or teacher of groups of people but no formal preparation for it. A three-syllable name is used for people with at least some experience in both professional learning for teaching and with tutoring or teaching groups of people.

Instrumentation

The data gathering tools in this study were three surveys and two interviews. There was a survey at the beginning of the Fall 2021 semester with a follow-up interview mid-semester. There then was another survey at the beginning of the Spring 2022 semester with a follow-up interview mid semester. Finally, there was one last survey at the end of Spring 2022. The main survey item for this was repeated across all three surveys: *In a few sentences, please explain what "student-centered instruction" means to you.* Surveys contained other questions. Survey 2 had a set of questions that asked GTAs to consider their teaching from their students' point of view. Survey 3 asked for GTAs' reflections on student-centered teaching and what they had learned during their professional activities across the year and a set of questions about personal experiences as learners with student-centered instruction. I conducted two follow-up interviews with each participant using the Zoom web conferencing tool. Each GTA consented to recording of each interview. Interviews were completed by mid-Fall (#1) and end of Spring (#2).

Data Analysis

There were three questions directly about student-centered instruction in survey 1, two in survey 2, and one in survey 3. I used three coding passes through that data to write a summary of each GTA's progress over time, as reported in the Cases section of the results. Interviews were transcribed into a spreadsheet, one row per utterance (i.e., a complete thought, a new thought or topic was a new utterance). I assigned a code to each row. The initial code ranged anywhere from one word to a sentence and was intended to capture and summarize the essence of the utterance. After this initial coding of each interview, I went through each interview again. The goal of the second coding was to consider each of the other interviews when generating new categories that grouped together initial codes that had something in common. In some cases, the commonality was the topic, like "first week expectations." In other cases a new category code connected across initial codes. The third pass through the interviews involved noticing themes across the existing codes. I used pivot tables to organize and review utterances and categories (from the second pass). From the interviews there were a total 537 utterances across 19 different themes. The next section includes descriptions of the central, most discussed, themes.

Results

First, I share the main themes that emerged from the interviews. Then I connect the themes and survey findings to directly address the research question through cases that illuminate GTAs' thought processes while they were trying to implement student-centered instruction as a first-time instructor. In what follows, "a few" means two to three, "several" means three to four, "many" means at least five, "most" means six or more, and "all" means all who responded.

Knowing and Doing Student-Centered Instruction

The challenges of implementing student-centeredness. In interview 1, a few of the interviewees had a similar statement to Patricia who said "I'd like to know where the line crosses from student-centered teaching to like babysitting and hand-holding." Many reported struggling with a different teaching style than they were used to themselves. Robert found student-centered instruction challenging because it required more of him than he had expected:

> *Robert:* To be student-centered they (the instructor) need to put a lot of effort into the way they lecture or design the class because you need to have enough activities that need to be engaging enough, it can't be too difficult, but it needs to drive the point (of the lesson).

Patricia also suggested the department's courses had a higher pass rate than first-year courses at other universities because student-centered instruction made the course too easy for students. The following semester, in interview 2, a few GTAs discussed dealing with student push-back. Queenie said, "I felt like every time I tried to implement anything student-centered or group worthy my students would kind of riot a little bit." Also, most of the GTAs reported having a tough time balancing students taking the lead and the demands of keeping "on track." For example Oliver reported, "I might be intervening too early in group work and telling them the answers before they can figure it out, but …we only have so much time."

Learning without a referent experience. In interview 1, some GTA comments agreed with Queenie's, "Encouraging students to do math in a student-centered way . . . I think it's very difficult for me. I never even experienced it; I don't know how I can implement it." Many of the interviewees weren't sure what they would like to learn, with Oliver saying, "There are things that I don't need to know and I can point to those easily, but the thing is I don't know what I need to know." In interview 2, a few of the GTAs felt it was hard to implement some of the lessons from the workshop, for example:

> *Tom:* I can't say that I always saw the point of what we were talking about [in the workshop] ...We were being taught about a bunch of things without really being told how to actually go and use that knowledge to improve our own teaching.

At the same time, a few female GTAs encountered new experiences (e.g., with male students) that they did not know how to deal with, as an example:

> *Patricia:* I find myself constantly trying to make sure that I'm keeping up a very professional demeanor and the right level of respect and professionalism. I haven't heard any of my male peers speak about that . . . I think it would have been helpful to have a discussion about how to handle something like that.

Student participation, engagement, and communicating with students online. There were many comments about black screens and frustration at trying to get students engaged and not being sure how to change that, for example:

> *Robert:* I was expecting college students to want to get a good grade and be sort of motivated . . . So, on the first day of class, everything [cameras and microphone] was turned off. No people are really talking. Had to overcome that.

Some GTAs talked about reaching out to students who were falling behind. The Graduate Teaching Workshop helped Patricia figure out how, it helped her in "knowing how and when to reach out to students who are not staying caught up on work or showing up to class all the time." In interview 2, GTA comments focused on disappointingly low attendance and disengagement by students in Zoom class meetings. GTAs noted "fluctuations" and "students seeming lost." For all the GTAs, arriving in a silent breakout room and eliciting any response was a recurring challenge in their first semester of teaching. Several GTAs echoed Queenie who said "online it was like pulling teeth to get them to share their screen." Sandra had challenges trying to communicate with students who were not doing the work saying:

> *Sandra:* Students who wouldn't show up to class and put in effort, they still wanted to pass, but they weren't doing any work. So having to reach out to them and figure out what was going on was challenging.

This sentiment was shared by most and they all struggled with connecting with students online. All of the GTAs who later taught in person the second semester noted an improvement in communication and student engagement.

Less frequent themes that emerged from interviews. Though not universal, multiple GTAs reported on: learning to be a teacher and what made them feel more like a teacher, giving and receiving peer support, joys and challenges of planning, time management, working with the university's Learning Management System (Moodle), grades and grading, and balancing the role of teacher with other roles (e.g., graduate student).

Cases: How GTA Knowledge about Student-Centered Instruction Changed Over Time

This section draws on survey and interview data to offer five cases that answer the research question. These cases characterize five ways GTA knowledge on student-centered instruction changed over time. The primary value of the surveys was the snapshots of GTA knowledge at different points in time. In this section, I use the seven touchstones from Goodyear and Dudley (2015) to organize the comparison of the open-ended survey responses across time and link that information to the interview themes. This framework uses seven ways teachers support engaging students in: 1. how to learn; 2. how to collaborate; 3. how to evaluate knowledge claims; 4. how to seek help; 5. how to become (formative) assessment capable; 6. how to be resilient; 7. what to do when they do not know what to do.

For each GTA, I report on the evidence from the survey items and the previously discussed themes to characterize the change in that person's knowledge about student-centered instruction and indicate theme by #1 through #7. I have grouped the cases where there were large similarities (e.g., the growth for Nicholas was similar to that for Mateo and to save space only Mateo's case is included). At the end of the section, Table 1 summarizes the results.

Case A: Mateo (& Nicholas). Mateo's first definition of student-centered instruction was that "it is more about what the student is doing rather than the instructor." He also mentioned how student-centered instruction "is about conceptual change as opposed to information transmission" and that it "related content to what the student already knows" with a focus on the "development of learning skills." His definition showed evidence of his knowledge including supporting students in learning how to learn (#1). In survey 2, Mateo said that student centered instruction "means giving up most of the control of what happens in the classroom to the students," which suggests evidence of attention to supporting students in decisions about how to learn (#1). Mateo noted that he felt that he was effective at providing feedback to students, with a focus on his job of assessing students rather than supporting students to assess themselves. His third definition stated that "running more carefully-designed activities in groups" was important to student-centered instruction. This suggests knowledge about supporting his students to collaborate (#2). In interview 1 he realized the importance of wording questions to get answers that aren't just a yes or no which would promote critical thinking. This could be considered evidence of him supporting his students to evaluate knowledge claims (#3).

Case B: Oliver. Oliver's first definition stated that a "student-centered approach to instruction focuses on how students learn rather than the material." He also mentioned a need to "give space for students" and to allow for "a hands-on approach to learning" to accomplish this. This showed evidence of knowledge for supporting students in learning how to learn (#1). His definition of student-centered instruction in survey 3 (he did not respond to the prompt on survey 2) included that "student-centered teaching puts more weight on the will of those who lack knowledge [the students]." Meaning that "students create the focus of the course, rather than the teacher." This definition also suggests evidence of knowledge related to students learning how to learn (#1). In interview 1 Oliver noted the value of student-centered instruction saying that "in order to understand something you should be working with your hands." This suggests further evidence related to students learning how to learn (#1). In interview 2 he said he was maybe "intervening too early in group work" This awareness about giving more time for struggle, supporting students to persist in problem solving provides some evidence of his knowledge in supporting his students to evaluate knowledge claims (#3).

Case C: Patricia (& Robert). In the first survey, Patricia said that she thought student-centered instruction was "focused on student interests and needs" and that it included "getting students involved in the direction" of the course. This could be evidence of knowledge of supporting students in how to learn (#1). In survey 2, Patricia's definition of student-centered instruction included "creating a classroom environment in which students have an equal voice with their professor" and "actively doing work rather than passively listening to a lecture." This gave evidence of her growing knowledge about supporting students in how to learn (#1). She said she was effective at "giving helpful feedback" and encouraging "students to ask myself and each other questions." This was evidence of her knowledge expanding to include supporting students in how to seek help (#4) and how to collaborate (#2). In survey 3 Patricia said "the focus is on getting the student actively participating in their own learning" (i.e., supporting students in how to learn, #1). Patricia also said she used group activities instead of lecturing so that "students can explore concepts and learn from each other" (collaborate, #2). In interview 1, Patricia said the orientation workshop helped her be more supportive of students who needed disability resources (knowledge growth related to supporting students to seek help, #4). In interview 2, she said the workshop course helped her "to ask better questions that would lead to more discussion, rather than just like a yes or no answer." This encouragement of critical thinking provides evidence for supporting students in evaluating knowledge claims (#3).

Case D: Queenie (& Sandra). Queenie's definition of student-centered instruction in the first survey mentioned "allowing students the space to form their own understanding and ask questions". This shows evidence of knowledge related to supporting students in learning how to learn (#1) and how to seek help (#4). She also said that student-centered instruction "requires group work and students discussing what they are learning" while giving "the tools to explain back what they are figuring out." These show evidence of knowing to support students in how to collaborate (#2) and how to become formative assessment capable (#5). By survey 2 Queenie was less sure about a definition for student-centered instruction, saying "all teaching has to be student-centered" since teaching students is the focus. She also said that "teaching becomes motivational." In survey 3 her definition of student-centered instruction was mostly the same as her first definition saying that it included “giving space” and for students to “come to me with their own ideas.” In both interviews, Queenie mentioned implementing group worthy activities – evidence of her knowledge including support for students to learn to collaborate (#2).

Case E: Tom. Tom’s definition in survey 1 stated that student-centered instruction “describes an approach to teaching where each student’s needs and background are considered.” This could be evidence of knowing to support students in a variety of ways in learning how to learn (#1). He also mentioned that it “involves a high level of student feedback and interaction.” This statement provides some evidence of knowledge about supporting students in how to collaborate (#2) and how to become formative assessment capable (#5). In the second survey Tom stated that student-centered instruction puts “students in the driver seat” and makes students “active members in the classroom and in their own learning.” This is more evidence related to how to learn (#1). In interview 1 Tom said, “I’ve tried to be more careful in how I handle student questions... thinking of understanding why something happened, not just what happened.” This showed evidence of him supporting his students in evaluating knowledge claims (#3). In interview 2 Tom said he would like to learn to create activities that will help students discover knowledge on their own. This was evidence of supporting students in learning how to learn (#1).

Summary. Table 1 summarizes, grouped by case, what GTAs described in defining student-centered learning. Notice there was evidence for all GTAs of supporting students in learning how to learn (#1) and, with one exception, learning how to collaborate (#2). Most of the GTAs had evidence of supporting their students in evaluating knowledge claims (#3). For several of the GTAs there was evidence of supporting their students in how to seek help (#4). There was sparse evidence of GTA awareness or use of supporting their students in how to become assessment capable (#5), how to be resilient (#6), and what to do when not sure what to do (#7).

Table 1: Summary of GTA reporting on aspects of student-centered instruction.

Case	Name	1. learn	2. collaborate	3. evaluate knowledge claims	4. seek help	5. become assessment capable	6. be resilient	7. what to do when unknown
A	**Mateo**	X1, X2	X3	Y1				
	Nicholas	X2	Y1, X3	Y2				
B	**Oliver**	X1, Y1, X3		Y2				
C	**Patricia**	X1, X2, X3	X2	Y2	Y1, X2			
	Robert	X1, X2	Y2	Y1	X2, Y2			
D	**Queenie**	X1, X3	X1, Y1, Y2, X3		Y1, X2			
	Sandra	X1, X2, Y2, X3	X1, X2, X3		X1, X2, X3			
E	**Tom**	X1, X2	X1	Y1		X1		

Note: X1=survey 1, X2=survey 2, X3=survey 3; Y1=interview 1 and Y2=interview 2.

Discussion

The question driving the study was: How does GTA knowledge about student-centered instruction develop over time when GTAs are in online professional development for online teaching? The short answer: Slowly. The surveys indicated that the majority of the new GTAs at the master’s granting study site in the 2021-2022 academic school year built substantive knowledge about student-centered instruction (as indicated in Table 1). At the same time, consideration of each GTA experience shows differences in the nature and timing of those changes. In Survey 1, most GTAs' ideas seemed to be based on the literal meaning of the phrase "student-centered." By Survey 2, GTAs had a formal definition and talked about what the goals were for the *students* in student-centered instruction but said little about what the *instructor* did. As time progressed, more GTAs included the teacher, using examples from their own instruction in Survey 3 and some expanding on ideas in Interview 2 with additional classroom examples.

Not only GTA knowledge changed. The GTAs perceptions of themselves and students changed in many ways. GTAs were not just learning about student-centered instruction for teaching, many were experiencing it as a student for the first time in their own graduate courses. Most of the GTAs had not experienced student-centered instruction as a learner before teaching. Moreover, no one reported they had been a college student in the class they were teaching. Finally, for most, experience of online learning was only under the conditions of the pandemic.

In the surveys and interviews all of the GTAs mentioned supporting students to learn how to learn as a goal, but did not offer specifics about what instructional moves or approaches might achieve that goal in the examples they provided. GTA focus was on "getting" students engaged – a teacher-centered view about having students look at and do the things the teacher and/or curriculum wanted/expected. That is, for #1 in Table 1, all of the GTAs appeared to include learning how to learn as an important component in student-centered instruction, but they were still working on how to accomplish it.

Throughout the surveys and interviews all but one GTA mentioned the use of group work as an important part of student-centered instruction. They all seemed to accept the idea that working with others could be an effective form of learning in addition to or instead of lecturing only. The one GTA, Oliver, who did not mention it was using a curriculum that had activities that required group work, but he did not directly mention using group work in the surveys and interviews. Thus, for #2 in Table 1, the GTAs in this master's granting department were unlike the GTAs in previous studies among doctoral students (Beisiegel, 2012, 2017, 2019).

Directions for future work include:

- Following GTAs who start in a master's program and continue on to a doctoral program; capturing what ways their PD in their master's program may have influenced their knowledge about teaching and how that compares to their peers who went directly into doctoral programs.
- Purposefully examine the future graduate experience and teaching development of today's undergraduates, who are experiencing student-centered instruction (unlike the GTAs in this study).
- What are the benefits and pitfalls of extended PD for master's program GTAs who are instructor-of-record in terms of frameworks in previous work (e.g., Beiseigel, 2019)?

Limitations and Delimitations

The main findings are from a study of a particular GTAs in the specific context of teaching online synchronous courses at the study site and are not intended to be generalizable. Rather, the goal is transferability: giving sufficient detail to support the reader in interpreting the results for a situation similar to that presented here. This small study did not gather or analyze information about societal structures and systemic influences (and consequences) of student and instructor perceptions. Nonetheless, a useful example can anchor future research and GTA development.

Acknowledgments

First, thanks to the participants for their time and energy in doing the surveys and interviews. Also, my thanks to my thesis committee and reviewers for improving the quality of this report.

Exploring How Computation Can Foster Mathematical Creativity in Linear Algebra Modules

Sarah D. Castle
Michigan State University

The mathematics education community has simultaneously experienced a call for mathematical creativity and the implementation of computing within the classroom. What has not been explored are the ways in which these two calls are complementary. This study investigates how computation, enacted through coding, can bring about mathematical creativity within a series of linear algebra computational notebooks designed using the Understanding by Design framework. Specifically, through the analysis of a group of students, this paper highlights how a computational prediction and reflection cycle enables exploration and student originality while also facilitating connections to multiple representations.

Keywords: Computation, Linear Algebra, Mathematical Creativity, Coding

Mathematics – a field of beauty, creativity, and innovation, yet what is echoed by students is not how mathematics allows students to explore, but rather the ways in which it constrains and does not necessitate creativity (Silver, 1997). Students state mathematics is "a dead subject [with] hundreds of methods and procedures to memorize that [students] will never use, and hundreds of answers to questions that they have never asked" (Boaler, 2022, p. 35). This decline in creativity within school mathematics has coincided with the evolution of computation. Computation is now a scientific pillar (Skuse, 2019) as well as a pedagogical tool within the mathematics classroom (Castle, 2022; Lockwood, 2022). Further, many students associate coding with freedom to create and express themselves (Isomöttönen et al., 2020) which is in sharp contrast with students' views of mathematical creativity. Therefore, a natural question that arises is what if computation could offer mathematics education more, specifically with relation to mathematical creativity. This study is part of a larger research project that aims to address the ways in which computation enacted through coding can aid mathematical understanding and promote mathematical creativity, while preparing students for careers in the upcoming computational world. Within this paper, I seek to answer the following research question: *What are the affordances and constraints that computation, as enacted in coding through a creative environment, provides for students' learning of linear algebra concepts and procedures?*

Theoretical Perspective

Cultural Historical Activity Theory (CHAT) is based on the of the work of Vygotsky, Leontiev, and Engeström (1987). It provides a framework for studying collective activity, specifically emphasizing the role of mediated activity, a key consideration when considering computing. Within CHAT, subjects are the people involved in the activity, whereas the object is the aim of the activity. Subjects' actions are mediated by artifacts or tools. Further, it is imperative that individuals are understood within the context of their actions, and that the social elements must be brought in. Therefore, within this study individuals cannot be divorced from their group and context. There are different levels at which you can analyze the relationship between subject and object: activities, actions, and operations (Leontiev, 1974). Activity is composed of actions, and actions are composed of operations (Batiibwe, 2019). Operations are automatized or routinized behaviors and many times do not require conscious effort (Jonassen & Rohrer-Murphy, 1999). The conditions determine the operations. At the next level up, the goal an individual holds results in actions, but the goal is also affected by the conditions. This is the functional level that uses planning and problem-solving to complete the activities. Finally, it is motive that generates activity, which is composed of actions, and the motive determines the goal. This hierarchical structure is used in order to operationalize activity theory within observations, as there are multiple units of analysis that can be used to build up the overall activity. As the action level is what is of interest within this study, applying this framework necessitates establishing what actions are manifestations of mathematical creativity, thereby providing a way of documenting how the relationship between the students and the aim (mathematical creativity) is mediated by the tool (Jupyter notebooks).

Mathematical Creativity

In order to engage with the notion of mathematical creativity it is important to define what I mean, as there is a plethora of definitions. Based on literature (Haylock, 1997; Savic, 2016; Savic et al., 2017; Silver, 1997; Sriraman et al., 2013) I define mathematical creativity as:

> A process that can be fostered, is context-dependent, and manifests in fluency, flexibility, and originality with respect to the mathematics which results in the connection and abstraction of ideas that bring a new perspective that is of use to the community and is many times the result of prolonged work and reflection.

It is important to note that the focus is on creativity as a process, rather than a trait. This is an important distinction as it means there is the possibility to design opportunities to foster creativity and it is not a stagnant attribute of students. Further, I draw from mathematical creativity rubrics (Blyman et al., 2020; Henriksen et al., 2015; Savic et al., 2017) in order to establish an operationalization of mathematical creativity - specifically six dimensions of creativity: *originality* (ability to try novel or unusual approaches towards a problem), *flexibility* (ability to use multiple methods for solving the same problem), *fluency* (ability to apply the same mathematical idea, concept, or procedure, to a variety of problems and situations), *visualization* (development and use of illustrations, either physical or mental, to clarify or present concepts), *elaboration* (ability to establish meaningful connections between concepts), and *risk* (willing to take action where result is unknown, or a novel approach, to advance problem solving process).

Methodology

This paper reports on data collected from a study investigating the role of computation in developing mathematical creativity. This study consisted of 8 different students recruited from an introduction to computational modeling course (Silvia et al., 2019) who met recurringly with a small group (2-3 members) for a total of 6 weeks. Each week students engaged with a Jupyter Notebook designed to introduce new linear algebra concepts while fostering opportunities for mathematical creativity and understanding for a total of two hours. Afterwards students would complete a reflection about the module. Additionally, I conducted semi-structured pre- and post-study interviews with all participants as well as pre- and post-surveys. For the purposes of this paper, I will focus on a sole group composed of three students: Ivy, Alex, and Kylie, all of whom were non-mathematics STEM majors. This was done for space considerations, allowing an in-depth exploration into their experience across the study and for a more nuanced understanding.

Module Design

An underlying portion of this study centers around the design of the computational modules, accomplished by implementing Understanding by Design framework (Wiggins & McTighe, 2005). This process employs backwards design where the learning goals are first established, then potential evidence for meeting the goals, and finally the activity design itself using the prior work. A textbook, syllabi, and curriculum analysis yielded potential topics and desirable understandings. As this was not an official course, nor a prerequisite, I had latitude in selecting the broad understandings that the modules would center on, specifically for students to develop geometric understandings of linear algebra ideas and properties, as well as how to represent and model systems using their understanding of these concepts. Learning goals were established for each module and the evidence for meeting these goals were written out. Finally, pairing the tasks with opportunities to foster mathematical creativity as well as computational pedagogies such as use-modify-create cycles (Lee et al., 2009) resulted in the final construction of these modules.

Data Analysis

For the results shared within this paper, I transcribed and coded all interviews, observations, and reflections along the mathematical creativity dimensions and whether they were mediated through the notebook. The unit of analysis for coding was individual actions, as determined from the CHAT framing. I then wrote analytical memos detailing the initial themes of mathematical creativity followed by grouping codes along the dimensions of creativity and then along whether the action was mediated, resulting in sets of common elements. These groupings gave rise to two main themes within this set of students' experiences: (1) computation enabled experimentation via prediction and reflection cycles and (2) prediction and reflection facilitated the connection of multiple representations.

Results

Computation Enabling Experimentation Within Mathematics via Prediction and Reflection

During the fifth module, students were introduced to Markov chains. They wrote a function that would take in a state vector, a stochastic matrix, and the number of observations, and return the final state vector. They used the function to predict the population levels of a related suburb and city after 1, 2, and 5 years. The following exchange occurred after writing their functions:

Kylie: I'm just like running them all. Uh, it basically just keeps going in the same direction.

Alex: I think eventually it would, I don't know if we did, like, a thousand that would probably make our computers freeze, but um, would eventually it balance out somewhere.

Ivy: Maybe we can try like 10 and see what happens.

Alex: Maybe balance out, balance out isn't the right word. But eventually it would like 50-50, the directions would've reversed. Yeah.

Ivy: Let's try this. Yeah. It reversed at 10. So, the city is less than the suburb.

Alex: I mean like eventually they would get like eventually a year would go by and the city would increase while the other one would decrease.

Within this example, a key point is that students were never explicitly prompted to explore beyond the 5-year mark. Rather, they were designing a function in order to be able to easily model the Markov chains, and then testing that function to check predictions for a model. After completing the task at hand, the group demonstrated both originality and risk by asking a question that was of interest with a coupled prediction. Note that they had not specifically encountered the concept of steady state yet. After this prediction they tested their hypothesis, using their function, and then reflected on the output itself. Within this example, the computational environment enacted through coding enabled a cycle of prediction and reflection, which ultimately later led to a concept of steady state vectors. The coding enabled function creation, which allowed for an efficient way to engage in experimentation. The students were able to create a prediction and then check their result.

The fourth module focused on linear transformations and matrices as linear transformations. Prior to the discussion, the students had just finished up with figuring out how to take a matrix of points that defined a cat outline and double the cat image in size. They had experimented with this and graphed the resultant set of points. The next prompt within the notebook was *"It will now be your turn to explore! See what happens when you try different matrices. Use the cell below to document your thoughts or whatever you find easiest! Try and state what you think will happen before you run the code"*. This was followed by multiple cells designated for students to try different matrices. This portion was specifically designed for students to experiment.

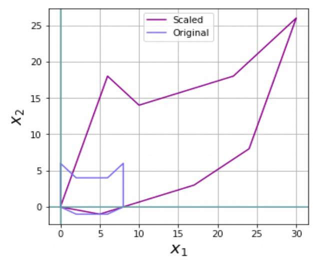

Figure 1. The output from Ivy's Jupyter Notebook when using a matrix transform along a set of points.

Ivy: I wonder if you like had like 3, 1, what would happen like anything that's not a zero.
Alex: Or you wanna do 3, 1, 3, 1. *(Referring to a 2x2 matrix)*
Kylie: Do you think it will work?
Ivy: Um, we can say, we don't think it will work.
Alex: What do you mean? What do you think?
Kylie: I guess it will just change. Like it'll disproportionately change the width and length.
Alex: Uh, I think the X values will be three times X plus Y and the Y values will be, uh, Y plus three X. So I think it, the X and Y will turn out to be the same, if that makes sense…
Ivy: So you think that it's gonna, they're gonna be multiplied by three, but then the value, like a value's gonna be added to them as well…
Kylie: Okay. And then what do we think that's gonna do the graph. It's gonna make it larger and move it?
Alex: I don't think it'll look like a cat anymore.
Kylie: Yeah. It's gonna move him around. So it's gonna like break up the lines. That is correct. It looks really weird. Oh! *[Output graphic shown in Figure 1.]*
Ivy: It kind of looks like it just stretched linearly. Like, kind of like on a line.
Kylie: It's it looks like if you took a side of it and just pulled yeah. You like took one of the cat ears and pulled it.
Ivy: So it's still cat.
Alex: I think it, it kinda looks like you took, like, we took the lines and multiplied them each by like some number, but it looks consistent, you know? You know what I'm saying?
Ivy: Kinda like, it just looks linear to me. I don't know why.
Alex: So for the next one, what do you guys wanna do?
Kylie: What about if we did it like negative numbers?
Alex: Oh, it'll flip it over. Like the X, Y or something?

This process continued on and the students each completed 6-8 different trials, deriving their own novel transformations, and plotting the visualization. From here, students were then asked to define the matrices that would correspond to the points undergoing: reflection across each axis, lines, and through the origin, as well as contractions and expansions, and shears. During each of these phases students then took what they had learned through experimentation to abstract, make meaningful connections, and create general representations of the types of transformations and the corresponding matrix. If they were usure, then they would experiment, using the insight they gained during the first part. Then they used code to validate their approaches and show the transformation on a set of points.

During this activity, there was specific reference to 'exploring' within the prompt. However, it was previously shown that students engaged in experimentation via prediction and reflection even when not prompted. This new excerpt highlights the potential ways in which the prediction and reflection cycle can take place. Specifically, the students were able to predict the ways that a 2x2 transformation matrix would affect an image and how the corresponding vertices would shift. The experimentation highlighted their initial choice in what matrix to start with and followed by different modifications. This allowed for their thoughts to guide the exploration. Further, during this experimentation, students were not simply 'pushing buttons'. Rather, they actively engaged in the sense making and making predictions based on their current understanding of the materials. This exploration piece allows for an inquiry-oriented approach to transformations, and the computational environment is something that enabled this to be fostered, especially the visualization. This was drastically different than previous mathematics experiences for most students. When reflecting on the experience as a whole, Alex stated:

> "I know it was a math, you know, teaching us math, but it didn't feel like math the same way as like solving integral does … it was more so recognizing like what was changing … it felt much more like recognizing patterns... Yeah. Just, just figuring that out. It didn't feel so much like, step by, I move this over here and then simplify this, it felt more like, playing a game, trying to, trying to figure out the way to get to the end goal."

This quote highlights the fact that the experimentation portion felt different to Alex than previous math classes. Although he does not explicitly name experimentation, he discusses this concept of changing pieces and looking for patterns to get to the end goal, which mirrors the notion of prediction and reflection. Within the previous examples from the observations, the group engaged in making changes in order to figure out the corresponding effect, thereby developing a deeper understanding of the system. This experimentation fostered via computation countered Alex's prior notions of mathematics, and specifically gave a framing of exploration rather than following a series of given steps, thereby promoting opportunities for creativity.

Prediction and Reflection Facilitating Connections to Multiple Representations

The second area highlighted during this pilot study was the ways in which the computational environment facilitated students making connections to multiple representations. To start, consider the following excerpt from the group's sixth module. It shows the interplay between group members and the ways in which the development and running of code supports multiple representations. Within this activity, participants were provided a function that takes in three vectors and displays the corresponding parallelepiped. Kylie was sharing her screen with the group at this time, and began by plotting the identity matrix, which represents a unit cube. The group ensured the determinant was 1 since the volume of the cube was 1. They read through the plotting function to ensure they knew what was occurring and how to use the function. This is where the following excerpt picks up. The exchange has actions added within brackets in italics; also, some of the points of general conversation were removed for the sake of space.

Alex: So, let's use the columns of A as our vectors. Okay. So, um, I guess that kind of makes sense. Cause the determinant is like doing the, it's kinda like doing the cross products a couple times. Right. And cross products, like the area of a parallelogram. So anyway, um, that's our parallelepiped… Cool. What would cause the determinant of A, to be zero? Uh, if it were, how do you get a volume of zero?

Ivy: Would it be like a 2D shape?

Alex: Oh yeah! Yeah that makes sense.

Ivy: But how would we express that?

Alex: We could try different matrices. So v_1, v_2, and v_3 are probably all gonna be in the same plane is my guess. I guess. Yeah but how do we –

Ivy: Should we set one of them to all zeros? No –

Kylie: We could try it! I guess we don't need to plot it right now. We're just looking at the determinant…. Uh okay. So we are trying. Yeah. Here is our original -

Ivy: I'm just gonna change the first value to be zero for all of them. See if that does. Yeah. That is how you can do it… Cause technically you're saying v_1 has like zero value…

[Kylie then sets one of the columns of A to be 0 and uses linAlg.det() to check determinant]

Alex: Okay so that one is like on the same plane? …

[Kylie then runs the plotting code with the new matrix that has a determinant of 0]

Kylie: … How does – no. Cause it's all on the same plane, because one of them is zero. What must be true for one of them to not be zero?

Alex: They must be on the same plane

Ivy: So if we have three vectors that are all on the same plane or that they're all, oh wait, like 2d plane…

Alex: Right. Well there's no volume if they're all on the same.

Kylie: Plane. Yeah okay. No, no, okay, got it. Got it. We're good.

Ivy: Which means that they must be linearly dependent!

Alex: … Oh yeah. So we can say they're linearly dependent - if the determinant is zero.

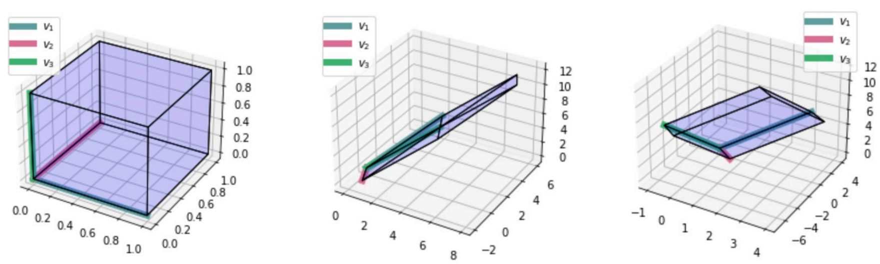

Figure 2. Visualizations Kylie created during the exploration of determinants, trying: (a) unit basis vectors, (b) linearly independent vectors, (c) linearly dependent vectors

The group then goes on to check another set of known linearly independent vectors to verify the determinant is not zero. The three visualizations produced through this experimentation and reflection are shown in Figure 2. The activity does engage the previously discussed prediction and reflection cycle, but also leverages multiple representations as well. This in turn enabled students to discover the relation between the determinant being zero and the linear dependence of vectors, proving opportunities for flexibility and visualization. During the excerpt, the computational representations were the code itself and the actual output of the code, referring both to the visualization of the vectors in 3D as well as the numerical value of the determinant. That is, they were representations that existed via the computer alone. The code itself had students decompose the matrix into a set of vectors in order to calculate the volume to determine the determinant while simultaneously using the full definition of a matrix to calculate the determinant. It was up to the students to determine the test matrices, how the matrix was then used to determine the parallelepiped, and then calculate and visualize the determinant. Besides the scaffolded plotting code, students are enacting all of these concepts, necessitating a switching between resources. Further, when they discussed the notion of determinant, they draw on the algebraic notion alongside the graphical interpretation, leading to the discovery of the impact of linear dependence on the determinant.

Computation enabling prediction and reflection, as previously discussed, means that students are maintaining a constant balance between computational representations. Namely, the code itself and the output, such as Ivy coordinating the input and execution of code with the output value of the determinant. Therefore, since students are already engaging in this process of bridging representations (lines of code and output) then there is a natural way of connecting the tradition of multiple representations, namely students balancing both the graphical, numerical, and algebraic representation. All of these representations were brought into the excerpt, and this facilitated not only flexibility but also the creation of personal visualizations and elaborations.

Discussion and Conclusion

This work highlights the potential that computation has for engaging students in mathematical creativity, specifically when enacted through coding. Within the focal group of students, this was accomplished by computation naturally supporting experimentation through cycles of coding predictions and reflections. Specifically, students adapted their code to follow their own ideas and fluidly check how this altered the result. This cycle of prediction and reflection is not new to linear algebra (Wawro, 2009) nor computation (Lockwood, 2022). However, what this study contributes is specifically how computation enacted through coding can be leveraged to bring about this cycle to promote mathematical creativity. Students naturally explored utilizing the code and engaged in this cycle with and without prompting. These cycles contained multiple dimensions of creativity, especially along originality and risk, which is consistent with research on students' epistemic agency within computational notebooks (Odden et al., 2021). Further, these cycles of prediction and reflection facilitate connections to multiple representations. During the determinant cycle, the group continually bridged and connected their code with the output produced. The modification of the code led to the determination of multiple cases of linear (in)dependence where they then pivoted to make connections between the concepts they had already encountered and the code output. This enabled for a natural bridging between the graphical, algebraic, and numerical understandings of a determinant. A key point within the literature is how students are able to develop great insight and creativity when developing geometric interpretations of key linear algebra concepts (Larson et al., 2008). This is one of the particular strengths of these specific modules but more broadly within computation enacted through coding. Many programming languages have supports built in for visualization which allows students to plot different objects that were previously unattainable by hand. Further, the act of coding coupled with students' control over the representation enable not only originality but also constant maintenance of multiple representations. Within this paper evidence was presented for how computation enacted via coding can lead to opportunities for fostering mathematical creativity through experimentation within computational prediction and reflection cycles, promoting connections to multiple representations. As the relation between computation and mathematical creativity is relatively new, future work should entail focusing on computation as a pedagogical tool for mathematics education in addition to exploring the potentially unique insights that computation offers students.

What Do Students Do To Develop Understanding of Definitions in Proof-Based Courses?

Holly Zolt
Texas State University

Anthony Tucci
Texas State University

Kathleen Melhuish
Texas State University

Timothy Fukawa-Connelly
Temple University

Advanced, proof-based mathematics courses typically include learning goals of developing understanding of the relevant content of the class. The content always includes definitions of concept in that they are foundational to theorems and proofs. This study explores what three students believe it means to understand a definition, the actions they take to develop that understanding, and the rationales they use to explain why their actions are productive. The students held divergent beliefs about what it means to understand a definition. While all cited lecture attendance and homework as critical activities in their learning, they diverged on the use of outside resources and the rationales for why they might or might not be useful.

Keywords: proof-based mathematics, student understanding, definitions, learning goals

Mathematical definitions serve an essential purpose in proof-based courses, which require students to attend to these definitions in a distinct way: as stipulated rather than descriptive (Edwards & Ward, 2004). Definitions are often provided during lectures; however, we know little about what students understand from these settings. In one of the few fine-grained studies of what students gain from specific lectures, Lew et al. (2016) described that students may not apprehend the content that professors are attempting to convey. Melhuish et al.'s (2022) recent literature review points to a lack of empirical studies focused on student learning or what students might do outside of class to develop understanding.

As understanding and using definitions constitute a major content goal of proof-based courses, we explore two primary research questions and two that provide context and explanation for the findings of the first two:

- What activities do students engage in to try to develop understanding of a definition?
- Why do they engage in those activities?

To provide context, we also explore:

- What do students believe a definition is in advanced mathematics and why?
- What do students believe it means to understand a definition and why?

Literature Review

In formal mathematics, definitions stipulate the nature of a mathematical concept, and any object that meets the definitional criteria is an example, and any that does not is a non-example. Such definitions are referred to as *stipulative* (Edwards & Ward, 2004). Alcock (2010) suggested that mathematicians desire students to understand the stipulative nature of mathematical definitions. At the same time, extant research suggests that students do not consistently hold similar beliefs about definitions (c.f., Edwards & Ward, 2004; Alcock & Simpson, 2004; Krupnik, et al, 2018), and may operate with the definitions as if *descriptive* (that is they are extracted and created from use) rather than *stipulated.* Some studies have pointed to complexities in students' thinking of definitions attending to issues of mathematical criteria and communicative goals (Zazlavsky & Shir, 2005) or ways students may reinvent stipulative mathematical definitions (Zandieh & Rasmussen, 2010).

In terms of lecture courses, mathematicians have argued that much of the work of learning, such as learning definitions, occurs outside of class (Wu, 1999; Weber & Fukawa-Connelly, in press.). This may involve homework activities (Rupnow, et al, 2020) and other types of at home activities. Yet, we know little about what types of activities students intend to and do engage in at home to meet learning goals. If we focus on definitions, we can find some papers on what mathematicians do to learn new definitions and content (e.g., Parameswaran, 2010; Wilkerson-Jerde & Wilensky, 2011). In the context of definitions, Parameswaran (2010) interviewed and surveyed a set of mathematicians finding they studied examples, used definitions to prove theorems, explored equivalent definitions, and resolved cognitive conflicts while trying to understand a new definition. Others have pointed to how mathematicians' use intuition and diagrams (c.f., Johansen & Misfeldt, 2020; Sinclair& Gol Tabaghi, 2010) in connection with formal definitions. That is, there may be reason to hypothesize that understanding a definition in a formal proof context, may also involve drawing on not just definition, but also concept image (as defined in Tall & Vinner, 1981).

Theoretical Perspective

The practical rationality framework, initially designed to analyze teacher decision making at the K-12 level (Herbst and Chazan, 2003), posits that decision-making is regulated by rationality. More specifically, the knowledge, beliefs, and goals of the teacher mediate the obligations and norms from stakeholders (Chazan, et. al. 2016; Webel 2013) and ultimate decisions. Since its development, it has been extended to investigate the students' decision making. Webel (2013) argued for attention to "both social and individual factors in describing how particular student actions come to take place in mathematics classes" (p. 25). In our study we hold that the beliefs students held and the actions that they took were rational considering the obligations placed on them and their experiences within the mathematics discipline.

Methods

The results discussed here are a part of a pilot study aimed at exploring students' beliefs about definitions. Data collection took place at a large research university in the southern United States. Our first round of data collection was an online questionnaire in which students were asked about what activities they engaged with in between classes that helped them better understand definitions and why they think these activities helped them. This survey was given to students in two undergraduate math classes (modern algebra, real analysis) a few days after their professor had introduced a new definition in class (direct products, continuity). Two students in modern algebra and one student in real analysis completed both the questionnaire and the interview.

Data Collection Methods

The goal of the survey was to document in-the-moment activities that students claimed to engage in to develop understanding of new definitions. During the follow-up interview, students were asked questions about their background, their beliefs about definitions – including what it means to understand a definition – and questions about how they come to understand definitions. For questions relating to how they developed understanding, we encouraged the students to think back to their most recent activity to understand a new definition which often focused on a homework assignment. They were also given the opportunity to respond to other contexts such as preparing for exams or their general practice with new definitions.

Data Analysis Methods

To analyze our data, we began with an open coding scheme in which each interview was first transcribed and then coded for beliefs and activities. All four authors coded Kurt's transcript for both beliefs and actions. For Kris' and Dave's transcripts, each transcript was coded for beliefs by two members of the research team and for actions by three members of the team. We then met to reconcile the coding and any discrepancies were worked out through discussion. Using these codes, we built profiles of each student that addressed the following five areas: what is a mathematical definition, what is the purpose of a definition, what does it mean to understand a definition, what actions are taken to understand a definition, why the student holds each of these beliefs. Note that these are from the student's perspective. The results of this process are addressed in the sections below.

Data and Results

Table 1. Definition Profiles of Participants

Participant	What is a definition?	What is the purpose of definitions?	What it means to understand a definition
Kurt	Rigid criteria categorizing a set of objects ("black and white, either in or out")	The purpose of a definition is to create and prove claims about objects that fit the definition.	• Determine whether an object meets the definition • Developing Intuition
Dave	Axiomatic "Foundation" of mathematics that cannot be changed	The purpose of definitions is to construct and prove mathematical propositions.	• Knowing the definition • Being able to apply the definition in proofs
Kris	Fixed and cannot be argued as incorrect	The purpose of a definition in mathematics is to contribute to the development of propositions and proofs	• Understanding its purpose • Knowing when to use in proofs

Before providing an overview of the at-home activities, we first share a brief overview of the three students' beliefs (Table 1). All the students held stipulated views of mathematical definitions with all three making explicit comments about the definitions being rigid. We also note that all shared a common view that definitions were in service of proofs and propositions. However, the three students reported somewhat distinct views on understanding definitions.

Additionally, we note that none of the students claimed to take any specific activities to learn a definition the day it was presented in class. As we detail below, they all describe some activities that they take to learn definitions, and have well-developed rationales, none are taken immediately after the presentation.

Kurt

Kurt explicitly described four activities that he engages in to try to develop understanding of a definition and we inferred one additional activity, repetition. The first three that he named are attending class, looking at his notes, and doing the homework. He also claimed to look at online videos when those were insufficient or when he thought animations might be helpful.

Kurt explained that he went to lecture diligently, took notes, and asked questions if he was not understanding. In particular, he explained for continuity,

> I've mostly been relying on lectures for that too, like the first day that it was introduced to us. I was like I don't really get it, so I just I kept like, you know, going to class and like OK like let's try this again and my professor was really good about when we were like getting in deep with continuity being like OK class.

He noted that he asked questions like, “When something isn't continuous, why does it break? Why doesn't it fit that definition? You know? Why does it break? So, I was like, can you show us like a picture of like the epsilon bubble and the delta bubble like show us like how its discontinuous function like breaks that so to speak.”

Outside of class he then sought out YouTube animations to further develop his understanding with visuals in the cases he found lecture insufficient elaborating that, “OK, here's that curve, and here's what happens when we do this and this and this, that could be really handy. That's something that's kind of you can't replicate on a chalkboard super easily, you know.” He appreciated another perspective but noted sometimes what the professor said was simpler.

Kurt also explained homework as his most valuable tool to develop his understanding of definitions, explaining that he needs to “play with [the definition] himself” and understand how to apply them in proof. This was a prevalent theme throughout the interview.

Reflection. Kurt emphasized several activities that aligned with his view on understanding a definition, including attention to examples (categorizing in or out), and developing intuition from animations (often found online.) He did not see memorizing a definition as part of understanding nor did that influence his activity and uses homework as the primary way to achieve understanding. Although Kurt did not explicitly say using definitions to prove as part of understanding, this was stated as a purpose of definitions and the primary activity for Kurt, likely reflecting the nature of homework prompts.

Dave

When we consider the actions that Dave takes to understand a definition, we can summarize his activity by saying that he believes that he tends to do better on the coursework when he simply does the homework and try to understand each question conceptually. This approach is believed to lead to remembering definitions and proof strategies. If he does get stuck there is a preference of talking with the professor, but, if necessary, he will use the internet. We noticed that Dave has a nuanced stance on the actions he takes. For instance, he will make statements such as “maybe it's just me. But memorizing does not help. I think understanding the big picture helps a lot more than any amount of memorization.” We do not take this statement from Dave to mean that he is against knowing the definition. Instead, we take this to mean that Dave holds the belief that definitions are learned progressively and through doing mathematics as opposed to the use of flash cards or other memorization tools. Also in his internet use, there is a strong preference towards seeking help from the professor before turning to the internet as the internet often lacks the ability to give insight and creates confusion with different notation usage.

In further consideration of Dave’s actions, he seems to take actions that he believes will support him in better developing his concept image of the topic at hand. During the interview Dave provided an instance in which talking to the professor was of greater benefit than the internet. In this dialog he stated

> And then [Dr. X], I went to his office hours once and I was like I don't understand what this looks like. Help me. So, then he pulls out his Rubik's Cube and he's like see how the face doesn't go anywhere. This is the stabilizer. Like I love stuff like that. I think that's way more helpful to me in the grand scheme of things than like just knowing that

definition, then trying to apply it, you know. That I can think about it better if I asked directly for help from the professor versus random Internet strangers online.

In this case, directly talking with the professor allowed Dave to develop a richer concept image of the stabilizer than turning to "random internet strangers."

The rationality for each of these actions was traced back to Dave's intro to proof course. In the following excerpt, Dave describes his experience transition into proof-based mathematics courses

> I can trace it back to intro to advanced math. Umm? There was just kind of like this. I guess wall, right? Because when, when you're like doing computation, computation, computation for years. You hit calculus 3 computation, differential equations computations. And then suddenly, you're just thrown in this theorem land where like everything's completely different, and there's no computation. It's just you need to know how to use definition to prove big idea. It's just a completely different beast, I guess. Like in terms of like math. And I didn't see it coming, so I had to shape up.

In this quote, Dave describes a form of distinction between the computational mathematics that he had been doing and the theoretical mathematics that he was beginning. This distinction between theoretical and application-based mathematics forced the development of new activities for learning.

Reflection. Like Kurt, Dave's activity was tied to his homework. Dave's description of understanding definition aligned with his activity where he explicitly teases apart the ideas of "knowing how" and "knowing what", both of which are a part of understanding. There is more value placed on the "knowing how" category, that is applying definitions to proofs, which we can see in the quote above dealing with the stabilizer.

Kris

Like his peers, Kris uses both lecture and homework as a primary means to engage in definitions. He also attends office hours and seeks out information from the internet. Kris claimed that his two primary activities to develop understanding were to attend lecture and do the homework, "But in my opinion, I think it's, that's the only two ways to help me to understand the definition is you just do the homework or see what Dr. X, like in know the instructor, what they expand for the definition."

Kris also acknowledged the importance of extended time noting that it "takes time to understand the definition and what's the purpose…" and a single lecture is too short, and he may need to revisit ideas on the weekend. He also explains that during lecture it helped when the professor paused and gave "a little bit of time to think about the definition" and how important that time was for him to understand.

While Kris said that those are the only two ways to develop understanding, he specifically describes other activities that he uses to develop understanding including office hours and using the internet as a resource. He would opt for the internet if his instructor was unavailable to meet searching out," Where is this definition come from? And the work, the purpose of this definition for sometimes it helped me to understand more, but some not all the time." He also would seek out different points-of-view on the definitions such as reading online arguments between different people. He also sometimes asked his peers for what the "purpose" of a definition is.

Kris's last observation from his coursework is that while he tries to be able to state theorems in his own words, he does not do this for definitions. He explains that "if I change the words in my, I have a different story than a definition." He elaborated how this led to him developing incorrect quantification in prior classes. That prior experience led to his decision to "force [himself] to memorize" the definition exactly which can also help when they need to be stated on exams.

Reflection. Like other cases, homework and lecture played a substantial role in Kris's activity were using definitions to prove statements was a key activity and addressed the "purpose" of a definition. However, we can see one substantial way that Kris's case differed from the prior. He placed outsized value on memorizing a definition exactly as stated. This may reflect his beliefs on definitions as the "inarguable" parts of mathematics. He also did not go to the internet for animations or intuition, but rather history, which again may reflect how he sees the roles of definitions as foundational.

Table 2. Actions taken by Participants

Participant	Actions taken to understand a definition	Beliefs and Rationale for Actions Taken
Kurt	• Attending class • Reviewing notes • Doing homework • Using online resources	• He needs to "play with it [the definition] himself" and understand how to apply them in proof. • Justifies actions using prior experiences in math courses and advice from friends.
Dave	• Doing homework • Talking with professor	• Memorization is not useful to developing the ability to use the definition in writing proofs. • Justified actions based on the goals of understanding/ desired learning outcomes set for himself and prior experience in math courses
Kris	• Attending class • Doing homework • Talking with professor, online resources	• Kris wants to know the historical uses and evolution of a definition, and this can be found via lecture and online

Discussion

The purpose of this study was to address two primary questions:

- What activities do students engage in to try to develop understanding of a definition?
- Why do they engage in those activities?

In addressing these two questions, we also examined two additional questions:

- What do students believe a definition is in advanced mathematics and why?
- What do students believe it means to understand a definition and why?

Regarding these first two questions, through both our survey and interview, we found that there are a range of activities that students engage in when trying to understand definitions and some consistencies. All the students suggested that doing homework and attending lectures were their primary means of developing understanding. Kurt also relied on additional resources, including those found on the internet, as part of their coming to understand. In contrast, Dave preferred not using outside resources like the internet. However, he does acknowledge that he has looked at them in the past. To account for differences in what students saw as useful, we return to the notion of the rationality of students and consider the goals that the students had. We do hold that each of the students utilized resources that were rational from their perspective as they considered their own learning goals. Webel (2013) had stated the importance of understanding the students' goals when trying to examine the motives of their behavior.

The students had relatively similar backgrounds in terms of the mathematics coursework that they had taken. The students always engaged in the activities they believed would best help them achieve their learning goals but had developed very different sets of learning behaviors and rationales to explain them. Kurt, for example, believed that he should develop understanding of the definition through repeated exposure via lecture and practice with homework tasks. In contrast so as to be able to reliably classify sort candidates into the class of example and non-example. In contrast, Kris memorized definitions for exams, but sought to understand the historical reasons that they were created and what theorems they lead to by using lectures, office hours, and resources found on the internet. Dave wanted to know when to use a given definition (akin to Weber's (2001) *strategic knowledge*) and so did the homework, go to office hours, and sometimes use the internet. Dave was leery of the internet due to changes in 'notation' that might confuse him. That is, different goals for understanding appear to support different collections of behaviors.

Through documenting both the activities students engage in when coming to understand a definition and the rationale behind why students engage in activities, we make a minor contribute to the literature on how students engage with definitions as there was little existing literature. We note two limitations that also suggest next directions for study. First, due to our limited sample of three students, we have no reason to believe that they are representative of students in advanced mathematics courses, and so one way to explore that would be to replicate the study with a larger sample. As a second limitation, we found that students provided incongruous responses during the survey and their initial claims during the interviews. We found that students recalled different behavior when prompted with their own survey responses than when asked to describe their behavior without prompting. At the same time, because the survey did not attempt to capture the logic for their behavior, more research is needed in order to explore the in-the moment decision-making processes that students use to seek out outside resources and evaluate them. Finally, in addition to replication, we noticed that preferences and sense of self-efficacy may influence their behavior. Thus, it would be of interest to examine the relationship between students' actions and their self-efficacy.

While we note that this is a small group of students, all three noted that they did not recall their professors describing any practices or behaviors that would support coming to understand definitions outside of class to come to understand a definition. The research on classroom instruction (c.f., Pinto, 2019; Fukawa-Connelly, 2012) suggests that mathematicians engage in modelling behaviors that could support coming to understand the concept in ways that go beyond memorizing the words of the definition. There also is reason to believe that mathematicians want to promote conceptual understanding (Nardi, 2007). Thus, these students do not believe that they have given any instruction about how to develop this understanding or what this understanding might entail, which could explain the divergence in their beliefs about what it means to understand a definition. As a result, we suggest that if mathematics professors have specific actions that they want students to take, they need to more explicitly teach them. At the same time, the literature does not currently allow us to link teaching activities and students' learning very well (c.f., Melhuish, et al, 2022). As a result, explorations of explicit instruction about coming to understand, how that relates to behaviors students actually carry out, and the types of understandings that result would be a valuable addition to the research literature.

Learning to interpret proofs is an important milepost in the maturity and development of students of higher mathematics. A key learning objective in proof-based courses is to discern whether a given proof is a valid justification of its underlying claim. In this study, we presented students with conditional statements and associated proofs and asked them to determine whether the proofs proved the statements and to explain their reasoning. Prior studies have found that inexperienced provers often accept the proof of a statement's converse and reject proofs by contraposition, which are both erroneous determinations. Our study contributes to the literature by corroborating these findings and suggesting a connection between students' reading comprehension and proof validation behaviors and their beliefs about mathematical proof and mathematical knowledge base.

Keywords: logic and proof, belief about mathematical proof, mathematical knowledge base

Learning to interpret proofs is an important milepost in students' mathematical development and maturity. Such development is especially crucial since proof is a structure unique to the field of mathematics (Balacheff, 2008; Fawcett, 1938). Though much variability exists in how transition-to-proof courses are delivered in the U.S., over 80% of them attend to principles of formal logic (David & Zazkis, 2020). Presumably among the many facets of students' development with regard to proof is their ability to correctly discern whether a proof justifies a given theorem. While undergraduate students' comprehension and behaviors have been a focus of research in the reading and validation of proofs (e.g., Dawkins & Zazkis, 2021; Selden & Selden, 2003), this study aims to provide insights of how students' beliefs and knowledge about proofs might be associated with their reading and validation thereof. Building on the existing research (e.g., Dawkins & Roh, 2022), this study explores the accuracy with which students validate theorem-proof pairs, the reasons they offer for their decisions, and the similarities and differences exhibited by students with different degrees of proof experience. By studying similarities and differences between these groups, we address the following research question: What differences exist between novice and experienced provers in how they read proofs and characterize the relationship between proofs and theorems?

Theoretical Perspective

In this study, we employ the lens of radical constructivism (Glasersfeld, 1988). Under this view, knowledge does not objectively reflect reality, rather it is stored in the mind of an individual learner who has organized their activity and experience idiosyncratically into schemes. As such, we designed our investigations to understand our participants' schemes regarding proofs of theorems in order to build models for their thinking.

As a way of organizing and interpreting our findings about students' schemes regarding proof, we introduce the constructs of *beliefs about mathematical proof* and *mathematical knowledge base*, both of which may differ from student to student. The former refers to general notions that students hold regarding the practice of proving or the properties that a proof should have. For example, a student might believe that a proof needs to make explicit the structure of their proof e.g., direct proof, contrapositive, while another would accept a proof which only implies the structure. The latter refers to content-specific knowledge that students accept without justification. For example, a student might conceive that the sum of two continuous functions is continuous and accept a proof that used this argument as valid. Another student might reject a proof which doesn't justify this claim. In either case, such knowledge is only relevant in proofs that pertain to functions and their analysis.

Though ideas in one's mathematical knowledge base do not require justification, students were asked on multiple occasions to explain why certain ideas were true. To more fully describe their understanding, we rely on *warrants* (Toulmin, 1958), the reason a prover gives for why their evidence is germane to their argument. In particular, we use the *warrant-types* described by Inglis et al. (2007) to make sense of our participants' knowledge bases.

Research Methodology

As part of a larger study, we conducted clinical interviews (Clement, 2000) with undergraduate students with various levels of proof experience at a large public university in the United States from spring 2020 to spring 2022. We recruited eight students who had already taken at least two proof-oriented courses by spring 2020. We labeled these participants experienced provers. To compare and contrast these provers' conceptions about proof, in the springs of 2021 and 2022, we recruited four students who had not yet taken any proof-oriented mathematics courses at the university level, labeling them novice provers. The second author of this paper served as the interviewer of all participants while the remaining authors served as witnesses. In the discussion of results, we label participants with E or N (indicating their experienced or novice prover classification), a number from 1-8, and a pseudonym.

Each clinical interview lasted between 60 and 120 minutes. Some interviews in the spring of 2020 were conducted in person in a space other than their regular classroom while the rest of the interviews were conducted remotely. To facilitate retrospective analysis, we video- and audio-recorded all interviews. Participants completed all annotations on tablet computers, allowing us to collect digital copies of their work.

Interview Tasks

The tasks for the clinical interviews consisted of a series of theorem-proof pairs. After showing a theorem and at least one proof associated with it, we asked a student participant to think aloud while reading and interpreting them. When the student had indicated that they had sufficiently reviewed the theorem and proof, we asked whether the proof proves the theorem. If they determined that the proof did not prove the theorem, we asked if there were other statements that it proved. As the student responded to our questions, the interviewer asked follow-up questions in tandem to understand the student's reasoning for their decision.

While we asked all student participants the same questions for each theorem-proof pair, these pairs were not the same across the three all data collection periods. In spring 2020, we offered our experienced provers five different theorems (Theorems 1, 2, 4, 6, and 9 in Figure 1), each of which was accompanied by two or three different proofs. In spring 2021, we provided one theorem (labeled Theorem in Figure 1) to two of our novice provers and four associated proofs. In spring 2022, we presented the remaining novice provers four different theorems (Theorems $\alpha, \beta, \gamma,$ and δ in Figure 1), each with a single proof of its converse or contrapositive.

For all of the theorems in Figure 1 below, we provided students additional information such as relevant definitions or supporting theorems which may be needed for their reading of the proofs. We informed students that the proofs we provided were mathematically valid, but proofs associated with a theorem may not necessarily prove the theorem.

Theorems presented to experienced provers in Spring 2020:

Theorem 1: If x is a multiple of 6, then x is a multiple of 3.
(Associated proofs are direct, disproof of converse, and contraposition)

Theorem 2: If x is a multiple of 2 and a multiple of 7, then x is a multiple of 14.
(Associated proofs are direct and proof of converse)

Theorem 4: If $ABCD$ is a rhombus, then the diagonal AC forms two congruent isosceles triangles.
(Associated proofs are direct and disproof of converse)

Theorem 6: For any line segment AB, if a point X is on the perpendicular bisector of AB, then $AX = BX$.
(Associated proofs prove the converse and prove directly)

Theorem 9: If f and g are continuous on $[a, b]$, $f(a) = g(b)$, and $f(b) = g(a)$, then there is a c in $[a, b]$ such that $f(c) = g(c)$.
(Associated proofs are direct, disproof of converse, and contraposition)

Theorem presented to novice provers in Spring 2021:

Theorem: For any integer x, if x is not a multiple of 3, then $x^2 - 1$ is a multiple of 3.
(Associated proofs are direct, inverse, converse, and contrapositive)

Theorems presented to novice provers in Spring 2022:

Theorem α: Given a line segment AB, for all points X, if X is on the perpendicular bisector of AB, then $AX = BX$.
(Associated proof proves the converse)

Theorem β: For any triangle XYZ, if no two angles are congruent, then the triangle is scalene.
(Associated proof proves the contrapositive)

Theorem γ: For any integer x, if x is a multiple of 4 and a multiple of 21, then x is a multiple of 84.
(Associated proof proves the converse)

Theorem δ: For any integer x, if x is not a multiple of 3, then it cannot be written as the sum of three consecutive integers.
(Associated proof proves the contrapositive)

Figure 1. Theorems and types of proofs associated with them

Data Collection and Analysis

To facilitate our analysis, we transcribed each interview and created detailed field notes to describe how students processed each proof. We analyzed data in hopes of building a theory grounded in the available data (Strauss & Corbin, 1998). We first coded each line of each transcript by describing student behavior e.g., reviewing given definitions, drawing diagrams, deciding on the validity of a proof. We further coded the transcripts to attend to students' reasoning underlying their responses to questions, which revealed five different phenomena which we present in more detail shortly. These phenomena gave rise to two ways of categorizing students' conceptions – belief about mathematical proof and mathematical knowledge base.

Results

The goal for our research was to characterize the differences between how novice and experienced provers understood proofs, theorems, and the relationship between them. We begin by discussing their commonalities in order to provide a reference for their differences. We found that students' comprehension and validation of proofs are associated with their beliefs about mathematics proof and mathematical knowledge base. Various sub-categories of each construct emerged from our analysis. In particular, we found two different sub-categories of students' beliefs and three sub-categories of their knowledge. Once we identified all students with these categories, we compared and contrasted novice and experienced provers. Our findings are summarized below (See Table 1).

Table 1. Summary of conceptions about mathematical proof

Conception	Phenomenon	Novice	Experienced
Beliefs about Mathematical Proof	Valid proofs require logically sequenced arguments.	✓	✓
	Valid proofs require correct overall structure.	×	✓
Mathematical Knowledge Base	Arguments rely on empirical evidence.	✓	×
	Arguments rely on definitions.	×	✓
	Arguments rely on logically sound principles.	×	✓

Summary of Conceptions of Proof of Novice and Experienced Provers

Both groups of provers exhibited a belief that valid proofs require correctly sequenced arguments, yet only experienced provers believed that proofs must also follow the correct structure i.e., assumptions and conclusions are correctly identified. Regarding mathematical knowledge base, novice provers primarily argued using empirical evidence while experienced provers preferred arguments based on definitions. Lastly, experienced provers alone showed consistent sensitivity to logically sound principles.

Beliefs about Mathematical Proof

This category pertains to what students generally believe a prover should do when formulating a proof or what properties a proof ought to include. Our findings refer specifically to the characteristics that students believe contribute to the validity of a proof, or lack thereof.

Valid proofs require logically sequenced arguments. A logically sequenced argument is such that each line in a proof is both justified by the ones that precede it and justifies the ones that follow. Put alternately, students attended to the body of the proof without necessarily attending to the assumptions and conclusions. In each of the following excerpts, one each from a novice and experienced prover, participants discussed why this coherent flow is necessary in a valid proof.

Interviewer: "Can you explain why [this proof doesn't prove the theorem]?"

Priya (E4): "Because they're not justifying their steps. When they don't justify their steps, the steps they've omitted don't indicate that they understand what's going on. It just seems like they're fudging because they know where they need to go."

Interviewer: "Can you explain why the proof proves the theorem?"

Carl (N2): "If x wasn't on the perpendicular bisector…Therefore, the lines AX and BX would not be equal. Because it is on the perpendicular bisector, triangles AMX and BMX would be equal. By the SAS theorem, the triangles would be equal."

Priya referred to the desired conclusion as "where they need to go," thereby acknowledging a proof framework, but rejected the arguments used to arrive there. Carl accepted his proof based solely on the links between arguments and did not attend to the hypothesis and conclusion.

Valid proofs require correct overall structure. If the category above pertains to the body of a proof, this category pertains to its head and tail, the assumptions and conclusions, respectively. The belief that a proof's validity depends on its hypotheses and conclusions, and the flow from the former to the latter, was prevalent only among experienced provers.

Interviewer: "Can you explain why [the proof doesn't prove the theorem]?"

Nate (E6): "In proof 1.2, your given assumption is actually what we're trying to prove…This statement is what we're needing at the end of our proof…So they're starting at the opposite end of the proof…This is saying that if x is a multiple of 3, then it's not a multiple of 6, which is not what we're actually trying to prove."

Interviewer: "What is your top criterion for this to be a valid proof?"

Heather (E2): "It starts by assuming that the if condition is true."

Nate and Heather each attended to how the proof began and ended. Nate rejected the proof because it assumed the wrong premise. Heather cited the correct assumption as her top validation condition. In each case, the student attended to the ends of the proof rather than the body thereof.

Mathematical Knowledge Base

A student's knowledge base refers to the information that they have at their disposal which helps them read, interpret, and formulate proofs. Most relevant to this study is the set of content-specific tools that students have which allows them to analyze and compare arguments.

Arguments rely on empirical evidence. Under this approach, students cited particular examples to substantiate their claims. On several occasions, novice provers used one or more particular examples directly before declaring that a theorem was indeed valid.

Interviewer: "Can you explain why [proof 1 proves for any integer x, if x is not a multiple of 3, then $x^2 - 1$ is a multiple of 3]?"

Joaquin (N4): "I didn't realize that the proof would approach the problem like this…It says let x be an integer that is not a multiple of 3…We could pick 8, 7 even…For me personally, I experimented with some numbers. For example, I let k equal 1."

Joaquin's acceptance of the theorem stemmed from his ability to satisfy it with several spontaneously chosen examples. Though he convinced himself of the validity of the proof inductively, we do not necessarily claim that he would have accepted a proof by example. Nonetheless, his empirical reasoning was fairly common among novice provers.

Arguments rely on definitions. Rather than using particular examples, provers in this category reasoned arbitrarily i.e., using examples which represent all examples. Put alternately, experienced provers reasoned from definitions and properties rather than from examples.

Interviewer: "Can you explain in your own words what this theorem states?"

Priya (E4): "Given any integer x, if x satisfies the property of being a multiple of 6, meaning there is some number that multiplied by 6 gives you x,…There is another number that when multiplied by 3 gives you x."

Whereas Joaquin reasoned via empirical evidence, Priya reasoned arbitrarily and directly from the definitions. Joaquin's and Priya's preferred modes of reasoning were common among other novice and experienced provers, respectively.

Arguments rely on logically sound principles. Provers in this category were adept at employing logic, most notably for this study contrapositive equivalence and converse independence (CE/CI). Novice provers did not consistently exhibit understanding of CE/CI. Nevertheless, the manners in which experienced provers justified these principles varied greatly.

Interviewer: "Can you explain why [this proves if x is not a multiple of 3, then $x^2 - 1$ is a multiple of 3]?" (proof proves the converse)

Violet (N3): "They're showing that x is not a multiple of 3 by saying that x equals k times 3…But it can't be since in the theorem it says that x is not a multiple of 3…I think it [proves the theorem] because they're showing in their work that x is a multiple of 3, because they're assuming that it's a multiple of 3."

Note that Violet attended to the arguments in the body of the proof but exhibited no sensitivity to the overall structure of the proof.

Experienced provers, on the whole, reliably recognized CE/CI. Significant differences however existed in the way they justify these ideas. For example, some participants took CE/CI as given, but did not provide a justification.

Interviewer: "Why do you think that since this disproves the converse that it does not prove the theorem?"

Priya (E4): "Because the converse is not logically equivalent to the original."

I: "What do you mean that they are not equivalent?"

Priya (E4): "That's a good question. Like how do I know that two things aren't logically equivalent? I guess at this point, that's just an inherent fact to me."

Provers who reasoned about CE/CI in this fashion perhaps viewed CE/CI as a belief rather than knowledge since it is neither requires nor is accompanied by warrant.

Other experienced provers were able to warrant CE/CI with concrete examples which were specific to a particular context. These contexts were not always overtly mathematical in nature, as shown by the excerpt below.

Interviewer: "You said this proves if Q, then P, right? My question is why a proof of if Q then P is not a proof of if P then Q."

Mark (E7): "Let's say I say that if an animal is a blue jay, then it is a bird…This is the example I always think of when I have to think of if-then statements."

Though not explicitly stated by the student, it can be reasonably presumed that since the statement he gave had a false converse, its purpose is to illustrate general converse independence through a particular example. Note that while empirical evidence was primarily used by experienced provers, this was not exclusively the case.

Finally, our participants also justified their knowledge of CE/CI through abstract warrants which were not beholden to any particular contexts. Such justifications most often took the form of truth tables, subset relationships, and logical manipulations (see Figure 2).

Mark (E7): "It works from logic that for an implication to be true, either the hypothesis is false or the conclusion is true. Since they have the same truth table, we know that the statements are going to be equivalent." (see figure 2, left image)

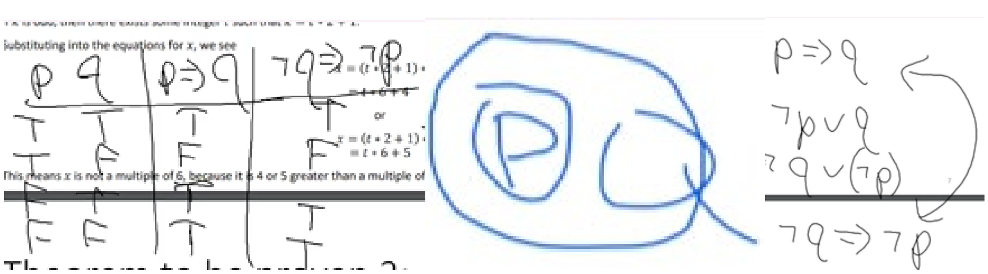

Figure 2: Mark's truth table and Euler diagram as well as Nate's syntactic argument

Interviewer: Can you explain why the proof demonstrates [if Q, then not P]?"

Mark (E7): "So it could be the case that x is a multiple of 3 and not a multiple of 6. It could be the case the Q and we don't know anything about P. So, what the theorem says is that if I am anything in P, then I will also be in Q. But what this shows is that if I'm in Q, then I might not be in P." (see Figure 2, middle image)

Interviewer: "How can you tell that the proof of the contrapositive also proves the theorem?"
Nate (E6): "I think the easiest way would be through logic. The statement is P implies Q. That's the same is not P or Q. Then, if we do double negation, we get not Q implies not P. So, these two are exactly the same." (see Figure 2, right image)

Discussion and Conclusion

The goals of this study were to characterize the ways in which undergraduate students interpret proof-texts, their relationships to underlying theorems, and to describe the differences between novice and experienced provers. Though our tasks were designed to gauge reading comprehension through student behaviors, we learned much about their conceptions of proof, suggesting that the phenomena are related.

With regard to beliefs about mathematical proof, both groups of provers asserted that a logical linking of ideas should be present in a proof. Our research is thereby consistent with prior literature (e.g., Ko & Knuth, 2013; Selden & Selden, 2003; Dawkins & Zazkis, 2021). Similarly, we found that students with more mathematical development were more likely to attend to the assumptions that are made at the outset of the proof and the overall structure, which is also consistent with prior studies (e.g., Heinze & Reiss, 2003; Weber, 2008). Indeed, experienced provers validated proofs correctly more often than novice ones, though experienced provers make occasional errors. Our findings in this regard support the work of Inglis and Alcock (2012).

The results of our study also highlight the different ways in which our participants justify the ideas of contrapositive equivalence and converse independence. Our findings are consistent with prior literature. In their discussion of modeling arguments, Inglis et al. (2007) discuss the warrants used by graduate students of number theory. Though their participants were more mathematically developed than ours, parallels exist between our findings and theirs. Inglis et al. (2007) do not discuss participants who offer no warrant, but our provers who readily asserted the ideas of CE/CI but could give no reason for their validity exhibit what Krupnik et al. (2018) call *psychological knowledge*, a belief that an idea is true which the knower cannot justify. Our participants who warranted CE/CI with a single example e.g., the blue jay, parallel what Inglis et al. (2007) call the inductive warrant-type, wherein a prover evaluates a conjecture using one or more specific examples. Inglis et al. (2007) also describe a structural-intuitive warrant-type, wherein a prover uses a mental or visual structure to support a conjecture. This is consistent with our experienced provers who used set-theoretic notions and Euler diagrams to justify CE/CI. Inglis et al. (2007) describe the deductive warrant-type as reasoning solely from axioms. Since our provers who used truth tables and logical manipulations were relying on the base relationships between propositions in an implication, their reasoning was consistent with this warrant-type.

Our findings suggest that students with formal training in proof validate proofs with greater reliability but greater attention may be paid to the justification for CE/CI. Ongoing studies are testing instructional interventions using set-theoretic activities to effect deeper conceptual understanding of proof structures (Dawkins et al., in preparation).

“I want this to be the last time. I don't want to teach myself anymore”: Relearning Factorization from Middle school through College

Kristen Amman
Colorado Mesa University

Juan Pablo Mejía-Ramos
Rutgers University

We report results of a longitudinal case study of one Intermediate Algebra student Sierra’s experiences relearning factorization from 8th grade through Precalculus. This data comes from a larger project investigating six developmental mathematics students’ perceptions of the experience of relearning individual topics and reflections on relearning across two semesters of college algebra courses. Such a student-centered perspective is critical to developmental mathematics educators who are currently grappling with high rates of failure and attrition in such courses nation-wide. In examining Sierra’s learning experience as one of relearning, this report sheds light on how students may use their previous algebra learning experiences to make predictions about the kind of understanding they will come to have about particular topics, and to motivate particular behaviors and affective states during instruction. Furthermore, we illustrate how such topic-level experiences may be used to shape learning experiences in subsequent mathematics courses involving algebra.

Keywords: developmental mathematics, relearning, factoring

This report centers on student perceptions of the experience of relearning, i.e., the experience of learning about content one has already tried to study in a previous course (Amman & Mejía-Ramos, 2022). In particular, we focus on traditional developmental math courses: semester-long courses whose content focus mirrors that of middle and high school pre-algebra to algebra courses. Such courses persist in making up a significant portion of developmental math offerings (Kosiewicz, Ngo & Fong, 2016) and lie at the heart of scrutiny in the developmental math space. We argue that understanding students’ expectations and perceptions surrounding the relearning process can help explain their motivations, behaviors, and affective dispositions while learning in courses with previously seen content (Amman & Mejía-Ramos, 2021). While relearning is not exclusive to developmental mathematics courses, it is a uniquely central feature of these courses (due mainly to the prevalence of Algebra in United States middle/high school curricula). This work contributes to a small but growing body of literature that seeks to open up the “black box” of teaching and learning in developmental mathematics courses (Grubb, 2001; Sitomer et al., 2012; Mesa, Wladis & Watkins, 2014) to better understand their historically high failure rates (Chen, 2016) and reputation as deterrents to college completion (Bailey, Jeong, & Cho, 2010).

In a previous report (Amman & Mejía-Ramos, 2021) we discussed students’ perceptions of the experience relearning an Intermediate Algebra topic that they had seen in a previous algebra course. Although the topics studied were presented within the first third of the semester, students described having complex relearning experiences. Contrary to current depictions of developmental mathematics students, which collapse their learning needs across individual topics to describe them as needing either a “refresher” of course material or an intensive review of “basic skills” (e.g. Grubb & Gabriner, 2013; Cox & Dougherty; 2019), these students’ experiences shifted according to both the sub-topic under discussion and whether the interview was predictive or retrospective. The data presented in the current report come from a larger study motivated by the question of how such relearning experiences might evolve over the course of a semester, as students are exposed to topics of varying complexity, and as their familiarity with the notion of relearning grows. Specifically, we report findings related to one student's relearning experiences throughout two semesters of algebra-based, college-level coursework. In doing so, we seek to contribute to educational theory concerning the variety of possible impacts of relearning on one's understanding of content seen before, as well as the behavioral and affective associations with relearned content that distinguish it from learning for the first time.

Literature Review

Typical profiles of developmental mathematics students describe them as having a lack of sufficient algebra coursework in high school (e.g. Kinney, 2001; Grubb & Gabriner, 2013; Boylan, 2011). However, current research suggests that many developmental mathematics students completed at least Algebra II in high school, and that a substantial portion were enrolled in mathematics courses for all four years in high school (Benken et al., 2015; Ngo, 2020; Moran, 2008). For instance, in their study of 306 first-year students placed into Intermediate Algebra at California State University, Benken et al., (2015) found that nearly 60% of these students had taken courses beyond Algebra II in high school. Additionally, 66% of participants had taken mathematics all 4 years of high school, and 23% had spent 3 or 4 of those years just attempting to pass coursework at or before Algebra II. Likewise, Ngo (2020) investigated the percentage of college students who take "redundant" math courses, or courses whose content is either at the same or lower level than their highest completed math course in high school (or lower than what they would be predicted to pass given their results on a 12th grade math assessment). He found that while roughly 20% of all college students take redundant math courses, that percentage increases to roughly 40% when looking at developmental math students specifically. This suggests that roughly 40% of students in these developmental mathematics courses had completed coursework above the level of at least Algebra I in high school. Thus, counter to the belief that a sizeable number of developmental math students enroll in such courses because they were never exposed to algebra concepts in high school, these studies suggest that a sizable number of students have taken algebra prior to developmental mathematics enrollment. While these studies do not make explanatory claims to help us understand student outcomes, they provide valuable insights into the widespread nature of relearning in developmental math classes. In attempting to explain phenomenon such as high failure rates and attrition, it would seem critical to better understand student relearning experiences in this context.

In contrast to the lack of research on student perceptions of their experience with developmental mathematics content, there is a growing number of studies that focus on describing how developmental mathematics instructors view students in terms of their readiness for college mathematics and the detriments to their success mathematically. These studies suggest that instructors perceive many developmental math students as lacking in basic skills that are both meant to be formed in high school courses and critical for mathematical success (Er, 2018; Reichwein, Schneider & Onwuegbuzie, 2014; Grubb & Gabriner, 2013). For instance, in their interviews with instructors from over 20 community colleges in California, Grubb and Gabriner (2013) found that instructors perceived the majority of developmental math students as being placed into such a course due to a need for an in-depth review of basic skills, whereas a minority of "brush up" students are misplaced due to a time lapse since their previous mathematics course and a need for only a quick review of the material in order to be college ready. However, instructors surveyed by Benken et al., (2015) thought it was problematic to approach the course as a "review" rather than an "opportunity to learn new content", assuming such an approach stems from an overconfidence in students' skills as opposed to a true need for a quick review. Furthermore, there appears to be inconsistencies in which skills specifically instructors are referring to. Whereas some studies of instructor perceptions relate a lack of basic skills toa likelihood to engage in unproductive learning behaviors such as self-handicapping strategies (Mesa, 2012), others note poor study skills (Reichwein, Schneider & Onwuegbuzie, 2014), while still others note basic mathematical skills related to arithmetic and algebraic procedures (Grubb & Gabriner, 2013).

An interesting question is how instructors' perceptions relate to those of their students. For instance, Cox and Dougherty's (2019) interviews with 25 community college pre-algebra students indicated that while many students perceived the course to be useful in "refreshing" their memory, others found 'reviewing' to be a waste of time given their prior experience with the content. Consistent with findings reported by Mesa (2012), 18 students indicated that they "wanted to 'really understand'" the reasoning behind their use of procedures in the course in way that they had not accomplished previously (p. 256). However, it was relatively uncommon for students to indicate that they felt this had been accomplished by the end of the course. Indeed, a critical finding of Mesa (2012) was the vast discrepancy she found between instructor perceptions of students and students' perceptions of themselves. Namely, she found that students indicated preferring mastery over performance goals, a lack of engagement in self-handicapping behaviors, a disposition towards hard work, and an expectation that instructors would challenge them. As illustrated above, instructors perceived students in a near complete opposite manner. The results of these studies raise interesting questions about how student perceptions of their own learning needs, behaviors, and affective dispositions relate to those of their instructors. These results, as well as the muddling of "refresher" students and "basic skills" students led us to conduct the current investigation into student perceptions of their experience learning about content seen before.

Theoretical Framework

Consistent with Amman and Mejía-Ramos (2021; 2022), we conceptualize the experience of relearning as broader in scope compared to previous work on memory in cognitive psychology (Ebbinghaus, 1885; Bahrick, 1979; Rawson, Dunlosky & Janes, 2020) and mathematics teacher education (Zazkis, 2011). We define relearning in mathematics as the experience of learning about content (T1) one has already tried to study in a previous mathematics course (T2). Importantly, the target content must remain stable across the two learning experiences. That is, the mathematical content in the second learning experience cannot be simply reviewed or relevant for the purpose of teaching something else. In such scenarios, we typically consider students to be using their *prior knowledge* in service of learning about new content. The definition of relearning used here is broader in the sense that it does not require specific learning outcomes at T1 or T2 (e.g., work on memory in cognitive psychology traditionally requires content to be fully memorized and recalled in order for relearning to occur). Similarly, this definition does not characterize specific relearning experiences as successful or unsuccessful. Instead, it is deliberately general to allow researchers to more broadly describe how students' existing understanding of content can be (or be perceived to be) impacted by relearning, without a predetermined framing in mind.

In developmental mathematics courses, relearning occurs at multiple levels. The results presented here consider two such levels. The first is what we refer to as "topic-level" relearning in which the focus is on a student's experience relearning a single topic (e.g., the content of a single chapter or unit) in an algebra course. Topic-level relearning was the sole focus of our earlier work (Amman & Mejía-Ramos, 2021), in which we asked questions about what it was like for students to relearn content from one of two specific textbook chapters in an Intermediate
